CIVIL ENGINEER, B.Sc. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.Sc., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C. '29); M.S. Age 27. Single. Four years experience in research work in applied mechanics and materials testing. Desires position involving analytical work in design, development or testing. Available on short notice. Apply to Box No. 1123-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box. No. 1127-W.

Situations Wanted

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.Sc., Queen's '33 Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.Sc., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.Sc., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Write and speak both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211 W.

CIVIL ENGINEER, B.Sc. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

COMBUSTION ENGINEER, A.M.E.I.C., with extensive experience in all phases of combustion engineering, including plant layout, piping, etc. Lately connected with prominent firm of automatic oil burner manufacturers. Apply to Box No. 1224-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet and tissues. Apply to Box No. 1246-W.

CIVIL ENGINEER, B.Sc. '29, JR.E.I.C., age 29, single. Experience in all types of surveying including use of aerial photographs. Three years on hydro-electric power development in field and office. Instrumentman on concrete road construction. Location immaterial. Apply to Box No. 1254-W.

CIVIL ENGINEER, Univ. Toronto '33, age 24, married. One year as instrumentman with provincial department of highways. Experience in concrete and retread construction grading, culverts, etc. Also draughting, estimating and general office practice. Apply to Box No. 1265-W.

INDUSTRIAL ENGINEER, B.Sc. in Mech. Eng (McGill '31), Rockefeller Research Associate in industrial engineering on economic and statistical analysis. Previous experience in manufacturing plants. Desires connection with industrial firm. Apply to Box No. 1269-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '29) Age 28. Six years experience in automobile office and plant; two years as supervisor of inspection in body assembly. Good understanding of modern business methods applied to manufacturing. Desires position with production department of smaller Ontario industry. Good references. Interviews anywhere in central Ontario. Apply to Box No. 1270-W.

ELECTRICAL GRADUATE, S.E.I.C., B.Sc. '32, M.Sc. '34. Experience includes four years as part time operator and announcer for a radio broadcast station At present employed in radio repair dept. of a large wholesale firm. Apply to Box No. 1283-W.

CIVIL ENGINEER, JR.E.I.C., JR.AM.SOC.C.E., Stud. Inst. C.E. Age 25, Scottish. B.Sc. Edinburgh '30. Three and a half years designing, estimating and draughting bridge and structural work; steel and concrete. Six months asst. supervising engineer on bridge construction. Passed final examination for A.M.Inst.C.E. Available immediately. Apply to Box No. 1295-W.

For Sale

Rolling sphere planimeter, Eugene Dietzgen Co., No. 1810. Adjustable tracer arm, max. 19¼". Any reasonable offer considered. Apply to Box No. S-27.

Volume XVIII — Montreal, June, 1935 — Number 6

Recent Developments in Sound Pictures

S. T. Fisher, Jr.E.I.C.,

Special Products Engineering Department, Northern Electric Company Limited, Montreal.

Presented before the Montreal Branch of The Engineering Institute of Canada, March 7th, 1935.

SUMMARY.—After discussing available methods of recording sound and the basic principles of sound reproduction, the paper describes the greatly improved recording units now in use and the reproducing equipment by means of which a sound range of from 50 to 8,000 cycles can be accurately reproduced as compared with the 100 to 5,000 cycle range formerly possible.

Sound pictures are not of recent origin. Forty years ago experimenters were endeavouring to combine Edison's, and later Berliner's, phonograph with the motion picture camera and projector. Their problem was, however, one which was not capable of solution in a commercially practicable form, because the tools they had at hand placed fundamental limitations on their methods. In the first place, the only power available to press or engrave the disc or cylinder which was to serve as the storing medium was that derived from the lips or instruments of the performers. This meant that all sounds had to be emitted within a small area at the mouth of a collecting horn which terminated at the diaphragm to which was attached the recording stylus. Secondly, due to the necessity for placing the reproducing machine behind the screen in order to preserve the illusion that the sound originates from the image, the problem of synchronizing sound and picture was very difficult, and was solved only by a cumbersome arrangement of belts and shafting extending from the projection room to the stage. The third obstacle which made sound pictures impracticable was that the reproduced energy was limited to that which could be obtained directly from the record.

Thus for some years the development of sound pictures was retarded, just as was that of the long distance telephone, the radio and the phonograph. The invention and development of the vacuum tube gave an impetus to all these projects, by making available power to operate their devices. Present day sound picture technique did not descend from the attempts of the early inventors to make motion pictures talk; it came down through other arts, notably the allied sciences of radio, telephony, and the phonograph, and owes almost nothing to the first experiments in talking pictures. It was not until the advent of the vacuum-tube amplifier that sound pictures in the modern sense became feasible. The use of a microphone-amplifier-electromagnetic recorder system gave the performers the necessary freedom for dramatic effect. The electric reproducer-amplifier-loudspeaker combination in the theatre provided the necessary acoustic energy and simplified the synchronizing problem; and in 1926 the modern sound picture systems were placed on a commercial basis.

General Principles of Recording

In 1926 two general methods of sound recording for sound pictures were introduced in a commercial form:—

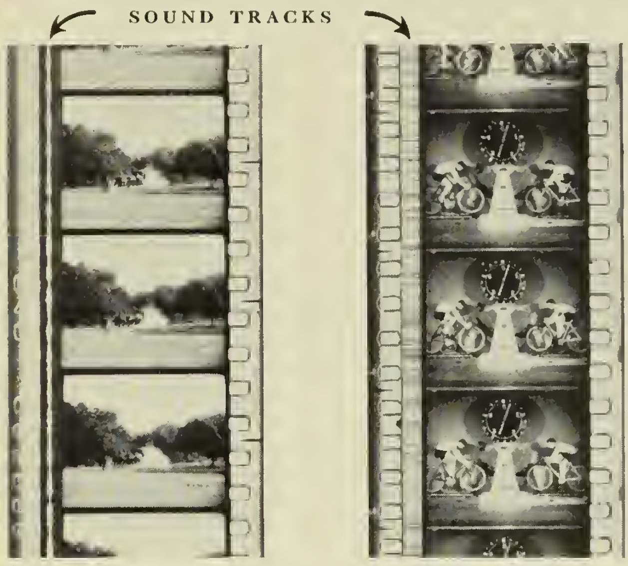
(*a*) The record could be made by a mechanical engraving process on wax, just as the familiar phonograph record is made. As far as sound pictures are concerned, disc recording is now a thing of the past, although it has recently been revived in a secondary function which will be described later.

(*b*) The record could be obtained photographically on film. This system is now used universally. Originally theatres were equipped for both disc and film reproduction, but now only film synchronous reproducers are in general use.

Wax Recording

Wax recording is done by engraving the surface of a wax disc with a cutting stylus attached to a vibrating armature. The armature is rocked between the poles of a magnet by the voice currents from the recording microphone, much amplified. The recording may be either lateral or vertical, that is, the movement of the stylus may be parallel to the surface of the wax disc, in which case the record appears as a wavy line of constant depth; or the stylus may move vertically to the surface of the wax. In this case, a straight cut of varying depth is obtained. Lateral recording is generally used for phonograph records, and was widely used in the early days of sound pictures. Vertical recording has, however, inherent advantages over lateral recording and will probably assume considerable importance as an intermediate process in film recording.

The discs are either of heavy wax or are made by flowing a thin surface of wax onto a heavy metal plate. The surface of the disc is then made conducting by brushing on a thin coat of finely powdered conducting material such as graphite, or in a more recent process by "cathode sputtering" of gold onto the wax surface. "Cathode sputtering" is a process of evaporating gold in a vacuum by the application of a high potential, and results in the deposition of an extremely thin, smooth, and uniform layer of gold on the wax surface. A heavy layer of copper is deposited electrically over this conducting film, and the wax is stripped off. This copper reverse impression is the "master." A separating fluid is applied to its surface, which is then given a heavy copper plating, which, separated from the master, gives a surface identical with the original wax. From this mould "sub-masters" or "stampers" are made again by electrolytic deposition of copper. A flash-



Variable Area Variable Density

Fig. 1—Sound Picture Records.

ing of chromium on these "stampers" makes them durable enough to stamp out the records actually used for reproduction from a thermo-plastic compound. Lateral-cut records have generally been made of a shellac-base compound. Vertical-cut records are now pressed in cellulose-acetate or similar materials.

Film Recording

In film recording systems the sound record is obtained photographically as a narrow strip along the edge of the same track that carries the picture. There are two main forms which this record may take:—

(*a*) It may be of uniform area but of varying opacity, the opacity being a definite function of the amplitude of the sound recorded. This is the "variable density" film recording system.

(*b*) It may be of uniform opacity with a variation in area corresponding to the variations in the sound it represents. This is the "variable area" recording system.

Variable area and variable density records are shown in Fig. 1, combined with the film carrying the picture. Other arrangements are conceivable by which a reproducible sound record may be obtained photographically, but these two are the only ones in use commercially.

The variable density sound record is made with a recording lamp of constant brilliancy, focussed on a light-valve, the opening of which in turn is focussed on the sound track of the film. This arrangement is shown in Fig. 3. The motion of the film is in a line perpendicular to the opening of the valve. The light valve is simply an electromagnetic shutter which is operated by the sound currents generated by the microphone. The present standard in recording practice is to use an average light valve opening of one mil,* focussed on the film half size. This gives an indication of the minuteness of the apparatus with which film recording is accomplished.

*One mil = .001 inch.

As is shown in Fig. 2, the light valve consists of an edgewise loop of duralumin tape with the inner edges of the two ribbons forming a slit .256 inch long and having a normal width of .001 inch. When an alternating current, such as the amplified current from a microphone, is passed through the ribbons, which are connected in series to form a continuous circuit, the two ribbons under the action of the magnetic field induced by the permanent magnet pole-pieces oscillate about their mean positions. In the two sides of the loop the ribbons move in opposite directions; that is, on one half of a cycle they move together and on the other half they move apart. Since the average opening of the valve, obtained when no current is being passed through it, is .001 inch, each ribbon has a maximum allowable displacement of .0005 inch; the total opening of the valve varies from 2 mils to complete closure, when an alternating current of maximum allowable amplitude is passed through it. This variation in the valve opening causes a corresponding variation in the width of the beam of light projected through it, and in the exposure of the film.

The valve forms a simple resonant system and the tension of the ribbon is adjusted so that the resonance lies just at the upper end of the frequency band it is desired to transmit. At frequencies below this fundamental resonance the ribbons have substantially the same displacement for equal currents.

In the variable area type of film recording, the record is made also with a lamp of constant brilliancy. The sound track is made by moving the light beam lengthwise across a slot interposed between it and the film. The film

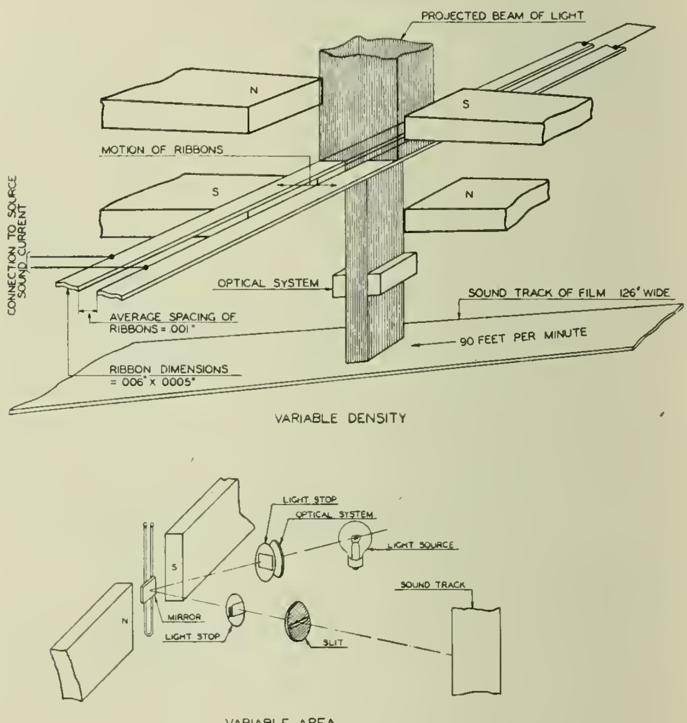


Fig. 2—Film Recorders.

moves at right angles to the direction of motion of the light. The recorder, or vibrator as it is called, consists of a tiny mirror cemented across a stretched loop of wire. The vibrator is placed between the poles of a magnet so that the wires are across the plane of the field. The light from the lamp is focussed through a square light stop onto the mirror of the recorder and is reflected through a cylindrical lens and a slit onto the sound track of the film. The edge of the light stop is focussed on the centre of the sound track which, therefore, under silent conditions is half exposed and half non-exposed. Sound currents through the vibrator cause it to rotate about a vertical axis. This oscillation causes the edge of the light which falls on the sound track to shift back and forth, thus producing a varying width of exposure on the sound track. Figure 2 shows a skeleton view of a variable area recording system. It should be noted that the variable area record shown in Fig. 1 consists of a double trace and is obtained by using a double recorder.

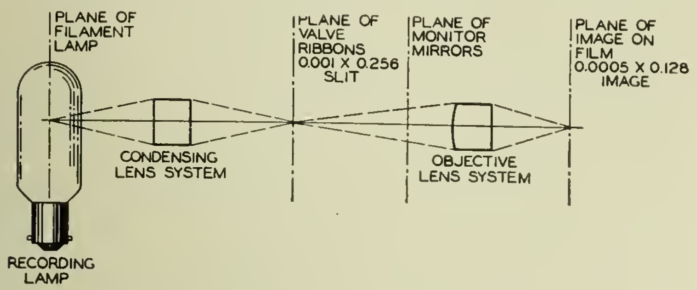

Fig. 3—Recorder Optical System.

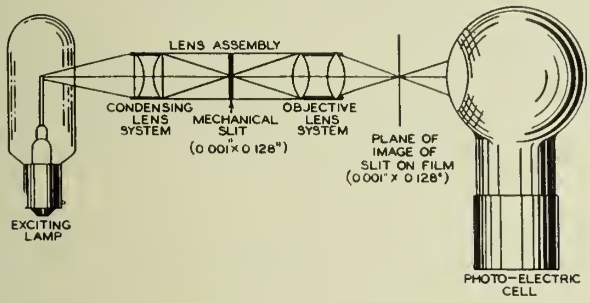

Fig. 4—Reproducer Optical System.

A third method of film recording, used until recently, has now been abandoned. In this system, a variable density record is produced, by means of a varying light source, through a slit of fixed area. A gaseous discharge lamp which varies its illumination in accordance with the amplified voice currents is used. The results of this method were not satisfactory when compared to those produced by the technique developed in the use of the other systems, and this method has now fallen into disuse.

General Principles of Reproduction

There are three essential elements in a reproducing system:—

(*a*) A reproducer to work from the film or disc record.
(*b*) An amplifier.
(*c*) The sound projectors.

An electromagnetic reproducer is used for translating the mechanical motion derived from the disc record into electric currents. These reproducers assume various forms, but all are of the general design in which an armature within a small coil vibrates as a needle attached to it follows the grooves in the record. The armature forms part of a magnetic circuit through which passes the flux from a permanent magnet. Variations in this flux cause a corresponding electric current in the coil. This is amplified, and projected through the loudspeakers as sound.

The reproducer for the film record uses as its essential device a photoelectric cell. Under the action of light the cathode of the photoelectric cell generates electrons which will carry a current across between the cathode and anode. Variations in this current reproduce faithfully variations in the light. The cell does not differentiate between a light pattern of constant intensity and varying area, and a light pattern of constant area and variable intensity. The reproducing arrangement is shown in Fig. 4. The light from the filament of the high-intensity exciting lamp is focussed on the film as a beam 1 mil wide. After passing through the sound track it falls on the light-sensitive surface of a photoelectric cell. It will be noticed as a fortunate circumstance that this system reproduces equally well variable-area or variable-density records.

Requirements for Reproducing Sound

A system for recording and reproducing speech, music and noise satisfactorily must perform within well-understood and clearly defined limits. Thanks to researches which have been carried on for many years, to-day we have a fairly complete picture of the types of distortion, discussed in purely physical terms, that are introduced in recording, transmission and reproduction. What is equally important, we know just how much distortion of each type is tolerable in various kinds of systems, we know what the performance of a system must be for distortionless transmission, i.e. transmission in which the distortion is not perceptible, and from a knowledge of the physical characteristics of our pieces of apparatus we can form an accurate idea of how the reproduced sound will compare with the original. We now have the dictionary that will translate terms describing sound like dull and brilliant, shrill and heavy, harsh, smooth, full, thin, and a host of others, into definite technical statements.

In the electrical transmission of sound we are mainly concerned with three types of distortion. The first is that caused by the fact that the reproducing system transmits different frequencies unequally, and is called *frequency distortion.* In the degree in which the three types are usually heard, this is the most noticeable. The second form of distortion is called *harmonic distortion* and is due to the presence in the reproduced sound of frequencies which were not present in the original. This is the form of distortion present when a vacuum tube circuit is overloaded. The spurious frequencies generated are integral multiples or *harmonics* of frequencies in the original sound; hence the term harmonic distortion. The third type of distortion is *phase distortion.* This occurs when the time taken for the transmission of sounds through the system varies with the frequency, that is, different frequencies have different times of transmission. Phase distortion takes place when the phase shift of each component is not proportional to its frequency, and is ordinarily not present in recognizable amounts.

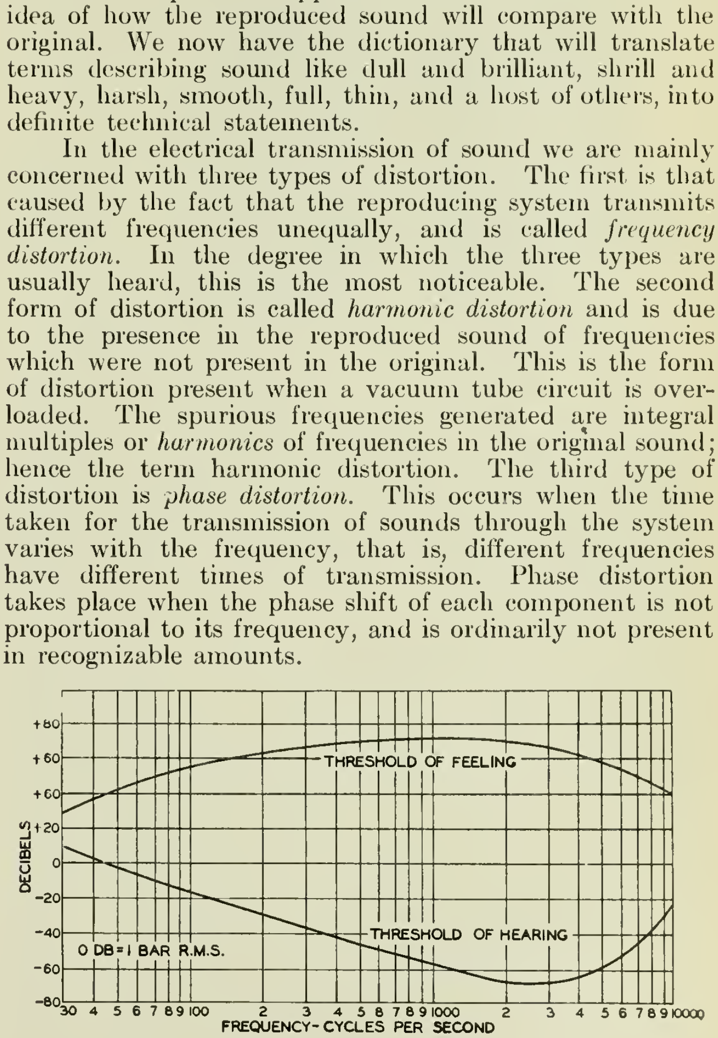

Fig. 5—Audibility Curves.

Figure 5 shows the audibility curve for the human ear. All acoustic vibrations of such an intensity and frequency that they fall within the area enclosed by the two curves, are audible, and are perceived as sounds. Acoustic disturbances of high intensity lying above the upper curve give rise to the sensation of feeling. This effect is commonly experienced when the bass pipes of a large pipe organ are played. Vibrations which lie below the lower curve are not perceived at all. That is to say, there is a definite intensity limit for the human ear, below which disturbances are inaudible and above which they are audible. This limit is called the "threshold of audibility" and its exact value for any person depends on the average noise level; for the city dweller it is much higher than for one who lives in the country. The horizontal frequency scale of this figure is logarithmic; the vertical intensity scale is plotted in decibels. The zero line represents an

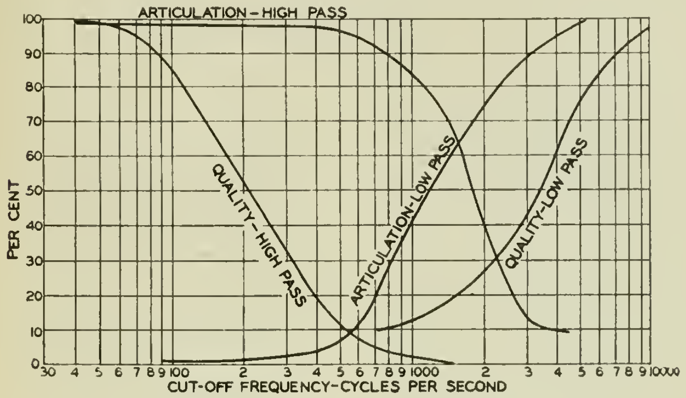

Fig. 6—Quality and Articulation Curves.

r.m.s. sound pressure of one bar (one dyne per square centimeter). The decibel is a logarithmic unit in general use to-day for expressing power ratios, and the number of decibels expressing the ratio of two powers is obtainable thus:—

$$\text{Decibels (abbr. "db.")} = 10 \log_{10} \frac{\text{Referred power}}{\text{Reference power}}$$

The 20 db. intervals on Fig. 5 each represent, therefore, power ratios of 100 : 1. It is interesting to note that at the widest part of this area the human ear can distinguish about 1,300 pure tones perceptibly different in pitch. At 1,000 cycles about 270 perceptible loudness increments exist, and it is estimated that the ear can detect a total of about 300,000 pure tones differing in pitch and loudness. This gives some measure of the magnitude of the problem which confronts us when we propose a distortionless sound reproduction system.

Figure 5 indicates a type of distortion which is not connected with the reproducing system itself, but is a result of the characteristics of the ear. This distortion results when sound is reproduced at a different volume than that existing at the point at which the original sound was picked up. In other words, if two sounds are projected, identical in waveform but of a different amplitude, the ear hears them as different not only in loudness, but also in composition. This is readily seen by reference to the figure. Suppose the music of an orchestra was picked up by a microphone at an average intensity of −10 db. and reproduced through a loudspeaker at an intensity of −30 db. The effect is seen to be that all frequencies between 75 cycles and 200 cycles in the original sound have been largely eliminated. Exclusive of any electrical and acoustic requirements on the transmitting system itself, then, distortionless transmission requires that the sound be reproduced at the volume of the original. In general, if sounds are reproduced at less than natural volume, the frequency range will be narrowed.

The two "quality" curves of Fig. 6 show the effect of the upper and lower cut-off frequencies of a transmission system on the quality of orchestral music. These curves may be considered to be approximately true also for quality of speech. It is seen that a noticeable deterioration in quality occurs when the lower cut-off point is higher than about 70 cycles. The upper point at which quality deterioration is evident is very high, about 16,000 cycles for orchestra music and 10,000 cycles for speech.

The audibility curves of Fig. 5 show that the ear is capable of hearing sounds which differ in amplitude by about 140 db. For distortionless reproduction, however, it is not necessary to reproduce this range, since the maximum volume variation of the human voice is only about 40 db., and of a symphony orchestra, 70 db. Apparently the requirement for a distortionless system is not greater than 70 db. What we mean when we say that a transmission system will reproduce a volume range of 70 db. is that when the sound is reproduced at its original level, the system will not overload on the maximum peaks, and the sound at the lower edge of the 70 db. band will not be masked or interfered with by extraneous noise; this implies that at normal volume, noises introduced in the system must be near or below the threshold of audibility.

How well are these requirements for distortionless transmission met in sound picture systems? The over-all frequency response from the sound pressure in the recording studio to the intensity at the listener's ear in a theatre is substantially uniform from 50 to about 8,000 cycles, the harmonic distortion is nearly negligible when the equipment is properly adjusted and the photographic processes are carefully controlled; the noise level is near or below the threshold of audibility, and the intensity at the listener's ear is of the same order as it would be were he actually viewing the scene being projected. The normal volume range of 40 to 60 db. for ordinary action has been somewhat compressed, however.

Description of Reproducing System

In a theatre there are two projection machines, and a continuous show is obtained by running one machine

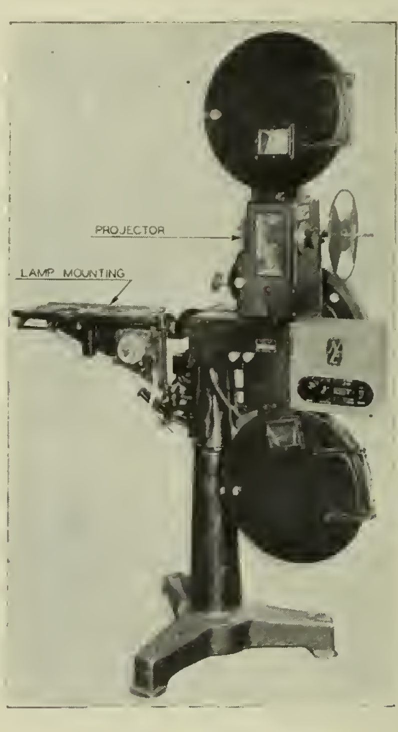

Fig. 7—Projection Machine.

while film is being threaded into the other. The operator then watches and listens for a cue which is indicated on a cue-sheet sent out with each set of prints. This cue generally takes the form of punch-marks in the upper right-hand corner of several successive pictures. When he sees this, he starts his second machine, and when it has come up to speed, switches over picture and sound simultaneously. The uniformity of projectors and the acuteness and dexterity of operators are such that this change-over is generally accomplished without being in any way perceptible to the audience. In theatres, where the fire hazard is severe, the projection machines are always in fireproof projection rooms.

In Fig. 7 is shown a projection machine, which includes the mechanism for projecting the picture, and also for picking up the sound track from the film. The picture projector includes the lamp, which is usually an arc lamp, the mechanism for imparting to the film the intermittent motion required for motion pictures, a shutter and the necessary optical system.

The film is on a reel in the upper magazine. It is drawn down through the picture projector, then through the sound reproducer mechanism below the projector, and finally winds up on a reel in the lower magazine. There is a distance of about 14½ inches between the points where the picture and sound are taken off the film; this is compensated for by displacing the picture and the sound-track 14½ inches when making the positive prints.

The sound reproducer shown in Fig. 8 is a standard design used generally throughout the world. The driving motor is a squirrel-cage induction motor with a split-phase starting winding, mounted in a rubber cushioned frame to minimize vibration. It drives a large flywheel through two parallel fabric belts. This type of drive provides a very efficient filtering action, resulting in uniform speed of the film past the photoelectric cell, and consequently, freedom from objectionable flutter disturbances. The *sound sprocket* on the same shaft as the flywheel pulls the film past the photocell, and a floating gear on the same shaft drives the projector through a gear and pinion above it, and a second film sprocket below it. The lower or *take up* reel is driven through a friction clutch by a belt, and this second or *hold back* sprocket prevents the film being pulled tight on the sound sprocket as the diameter of the reel of film in the take-up magazine increases. Since the smallest variation from uniformity in the velocity of the sound track past the photocell will appear as noise in the loudspeakers it is important that gear ripple and flutter due to the *intermittent* mechanism should be filtered out of the system before they reach the sound sprocket.

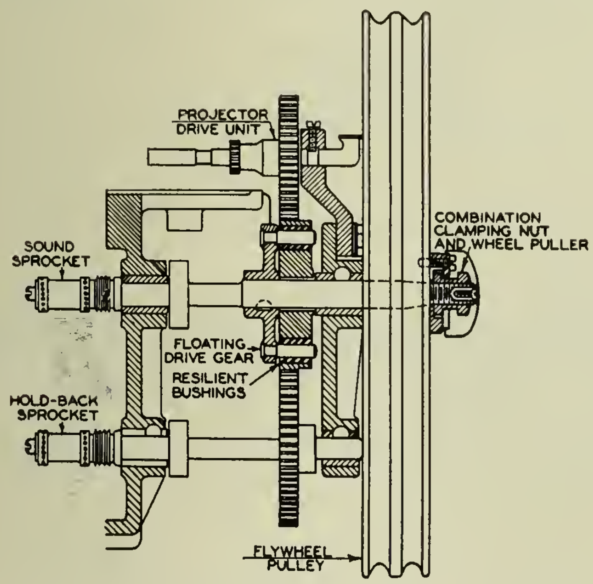

Fig. 8—Cross Section of Film Reproducer Mechanism.

The photocell, which performs the function of converting the light variations into current variations, is contained in the unit on the forward end of the projection machine. The photocell on each machine is transformer-coupled to the control and switching circuit. Since the alternating current output of the photocell is only a few millionths of an ampere, extreme care has been taken in the design of this part of the equipment to ensure against extraneous electrical disturbances. From these photocell coupling units which transform the high impedance of the photocells to a low value, suitable for transmission over ordinary paired wire to the rack-mounted equipment, the sound currents enter the main amplifier.

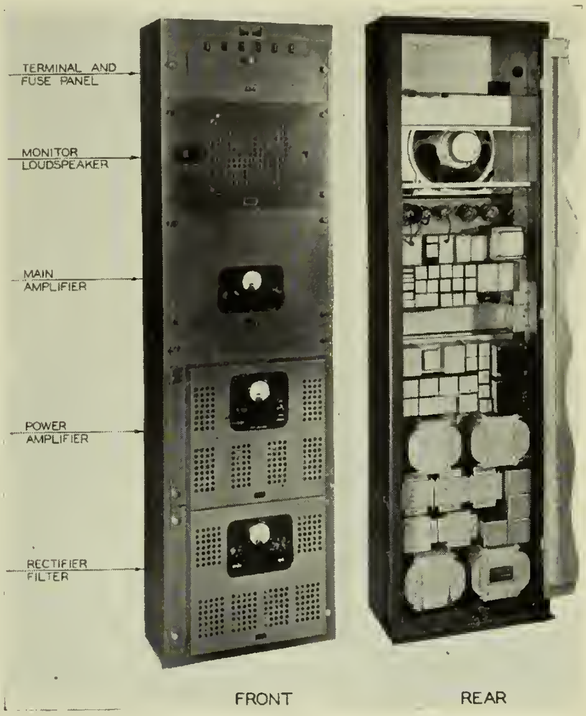

Fig. 9—Theatre Amplifier Equipment.

This is one of the five units mounted together to form an integral assembly, shown in Fig. 9, which is located in the projection room along with the projection machines. It is an a.c. operated four-stage amplifier with characteristics which represent about the ultimate reached to-day in commercial amplifier design. In all but the very large theatres the output of this amplifier operates the loudspeakers. In very large theatres its output is used to drive the power amplifier below it. It has a maximum gain of about 110 db. (equal to a power amplification of 10^{11}) and a maximum non-distorted single-frequency output power of about 15 watts. All the tubes have a.c. heated cathodes, and the plate supply is obtained from a full wave rectifier and filter forming part of the amplifier itself. Due to the extraordinary efficiency of the output tubes, the plate power supply is relatively small.

At the bottom of the rack is the 24-volt rectifier-filter unit that supplies direct current to the exciting lamps, the signal lamps and the speaker fields; this unit uses two half-wave tungar bulbs in a conventional arrangement. All the a.c. and d.c. power circuits are fused here. The rack is completely assembled and wired in the factory, and the installation work consists of connecting a factory-made cable between the terminal panel and the machines, and the power leads and circuits to the loudspeakers on the stage. Below the terminal panel is mounted a small loudspeaker, which enables the operator to follow the action.

The mechanical arrangement of the apparatus is novel, and has resulted in extreme accessibility of the component parts and wiring, compactness, lowered costs, and improved appearance. The construction is shown in Fig. 10. The apparatus of each unit is mounted on a bent and welded pan-shaped chassis which is mounted on the rack by flanges at the ends. The rack itself is in the form of a completely enclosed cabinet. The controls and meters of each unit are mounted on hinged panels. The wiring is cabled and flexible conductors are used so that the cable bends with the hinge. Each chassis is fastened to the rack with flat-head machine screws; the front of each panel is covered by a sheet metal mat which fastens to the rack with thumb screws and has a square cut-out to expose the controls.

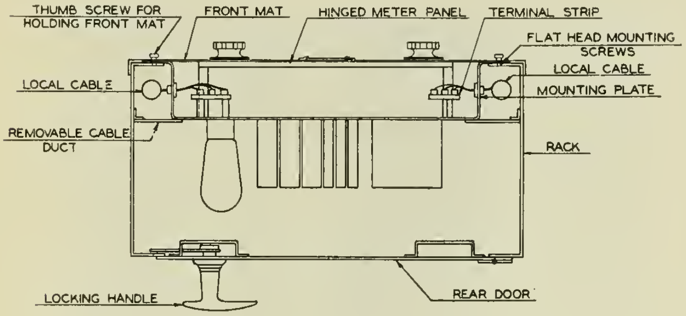

Fig. 10—Cross Section Through Typical Depressed Panel Type Unit Mounted on Cabinet Type Rack.

The wiring and terminal strip for each unit are contained in the face of the chassis, under the mat. The cabling between units comes through bushings in the edge of the chassis, and is concealed along the length of the rack by a removable cable duct.

The mechanical arrangement of the photocell coupling units, shown in Fig. 7, is somewhat different. They are composed of stud-mounted apparatus mounted on the top of a horizontal chassis, with the controls mounted on the front edge. The front cover-plate has an oblong cut-out to expose the controls. The unit slides into a bent and welded sheet-steel case; to examine the wiring it is only necessary to remove the front cover, slide the unit forward, and then let it drop forward about a hinge on the front lower edge.

The photoelectric cell consists of a caesium-oxygen coated silver cathode and an anode in an evacuated bulb. Although the current from it under the usual illumination used is measured in microamperes, even so this is ten times that obtained from the photocells originally used. This increased current, together with the lower internal impedance of the cell have made possible the great simplification in the new equipment due to the use of a transformer coupling circuit between the photocells and the main amplifier, in place of the preliminary amplifiers immediately associated with the photocells, necessary in the previous equipments.

It is only the extremely useful characteristics of the tube used in the first three stages of the amplifier which have made it possible to produce all a.c. operated equipment of this type. The limiting factors in a.c. operated amplifiers have previously been, first, the power noise introduced into the circuit from the alternating heating current of the cathode of the first tube and, second, the cathode hiss or emission noise generated in the first tube due to the statistical variation in the emission of electrons from the cathode. In this tube these factors have been reduced by about 20 db. over previous designs, so that it is now possible to build commercially this a.c. operated amplifier with a gain of over 110 db., in which thermal noise, which is a natural limiting noise level, masks other noise present.

Two tubes are used in push-pull in the output stage of the amplifier in a straight class "A" arrangement, and a plate circuit efficiency of better than 40 per cent is realized. The ideal efficiency (i.e. ratio of maximum undistorted single frequency a.c. output to d.c. plate input power) of a class "A" amplifier is 50 per cent, and the figure 40 per cent represents an efficiency several times that of previous tubes and amplifiers.

When very high output power is required the power amplifier, shown in Fig. 9, using a pair of triodes in push-pull in a modified class "A" circuit, is used. A plate supply of 1,500 volts is obtained from a full wave bridge rectifier, using mercury vapour tubes, and the grid bias is obtained from a separate full wave rectifier circuit. This amplifier will deliver upwards of 100 watts of audio power with negligible distortion and is used for extremely large theatres and auditoriums.

The loudspeakers employed with the new theatre equipment are of three general types: first, large dynamic cone units similar in general arrangement to the conventional radio set loudspeaker, second, large exponential wooden or steel horns equipped with moving coil driving units and third, small high frequency units consisting of a coil driven diaphragm coupled to a small metal horn. The large horns are of the conventional type that have been in use for a number of years, in fact since the inception of sound pictures. The high frequency units are, however, a recent development; the cross-section of one of these units is shown in Fig. 11. This unit transmits with an efficiency of about 50 per cent the frequency range from 3,000 to 13,000 cycles and is always used in conjunction with one or both of the other types of speakers. When the large dynamic speakers are used, they may be used alone or with either or both the other units. When used alone, they transmit the frequency range from the low end of the frequency spectrum to about 8,000 cycles at the upper end and a group of them are mounted together on a large baffle. In equipments where it is desired to get extremely good frequency response, the small high frequency units are used in addition, and an electrical dividing network is connected to split the amplifier output, transmitting frequencies up to 3,000 cycles to the large dynamic cones and frequencies above 3,000 to the high frequency units.

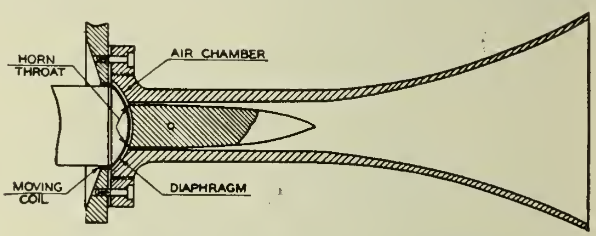

Fig. 11—Cross Section of High Frequency Unit.

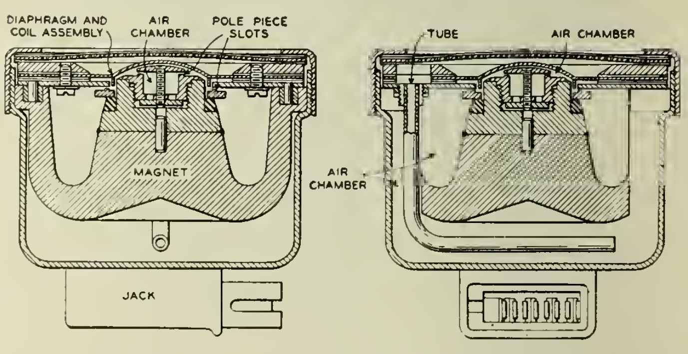

Fig. 12—Cross Section of Microphone.

In large auditoriums and wherever it is difficult to get good sound distribution, the large horn type projectors are used in addition, transmitting the middle frequency range, for which they project a somewhat directional beam of sound.

The new tubes, the new photocells and the new loudspeakers have permitted a considerable improvement to be made in the performance of the original theatre equipment placed on the market in 1926. This improved reproduction is perceptible to the audience in three ways:—First, the transmitted frequency range is considerably improved; in place of the former 100 to 5,000 cycle range it is now possible to reproduce accurately a 50 to 8,000 cycle range. Second, the volume range has been considerably improved. Sound pictures up till a year or two ago rarely were able to effect a volume range greater than about 30 db.; this range has been increased by some 10 or 15 db. due to lower noise levels which previously limited the lower end, and higher power amplifiers, which have increased the range upward. Third, the background noise caused by the film and the reproducing system has been markedly reduced.

Description of New Recording Units

A great improvement in recording has been effected in the last few years. This has been due both to the development of new apparatus and to experience gained in the technique of film recording. The dynamic microphone, of which a cross-section is shown in Fig. 12, has greatly improved the pick-up technique in the sound studios. It consists of a formed duralumin diaphragm to which is cemented a voice coil moving in the slot of a permanent cobalt-steel magnet. This microphone has an extremely uniform response characteristic, being substantially flat from 30 cycles at the low end to over 10,000 cycles at the high end. It is small, compact, sturdy, and is not subject to barometric or humidity conditions and does not require, like the condenser microphone, a closely associated amplifier, or like the carbon microphone, a direct current supply. Recording amplifiers have been equalized to obtain a frequency response characteristic uniform to 10,000 cycles.

The technique of light valve recording has been the subject of continuous development work. One improvement which has been generally put into use is that known as noiseless recording. A large part of the film noise or film hiss previously obtained in film recording was due to the fact that during silent periods when no sound was being transmitted, the light valve was open to its normal operating point and the film was partially exposed at a constant density. Due to the grain of the photographic deposit on the positive, this partial exposure gave a steady scratching or hissing noise when reproduced. This hiss is directly proportional to the exposure of the negative. In noiseless recording the light valve is biased partly shut by direct current, thus reducing the average exposure during silent periods. When sound is being transmitted, the d.c. bias is reduced automatically, permitting the average spacing of the valve to increase sufficiently to pass the signal without clashing.

Other developments which are under way by many workers in the field look towards more satisfactory control of the photographic processes. Figure 13 shows the characteristics of photographic emulsions. On this curve the relative density of the photographic deposit is plotted on the ordinate scale and the logarithms of the exposures giving these densities are plotted as the abscissae. Since the variable density system of film recording depends for its success on a linear relation between the amplitude of the sound to be recorded and the intensity of the light falling on the reproducing system photocell, this linear relation must be preserved through the intervening photographic processes. The least number of processes through which the record must pass is four—that is, exposure of the negative, development of the negative, printing of the positive, and development of the positive, and the sum total of these processes must yield a linear relation. This means, then, that the film must be worked along the straight line portion of the overall negative-exposure positive-density curve. It is evident that the length of the straight line portion of this curve limits the volume range which can be recorded. A further requirement on the photographic processes and one which is equally important is that the contrast in the record must be preserved at approximately the correct value, since to reduce the contrast would result in a compression of the volume range and to increase it would result in an extension of the volume range. If the original exposure of the film made full use of the volume range indicated by the exposure-density curve, then this increase in contrast obtained in the developing and printing processes would, of course, result in serious

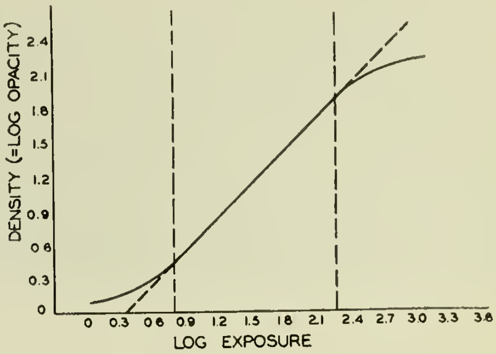

Fig. 13—Exposure-Density Curve for Typical Emulsion.

non-linearity. It can readily be shown that another way of stating the requirement that the contrast must be maintained is to say that the slope of the exposure-density curve obtained by plotting the density of the final print against the exposure of the negative must be unity. Since the first days of sound pictures a great deal of development and research work has gone forward to determine the exact relations involved in order to produce photographic emulsions for which the straight line portion of the exposure density curve is of adequate length and this work is producing results in greatly improved film and film processing.

Due partly to the difficult technique and the sometimes uncertain results obtained in the photographic processes, but mainly due to the fact that vertical disc recording inherently has advantages over film processes so far as frequency range, volume range and noise level are concerned, a new technique has been developed recently by which all intermediate processes in sound film production are carried out on vertical cut disc records. The vertical cut disc has a frequency range extending to 10,000 cycles and a noise level near the threshold of audibility. In addition, the non-linear distortion introduced is negligible. In the production of sound pictures, there are frequently a number of re-recordings required in the editing and piecing together of the film so that an improvement in the re-recording process will result in a considerable overall improvement in the quality of the final prints.

What new developments may we expect in sound pictures in the future? We now have high quality sound, and coloured pictures, so that our representation is reasonably close to good illusion. There are two things which we may now expect; first, production of pictures in relief, that is, stereoscopic projection, and second, production of sound in relief—stereosonic projection. Both these effects have been accomplished on a small scale basis and now await only commercial development. Both will add considerably to the effect of reality in the motion picture theatre and will add immensely to the enjoyment of motion pictures by the many millions who rely on that theatre as their main source of entertainment.

DISCUSSION

W. M. Gardner, A.M.E.I.C.[1]

How does the frequency characteristic of the system described, of which we have heard a demonstration, compare with the ranges transmitted by the telephone and the phonograph?

[1]Supt. of Construction and Maintenance, Montreal Tramways Company, Montreal.

S. T. Fisher, Jr.E.I.C.[2]

In these films you have heard, a frequency range of about 70 to 7,000 cycles was transmitted with substantial uniformity. In a first-rate theatre installation, where equipment of this type is used and where care has been taken to adjust the acoustic conditions and to obtain proper distribution of the whole frequency spectrum, a characteristic flat between 50 and 8,000 cycles is obtained. As you will note from the curves of Fig. 6, transmission down to 70 cycles results in reproduction which is almost ideal at the lower end; at the upper end of the audible range cut-off at 8,000 cycles results in only a small deterioration in quality. This wide frequency range is necessary to give naturalness to speech and to preserve adequately the dramatic effects of music. In the mechanical phonograph a frequency range from about 150 cycles to 4,000 cycles is attained; the electric phonograph does somewhat better, reproducing frequencies from about 70 to about 5,000 cycles. A direct comparison would show plainly that this is much poorer than the reproduction you have heard to-night.

On commercial telephone circuits a very much narrower band of frequencies is transmitted. It is seen from the curves of Fig. 5 showing how articulation (or intelligibility) varies with the transmitted frequency range that cut-offs of 300 cycles and 4,000 cycles give almost ideal articulation, even though the quality of transmission is very poor.

Where telephone circuits are used for transmission of broadcast programme material a transmission from 50 to 8,000 cycles is frequently provided.

J. L. Clarke, M.E.I.C.[3]

It has been my experience that when small photographs are enlarged, the photographic grain becomes very noticeable. Are not the effects of this grain serious in sound-on-film recording?

S. T. Fisher, Jr.E.I.C.

As Mr. Clark has pointed out, in sound-on-film recording, where the dimensions of the recording and reproducing light beams and of the variations in the density or area of the record are extremely small, the grain of the photographic deposit presents a problem. You will remember that in the days of silent pictures the grain was very noticeable on the screen, and in the first sound-on-film recording this was one of the major problems. The noise due to this grain has been overcome largely by the development of new emulsions and new processing technique, which have resulted in a much more homogeneous deposit on the positive prints. Another factor, of course, has been the introduction of the so-called "noiseless" recording, which reduces the grain noise by reducing the average exposure of the negative.

E. S. Kelsey, A.M.E.I.C.[4]

The noise introduced by the grain of the deposit on the film is due to variation in the grain, that is, it is a statistical effect, and is proportional, not to the grain itself, but to the variation in the grain.

F. S. Fisher, Jr.E.I.C.[5]

What proportion of the theatre reproducing equipment demonstrated is manufactured in Canada?

S. T. Fisher, Jr.E.I.C.

About 95 per cent of the total cost of the equipment is represented by material and parts purchased in Canada, and Canadian labour.

A Concrete Bowstring Arch Bridge

Across the Grand River at Bridgeport, Ontario

D. J. Emrey, A.M.E.I.C.,
Engineer, Kitchener Good Roads' Commission, Kitchener, Ont.

Bridgeport is one of the pioneer villages of the county of Waterloo, being situated on both the east and west sides of the Grand river, and equally distant from Kitchener and Waterloo. At one time Bridgeport gave promise of growing into one of the more prosperous and thriving villages of the county, but on the building of the Grand Trunk Railway through this section about 1852, the line passed through Kitchener some two miles distant from the village, and this had the effect of retarding its growth while the city of Kitchener continued to forge ahead.

The construction of a new bridge across the Grand river at Bridgeport had been contemplated for some time by the Kitchener Suburban Commission, but due to the depression the Commission did not think it wise to proceed. Last year the Federal and provincial governments suggested a scheme of work for the unemployed by which the Federal government was to pay one third, the provincial government one third, and the owner the remaining one third of the labour costs; that is, for projects approved by the combined governments. The Commission decided to take advantage of this scheme and made application for permission to construct the bridge, which offer was accepted.

The old bridge was located on a curve of the river and it was decided to rebuild in the same location. Figure 1 shows the old bridge and the river in flood.

The old bridge consisted of two main spans each 107 feet long and 16 feet wide, then came a section of highway about 117 feet long, located on an island and contained between two concrete retaining walls. This was followed by another bridge 96 feet long by 16 feet wide over a flood channel. Due to the height that the floods attained at times, it was decided that (*a*) a girder bridge was out of the question; (*b*) as it was an unemployment scheme for local labour it should be a concrete bridge; (*c*) due to (*a*) and (*b*) the only type of bridge to fit the location was a bowstring arch; (*d*) the island should be excavated to 2 feet above the approximate low water level; (*e*) the bridge should be designed to consist of five spans each of 82 feet 2 inches with a 24-foot roadway and a 5-foot 6-inch sidewalk on the upstream side.

The total length of the bridge is 457 feet 2 inches to the ends of the wing walls. The height of the floor is 19 feet above approximate low water level, and the foundations extend to a maximum of 15 feet below low water level into hardpan. Figure 2 shows the completed bridge. The lamp posts are of concrete and add a decided finishing touch to the structure.

Design

In figuring the stresses, class 20H loading in accordance with the general specifications for Highway Bridges, 1933, was used. The loading allows for:

(*a*) Maximum uniform live load of 100 pounds per square foot of roadway or (*b*) two lanes of 15-ton trucks with the trucks following each other at 30 feet apart, or

Fig. 1—Old Bridge across Grand River at Bridgeport, Ont.

one lane of 20-ton trucks following each other at 30 feet apart.

(*c*) A uniform live load of 100 pounds per square foot on the sidewalk, but only 25 pounds per square foot to be used with case (*a*) or (*b*) in figuring loads in arches. An impact factor of 30 per cent was added to the truck load stresses. Influence lines were used to ascertain the position of trucks for maximum stress in the arch ribs. Hard grade steel was used throughout with an allowable working stress of 20,000 pounds per square inch except for hangers and ties, where soft grade steel was used with a permissible stress of 16,000 pounds per square inch.

The piers and abutments were designed as straight gravity piers and abutments. A typical pier is illustrated in Fig. 3 and abutment No. 1 in Fig. 4.

A general elevation plan of the bridge is shown in Fig. 5.

The floor is a straight beam and slab design, with the concentrated load for a 20-ton truck with 80 per cent of the load on rear axle found by

$$P = \frac{\text{40 per cent of weight of truck}}{(2/3\ l) + t \text{ (not to exceed 6 feet)}}$$

l = clear span in feet

t = width of tire in feet − 1 inch per ton.

it will easily be seen that in this type of bridge the beams supporting the deck must be arranged transversely as shown in Fig. 6 which shows a cross section of the bridge.

There is an economical thickness of the slab which in turn governs the spacing of the beams. This thickness of slab is governed by the shearing stresses, in other words the slab has to be of a certain thickness in order that the shearing stresses shall not become serious. Referring to Fig. 6, it will be seen that the deck platform is on the same level as the tie beam. This is done purposely, and in conjunction with the vertical suspender at the end of each beam provides an inherent transverse stiffness at frequent intervals.

Design of Curved Rib

The curved rib members are considered as two-hinged arches, and are made of parabolic form. The rise of the curved rib is taken as at about one-sixth the length of the span.

The horizontal thrust $H = Pl/8f$ where P = load, l = span, f = rise.

The axis of the arch is a parabola of the second degree. Thus, the line of resistance for a uniform load over the entire span falls on the axis of the arch and causes no bending moments or shearing forces to be developed in any section of the arch. The bending moment at any point is $Ms = Mf - Hy$ where Mf is the bending moment in a freely supported beam, y = vertical distance of the centre of the section from the support, and H = horizontal thrust at the point. Calculations for several different arrange-

Fig. 2—New Bridge at Bridgeport.

ments of loading have to be made to ascertain the maximum positive and negative moments developed.

$$S \text{ max.} = \frac{H}{\cos\alpha\ Ae} \pm \frac{My}{Ie}$$

α = angle of tangent to rib axis with horizontal at section considered.

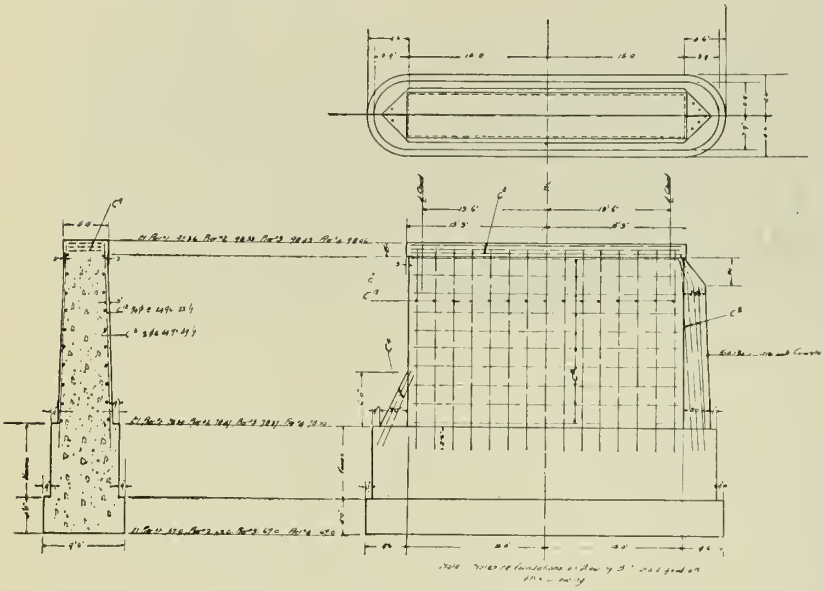

Fig. 3—Detail of Typical Pier.

Connection of Curved Ribs with Horizontal Ties

A point of vital importance and one requiring most careful attention when detailing the reinforcing and during construction, is the connections between the curved rib and tie.

The distribution of stress at these points is by no means uniform, and great care is required to design the junction of these members in such a way that the tension in the horizontal tie is gradually absorbed from the longitudinal reinforcement and transmitted to the curved rib, where it neutralizes the horizontal component of the normal compression force in this member.

Another point of interest is that of extending the bottom portion of the expansion plate under the fixed end of the arch. (See Fig. 7.)

Construction

Bids for the construction of the bridge were received from several contractors as follows, the Commission supplying the cement and reinforcing:—

	Total cost
Storm's Contracting Company Limited	$67,680.95
Windsor Construction Company Limited	67,838.52
Cameron and Phin	68,183.80
R. A. Blyth	69,306.60
Dunker Brothers	69,306.60
Bowman and Martin	72,318.50
Aiken, Innes and MacLachlan	79,084.00
W. Holdcroft and Co. Ltd	79,175.30
Ball Brothers	79,239.65
Ryan Contracting Company	79,200.84

and several others.

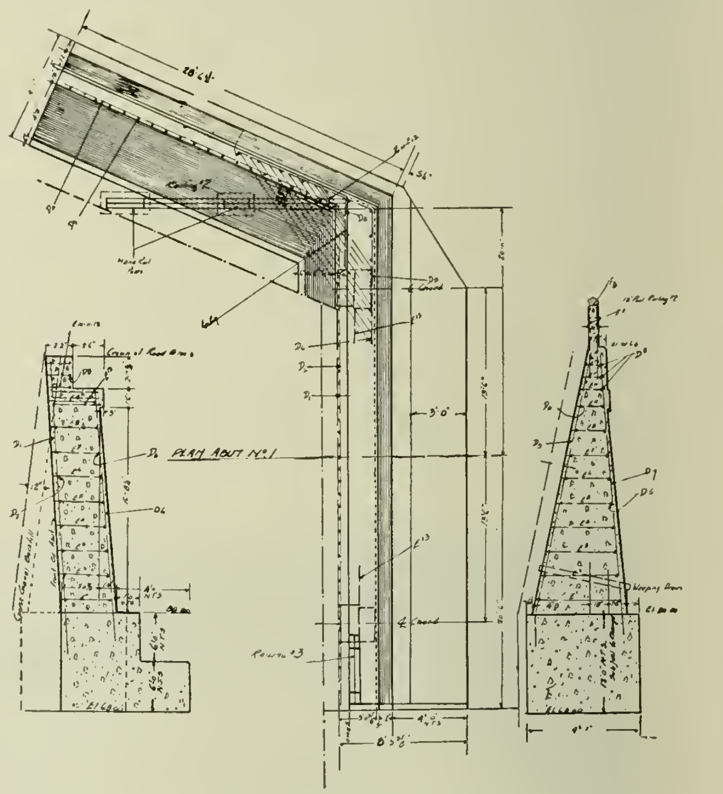
The contract was awarded to the Storm's Contracting Company of Toronto, and was carried out under Mr. Harry Weller as general superintendent. The work was done in a thorough workmanlike manner to completion, and if all contracts were carried out as satisfactorily the life of the inspector and resident engineer would be a happy one. The construction was started toward the end of April, 1934, and the work carried on with one shift except for the pouring of the floor and sidewalk, when two shifts were used.

As the water level at this time was about 3 feet above normal low water and the current was consequently rather fast, it was decided to begin at the easterly end so that by the time the work had progressed to the completion of the east abutment and two easterly piers, the water would be sufficiently low to warrant work on the west abutment and the two westerly piers which were in the river proper.

This programme was successful beyond expectation as contrary to the general belief there were no floods or high water of any kind during the entire summer. In fact the water was so low and the flow so small that a ford was constructed upstream from the bridge. This was used to divert traffic and also made both ends of the bridge accessible.

The existing steel spans were practically coincident with the new structure and all possible use was made of them; the spans being dismantled only as the progress of the new work required.

The excavation of the island was carried out by pick, shovel and teams. Excavation for the east abutment and the two easterly piers was done by the open cut method, using a Koehring crane and clam shell bucket. The material encountered was clay hardpan underlying a 12-foot layer of water-bearing gravel. Continuous pumping was necessary, which lowered the water table to such an extent that the neighbouring wells were put out of action temporarily.



a b c

Fig. 4—Detail of Abutment No. 1.
a Section through Abutment.
b Plan of Abutment.
c Section through Wing Wall

The hardpan was excavated with the use of air spades. Excavations were cut neat to line and concrete poured

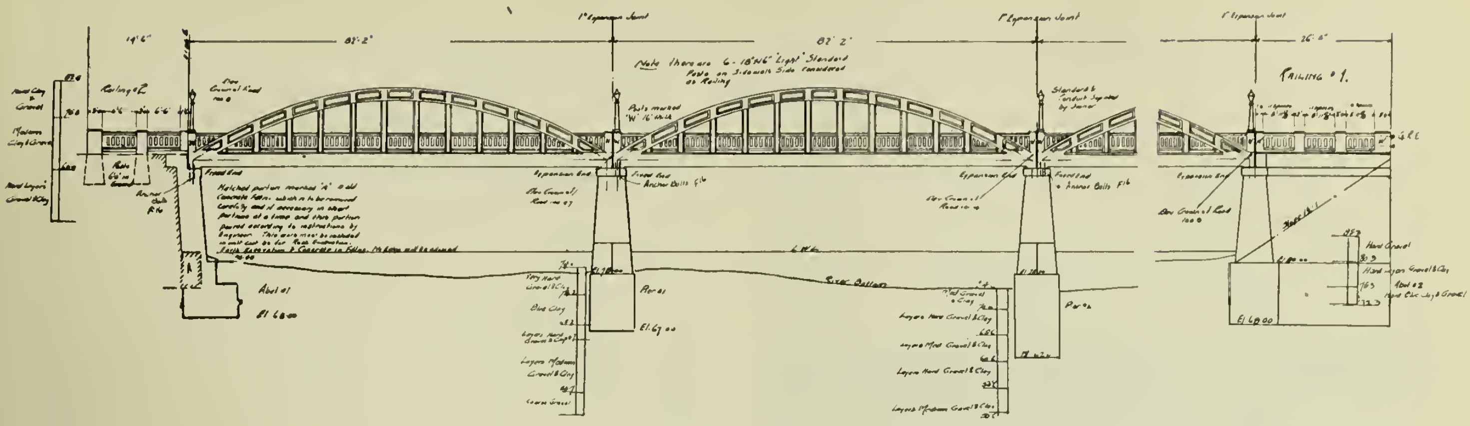


Fig. 5—General Elevation of Bridge.

without forms to 2 feet below the surface of the hardpan.

The excavation for the west abutment and the two westerly piers being in the river proper, had to be unwatered. This was accomplished without any trouble by throwing an earth dam from the island to the old pier which was about the centre of the river. This dried out half the river and besides allowing the excavation to be done in the dry, also allowed the placing of underpinning piles by hand. This was accomplished by sinking the butts of the piles down about 2 feet into the hardpan. The material encountered in this section was the same type of hardpan as on the east end with a layer of large boulders in the river bed. When work was finished in this part of the river, the wings of the dam were thrown back to the west shore and that section handled in the same manner. Figure 8 is a general view showing the old cofferdam from the island to the old pier and the cofferdam in use from the old pier to the west bank. The excavation for pier No. 1 is also shown with abutment No. 2 and piers No. 2, 3 and 4 completed.

The underpinning for the easterly half of the bridge consisted of piles placed on mud sills resting on gravel while the westerly half was as described with the piles being sunk into the hardpan. Practically no settlement was experienced in the latter but in the former there was a maximum of three quarters of an inch. Enough piling was supplied for the entire structure and enough timber for three spans which allowed the work to proceed without interruption.

Five-inch quarter dressed lumber and two-by-six-spruce was used for form work, and enough supplied for three spans. Band iron and clamps were used for form ties.

The concrete was mixed at either end and transported by buggies and duckboards. A Koehring No. 7S mixer was used. The deck and sidewalk for each span were

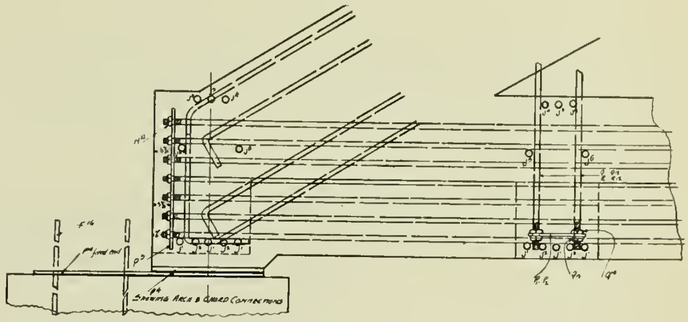

Fig. 7—Section of Arch Rib and Lower Chord.

poured without intermission and the arch ribs were poured with a small wooden tower and special bucket.

Washed sand and gravel were supplied from a local pit about one mile from the site, and the cement was used direct from a Canadian National Railways siding a short distance from the bridge. Both the cement and gravel were hauled across the ford without difficulty.

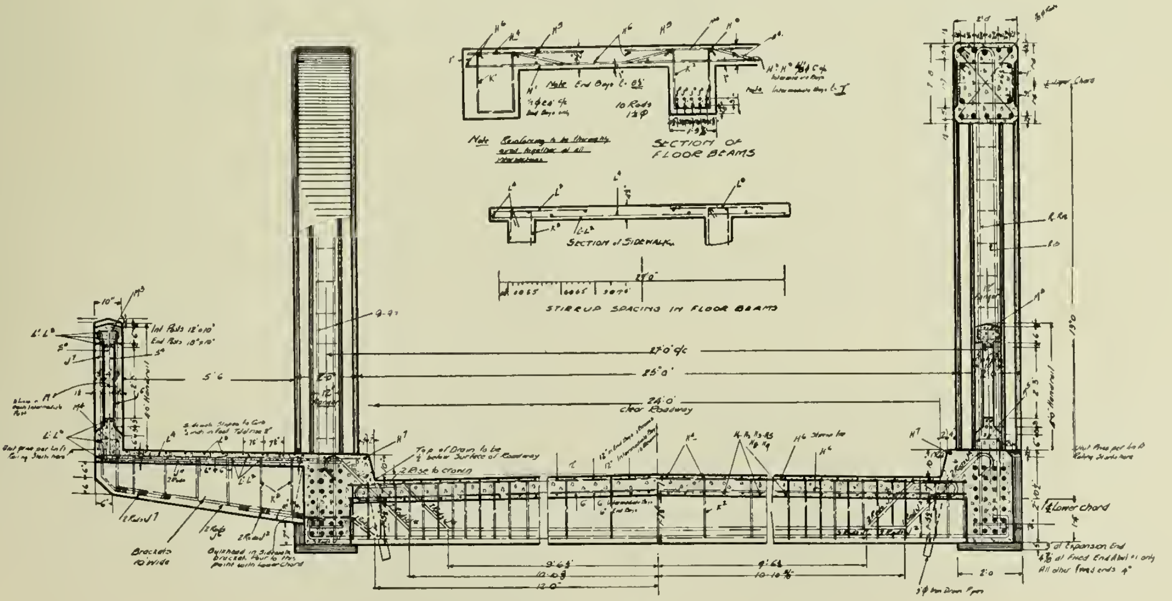

Fig. 6—Cross Section Through Superstructure.

The concrete mixes used in the structure were as follows: the mass concrete in the piers and abutments, Class C—1-2¼-3¾ for 2,000 pounds per square inch concrete, in the floor and sidewalk class B, 1-1¾-3¼ for

Fig. 8

2,500 pounds per square inch concrete, and in the arch hangers, railing and lamp-posts. Class A—1-1½-2½ for 3,000 pounds per square inch concrete. The following was the average result indicated from several tests of each class of concrete:

Class C—3,165 pounds per square inch.
Class B—2,775 pounds per square inch at fourteen days.
Class A—3,450 pounds per square inch.

The class C concrete for the piers and abutments was naturally poured much stiffer than was possible for classes B and A. It is interesting to note that the leaner and dryer concrete gave results almost as high as the richer but wetter concrete.

The contract was completed within the scheduled time and the total construction cost of the bridge amounted to approximately $68,000. The main items included were:—

Excavation for abutments and piers	1,262.4 cubic yards
Removal of old masonry and concrete	958.3 cubic yards
Island excavation	14,580.0 cubic yards
Concrete	2,680.9 cubic yards
Reinforcing steel	158.3 tons
Cement	4,400.0 barrels
Labour man-days	6,964

The cost was distributed as follows:

	Labour	Material
Federal Relief	33⅓	
Provincial Relief	33⅓	
Provincial	16⅔	50 per cent
County	8⅓	25 per cent
Kitchener	8⅓	25 per cent

The bridge was designed by and built under the supervision of the writer.

Testing and Research for the Hydro-Electric Power Commission of Ontario

W. P. Dobson, M.E.I.C.[1]

DISCUSSION

Dr. R. W. Boyle, M.E.I.C.[2]

With regard to the question of vibration of transmission wires. This is a rather serious problem as far as line maintenance is concerned and it seems it is very difficult to identify the source of vibration on the line by which the actual damage is done. As various types of vibrations can occur all at once when there is a gale or a gust of wind, where failures take place there must have been a compounding of stresses such as tension and torsion. This paper does seem to give new light and information on what may take place. Now spans have been lengthened and it has been necessary to increase the tension in the transmission wires and to reinforce the line with additional strength, therefore a steel core is used; but it seems that some research ought to be pursued by someone in an endeavour to find new alloys. A new alloy of a tougher material less subject to bend and of better torsional strength so that so much steel reinforcement would not be required. Is there anybody in the world attempting to solve this particular problem?

J. P. Henderson, A.M.E.I.C.[3]

Wind vibrations in transmission wires would seem to cause a similar problem to that encountered in the construction of aeroplanes, aeroplane struts and wires. All are familiar with the singing of the wires in the wind. Has streamlining ever been considered feasible in any way for transmission wires?

O. W. Titus[4]

The question Mr. Henderson has raised about developing a streamlined conductor has been considered in the past and there are some objections to it. Take the aeroplane: the wire is supported between two reasonably rigid supports. It cannot turn transversely to the line of flight. But with line conductors one must consider supports which are not particularly rigid and with these one thousand feet apart the stresses are somewhat complicated at a midpoint five hundred feet away.

The wires turn transversely and this increases the difficult conditions. Another objection to streamlining is that corona losses must be cut down. This would not seem to amount to much but when there is 270 miles of wire it becomes an economic factor. The most efficient way to reduce corona losses is to obtain something that is an absolutely smooth cylinder. The moment this is departed from the corona losses are higher. Streamlined types being of non-uniform cross-section, that is, not being completely circular, tend to increase the corona losses.

Another question that has been raised is the development of alloys. In this connection the manufacturer runs into a problem immediately. When you take a metal which is a very efficient electric conductor and start to mix things with it to increase its strength, you usually

Trans-Atlantic Air Transport

J. H. Parkin, M.E.I.C.,
Ottawa, Ont.

Paper presented before the Aeronautical Section of the Ottawa Branch of The Engineering Institute of Canada, on May 11th, 1934.

SUMMARY.—The various routes for air traffic across the Atlantic are considered with respect to climatic, navigational and other difficulties, and the capabilities of existing aircraft for this service are discussed. It is suggested that there is now a favourable opportunity for the establishment of a fast air-and-steamer service and ultimately an all-air service between Europe and North America via the St. Lawrence.

Canada occupies a geographical position whose importance in connection with future air transport routes, particularly those between Europe, America and the Orient, can hardly be exaggerated. At the present time, due to the excellence of the trans-Pacific service of the Canadian Pacific steamships and of her transcontinental railways, one of the greatest trade routes between east and west lies through Canada.

With the development of air routes to the east via Europe and India, Canada is in danger of losing this traffic and the benefits accruing therefrom. However, with the proper development of air lines, the advantage will still rest with the Canadian route. There will be the additional great advantage as compared with the Europe-India route, that it will be an all-Empire route.

Examination of a map prepared on the conical orthomorphic projection will disclose important facts concerning the geographical position of Canada not generally realized from a study of a map on the Mercator projection. It will be observed that the great circle route, the shortest and most direct, between the industrial region of Europe through London to Montreal and the industrial region of North America passes via Newfoundland almost directly down the valley of the St. Lawrence. Similarly, the great circle route to the Orient from Chicago passes through Winnipeg, north of Edmonton, through the Yukon and Alaska, across Behring Straits, down the coast of Siberia and through the Japanese Islands. Canada thus occupies a key position on these routes and one which is fully realized by the powerful aviation interests already at work endeavouring to establish and dominate world air routes. In fact, Canadians perhaps least of all realize the economic importance of the position of the Dominion at the cross-roads of the future air routes of world commerce.

History shows that great trading centres always develop at the cross-roads, and modern London, New York, Hamburg, Amsterdam and Montreal all demonstrate this fact. Through traffic creates permanent trade at the junction points, and railways, hotels, merchants, and manufacturers all derive profit from the flow of commerce and passengers. Montreal, Winnipeg, Vancouver and the whole Dominion will derive manifold benefits from the flow of this international air traffic if preparations are made to take advantage of Canada's favourable geographic position and conduct future air traffic via the Dominion.

The great barrier to communication between the continents of Europe and America is the Atlantic ocean. This barrier has been successively overcome by sailing vessels, steamships, submarine cable and wireless telegraphy and telephony. It is in process of being surmounted by aircraft, since over fifty non-stop crossings have been made of the North and South Atlantic oceans. The flights of the Graf Zeppelin between Germany and Brazil are the nearest approach to a regular service as yet attempted.

To circumvent the great length of the open sea crossing, many flights have been made around the north and south of the North Atlantic and these routes and those proposed for future commercial use may be broadly classed as northern, southern and direct.

Northern Routes

The northern routes, a number of which already flown are shown in Fig. 1, touch the Shetland and Faroe Islands, Iceland, Greenland and run then either via Labrador and Newfoundland to New York or cross Davis Strait, Northern Quebec to the east shore of Hudson Bay and thence through Northern Ontario via Cochrane to Detroit or to Chicago.

In addition to its greater length, the disadvantages of the northern route, as given by Commander von Gronau, who has thoroughly explored its possibilities in the course of three flights by different routes from Europe to America via Greenland, are outlined below.

The extraordinary gustiness on the Iceland coast is notorious and fogs, typical phenomena of oceanic islands, frequently envelop the coast and hide the coastal mountains. Floating ice and icebergs are prevalent between Iceland and Greenland and may cover the entire stretch of sea even in August. The ice makes landing and taking off dangerous and difficult on the east coast of Greenland.

There are no reliable maps of Greenland and the interior is unexplored, although in recent years several expeditions have been at work. On the east coast there are only two settlements—Angmagsalik and Scoresby Sound and only one region where musk ox can exist. The east coast marginal area of fjords, high promontories, glaciers and mountain ranges, of which there are two, is some 150 miles wide. The coastal range on the west coast is of equal width with deep fjords and glaciers. The mountains range in height from 8,000 to 13,000 feet.

The inland ice region ranges in height from 9,000 to 10,000 feet. While this appears flat and an emergency landing could possibly be made with a seaplane, it is quite uninhabited and to reach the coast settlements would be difficult, in fact, toward the warmer west coast, walking is practically impossible. In the interior, low clouds, mist and snow frequently reduce the visibility to zero and conditions favourable to the formation of ice on aircraft prevail for six months in the year. There is an extensive radio dead region, of some five hours' flight, precluding receipt of weather reports or direction bearings and magnetic variations of 40 to 70 degrees render the magnetic compass of doubtful value.

The west coast is heated by the Gulf Stream to some extent and by warm air from the tropics which, under certain atmospheric conditions, penetrates these regions, so that the coast and fjords are relatively free of ice for most of the year except when southwest winds fill or block the fjords with drift ice. In the summer, there is much floating ice in the stream flowing north along the coast, which, with the cold water of Davis Strait gives rise to surface fog. Westerly winds blow this fog inland and into the open fjords. Narrow fjords, closed toward the sea by high mountains, are not penetrated by the mist and hence might serve as airports were it not for the frequent strong down-gusts within them. With east winds, the fogs remain less than a mile off shore. Fog renders points on the central and south sections of the west coast unsuitable for airports for a regular service. Ice should give little trouble. The coast in the neighbourhood of Godhaab may be regarded

as ice free as there is little drift ice this far north and the winter pack ice begins considerably to the north.

Very often weather conditions on the east and west coasts are exactly the opposite, i.e., good in the west and bad in the east.

The Davis and Denmark Straits are favoured passages through which Arctic air drains southward into the middle latitudes. The Davis Strait is a region of frequent storms, low clouds and freezing temperature except for short periods in midsummer. The northeast storms with long periods of cold rains and low visibility are particularly hazardous. Fog and floating ice characterize the Strait of Denmark.

Low pressure areas, moving across the continent from the west pass over the New England coast or Gulf of St. Lawrence and while many continue their former track for some distance over the ocean, about 50 per cent turn northward toward the west coast of Greenland or into Davis Strait. These constitute a serious storm hazard since they are preceded by strong easterly winds, low clouds and for at least half of the year by temperatures near or below freezing.

Over Labrador and Northern Quebec (Ungava) conditions are not quite as bad. However, correct maps are non-existent and even if available, the country is featureless, composed of masses of rock interspersed with thousands of water-holes and pools, all alike, rendering identification difficult. The country is uninhabited except for occasional Eskimo encampments on the coasts. The nearness to the magnetic pole results in a deviation of 50 degrees in the magnetic compass. There are occasional sandy beaches on the east shore of Hudson Bay suitable for emergency landings.

The remainder of the route is one of frequent ocean-borne storms from the southwest. Clearly defined horizons are very unusual. As a result of his experiences, von Gronau considered that the best route would be from Reykjavik to Cape Farewell and directly across to south Labrador. Given reliable organization so that help would be available in case of an emergency landing, he thought a regular route possible, but did not dare to say that it could be operated all the year round.

Lindbergh, after flying over this route, is reported as stating that there must be no forced landings. Other expeditions have reported the route very difficult.

Unknown weather is the major hazard on the Arctic routes. There are but few weather stations in these regions. The Canadian stations are along the St. Lawrence; in Greenland, there are two on each coast with one on the southern tip; in Iceland there are two and in the Faroe Islands one. There are few ships in these regions to supply weather reports. The period of daylight is very short during the winter months.

The great length of the northern routes largely offsets the greater speed of aircraft and there would be no saving in time over the present four or five day crossing in palatial steamers. The one advantage is the short stages or ocean flights. The provision of the necessary ground organization, main and intermediate landing fields, radio and meteorological services in such regions, however, presents enormous difficulties. The price of avoiding long oversea flights afforded by these routes, however, is not worth the effort, expense and discomfort.

In spite of these disadvantages, the northern route is receiving much attention and the Pan-American Airways of New York in 1932 acquired a 15-year monopoly of landing and aviation development rights in Iceland and a license to explore Greenland with a view to a Detroit-Copenhagen service.

The flights of Cramer and Pacquette (1931), Preston and Collignon (1931) and Lindbergh (1933) over these routes were made under American auspices.

Southern Routes

There are a number of so-called southern routes, that followed for the first Atlantic crossing in 1919 and on several subsequent occasions, the latest being the Italian formation flight in 1931, runs from Newfoundland via the Azores to Lisbon. Another runs from New York to the Azores, roughly following the New York-Gibraltar steamer lanes, while the most southerly is that from New York, Charleston or Norfolk via Bermuda and the Azores.

Pan-American Airways are negotiating for permission to use the Azores and Portuguese territory in connection with a regular service.

The principal disadvantage of these routes is the long sea crossings varying from 800 to 2,000 miles. The islands of Bermuda and the Azores, after flights of such lengths over sea, present very small landfalls and call for accurate navigation. In addition, there are relatively few ships in the neighbourhood of the most southern route to supply information on which to prepare accurate weather maps and forecasts.

Horta, on the southeast coast of Fayal, the only harbour worth considering in the Azores, is only useful in relatively calm weather and is none too favourable for flying boats. The harbour is considerably silted up and its effective size is much smaller than appears from the charts. It could be made an excellent harbour at considerable cost.

Weather conditions are said to be generally favourable on the southern route (Bermuda-Azores) for all year round flying. The air is generally clear, fogs are infrequent and over most of the course the winds are not stormy. There are tropical cyclones which usually occur in late summer and autumn and cannot be foreseen since they originate south of the Bermuda-Azores line, in a region rarely traversed by ships. Local thunderstorms also occur. In daylight these disturbances may be avoided, but at night their course and extent are difficult to estimate.

The best known storms forming over the warmer parts of the ocean are the hurricanes. As a rule, they appear in the doldrum area, travelling first in a westerly direction, then turning to the north on some meridian west of Bermuda and finally to the northeast. Many of these leave the tropics between Bermuda and the Azores. They usually form in the late summer. Those of the early part of the season originate near the Azores and proceed on a course north of west before leaving the tropics to join in the eastward procession. After August, they form in mid-ocean. No doubt many lesser storms and some severe ones come north from the southern portion of the ocean at other times of the year as well. Severe storms often breed over the coastal waters south of Hatteras and are rejuvenated continuously as they follow the Gulf Stream, often acquiring sufficient energy to carry them across the ocean.

Of some thousands of ocean storms studied, only 10 per cent were traced from one continent to the other, 21 per cent were observed on one coast or the other and 32 per cent of those that reached Europe were ocean born.

Weather maps indicate that slightly north of the direct Bermuda-Azores line the prevailing winds are light westerly and northwesterly and a little south of the line the winds are light northeasterly, calm or light westerly. By flying somewhat south of the direct course on westerly flights and north on easterly flights, advantage could be taken of favourable winds. From New York to London via Bermuda and the Azores is 4,700 miles approximately.

The route from New York, following the steamer lane for some 1,200 miles and then via the Azores to Vigo or Corunna possesses many desirable features, but is long and requires accurate navigation. From New York to London via Vigo is some 4,200 miles by this route. Compared with the direct Great Circle route, it is less stormy, less cloudy and lies south of the fogs of the Grand Banks. Weather

information may be had all along this route. If radio-equipped, aircraft may always be able to reach assistance within a few hours' flying. It has much promise as a two-way route even in winter.

Two proposals have been made to overcome the handicap of the long ocean flights of the southern route, one using seadromes and the other the ship-to-shore service.

Seadromes

Floating islands, by providing refueling facilities at short intervals, reduce the necessary fuel load with a corresponding increase in pay load. The United States government in 1933 voted some $1,500,000 for the construction of a quarter-section of one of the so-called Armstrong seadromes. If tests with this are successful, it is proposed to build a complete unit at a cost of $6,000,000 and contingent upon its success, a total of five are proposed to be anchored at not less than 500-mile intervals between New York and the Azores along the 39th parallel of latitude and between the Azores and Vigo, Spain.

The landing-deck of the seadromes is to be 1,000 by 300 feet, supported 100 feet above the sea on a structure incorporating twenty-eight buoyancy tanks floating about 100 feet below the surface to avoid wave action and another 100 feet below which are ballast tanks. The tank columns (streamlined in the region of wave action) are some 300 feet in overall length and are interconnected by tubular struts and cables. The structure is anchored to the sea bottom, which will be as much as three miles below the surface. The proposed seadromes are provided with hangars, hotel accommodation, etc., below the flying deck. The normal population of each seadrome would be about one hundred and twenty-five, with hotel accommodation for three hundred.

It is considered that there would be considerable difficulty in landing aircraft on this relatively small platform in fog or unfavourable weather, even with modern blind-flying facilities. To avoid this trouble insofar as possible, it is proposed to anchor the seadromes in regions least susceptible to fog.

The chief objection to the floating island plan, since it appears technically feasible to construct the enormous floating platforms of sufficient strength, although anchoring them presents difficulties, is the enormous cost, some $50,000,000 for the whole undertaking. This is a serious handicap to the operation of a commercial air route on an economic basis. Assuming aircraft capable of carrying one ton of payload for 500 miles between the seadromes, it would appear much cheaper to employ four or five times the number of aircraft, each carrying a payload of only 400 to 500 pounds over the 2,000 miles between Newfoundland and Ireland.

From an aeronautical viewpoint, the seadrome is an evasion of the real problem, namely the provision of a land-to-land service without intermediate landings.

Ship Refueling and Launching

Germany has been trying out a somewhat similar plan in the South Atlantic. The ship, *Westfalen*, equipped with catapult and a special trailing apron was stationed midway between Bathurst, Gambia and Natal, Brazil. In landing, in rough weather, the ship steams slowly into the wind, trailing the fabric apron behind. The flying-boat lands and taxies up on the apron, is lifted aboard, refueled and launched by catapult.

The first flight was made in June 1933, from Berlin via Cadiz-Bathurst-Westfalen-Natal, the ocean stage taking fifteen hours five minutes.

Ship-to-Shore Service

In 1928, the *Ile de France*, of the French line, was equipped with a catapult for a ship-to-shore service. The Germans, in co-operation with the French and Swiss, have operated since 1929, during the summer months, a ship-to-shore service for first class mail between Southampton and New York. The liners *Bremen* and *Europa* are equipped with catapults. On the western trips, the Heinkel seaplane, carrying 300 to 400 pounds of mail, is catapulted from the liner at distances varying from 70 to 1,545 miles from shore, depending on weather conditions, generally 600 miles out, off the Nova Scotia coast, and flies to New York. In some cases, Canadian mail is landed at Halifax before proceeding to New York and stops are sometimes made at Boston. Of seventeen such flights made in 1931, savings in time ranged from zero to seventy-two hours.

On the eastbound trips, the aeroplane leaves the liner some 500 to 600 miles out and flies to Southampton from which the mail is carried to Croydon and flown thence to Cologne. Of sixteen flights in 1931, thirteen showed an average saving in time of forty-seven hours. It was proposed to extend this service to include despatch of mail by seaplane from shore to overtake the ship some 600 miles from shore.

There were several serious accidents in this service, in which pilots, machines and mail were lost and it was considered so hazardous that neither the British nor United States post offices will have anything to do with it. There is also the consideration that the catapults take up valuable space in the liners. The arrangement provides a five-day service between London and San Francisco.

Direct Route

There remains the direct great circle route from Montreal to London via Newfoundland and Ireland, which possesses the great advantage of being wholly British.

At the present time, the fastest crossing by ship, the *Empress of Britain*, from Southampton to Quebec, is four days, twenty-three hours, forty-eight minutes, at an average speed of 24.8 knots (1932). By taking the mails off at Belle Isle and flying them to Montreal, a saving of about thirty-six hours has been effected and the time between London and Vancouver reduced to five days, seventeen hours.

Experimental Ship-to-Shore Services—St. Lawrence

During the summer of 1927, experimental flights made by the Department of National Defence, conveying British and Foreign mails between Montreal and Father Point near Rimouski to connect with liners, demonstrated that from twenty-four to seventy-two hours could be saved in the delivery of incoming and outgoing mail. As a consequence, a regular contract air mail service between Rimouski and Montreal was commenced on May 5th, 1928, and has been operated each summer since then, with great success, up to 800 pounds of mail per trip being carried.

The success of this service led to the laying of plans for its extension to Bradore Bay on the Strait of Belle Isle, just within the Canadian boundary. The first experimental flight over the extended route was made by two seaplanes of Canadian Airways in 1930. Carrying 1,000 pounds of mail, the machines left Quebec at 8.30 a.m. and arrived at Bradore, 785 miles distant, at 5 p.m., where, despite adverse weather conditions, the mail was transferred to the *Empress of Australia* which had left Quebec the day before, thus effecting a clear gain of twenty-four hours.

During the Ottawa Imperial Conference in 1932, a series of ten experimental flights were made between Red Bay on the Strait of Belle Isle and Ottawa, to provide faster mail service for the Conference and to determine the commercial feasibility of the service. The mail left London at 2 p.m., was flown to Cherbourg and placed on the *Empress of Britain* which sailed at 6.30 p.m. From the *Empress*, passing Red Bay about 2.30 a.m. of the third following day, the mail was transferred to a seaplane by naval tender, without deviation or appreciable delay to the *Empress*. The mail was flown 386 miles in four hours to Havre St. Pierre (opposite Anticosti), transferred to a flying boat and flown 290 miles in three and a half hours to Rimouski and again transferred to a landplane and flown 314 miles in three and a half hours to St. Hubert (Montreal) reaching there at 4 p.m. of the fourth day. After sorting, the American mail was placed on the regular aeroplane for Albany and the Ottawa mail flown to Ottawa, covering the 110 miles in one hour, arriving at about 5.30 p.m. The 1,100 miles was covered in a flying time of twelve hours and an elapsed time of fifteen hours, the elapsed time from London being one hundred hours, resulting in a gain of thirty-six hours. Eastbound, the mail left Ottawa at dawn, reaching Red Bay at 5 p.m. to connect with the *Empress* passing at 8.30 p.m., having left Quebec the day before.

This schedule was well maintained during the Conference and mail posted in London was delivered as follows:—

Montreal	—4 days	6 hours later	
Ottawa	—4 "	8 "	"
New York	—4 "	10 "	"
Vancouver	—6 "	7 "	"
Los Angeles	—5 "	10 "	"

Alternative Routes—Ship-to-Shore Service

It was found, in operating the Belle Isle service in 1932, that fogs were prevalent along the north shore of the Gulf from Cape Whittle to the Strait and aircraft had difficulty getting through from Montreal to the Strait, although the westbound flight from the Strait was readily made. At the same time, the west coast of Newfoundland is said to be relatively free from fog and an alternative route to that following the north shore and thence to Rimouski is to fly the mail down the west coast of Newfoundland, dropping the Newfoundland mail at St. George's Bay for transfer to the Newfoundland Railway and thence via Cape Ray, Magdalen Islands, Prince Edward Island and Shediac to Moncton and via the trans-Canada airway to Montreal. The route possesses the advantages of established airports and ground organization over a large part of it. Further, as ice limits the use of the Straits of Belle Isle to about five months in the year, during the remainder of the open season the transfer from ship to plane could be made in Cabot Strait, off Cape Ray (possibly Cape Race and fly to Sydney) and the same route followed to Montreal. In winter, the mail would be transferred from ship to aeroplane at Halifax or St. John. The suggestion that the mail should be transferred, in winter, at sea, off Halifax, does not seem feasible. Experience will quickly show the most practical route or routes down the St. Lawrence, all of which possess the great advantage that nowhere are the machines out of sight of land.

Fig. 3—Junkers G 38 Monoplane.

Possibilities of Combined Air-Steamship Service

The St. Lawrence route between Europe and America, the shortest of the North Atlantic routes, lends itself admirably to a combined air and steamship service. From Southampton to Montreal is 3,343 miles, of which 1,100 miles are within sheltered waters.

The success of the experimental services, operated with slow and unsuitable machines and insufficient ground organization and radio service, has demonstrated beyond doubt the practicability of such a ship-to-shore service and the experience gained in operating the services will be invaluable in planning a practical air mail connection between London and Montreal. With fast aircraft, suitable equipment and adequate organization, by flying the mail from London to Southampton, placing it on a fast ship for carriage to Belle Isle, transferring there to aircraft and flying to Montreal, a 4-day service between London and Montreal and a four and a quarter-day service between London and New York are quite feasible.

With a regular combined air and steamship service in operation, via the St. Lawrence, effecting savings in time of twenty-four hours and upward between Europe and points in America, the flow of mail will undoubtedly be diverted to this route despite the greater frequency of sailings on the present New York route.

The Complete Air Service

The great circle distance from London to Montreal is some 3,225 miles, of which 300 to 400 is between London and Ireland and about 1,000 miles between Newfoundland and Montreal, leaving only 1,700 to 1,800 miles of open sea distance between Ireland and Newfoundland. Much would be learned by operating initially a ship-to-shore service at both ends of this route. There is no doubt, after the success attending the experimental services already operated, that such services, in a few years, could be run regularly and satisfactorily. By that time, suitable aircraft for the trans-Atlantic service would be available and the complete London-Montreal air service could be placed in operation.

Great Circle Route

The great circle Atlantic routes between Newfoundland and the British Isles are, of course, the shortest between terminals. Aside from the length of the oversea flight, the great disadvantages are those due to the weather. The prevailing winds are westerly, varying from southwest to northwest. The routes pass through the zones of greatest storm frequency and thickest clouds and the Newfoundland fogs. The region is one of the most completely overcast areas in the northern hemisphere and about one-half the observations from ships on the great circle course report precipitation.

Conditions favourable to the formation of ice on the aircraft are frequent. Pilots flying in midsummer, well south of the steamer lane and at otherwise desirable flying levels, have encountered ice. In summer, temperatures range from around 40 degrees near Newfoundland to over 70 degrees. Flight at high altitudes would encounter steadier and stronger westerly winds, the prevalence of clouds would necessitate blind flying and the thick cloud banks reported by many pilots suggest freezing temperatures and ice formation in their upper levels, even in midsummer.

As already mentioned, most American storms enter the Atlantic from the Newfoundland area. Only a few continue on the easterly course to Europe. About half turn toward the west coast of Greenland and Davis Strait. The remainder reach a point of dispersal southeast of Greenland, whence most continue toward the British Isles, while some turn northeast toward Ireland and a few bear off southeast.

An advantage of the route, since it approximates the steamer lanes, is the wealth of weather reports available from the ships. In one day, reports were received from over twenty vessels in this region.

While prevailing currents of winds and water, and the average tracks of storms, and the areas of greater gale frequency have been established for the shipping zones, the weather information and maps are as yet inadequate for scheduled Atlantic air route operation. Upper air observations of temperature, wind and cloud are necessary, but there is at present no feasible method of obtaining such information. Eventually, the accumulation of information from many flights across the ocean will be a source of much needed information.

Means of Surmounting the Ice and Fog Hazards

In surmounting the fog difficulty, the fog- and haze-penetrating properties of infra-red rays may prove of value. A recent development for use on ships is a camera using infra-red sensitive plates, taking photographs forward in the direction of the ship's course. The photograph is available in about a minute and, in foggy weather, provides the ship's officers with a view, through the fog, about one mile ahead. This, of course, is too slow for aircraft use.

In the case of ice formation, there are certain factors which render the problem less difficult than appears at first glance:—

(*a*) The critical temperature for ice formation on aircraft is near the freezing point. In very cold weather, ice does not adhere. For this reason, aircraft operating in the United States experience more trouble from ice than in Canada.

(*b*) The ice generally builds up on the forward portions of the wings, struts and other parts of the machine.

(*c*) To prevent the formation of ice on the aeroplane, it is only necessary to maintain the surface at a fraction of a degree above the freezing point. This has been proved in the freeing of hydro-electric plants of the ice trouble.

Hence, the areas to be heated and the amount of heating required are not as large as might be expected. The exhaust gases, or a medium heated by the exhaust gases, are possibilities for the heating of the leading edges of the wings and tail surfaces. Struts, in modern machines, are few in number and will doubtless eventually disappear entirely. Electric heating, as in power plants, is also a possibility. In the United States, a rubber "overshoe" for the leading edge of the wings has been tried. This overshoe can be inflated to dislodge ice when it forms.

While the fog and ice hazards are admittedly serious, they are by no means insurmountable, given suitable machines and adequate ground, meteorological and radio services. There is a good deal of fog in England and on the Paris-London route and yet this service operates with excellent regularity and there are few cases of interruptions due to fog. In fact, on occasions, aircraft have got through when there was a complete tie-up of shipping.

In any case, the planning of air services to avoid fog and ice troubles is evading the issue. Means must be devised and will be devised to overcome these hazards and enable aircraft to operate irrespective of such weather conditions. If fog had been allowed to divert shipping, the St. Lawrence route would not be the important shipping lane it is today.

Fig. 4—Fairey Long Range High Wing Monoplane.

Capability of Existing Aircraft

Because of the prevailing westerly winds and of the fog and ice hazards, most of the stunt crossings of the Atlantic have been from west to east, generally from Newfoundland to Ireland. Some flights have been made by the southern route via the Azores. In most, if not all cases, the machines making these flights have been so loaded with fuel that there was little margin of safety and no pay load. In fact, difficulty was generally experienced in getting off the ground and, in not a few cases, failures occurred during the take-off. No machine so loaded would be permitted to operate on a commercial air route. This fact does not mean that there is no machine at present capable of flying the Atlantic with a pay load and the required margin of safety. Several machines have flown 5,000 to 6,000 miles non-stop. If, in such a machine, only half the gasoline supply for 5,000 to 6,000 miles is carried, the machine will have a range of 2,500 to 3,000 miles with a fair pay load and such a machine could make the flight from Newfoundland to Ireland with 500 to 1,000 miles to spare for emergencies. This being the case, it is reasonable to expect that, within a few years, aircraft will be regularly flying between England and Canada.

In the following table are listed a number of present-day aircraft capable of flying the Atlantic with a pay load. The range, as given by the makers, is tabulated, together with the actual range attained, and a range estimated for purposes of this paper, in a rough approximate way, described later. In addition, assuming a required range of 2,500 miles for the Ireland-Newfoundland flight, based on about 2,000 miles of distance and a 30-mile per hour head wind, the pay load has been estimated approximately.

The range calculations have been based on:—

Data as given in Jane's "All the World's Aircraft," 1933.

Initial fuel and oil consumption—gasoline engines, 0.5 lb. per h.p. per hr.

Initial fuel and oil consumption—oil engines, 0.4 lb. per h.p. per hr.

Weight of crew—160 lb. per man.

To avoid going into too great detail and the use of cumbersome formulae, the calculations have been based on the following assumptions:—

Average cruising speed, 85 per cent of maximum speed.
Average cruising engine power, 90 per cent of normal rated power.
Average specific fuel consumption during flight, due to lightening of aircraft as fuel is consumed, 90 per cent of initial consumption.

Based on the foregoing, the fuel consumption employed, based on normal rated engine power, were:—

For gasoline engines—0.40 lb. per h.p. per hr.
For oil engines—0.32 lb. per h.p. per hr.

The agreement between ranges, as given by the builders and as calculated by the foregoing method, is generally sufficiently good for the purpose. When large differences occur, they are generally due to either the maker's range being based on the aircraft with normal pay load or on the aircraft stripped for record flights and loaded beyond airworthiness requirements, whereas the ranges here calculated are for the machines in which the disposable load comprises fuel, oil and pilots.

At the present time, there is considerable activity, principally in France and the United States, in the construction of aircraft for trans-Atlantic service. France is interested in the postal service to South America and is preparing to replace the present steam packets operating between Dakar and Natal by aircraft. The following machines have been built in France with this end in view:—Latécoère (Croix du Sud), Bleriot 5190, Couzinet (Arc en Ciel) and Lioré et Olivier H-27. In America, a large Sikorsky flying boat for trans-Atlantic operation is under construction.

Fig. 5—Junkers Ju 52 Low Wing Monoplane.

Germany and Italy are also planning air mail services to South America.

Type of Aircraft

There is some difference of opinion regarding the type of machine that should be used for the ocean flight. Some

maintain that land machines should be used, while others favour the flying boat. In the former case, the flight would be made between an airport in Ireland and one in the interior of Newfoundland, and in the latter, between ports on the coasts. Newfoundland offers many protected waters around the coast for landing seaplanes or flying boats and there are many lakes in the interior. In Ireland, it would appear that the most suitable localities for landing would be the flat country near Galway or Limerick (south of the Shannon) since there are no mountains between these districts and the sea. The area immediately west of Dublin might also be used, or in the neighbourhood of Cork, although the highest mountains in Ireland are to the west of Cork.

It is claimed that land machines may well be used, since the seas in the North Atlantic, during a large part of the year, would be equally destructive to either a land plane or a flying boat, in the event of a forced landing at sea. On the other hand in 1931, a German all-metal aeroplane (Junker W-35 land machine) was forced down near Newfoundland on an east-west trans-Atlantic flight from near Lisbon and remained afloat in a fairly heavy sea for nearly a week, the crew of three being eventually rescued. On the whole, the flying boat would seem to have a better chance of surviving a forced landing. However, the important point is that machines must be so constructed and operated that forced landings do not occur. With multi-engined aircraft, there is no reason why forced landings should be any more frequent than are losses of trans-Atlantic liners.

By virtue of her favourable geographical situation, Canada is afforded an opportunity which should not be missed to establish first, a fast air-steamship service between Europe and America via the St. Lawrence and ultimately, an all-air service via the same route. The benefits to be derived from the establishment of such services will be such as to more than compensate for the cost and effort required.

DISCUSSION

(*Continued from page 304*)

cut down its conductivity or rather increase the resistance. There have been a number of conductor alloys developed but all have seemed to encounter this problem. There have been alloys developed and utilized in England, alloys of aluminum, but these apparently have not taken hold here.

J. W. Purcell, A.M.E.I.C.[5]

Our research doesn't go quite far enough. For example, in connection with soil heating research, it involves a number of problems that are not electrical nor mechanical. While electric soil heating does not involve extensive engineering, it will be used extensively and the ultimate load assume proportions that are perhaps startling. Therefore, engineers should co-operate with agricultural specialists and the farmer to solve these problems.

W. P. Dobson, M.E.I.C.[6]

Dr. Boyle refers to the complicated stresses which occur in vibrating transmission line conductors. A good deal of attention has been devoted to this by mathematical physicists but no complete solution has been obtained. It is believed, however, that the instrument which has been developed by the Commission's Research Committee gives reliable information about these stresses. There is certainly a need, however, for more extensive theoretical work in this field.

There are two main divisions in this problem. The first has to do with determining and recording the vibrations and the development of means to absorb their energy. There is also the question of effecting improvement in conductor materials. This is distinctly a manufacturer's problem but the user can from his studies determine the necessary characteristics which a material should possess.

In the construction of the Boulder dam transmission line a copper conductor of special type is being used which it is claimed will not vibrate. This result is accomplished by developing a new design of conductor. Much can without doubt also be accomplished in the development of materials more resistant to vibration than those now in use.

In reply to Mr. Henderson the author stated that experiments had been performed on conductors of different shapes and it was found possible to practically eliminate vibration with some of these shapes. Most of them, however, could not be incorporated in present types of construction without considerable change in fittings, etc. Some work had also been done in injecting viscous material between the conductor strands and some success had been obtained in this direction. Mention had already been made of the Boulder dam conductor. The main lines of attack had been first to find a conductor that would not vibrate; to produce a conductor which would absorb the energy of the vibrations; or to add something to the conductor which would absorb or diminish the vibrations. A large number of devices had been developed with this last purpose in view.

VOLUME XVIII JUNE 1935 No. 6

The King's Silver Jubilee

The wave of enthusiasm which swept over the British Commonwealth of Nations on May the sixth was worthy of the historic occasion which was its cause.

The most striking feature of the demonstrations was their spontaneity, voicing as they did the loyalty and devotion of all parts of the Empire. Their extent and sincerity must have deeply touched the sovereign whose simple unaffected messages to his peoples have shown so clearly his unceasing regard for their welfare, his high sense of public duty and the share which he has always taken in their trials and difficulties. A statesman who has been privileged to know His Majesty well has spoken of him as "the King whose life is spent for his peoples and who has no thought of self. He embodies the simple ideals which are the real achievements of the race . . . As his reward, he has the loyalty and affection of his many peoples all over the world."

Nor is this esteem limited to citizens of the Empire. In the recent celebrations a particularly welcome note was sounded in the congratulations and friendly messages which came from the United States and the kindly sentiments expressed editorially in so many of its leading papers.

In Canada we may feel justly proud of the manner in which the country's loyalty has been manifested. Over the whole Dominion—on Parliament Hill and in all the centres of population—there has been nothing artificial about the homage universally offered to the King and Queen on their silver jubilee.

Twenty-five years ago there still remained something of the feeling of stability which characterized the closing years of the nineteenth century. Vital changes in social and industrial affairs seemed unlikely, and the future seemed full of promise. Trade and commerce were active, and in applied science and engineering new avenues of development were opening on every side. Physicists and chemists were making great strides, but there was as yet comparatively little co-operation between industry and science, and industrial research was only just commencing. The mechanization of industry was practically in its infancy. Bleriot had just flown across the English Channel, and while there were automobiles on the roads, hardly anyone anticipated the coming revolution in road transportation, or the extraordinary results which were to follow the development of the internal combustion engine. The steam turbine was beginning to replace the reciprocating engine for power generation. The steel industry was being revolutionized by new methods of production, and more complete knowledge of the properties and possibilities of the material, and the replacement of coal by oil fuel, which was to have such far-reaching social and economic effects, had just begun in Britain. Advances in fuel technology had commenced, leading to remarkable increases in fuel economy, and the better utilization of fuel resources.

In the field of land transportation the railway was still supreme. At sea the speed, size and power of ships was increasing, and special types of ship such as the oil tanker and refrigerated meat carrier were beginning to appear.

In communication, the electronic valve was making continuous wave radio transmission commercially possible, and was about to lead to great extension in the power and range of telephony.

In Canada the development of our national resources had already broadened out during the first decade of the new century, notably as regards hydro-electric power, the mining industry, and agriculture in the west. The first years of King George's reign saw a continuation of these peaceful activities which were violently transformed by the advent of war. There was an immediate recognition of the utility of the engineer and his scientific training, whether on the firing line or at home. At the front, new technical problems were continually presented, and had to be solved by the best means available at the moment. At home, mass production of munitions had to be developed almost over-night. New materials and processes were called for and were needed without delay, transportation of men and supplies by sea and land had to be improvised and safeguarded, and in Canada, as in Britain, we were plunged into all manner of essential industrial problems and undertakings. Members of The Institute of all classes took a worthy part in this work, both overseas and on this side of the Atlantic.

The post-war period was one of remarkable engineering development in Canada. Hydro-electric undertakings aggregating some 5,000,000 h.p. were installed between 1920 and 1930. The construction industry grew rapidly until in the year 1929 nearly $600,000,000 were expended on such work. The provinces embarked on the construction of thousands of miles of new highways and the rebuilding of existing roads, the railways carried out an ambitious programme of extension, and the mining, metallurgical and chemical industries showed rapid growth.

Some idea of the rate of this progress may be gleaned from the facts that the total power installed in manufacturing industries and in central stations in Canada increased from about 4,000,000 h.p. in 1921 to over 11,000,000 in 1930, while during the same period the power generated by internal combustion engines, largely for motor traction purposes, rose from a negligible amount to an estimated total of over 60,000,000 h.p.

No outline of engineering activities in Canada in the past fifteen years would be complete without mention of the progress made in those branches of engineering work which bear directly upon public health and the amenities of life; as regards water supply and sanitation great advances took place, not only in the larger cities but in the smaller towns and rural districts.

In Canada, as in other countries, the last quarter of a century has seen the rise of many highly specialized branches of engineering work related to the numerous new processes, methods or materials which have been developed and to new activities in transportation and communication. To take only one or two examples, the work of the chemical engineer, the welding engineer, or the radio engineer calls for new and highly specialized training. Accordingly the scheme of engineering education has broadened and undergone a development not less striking than the changes in engineering and industry which have caused it. The engineering schools have grown in efficiency, in numbers of students and in diversity of subjects taught.

The peak of all these activities was reached in 1929, and the course of events since that time is fresh in our minds. In Canada, as elsewhere, the years of depression have checked development for a time, but there are now definite signs of revival.

After thus reviewing the record of the past twenty-five years, and noting the political and social turmoil of the post-war period, it seems hardly possible that later generations can have any experiences more stirring than have fallen to the lot of those of us who have witnessed the dramatic events of the years following the accession of King George V.

OBITUARIES

Harald Leicester Leverin, Jr.E.I.C.

Deep regret is expressed in placing on record the untimely death, in an automobile accident, on May 14th, 1935, of Harald Leicester Leverin, Jr.E.I.C. Captain Leverin, who was stationed at Work Point Barracks, Esquimalt, B.C., was driving into Victoria when the fatal accident occurred.

Captain Leverin was born at Sault Ste. Marie, Ont., on September 22nd, 1905. He received his early education at Ashbury College, Ottawa, and graduated from the Royal Military College, Kingston, in 1928, and from McGill University, with the degree of B.Sc., in 1930. He also attended the School of Military Engineering at Chatham, England. Following graduation Captain Leverin was attached to the Royal Canadian Engineers as works officer, at Quebec, and in 1931-1932, was assistant works officer at Halifax, N.S. In 1932 he was transferred to Esquimalt, B.C.

Captain Leverin joined The Institute as a Student on February 4th, 1930, and transferred to the class of Junior on September 21st, 1934.

Charles Melville Macreath, A.M.E.I.C.

Regret is expressed in placing on record the death at Sault Ste. Marie on May 12th, 1935, of Charles Melville Macreath, A.M.E.I.C.

Mr. Macreath was born at Glasgow, Scotland, on June 25th, 1878, and received his early education at the Glasgow and West of Scotland College, later serving a pupilage of five years with Sir William Copland.

In 1900-1901 Mr. Macreath was contractor's engineer during construction on the Muirkirk section of the Caledonian Railway, and was subsequently assistant resident engineer of construction and later resident engineer on the Strathaven section of the same railway, remaining in that position until October 1905, when he went to Ashanti, West Africa, to carry out a branch railway for Attasi Mines Limited. Following this Mr. Macreath came to Canada, and was connected for a time with the Canadian Pacific Railway Company on the construction of the Westmount low level yard and relative approaches to the main line. Mr. Macreath then went to the Sault and was employed by the Algoma Central Railway. From 1915 to 1919 he was overseas with the 37th Battalion, having the rank of lieutenant. At the time of his death he was connected with the Department of Public Works, at Sault Ste. Marie, having held that appointment for a number of years.

Mr. Macreath was interested in public affairs, and held the post of sheriff, to which he was appointed on May 29th, 1920.

He joined The Institute (then the Canadian Society of Civil Engineers) on December 12th, 1907, as a Student, and became an Associate Member on April 9th, 1910.

PERSONALS

G. K. Waterhouse, A.M.E.I.C., has recently become identified with Toronto Iron Works as local representative at Montreal.

D. G. Elliot, Jr.E.I.C., is now on the staff of the Anglo-Newfoundland Development Company Ltd., at Grand Falls, Newfoundland.

Jas. W. Houlden, Jr.E.I.C., who was formerly with the Canadian Ingersoll-Rand Company Ltd., at Sherbrooke, Que., has joined the staff of Canadian Industries Limited, and is located at Brownsburg, Que.

Boyd Candlish, A.M.E.I.C., formerly chief engineer of the gear division of the Palmer Bee Company, Detroit, has resigned his position with that firm, and will carry on his studies of gearing as an individual venture.

C. H. Fullerton, A.M.E.I.C., has become Surveyor-General of the Province of Ontario. Mr. Fullerton has held the office of Deputy Minister of Northern Development for some years, and during the reorganization of the department he was appointed head of the Settlers' Loan Board.

J. Lyle McDougall, Jr.E.I.C., is now with Somerville Paper Boxes Limited, at London, Ont. Mr. McDougall was formerly on the staff of Price Brothers and Company Ltd., at Kenogami, Que.

J. M. Robertson, M.E.I.C., consulting engineer, Montreal, has been nominated by the Montreal Board of Trade as its representative on the commission to study the problem of a purification plant for the city. Among the questions with which the commission proposes to deal is the basic one as to whether immediate action is necessary in connection with the sewage disposal problem.

J. Antonisen, M.E.I.C., who recently retired from the office of city engineer of Port Arthur, Ont., was tendered a complimentary dinner by the Lakehead Branch of The Institute. Mr. Antonisen is chairman of the Branch.

E. M. Proctor, M.E.I.C., president of the firm of James, Proctor and Redfern, consulting engineers, Toronto, has been elected a director of the Guaranty Trust Company of Canada, of Windsor and Toronto.

A. Cousineau, A.M.E.I.C., superintendent engineer, Division of Sanitation, Health Department, City of Montreal, is the first recipient of the award which the City Improvement League of Montreal has decided to make annually for distinguished public service, to go to the educator, social service worker, civic official or other public spirited citizen who in the opinion of the judges has rendered the most outstanding service in helping to improve the city. Mr. Cousineau is a graduate of Mount St. Louis College, Ecole Polytechnique, Massachusetts Institute of Technology, and Harvard University. Prior to his appointment to the city health department he was attached to the scientific division of the topographical surveys of the Federal government. Mr. Cousineau has been particularly interested in all matters pertaining to sanitation for the past twenty-one years and was one of the collaborators of Dr. S. Boucher, medical officer of health, under whom he has prepared and enforced several by-laws.

Professor R. W. Angus, M.E.I.C., Head of the Department of Mechanical Engineering, University of Toronto, Toronto, Ontario, sailed from New York on May 15th, 1935, on the *President Roosevelt* for Hamburg. Professor Angus will visit water power plants in Sweden and Germany, and then spend some time in England. He will return to Canada about the middle of August.

C. D. Evans, Jr.E.I.C., has been appointed sales manager of the Canadian Gypsum Company Limited for Quebec and the Maritime Provinces, and will be located in Montreal. Mr. Evans has been with this company for the past five years, in Montreal and Halifax, N.S., having previously been estimator and engineer for Gypsum Lime and Alabastine Canada Ltd. at Toronto. He was at one time with the Fraser Brace Engineering Company. Mr. Evans graduated from McGill University in 1924.

Harry H. Bell, A.M.E.I.C., who was formerly connected with the Calgary Power Company, Calgary, Alta., has joined the staff of the Montreal Engineering Company, Montreal. Mr. Bell graduated from the Nova Scotia Technical College in 1929 with the degree of B.Sc., and secured the degree of S.M. in business and engineering administration from the Massachusetts Institute of Technology in 1933. He takes an active interest in Institute affairs, and has been serving as Secretary-Treasurer of the Calgary Branch.

L. M. Jones, M.E.I.C., was recently appointed vice-president and general manager of the Warren Bituminous Paving Company Ltd. Mr. Jones, who was born in Wales, came to this country in 1896, and three years later entered the service of the Canadian Pacific Railway Company as a draughtsman at Winnipeg, subsequently becoming instrumentman in charge of a survey party. In 1903 he became connected with the Winnipeg Electric Railway Company and for three years had charge of laying out track, construction car barns and sub-stations, including the large Portage Avenue sub-station. In 1906 Mr. Jones was appointed assistant city engineer of Port Arthur, Ont. remaining in that position until 1909 when he joined the staff of Smith, Kerry and Chace, Toronto, being engaged on hydro-electric power plant design. In 1910 he returned to Port Arthur as assistant city engineer, and in 1911 was appointed city engineer. In 1920 Mr. Jones resigned in order to become general superintendent at Toronto for the Warren Bituminous Paving Company Ltd., and in 1923 he was elected to the board of directors of that company and made chief engineer and secretary, which position he has held up to the present time. Mr. Jones is a member of the American Society of Civil Engineers and also of the Association of Professional Engineers of Ontario.

Results of May Examinations of the Institute

The report of the Board of Examiners, presented at the meeting of Council held on May 21st, 1935, certified that the following candidates, having passed the examinations of The Institute, have satisfied the examiners as regards their educational qualifications for the class of membership named:

Schedule C—For admission to Associate Membership:

William Herbison,	Lachine, Que.
Cecil George Kemp,	Montreal, Que.

Schedule B—For admission as Junior:

Eric Grant,	Montreal, Que.

Report of Committee on Consolidation

The Committee held its sixth meeting at The Engineering Institute Headquarters on Friday, May 10th, 1935, at 8 p.m., and continued at the University Club on Saturday, May 11th, at 1.30 p.m. The reports from the various organizations, Branches and Associations in the different provinces were reviewed. The reports and resolutions received indicate good progress is being made in the organization and consideration of the question of Consolidation.

The Committee approved a letter and questionnaire covering certain fundamental points relative to Consolidation, and authorized that it be issued to the Secretaries or Corresponding Members of Branches, and the Registrars of Provincial Associations and the Secretary of the Committee of Eight. This letter and questionnaire is published herewith and reprints may be made available to Branches or Associations desiring to use the same to obtain the individual opinions of their members. This Committee urges Branches and Associations to take the necessary steps to insure replies to this questionnaire being returned on or before June 30th.

The seventh meeting of the Committee was held at The Engineering Institute on Tuesday, May 20th, 1935, at 6 p.m., at which time it was reported that the letter and questionnaire had been issued, together with statistics on the membership of The Institute Branches and the Provincial Associations, the progress report and questionnaire of the Saskatchewan Co-ordinating Committee, and the progress report of this Committee.

The Committee received the resolution of the Executive of the Saint John Branch appointing Mr. G. G. Murdoch and Mr. A. A. Turnbull as a special committee for the consideration of Consolidation, and to co-operate with a similar committee from the Moncton Branch and the Professional Association of New Brunswick.

It was reported that a meeting of a special committee of the Ontario Professional Association, under the chairmanship of Mr. J. Clark Keith, met in Toronto on May 17th, to consider the questionnaire and other phases of Consolidation. Mr. H. A. Lumsden, M.E.I.C., has been appointed by the Executive of the Hamilton Branch to represent the Branch on a Provincial Consolidation Committee. The Toronto Branch Executive has appointed the following special committee on Consolidation,—C. E. Sisson, M.E.I.C., Chairman; O. Holden, A.M.E.I.C., and W. W. Bonn, M.E.I.C., Mr. Sisson was also appointed to represent the Branch on the Joint Provincial Committee on Consolidation.

The Victoria Branch held a meeting on May 7th, to review all reports and correspondence relative to Consolidation, and reported that they were now awaiting action by the Vancouver Branch on their suggestion of a joint committee of the two Branches in British Columbia to consider this question.

Under date of May 20th, the Saskatchewan Branch of the E.I.C. and the Association of Professional Engineers of the Province of Saskatchewan, through their joint committee, returned the questionnaire with all five questions answered in the affirmative.

The Saguenay Branch of The Institute have appointed Messrs. H. R. Wake, A.M.E.I.C., J. Shanly, A.M.E.I.C., G. F. Layne, A.M.E.I.C., and H. B. Pelletier, A.M.E.I.C., as a special committee of the Branch to study and submit a recommendation on Consolidation.

QUESTIONNAIRE OF THE COMMITTEE ON CONSOLIDATION

The Committee appointed by the Annual Meeting of The Engineering Institute of Canada at Toronto on February 7th, to "Develop the Possibilities of the Consolidation of the Engineering Profession," has arrived at a point in its deliberations where it becomes necessary to obtain an expression of opinion from the various interested organizations throughout Canada on certain questions fundamental to Consolidation.

The Committee has received many resolutions relative to Consolidation and to the proper procedure leading to its realization, and to many of the details of its organization. In order that all opinions and suggestions may be expressed in a uniform and comparable sense, it has been decided to issue this questionnaire.

Though your Branch or Association may have already expressed itself on the broad principle of Consolidation, might we ask you to again indicate your attitude.

1. Are you in favour of the broad principle of Consolidation of the Engineering Profession in Canada?

YES ☐ NO ☐

Consideration of the possibilities of the Consolidation of our profession suggests three main features:—

1. Membership.
2. Fees.
3. Organization.

Under the heading of "Membership" it is only necessary at this time to consider the principal classification of corporate or practising member, and to obtain an expression of opinion as to those to be included therein. All secondary classifications can be discussed at a later date with other details.

It would appear that engineers who are members of the Provincial Professional Associations and/or corporate members of The Engineering Institute of Canada, form the essential units of Consolidation. The question is to determine the most satisfactory and acceptable method of harmonizing the interests of these individuals and organizations so as to produce the most practical and effective and united professional body.

It should be borne in mind that the existing Professional Associations are legally constituted and that it is essential that the rights and privileges conferred by these Provincial enactments, which must be maintained under the British North American Act, be conserved and developed in the interests of the profession.

If this principle is accepted, a definite line of procedure is indicated. The first question concerning membership would therefore appear to be:—

2. In your opinion, should the corporate membership of the Provincial Professional Associations and of the National organization be identical?

YES ☐ NO ☐

In view of the fact that The Engineering Institute of Canada has for many years represented the engineers of this country both at home and abroad, and by its activities, its traditions and its many connections is most admirably suited to such a function:—

3. Are you in favour of The Engineering Institute of Canada being accepted as the National body of the consolidated engineering profession in Canada?

YES ☐ NO ☐

The next feature of Consolidation to come up for consideration is that of Fees. At present the fees of the corporate members of The Institute vary from $8.00 to $15.00 per annum net, while the membership fees of the Provincial Associations vary from $2.50 to $10.00 net per annum in the different provinces. On the basis of the membership statistics of The Engineering Institute and of the various Provincial Professional Associations for the year 1934, Consolidation would provide a corporate membership in the National body of some 5,000 engineers.

In view of the fact that the general expenses of the Provincial Associations vary in the different provinces, while the activities of the National organization call for a uniform per capita contribution from each member, it would appear that the total fee payable by a member would be a summation of a variable Provincial fee plus a fixed amount required for the maintenance and promotion of the National organization.

4. Under Consolidation, would you be willing to pay a single annual membership fee which would include a uniform subscription from each member of the profession throughout Canada to the National organization?

YES ☐ NO ☐

We have next to consider the organization of the profession in a Provincial and in a National sense. As the legal constituencies must be recognized, it is evident that the detailed administration of the profession in respect to admission, collection of dues, discipline, legal action, etc., should be Provincial matters, carried out by the Provincial organization. Such an arrangement tends to directness and promptness in the management of the detailed affairs of the profession.

The National organization should carry on all the more general activities of the profession, such as maintaining the publications, promoting uniformity in ethical procedure and in the legal recognition of the profession throughout Canada, and providing a contact with other national organizations and a unity of expression on national affairs and in the interests of the profession as a whole.

5. In view of the fact that discipline and legal action are at present a function of the Provincial Associations, are you in favour of the administration of admission to membership and collection of fees also being made the responsibility of the Provincial organizations?

YES ☐ NO ☐

This questionnaire is not a ballot, but is intended to provide information on certain aspects of Consolidation to assist the Committee in its deliberations. The questions are drawn so as to be answered in the simple affirmative by marking an X in the square opposite "Yes" and similarly for a negative. If for any reason it is necessary for you to answer in the negative, please outline your alternative suggestion covering the point.

We would ask that your Branch or Association consider these questions at such time as to give this Committee your replies on or before June 30th, 1935. Your cooperation in this matter would be very greatly appreciated.

Signed..

Dated........ ....
(Institute Branch)

Elections and Transfers

At the meeting of Council held on May 21st, 1935, the following elections and transfers were effected:—

Members

BOWEN, Henry Blane, chief of motive power and rolling stock, C.P.R., Montreal, Que.

DEMIFFONIS, Louis Fernand Henri, (Univ. of Paris), acting chief engr., Dept. of Marine, Ottawa, Ont.

FYSHE, Thomas Maxwell, B.Sc., (McGill Univ.), private practice, investigations and reports, 388 St. James St. West, Montreal, Que.

GRATTON, Alphonse, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), district engr., Dept. of Roads, Prov. of Quebec, Quebec, Que.

NEWMAN, William Arthur, B.Sc., (Queen's Univ.), chief mech'l. engr., C.P.R., Montreal, Que.

Associate Members

BUCK, Leslie Gordon, B.A.Sc., (Univ. of Toronto), divn. plant engr., Montreal Divn., Bell Telephone Company of Canada, Montreal, Que.

*HERBISON, William, (Montreal Tech. Inst.), dftsman., Dominion Bridge Company, Ltd., Lachine, Que.

*KEMP, Cecil George, (Sydney Tech. Coll., N.S.W.), constrn. supt. and engr., Consumers Glass Co. Ltd., Montreal, Que.

MACGILLIVRAY, Malcolm Stuart, B.Sc., (Queen's Univ.), elect'l. and mech'l. engr., T. Pringle & Son Ltd., Montreal, Que.

SPENCER, Henry Cyril, (Montreal Tech. Inst.), i/c design dept., screwmach. tools and equipment, Northern Electric Company Ltd., Montreal, Que.

Juniors

*GRANT, Eric, (Montreal Tech. Inst.), field engr., Montreal Light, Heat and Power Cons., Montreal, Que.

HERSHFIELD, Charles, B.Sc., (Univ. of Man.), Room 310, 68 King St. East, Toronto, Ont.

LYMAN, Charles Philip, B.Eng., (McGill Univ.), 4155 Cote des Neiges Road, Montreal, Que.

Affiliate

ALEXANDER, Stanley George, (Chicago Tech. School), chief operating engr. of steam power plants, Canadian General Electric Co. Ltd., Peterborough, Ont.

Transferred from the class of Associate Member to that of Member

ARCHIBALD, Samuel Wallace, B.A.Sc., (Univ. of Toronto), consltg. engr. and O.L.S., London, Ont.

BEACH, Floyd Kellogg, engr., Petroleum and Natural Gas Divn., Dept. of Lands and Mines of Alberta, Edmonton, Alta.

CORMIER, Ernest, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), architect and consltg. engr., Montreal, Que.

FARRELL, James Wardrope Dick, B.Sc., (Queen's Univ.), supt. of waterworks, Regina, Sask.

LAFLECHE, Alphonse, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), asst. chief engr., River St. Lawrence Ship Channel, Dept. of Marine, Ottawa, Ont.

MOTT, Harold Edgar, B.Sc., (McGill Univ.), President and Gen. Mgr., H. E. Mott Co. Ltd., Brantford, Ont.

YOUNG, Stewart, B.A.Sc., (Univ. of Toronto), director of town planning, Prov. of Sask., Regina, Sask.

Transferred from the class of Junior to that of Associate Member

CHANDLER, Edward Sayre, B.Sc., (N.S. Tech. Coll.), prov. elect'l. inspr., Charlottetown, P.E.I.

Transferred from the class of Student to that of Associate Member

PETURSSON, Franklin, B.Sc., (Univ. of Man.), location engr., Dept. of Northern Development, Kenora, Ont.

Transferred from the class of Affiliate to that of Associate Member

SAMUEL, Myron, Diploma, (Engrg. College, Danzig), proprietor, Empire Engineering Company, Toronto, Ont.

Transferred from the class of Student to that of Junior

SMITH, Carl Clifford, B.Sc., (Queen's Univ.), induction motor engr., Canadian Westinghouse Co. Ltd., Hamilton, Ont.

SMITH, Walter Alexander, B.Sc., (Univ. of Alta.), Dominion Bridge Co. Ltd., Calgary, Alta.

*Has passed Institute's examinations.

Students Admitted

BENSON, Willard McLean, B.Sc., (Univ. of N.B.), Fredericton, N.B.

BRANCHAUD, Henri, (Ecole Polytechnique, Montreal), 636 Dunlop Ave., Outremont, Que.

BRANNEN, Edwin Ralph, B.Sc., (Univ. of N.B.), North Devon, N.B.

CLARKE, Ross Eugene, B.Sc., (Queen's Univ.), R.R. No. 3, Gananoque, Ont.

COOMBES, David Eaton, B.Sc., (Univ. of N.B.), North Devon, N.B.

DARWIN, Bascom Herman, B.Sc., (Queen's Univ.), 132 Earl St., Kingston, Ont.

GREGOIRE, Armand E., B.A.Sc., C.E., (Ecole Polytechnique, Montreal), 6349 St. Denis St., Montreal, Que.

HORNFELT, Harvey Andrew, (Univ. of Toronto), 45 Sussex Ave., Toronto, Ont.

HUGGARD, John Harold, B.Sc., (Univ. of N.B.), Norton, N.B.

KAZAKOFF, John, B.Eng., (McGill Univ.), P.O. Box 252, Kamsack, Sask.

LEAHEY, James C. P., B. Eng., (McGill Univ.), c/o C. A. P. Leahey, Esq., Bank of Montreal, Ottawa, Ont.

LILLEY, Ledford George, B.Sc., (Univ. of N.B.), 57 Havelock St., Saint John, N.B.

MEUSER, Henry Lloyd, B.Sc., (Queen's Univ.), (Grad., R.M.C.), 132 Earl St., Kingston, Ont.

MILLER, Alex. Matthew, B.Sc., (N.S. Tech. Coll.), New Waterford, N.S.

MUSSEN, Guy Aubrey, B.Eng., (McGill Univ.), 2076 Sherbrooke St. West, Montreal, Que.

PEQUEGNAT, Jared Marc, B.Sc., (Queen's Univ.), 9 Samuel St., Kitchener, Ont.

PRESTON, William Walford, B.Sc., (Queen's Univ.), 25 Walnut St. North, Hamilton, Ont.

PURVES, William Franklin, B.Eng., (McGill Univ.), 3508 Durocher St., Montreal, Que.

REYNOLDS, George Kenly, B.Eng., (McGill Univ.), 3737 De l'Oratorie Ave., Montreal, Que.

ROSS, Donald, (Univ. of N.B.), 126 Douglas Ave., Saint John, N.B.

ROWELL, Lorne Archibald, B.Eng., (McGill Univ.), 3420 Hutchison St., Montreal, Que.

ST-JACQUES, Gustave F., (Ecole Polytechnique, Montreal), 425 Blvd. St. Joseph West, Montreal, Que.

SADLER, Robert Francis, (Univ. of N.B.), Chatham, N.B.

SCHOFIELD, Robert John Graham, B.Eng., (McGill Univ.), 340 Ballantyne Ave. No., Montreal West, Que.

SUTHERLAND, James Gordon, B.Sc., (N.S. Tech. Coll.), St. Peter's Bay, P.E.I.

TWEEDDALE, Reginald Estey, B.Sc., (Univ. of N.B.), Arthurette, N.B.

WISDOM, Charles Stuart Cotton, (Grad. R.M.C.), (McGill Univ.), 47 Hemlock Ave., Shawinigan Falls, Que.

BOOK REVIEWS

Electric Wiring

By W. S. Ibbetson, E. and F. N. Spon, London, 4th edition, 1935. 4¾ by 7½ inches, 253 pages, diagrams, etc. 6/-. Cloth.
Reviewed by W. P. Dobson, M.E.I.C.*

That this book has, in England, served a useful purpose is indicated by the fact that it has already run through three editions there. On this side of the Atlantic one may cull from it, here and there, items of information which are new and interesting, but the book is necessarily of less practical value to men living and working in Canada. The reason for this is of course that Canadian electric wiring practice, following closely as it does that of the United States, differs widely from that of England and other parts of the Empire, both as to types of equipment used and to the methods of installation in vogue.

The book is clearly written in simple style and has many good wiring and other diagrams; it is manifestly intended for the practical man and the calculations given are by no means abstruse.

The various chapters cover such subjects as Ohm's law applied to a.c. and d.c. circuits; distribution; wiring systems; joints, soldering, etc.; testing; illumination; motors, a.c. and d.c.; all treated from the standpoint of installation work.

Chief Testing Engineer, Hydro-Electric Power Commission of Ontario, Toronto.

Mechanics and Applied Heat with Electrotechnics

By S. H. Moorfield and H. H. Winstanley, Longmans, Green and Company, Toronto, Ont., 1935. 4¾ by 7½ inches, 392 pages, Cloth. $2.00.
Reviewed by Lieut.-Colonel L. W. Gill, M.E.I.C.*

This book, as stated in the preface, has been written with the object of producing in one volume a course in engineering science which will prepare a student for his entry upon the final year of the Ordinary National Certificate Course (England). It covers a very broad field, 143 pages being devoted to mechanics, 160 to thermodynamics, 15 to hydraulics and 63 to electrotechnics. For the special purpose specified by the authors this book should serve the student effectively. Notwithstanding this, the reviewer is inclined to think that there is some room for improvement. The principles of mechanics have been presented clearly and in logical sequence, but one wonders why, in the section on thermodynamics, the chapter on gases should be placed before the chapters on steam, production of power and measurement of power rather than after. Apart from this the presentation is clear and concise.

The 16 pages devoted to hydraulics cover such a small part of the field that one is inclined to question the value of such a presentation in a text of this kind.

The section on electrotechnics is well written and well illustrated. To the electrical engineer, however, the treatment of induced electromotive force is very inadequate. Its relative importance entitles it to more than 2 pages out of 63.

In all sections of the book the principles presented are well illustrated by figures and typical applications. Many suitable problems are included in each section. With a very few exceptions technical terms are accurately defined and accurately used.

Principal, Hamilton Technical Institute, Hamilton, Ont.

Mechanics

A Text-Book for Engineering Students

By Frank Gardner, Oxford University Press, London, 1934. 5 by 7½ inches. Diagrams, 254 pages. Cloth. $2.25.
Reviewed by Mr. Ian McLeish*

This text-book, as the title implies, is intended primarily for engineering students, but it would serve equally well for students in technical schools, since calculus or complicated mathematical expressions are conspicuous by their absence. The author's method of approach is somewhat different from that usually employed in text-books on mechanics, for most writers start with a consideration of the law of moments and polygon of forces. Mr. Gardner begins with the principle of the ideal machine, and explains, for instance, how a small force acting through a long distance can be made to balance a large force moving through a shorter distance. This idea leads to the study of work and power. The use of vectors is introduced and then the effects of friction are considered. Dimensional methods are used throughout the book. Chapters follow on the conditions of equilibrium, mechanisms and velocity diagrams, and structures and stress diagrams.

The second section of the book deals with strength of materials, and the concluding chapters are devoted to elementary dynamics.

Throughout the book care is taken to present clearly the fundamental ideas on such points as momentum and acceleration and dimensional arithmetic is not forgotten. It is somewhat difficult to understand why English text-books of this kind stil use in their examples cwts. and tons instead of expressing weights in pounds.

The book is well illustrated with clear and simple diagrams, a feature which will be found a great help in driving home the various principles enunciated. There are plenty of problems of a practical nature which give ample scope for the drill which is so necessary for the proper comprehension of all mathematical subjects. Answers are given as a check on the solution of the various problems. The book is suited for a first year course in engineering and its methods of treatment should be of interest to all connected with the teaching of mechanics, strength of materials and hydraulics.

Assistant Principal, Montreal Technical School, Montreal.

Canadian Trade Index—1935

The eleventh annual issue of the Canadian Trade Index which has been received contains an alphabetical directory of Canadian manufacturers with addresses, branches export representation, trade marks and brands; a directory of Canadian manufacturers classified according to articles made; a directory of exporters of agricultural produce and an export section which gives details of government services, export procedure, costs and financing statistics of Canadian trade and production. This new edition, which has over 800 pages, includes the names of some three hundred new manufacturers.

The publication of this book, containing as it does the names of members and non-members alike, is one of the many services rendered by the Canadian Manufacturers' Association to the manufacturing community and the business public at large. The continuance of old and new features will prove most valuable in keeping Canadian users fully informed respecting goods produced in Canada and in putting importers in other countries expeditiously and efficiently in touch with Canadian sources of supply.

World Survey

Published under the Auspices of the World Power Conference by Lund, Humphries and Company Limited, 12 Bedford Square, London, W.C.1, England. Monthly. Single copies 5/-, 12 issues £2-0-0.

This monthly periodical is being issued under the auspices of the World Power Conference, for the exchange of economic and technical information. Its contents will include authoritative articles on industry and economic thought, largely from the point of view of the analysis of economic forces and their effect on the development of international trade and industry. It will also contain statistical information, in the form of world economic indices, and an international power and fuel bibliography of a selective and authoritative nature, giving abstracts of the more important items published in current literature dealing with power and fuel. The first number gives promise of a valuable addition to our available sources of information on these topics.

BULLETINS

Pipe Threading.—An 8-page booklet has been received from The Steel Company of Canada Ltd., Montreal, containing practical tips on pipe threading.

Steel Sheet Piling.—The Canadian Sheet Piling Co. Ltd., Montreal, have issued a 4-page leaflet explaining the application of Larssen sheet piling to the Lakeshore retaining wall of the Victoria Park filtration plant, Toronto.

Concrete Machinery.—A 20-page bulletin received from the London Concrete Machinery Company Ltd., London, Ont., contains particulars of various types of mixers, hoists, engines, pumps, barrows, etc., for the handling of concrete.

Induction Motors.—A 4-page pamphlet issued by the English Electric Company of Canada Ltd., St. Catharines, Ont., gives information regarding the new completely protected induction motor.

Caterpillar Tractors.—The Caterpillar Tractor Company, Peoria, Ill., have issued a 24-page booklet illustrating the various applications of tractors to ploughing.

Wood Preservation.—A 10-page publication received from the Tennessee Eastman Corporation, Kingsport, Tenn., describes the preservation of wood with NO-D-K, a form of creosote oil.

The Panama Canal

Opened to traffic on August 15th, 1914, the Panama canal last year completed twenty years of successful operation, during which it has been navigated by 77,493 vessels having a total net tonnage of 366,761,032 and carrying 363,766,614 tons of cargo. The annual report of the Governor of the Canal for the year ending June 30th, 1934, shows that after two years of traffic decline the returns for the twelve months under review show welcome increases in the number of ships passing through the canal, the total tonnage of the vessels, the tolls collected and the tonnage of the cargo carried. The ocean-going vessels which utilized the canal in 1933-34 totalled 6,036 making together 28,566,595 net tons against 4,939 vessels and 22,821,876 tons in 1932-33.

The cargo conveyed through the canal in 1933-34 amounted to 24,718,651 tons and was 36 per cent higher than that passing through in the previous twelve months. Traffic in both directions contributed nearly equally to the increase in cargo tonnage, the rise in shipments from the Atlantic to the Pacific being 36.7 per cent, and that from the Pacific to the Atlantic 35.7 per cent.—*Engineering.*

CORRESPONDENCE

THE EDITOR,
THE ENGINEERING JOURNAL,
Montreal, Canada.

Woodbridge, N.J.
April 26th, 1935.

DEAR SIR:—

The writer of this letter has been absent from Canada for some years, and consequently is not so familiar with the problem of engineers' organizations as most of the resident members. I have received a circular containing a resumé of this situation by our past-president, Mr. F. P. Shearwood, M.E.I.C.

Mr. Shearwood refers to the difficulty of defining the status of many of our members who are designated as employees. This is a difficulty which The Institute must resign itself to and I fear will aggravate itself with the further development of our industry. Personally I would like to urge our president to consider the timeliness of formulating a policy along this very important phase of The Institute's relationship, i.e. to the engineer who is an employee. He probably constitutes a majority of our membership.

In many ways Canada is similarly constituted in its social structure to the United States. It must be recognized that while we may have a much larger diffusion of wealth throughout our society than most radical politicians are ready to admit, we are nevertheless subject to an increasingly greater concentration of control. This implies larger units of management, more employees and more stockholders but fewer managers and independent professional specialists. These tendencies undoubtedly are at work in the Dominion.

To the writer, the idea of provincial or state engineers' associations composed of land surveyors, town engineers and construction engineers, to the exclusion of industrial engineers is an anachronism. It is even a moot question as to whether the medical profession can long defend itself against some form of socialization.

I think our Institute should recognize these tendencies and influence their course for the benefit of the rank and file of our members. Protection of the public is a favourite argument with those who would restrict the practice of the profession.

Certainly adherence to narrow legal standards would restrict many good engineers of sound scientific training and experience from ever entering private practice. In a complex industrial society many problems of design exist which are utterly beyond the ability of the general practitioner type of engineer. Were it not for the creative ability of our employee engineers our modern industry would hardly advance. I can readily conceive of regulations obtaining legal sanctions which would exclude even a Steinmetz from private practice.

The importance of the consulting engineer is rapidly declining. He has little or nothing to offer to many industries who have as a matter of fact developed their own consultants. Many of our engineers while in the service of employers have created their own status and are in fact just as truly consultants as the private practitioner.

Personally I believe more recognition to general scientific training is desirable, especially in the case of the engineer who has a post graduate degree. A publicity campaign seeking to increase the compensation of the employee engineer might be of advantage. This would discourage overcrowding during periods of inadequate compensation, while a knowledge of salaries paid in different districts might encourage engineers seeking employment to demand more reasonable returns for their labour.

Our Journal appeals to me because of the variety of subjects dealt with in the published papers. It loses greatly in value however, because of the omission of the Engineering Index. I for one, hope this feature will be restored.

Our Institute should continue to be a clearing house for sound scientific knowledge. It should also be in a position to attest the ability of its members, in other words membership in The Institute should of itself be evidence of the engineer's competence.

Very truly yours,
(Signed) W. K. THOMPSON, A.M.E.I.C.

Rapid Development of God's Lake Gold Mine

God's Lake mine is described by W. F. Baker in a paper entitled "Geology of God's Lake Gold Mine Limited" in the May Bulletin of the Canadian Institute of Mining and Metallurgy. Discovered in the summer of 1932, the deposits were diamond-drilled in 1933, indicating ore of fairly high grade in payable quantity. During the winter of 1933-34 a mining plant and supplies totalling 1,260 tons were hauled from the railway, and levels were opened at 150 and 275 feet depth. As this confirmed the presence of sufficient ore for two year's supply for a 150-ton mill, the machinery for this was hauled in during the past winter and will be ready for operation by the early autumn. A water-power site nearby is also being developed to provide ample power. Thus in three years from the time of its discovery a profitable operation will have been established in this remote locality.

The distance by winter road from the Hudson Bay Railway is 130 miles; but so cheaply can supplies be taken in over the level winter road by tractor train, and so little is required per ton of ore treated (20 pounds) that the charge for this freighting per ton of ore treated is only 30 cents. This 30 cents thus measures the additional cost of operating at a distance of 130 miles from the railway, compared with operating at the "jumping-off" point.

Electric Furnace Foundry of the Ford Motor Company of Canada Ltd.

The $425,000 electric furnace foundry of the Ford Motor Company of Canada, Limited, at East Windsor, Ont., went into production toward the end of March. It was formally opened March 29th when the Border Cities Branch of The Engineering Institute of Canada held its monthly meeting at the Ford plant. The engineers were guests of the company at dinner in the home office restaurant, and John Coulter, A.M.E.I.C., president of The Institute Branch, acted as chairman. Wallace R. Campbell, president of the Ford company, welcomed the nearly one hundred guests, and John S. Beaumont, chief chemist, gave a paper on the chemistry of the steel used and the physical characteristics of the cast alloy steel crankshaft produced in the new unit.

The new foundry is a smaller counterpart of the huge crankshaft foundry at the Rouge plant of the Ford Motor Company, which was the first in the world to make cast steel crankshafts in volume for modern motor car engines.

It is now commonplace Ford practice to cast a steel crankshaft for its V-8 engine which is superior in service and longer lived than the forged crankshaft formerly used. Whereas in tests the forged shaft shows measurable wear after 10,000 miles of car operation, the cast shaft shows none (less than 2/10,000 inch).

Aside from an improvement in the product from the standpoint of serviceability, there are appreciable advantages in manufacturing a cast as compared with a forged crankshaft. It is about 10 pounds lighter than the forged shaft because of the use of cored crankpin journals and the reduction in weight of the corresponding counterbalances. The forged shaft weighed approximately 90 pounds in the rough and 66 pounds when finished, 24 pounds being removed in the machining process. Only nine pounds of metal is taken off the cast shaft in machining, and the machining operations now number 50 as against 62 on the forged shaft. A considerable saving in manufacturing cost is expected to be realized.

Metal for the castings is prepared in a five-ton electric furnace, the charge consisting of 40 per cent steel scrap and the balance pig iron, back stock and alloys. All the scrap comes from the company's own production in East Windsor, and can therefore be carefully controlled as to analysis.

The foundry is successfully handling five heats a day, which permits of a maximum production of 475 crankshafts, enough to take care of production at the maximum of about 460 engines per day, the rate at which the East Windsor plant has been currently operating.

After the steel is poured, the moulds move for some distance on an overhead conveyor from which are suspended special carriers. When the moulds have had time to cool slowly, the sand is knocked off and falls into a pit, from which it begins its journey by conveyor to the dump bins. New sand is used for all cores, no reconditioning being possible for this casting. The castings themselves remain on the conveyor and are further cooled, after which the "gates" of the castings are removed. The individual cast shafts are hung on conveyors for cleaning, grinding and inspection prior to heat treatment. The entire casting of four crankshafts, together with gates and risers, weighs about 420 pounds.

Fig. 1—Charging the Five-Ton Electric Furnace.

The shafts are now passed through a double heat treatment in one 62-foot continuous furnace. After the heat treatment the shafts are loaded on the return half of the conveyor, and then are transferred to the first operation of a drop test to make sure the shaft is perfect before commencing to machine. Brinell hardness is taken and machine shop operations commence.

Cores are made on a rotary core-table of special design. This is a Ford development, built especially for their requirements.

Operators transfer the cores from the core-table to a vertical core oven of the continuous type, where they are baked under controlled conditions of time and temperature. Core plates are hung on a conveyor which takes them through a washing machine and back to the core-making machine.

Fig. 2—Pouring from the Electric Furnace.

After being baked, cores are placed on a flat rotary type carrier on a chain conveyor, where they are faced and washed. They are then inspected, gauged and inserts are placed in position.

After a further inspection cores are placed on racks on a continuous storage conveyor running along the core assembly line. This conveyor eliminates the necessity of having a storage room for cores with the consequent handling expense. It enables operatives along the assembly line to have available constantly at their elbows a correct supply of the various cores going into the build-up. The build-up is held to an overall accuracy of 30/1,000 inch.

By carefully watching the heat treatment factors, the shafts will remain straight and the Brinell hardness and physical properties will be within the proper limits. The allowable limits on physical properties are:—

Elastic Limit	Ultimate	Twist at Elastic Limit	Twist at Ultimate	Brinell
Maximum 88,000	128,000	9°	16°	255
Minimum 96,000	130,000	6°	25°	321

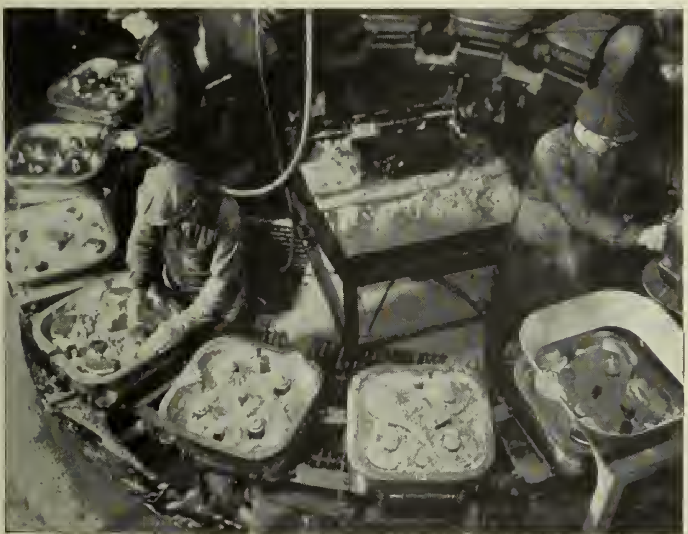

Fig. 3—Rotary Core-Making Machine.

Impact: Drop of 50 pounds 40 inches to flange of centre main bearing —2,000 inch-pounds.

Test Bar:	Elastic Limit	Tensile Strength	Elongation	Reduction Area	Brinell
Maximum	91,000	108,000	1.5	2.0	255
Minimum	93,500	107,000	2.0	2.5	269

Transverse:	Breaking	Deflection	Brinell
Maximum	9,565	.420	255
Minimum	9,330	.430	269

The composition of the cast steel is as follows:—

Carbon	1.35/1.60
Manganese	0.50/0.60
Silicon	0.85/1.10
Chromium	0.40/0.50
Copper	1.50/2.00
Phosphorus	0.10 maximum
Sulphur	0.06 maximum

Fig. 4—Assemblies of Crankshafts Before Separation.

Because of the difficulty in machining this unusual material, which can be classified as "high carbon, high copper, chrome-silicon cast steel," special hammered high-speed steels are employed. Work speeds of machine tools have been cut down, but feeds have generally remained the same in machining the cast shaft as compared with the forged product. The cutting tool is fed into the work as heavily as possible without chatter or breakage, due to the fact that a light feed causes the tool to glaze quickly and dull.

Following rough machining all shafts are given a torque test. After being finish-machined they are given a reverse torsional test in a machine especially designed for this purpose. A torque of 45,000 inch-pounds is applied in either direction, this being ten times the calculated maximum stress occurring in service and being close to the elastic limit of a forging of the same design. Although this shaft possesses about the same modulus of elasticity as the forged shaft, the cast shaft is capable of withstanding repeated reverse stresses for more than twice the time.

Brinell tests reveal that the exceptional fatigue strength of the cast crankshafts, claimed to be more than twice that of forged shafts, may be attributed to the uniform hardness of the metal from the heart of the core to the surface. This is not true of forged shafts, which show a Brinell hardness varying from the centre to the surface. Before heat treatment the Brinell reading of the cast shaft is 340 to 360, and when finished from 255 to 321, with the average hardness around 300.

The electric furnace installation is the first completely automatic unit in Canada. It utilizes 10-inch electrodes and pulls 2,400 kv.a. from the Ford power house. One unit in the power house provides the electricity.

Unwin Memorial Fund

The late Dr. W. C. Unwin will long be remembered for his services on many large engineering problems as well as for his educational work. Dr. Unwin died on March 17th, 1933, in his ninety-fifth year, and thus outlived most of his contemporaries. During his long life he was the recipient of nearly every honour that could be conferred upon him by his fellow engineers. He was president of the Institution of Civil Engineers in 1911, and of the Institution of Mechanical Engineers in 1915, and again in 1916; both institutions conferred upon him the distinction of honorary membership. In 1921 Dr. Unwin was awarded the first Kelvin Medal, the highest honour bestowed by British engineers. In America, where he was so well known for his work on the International Niagara Commission, he received many marks of appreciation, among which were the honorary memberships of the American Society of Civil Engineers and the American Society of Mechanical Engineers.

Many of his former students in Canada will be interested to hear that a memorial fund is now being collected by a committee in London under the chairmanship of Sir Alfred Chatterton, the proceeds of which will be devoted to a scholarship fund, to the publication of an extended memoir, and to a portrait to be hung in the Central Technical College, which was for so many years the scene of his labours. Contributions to the fund, and orders for copies of the memoir, may be sent to The Treasurer, Unwin Memorial Fund, 15A Grosvenor Mansions, 82 Victoria Street, London, S.W.1.

BRANCH NEWS

Border Cities Branch

C. F. Davison, A.M.E.I.C., Secretary-Treasurer.
F. J. Ryder, S.E.I.C., Branch News Editor.

There were twenty-seven persons present at the regular monthly meeting held after dinner at the Prince Edward hotel on February 15th, 1935.

O. Rolfson, A.M.E.I.C., presented the councillor's report. The activities at the General Meeting were reported upon by our member, R. A. Spencer, M.E.I.C.

Owing to the inability of Dr. Clements to attend as announced, B. Candlish, A.M.E.I.C., introduced Mr. T. A. Boyd of the General Motors Research Laboratories, Detroit, who presented a paper on the "Value of Research to Industry."

The first question asked by visitors to an automobile laboratory is "What is the use of all this research anyway? The automobile is just as perfect as it ever will be." This idea is all wrong for even as far back as 1909 one manufacturer advertised the perfect car. One has only to look back a few years to see what progress has been made during the intervening years. The automobile has been a gradual development, not one big discovery or improvement.

However, discoveries and inventions do not spring forth suddenly but are the results of long tiresome hours of research. The most important thing in research is the ability to get new ideas. Only a small percentage of ideas are new or practical.

The history of all new ideas is quite similar. At first presentation it is thrown into the waste paper basket without consideration, similarly for the second and even the third time. After persisting for several years, if your idea is still good, it will get the notice which it deserves.

There is much room for improvement in present day cars. They could be more dependable, have lighter and smoother engines; better carburetion and ignition; improved transmission; easier and safer brakes; and many other mechanical advantages.

After a number of slides had been shown the meeting was thrown open to discussion.

The one method of research in laboratory work, is to put a man in a laboratory and let him work unhindered on any ideas he may have and in any way he likes. The other and the more common way, is to put a man at work solving one definite problem.

H. J. A. Chambers, A.M.E.I.C., and L. E. Krebser, A.M.E.I.C., moved a vote of thanks to Mr. Boyd for his excellent paper.

Hamilton Branch

A. Love, M.E.I.C., Secretary-Treasurer.
A. B. Dove, Jr.E.I.C., Branch News Editor.

Weather Forecasting

At a joint meeting of the Hamilton Branch of The Institute and the Hamilton Centre, Royal Canadian Astronomical Society, at McMaster University on April 22nd, 1935, Mr. John Patterson, F.R.C.S., addressed the gathering on the subject of "Weather Forecasting."

Mr. Patterson after being introduced by Dr. Dawson of McMaster University, told the meeting of the value of forecasting to shipping and farm areas, as well as to the populated districts. He described a great chain of Canadian meteorological stations working in conjunction with the United States stations without which only half the story would be evident.

By diagrammatic slides Mr. Patterson demonstrated the cutting of warm wave fronts into cold bodies with very definite lines of demarcation over the continent. Strange as it may seem, the warm and cold bands may lie side by side, unmixing for great periods. Warm air of course is saturated with moisture to a much greater extent than cold, giving rise to precipitation on meeting the cold wave front. The driving force of the cold band may lift the warm air in mass and give heavy rains.

The cold front is preceded by a "roll-cloud" formation with winds of 15 to 20 miles per hour. In the cold region the sky may be bright and clear while at the junction of hot and cold fronts rains will be pronounced. The winter systems have great variations and are much more difficult to show graphically.

The lecture was further illustrated by motion pictures of cloud formation and dissolution, at high speeds. The pictures were taken from a mountain top in Oakland, Cal., and showed clouds rushing by, increased in motion by the camera to a speed of six times that actually photographed. Clouds were shown to form on meeting a cold current and to dissolve when passing into warm paths over hills.

A vote of appreciation was passed for a most interesting lecture and the meeting adjourned for refreshments.

Several members of the Branch journeyed to Welland on the afternoon of May 2nd and enjoyed the programme arranged by the Niagara Peninsula Branch of The Institute and the Ontario Section A.S.M.E., visiting the plants of the Page-Hersey Tube Company and the Atlas Steel Company, also the heavy forging and the drop forging plants of the Canada Foundries and Forgings Ltd.

Following the visits dinner was served, then followed a meeting which was both instructive and enjoyable. The Niagara Peninsula Branch is to be congratulated on carrying out so successfully such an elaborate programme.

Niagara Peninsula Branch

P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

A joint meeting with the A.S.M.E. (Ontario section), was held in the city of Welland on May 2nd, 1935, with about 250 members attending. The afternoon session was devoted mainly to visiting the following plants:—

Canada Foundries and Forgings	Heavy and drop forgings.
Canadian Atlas Steels Ltd	Tool and special steels.
Page-Hersey Tubes Ltd	Pipe and tubes.

Other industries which were also open for inspection through the kindness of their Executives are as noted below:—

Plymouth Cordage Co.	Empire Cotton Mills Ltd.
Dominion Fabrics Ltd.	Standard Steel Construction Co.
Mead-Morrison Co. Ltd.	National Refractories Ltd.
Welland Electric Steel Foundry.	John Deere Mfg. Co. Ltd.

After an excellent dinner, which was served by the ladies at the Raymond Auditorium, motion pictures were presented showing the process at the Atlas Steels plant and slides to illustrate papers by Messrs. M. F. McCarthy, R. McGlone and Mr. Voorhees of the Erie Forge Company. These combined addresses reviewed the history of forging, the rapid growth in the use of alloys and their particular application, the practical problems of forging and heat treating and pictures of micrographic structure as well as some of the heavy forgings for crankshafts, guns, etc., which are now being used.

Mementoes of this visit, in the form of paper knives and ash trays, were distributed among the guests; also a number of prizes, donated by various local firms, were drawn for by means of a free raffle and presented by Mr. Batchelder.

C. H. McL. Burns, A.M.E.I.C., acted as chairman of the committee, which is to be congratulated upon an excellent programme. Other members of the local committee were Messrs. F. L. Haviland, M.E.I.C., of the Standard Steel Construction Company; Paul E. Buss, A.M.E.I.C., of the Provincial Paper Mills; J. C. Street of the Welland Water Works; E. P. Johnson, A.M.E.I.C., of the Welland Ship Canal; N. A. Batchelder of the Empire Cotton Mills.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Geological Mapping with Aeroplane Assistance

How the aeroplane can prove of tremendous assistance in the geological mapping of the Pre-Cambrian regions of Northwestern Canada was ably described in a noon luncheon address by F. J. Alcock, Ph.D., of the Geological Survey of Canada, at the Chateau Laurier before the local Branch on April 25th, 1935. Dr. Alcock, who has made a special study of Pre-Cambrian geology, was engaged during the summer of 1934 on a geological exploration of the area in northern Saskatchewan lying north of the Churchill river and drained by two of its tributary streams, the Mudjatik and Haultain rivers. The exploration was a co-operative undertaking between the Dominion and the Saskatchewan governments.

A flying boat was placed at the disposal of the party as well as a radio receiving set and a wireless sending set. With the flying boat it was a simple matter to keep the party well supplied with provisions and to transport the party from one place to another without the laborious work of canoeing and portaging over long distances. By means of the wireless equipment communication was maintained with Ile-a-la-Crosse, the nearest wireless station. Through this station the party was able, in turn, to keep in touch with Prince Albert and other points in civilization. The party also had the advantage of detailed maps of the area prepared from aerial photographs previously taken by the Royal Canadian Air Force, as well as copies of the photographic prints themselves for direct reference.

Canoes, of course, had to be used for the ground work proper and frequently side trips by canoe had to be made for a few days at a time, in which case usually two men would take part and all equipment was so reduced that only one trip across the portages would be required. For some particularly inaccessible regions the plane would frequently be used when it would land the party on a nearby lake with a small folding canvas canoe.

The region covered, stated Dr. Alcock, was one where the relief was somewhat more pronounced than usual with the Pre-Cambrian formation. Hills up to 300 feet in height were quite common; the streams in general were small, and many of the water areas lay in deep basins difficult of access.

The work was greatly speeded up by the plane and much investigation, non-productive of results, was obviated merely by inspection from the air.

Dr. R. W. Boyle, M.E.I.C., chairman of the Branch, presided, and in addition head table guests included: Hon. W. A. Gordon, Major General A. G. L. McNaughton, M.E.I.C., Dr. C. Camsell, M.E.I.C., Dr. W. H. Collins, G. J. Desbarats, M.E.I.C., L. L. Bolton, M.E.I.C., J. A. Wilson, A.M.E.I.C., F. C. C. Lynch, A.M.E.I.C., F. H. Peters, M.E.I.C., Alan K. Hay, A.M.E.I.C., Group Captain E. W. Stedman, M.E.I.C., and Dr. J. H. Parkin, M.E.I.C.

Quebec Branch

Jules Joyal, A.M.E.I.C., Secretary-Treasurer.

La Canalisation du St-Laurent

Ce sujet est évidemment d'envergure trop vaste pour être traité à fonds dans l'espace d'une vingtaine de minutes, mais, lors d'une réunion générale de notre section, tenue au Palais Montcalm le 4 mars dernier et spécialement organisée pour mettre en vedette le groupe de nos jeunes membres, M. René Dupuis, A.M.E.I.C., assistant surintendant de la division du pouvoir à la Cie Quebec Power, nous a donné un aperçu remarquable de l'ensemble du projet.

Monsieur Dupuis traite d'abord de la géographie du St-Laurent dont la longueur, à partir du détroit de Belle-Isle jusqu'à l'extrémité ouest du lac Supérieur, est de 2375 milles; sous la rubrique distances verticales il mentionne que Montréal est à 20 pieds au-dessus du niveau de la mer, le lac Ontario à 245 pieds, le lac Erié à 570 pieds, le lac Michigan à 580 pieds et enfin le lac Supérieur à 600 pieds.

Cette chaîne de lacs forme un immense réservoir d'environ 95,000 milles carrés et assure au fleuve une stabilité de débit naturel unique au monde; le conférencier nous fait ensuite remonter le St-Laurent jusqu'à ses sources en notant les profondeurs d'eau jusqu'à Montréal et les différents rapides à l'ouest de ce dernier endroit.

Dans la seconde partie de sa causerie Monsieur Dupuis donne la liste des différents canaux avec leurs caractéristiques respectives soit: la longueur en milles, le nombre d'écluses et de pieds de montée, puis la profondeur d'eau. En passant le conférencier s'arrête quelque peu sur la diversion des eaux du Lac Michigan par la ville de Chicago, et énumère les motifs de la construction de ce canal de diversion et démontre que cette dernière a pour effet d'abaisser le niveau de l'eau de plusieurs pouces dans le port de Montréal qui en souffre gravement.

Les canaux projetés devront avoir les caractéristiques du canal Welland dont la profondeur est de 25 pieds; le fleuve St-Laurent avec ses canaux forme un cours d'eau navigable depuis son embouchure jusqu'à la tête des grands lacs; les sujets de sa Majesté Britannique et des Etats-Unis ont le droit d'y naviguer en vertu de traités dont le conférencier nous cite certaines clauses se rapportant à la navigation.

Un bref aperçu est aussi donné des forces hydrauliques utilisables le long du fleuve.

En troisième lieu Monsieur Dupuis parle du coût anticipé de la canalisation et du revenu qu'on en attend, il donne dans cette partie une foule de chiffres très intéressants mais que nous ne pouvons citer faute d'espace et pour conclure le conférencier énumère les raisons "pour" et "contre" la canalisation sans en faire l'appréciation.

A cette même réunion nous avions le plaisir d'entendre MM. James O'Halloron, A.M.E.I.C., et Jean St-Jacques, S.E.I.C., sur des sujets très intéressants; un résumé de leurs causeries sera publié prochainement dans la section des "Branch News" du Journal de l'Institut.

Sault Ste. Marie Branch

H. O. Brown, A.M.E.I.C., Secretary-Treasurer.

Construction of a Modern Highway

The Sault Ste. Marie Branch held the general meeting for April at the Windsor Hotel on Tuesday evening, April 30th, 1935, instead of on the regular meeting night of Friday, April 26th. This was arranged for the convenience of the speaker for the meeting.

The dinner preceding the meeting was well attended and twenty-seven members and guests sat down at 6.45. Following the dinner the chairman, F. Smallwood, M.E.I.C., called the meeting to order.

After the routine business was transacted the chairman introduced the speaker of the evening, Mr. R. T. Lyons, B.A.Sc., of the Department of Northern Development, Sault Ste. Marie. Mr. Lyons' subject was "Construction of a Modern Highway," illustrated with photographs and lantern projection views.

Starting with reconnaissance surveys of the proposed road by aeroplane, the various steps in the development of the standard 30-foot gravel highway were described. Most of the photographs shown had reference to the construction work done in the Kenora area on the Trans-Canada Highway, and, therefore, were of special interest at this time owing to the discussions which have taken place about the proper location for the connecting link between this district and Kenora.

Another feature of road-building and maintenance which is of special interest at this time in this area is dust laying. The relative merits and costs of the oil treatment and calcium chloride treatment were referred to by the speaker.

After the address further information was brought out by the questions presented by the members. The discussion indicated that the majority present had a very active interest in the subject.

At the close of the discussion the chairman, on behalf of the Sault Ste. Marie Branch, thanked Mr. Lyons for addressing the meeting

Winnipeg Branch

J. F. Cunningham, A.M.E.I.C., Secretary-Treasurer.
H. L. Briggs, A.M.E.I.C., Branch News Editor.

Modern Sewage Treatment

On April 18th, 1935, W. D. Hurst, A.M.E.I.C., gave a paper entitled "Modern Sewage Treatment." The subject was of particular interest to Winnipeg engineers because of the proposed scheme of interceptor sewers and a treatment plant for that city.

At the present time the Assiniboine and Red rivers are carrying the discharge from 49 untreated main outlets and 12 private outlets, in Greater Winnipeg, which with the present low flow in the rivers has resulted in nuisance conditions. The speaker outlined three criteria whereby nuisance due to sewage in a stream is currently judged, namely, if the river flow be less than 3.5 c.f.s. per 1,000 population, if the dissolved oxygen in the river water fall below 50 per cent, or if the ammonia content of the water exceed a certain percentage. Interesting slides were shown demonstrating that for the last years, these three boundary lines had been definitely transgressed. Other information was presented which showed that increase in river flows of sufficient amount to alleviate these conditions in the next few years was exceedingly doubtful. The proposals for a system of interceptor sewers, to convey the discharge to a treatment plant north of the city, were outlined.

A wide variety of treatment processes, from mechanically cleaned screens to the incineration of the sludge, were described, and illustrated by a large number of slides.

Those contributing to the lengthy discussion which followed included D. L. McLean, A.M.E.I.C., Wm. Aldridge, A.M.E.I.C., J. W. Porter, M.E.I.C., E. V. Caton, M.E.I.C., W. M. Scott, M.E.I.C., T. C. Main, A.M.E.I.C., G. E. Cole, A.M.E.I.C., and Chas. T. Barnes, A.M.E.I.C. Mr. G. E. Cole paid tribute to the mining engineer Dorr for his extensive inventions of metallurgical machinery which had been so widely adapted to sewage treatment.

A hearty vote of thanks to the speaker of the evening was moved by E. V. Caton, M.E.I.C.

List of New and Revised British Standard Specifications

(issued during March, 1935)

B.S.S. No.

9—1935. *Bull Head Railway Rails.* (*Revision.*)
Introduction of medium manganese quality of rail with analyses and tests and alteration in permissible percentage of short lengths in the case of rails 60 feet long.

138—1935. *Portable Chemical Fire Extinguishers.* (*Revision.*)
Specification for materials, constructional strength and performance of portable chemical fire extinguishers of the acid alkali or soda acid type.

412—1935. *Engine Testing Equipment.* (*Revision.*)
Includes two further sections, one standardizing dimensions of attachments for testing fittings, i.e. thermometer pockets, etc.; the other to deal with suitable forms of indicator gear to ensure adequate accuracy.

590—1935. *Electrically Welded Mild Steel Chain Short Link and Pitched or Calibrated.*
Provides for sizes, quality and mechanical strength of electrically welded short link pitched or calibrated mild steel chain of sizes ranging from 6 S.W.G. to 17/32 in., representing a range of maximum permissible loads of from 1/5 ton to 1 ton 14 cwt.

591—1935. *Wrought Iron and Mild Steel Hooks of the "C" or Liverpool Type.*
Specifies design and mechanical strength of special type of hook used for unloading of ships, general cargo, and in building operations. Loads ranging from one to ten tons.

592—1935. *Steel Castings for General Engineering Purposes.*
Provides for four classes to cover the normal range of steel castings used in all sections of engineering industry. Requirements included for details of manufacture, heat treatment and mechanical properties.

593—1935. *General Purposes Laboratory Thermometers.*
Provides for workmanship, dimensions and constructional details and figuring of total immersion and partial immersion thermometers for general laboratory work.

599—1935. *Pump Tests.*
Designed to cover determination of performance and efficiency of pumps when handling clean water at temperatures up to 85 degrees F.

601—1935. *Steel Sheets for Transformers for Power and Light.*
Sheets of one thickness are standardized in two sizes. Three qualities of sheet are however specified according to the loss in watts per lb. Other tests include permeability, ageing, finish, etc. Details of methods of testing given in Appendices.

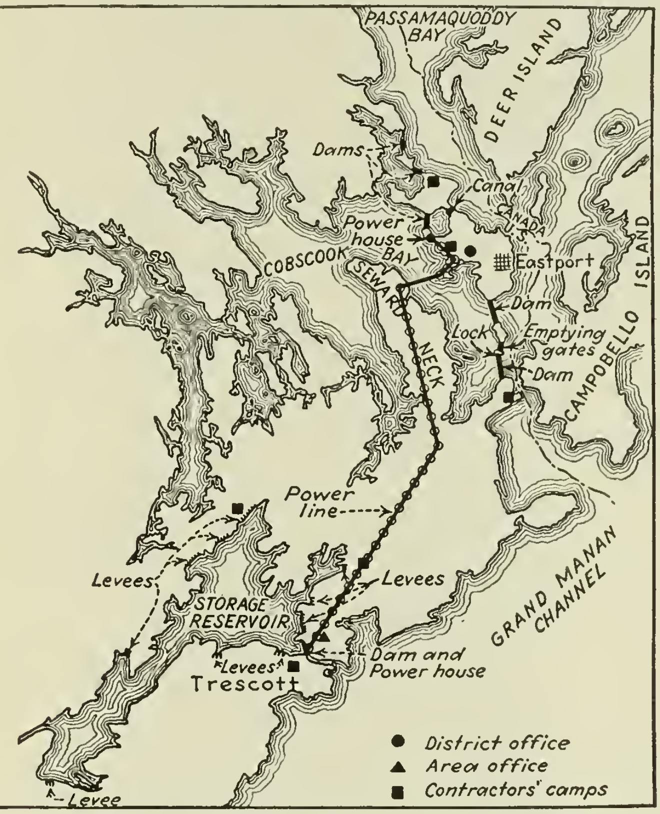
Copies of the new specifications may be obtained from the British Standards Institution, 28 Victoria Street, London, S.W.1, England, and, in Canada, from the Canadian Engineering Standards Association, 79 Sussex Street, Ottawa.

The S. R. Dresser Manufacturing Company, Bradford, Penn., and Toronto, announce a new type of compression coupling, style 65. This is supplied in standard steel pipe sizes from ⅜ inch to 2 inches I.D. inclusive. It is suitable for plain end pipe, no special preparation of pipe ends being needed.

United States Passamaquoddy Power Project

The federal government will take over the construction of the long-discussed Passamaquoddy Bay tidal power project in Maine, if the recommendation of the Advisory Committee on Allotments that $10,000,000 of the relief works funds be allocated to the Corps of Engineers to start construction of that project is approved by the President.

As originally proposed by Dexter P. Cooper several years ago, the project included all of Passamaquoddy Bay (mostly in the province of New Brunswick), Cobscook Bay in Maine and several dams to shut off the two bays from the ocean and to separate them into an upper and lower pool. The present project, as shown in the accompanying



The Tidal Project Originally Designed to Include Passamaquoddy Bay is now confined to the much smaller Cobscook Bay supplemented by a Pumped-Storage Reservoir.

map, includes only Cobscook Bay in the tidal power scheme and adds a pumped-storage reservoir to be located along the coast south of Cobscook Bay.

As has been the case ever since the project was first put forward no engineering drawings of the proposed dams, control gates and power houses have been made public. About a year ago the project was put up to the Public Works Administration for financing but it was disapproved by the P.W.A. board of review, and no details other than the estimated cost of $47,000,000 have been made public. The present project, according to the official statement, is designed to create and maintain a low level pool in Cobscook Bay and to use the difference in head between this pool and the ocean which will vary with the tide, to generate electric energy. The initial development will utilize the head above 5 feet in a main power station with an installed capacity of 166,670 kv.a. but the powerhouse will be constructed for a maximum capacity of 366,874 kv.a. with 12 units not installed. The estimated cost is placed at $36,284,000. The normal range of tide in Cobscook Bay is 18 feet.

The storage reservoir will have a surface elevation of 130 feet above sea level, and surplus power will be used to pump water into this reservoir, to be converted into electric energy during the low tide period. The emptying gate which will control the level of the Cobscook pool, and the navigation lock, will require a cofferdam of 75 feet in depth, capable of withstanding a maximum of 20 feet tidal range and ocean storms. Three of the rock dams are to be placed in water in excess of 100 feet in depth and subject to high velocity due to the periodic reversing of the tide.

The Corps of Engineers has passed upon the practicability but not upon the economics of the project.

Major Philip B. Fleming of the Corps of Engineers who acted as deputy administrator of public works from September 1934 until May 1935, is to be engineer in charge of the Passamaquoddy project for the army engineers.—*Engineering News-Record*

The Development of Building Codes in the United States

For years, architects, engineers, builders, manufacturers and others whose work or products go into building construction in the United States, have complained bitterly about existing building regulations. Architects have said that their freedom of design has been unnecessarily restricted. Engineers and builders have claimed that obsolete or ill-considered code provisions increased building construction costs without adding any compensating benefits in the way of increased public health or safety. Manufacturers of building materials have pointed out that their tested and tried products have been compelled to run a gauntlet of conflicting regulations, and that promising new materials and methods sometimes died in the struggle for recognition.

The public, on the other hand, has voiced its disapproval of poor or uncontrolled construction in no uncertain terms following the destruction wrought by earthquakes, tornadoes, fire, time and other causes. In addition, those who advance money on building construction, those who insure building loans, and those who insure buildings demand sound building regulations as a protection for their investment.

When questions of public health and safety, requirements for countless varieties of building materials and design and construction problems must all be considered in formulating a building code, it is obvious that the procedure requires a broad range of representation and a permanent, long-range plan for insuring retention of advances made, as well as providing machinery for necessary revisions.

A special committee, composed of representatives of national organizations having an interest in the entire building code field and private experts, has been appointed under the procedure of the American Standards Association to investigate methods for continuing the work on building codes of the Department of Commerce Building Code Committee, recently disbanded.

The Department of Commerce Committee was discontinued for reasons of economy and in line with the principle that agencies outside of the government should have an opportunity to participate more directly in the work. The Department of Commerce and the American Standards Association arranged to co-operate in the future development of building code recommendations.

Frequent surveys have brought out the salient facts about the current status of building regulations. There are to-day something like fifteen hundred local codes of all sizes and descriptions in existence in the United States and half a dozen state codes. In spite of sustained efforts to bring about scientific treatment of topics in the interest of safety and health these codes still differ widely in their treatment of fundamentals. Without necessarily recommending complete uniformity in building codes the sentiment is often expressed by architects, building officials, engineers and others that a vast amount of work remains to be done in bringing them up to an acceptable standard.

It is true that there are model codes in existence sponsored by organizations of building officials and by insurance interests. While these have made definite contributions towards better requirements, they differ both in method of presentation and actual provisions.

In general, the task of the A.S.A. committee will be to consider matters of general interest with respect to building codes; to act as an advisory committee to the Association; to consider what subjects are appropriate for development in the A.S.A.; to define and limit the scope of projects for which it recommends sponsors; to follow up work in progress in the development of projects; to review the personnel of committees responsible for building code projects to insure their having a representative character; to examine recommendations submitted by sectional committees and to harmonize conflicts between the several recommendations; and to act upon such other matters that may be brought before it with relation to the development of building codes as it may consider within its province.

Individual projects will be handled by sectional committees, thus affording representation for all those having an interest in one or more phases of building codes, but not in the entire field.

Canadian Standard Forms of Construction Contract

In the editorial dealing with this topic in the January issue of The Journal the statement should have been included that these forms, as approved by the Council of The Engineering Institute of Canada and issued by the Canadian Construction Association, are essentially those originally produced by The Royal Architectural Institute of Canada jointly with the Canadian Construction Association, applying to work executed under the supervision of an architect.

Association of Canadian Fire Marshals and Dominion Fire Prevention Association

On Tuesday, Wednesday and Thursday, June 18th, 19th and 20th, 1935, the joint annual meetings of the Association of Canadian Fire Marshals and the Dominion Fire Prevention Association will be held at the Chateau Laurier, Ottawa.

The Fire Marshals Association will convene on June 18th at 10 o'clock and the Dominion Fire Prevention Association will convene at 2.30 p.m. on June 19th, following a joint luncheon of both organizations.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situations Wanted

SALES ENGINEER, S.E.I.C.; B.SC. C.E., 1930 (Univ. New Bruns.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.SC., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ENGINEER AND ACCOUNTANT, JR.E.I.C., (Capt. Can. Engrs., reserve). Age 35, Canadian. Experienced in mechanical and civil engineering, Diploma; general office, draughting and instrument work; assistant engineer erection Royal York hotel; assistant resident engineer T. & N.O. Ry. const. Desires position in Toronto where combination of technical and business experience will be of value, as have been director and accountant last three years. Apply to Box No. 377-W.

CIVIL ENGINEER, B.A.SC. and C.E.; A.M.E.I.C., A.M. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.SC. Univ of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

MECHANICAL ENGINEER, B.SC. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

CONSTRUCTION ENGINEER, age 26, unmarried, graduate C.E. Experience includes hydro-electric, railroad, highway, and industrial plant construction, both field and office, including cost accounting, estimating, stores, layout, general engineering and supervision, as well as practical work in mechanical trades. Apply to Box No. 567-W.

MECHANICAL ENGINEER, A.M.E.I.C. Experienced on plant maintenance, steel plant, cement plant and mining plants. Available on short notice. Apply to Box No. 571-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

ELECTRICAL ENGINEER, McGill '31, desires permanent position in engineering field. Experience includes draughting, designing and testing of induction motors, radio supervision and test, and some construction. Available immediately. Apply to Box No. 626-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

Situations Wanted

ELECTRICAL ENGINEER, B.SC. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box. No. 651-W.

ELECTRICAL ENGINEER, Univ. Grad. 1928. Two years Students' apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660 W.

ELECTRICAL AND RADIO ENGINEER, B.SC. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

Employment Service Bureau

This bureau is maintained by The Engineering Institute of Canada for the benefit of members and organizations employing technically trained men.

An enquiry addressed to 2050 Mansfield Street, Montreal, will bring full information concerning the services offered. Details can also be obtained from Branch secretaries who are located in the larger centres throughout Canada.

Brief announcements of men available and positions vacant will be published without charge in The Engineering Journal and the Bulletin. Replies addressed in care of the required box number will be forwarded to the advertiser without delay.

An additional service also offered those who are unemployed or wish to change their positions, is the opportunity of placing their names and records on file at 2050 Mansfield Street for consideration by employers wishing to employ engineers. This is of great assistance as many employers will not advertise or wish to locate a suitable man on short notice. If desired the information contained in these records can be kept confidential.

Forms for registration purposes may be obtained from The Institute Headquarters of Branch secretaries.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC., Elec., '29, B.SC., Civil '33. Age 27. JR.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.SC., '27, JR.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

Situations Wanted

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.SC., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.SC. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.SC. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box. No. 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.SC., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

RADIO AND ELECTRICAL ENGINEER, B.SC. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.SC. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, S.E.I.C., B.SC. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.SC., '25, JR.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

Situations Wanted

CIVIL ENGINEER, B.E. (Sask Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.A.SC., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No 831-W.

CIVIL ENGINEER, S.E.I.C., B.SC. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.SC. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.SC., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.SC. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W

CHEMICAL ENGINEER, B.SC. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box. No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No 887-W.

AGENCIES WANTED Young engineer, B.A.SC. in C.E., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A. C., JR E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

Situations Wanted

CIVIL ENGINEER, B.SC., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.SC. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.SC., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.SC. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.SC. Univ Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.SC. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.SC., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.SC.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.SC. (Univ. of B.C. '29); M.S. Age 27. Single. Four years experience in research work in applied mechanics and materials testing. Desires position involving analytical work in design, development or testing. Available on short notice. Apply to Box No. 1123-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box. No. 1127-W

Situations Wanted

PETROLEUM CHEMIST, B.SC. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.SC., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.SC., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.SC. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.SC., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Write and speak both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211 W.

CIVIL ENGINEER, B.SC. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

COMBUSTION ENGINEER, A.M.E.I.C., with extensive experience in all phases of combustion engineering, including plant layout, piping, etc. Lately connected with prominent firm of automatic oil burner manufacturers. Apply to Box No. 1224-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet and tissues. Apply to Box No. 1246-W.

CIVIL ENGINEER, B.SC. '29, JR.E.I.C., age 29, single. Experience in all types of surveying including use of aerial photographs. Three years on hydro-electric power development in field and office. Instrumentman on concrete road construction. Location immaterial. Apply to Box No. 1254-W.

CIVIL ENGINEER, Univ. Toronto '33, age 24, married. One year as instrumentman with provincial department of highways. Experience in concrete and retread construction grading, culverts, etc. Also draughting, estimating and general office practice. Apply to Box No 1265-W.

MECHANICAL ENGINEER, B.SC. (Queen's Univ. '29) Age 28. Six years experience in automobile office and plant; two years as supervisor of inspection in body assembly. Good understanding of modern business methods applied to manufacturing. Desires position with production department of smaller Ontario industry. Good references. Interviews anywhere in central Ontario. Apply to Box No. 1270-W.

ELECTRICAL GRADUATE, S.E.I.C., B.SC. '32 M.SC. '34. Experience includes four years as part time operator and announcer for a radio broadcast station At present employed in radio repair dept. of a large wholesale firm. Apply to Box No. 1283-W.

Standards of Engineering Education

An Engineers' Council for Professional Development has recently been formed in the United States for the purpose of preparing a list of "accredited colleges," whose curricula in engineering subjects is considered worthy of recognition. The participating institutions are the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the Society for the Promotion of Engineering Education and the National Council of State Boards of Engineering Examiners. Six major curricula, viz., chemical, civil, electrical, mechanical, metallurgical and mining engineering will be recognized and, though these may be either of undergraduate or graduate standard, the former must lead to degrees. In determining the suitability of an institution for recognition, the qualifications of its staff and the standard of its instruction, both in engineering and cognate subjects, will be considered, together with the records of past students, conditions of admission, degrees offered, size and finance. A necessary preliminary will be a visit of inspection by a joint committee of teachers and engineers. Such visits, as a first step towards accrediting, will only be taken on the invitation of the educational institution concerned. In this connection, it is pointed out that the Engineers' Council for Professional Development is merely authorized by its constituent organization to publish a list of accredited colleges. It has no authority to impose any restrictions upon the colleges, nor does it desire to do so. On the contrary, it aims at preserving the independence of action of individual institutions and thus promoting the general advancement of engineering. It will, however, have the advantage of substituting a single accrediting body for the uncoordinated methods of the past. Mr. G. T. Seabury is the Secretary of the Council, the offices being at 29, West Thirty-Ninth street, New York.—*Engineering.*

VOLUME XVIII — MONTREAL, JULY, 1935 — NUMBER 7

Common-Frequency Radio Broadcasting

C. B. Fisher, S.E.I.C.,
Northern Electric Company Limited, Montreal.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, March 8th, 1934.

SUMMARY.—In the following paper the general problems of common-frequency radio broadcasting are first discussed, the material being mainly compiled from papers previously published in the technical press. The problems include a study of the degree of synchronization required, the relative carrier field strength ratios desired in the service areas, the effects of noise and detector action and calculations on the increased service areas to be expected. There follows a description of two methods of securing synchronization: radio-frequency monitoring method, and electric control over wire lines between the stations. Commercial types of apparatus are briefly discussed, and the results of field tests given.

Common-frequency radio broadcasting, or less accurately, synchronized broadcasting, is a phrase used to describe a radio transmission system whereby two or more radio transmitters operate with the same carrier frequency. In an older parlance, the stations have the same wavelength. In this definition the quite common situation is not discussed where two stations operate on the same frequency, but are so widely separated geographically that neither one lays down an appreciable signal strength inside the territory covered by the other station.

Consider primarily the conditions existing when two or more stations operate on the same frequency, and radiate sufficient power, or are so closely spaced, that their areas of appreciable field strength overlap to some extent, or at least the "nuisance area" of one station overlaps the "service area" of the other. These terms are self-explanatory. To one not previously acquainted with the subject, it is not at once clear just what problems will be involved. It may safely be concluded, however, that some or all of the following questions will have to be answered:—

A. When the two stations are on the same frequency, how closely will this condition have to be met? Will not the allowable difference in frequency depend on relative carrier strengths of the two stations, relative depths of modulation, whether the stations are carrying the same, or different, programmes? Will not the type of receiver used, and particularly the demodulation or detection device be important?

B. If some law of radio wave propagation is assumed, what is the normal service area of two stations, not synchronized? How much will this service area be increased by synchronization?

It seems fairly clear that one may also want to look into the economic questions, glance at some existing installations, and finally consider what results have been achieved in field trials.

Purpose of Synchronization

Now to retrace our steps a short way, and consider, as the Marx Brothers would say, "Why is a synchronized station?" The answer is at once: there are not sufficient frequency channels available in the broadcast band. Table I shows the situation clearly.

Table I
Division of Radio Broadcast Spectrum in North America

	No. of Existing Stations	No. of Clear Channels	No. of Shared Channels	Total Number of Channels
Canada	70	9	27	36
United States	422	20	45	65
Mexico	62	0	48	48
Cuba	56	0	40	40
Totals	610	29	68*	97

Canadian clear channels: 540, 690, 730, 840, 910, 960, 1030, 1050 and 1100 kilocycles.

*Total number of shared channels equals total number of channels less total number of clear channels.

At the present time the broadcast band in North America extends from 540 kc. to 1500 kc., inclusive. Channels are 10 kc. wide, so that there are available ninety-seven different carrier frequencies. After the radio conference at Mexico City in July and August of 1933, these channels were allotted as shown, and Canada secured nine clear channels and twenty-seven shared channels, these to be divided among seventy stations. This situation means that many frequencies must be shared between two or more stations. With wide separation, or low power, little interference results. In some cases, however, it is highly desirable to operate additional stations within a given area, in order to give good service to the listening public, and it is here that synchronized broadcasting may prove of great value.

A second place where synchronization shows advantages is in the satellite system. Consider a hypothetical transmitter located say in Montreal, which gives good signal strengths about and beyond Sherbrooke, some 80 miles distant, but which fails to deliver a satisfactory signal in the town itself, due to local electrical interference. A low-power transmitter might then be installed in Sherbrooke, designed to cover the town only, and it would be advantageous to synchronize the Sherbrooke and Montreal transmitters.

There is also another aspect of synchronization. In the example given above, it would not have been economical to increase the power of the Montreal transmitter merely to increase the signal strength at Sherbrooke. There might also be the case where it might be economical to increase the main transmitter power, but in doing this, so high a signal strength would be delivered to nearby areas, that the local receivers would be unable to receive anything except the local station, and also the nuisance area of the station on the outskirts of its service area would be increased beyond the tolerable limits. Again synchronization might prove of value.

Fig. 1—Relative Density of Population in Canada.

In Canada common-frequency broadcasting is of especial interest. There is a large area to be covered, with a comparatively small population, which means many stations, but few channels. Moreover, the population is settled in fairly concentrated areas separated by considerable distances. It will be seen that this situation lends itself admirably to synchronization. There is given in Fig. 1 a map of Canada with density of population shown, which shows clearly the extent of this concentration of population. And last, and most important, radio broadcasting is under a unified control, an absolute necessity where extensive synchronized systems are to be intelligently planned. This principle may thus become one of the most important factors in Canadian radio development.

Reception of Synchronized Stations

Now to attack the technical phases of the problem by considering the reception of two synchronized stations in detail. First consider the case in which the stations carry the same programme, and the difference of frequency of the carriers is of the order of a few cycles per second. Waves from both stations are amplified by the high-frequency stages of the receiver, and reach the detector, where a number of spurious frequencies are generated. Table II shows these in detail.

Table II

Detection of Two Modulated Waves

Audio-frequency components for waves of carrier frequency-difference ΔP, carrier amplitude ratio K, depth of modulation of each wave M, frequency of modulation Q for each wave, waves modulated in phase, square-law detector.

Frequency of Component	Relative Amplitude $M, K.$	Relative Amplitude $M=1.0$ $K=1.0$	Description
Q	$1+K^2$	1.00	Desired Frequency.
ΔP	$\frac{K}{M}\left(1+\frac{M^2}{2}\right)$	0.75	Beat Frequency.
$Q+\Delta P$	$K.$	0.50	Desired Frequency + Beat.
$Q-\Delta P$	$K.$	0.50	Desired Frequency − Beat.
$2Q$	$\frac{M}{4}(1+K^2)$	0.25	2nd Harmonic.
$2Q+\Delta P$	$1/4\ MK$	0.125	2nd Harmonic + Beat.
$2Q-\Delta P$	$1/4\ MK$	0.125	2nd Harmonic − Beat.

There is first shown the amplitude of the various components as a function of the depth of modulation, M, and of the ratio of the carrier amplitudes, K. These values have then been computed for the case of 100 per cent modulation and equal carrier amplitudes. This is about the worst case to be encountered. What should be noted here particularly is that not only is the beat note of importance, but other components are also present, principally those having frequencies equal to the modulation frequency plus or minus the beat frequency. Since in practical cases the beat frequency is much too low to be heard, it is these latter components which impair the quality.

In Fig. 2, in order to give a more general picture of the production of spurious frequencies, there are shown their relative amplitudes as a function of the ratio of the carrier amplitudes, for 50 per cent modulation. If it is assumed that for satisfactory reception the relative amplitude of the total sideband noise should not be more than one-tenth that of the desired frequency, this would restrict reception from two stations to areas where the relative carrier amplitude is 20 to one or greater. A series of measurements to determine this point has been made by G. D. Gillett,* and his results are shown in Fig. 3. Tests were made with both music and speech, running up to 80 per cent modulation on peaks. With voice transmission the situation was the less critical, but in general a carrier ratio of 10 to 1 had to be maintained in order to avoid serious impairment of quality.

The next problem for consideration is the reception of two synchronized stations, carrying the same programme, when the carrier frequency difference is made very small, of the order of one cycle or less. The waves may be considered to be of the same frequency, but with a phase difference which slowly varies. Under these conditions reception is obtained very different in character to that previously considered. In the first place the beat frequency is absent. This in itself is of little importance, but the concomitant result is that the spurious frequencies made up of the modulation frequency plus or minus the beat frequency are also absent. The removal of this sideband noise gives a freedom from harshness in the sound reproduction, to an extent not easily obtainable when the carrier frequencies are appreciably different. An important

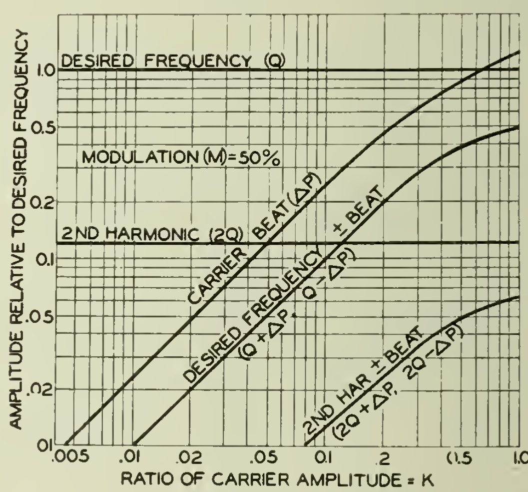

Fig. 2—Detection of two modulated Waves of Frequency-Difference ΔP, each modulation 50 per cent in Phase, by Frequency Q. Curves show relative Amplitude of Audio-Frequency Components in Output of Receiving (Square-Law) Detector.

effect to be considered is the way in which the two carrier waves add together in the detector. Assume for an example that the signal strength from the two synchronized stations is equal. Then when the two carriers are in phase aiding, twice the voltage due to either station alone is applied; when the carriers are in phase opposition, the resultant voltage is zero. As the carriers change phase through 180 degrees, or as the receiver is moved across the country

*Previously published material used in the preparation of this paper is listed in the bibliography under the appropriate subject heading.

one-half wave length, a signal strength is received varying from zero to twice the normal value. For areas where the carrier amplitudes are not equal, the variations will be smaller. In Fig. 4 an assumed case has been plotted. The central curves show the relative field strengths received separately from two hypothetical stations of equal power, 150 miles apart. The upper curve shows the sum, and the lower curve shows the difference, of the field intensities from the two stations. Then at any one position the signal amplitude will vary between these two limits. The

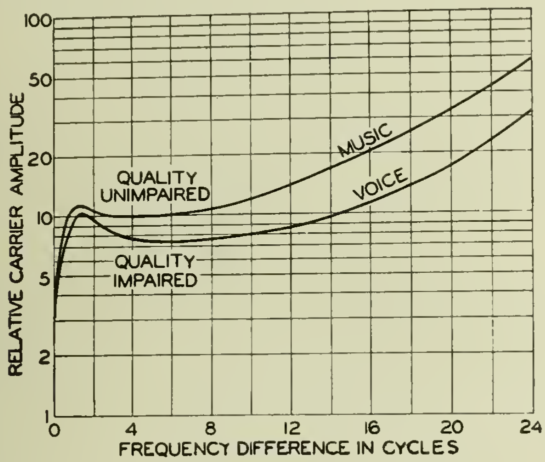

Fig. 3.

most obvious result will be fading. It is usually concluded that this factor is negligible, due to the prevalence of receivers incorporating automatic volume control, and in the small area where the resultant signal goes below the noise level during the fading cycle, it is stated that a slightly directional antenna will solve the problem. Surely these conclusions are much too optimistic. It is doubtful if at the present time one receiver in three in Canada has an effective automatic volume control circuit, and in the area of equal strength probably not one listener in ten would have the knowledge, the facilities, and the energy to erect the simplest form of directional antenna. The manner in which an opinion is reached on these two points, simple as they may seem, profoundly affects the design of any synchronized broadcasting system.

If it is assumed that a fading ratio is permissible between peaks and troughs of 1.4, or 3 db., then reception is restricted to areas where the relative signal strength ratio of the two stations is about six to one, or greater. If, however, an increased fading ratio is permitted, other

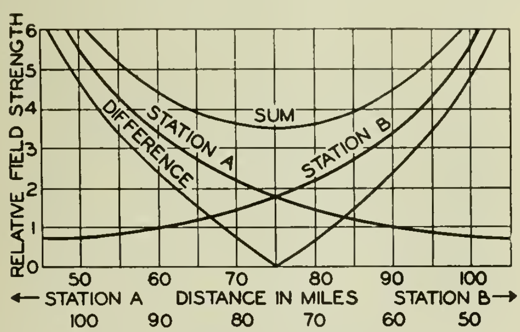

Fig. 4—Field from Two Synchronized Stations of Equal Power.

factors demand attention. The first of these is the question of the depth of modulation.

The usual type of receiver can receive with tolerable distortion a modulated wave in which the sidebands are of equal amplitude, and separately do not exceed half the carrier amplitude, i.e., the depth of modulation does not exceed 100 per cent. Since the carrier and sidebands are not of the same frequency, one of the following conditions may be obtained, depending on the relative phase of the waves from the two stations, at the receiving point.

(*a*) Both sidebands completely or partly phased out, causing amplitude fading additional to the carrier fading already considered.

(*b*) One sideband phased out, causing some fading, but principally severe distortion of the modulated wave.

(*c*) Carrier fading, without sideband fading, which may cause the resultant wave at the receiver to be overmodulated, with consequent distortion upon demodulation.

(*d*) Where the modulation takes place at several frequencies simultaneously, certain of these frequencies may phase out and be lost at the receiver, with a resultant loss of fidelity; this is selective fading, and is usually accompanied by (*b*) and (*c*).

(*e*) Where the audio-frequency modulating waves are out of phase results similar to (*d*) may result.

Figure 5 shows the relative amplitude of second harmonic components for the case of equal carrier amplitudes over a range of carrier and modulation phases, as measured at the output of the receiving detector.

There remains one more case to be considered. This is the effect of difference in time of arrival of the corresponding waves from two exactly synchronized transmitters. Echo effects are easily avoided in practical operation, as delays of several thousand micro-seconds are ordinarily required before these become perceptible. However, much

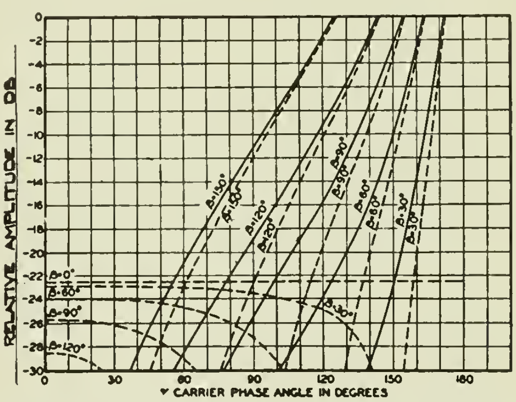

Fig. 5—C.-F. Broadcasting Detection of two Modulated Waves. Second Harmonic Output for Waves of same Amplitude and Frequency Modulated 30 per cent by same Frequency.

smaller delays have been found quite perceptible from a distortion standpoint, due to the phasing effects of the two modulated waves. Figure 6 shows the results of observations by Aiken on the relative time-delay which is permissible for various ratios of carrier amplitude and various carrier phase angles. It will be noted that the worst effects are obtained with a carrier phase angle of 180 degrees and in Fig. 7 the permissible time-delay, or alternatively the permissible difference in distance from the receiver to each of the synchronized stations, is plotted against the required carrier amplitude ratio. If a carrier ratio of about 14 or more to one is maintained, time-delay of any reasonable amount causes negligible distortion. On the other hand, if the stations are accurately synchronized, and the difference in the length of paths to the receiver is less than 10 miles, perfect reception may be obtained at any point in their normal service area.

Some consideration should be given to the type of detector employed in the receiver. In most of the calculations of spurious frequencies the linear detector shows to considerable advantage over the square-law detector. In practice, however, as the actual conditions of carrier ratio, frequency difference, depth of modulation, and time-delay vary widely, and as commonly used detectors are intermediate between the two theoretical types, very little distinction can be made. In general, of course, the linear detector will show smaller relative distortion components.

So far only the case where the two synchronized stations carry identical programmes has been considered. When stations carrying different programmes are synchronized, however, very little advantage is ordinarily gained. The beat note will normally be inaudible in any case, and the only spurious frequencies which will be eliminated are the desired frequency plus and minus the beat frequency. These components will be much smaller than the components of the unwanted modulation frequency, so that about the same carrier ratio must be maintained at the receiver for synchronized as for non-synchronized stations.

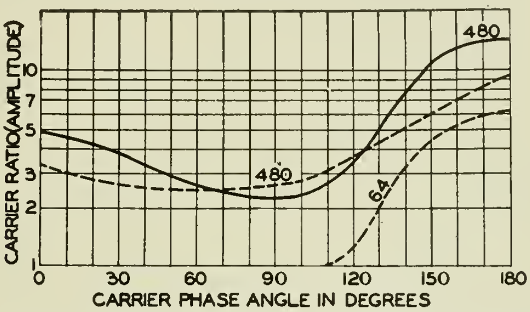

Fig. 6—Detection of two Modulated Waves of same Carrier Frequency, modulated 80 per cent on Peaks of same Programme. Curves show limiting values of Carrier Phase Angle and Carrier Amplitude Ratio at which indicated Time-Delay in Microseconds causes Perceptible Distortion.

There is also another effect in the reception of synchronized stations which becomes important when the frequency-difference is greater than about one cycle. If static or circuit noise is present in even quite small amounts, a noticeable flutter will be heard, although the carrier ratio may be of such a value that reception is otherwise satisfactory. This effect has been extensively studied by C. B. Aiken of the Bell Telephone Laboratories, who kindly permitted the writer to see an unpublished memorandum giving complete quantitative data.* This flutter is much more noticeable with a square-law than with a linear detector, and in the former case is independent of the amplitude of the noise over quite a wide range. As a quantitative example, Aiken found that with two carriers of a frequency-difference of 3 cycles, the stronger signal being modulated by speech or music with a strong background of circuit noise, the square-law detector gave easily perceptible flutter for a carrier amplitude ratio of 3 to one, the flutter becoming imperceptible for ratios greater than about 6 to one. Under similar conditions the linear detector gave perceptible flutter for a carrier ratio of 1.2 to one, distortion disappearing for a ratio of about 1.8 to one.

The flutter effect may also be intensified with receivers employing automatic volume control. As the two incoming carriers alternately add and subtract in amplitude, the automatic volume control will first increase and then decrease the gain of the receiver in order to keep a constant carrier voltage at the detector input, thus causing a corresponding flutter in any background of noise which may be present.

This section may be concluded with a rough estimate based on the experience of workers in the field of synchronized broadcasting, as to what ratios of carrier amplitudes from the two transmitters are permissible for satisfactory reception.

For accurate synchronization, with carrier-frequency differences of a fraction of a cycle, and small time-delay, ratios of 1.4 to one or greater must be maintained. Eckersley gives a ratio of 5 to one for low-power stations of equal power separated forty miles.

*Since this paper was written, Mr. Aiken has published the results of his study. See reference (10) in bibliography.

For close synchronization with carrier frequency-differences of a few cycles, ratios of about 12 to one or greater are necessary, particularly if noise is present.

For stations without synchronization having frequency-differences of the order of 20 to 100 cycles, the carrier ratio should be about 30 to one or greater.

It is a fact of experience that where synchronized stations are received at a considerable distance from either station, or in cases where the stations are widely separated, reception may be much better than would be predicted from the data given above. This is due to the fact that in these cases transmission from each station may occur over several paths of different lengths. All the effects tending to depreciate the quality of reception depend on the phasing-out of particular components, and where a number of paths exist, the probability of these phasing effects becoming serious is considerably lessened.

Service Area of a Single Station

Having considered in some detail the reception of two synchronized stations, the associated transmission problems may be now looked at briefly. The steps necessary are first to arrive at conclusions as to what constitutes a satisfactory signal strength, and then to examine available data to find the extent of the service area of a single station operating on a clear channel. With this information on hand we shall be able to see to what extent synchronization is of value.

The United States Federal Radio Commission has set up standards for reception as follows:

The *good* service area of a station is defined as that area in which reception is obtained free from noticeable interference for 90 per cent of the time. *Fair* and *poor* service areas are defined relative to the good service area. The field intensity which is considered to correspond to each grade of service for different reception conditions is shown in Table III.

Table III

Minimum Field-Intensity Standards Established by the U.S. Federal Radio Commission

Values are in millivolts per meter

District \ Service	Good	Fair	Poor
Business	10	5	2
Residential	2	1	0.5
Rural	0.5	0.25	0.125

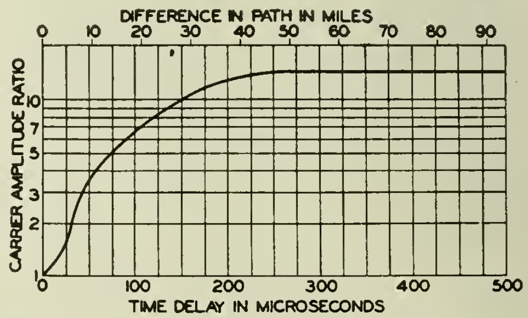

Fig. 7—Detection of two Modulated Waves of same Carrier Frequency, of Relative Phase 180 Degrees modulated by same Programme. Curve shows Time-Delay (or Difference in Lengths of Path to Receivers) versus Carrier Amplitude Ratio at which Distortion is just Perceptible.

A standard for non-synchronized stations of the same frequency is set at a field-intensity ratio of 20 to one, although admittedly this is not satisfactory under many conditions.

Definitions of service areas in northern Europe, given by P. P. Eckersley, sometime chief engineer of the British Broadcasting Corporation, agree with the values shown in Table III for business districts.

It should be realized that the classifications arrived at, in America at any rate, are governed almost entirely by local electrical noise conditions. It is assumed that listeners in any area will have receivers sufficiently sensitive to utilize even much weaker field intensities than are accepted as satisfactory.

Now to consider the question of the field due to a broadcasting station. The field intensity laid down by a station at a given point is greater during the night than in the day, the ratio between the two values growing greater as the distance from the station is increased. In synchronized broadcasting one station on the channel is generally at a considerably greater distance from a receiver in the good service area than is the other station. The greatest impairment of reception occurs when the distant station has its maximum field intensity, hence night-time conditions are of the greater importance. Accordingly in Fig. 8 curves are shown relating field intensity and distance from the station, for a wide range of antenna power. These curves are the average of several hundred night-time observations on American broadcasting stations, co-ordinated by the United States Federal Radio Commission. In situations where stations of widely different powers are synchronized, reception at some points may be governed by the day-time field intensity ratio. The curves of Fig. 8 may be used for estimating field intensities in these cases, up to distances of 20 miles.

The data used in drawing Fig. 8 were averages only, and in individual cases the actual field intensity may vary above or below the value shown by a factor of 5. It will be noticed that these curves show the transmission as obeying quite closely an inverse-distance law. Similarly the day-time transmission obeys an inverse-square law at distances from 20 to 200 miles.

Service Area of Synchronized Stations

One is now in a position to calculate the area and the population served by a single station; and also to estimate these quantities for a pair of synchronized stations.

In order to clarify the situation, Fig. 9 has been drawn to show the field-intensity ratio contours around one

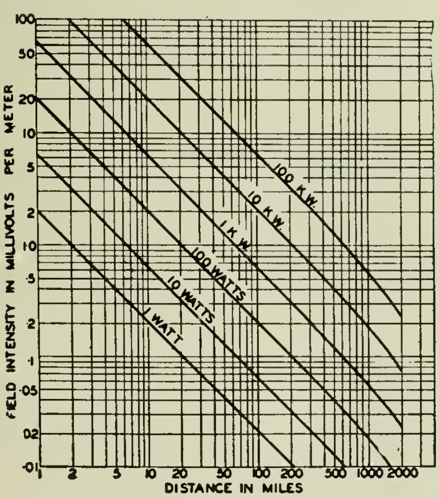

Fig. 8—Average Night-Time Field Intensities.

station of a synchronized pair. Underlying assumptions are made that the stations are of the same power and that the inverse-distance law holds throughout the region covered. In regions of greater attenuation, or where greater distances are covered, the contours will not lie so close to the station, that is, the service area will be increased.

Commercial Synchronizing Equipment

Common-frequency broadcasting has been attempted in many cases with varying degrees of success, but at the present time appears to be of particular importance, partly due to a general increase in transmitter power both here and in Europe, and partly due to recent progress in synchronizing equipment.

Perhaps the most ambitious system that has been operated is the British Broadcasting Corporation's chain

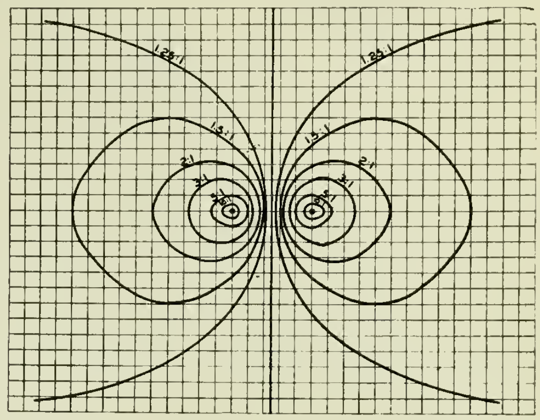

Fig. 9—Field Intensity Ratio Contours around Two Synchronized Stations of the same Power.

of ten stations, set up on the basis of satisfactory results realized as early as 1926 from four British stations synchronized within a hundred cycles or so, and from two German stations operated synchronously in 1928. In the B.B.C. system, 1,000-cycle tuning forks were used at each station with a series of doubler stages to give the carrier frequency. Stability was maintained within about 10 cycles, and the forks were probably re-adjusted every few days to the frequency of a master station. The system apparently operated with good success, the stations all being of low power, and situated in centres of relatively dense population.

In 1929 and 1930 Bell Telephone Laboratories undertook extensive experimental work in connection with synchronized broadcasting, and commercial equipment was designed to synchronize two 1-kw. stations 150 miles apart. The stations had not previously operated simultaneously. Independent crystal-controlled oscillators were used, capable of maintaining their frequency within about 5 cycles over long periods. At a mid-point between the stations a monitoring receiver was located, and the beat frequency from the two carriers was transmitted back to one station.

At this point the frequency of the crystal-controlled oscillator was shifted a small amount by the operator, the frequency difference being maintained in this way at less than 1/10 cycle. This is the so-called radio-frequency monitoring system.

With this arrangement it was found that the normal service area of each station was maintained, and the night-time reception was improved at points 100 miles or more distant from either station, where amplitude and selective fading had previously been severe.

More recently rather elaborate automatic synchronizing equipment has been developed by Bell Telephone Laboratories. A diagram of one terminal of the equipment is shown in Fig. 10. Each synchronized station (of which there may be a number on one frequency) is equipped with two quartz crystal-controlled oscillators, one a spare. These oscillators are capable of maintaining their frequency within a few cycles over long periods. From a central location an oscillator of quite high frequency stability transmits 4,000-cycle current over telephone lines to each station. At this point, by a process of frequency multiplication and modulation two currents are obtained, each of

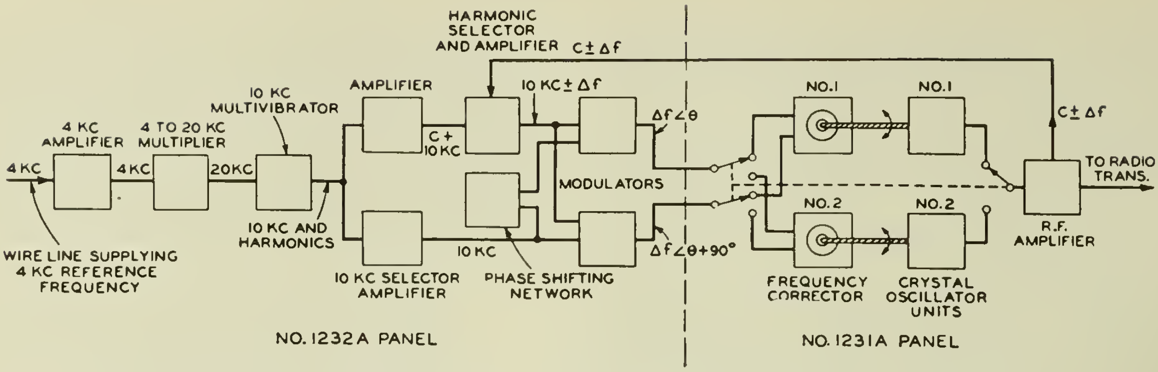

Fig. 10—Diagram of Synchronizing System for Common Frequency Broadcasting.

frequency ΔF equal to the difference of $C + \Delta F$, the frequency of the local crystal-oscillator, and the correct carrier frequency, C, as derived from the 4,000-cycle oscillator. One current, however, is advanced 90 degrees in phase ahead of the other. The two-phase current resulting from the combination is applied to a motor unit which revolves a variable condenser giving small variations in the crystal-controlled carrier oscillator. The motor unit tends to revolve until the carrier oscillator is brought into synchronism with the carrier frequency which would be derived from the 4,000-cycle transmission. Thus the equipment at each station automatically adjusts the carrier frequency to a fixed multiple of the driving oscillator frequency. In extended trials this equipment has been shown to be capable of maintaining the frequencies of two stations within about 1/10 cycle over a period of several months. It is interesting to note that even in case the control circuit is disrupted between the master oscillator and a station, due to the high stability of the local oscillator the carrier frequency will drift by only a very small amount over the time of any probable interruption of the service. This system has been called the wire-line reference method for securing synchronism.

It seems probable that from the point of view of accuracy of synchronization and reliability this equipment is close to the ultimate.

A third method of synchronization which has received some attention is that of generating a carrier wave and modulating it at a central point. High-frequency transmission lines, perhaps two-conductor concentric cables, carry the modulated wave to the transmitter locations where the wave is amplified through a series of stages, and finally radiated by an antenna. This system would of course give accurate synchronization, but the problems associated with the high-frequency transmission lines appear to be nearly insoluble at present.

Acknowledgment

The present writer is indebted to the Northern Electric Company, Limited, for permission to publish this study. Figure 3 has been taken from ref. (4) and Figs. 5, 6, and 7 from ref. (9).

BIBLIOGRAPHY

The following list of references to the periodical literature is not complete, but comprises all the sources which were used in the preparation of this paper, as well as a few which were not available, but whose chief conclusions were known. An attempt has been made to classify these references by subject, but this is of necessity somewhat indefinite, as many of the papers deal with several aspects of the subject.

La Route Moderne

Avec quelques renseignements sur le système routier de la province de Québec

Alphonse Paradis, M.E.I.C.,
Ingénieur en Chef, Ministère de la Voirie, Province de Québec.

Causerie donnée à la Section de Québec de l'"Engineering Institute of Canada" le 18 février 1935.

Les voies de communication et les modes de transport se sont adaptés comme toute autre chose aux besoins de leur temps.

Depuis les jours lointains des chariots à deux roues traînés par des bœufs à demi-sauvages, et des galères à double rangée de rames, le monde a vu se succéder l'âge du carrosse, de la diligence et de l'omnibus, des navires à voile, des bateaux à vapeur, des chemins de fer, des tramways électriques et enfin de l'automobile et de l'aéroplane.

La machine à vapeur fut la merveille de son temps. Son apparition a mis en branle des centaines de cerveaux qui s'ingénièrent non seulement à la perfectionner, mais aussi et surtout à l'appliquer au transport au moyen d'inventions corollaires comme le bateau à hélice et le wagon sur rail de fer, etc. On vit alors les continents se couvrir d'un treillis de voies ferrées et les mers s'émailler de vaisseaux toujours plus lourds et plus rapides. Ce fut sur terre l'âge d'or de la locomotive et du rail. Les grandes compagnies ferroviaires régnaient en souverains dans le monde du transport.

Un petit incident, l'invention du moteur à explosion, devait terrasser le colosse d'un siècle.

Les milliers de wagons qui dorment sur des voies principales désaffectés, les centaines de locomotives qui encombrent les abords des usines de chemin de fer, les démarches répétées de compagnie pour essayer de vendre aux divers départements ou commissions de voirie, l'assiette de voies qu'on projette d'abandonner, les vieux rails à demi-recouverts d'asphalte qu'on aperçoit encore dans les rues des petites villes comme un vestige d'un autre âge, sont autant de témoignages irréfutables de la révolution opérée dans le domaine du transport depuis une vingtaine d'années.

Il avait semblé tout d'abord que le moteur à essence arrivait comme un adjoint pour combler une lacune dans le système de transport établi. Sa légèreté et son adaptabilité aux petits véhicules le désignaient clairement comme agent de propulsion pour transport rapide à courte portée. Il devait former les rameaux de cet arbre dont le lourd train à vapeur constitue le tronc rigide et les grosses branches. Eh bien non!... C'est un enfant qui a grandi vite, et qui déjà se dégage de la tutelle qui croyait le tenir indéfiniment en sujétion. Il est devenu un arbre par lui-même. Il a engendré un système de transport sur terre, indépendant des autres, sans mentionner son frère cadet qui s'appelle le transport aérien. De véritables trains circulent maintenant sur certaines de nos routes durant les douze mois de l'année, et cela vingt-quatre heures par jour.

Les trains automobiles d'aujourd'hui pèsent 60,000 livres, avec la souplesse qui donne l'avantage de porter jusqu'à la porte de l'acheteur, la marchandise transportée.

Que sera l'avenir? L'examen du passé et des conditions présentes le font entrevoir. Depuis trente ans on construit des routes modernes. Certaines d'entre elles ont été reconstruites deux fois depuis ce temps, et combien pitoyable apparaît l'ancienne à côté de la nouvelle. Celles qui faisaient l'enchantement des voyageurs de leur temps, sont devenues un sujet de critique ou de risée. On s'indigne et on peste encore contre les chemins poussiéreux sans songer que nos premières routes ne permettaient pas assez de vitesse pour faire de la poussière. Il y a dix ans passés, nos rapports de voirie décoraient la province de Québec du titre pompeux de "Good roads province". Il faut voir comment figurent aujourd'hui ces bons chemins de la première heure comparés aux auto-routes qu'on construit en Europe et aux "super-highways" qu'on voit aux Etats-Unis. Il suffit de lire les publications étrangères et les rapports des congrès de la route pour constater que dans tous les pays, aussi bien en Europe qu'en Amérique, les procédés de construction et les données qui servent de base aux "standards" ont une vie éphémère. Les projets de quelque importance sont souvent modifiés et remodelés au cours de leur exécution au point d'être méconnaissables. Bien des ingénieurs de voirie ont vu tomber leurs illusions lorsqu'après un travail patient et prolongé, ils avaient cru avoir fait œuvre durable dans la préparation des devis généraux pour la construction des routes.

Si nous demandons aux états américains une copie de leurs devis, ils nous répondent: "under revision". Les auteurs qui se sont efforcés d'établir des règles fondamentales et de tracer des directives générales basées sur les conventions adoptées par les congrès internationaux ou autres, pour la construction des routes, se voient continuellement acculés à la nécessité de rééditer leurs ouvrages.

L'Europe, le foyer reconnu de la science et de la civilisation est, comme les jeunes pays d'Amérique, en pleine période de développement et d'expérimentation dans ce domaine. Il est très intéressant de constater que les vieux pays sont en face des mêmes problèmes et des mêmes difficultés que nous avons à envisager dans notre province. La question des pavages antidérapants est étudiée, mais n'est pas résolue. On n'est pas encore fixé sur les composés asphaltiques les plus avantageux, ni sur la possibilité d'émulsifier les goudrons, ce qui serait un avantage considérable dans un pays comme l'Angleterre. Les changements de tracés pour redresser et élargir les routes, dans des limites raisonnables de dépenses, en évitant les agglomérations des villages et des petites villes, rencontrent des protestations tout comme dans la province de Québec.

Les lois régissant les procédures pour expropriations, déplacement de bâtisses et paiements d'indemnités ont été, encore récemment, en France, l'objet d'amendements importants pour simplifier les procédés en usage et réduire le coût de l'établissement des routes sur de nouveaux tracés.

Cependant, l'étude de tous ces problèmes n'empêche pas les européens d'aller de l'avant. Les "auto-strade" en Italie et les auto-routes en France et en Allemagne rivalisent avec les "super-highways" des Etats-Unis. Ces grandes artères modernes sont destinées exclusivement aux véhicules moteurs, sans limite de vitesse. Les croissements à niveau sont éliminés par des passages inférieurs et supérieurs avec raccordements sans virage à gauche, ou améliorés au moyen d'intersections circulaires que les américains appellent "traffic circles," de manière à réduire les dangers d'accidents.

On projette actuellement un système d'auto-routes pour les sorties de Paris, composé de cinq grandes artères radiales, raccordées par une route de ceinture encerclant la ville à une distance de vingt kilomètres du centre; et l'auteur de l'article de la Revue Générale des Routes qui décrit cet immense projet ajoute: "Paris aura enfin des sorties convenables," tout comme nous pourrions dire si les projets dont nous avons commencé l'étude l'été dernier s'exécutent: "Québec aura bientôt des sorties dignes d'une grande ville."

Le programme des auto-routes dans la banlieue de Paris comporte des données ultra-modernes: — pentes et rampes de pas plus de 5 pour cent rayons de courbure de mille mètres, largeur d'emprise de 70 à 100 mètres, avec chaussée double, pour circulation à sens unique d'une largeur de 9 mètres pour chaque voie, flanquée d'une voie latérale de desserte également de 9 mètres de largeur. Les trois voies seront séparées par des terre-pleins plantés d'arbres et d'arbustes. Les pavages seront le béton de ciment, le

Fig. 1—Province de Québec Route 1—Montréal-Sherbrooke. Section du lac Orford.

pavage mosaïque ou bien le revêtement noir épais, reconnus comme les plus aptes à porter une circulation intense. Elles ne traverseront à niveau aucune autre voie et les raccordements peu nombreux seront du système "grade separation." Elles seront éclairées abondamment.

Les trois principales artères de ce réseau auront une longueur totale de 90 kilomètres et coûteront 500 millions de francs.

On voit que si la France fut devancée par l'Italie, avec ses "auto-strade," elle est bien résolue à reprendre le terrain perdu. Inutile de dire que l'Angleterre et l'Allemagne progressent dans le même sens pour l'aménagement de leurs réseaux routiers.

Si nous retraversons la mer pour voir ce qui se passe chez nos plus proches voisins, nous constatons que les "super-highways" sont un fait accompli depuis plusieurs années, et les récents hauts-faits des Américains dans ce domaine dépassent nettement ce qu'il y a de plus remarquable en Europe. Je suggère à ceux qui en auront l'occasion, de visiter les dernières créations de l'état de New-Jersey pour les sorties de New-York vers l'ouest. Le chemin d'approche du tunnel Holland est un colossale monument qui émerveille les visiteurs, sinon par sa beauté, du moins par sa masse. Les ingénieuses combinaisons de raccordements avec les voies transversales et les imposantes dimensions de ce chemin élevé sur des milles de longueur contournant la ville de Newark, passant au-dessus d'une multitude de voies ferrées, en font un chef-d'œuvre dans son genre.

L'approche du pont Georges Washington est une autre production épatante du génie américain. Ce tronçon reçoit le trafic de quatre grandes artères venant du nord, de l'ouest et du sud pour donner accès à New-York, à la plus grande partie des quelques deux cent mille personnes qui entrent et sortent de la ville chaque jour, sans compter le va-et-vient du trafic local.

Une chose très remarquable dans le réseau du New-Jersey, c'est la diversité des formes d'intersections. Chaque cas semble être un problème spécial, parfois très compliqué. Aucune grande artère n'est traversée à niveau par une autre voie, et le genre d'intersections varie non seulement selon l'importance des routes, mais aussi selon la topographie des lieux. L'intersection circulaire "traffic circle" est la plus simple et la plus économique. Toute voiture qui s'engage dans le cercle tourne à droite. Il en résulte que la circulation sur le cercle même se fait toujours en tournant à gauche et par conséquent c'est "one way." Ce système a l'inconvénient de ralentir la circulation, mais élimine pratiquement tout danger de collision. Il occasionne, quelquefois, des accidents par des voitures qui vont se buter sur l'îlot au centre du cercle.

L'intersection "clover leaf" paraît être devenue "standard" mais n'est pas fréquemment employée à cause de son coût excessif et de l'espace considérable requis pour l'établir. Il permet de franchir le croisement à toute vitesse. Le passage d'une route à l'autre en tournant à droite est simple, mais pour aller à gauche, il faut faire une boucle complète dans un virage à droite et en passant du niveau bas au niveau élevé ou vice-versa. Il est également remarquable que certains croisements ne comportent aucun raccordement entre les deux routes, d'autres sont pourvues d'un virage dans un seul sens. Nos amis, les Américains, ont-ils des formules basées sur l'intensité de la circulation pour déterminer ce qu'il y a à faire dans chaque cas? Il n'y aurait pas lieu d'en être surpris si on considère l'armée d'ingénieurs qu'ils emploient. Le seul état de New-York occupe onze cents ingénieurs pour le service de la voirie et des canaux.

Le comté de Wayne dans l'état de Michigan a aussi un système de "super-highways," très avancé. Les grandes artères qui rayonnent en lignes droites de la ville de Détroit, peuvent desservir un trafic énorme, probablement beaucoup plus considérable que celui qu'elles portent actuellement. La largeur d'emprise de ces routes est de 204 pieds. La chaussée est formée de deux voies bétonnées de 30 à 40 pieds de largeur chacune, séparées par un terre-plein d'environ 75 pieds, orné de plantations diverses. Les croisements sont du genre "grade separation." Les voies doubles nécessitent deux ponts à chaque intersection et les masses de béton qui entrent dans ces ouvrages sont énormes. Le pays étant très plat, les traverses de voies ferrées se font toujours par des passages supérieurs.

Une tournée d'inspection faite l'été dernier sur les routes de l'état de New-York, en compagnie des principaux officiers de la commission des chemins, nous a permis de constater une fois de plus, l'esprit pratique des Américains qui savent malgré leurs richesses, faire rendre à chaque dollar employé dans la construction, sa pleine valeur. Leur main-d'œuvre, il faut bien l'admettre, est considérablement supérieure à la nôtre tant au point de vue de l'habileté qu'au point de vue de la rapidité dans l'exécution des travaux.

La construction d'un chemin de première classe pour atteindre le sommet du mont Whiteface, près du lac Placid, en voie de parachèvement, est une entreprise digne de leurs émules du New-Jersey, non pas tant par son envergure que par sa particularité et la fantaisie qui semble l'avoir inspirée.

Cette route de 9 milles de longueur en rampe continue, variant de 4 pour cent, qu'elle est au bas, jusqu'à 10 pour cent vers le sommet, a pour seule fin d'atteindre un point d'observation à 4,600 pieds d'altitude d'où l'œil embrasse un panorama grandiose de montagnes et de lacs. Cette route coûtera un million. Elle est construite avec des fonds souscrits librement pour l'érection d'un monument aux vétérans de la guerre. Environ la moitié du parcours est taillée dans le roc vif sur une pente escarpée, avec mur de soutènement en grosses pierres atteignant jusqu'à 80 pieds de hauteur. Elle comporte des lacets remarquables dont l'un appelé "hair pin" permet de voir la route cent pieds en dessous de soi à une distance horizontale de cent pieds.

D'une manière générale dans l'état de New-York, les grandes routes qu'on reconstruit sont tracées à neuf avec des profils et des courbes d'un "standard" beaucoup plus élevé que les anciennes. La largeur des nouvelles chaussées en rase campagne, varie de 20 à 30 pieds et le pavage est exclusivement de béton armé.

Les routes de seconde classe sont améliorées sans modifier les tracés, ni les profils. On utilise comme fondation les vieux macadams qui les recouvrent en les élargissant à 18 ou 20 pieds. Cette fondation est ensuite recouverte d'un revêtement bitumineux genre "low cost."

Le réseau de l'état a une longueur totale de 14,000 milles de grandes routes, entretenues au coût de 8 millions par année. La dépense de réfection ou de reconstruction se chiffre à 35 millions par année. Ces montants représentent environ la moitié des revenus annuels des véhicules automobiles qui s'élèvent à environ 85 millions.

Laissons là, si vous le voulez bien, ces gros chiffres et revenons dans notre pays. La modeste histoire de notre voirie provinciale n'est pas sans intérêts. Les développements atteints et les "standards" établis pour le réaménagement de nos grandes routes sont les fruits d'un travail persévérant et d'efforts soutenus durant plusieurs années.

Il y a quelque quinze ans, on trouvait fort extravagant les quelques terrassements que nous faisions pour corriger les profils. Quant aux alignements et courbes, il fallait se contenter de l'espace compris entre les clôtures.

Cependant, à mesure que les automobiles et les camions pénétraient dans les milieux ruraux, la mentalité de nos populations évoluait dans le sens du progrès et les propriétaires de véhicules automobiles se faisaient nos collaborateurs sur ce point. Leurs suggestions ont parfois dépassé la manière de voir des ingénieurs sur l'élargissement, le redressement et le reprofilage des routes. Les clubs d'automobilistes ont aussi agi dans le même sens, mais leurs observations et suggestions sont presque toujours d'un caractère général et plutôt vague. Les autres corps publics, chambres de commerce, et corporations municipales, grandes et petites, ne semblent pas s'être intéressés considérablement aux questions d'améliorations modernes des routes. Les conseils municipaux des campagnes font bien des représentations pour obtenir dans leurs limites des améliorations sans beaucoup d'envergure, à l'ancienne façon et en fonctions des intérêts purement locaux. Et, il faut le dire, souvent en opposition avec l'intérêt public et les projets des ingénieurs, surtout lorsqu'il s'agit de changement de tracés.

Evidemment, l'exemple des pays voisins a fait beaucoup pour amener l'opinion publique à accepter les conditions nouvelles et à ne pas se scandaliser des "standards" proposés par les ingénieurs.

C'était l'automobile qui transformait les idées avant de transformer les routes. Force nous est d'admettre que dans de telles conditions, nous suivons nos voisins au lieu de les précéder ou de marcher de front avec eux. A tout prendre c'est peut-être aussi bien qu'il en soit ainsi au moins pour quelque temps. Nous savons combien il est difficile de prévoir avec quelques précisions le développement des problèmes de voirie et du transport routier en général, pour saisir la nécessité qu'il y a d'avancer prudemment sur ce terrain. Les ressources très limitées de notre province, comparativement aux états de l'union américaine, les rigueurs de notre climat qui paralysent la circulation routière durant quatre ou cinq mois de l'année en réduisant d'autant le rendement de nos routes et leur valeur économique, sont des faits qu'il ne faut pas perdre de vue dans l'étude de nos problèmes de voirie. L'important, c'est de prévoir suffisamment les besoins futurs du trafic routier pour établir nos plans et marcher sur les données qui ne nous obligeront pas à des démolitions ruineuses lorsque le moment sera venu de recourir à des nouveaux revêtements de surface et à des pavages plus forts et plus dispendieux. Il importe donc d'étudier soigneusement les tracés et les profils et d'établir l'assiette des routes en rapport avec les besoins du trafic pour une période de temps donnée, en se basant sur les probabilités de développement de la circulation routière. C'est là que se trouve le point critique. Où vont s'arrêter la vitesse, les dimensions et le poids des convois, et surtout l'accaparement du transport de toute sorte par l'automobile, le camion et l'autobus? Les ingénieurs de tous pays se fatiguent les méninges à trouver une solution rationnelle à ce problème! En fait sur la question des tracés et des profils, il n'y a pas de différences considérables entre nos devis et ceux des états américains.

Fig. 2—Province de Québec Route 11a—Montréal-St-Agathe. Près de Ste-Rose.

Notre réseau de grandes routes d'une longueur totale de 5,585 milles est divisé pour fin de reconstruction en quatre classes — Nos "standards" pour chaque classe fixe la largeur entre clôture ou largeur d'emprise, la largeur entre fossés ou largeur de la plate-forme, largeur du pavage, rayon de courbure minimum, et distance de visibilité, tant dans les courbes verticales que dans les courbes horizontales. Nous n'avons pas de rampes maxima, mais nous tâchons de ne pas dépasser sept pour cent, sauf dans les régions de montagnes où nous admettons des rampes beaucoup plus fortes. Le devers de la plate-forme dans les virages est le même pour toutes les classes et varie en proportion du degré de courbure, à partir de 2°. Il augmente de $\frac{1}{8}$ de pouce pour chaque degré de courbure additionnel jusqu'à 9° où il est de 1″ par pied de largeur de chaussée. C'est le devers maximum qu'on applique à toute courbe au-delà de 9°.

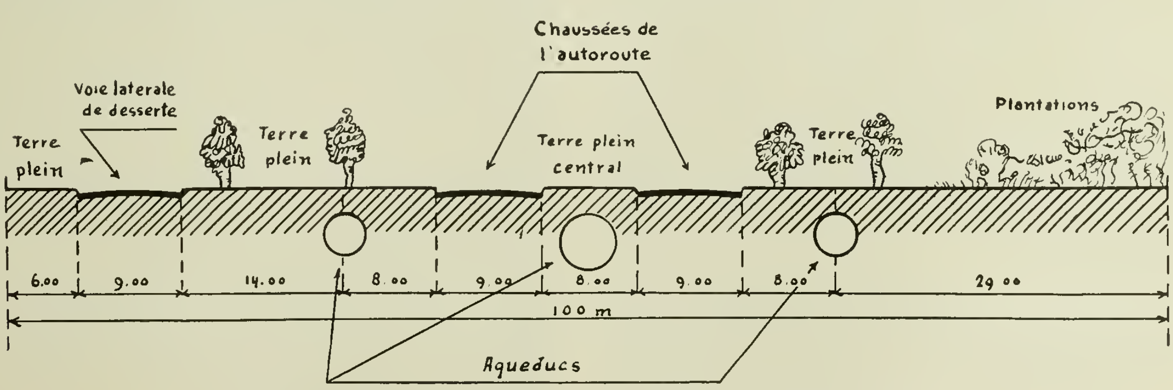

Fig. 3—Profil Type de l'Autoroute du Sud. Banlieue de Paris.

Le degré de courbure maximum est de 11°-30′ correspondant à un rayon de 500 pieds. Il s'applique aux classes C et D, qui comprennent les routes de moindre importance. Pour les classes A et B, qui constituent nos grandes artères, les degrés maximum de courbure sont respectivement de 6° et 8° et la distance de visibilité de 500 pieds. La longueur maximum des courbes verticales et horizontales est de 500 pieds.

La largeur de la chaussée varie de 18 pieds à 30 pieds, et la largeur d'emprise de 50 pieds à 90 pieds.

Durant les dernières années nous avons reconstruit sur ces données environ 103 milles de routes.

Fig. 4—Province de Québec Route 4—Montréal-Malone. Près de Montréal.

Notre climat avec ses pluies abondantes l'automne, et ses fortes gelées l'hiver, introduit dans nos problèmes routiers des difficultés qu'on trouve rarement ailleurs.

Après de nombreuses expériences et de longues observations nous avons trouvé que le meilleur remède contre les dommages causés par la gelée est un coussin de sable placé en-dessous de la fondation. La plupart de nos dernières constructions sont faites d'après cette méthode.

Les fondations sont faites en pierre ou en gravier et quelquefois une combinaison des deux. Une couche de gravier de 12″ durcie ou 10″ de pierre roulée et partiellement liée constitue une fondation suffisante pour les charges admises à circuler sur nos routes. La vieille méthode du macadam à l'eau comme revêtement de surface est abandonnée. On se contente de faire durer autant que possible les surfaces macadamisées en les recouvrant périodiquement de tapis bitumineux. Les revêtements modernes sont en macadam bitumineux, béton bitumineux ou béton de ciment. Nous avons commencé récemment un genre de revêtement mince de goudron, sur les surfaces gravelées. C'est une mesure temporaire pour faire disparaitre la poussière durant l'été et empêcher la boue de se former à la surface durant la période pluvieuse de l'automne. Ce mode de revêtement, peu dispendieux, à en outre l'avantage de supprimer les apports de gravier continuels qu'il faut faire pour maintenir les surfaces gravelées en bon ordre, et de ce fait, nous dispensera dans un avenir prochain d'une quantité considérable de machineries employées actuellement au grattage et au transport des matériaux de rechargement. Elle supprimera également, en attendant qu'on puisse construire des pavages plus durables, un danger d'un nouveau genre occasionné par les petites pierres volantes du gravier concassé.

Les revêtements bitumineux qu'on a appelé permanents ou semi-permanents, mais qui n'ont rien de permanent, varient en épaisseur de 2″ à 4″. Ils comprennent 1o. — Les macadams bitumineux formés d'une couche de pierre de 4″ d'épaisseur qu'on enrobe par simple pénétration d'un liant bitumineux quelconque. 2o. — Les bétons bitumineux qu'on nomme ainsi par analogie avec les bétons de ciment hydrauliques, parce que le mélange des agrégats et des ciments bitumineux se fait mécaniquement.

Il y a un nombre considérable de types, dont la plupart sont brevetés dans notre pays. Par ordre d'ancienneté on les nomme: Amiésite, Macurban, Colprovia, Creomix, Macasphalt, Coldsphalt, et comme Benjamin de cette famille, le Gécomac qui a fait son apparition l'été dernier.

Tous ces produits ont été généralement appliqués pour des revêtements de 4″ d'épaisseur. On a vite constaté cependant qu'ils étaient trop dispendieux pour le pavage des chemins ruraux, et aujourd'hui on adopte un peu partout des types de pavage dits économiques (low cost), de 2″ à 3″ d'épaisseur tels que le "retread," pierre et bitume mélangés sur le chemin, le "gravel mulch", mélange de gravier et bitume, et d'autres types de mélanges à pourcentage réduits de liant bitumineux qui ne coûtent pas beaucoup plus cher que les anciens macadams, et qui donnent de très bons résultats sous un trafic moyen.

Enfin ce sont les pavages en béton de ciment hydraulique qui sont les seuls à peu près permanents et encore faut-il qu'ils soient faits avec les meilleurs matériaux, et d'après les méthodes modernes de fabrication du béton. Nous pouvons dire sans exagération que ces nouvelles méthodes ont augmenté de 100 pour cent la valeur des pavages en béton. Je ne tenterai pas de décrire ces méthodes. J'indiquerai toutefois les points saillants des récents perfectionnements dans ce domaine. Le contrôle de la qualité des matériaux et des travaux se fait entièrement sur place et tous les essais sont faits dans un laboratoire temporaire établi sur le chantier. Dans ce laboratoire tous les matérieux sont soumis à l'analyse et aux épreuves ordinaires, granulométrie, contenu d'humidité, pourcentage de terre ou de matières végétales dans les sables; résistance à la traction et à la tension ainsi que le dosage des matérieux basé sur la granulométrie. Le laboratoire est muni des instruments et appareils modernes, tels que la presse pneumatique d'une capacité de 100,000 livres pour briser les cylindres dans les essais à la compression, l'appareil pour casser les briquettes et l'appareil pour casser les poutres, balance de précision, sécheur, bain pour le curing, etc. Sur le chantier, le dosage des matériaux se fait par balances automatiques pour le sable, la pierre et l'eau. Ces balances sont surveillées par un employé du gouvernement et ajustées aussi souvent qu'il est nécessaire selon la graduation de la pierre, la granulométrie du sable et son contenu d'humidité.

La rupture des cylindres est faite à sept jours et à vingt-huit jours. Pour le "curing" on procède encore d'après l'ancienne méthode de recouvrement et d'arrosages répétés. La méthode qui consiste à appliquer du chlorure de calcium à la surface pour capter l'humidité de l'air ne semble pas devoir se généraliser. Par contre l'application d'une huile asphaltique légère après la prise du béton pour retenir l'humidité dans la masse, prend de la vogue aux Etats-Unis depuis une couple d'années. L'usage des formes en acier et l'appareil à comprimer (qui supprime le dommage) permet d'obtenir un profil parfait et une compacité du béton très remarquable, sans danger de ségrégation des matériaux. Des gabarits métalliques très rigides que l'on fait mouvoir sur les coffrages en acier assurent la régularité de l'infrastructure. Malgré ces précautions, l'épaisseur du pavage est vérifiée après coup en mesurant les carottes obtenues en perçant le pavage avec une foreuse spéciale. Des joints transversaux et longitudinaux sont ménagés au besoin pour tenir compte des retraits et expansions dus aux écarts de température.

La tendance actuelle est d'armer tous les pavages en béton et sur ce point les devis sont variés sans limites. Les uns placent l'armature près du fond, les autres, près de la surface. Le poids par cent pieds carrés se tient à peu près entre 40 livres et 82 livres.

Nous avons actuellement 16,000 milles de chemin améliorés dont 5,585 milles classés comme grandes routes. Inutile de dire que ces grandes routes ne sont pas toutes des routes modernes. Tous ces chemins améliorés sont entretenus exclusivement par le département de la voirie au coût d'environ 3½ millions par année.

Nous avons dans la province de Québec, 174 milles de macadam bitumineux, 586 milles de pavage en béton bitumineux et 179 milles de pavage en béton de ciment. Le coût de ces pavages est de l'ordre de $20,000 du mille, et, si on ajoute les fondations, les travaux préliminaires et les acquisitions de terrain, nous arrivons à environ $40,000 du mille. L'introduction des pavages genre "low cost" nous permettra de réduire ce coût d'environ $12,000 du mille, tout en conservant un revêtement de surface capable de porter un trafic moyen d'une façon satisfaisante. Cependant, à cause de la grande longueur de notre réseau, nous ne pouvons espérer de paver, même avec ce système de pavage économique, la plupart des routes dans quelques années, c'est pourquoi nous avons entrepris un programme de revêtements minces de l'ordre de $2,000 du mille qui pourra s'exécuter à l'allure de 250 milles par année.

Nous espérons ainsi, tout en continuant notre programme de pavage, donner à nos automobilistes et aux touristes étrangers, des routes propres et sans poussière dans un avenir rapproché.

The Modern Highway

With Notes on the Highway System of the Province of Quebec

Alphonse Paradis, M.E.I.C.,
Chief Engineer, Department of Highways, Quebec, Que.

Paper presented before the Quebec Branch of The Engineering Institute of Canada, February 18th, 1935.

(*Translation*)

Means of communication and methods of transportation, like many other things, have become adapted to the requirements of the times. Since the early days of two-wheel carts drawn by half-wild oxen, and galleys propelled by two tiers of oars, the world has seen successively the eras of the horse-drawn carriage, the stage coach and the omnibus, the sailing vessel, the steamship, the railway, the electric tramway and finally the day of the automobile and the aeroplane.

The steam engine was the marvel of its age. Its appearance aroused activity in hundreds of brains, whose ingenuity was taxed not only to perfect it, but also more especially to apply it to transportation by the aid of auxiliary inventions like the screw steamer and the railway locomotive. Continents were covered by a network of railways, and the seas dotted with ships ever becoming larger and faster. On land this was the golden age of the locomotive and railway. The great railway companies ruled like emperors in the world of transportation. Finally, one small incident, the invention of the internal combustion engine, caused the collapse of this mighty empire.

Thousands of cars lying idle on disused tracks, hundreds of locomotives encumbering the neighbourhood of railway shops, repeated attempts by the companies to sell to various government departments or highway commissions the railway systems which they are anxious to abandon, old rails, half covered with asphalt which may still be seen in the streets of small towns, like relics of a former age, all constitute irrefutable evidence of the revolution which has taken place in the domain of transportation during the last twenty years.

At first it was thought that the gasoline motor would merely serve to fill a gap in the then established systems of transportation. Its lightness and adaptability to small vehicles clearly indicated it as a means of propulsion for rapid transport over short distances. It was to form a twig of the big tree of which the heavy steam train constituted the rigid trunk and the main branches. But no—it has proved to be a fast-growing child, which is already freeing itself from the tutelage which was to hold it indefinitely in subjection. It has become a tree itself. It has brought about a system of land transportation independent of all others, to say nothing of its younger brother, the aeroplane. Motor trains now operate twenty-four hours a day and twelve months of the year on many of our roads. Motor trains of to-day weigh 60,000 pounds, and have a flexibility which gives them the advantage of carrying supplies right up to the purchaser's door.

What does the future hold in store? A survey of the past and present conditions will indicate this. For the past thirty years we have been improving roads. Some of them have been built twice during this period, and how insignificant the old roads appear beside modern highways. Roads which were the delight of travellers in their day have now become a subject for criticism or laughter. People grumble about dusty roads without thinking that our early highways did not allow of sufficient speed to raise dust. Ten years ago our Highway Department's report bestowed on Quebec the imposing title of "The Good Roads Province." But see how these "good roads" of early days compare with the auto-roads which have been constructed in Europe and the super-highways to be seen in the United States. It is sufficient to read foreign publications and the reports of highway congresses, to note that in all countries in Europe as well as in America, methods of construction and conceptions serving as bases for standards are short lived.

Schemes of any importance are often so modified and remodelled during the course of their execution as to be hardly recognizable. Many highway engineers have seen their illusions vanish, when, after lengthy and painstaking work, they believed that they had accomplished something permanent in the preparation of general specifications for highway construction.

If we ask for copies of highway specifications from various states, they inform us that they are "under revision." Authors who have striven to establish fundamental rules and draw up general directions based on agreements adopted by international congresses for highway construction, see themselves continually obliged to revise their work.

Europe, the acknowledged home of science and civilization, is like the younger countries of America, in the midst of a period of development and experimentation in this domain. It is most interesting to note that the older countries are facing the same problems and the same difficulties that we have to confront in this province. The question of non-skid surfaces has been studied but not yet solved. Nothing has been decided as to the most advantageous asphaltic compounds, or as to the possibility of successfully emulsifying tars, a matter which would possess considerable advantage for a country like England. Proposed changes of location for widening and straightening highways, within reasonable limits of expenditure, while avoiding the congestion of small towns and villages, meet with objections in Europe, just as they do in the province of Quebec.

Important changes were made recently in France in the laws governing the procedure for expropriation, removal of buildings, and payment of damages, with the object of simplifying present procedure and lowering the cost of constructing highways on new locations.

Nevertheless, the study of all these problems has not prevented Europe from forging ahead. Italy's "auto strade" and the "auto routes" in France and Germany rival the super-highways of the United States. These great modern arteries are exclusively reserved for motor vehicles, with no speed limits. Level crossings have been eliminated by overhead or underground passages and junctions with no left turn, or improved by means of circular intersections, which the Americans call "traffic circles," so as to reduce the danger of accidents.

A system of auto roads for the exits from Paris, now contemplated, will consist of five great arteries connected by a belt highway encircling the city at a distance of twelve miles from the centre, and the author of an article in the "Revue Générale des Routes" who gives a general description of this immense scheme, remarks that "Paris will at last have suitable exits," just as we might say, if our projects are carried through "Quebec will soon have exits worthy of a great city."

The programme of auto-routes on the outskirts of Paris embodies ultra-modern data:—grades not more than 5 per cent, curves with a radius of 3,300 feet, right-of-way of between 215 and 330 feet, with double roadway, for one-way traffic, each roadway being 30 feet wide, flanked by a lateral service roadway, also 30 feet wide. The three roadways will be separated by platforms planted with trees and shrubs. The pavement will be cement concrete, blocks, or asphalt concrete of a high type, the most suitable to stand up under heavy traffic. There will be no level crossings of any kind on these roads, and the few junctions will be on the grade separation system. They will be brilliantly lighted.

The three main arteries of this network will have a total length of 45 miles, and will cost 500,000,000 francs.

It will thus easily be seen that if France was preceded by Italy, with its "auto-strade," it is determined to regain the lost ground. Actually both England and Germany are progressing along the same lines for the development of their highway systems.

If we recross the ocean, to see what is going on among our closest neighbours, we find that super-highways have been an accomplished fact for several years, and that recent American exploits in this domain definitely surpass the most remarkable achievements in Europe. Those having an opportunity should visit the latest achievements of the state of New Jersey for the exits from New York to the west. The approach to the Holland Tunnel is a colossal monument which amazes visitors, if not by its beauty, at least by its size. The ingenious methods of effecting junctions with transverse roads and the imposing dimensions of the elevated roadway, which extends for miles, by-passing the city of Newark, and passing over a multitude of railways, make it a masterpiece of its kind.

The approach to the George Washington bridge is another amazing production of American genius. This bridge handles traffic from four main arteries leading from the north, the south and the west, to provide access to New York for the majority of some two hundred thousand people who enter and leave the city each day, without counting local traffic.

A remarkable feature of the New Jersey highway system is the variety of types of intersection. Each case seems to be a special problem, often quite complicated. There are no level crossings on any of the main arteries, and the types of intersection vary not only according to the importance of the highway, but also according to the topography of the district. The circular intersection, known as the "traffic circle," is the simplest and most economical. All cars entering the circle turn to the right. This means that traffic in the circle itself is always turning to the left, and is one-way traffic. This system, while it has the inconvenience of slowing up traffic, practically eliminates all danger of collision. There are, however, accidents now and then when vehicles crash into the island in the centre of the circle.

The "clover leaf" type of intersection seems to have become a standard, but it is not frequently employed, owing to its excessive cost and the large space required to establish it. It permits of crossing the intersection at full speed. Turning to the right from one road to another is simple, but turning to the left necessitates first turning to the right, then making a complete circle and passing from low level to high level, or vice-versa. It is also remarkable that certain intersections fail to provide any connection between two roads, while others allow for a one-way turn only. Have our American friends formulæ, based on the intensity of traffic, to determine what is to be done in each case? This would not be surprising if one considers the army of engineers employed. In the state of New York alone there are eleven hundred engineers for the Highways and Canals Service.

Wayne county, in the state of Michigan, also has a very advanced system of super-highways. Main arteries which radiate in straight lines from the city of Detroit, can accommodate enormous traffic, probably much more than they are called upon to handle at present. The right-of-way on these highways is 204 feet wide. The roadway consists of two concrete lanes, each between 30 and 40 feet wide, separated by a platform about 75 feet wide, planted with ornamental shrubs. Intersections are of the grade separation type. The double roadways necessitate two bridges at each intersection and the masses of concrete which form these works are enormous. The country being flat, all railway crossings are overhead.

A tour of inspection of highways in the state of New York, carried out last summer, in company with the chief officers of the Highways Commission, enabled us again to appreciate the practical spirit of the Americans, who, despite their wealth, know how to get full value for each dollar employed in construction. Their workmanship is undoubtedly superior to our own, whether from the view-point of the skill or the speed shown in the execution of their work.

Fig. 5—Intersection of Route Carrying Traffic for George Washington Bridge and Teaneck Road, Teaneck, N.J.

The construction of a first-class highway to reach the top of Whiteface mountain, near lake Placid, now nearly completed, is an undertaking worthy of their New Jersey rivals, not so much on account of its extent as of its special character and the imagination which seems to have inspired it. This highway is nine miles long, has a grade varying from 4 per cent at the bottom to 10 per cent at the top, and its sole object is to reach an observation point 4,600 feet high, from which there is a magnificent panorama of lakes and mountains. This highway will cost a million dollars. It is being constructed with funds subscribed for the erection of a monument to war veterans. For about one-half of its length it is cut in solid rock on a side hill, with a retaining wall as high as eighty feet in some places, and of heavy masonry. The road includes remarkable bends, one of which, known as the hairpin turn, affords a view of the road one hundred feet below, and a hundred feet away horizontally.

In New York state, in general, the main highways that are being reconstructed are laid out anew with profiles and curves of a much higher standard than those of the old roads. The width of the new pavements in open country varies between 20 and 30 feet, and the surface is of reinforced concrete.

Second class roads are improved without changing their location. Old macadams are used as foundations and the pavements widened to 18 or 20 feet. This foundation is then covered with a low cost bituminous pavement.

The state highway system has a total length of 14,000 miles of main highways, maintained at a cost of $8,000,000 per year. Resurfacing and reconstruction expenditures amount to $35,000,000 per year. These amounts represent approximately one-half of the annual revenue from automobiles, which is about $85,000,000.

Let us leave these huge figures and return to our own country. The modest history of our provincial highways system is not without interest. Developments attained and standards established for the improvement of our main highways are the result of persevering work and sustained efforts during a number of years.

Some fifteen years ago, the few embankments made to improve the profiles of our roads were found rather extravagant, while as regards alignments and curves, we had to be satisfied with the space between fences.

However, as automobiles and trucks penetrated rural districts, the mentality of our population broadened, and automobile owners collaborated with us on this point. Their suggestions were sometimes ahead of the views entertained by engineers on widening, straightening and realigning roads. Automobile clubs also were active along the same lines, but their observations and suggestions are nearly always general in character and somewhat vague. Other public bodies, chambers of commerce, and municipal corporations, both large and small, do not seem to have been greatly interested in the question of modern improvements on highways. Municipal councils in country districts generally ask for improvements within their own limits, but usually disregard the general public interest. They often oppose the plans of engineers, especially when a change in alignment is proposed.

The example of neighbouring countries has evidently done much to induce public opinion to accept the new conditions and the standards proposed by engineers.

The automobile transformed ideas before transforming highways. It must be admitted that, under these conditions, we are not leading nor even keeping pace with our neighbours. On the whole, it is just as well that this be so, at least for a while. Knowing how difficult it is to foresee with any great precision the development of highway problems and of road transportation in general, we realize the necessity of advancing cautiously in this field. The resources of this province, very limited when compared to those of the states in the Union, the severity of our climate, which paralyses highway traffic for four or five months of each year, thus greatly reducing the efficiency of our highways and their economic value, are facts that must not be lost sight of in studying our highway problems. The important point is to foresee the future requirements of highway traffic so as to formulate our plans and proceed along lines which will not lead to ruinous demolitions when the time comes for new and more costly pavements. It is thus important that locations and profiles be carefully studied, and that the highway system be established according to traffic requirements for a stated period, by estimating the probabilities of development in highway traffic. There lies the question mark of the whole situation. Where is the limit to the increase of the speed, size and weight of vehicles, and especially the monopolization of transportation of all kinds by the automobile, truck and autobus? Engineers in all countries are looking for a rational solution to this problem, and the results obtained to date run along the same lines. As a matter of fact, there is very little difference between our specifications and those of the American states, as regards plans and profiles.

Our main highway system, with a total length of 5,585 miles, is divided for construction purposes into four classes. Our standards for each class determine the width between fences or right-of-way, the width between ditches or width of the subgrade, and the width of paving, the minimum radius of curves, and the distance for visibility, both as regards horizontal and vertical curves. We have no maximum grade, but we endeavour not to exceed seven per cent, except in mountainous regions, where steeper grades are used. The banking of the surface at curves is the same for all classes and is proportionate to the degree of curvature. Starting at 2 degrees, it increases ⅛ inch for each additional degree of curvature up to 9 degrees, where it is one inch per foot of width of pavement. This is the maximum amount of banking used on all curves over 9 degrees.

Fig. 6—Traffic Circle at Intersection of two Routes, New Brunswick, N.J.

The maximum curvature is 11 degrees-30 minutes, corresponding to a radius of about 500 feet. It applies in classes C and D, which include the roads of lesser importance. For classes A and B, which constitute the main highways, the maximum degrees of curvature are 6 and 8 degrees respectively, and the distance for visibility 500 feet.

The minimum length of vertical and horizontal curves is 500 feet.

The width of paved surface varies from 18 to 30 feet, and the width of right-of-way from 50 to 90 feet.

During the past few years we have reconstructed about 103 miles of highway according to these specifications.

Our climate, with its abundant rain in the fall, and heavy frost in winter, introduces into our highway problems difficulties that are rarely found elsewhere. After numerous experiments and lengthy observation we have found that one of the best means at our disposal to prevent damage caused by frost action is a sand cushion placed beneath the road foundation. We have applied this method to most of our recent road construction.

Fig. 7—Pulaski Skyway between Newark and Jersey City eliminating Railroad Grade Crossings and Intersecting Streets. Approach Road to Holland Tunnel.

Foundations are of stone or gravel and, in some cases, a combination of both. A layer of compacted gravel, 12 inches thick, or 10 inches of stone, rolled and partly bound, constitutes sufficient foundation for the loads allowed on our highways. The construction of water-bound macadam has been abandoned. Old macadam surfaces are treated with bituminous coatings to make them last as long as possible. Modern pavements are of bituminous macadam, bituminous concrete, or cement concrete. We recently started laying a thin coating of tar on gravelled surfaces. This is a temporary measure to avoid dust during the summer, and prevent surface mud forming during the wet autumn period. This kind of surfacing, low in cost, has the advantage of avoiding continual additions of gravel which are necessary to keep gravelled surfaces in good condition and, as a result, we shall be able to dispose of a considerable part of the machinery used in scraping and transporting resurfacing materials. It will also eliminate, pending construction of more permanent pavements, the new danger arising from small stones of crushed gravel flying in all directions.

Bituminous pavements, called permanent or semi-permanent, but which are neither, vary between 2 and 4 inches in thickness. They include, first: bituminous macadams formed of a layer of stone 4 inches thick, coated with some bituminous binder by simple impregnation; second, bituminous concrete, so-called by analogy with cement concrete, because a mixture of the aggregates and bituminous cements is made mechanically. There are a considerable number of these types, most of which are patented in this country. In order of seniority they are: Amiesite, Macurbam, Colprovia, Creomix, Macasphalt, Coldsphalt and, as the youngest member of the family, Gecomac, which only made its appearance last summer.

All these products were generally applied as surfaces 4 inches thick. It soon became evident, however, that they were too expensive for paving rural roads, and today low cost types of pavement are generally used, between 2 and 3 inches thick, such as the retread type, stone and bitumen mixed on the spot, "gravel mulch," a mixture of gravel and bitumen, and other types of mixtures with reduced percentages of bituminous binder, which do not cost much more than the old macadam pavement, and give very good results under medium traffic.

Finally, there are cement concrete pavements, which are the only ones with a certain degree of permanence, to obtain which they must be built with the best materials, and according to the most modern methods of concrete construction. It may be said without exaggeration that modern methods have increased the value of concrete pavements as much as 100 per cent. I will not attempt to describe them but will merely point out the salient features of recent improvements in this domain. Control of the quality of the materials is carried out on the job and all tests are made in our field laboratories. In these laboratories all materials are tested for grain size, moisture content, percentage of earth and vegetable matter in the sand, resistance to tension and bending, as well as the proportioning of the material. Laboratories are equipped with modern apparatus and instruments, such as a pneumatic press of 100,000 pounds capacity, for breaking cylinders in compression tests, apparatus to break beams and briquettes, precision scales, dryers, curing bath, etc. On the work the proportioning of aggregates is done by automatic scales for sand, stone and water. These scales are inspected by a government employee, and are adjusted as often as becomes necessary, according to the grade of stone and sand and moisture content.

Cylinders are broken at seven days and twenty-eight days. Concrete curing is carried out in the old way by covering and repeated watering. The method consisting of applying calcium chloride to the surface, for the purpose of attracting moisture, does not seem to have become general. On the contrary, application of a light asphaltic oil, after the concrete has set, to retain moisture in the mass, has increased in favour in the United States during the past two years. The use of steel forms and of the finishing machine yields a perfect profile, of remarkable compactness, and without danger of segregation of the aggregates. Rigid metallic templets, sliding on these steel forms, ensure the accuracy of the sub-grade. In addition to these precautions, the thickness of the pavement is verified afterwards by measuring cores obtained from the pavement by means of a special boring machine. Transverse and longitudinal joints are provided wherever necessary, to allow for expansion and contraction.

The present tendency is to reinforce all concrete pavements, and on this point specifications vary extensively. Some prefer the reinforcement near the bottom, while others want it near the surface. The weight per hundred square feet is generally between 40 and 82 pounds.

We have 16,000 miles of improved roads in the province of Quebec at the present time, of which 5,585 miles are classed as main highways. It is unnecessary to point out that these main highways are not all modern roads. All these improved roads are maintained entirely by the Department of Roads, at a cost of approximately $3,500,000 per year.

We have 174 miles of bituminous macadam, 586 miles of bituminous concrete pavement, and 179 miles of cement concrete pavement. The cost of these pavements is around $20,000 per mile, and if we add foundations, preliminary works and purchase of land, we reach a figure of nearly $40,000 per mile. The introduction of low-cost pavements will allow us to reduce this cost by approximately $12,000 per mile and still have a surface capable of carrying a traffic of medium intensity. Because of the great length of our system of main highways, however, we cannot hope to cover the majority of our roads within a few years, even with this economical system of paving. This is the reason for our having undertaken a programme calling for thin surface coatings, at around $2,000 per mile, which can be carried out to the extent of 250 miles per year.

Thus we hope, while continuing our paving programme, to provide, in the near future, a larger mileage of dustless roads for the benefit of our own motorists and for tourists.

Note.—Figs. 5, 6 and 7 are reproduced by courtesy of Mr. E. Donald Sterner, New Jersey State Highway Commissioner.

Electrical Control at Rapide Blanc

Wm. Spriggs, Jr.E.I.C.,
Shawinigan Engineering Company Ltd., Montreal.

Paper presented before the Junior Section of the Montreal Branch of The Engineering Institute of Canada, December 17th, 1934.

Satisfactory electrical control of apparatus and services is an important feature of modern power-house design. With the large developments of today, the wide interconnection between systems and the tremendous size of the loads carried, the importance of satisfactory voltage and frequency control and above all continuity of service becomes ever more important. In a big modern power-house such as Rapide Blanc, adequate, satisfactory and convenient methods of control play a considerable part in the efficient operation of the station.

As may be imagined, the subject of power-house control, in all the various forms in which it is applied, is a very wide one and the purpose of this article is only to outline in a general way the various classifications, and to run over briefly some of the more interesting types which are in service at Rapide Blanc and the reasons which led to their use.

The subject of power-house electrical control may be divided roughly, into six general classifications:—

1. Power Supply
2. Local Control
3. Remote Control
4. Automatic Control
   (*a*) Protective
   (*b*) Special Service
5. Interlocks
6. Alarm and Indication.

Power Supply

Except for small apparatus such as fans of various sizes, heaters, small motors and so on, almost all power-house equipment is controlled indirectly by means of magnetically operated switches or electrical relays.

In a large development, several different types of electric energy are needed for controlling these magnetic switches and relays. The selection of a.c. or d.c. and voltage depends on the type of equipment controlled, its degree of importance from a service standpoint and also on the method of control used.

Large motors such as gate hoist motors, air compressors, and oil pump motors which run on a.c. are controlled by a.c., since there would be no gain in reliability in using d.c. Motors and apparatus which are automatically controlled by delicate relays or instruments require a low control voltage. Equipment whose reliability of operation is of special importance, such as circuit breakers, field breakers and H.V. motor operated disconnects, must be d.c. operated and controlled from storage batteries. And finally, where miniature keys and lamp indicators are used for remote operation, low voltage d.c. is essential.

At Rapide Blanc the control voltages in use are 550 volts a.c., 110 volts a.c., 250 volts d.c. and 48 volts d.c. and there are also a few applications where 6 volts d.c. is required. Two separate storage batteries provide direct current at 250 volts and 48 volts and dry cells are used for the 6-volt supply.

Local Control

Local control of equipment, while perhaps more common than the various other methods, presents few features of special interest. It is applied in all cases where it is unnecessary or uneconomical to operate from a distance and takes the form of a knife switch, pushbutton operated magnetic contactor, or other well known type of starter. Such features as gate hoists, oil heaters, oil filter pumps and cranes come into this category.

Remote Control

The chief reason for making use of remote control is almost always that of convenience of operation. In times of trouble, when every moment counts in the effort to restore service, a convenient, compact and easily accessible arrangement of meters, control keys and lamp indicators

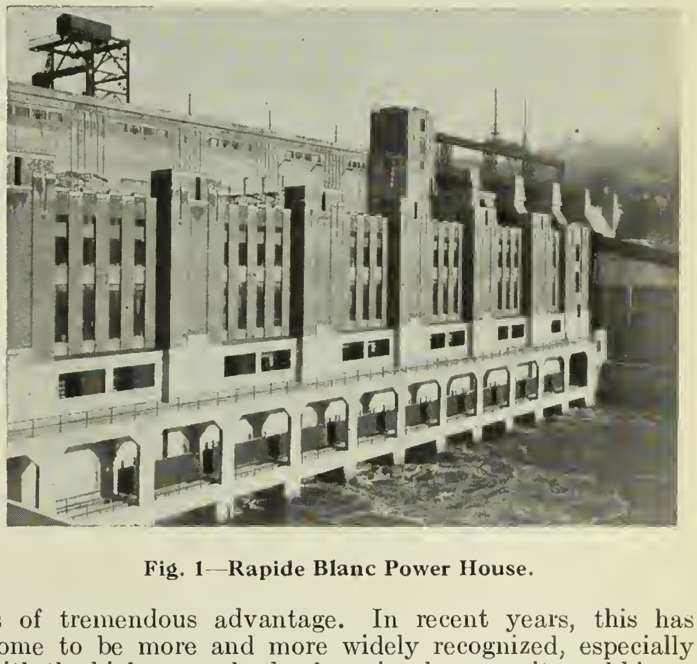

Fig. 1—Rapide Blanc Power House.

is of tremendous advantage. In recent years, this has come to be more and more widely recognized, especially with the higher standards of service, larger units and bigger developments that we have today. In fact, nowadays, a modern station of any size is generally controlled almost entirely from one large isolated room, usually located some distance from the generating machinery, switches and other equipment. As time went by, corresponding improvements in the controlling apparatus itself occurred. Benchboard controllers have been made smaller and better suited to their purpose, benchboard layouts more compact, more accessible, and more comprehensible; miniature meters were developed and finally, for large stations, the miniature type of benchboard and control panel using telephone-type equipment has been evolved and is steadily gaining in favour.

For the Rapide Blanc station, a careful study showed that, in addition to greater operating convenience, considerable economies could be effected by making use of miniature control equipment and consequently wide use has been made of small flush type meters and telephone type keys, push-buttons and indicating lamps.

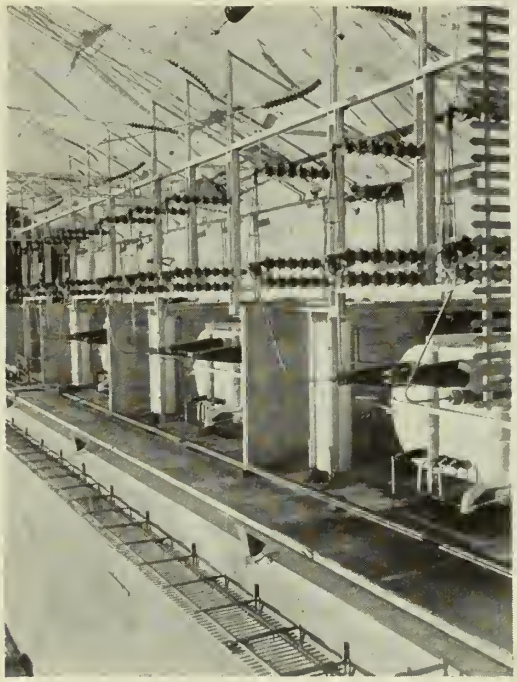

Fig. 2—Rapide Blanc Transformers and 220 kv. Disconnects.

The 48-volt battery, which was mentioned previously, supplies power to the benchboard and auxiliary feeder panel, and the signals and controlling impulses are transmitted at this voltage to interposing relays located adjacent to the equipment concerned. These relays in turn apply current from the main 250-volt battery to the oil circuit breakers, field breakers, motor operated disconnects, governors, rheostats, voltage regulators and similar apparatus.

Inasmuch as the controlling impulses merely operate relays rather than the apparatus itself, very little current is required and therefore, with a given amount of voltage drop, the connecting wires may be quite small. This, in turn, makes possible the use of a few multiconductor cables instead of a great number of conduit runs carrying much heavier wiring.

At Rapide Blanc the controlling impulses, lamp indications, signalling and interlocks for each unit are taken care of by three multiconductor cables made up of No. 16 gauge rubber-covered wires. One 20-conductor cable is for the 220,000-volt motor-operated disconnect, one 60-conductor cable for three 11,000-volt oil circuit breakers and their motor operated disconnects and one 60-conductor cable for the generator control group consisting of field breakers, field rheostat, voltage regulator, signalling equipment and governor adjustment.

Further economy lies in the small panel sizes and floor space required. Full control for fourteen auxiliary feeders with metering and dummy buswork is assembled on one vertical panel only thirty inches wide. Similarly, the benchboard, which is designed to accommodate complete control for six generators and transformers with all their associated equipment and metering, occupies a floor space of only nine feet by four feet.

Other remote control features which may be mentioned in passing are such things as the closing of head gates and ventilating air louvres, the starting, stopping and operation of battery charging motor generator sets and the manual control of auxiliary transformer bank "on-load" tap changers.

Automatic Control

Under the heading of automatic control there is first, the operation of oil switches and disconnects by means of protective equipment and second, the maintaining of special services, such as air pressures, oil and water levels, voltages, temperature, sump drainage and so on.

(a) *Protective Service*

The development of relay protective schemes has advanced in recent years to a high pitch of perfection. The fundamental idea back of all relay protection is the isolation of the faulty section in the shortest possible space of time. This time element in the automatic opening of circuit breakers and field breakers plays a very important part in reducing hazards, in eliminating or tremendously diminishing the damage to equipment and in greatly assisting the continuity of service. In order to give an idea of the rapidity with which modern high speed protective relays and breakers operate the following illustration is of interest. Imagine a three-phase transmission line with the three conductors placed 20 feet apart, horizontally. If an aeroplane travelling at sixty miles an hour were to run into the line and cause a short circuit between the first wire and the second, the circuit breakers would have opened and disconnected the line before the machine could reach the third wire.

At Rapide Blanc, a wide variety of protective systems is employed, such as differential current relays for generators and transformers, unbalanced voltage relays for low voltage grounds, duplicate impedance or distance relays for short circuits or grounds on the transmission line and over current relays for auxiliary apparatus. Further security is obtained from systems known as standby or back-up protection. They form a second line of defence and they operate after a small interval of time, in the event of the failure of an oil circuit breaker or of the ordinary relays. Separate groups of impedance relays are provided in this

Fig. 3—Rapide Blanc Control Room showing Benchboard, illuminated Diagram and Protection Panels.

protection for every generator and transformer with their associated busses, and for short circuits or grounds on the transmission line.

An interesting automatic protective feature which is applied to all the main and feeder circuit breakers at Rapide Blanc is what is known as "trip-free" protection. This prevents the breaker being held in the closed position

Fig. 4—Auxiliary Panels in Control Room.
These Panels control the following Equipment (left to right):
1. Main lighting and automatic a.c.-d.c. transfer.
2. 48-volt battery and rectigon chargers.
3. 250-volt battery and two motor generator sets.
4. Auxiliary feeders and associated circuit breakers.
5. Main transformer temperature indication and auxiliary watthours.
6. Alarm lamps and waterlevel indicators.

when closed in on a faulty circuit. For example: Assume a transmission line feeder to be affected by lightning resulting in a voltage surge, followed by a flashover and power arc. The line breaker will immediately open and the operator will at once close it again hoping that the trouble is a transient one. If it is not, then the trip-free equipment will permit the breaker to open again at once and remain open, although the operator may continue for a time holding the control key to the "close" position.

While on the subject of automatic protective control, the 220,000-volt grounding switch should be mentioned. This somewhat unusual switch, which is, in reality, an air break disconnect, places a dead ground on each of two phases of the high voltage bus. It is made necessary by the fact that there are no high voltage oil circuit breakers at Rapide Blanc. In the event of line or transformer trouble, the ground switch immediately places a grounded short on the line, thus ensuring that the protective relays at the far end of the line will operate, even though the fault may be on the low voltage side of one of the transformer banks. The ground switch is motor operated and in common with the other motor operated disconnects requires only a starting impulse, the mechanism then going to full travel by virtue of lock-in relays and limit switches. In order to guard against accidental operation due to grounds occurring on the d.c. system, the control relays are so arranged that both positive and negative supplies are entirely disconnected when the motor is not actually in operation.

(b) Special Service

In the classification of what is called "special service," automatic control performs a great number of jobs, the majority of them more accurately and reliably than they could possibly be done by hand.

Most of this control apparatus is more or less standardized and well known, float switches and pressure switches operating a variety of air pumps, oil pumps and water pumps; but there are some features which, being a little out of the ordinary, will be considered briefly.

The sump, which is below the level of the tail race, is drained by two pumps, one of 20 h.p. and one of 75 h.p. A special float switch, which was designed and built by Shawinigan, controls both pumps and, in addition, provides on a dial an indication of sump level. Under normal conditions, only the small pump operates, starting and stopping about every twenty minutes, but should the small pump for some reason be unable to prevent the water rising, the large one will come into action for as long as may be necessary.

Since the supply of lubricating oil to the generators must on no account be interrupted, special pump control is provided. From two large tanks, situated high up, the oil flows by gravity to individual unit tanks kept full by float valves. From these unit tanks the oil is delivered to the machines, is re-collected, filtered and pumped up again into the large tanks. Two pumps are provided, one of which runs continuously, the surplus oil returning directly to the lubricating oil sump. Should the oil supply from this pump fail, the second pump will start as soon as the tank level drops to a predetermined point and it will continue running until switched off by the operator. This procedure occurs regardless of which of the two pumps may normally be running.

Illumination being very important, particularly in the control room, generator room and switch room, an automatic throw-over switch is provided which, in the event

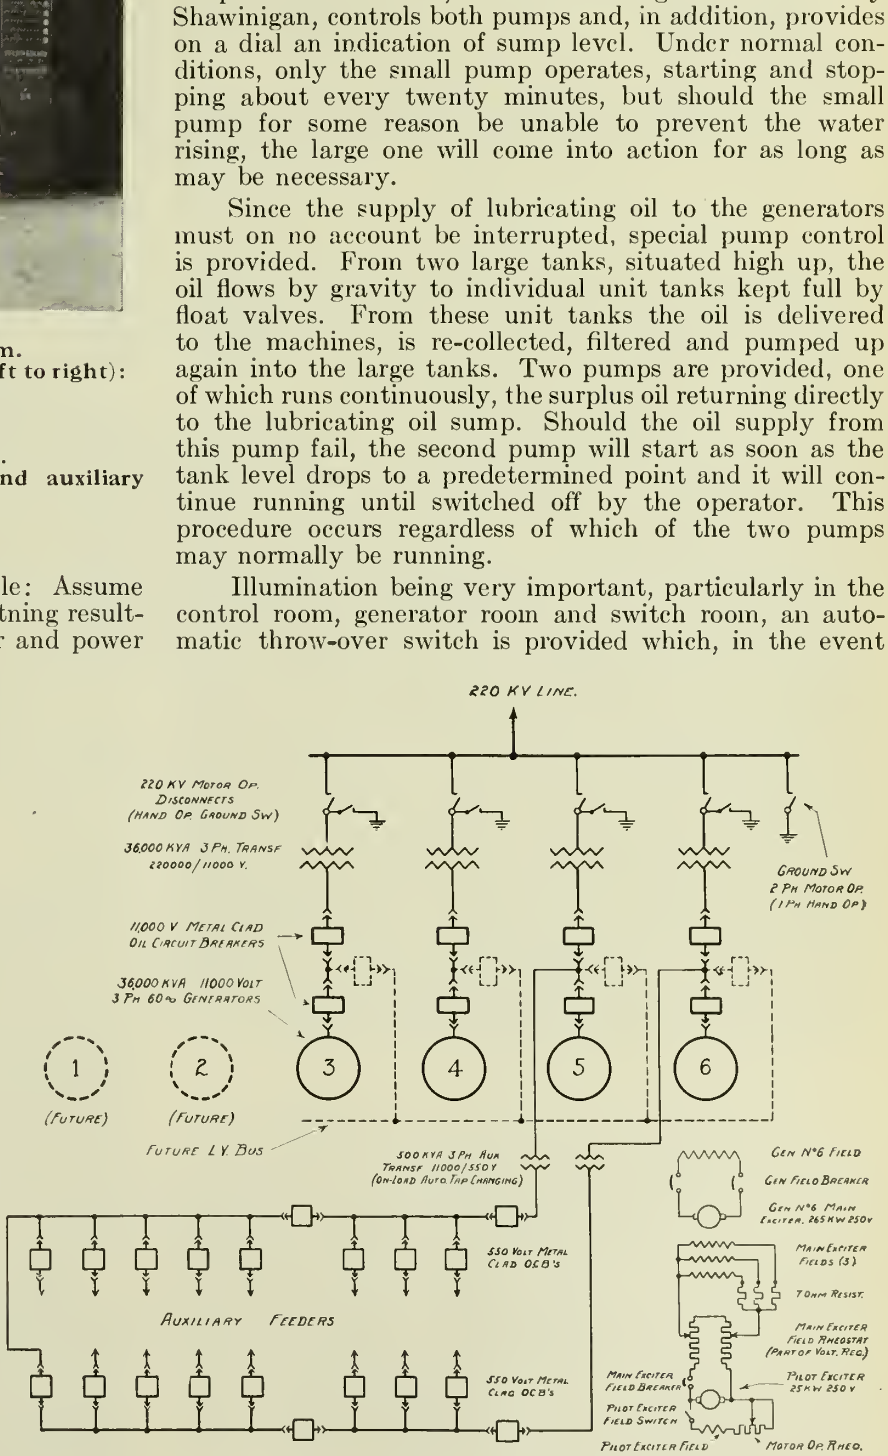

Fig. 5—Simplified Wiring Diagram.

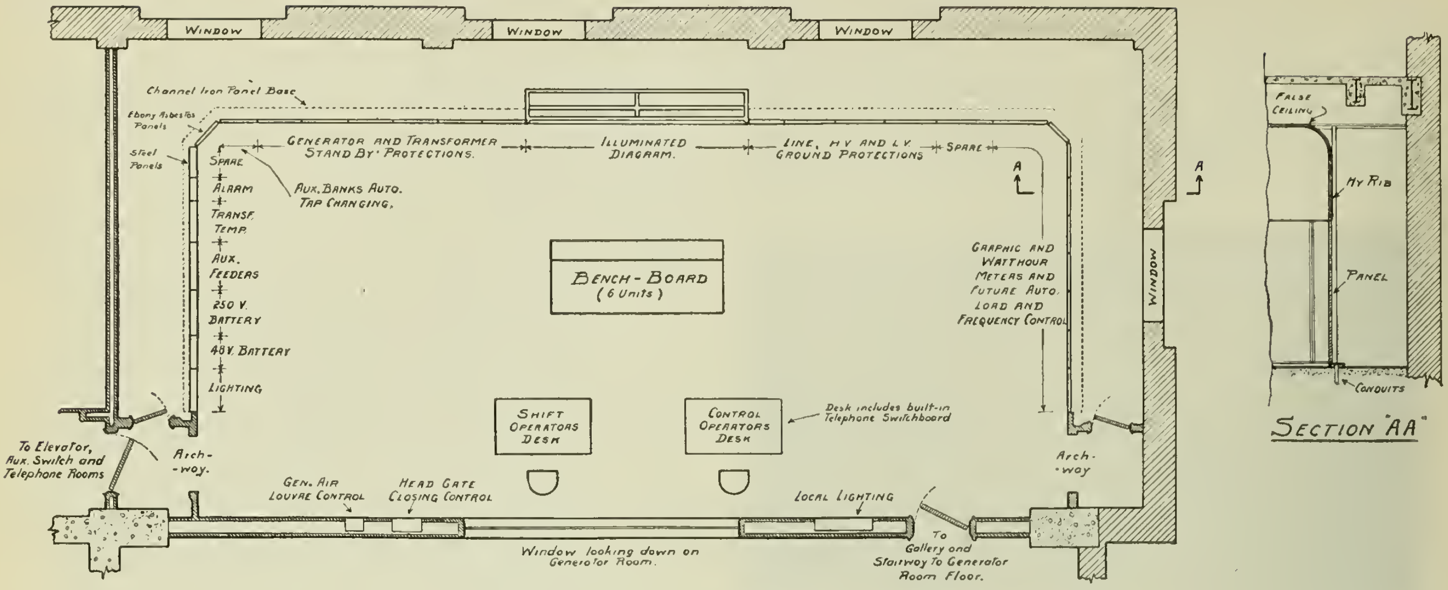

Fig. 6—Rapide Blanc Control Room—showing Panel and Control Layout.

of alternating current failure, transfers certain selected lamps throughout the power-house to the 250-volt battery, a mid tap from the battery taking care of the three wire lighting circuits. As soon as the supply is re-established, the lamps are returned to alternating current.

Automatic voltage regulation at Rapide Blanc is a little out of the ordinary and therefore interesting. The generator voltage regulators were manufactured by Brown Boveri in Switzerland and are of the high speed, heavy duty type, using oil pressure as an intermediate control. As far as the author knows, they are the only regulators of the kind in Canada. The regulating mechanism itself operates a rotary oil valve, which controls, by oil pressure, the position of two brushes which can move forward or backward around a fixed commutator. The bars of the commutator are connected to resistances in the output circuit of a pilot exciter and the brushes merely select the correct voltage for use on the field of the main exciter. In other words, it is really nothing more or less than an automatically operated potentiometer supplying d.c. to the field of the main exciter. Due to all the load being at a distance from the station, it is necessary to maintain constant voltage at the receiving point and this results in considerable variations in generator voltage as the load changes. To prevent this affecting the station auxiliaries, voltage control is provided in the form of on-load tap changers in the auxiliary transformer banks. These tap changers normally operate automatically but they can be worked by hand from the control room if desired.

Interlocks

An electrical interlock is merely an arrangement of wiring and auxiliary contacts whereby the operation of one piece of equipment is made dependent on the operation of another. Interlocks are exceedingly useful and are used in a great variety of ways. They guard against operating errors, prevent incorrect alarm indications and provide the correct sequence of operation in many types of automatic control. For instance, if an operator should attempt to open a transformer high voltage disconnect under load, without first opening the transformer oil circuit breaker, a very serious arc would be caused, probably developing into a cross short or ground. The disconnect is therefore interlocked electrically with the circuit breaker to prevent any possibility of this happening.

Alarm and Indication

In general, the work of an operator in a power-house consists of periods of uneventful routine with occasional hectic spells of activity when trouble occurs.

In order to lose as little time as possible in resuming service or eliminating danger to equipment, an alarm bell is essential. Several alarm bells, however, are a disadvantage. In the Rapide Blanc control room there is only one bell and it rings for every kind of serious trouble except two which are not urgent and are taken care of by a buzzer. Many troubles, such as overheated bearings, require some time to correct and meanwhile other difficulties may arise. Therefore an arrangement of relays is provided so that the bell may be stopped by momentarily pressing a button on the benchboard, after which it is immediately available again for any other trouble which may occur.

In a large plant, an immediate indication of the nature and location of the trouble is almost as important to the operator as the ringing of the bell itself.

Trouble indication at Rapide Blanc is carried out in two ways. What we may call mechanical troubles such as overheated transformers, overheated bearings, oil levels, water levels, oil pressures and so on, are shown by means of small red lamps and name-plates. There are sixty of these in the control room.

Electrical troubles are indicated by means of an illuminated station diagram on which the major circuits and equipment of the station are represented in lines and symbols of coloured light. Any alteration in the open or closed position of switches or disconnects and in the energized or de-energized condition of circuits or equipment is automatically represented by colour changes. In addition, any change resulting from the operation of the automatic protective relays will cause flickering of the section of the diagram affected and the symbol for the particular equipment or circuit which has failed will turn to a steady white.

The operators are thus advised instantly as to where the trouble is and to what extent it has affected the remainder of the station.

In concluding, one may see from the foregoing general outline that electrical control plays a vital part in the operation of a power-house and that correct design and application of control methods determine, to a considerable extent, the effectiveness of the station in supplying good power service.

VOLUME XVIII JULY 1935 No. 7

Transportation—The New Era

The changed conditions in the transportation industry have been the subject of recent addresses by a number of our public men, but there seems as yet to be little evidence that the serious nature of the problems that have arisen, and their vital effect upon the country's future, have been grasped by the general public. The man in the street does not yet realize that the railway problem, the development of highways and road transportation, the utilization of our waterways, and the establishment of airways, have such a bearing on the country's financial standing that a policy of drift in connection with them will have the gravest consequences.

Of these questions the railway problem is certainly the most pressing; its solution involves a study of all the other transportation agencies, with which the railways have to compete in their search for business. For this reason the timely information contained in a recent address by President Gaby, which we print elsewhere in this issue of The Journal, should be carefully studied. He very properly draws attention to the crushing burden of railway debt which weighs upon the Canadian people, and for which no political party seems able to provide any effective remedy. He points out that in the new era of land transportation, which has been brought about by the highway and the internal combustion engine, the railways, with their government controlled rates and strictly regulated methods of operation, are under a severe handicap in competing with the relatively unregulated busses and trucks operating on government built highways.

It is true that the railways have been criticized for not foreseeing and anticipating this competition. It is held that they should have forestalled the various private interests which have taken advantage of the new opportunities, and, assisted by the expenditure of public money on highways, and with the active support of the automotive industry, have covered the country with a network of bus and motor truck services. It must be remembered, however, that the railways, during this period of rapid change, have had to meet their own special troubles resulting from the depression, and that any expansion of their activities or change in their methods is subject to government approval. Any new developments in railway service are therefore liable to delay, so that private enterprise has, in many instances, been able to step in before the railway plans could be put into effect. In any case, the result has been that Canadian railways have not been able to do much in replacing unremunerative passenger trains by rail cars or their own motor busses, and, as regards freight, have seen a reduction in their revenue estimated at some thirteen million dollars per annum, due to the operation of privately owned motor trucks. The privately owned motor car has probably reduced the railways' passenger revenue by double that amount.

Dr. Gaby remarks, however, that the profitable operation of motor trucks is really limited to comparatively short hauls of small quantities of freight, and this is their natural field. Unregulated competition, or competition made possible owing to injudicious regulation, has nevertheless enabled trucks to take a considerable amount of the railways' long haul business, which, for runs of 500 miles, costs a railway less than one third of the real cost by motor truck.

Actually, our present composite transportation system, considered as a whole, is, like that in the United States, seriously inefficient and is not working to the best advantage of the country. Reduction in the volume of the railways' freight and passenger business has obviously increased its unit cost, in spite of the drastic economies which have been effected by the railway managements. Many of the main traffic routes, both road and rail, parallel each other, for they were laid out with a view of competition, not cooperation. Bus and truck operators often accept business at less than cost without due knowledge of all the factors entering into their financial operation. Nor is this kind of competition confined to the automotive field. As an example of the curious effect of governmental regulations and subsidies, it has actually been found worth while to transport loaded railway freight cars from New Orleans to New York in a specially constructed ocean-going steamer, instead of paying the regular freight rates for this service and permitting the cars to be hauled by locomotives over the railway tracks.

In aerial transport, the growth in Canada has been largely in districts, such as the northern mining areas, where other forms of transportation are as yet non-existent. In the United States, however, the air lines are in active competition with railways for long distance passenger traffic, and some progress has been made in coordinating their services with those of the railways.

"One of the lessons learned from the depression," said a recent speaker before the Franklin Institute in Philadelphia, "is that, throughout the world and on this continent particularly, we have gone ahead building up new forms of transportation and extending old forms without stopping to consider the relation which each must bear, one with another, or the relation of each to the whole economic structure. As a result, we have acquired an overhead of staggering dimensions. There may be some truth in the old saying that competition is the life of trade, but carried to extremes, competition, by placing too great burden on trade, may become its most deadly enemy."

What is the outlook for the future? Having regard to the new methods of transportation which have developed during the past twenty years, and which are undoubtedly here to stay, can the railways reasonably expect a growth of traffic from the sources still open to them which will enable them to meet their obligations out of their own revenue and not at the cost of the taxpayers? Even assuming that this growth will take place, there will still remain the waste due to the uncoordinated operation of our many transportation agencies. Dr. Gaby rightly observes that you cannot have duplication and multiplication of services in the same field and expect to have economy. Provision must be made for the reduction of unnecessary overhead, and the employment of each agency for the services which it is best fitted to perform. Only in this way can the efficiency of our transportation system as a whole be raised to the level which it should have if the Canadian public is to be properly served.

There is no prospect that this desirable result will be attained unless it is insistently demanded by well-informed public opinion. The supply of correct information on the various phases of transportation is peculiarly the province of the engineer, to whom the layman looks for a temperate presentation of the case, shorn of unnecessary technicalities and free from any political implications. Realizing this, the Council of The Institute is proposing to arrange, for the annual meeting of 1936, a symposium of papers on transportation subjects, designed to bring out, in as concise a form as possible, the basic facts and the relation of the various transportation systems to each other. This will enable members of The Institute to render a public service by first familiarizing themselves with the subject, and then using their influence to induce the laymen with whom they come in contact to take an active interest in the solution of its vital problems.

Report of Committee on Consolidation

No further meetings of the Committee on Consolidation have been held since the last report appearing in the June issue of The Journal, pending the receipt of replies to the Questionnaire at present before the Branches of The Institute and the Provincial Professional Associations.

The progress of the consideration of the questionnaire in the various provinces may be summarized briefly as follows:—

In Nova Scotia, the Association of Professional Engineers has been forwarded copies of the questionnaire for circulation to its membership and this matter will be discussed at a meeting of the Council at an early date. The Halifax Branch of The Institute has been forwarded copies of the questionnaire for study by their Executive, and a special committee on Consolidation is being appointed to co-operate with the central Committee. A Joint Committee of Eight for "Closer Union of the Association of Professional Engineers and The Engineering Institute of Canada in Nova Scotia" has made a report which has been approved by the Professional Association of Nova Scotia, the Halifax Branch and the Sydney Branch of the E.I.C.

In New Brunswick, the Moncton Branch is circulating the questionnaire to its membership for an expression of their individual opinion; also the Association of Professional Engineers of the Province of New Brunswick has requested copies of the questionnaire to circulate to its members. A meeting of the Council of this Association was held on June 21st, to consider Consolidation and to appoint members to act on a joint committee with the Saint John Branch and the Moncton Branch of the E.I.C. to discuss and report on the matter.

In the Province of Quebec, the Quebec Branch of the E.I.C. held a special meeting on June 17th, at which the questionnaire was considered and fully discussed and the engineers present unanimously approved affirmative answers to Questions No. 1, No. 3 and No. 5, also No. 2 with the qualification, "eventually." Question No. 4 was answered as "desirable" but an affirmative answer was considered to be dependent upon the uniformity of the benefits rendered by the National body to each member thereof. This report was accompanied by a memorandum by Mr. Hector Cimon, chairman of the Branch, dated January 25th, 1933, and submitted to the Annual Meeting of February, 1933. This most valuable recommendation should be made available to all members of the profession.

The Saguenay Branch of The Institute has appointed the following Committee to study the question of Consolidation and answer the questionnaire: H. R. Wake, A.M.E.I.C., J. Shanly, A.M.E.I.C., G. F. Layne, A.M.E.I.C., H. B. Pelletier, A.M.E.I.C.

At the request of the general membership of the Montreal Branch, a special meeting of the Branch was held on June 27th, to discuss the questionnaire and to take such action as may be considered to be in the best interest of the Branch and of the profession as a whole. The meeting resolved that the Questionnaire be sent to each member of the Branch to be returned on or before July 15th.

In Ontario, the Committee on Consolidation of the Niagara Peninsula Branch have returned the questionnaire with all questions answered unanimously in the affirmative. The Sault Ste. Marie Branch of The Institute is circulating the questionnaire to its members. The special committee of the Hamilton Branch of The Institute under the chairmanship of Mr. Hugh H. Lumsden, M.E.I.C., answered all questions in the affirmative. The questionnaire is being considered by a special committee on Consolidation of the Toronto Branch of The Institute. A special committee of the Professional Engineers of the Province of Ontario has been appointed to report on Consolidation and the questionnaire.

The special committee on Consolidation of the Province of Manitoba, under the chairmanship of Mr. A. J. Taunton, A.M.E.I.C., is issuing the questionnaire to all members of The Institute and the Professional Association of Manitoba.

In Saskatchewan, as previously reported, the special committee of The Institute and of the Professional Association, under the chairmanship of Mr. D. A. R. McCannel, M.E.I.C., have answered all questions in the affirmative.

In Alberta, the Edmonton Branch is circulating the questionnaire to its members.

In British Columbia, the Victoria Branch of The Institute is issuing the questionnaire to its membership. At an Executive meeting of the Vancouver Branch held on May 14th, a report on "The Engineering Profession in Canada and The Institute" prepared by Mr. P. H. Buchan, A.M.E.I.C., was accepted as being the expression of opinion of the Vancouver Branch on the Federation Problem, and forwarded to the Central Committee.

In order that the consideration of the question of Consolidation may progress uniformly across Canada, this Committee solicits the co-operation of all Branches, Special Committees and Associations, by their taking such action as will insure an early return on the "Questionnaire."

The Duggan Medal and Prize

The Council has great pleasure in announcing that through the generosity of Past-President G. H. Duggan, D.SC., LL.D., M.E.I.C., the series of prizes and medals of The Institute has been enlarged by the establishment of a fund, from the proceeds of which a gold medal and prize of a total value of approximately One Hundred Dollars will be offered annually for competition.

The founder's purpose is to encourage the development of the branches of engineering with which his name is associated, and accordingly the medal and prize will be awarded for the best paper submitted during The Institute prize year and dealing with some phase of constructional engineering in which metals are employed in moulded or fabricated shape for structural or mechanical purposes.

The competition will be open only to members of The Engineering Institute of Canada, and to be eligible, papers must not have been published elsewhere or have been presented before any other body.

Fuller details of the conditions attaching to this valuable donation are being worked out and will be published in an early issue of The Journal.

Field Marshal Julian Hedworth Byng, First Viscount Byng of Vimy, G.C.B., G.C.M.G., M.V.O., Hon. M.E.I.C.

It is with deep regret that it is necessary to record the death at Thorpe-le-Soken, England, on June 6th, 1935, of Field Marshal Julian Hedworth Byng, first Viscount Byng of Vimy, G.C.B., G.C.M.G., M.V.O., Hon.M.E.I.C.

The seventh son of the second Earl of Strafford, Lord Byng was born on September 11th, 1862, and like so many younger sons of the British aristocracy, he chose the army as his career. In 1883, following a short period in the militia, he joined the regular forces, and at the age of twenty-one was posted as a subaltern officer to the 10th Royal Hussars. Proceeding to Egypt within a few months from his joining the Hussars, he found himself in February, 1884, operating with a squadron of his regiment which was attached to the punitive force of General Graham against the notorious Osman Digna, and he was in action for the first time at El Teb on February 28th. He was adjutant of the Hussars for four years, and in 1890 was promoted captain. Another eight years elapsed before he attained field rank, but from then on the rapidity of the changes when developed in the army amply compensated Lord Byng for his lengthy period of probation. At the outbreak of the Boer War he went to South Africa with his regiment and was soon appointed to command the South African Light Horse as brevet Lieutenant-colonel. This regiment operated in Lord Dundonald's 2nd Mounted Brigade and Lord Byng was in action at Colenso and Standerton.

Returning to England in 1902 he was appointed to command his old regiment, the 10th Royal Hussars, and from that time until the opening of the Great War his military career followed a well-ordered course. Successively commandant of the Cavalry School at Netheravon and commander of the 2nd Cavalry Brigade, he was promoted major-general in 1909, and for two years commanded the East Anglian (Territorial) Division. In 1912 he proceeded to Egypt.

Field Marshal Julian Hedworth Byng, First Viscount Byng of Vimy.

The outbreak of the War found Lord Byng in Egypt, where after two years as General Officer Commanding the Army, he received the order, late in September, 1914, to report for service in France. Between October 6th and 8th, the 3rd Cavalry Division, commanded by Byng, and the 7th Division, landed at Ostend and Zeebrugge. Included in the former formation was Byng's own regiment, the 10th Royal Hussars, who had recently arrived from Potchefstroom, South Africa.

Lord Byng's force hastened to Bruges where, on October 9th, he learned that Antwerp had fallen that day. Falling back from Thourout to Roulers, Byng's division entered Ypres on October 13th, the first British soldiers to enter that town. On October 20th began the first battle of Ypres. Later on Lord Byng reported to duty in Gallipoli and was assigned to the command of the IX Corps. He remained in the Dardanelles until the evacuation and returned to France in February, 1916, to take command of the XVII Corps. His association with that force was brief, for within four months his transfer to the command of the Canadian Corps took place, and on May 28th, 1916, began a connection between Byng and the Canadian Corps which lasted for over a year and added to the renown of both. Subsequently Lord Byng was promoted to command the Third Army and later on became a full general.

During his command of the Canadian Corps, Byng won the affection and respect of all ranks, and nothing could have been more popular than his appointment in 1919 to be Governor General of Canada in succession to the Duke of Devonshire.

He came to Canada in 1921 and during his term as Governor General not only deepened the affectionate regard in which he was held by the Canadians who served under him in France, but also became one of the most popular representatives of the Crown in the history of the Dominion.

Following his return to England in 1926 Lord Byng retired to his estate at Thorpe-le-Soken in Essex, and for a time was out of the public eye, until in 1928 he was offered and accepted the post of Chief Commissioner of the Metropolitan Police Force of London. He retired from that office in 1931 after reorganizing the Force and restoring it to a position commanding public confidence.

In 1932 Lord Byng was elevated to the rank of Field Marshal. He was the recipient of many honours from foreign governments, being Grand Officer of the Legion of Honour, with the Croix de Guerre of France, the Grand Cross of the Order of the Crown of Belgium, and the Belgian Croix de Guerre, the Grand Cross of St. Vladimir of Russia (with swords), the American Distinguished Service Medal and the Order of the White Eagle of Serbia (with swords).

On his appointment as Governor General, Lord Byng graciously consented to become an Honorary Member of The Engineering Institute of Canada, and was duly elected on January 10th, 1922.

OBITUARY

George Henry Richardson, A.M.E.I.C.

It is with regret that we place on record the death at Kelowna, B.C., on June 10th, 1935, of George Henry Richardson, A.M.E.I.C., a member of many years standing.

Born at Toronto, Ont., on May 26th, 1868, Mr. Richardson graduated from the School of Practical Science, University of Toronto, in May 1888, and subsequently joined the staff of the Canadian Pacific Railway Company. From March to August 1889 Mr. Richardson was assistant engineer on construction of the railway between London and Windsor, and in April 1890 he was transferred to Toronto as assistant on the Don branch and Esplanade work. In 1891 he became assistant engineer on the Niagara Falls Park and River Railway, and in 1893 went west as transitman on surveys and location for the Crow's Nest Pass railway; later on he was assistant engineer on the Revelstoke and Arrow Lake branch of the Canadian Pacific Railway. In 1903-1903 Mr. Richardson was assistant engineer for the city of Ottawa. He went to Vancouver Island during the latter part of the Great War, and was engaged as location engineer on the railway extension from Alberni to Central Lake. After completing that work he retired and made his home in Victoria, but in 1923 was appointed municipal engineer of Oak Bay, B.C., which office he held until the time of his death.

Mr. Richardson joined The Institute (then the Canadian Society of Civil Engineers) as a Student on February 24th, 1887, and on May 23rd, 1895, became an Associate Member.

PERSONALS

Engineer Commander Angus D. M. Curry, M.E.I.C., has been appointed Director of Naval Engineering, Naval Service, Department of National Defence, Ottawa, Ont.

B. Russell, M.E.I.C., of Vancouver, B.C., has been appointed as senior engineer in charge of water supply investigations in the Prairie Provinces, and will make his headquarters at Medicine Hat, Alta.

A. N. Budden, A.M.E.I.C., of the Dominion Engineering Company Limited, has been transferred to the company's Toronto office. Mr. Budden was formerly located at Montreal.

K. M. Winslow, A.M.E.I.C., formerly with the Dominion Engineering Company Ltd., at Toronto, has been transferred to Montreal.

R. M. Smith, A.M.E.I.C., Deputy Minister, Department of Public Highways of Ontario, has been appointed by the Ontario government to assist the Grand River Conservation Commission in further projecting its conservation programme.

Horace L. Seymour, M.E.I.C., town planning consultant of Ottawa, has been retained by the Saint John, N.B., Town Planning Commission to advise them in the preparation of a new Town Planning Act for New Brunswick and to consult with them on specific problems of town planning and housing in Saint John and district.

John N. Flood, Jr., A.M.E.I.C., is chairman, and A. R. Crookshank, M.E.I.C., is secretary of the Saint John Town Planning Commission. Under the proposed act the scope of the Commission will be widened and the co-operation of local technical organizations is being sought. The local Branch of The Institute has shown great interest in the movement.

Major E. L. M. Burns, O.B.E., M.C., A.M.E.I.C., General Staff Officer Surveys, Geographical Section, Department of National Defence, Ottawa, was made an Officer of the Order of the British Empire (Military Division) in the King's Birthday Honours List for 1935. Major Burns who is a graduate of the Royal Military College, Kingston, of the year 1915, spent three years on active service during the late war. During the years 1928-1930 Major Burns was stationed at Quetta, India, where he attended the Staff College, and prior to his present appointment, he was district engineer officer for Military District No. 5, Quebec, Que.

Raymond A. Yapp, A.M.EI.C.

Raymond A. Yapp, A.M.E.I.C., has been appointed sales manager of Bepco Canada Limited, of Montreal and Toronto, which is an amalgamation, in Canada, of Bruce Peebles (Canada) Ltd., Harland Engineering Company of Canada Limited, Crompton Parkinson Canada Limited and the Lancashire Dynamo and Crypto Company of Canada Limited. Mr. Yapp graduated from the University of London in 1921 with the degree of B.Sc., and following graduation joined the firm of Lancashire Dynamo and Crypto Company Limited. About eleven years ago he came to Canada and joined the Toronto office of the company, and later was transferred to Montreal where he is now located.

Dr. Charles Camsell, C.M.G., LL.D., F.R.S.C., F.G.S.A., M.E.I.C., Deputy Minister of Mines, Ottawa, and a Past-President of The Institute was made a Companion of the Order of St. Michael and St. George in the King's Birthday list of Honours recently published. Dr. Camsell, who has explored all northern Canada, joined the Canadian Geological Service in 1904 and much of the mapping of the north was due to his exploration. Dr. Camsell was vice-president of the Canadian Institute of Mining and Metallurgy in 1921-1922, vice-president of the Royal Society of Canada in 1930, becoming its President in 1931, was President and one of the founders of the Canadian Geographical Society. Dr. Camsell was President of The Engineering Institute in 1932. Among his academic honours may be noted the degrees of LL.D. which he received from Queen's University in 1922 and from the University of Alberta in 1929. His achievements as an explorer were recognized in 1922 by the award to him of the Murchison Grant by the Royal Geographical Society as an appreciation of his services in exploring northern Canada; his long connection with the mining industry was fittingly acknowledged in 1931 when the Institution of Mining and Metallurgy, London, presented him with its gold medal for his work in promoting the development of the natural resources of the Dominion and furthering the general interests of the mineral industry.

Major-General A. G. L. McNaughton, C.M.G., D.S.O., LL.D., M.E.I.C., has been appointed chairman of the National Research Council, Ottawa, in succession to Dr. H. M. Tory. Major-General McNaughton has been for the past six years chief of the General Staff in the Department of National Defence. He graduated from McGill University in 1910 with the degree of B.Sc., and in 1912 with the degree of M.Sc., and during the years 1910 to 1914 was attached to the department of electrical engineering at the same university. In 1914 Major-General McNaughton was engaged in engineering practice in Montreal, carrying out numerous investigations for the late Dr. L. A. Herdt, M.E.I.C., on subjects connected with electrical engineering. He then served overseas with very high distinction, and, upon his return to Canada, joined the permanent force and was appointed to the command of military district No. 11, at Victoria, B.C. In 1929 he was transferred to Ottawa as Chief of the General Staff and member of the Defence Council. He has been largely responsible for the organization and administration of the relief camps and projects throughout the country, which were established in 1932 and have assisted many thousands of single unemployed homeless Canadians.

J. Clark Keith, A.M.E.I.C., chief engineer of the Essex Border Utilities Commission, has been appointed finance comptroller of the new City of Windsor, which includes Windsor, Walkerville, Sandwich and East Windsor. As comptroller he will be the chief executive officer of the new city in charge of all departments, and responsible to a newly-appointed three-man finance commission, which has general supervision over all financial affairs of the new city. Mr. Keith graduated from the University of Toronto in 1911 with the degree of B.A.Sc., and in 1912-1920 was municipal engineer of the city of Moose Jaw. In 1920 he was appointed deputy chief engineer of the Essex Border Utilities Commission and the following year was appointed chief engineer of the Commission. In 1932 Mr. Keith became business administrator of the Metropolitan General Hospital in addition to his other duties, and in 1934 he was made chief executive officer of the Commission. With the merging of the four municipalities, the functions of the Essex Border Utilities Commission will be assumed by the Windsor Utilities Commission with which Mr. Keith will probably still be identified.

Meeting of Council

A meeting of the Council of The Institute was held at Headquarters on Tuesday, June 18th, 1935, at eight o'clock p.m., with President F. A. Gaby, M.E.I.C., in the chair, and ten other members of Council present.

A report was received from the special committee appointed by Council, under the chairmanship of Mr. C. M. Pitts, A.M.E.I.C., to consider any action which it might be possible for Council to take in connection with the housing problem. Letters of comment from a number of councillors were also considered, and discussion took place, after which the report was approved and the Secretary was directed to draw the attention of the National Construction Council to the desirability of giving further consideration to the possibility of providing low cost houses, with an offer of Council's assistance should an investigation along these lines be thought desirable.

Prolonged consideration was given to a charge of unprofessional conduct and the representations of one of The Institute branches regarding it, after which it was resolved that in this case sufficient grounds had not been disclosed to institute a formal investigation.

A report was presented from a committee appointed by Council, under the chairmanship of Mr. J. A. Vance, A.M.E.I.C., to study the conditions of employment of engineers under the Highway Improvement Act of Ontario. After considerable discussion the report was approved, and the committee was authorized to make representations to the officers of the Provincial Government in accordance with the recommendations contained in the report.

The Secretary reported receipt of the securities donated to The Institute by Past-President Duggan and constituting the fund for the prize which he is establishing, and stated that in accordance with Council's directions he had written to Mr. Duggan expressing Council's gratitude for this generous gift.

It was noted with appreciation that Mr. E. P. Muntz, M.E.I.C., had consented to act as The Institute's representative on the National Construction Council of Canada, and that Mr. A. H. Harkness, M.E.I.C., would continue to act as alternate representative.

A progress report was presented from Colonel C. S. L. Hertzberg, M.E.I.C., chairman of the Papers Committee of The Institute, drawing attention to the service which could be rendered to The Institute by prominent members who have occasion to travel if they would take the opportunity of stopping off and addressing outlying branches.

Two resignations were accepted, three reinstatements were effected, one member was replaced on the active list, and a number of special cases were dealt with.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Assoc. Members	5	Assoc. Member to Member	2
Juniors	2	Junior to Assoc. Member	1
Affiliate	1	Student to Junior	3
Students admitted	7		

The Council rose at twelve o'clock midnight.

The Past-Presidents Prize 1935-36

The Council has selected as the subject of the essays to be submitted for the competition for the prize year July 1st, 1935 to June 30th, 1936:—

The Engineer's Contribution to Transportation

The rules governing the award of this prize are as follows:—

The prize shall consist of a cash donation of the amount of one hundred dollars, or the winner may select books or instruments of no more than that value when suitably bound and printed, or engraved as the case may be.

The prize shall be awarded for the best contribution submitted to the Council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by the Council at the beginning of the prize year, which shall be July 1st to June thirtieth.

The papers entered for the competition shall be judged by a committee of five, to be called the Past-Presidents' Prize Committee, which shall be appointed by the Council as soon after the Annual Meeting of The Institute as practicable. Members and Honorary Members only shall be eligible to act on this committee.

It shall be within the discretion of the committee to refuse an award if they consider no paper of sufficient merit.

All papers eligible for the competition must be the bona fide work of the contributors and must not have been made public before submission to The Institute.

All papers to be entered for the competition must be received during the prize year by the General Secretary of The Institute, either direct from the author or through a local branch.

THE ENGINEERING INSTITUTE OF CANADA

RECORD OF MEMBERS WHO SERVED OVERSEAS

1914-1918

Council has given instructions that the permanent bronze tablet giving a list of those members of The Institute who served overseas is to be proceeded with. This will complete The Institute's War Memorial and the following list of names will be placed on record. Corrections can be made if received not later than August 1st, 1935.

This list has been made up in accordance with the instructions of Council to include the names of all those who belonged to The Institute in any class of membership and during that membership served with the allied land, air or naval forces outside of Canada and the United States between August 1914 and November 1918.

Recent Graduates in Engineering

Congratulations are in order to the following Juniors and Students of The Institute who have recently completed their course at the various universities:—

McGill University

Honours, Medals and Prizes

Angel, John Bartlett, St. John's, Nfld.—B.Eng., (Met.); American Society for Metals Prize for Metallography and Thesis.
L'Allier, Lucien, Montreal, Que.—B.Eng., (El.); Honours in Electrical Engineering; British Association Medal; Montreal Light, Heat and Power Consolidated First Prize; The Jenkins Brothers Limited Scholarship.
McGregor, Douglas Robert, Sherbrooke, Que.—B.Eng., (El.); Honours in Electrical Engineering; Montreal Light, Heat and Power Consolidated Second Prize.
Paton, Charles Peter, Montreal, Que.—B.Eng., (Mech.); Honours in Mechanical Engineering; The Engineering Institute of Canada Prize (1934).
Pope, Francis Robert, Montreal, Que.—B.Eng., (Mech.); Honours in Mechanical Engineering; British Association Medal.
Rose, Alexander, Montreal, Que.—B.Eng., (Chem.); Honours in Chemical Engineering; British Association Medal.
Wadge, Norman Hilton, Winnipeg, Man.—B.Eng., (Mi.); Dr. James Douglas Fellowship in Mining Engineering.

Degree of Bachelor of Engineering

Beath, Lawrence Raymond, B.Eng., (Chem.), Regina, Sask.
Blair-McGuffie, Malcolm Hugh, B.Eng., (Chem.), Hayward's Heath, Sussex, England.
Brown, Ernest Frederick, B.Eng., (Mech.), Montreal, Que.
Burri, Henry William, B.Eng., (Mech.), Montreal, Que.
Christie, Robert Louis, B.Eng., (Mech.), Truro, N.S.
Cooper, William Everett, B.Eng., (El.), Moose Jaw, Sask.
Dobson, Richard Nesbitt, B.Eng., (Mech.), Montreal, Que.
Duncan, Gaylen Rupert, B.Eng., (El.), Fort William, Ont.
Dunlop, James Russell, B.Eng., (Mech.), Ottawa, Ont.
Ferguson, James Bell, B.Eng., (Mech.), Pictou, N.S.
Gunning, Merle Percy, B.Eng., (El.), St. Lambert, Que.
Houghton, John Ruse, B.Eng., (Mech.), Montreal, Que.
Ingham, Jason Harold, B.Eng., (Mech.), Montreal, Que.
Jeffrey, James Stewart, B.Eng., (Mech.), Vegreville, Alta.
Kazakoff, John, B.Eng., (El.), Kamsack, Sask.
Kimpton, Geoffrey Holiday, B.Eng., (Chem.), St. Lambert, Que.
Leahey, James Climacus, B.Eng., (El.), St. John's, Nfld.
Lockwood, Clarence Kingsley, B.Eng., (Met.), Montreal, Que.
MacKay, Ian Norton, B.Eng., (Mech.), Montreal, Que.
Morris, Harold Kempffer, B.Eng., (Mech.), Edmonton, Alta.
Mussen, Guy Aubrey, B.Eng., (El.), Montreal, Que.
Purves, William Franklin, B.Eng., (El.), Saskatoon, Sask.
Ransom, Rosmore Howard, B.Eng., (Ci.), Montreal, Que.
Reynolds, George Kenly, B.Eng., (Mech.), Montreal, Que.
Ross, Thomas Wilson, B.Eng., (Mech.), Hawkesbury, Ont.
Rowell, Lorne Archibald, B.Eng., (El.), Wapella, Sask.
Schear, Philip M., B.Eng., (Chem.), Montreal, Que.
Schofield, Robert John Graham, B.Eng., (Chem.), Montreal, Que.
Shortall, John Desmond, B.Eng., (El.), Montreal, Que.
Smith, Odric Henry, B.Eng., (Mech.), Montreal, Que.
Schnyder, Max, B.Eng., (Mech.), Montreal, Que.
Swift, John William, B.Eng., (Mech.), Montreal, Que.
Tatham, William Carlyle, B.Eng., (Mech.), Elora, Ont.
Thompson, Robert, B.Eng., (Met.), Lachine, Que.
Wigdor, Edward Irving, B.Eng., (El.), Montreal, Que.
Winn, James, B.Eng., (Mech.), Montreal, Que.
Wong, Henry Gee, B.Eng., (Ci.), Montreal, Que.
York, Fred Gilbert, B.Eng., (El.), Ottawa, Ont.
Zion, Alfred Bernard, B.Eng., (Mech.), Montreal, Que.

Degree of Master of Engineering

Clarke, George Frederick, B.Sc., (McGill Univ. '31); M.Eng., (Mech.), Ewarton, Jamaica, B.W.I.
Howe, Lawrence McLean, B.Sc., (Univ. of Manitoba '33); M.Eng., (El.), West Shefford, Que.

Degree of Bachelor of Commerce

Wisdom, Charles Stuart Cotton, B.C., Shawinigan Falls, Que.

University of Toronto

Degree of Bachelor of Applied Science (with Honours)

Bowen, John Alfred Clarke, B.A.Sc., (Ci.), Long Branch, Ont.
Finlay, Ruskin Reid, B.A.Sc., (El.), Toronto, Ont.
Hewitt, Robert, B.A.Sc., (Ci.), Toronto, Ont.
Howard, Albert Warren, B.A.Sc., (El.), Calgary, Alta.
Johnston, William David, B.A.Sc., (Ci.), Toronto, Ont.
Miller, Dudley Chipman Raphael, B.A.Sc., (Mech.), Toronto, Ont.
McMullen, William Francis, B.A.Sc., (El.), Toronto, Ont.

Degree of Bachelor of Science

Hornfelt, Harvey Andrew, B.A.Sc., (Ci.), Toronto, Ont.
Robson, William John, B.A.Sc., (Mech.), Toronto, Ont.
Shanks, Victor, B.A.Sc., (El.), Toronto, Ont.
Smith, Arthur James Edwin, B.A.Sc., (Ci.), Toronto, Ont.

Ecole Polytechnique

Honours, Medals and Prizes

Rowan, John James, Ottawa, Ont.—B.A.Sc., (Ci.); Honours in Civil Engineering.
Tasse, Yvon Roma, Montreal, Que.—B.A.Sc., (Ci.); Honours in Civil Engineering; Silver Medal offered by Lieutenant-Governor of the Province of Quebec; Bronze Medal offered by the Association des Anciens Elèves de l'Ecole Polytechnique.

Degree of Bachelor of Applied Science

Gregoire, Armand E., B.A.Sc., (Ci.), Montreal, Que.

University of New Brunswick

Honours and Medals

Brewer, Douglas Jared Brewer, Fredericton, N.B.—B.Sc., (Ci.); The Ketchum Silver Medal for the highest standing in Civil Engineering.
Smith, Wilfrid Ewart, Fredericton, N.B.—B.Sc., (El.); City of Fredericton Gold Medal for the highest standing in fourth year Hydraulics.

Degree of Bachelor of Science

Benson, Willard MacLean, B.Sc., (Ci.), Fredericton, N.B.
Bonnell, Alexander Robertson, B.Sc., (Ci.), Fredericton, N.B.
Brannen, Edwin Ralph, B.Sc., (El.), North Devon, N.B.
Coombes, David Eaton, B.Sc., (El.), North Devon, N.B.
Eagles, Norman Borden, B.Sc., (El.), Moncton, N.B.

Gibbons, James Fenton, B.Sc., (El.), Fredericton, N.B.
Huggard, John Harold, B.Sc., (El.), Norton, Kings Co., N.B.
Lilley, Ledford George, B.Sc., (El.), West Saint John, N.B.
Mackie, George Arthur, B.Sc., (El.), Saint John, N.B.
Sansom, Ralph Thomas, B.Sc., (El.), Campbellton, N.B.
Tweeddale, Reginald Estey, B.Sc., (El.), Arthurette, Victoria, N.B.
Webb, David Roland, B.Sc., (El.), Saint John, N.B.

University of British Columbia

Degree of Bachelor of Applied Science

Bell, Douglas E., B.A.Sc., (Chem.) Vancouver, B.C.
Davis, Ralph, B.A.Sc., (Ci.), Etzikom, Alta.
Sparks, Wilbur Hamilton, B.A.Sc., (Ci.), Vancouver, B.C.

Degree of Master of Applied Science

Lind, Walter J., M.A.Sc., (Me.), Sidney, B.C.

Queen's University

Degree of Bachelor of Science (with honours)

Darwin, Bascom Herman, B.Sc., (Ci.), Vancouver, B.C.
Meuser, Henry Lloyd, B.Sc., (Ci.), Regina, Sask.
Pequegnat, Jared Marc, B.Sc., (Ci.), Kitchener, Ont.

Degree of Bachelor of Science

Aman, Thomas F. Stewart, B.Sc., (El.), Belleville, Ont.
Bellamy, Keith Lacy, B.Sc., (El.), Niagara Falls, Ont.
Bonney, Albert Jay, B.Sc., (Mech.), Peterborough, Ont.
Clarke, Ross Eugene, B.Sc., (Ci.), Gananoque, Ont.
DeMocko, Gerald George, B.Sc., (El.), Fort William, Ont.
Ellsworth, Arthur Crayton, B.Sc., (El.), Ridgeway, Ont.
Hare, William Lester, B.Sc., (Mech.), Ottawa, Ont.
Preston, William Walford, B.Sc., (Ci.), Hamilton, Ont.
Rintoul, William Vance, B.Sc., (Mech.), Burk's Falls, Ont.
Soles, William England, B.Sc., (Mech.), Rock Island, Que.

University of Saskatchewan

Degree of Bachelor of Science

Upton, Virgil Stanley, B.Sc., (Mech.), Gregg, Man.

University of Manitoba

Degree of Bachelor of Science

Davidson, Arthur Campbell, B.Sc., (Ci.), Calgary, Alta.
Marshall, Lawrence James, B.Sc., (El.), Ashern, Man.
Pask, Arthur Henry, B.Sc., (El.), Zeneta, Sask.

University of Alberta

Degree of Bachelor of Science

Beach, John Edward, B.Sc., (El.), Turner Valley, Alta.
Herbert, Albert Cecil, B.Sc., (El.), Wilkie, Sask.
Stevens, Robert Leonard, B.Sc., (El.), Edmonton, Alta.
Weston, Norman Owen, B.Sc., (El.), Edmonton, Alta.
Woznow, John, B.Sc., (Ci.), Medicine Hat, Alta.

Degree of Master of Science

Sinclair, George, B.Sc., (Univ. of Alberta '33); M.Sc., Edmonton, Alta.
Williams, David Gabb, B.Sc., (Univ. of Alberta '33), M.Sc., Edmonton, Alta.

Nova Scotia Technical College

Honours and Medal

Wright, Charles Abbott, Halifax, N.S.—B.Sc., (El.); Honours in Electrical Engineering; The Alumni Medal.

Degree of Bachelor of Science

Berringer, Ormus Benjamin, B.Sc., (Ci.); B.Sc., (El.), Lunenberg, N.S.
Carson, James Russell, B.Sc., (Ci.), Pictou, N.S.
Miller, Alex Matthew, B.Sc., (Mech.) New Waterford, N.S.
Moores, Robert Vernon, B.Sc., (El.), Black Head, Baie de Verte, Nfld.
Shatford, Ralph Grant, B.Sc., (El.), Dartmouth, N.S.
Sutherland, James Gordon, B.Sc., (El.), St. Peters, P.E.I.

Royal Military College

Honours, Medal and Prize

Powell, Robert M., Ottawa, Ont.—Graduate R.M.C. '35; Highest awards of the R.M.C.; Sword of Honour for Conduct and Discipline; Governor-General's Gold Medal for the highest aggregate of marking during the entire four year course; The Engineering Institute of Canada Prize; The Toronto Branch of The Engineering Institute of Canada Trophy; the Province of Quebec Department of Public Instruction award; the Bexhill Cup.

ELECTIONS AND TRANSFERS

At the meeting of Council held on June 18th, 1935, the following elections and transfers were effected:

Associate Members

HAMILTON, Vesey Courthope, (Grad. R.M.C.), supt., Canada Cement Co. Ltd., Exshaw, Alta.

NELSON, Edward, engr.-in-charge, Northwestern Utilities Limited, Edmonton, Alta.

ROUSSEAU, Gabriel E., B.Sc., (Mass. Inst. Tech.), asst. to the Director General of Technical Education, Province of Quebec, also lecturer and asst. to the Dean, Ecole Polytechnique, Montreal, Que.

SHELDEN, William Leslie, Associate, (Working Men's Coll., Melbourne), designing engr., water supply section, works dept., City of Toronto, Ont.

TIMMINS, Wilbur W., B.A.Sc., (Univ. of Toronto), manufacturers' agent, 344 University Tower, Montreal, Que.

Juniors

*ATTENBOROUGH, Ernest A., (Central Tech. School), tracer, sewer dfting office, Dept. of Works, City of Toronto, Ont.

DAVIS, William Roe, Jr., B.Sc., (Univ. of Alta.), asst. engr., Calgary Power Co. Ltd., Calgary, Alta.

Affiliate

KING, John David, (McGill Univ.), manager, Detroit Stoker Co. of Canada, Montreal, Que.

Transferred from the class of Associate Member to that of Member

CROSS, Edgar Algernon, B.Sc. (Civil), (Birmingham Univ.), consltg. struct'l. engr., 25 Ferndale Ave., Toronto, Ont.

GARRETT, Julian, A.B. (Harvard Coll.), director, manager, and sec. treas., Northwestern Utilities Ltd., Edmonton, Alta.

Transferred from the class of Junior to that of Associate Member

*SHUTTLEWORTH, Wilbur Irvin, instr'man., engrg. dept., City of Ottawa, Ont.

Transferred from the class of Student to that of Junior

BUTLER, Howard Claude, B.Sc., (McGill Univ.), asst. to chief engr., Dominion Rubber Co. Ltd., Montreal, Que.

SEELY, Wallace Errol, B.Sc., (Univ. of N.B.), 1492 Bishop St., Montreal, Que.

Students Admitted

EAGLES, Norman Borden, B.Sc., (Univ. of N.B.), 110 Cornhill St., Moncton, N.B.

GIBBONS, James Fenton, B.Sc., (Univ. of N.B.), Bayswater, N.B.

LOCKWOOD, Clarence Kingsley, B.Eng. (Chem.), B.Eng. (Metal.), (McGill Univ.), 602 Cote St. Antoine Rd., Westmount, Que.

MACKIE, George Arthur, B.Sc., (Univ. of N.B.), 223 King St. East, Saint John, N.B.

ROWAN, John James, B.A.Sc., C.E., (Ecole Polytech., Montreal), 162 Friel St., Ottawa, Ont.

*Has passed Institute's examinations.

Results of May Examinations of The Institute

A further report from the Board of Examiners, presented at the meeting of Council held on June 18th, 1935, certified that the following candidate, having passed the examinations of The Institute, has satisfied the examiners as regards his educational qualifications for the class of membership named:

Schedule B—For admission as Junior:
Ernest A. Attenborough......Toronto, Ont.

Some Problems of Transportation

Frederick A Gaby, D.Sc., M.E.I.C.

An address delivered before the Canadian Credit Institute, March 13th, 1935. (Abridged.)

Rail transportation is a vital necessity for the stability and growth of our social and economic system. The very existence and the economic structure of the Dominion of Canada were based upon adequate railroad communication between the east and west. British Columbia had written into the terms of the Confederation compact a clause binding Canada to "undertake the commencement simultaneously within two years from the date of the union (Confederation) of the construction of a railway from the Pacific towards the Rocky Mountains, and from such point as may be selected east of the Rocky Mountains towards the Pacific, to connect the seaboard of British Columbia with the railway system of Canada, and further to secure completion of such railway within ten years from the date of the union."

The government attempted to carry out its undertaking, but by the end of ten years only 264 miles had been constructed. The difficulties were tremendous, and the government was faced with bankruptcy if its then programme was continued. The solution eventually obtained was the contract with the Canadian Pacific Railway in 1881 for the construction of the remaining trackage of 2,600 miles which was ultimately accomplished in 1885.

About the year 1900 there was no railway problem in Canada, but shortly thereafter duplication of services was evident in the construction of additional railway facilities, financed largely upon government credit.

In a little more than fifteen years the whole railway situation passed from the position of manageable cost and moderate expansion to one of confusion and over-extension.

From 1900 to 1916 the railway mileage in Canada had more than doubled—from 17,500 to 36,000 miles. The five main railway systems were: Canadian Pacific Railway, Canadian Northern Railway, Grand Trunk and Grand Trunk Pacific Railways, National Transcontinental Railway, Intercolonial Railway; the latter two being government railways. The railways in Canada had a combined investment for road and equipment of about $2,550,000,000, of which $2,020,000,000 was invested in all railways other than the Canadian Pacific Railway. They later on became parts of the Canadian National Railway System.

The inability of the railways now represented by the Canadian National Railway group to meet their financial obligations and the demand for further governmental support, resulted in the appointment of a Royal Commission in 1916, whose reports recommended the nationalization of the railways then in difficulties. This recommendation was effected in the case of all except the Grand Trunk, and the government embarked upon a programme of nationalization. Further capital commitments of over $350,000,000 were undertaken between 1915 and 1921 in the consolidation, extension and equipment of the systems referred to. The Grand Trunk Railway became a part of the government systems on May 21st, 1920. This was followed in the next decade by an extraordinary and extravagant programme of railway building resulting in the duplication and triplication of services, particularly between the years 1921-1931, during which period over $550,000,000 was spent in this way (in the extension and improvement of railway facilities). The railway situation reached a chaotic state in 1931. Again the increasing obligations of the government on account of the national railways were causing much concern, and during this time a Senate Committee reported that the railway question was one of extreme urgency.

Following the recommendation of a special committee of the House of Commons in 1931 a Royal Commission known as the Duff Commission was appointed to inquire into the whole question of transportation in all its forms, and after nine months of inquiry and study, this Commission reached conclusions designed to secure co-operation of the privately owned Canadian Pacific and the National Railways, while preserving competition and separate administration of the two railway systems.

This was the position of the railway problem in 1934 and it is unchanged to-day. It is one of Canada's major financial problems—with 42,000 miles of railway supplying a population of only 250 per mile of track and a capital debt of the railways of Canada in excess of $4,400,000,000 of which over $3,000,000,000 is attributable to the Canadian National Systems.

The following are a few pertinent facts and figures which have a direct bearing on the problem under discussion:—

The total government and railway debt of Canada as at March 31st, 1934, was $3,986,000,000.

The proportion of this debt attributable to the Canadian National Railway was $2,320,000,000 or 58 per cent of the total government and railway debt of Canada.

The deficits of the Canadian National, from 1923 to 1933, inclusive, totalled $644,000,000, which sum considered in terms of taxation, are equivalent to 99 per cent of the total receipts from the income tax and 94 per cent of the total receipts from the sales tax.

During the same period the total gold production of all Canada amounted to $469,000,000 or less than three-quarters of the Canadian National Railway losses.

In 1919, the Canadian National interest charges on funded debt owing to the public and the government, amounted to $38,200,000; by 1923 they had risen to $65,200,000; in 1933 they totalled $92,500,000.

For the year ending December 31st, 1933, the Canadian government was obliged to meet a railway deficit of approximately $96,000,000. This amount was made up as follows:—

Net income deficit before interest	$ 3,552,286
Interest due public on long term debt	56,465,427
Interest on Dominion Government loans	36,034,141
	$96,051,854

The average Canadian family pays approximately $46.30 a year in taxation to maintain the Canadian National Railways.

Speaking in the House of Commons on January 28th of this year, the Honourable Mr. Manion, Minister of Railways and Canals, made a statement that merits the attention of every Canadian. Mr. Manion pointed out that the government books show that the Canadian National Railways are indebted to the Government of Canada (apart from guarantees) to the extent of $1,490,000,000. This includes capital investment and accumulated interest and other charges. About one-half of this amount went into the building of the Canadian National Railways as they stand to-day. The interest payable per annum on the portion of the debt bearing interest amounts to about $36,000,000.

In addition to this government debt, however, there is a long term debt owing to the public amounting to $1,255,000,000. Of this, some 75 to 85 per cent are bonds owned in England, the United States and Canada, which are guaranteed by the Dominion government. These entail an annual interest payment of $57,000,000. The credit of the country is directly involved in maintaining the integrity of this debt to the investing bondholders.

To relieve this situation two recent schemes have been suggested for the administration of our two great railway systems—one by Mr. E. W. Beatty and the other by the Honourable Mr. Euler.

Mr. Beatty suggests unification and the appointment of an administrative body to operate the joint properties for administration purposes; the administration to be free from political control.

Mr. Euler suggests that a holding company be formed by the government and that the corporate status of the companies remain unchanged, but the merged railways would be thrown into a single system, the net earnings being divided between the two units.

It has been variously estimated that savings will accrue from such unification or amalgamation of from $56,000,000 to $75,000,000 per annum.

Both plans are estimated to assure a greater net operating revenue to apply on the obligations of the Canadian National and to provide a reasonable return to the owners of the Canadian Pacific Railway.

The above is the position in which we find the railway systems to-day in regard to the enormous debt the government has to carry, and the provision for the annual deficit and interest out of taxation and otherwise.

The Duff Commission in its report on the transportation problem in 1932 stated that unless some effective plan is adopted "to secure the efficient and economical working of both railway systems, and thereby not only reduce the burden on the Federal Treasury, but improve the financial position of the privately owned railway, then the only course that would be left would be either to effect savings in national expenditure in other directions or to add still further to the burden under which the industries of the country are suffering by the imposition of yet further taxation."

We are now living in a changed world. The aftermath of the Great War not only changed the map of Europe, but the face of the whole industrial, commercial and financial world. New and very important factors have entered the transportation field to-day and there is a major problem in co-ordinating them.

In 1909 there were registered in Canada 4,700 motor vehicles: in 1915, 89,000; in 1930, 1,235,000.

The extent to which the motor car is competing with the railways can be appreciated from the large increase in passenger miles travelled in private automobiles, which increase has been in excess of 500 per cent from the year 1925, exceeding the railway passenger miles by 300 per cent, or at a ratio of 12,000,000,000 annual passenger miles to 3,000,000,000 on the railways, with the buses operating a smaller total of 250,000,000 passenger miles.

The passenger revenue of the Canadian railways has been progressively decreasing from $75,000,000 in 1923 to $31,000,000 in 1934. A large part of this loss is due to the passenger auto and only a comparatively small amount to the operation of buses.

As regards freight the motor truck is in aggressive competition with the railway. There are in Canada 150,000 trucks of which 88,000 are registered in Ontario and Quebec.

A secondary land transport system of highways has been constructed, whose mileage, capital cost and potential capacities approximate or exceed that of the railroads. The railroad faces a competitor which challenges its supremacy in the short-haul field.

In certain of the provinces, trucks are licensed under various classes. Of the 88,000 trucks in Ontario and Quebec about 2,000, including trailers, are in the business of common carriers. That is, they operate a general public trucking business over defined routes and usually between fixed termini. A second class is that of contract carriers having no definite route or schedule but which may, either within certain limits or in an unlimited area, make contracts to carry the goods of a particular shipper. With the present inadequate methods of enforcement, it is very difficult, if not impossible, to confine the truckers to the restrictions contained in their licenses and to the legislation under which they operate. Violations are the rule rather than the exception.

The Duff Commission estimated that the revenues of the common and contract carriers by truck amounted to over $30,000,000 per annum, and that of this amount $13,000,000 was taken from the railways.

The tariff structure of the railways has permitted the truck to compete within a limited range. Railway tariffs have beeu built upon a social basis rather than upon an economic one, rates being determined upon a commercial value and not upon the cost of service based on weight, bulk and distance travelled. Thus the railways must, for the good of the country, carry grain, coal and like commodities over long distances in carload lots, at actually less than average cost, and as a result, they must depend upon short hauls of the more valuable commodities to make up this loss. The very character of the truck competition, which limits its profitable operation to short hauls in small quantities, is enabling the trucker to carry a large percentage of the L.C.L. freight originally carried by the railways. Although the L.C.L. freight forms only 2.5 per cent of the total tonnage carried by the railways, yet it represents more than 10 per cent of their total revenues.

Thus the trucks take the cream of the traffic that has been relied upon by the railways to compensate for the less-than-cost handling of certain commodities which must be hauled cheaply in order to maintain our economic system and our position in the markets of the world.

Motor traffic has been heavily subsidized by governments through enormous programmes of improved road construction. It is variously estimated that the highway system of Canada has cost from $800,000,000 to a billion, with annual expenditures in the past running from $60,000,000 to $90,000,000, against a collection of revenue from motor vehicle operation of approximately $40,000,000. The difference must be charged to capital account, or made up out of the general fund provided by taxation.

It is recognized that the motor truck and bus have an economic field in the world of transportation, that they are here to stay and cannot be taxed out of existence or legislated into oblivion. It is their unregulated competition in fields that are not economic that causes the waste and increased costs to industry. It cost trucks carrying merchandise for over 500 miles 4 to 5 cents per ton mile, whereas the railways could carry it for less than one-third of this cost. In order to meet railway competition, trucks very often accept business at less than cost, without due knowledge of all the factors entering into their financial obligations.

At present, due to this unregulated competition, national economy, so essentially dependent upon a solution of the present railway problem, is unhealthy. The truckers themselves realize this, and it rests with public opinion, exerted in the right direction, to bring about a solution.

The time must come, if prosperity is to be enjoyed by this country, when, through the elimination of the weaker, road monopolies are established, or some properly enforced regulations are set up so as to put an end to the present extravagant and wasteful competition from this source.

It has been truly stated that under present conditions, freight, which was once hauled by the railways which paid taxes to the government, is now shipped over highways which tax the government.

The railways have to meet another problem in the subsidized transportation provided by our waterways—an important competitor which is not required to pay tolls or other equivalent share of the expense of providing, maintaining and operating the canals by which the great waterways from the Atlantic to the head of Lake Superior are made available for the transport of merchandise. To illustrate the importance of competition from this source, take the changed conditions in transportation brought about by the opening of the new Welland canal in 1930, which permitted the operation of greater draught boats between Lake Erie and Ontario. Although the tonnage handled on the St. Lawrence and Sault Ste. Marie canals remained about the same over the years 1930 to 1934, the tonnage on the Welland canal increased by over 50 per cent, or from 6,000,000 odd tons per annum to 9,000,000 odd tons per annum. What was gained by water shipping was lost to the railways.

Recently bills have been submitted to the United States Congress providing for a closer co-ordination of rail and water traffic, with a recommendation for through rates and charging of tolls. This matter should receive the serious consideration of our Federal government in dealing with the co-ordination of such service with land transportation.

In air transportation we enter a field of activity, the importance, general magnitude and trend of which are but little appreciated except by those who are actively engaged in this work.

Last year, the air lines of the United States operated approximately 200,000,000 passenger miles.

Including five hundred and forty-three pilots, there were over six thousand persons upon the payrolls of the United Air Lines Company of the United States. This company last year served three hundred thousand meals in the air, requiring a staff of one hundred and fifty stewardesses. The passenger who leaves New York for Los Angeles, San Francisco or Seattle, is served with four meals aloft.

It is interesting to observe that a questionnaire recently sent out by the United Air Lines to six hundred and thirty business firms making enquiry respecting their use of and attitude towards air travel, received replies as follows:—

To the question "Do you travel by air on business" 53 per cent answered "yes." To the question "Do you encourage your sales staff to use air transportation" 40 per cent said "yes." This contrasted with but 21 per cent in 1931. In reply to the question "Do you intend to make greater use of air travel in the future" 50 per cent replied affirmatively.

Railroads are devoting increased attention to air transportation not only because of the possibility of having to cope with that form of competition, but also in order to secure a better co-ordination of air and rail services. In its prime function of supplying nation-wide transportation, the railroad companies may have to reach out into remote areas where it would be economically impossible to supply any other form of transportation than that by air. The northern areas of the Dominion, coming, as they are, into increasing economic importance, have already been receiving the advantages of air travel and transport—a service of great worth to mining and other activities in isolated territories where other forms of transportation would be financially impossible.

A dispatch from Edmonton in the middle of January stated that the chief pilot for Canadian Airways, Limited, had just completed a noteworthy winter flight with furs and mail from Aklavik to MacMurray, a distance of 1,462 miles, which he accomplished in two and a half days. The flight was the more remarkable because at this season of the year, with only four hours of arctic twilight, the pilot, Mr. Walter Gilbert, made the jump from Aklavik to Fort Norman, 730 miles, in less than four hours.

Northern Canada is recognized as lying along the logical airway from Europe to the Far East. The hope has been expressed that Canada will not rest content with simply providing airports, but that she may reach out to establish regular aeroplane routes supplied with Canadian planes and manned with Canadian pilots.

It is claimed in a recent survey of air transportation made by United Air Lines that travellers by air in the United States pay an average of 2½ cents less per mile, and at the same time travel from 40 to 50 miles an hour faster than is the case in other countries. The average fare in the United States is said to be 6 cents per mile as contrasted with 8½ cents per mile in Europe, and with what is frequently a 10-cent per mile rate in other territories.

The year 1933 is the last one for which complete Canadian government aviation statistics are available, but a few 1934 figures have been issued. A number of the classification headings, such as aircraft miles, flights, hours and passengers, show a decline from 1931, although Canadian Airways' 1934 operations show a marked recovery from the 1933 low. On the other hand, freight and express and mail carried show substantial increases; thus the freight and express carried in 1931 was 2,372,000 pounds; in 1933 it was 4,206,000 and in 1934 approximately 13,500,000 pounds. Truly a remarkable showing. In 1931 the mail carried was 470,000 pounds; in 1933, 539,000 pounds; and in 1934, 626,000 pounds. At the end of 1933 there were in Canada 405 private air pilots, 474 commercial air pilots, and 403 air engineers, and 49 private aircraft and 296 commercial aircraft. Several new air transportation companies have begun operations in the northern mining districts and are showing quite remarkable results.

At the present time practically all large transportation concerns are devoting attention to the study of such pertinent factors as exert individual and collective effects upon the problems of transportation in order that a definite and clear course may be selected for the progressive administration of railroad and other transportation facilities.

Such a course is the more essential at this time because practically every railroad has been working along the lines of strictest economy and avoiding, so far as possible, large capital expenditures. These special economies have been exercised in order to keep existing equipment in the best possible repair. The time, however, is approaching when new equipment must be obtained, and in this connection real wisdom is required. New ideas will have to be most carefully scrutinized and evaluated. There is not capital available for non-productive equipment.

It is well recognized that all forms of transportation are essential and have their economic place in the transportation world, but they do not always remain in their proper place. They extend into the legitimate field of the railways. It is the unregulated, indiscriminate competition of trucks and other forms of transportation that is increasing the cost of transportation to industry and the people. You cannot have duplication and multiplication of services in the same field and expect to have economy. The loss due to unwise operation ends in bankruptcy, and such financial loss has to be borne by some industry or individual.

In the last twenty years one of the most important items of cost in transportation has been obsolescence, due to the rapid advance of the art, and this applies especially to the motor vehicle and the aeroplane.

In the United States legislation has been recently submitted providing for transport regulation by governmental authority to be applied to co-ordinate agencies of transportation.

Three principal developments in the field of railway passenger service have already had a stimulating influence on traffic, namely, streamlined trains, air-conditioning and increased speed. By the end of 1935 it is expected that six thousand passenger cars will be air-conditioned.

Many records of increased speed in passenger and freight services have been set up in the past year.

The year 1934 definitely put certain railways in the United States in the truck business, and pick-up and delivery service is now an integral part of the railway operations. Fast merchandise train service, with overnight delivery, is now provided to all points up to 300 miles, involving better and more closely supervised service.

The history of transportation reveals the fact that when Canadians launched upon the construction of a second and then a third transcontinental railway system, with all that was involved in competition and in losses incident to wasteful duplication, the three transcontinental railways were headed for economic distress. The railways fully recognize the right of legitimate competition. Where it is conducted on a reasonable and fair basis, the railways, no doubt, will continue in the future, as they have done in the past, to meet such competition so far as it is economically possible. They have no inclination to proceed unjustly upon any coercive or destructive lines. They look rather to attainment by means of intelligent co-operation and just regulation.

Electrical Developments in Russia

Some further information on the ways in which electricity supply is being developed in Russia under the Second Five-Year Plan is given in recent issues of "Elektrichestvo." Broadly speaking, the object is to increase the annual output from the 13,400,000,000 kw.h. of the last year of the First Five-Year Plan to 38,000,000,000 kw.h., and to produce 24,500,000,000 kw.h. of this total in "regional" as compared with "industrial" stations. If this is achieved, it is estimated that Russia will take the first place in electrical output among European countries by 1937, and will only be outdistanced in the world by the United States.

This development will be based on the use both of local fuel supplies and of water power. The Stalinogorsk and other stations in the Moscow district will be operated on brown coal, and their annual consumption is expected to rise to 2,472,000 tons, as compared with 597,000 tons in 1933. Coal from the Ural will be burnt to the extent of 1,728,000 tons at Perm and Chiliabinsk, while the station at Cherenchevsky is being designed to use East Siberian coal. It is also proposed to use oil-shale from the Kashira field for the first time in the extended Samara station and at Saratov, while the employment of Gdovsk shale in the Leningrad district is being considered. A deciding factor in this connection may be the utilization of the ash, which is produced in large quantities, for industrial purposes. A large number of stations are also being built to utilize peat, including those at Gorkovsky, with an output of 201,000,000 kw.h., and at Shatura, with an output of 180,000,000 kw.h.

As regards water power, twenty-five stations with an aggregate capacity of 2,000,000 kw. are being built. These include one at Gizeldon in the Caucasus, with a capacity of 22,000 kw. and an operating head of 312 m., and one at Nijnisvirsk, with a capacity of 96,000 kw. and an operating head of 19.5 m. The former is equipped with Pelton, and the latter with Kaplan, turbines. A large station will be that at Verchnisvirsk, on the river Svir, with a capacity of 144,000 kw. This will be used to supply the Leningrad district. Plans are also being prepared for the construction of a station on the river Cherchik, in Central Asia, which will have a capacity of 170,000 kw. and will be used to supply the works of a chemical combine. Another station of some interest is that at the outlet of Lake Sevan in Armenia, which is at 2,000 m. above sea level. The most important hydro-electric schemes are, however, those on the river Volga, where stations are to be constructed at Yaroslav (100,000 kw.), and at Balachna (200,000 kw.), and on the river Kahma, where a station with a capacity of 360,000 kw. is to be built at Perm. These and other stations form part of the plan for improving the navigation of the Volga, Svir, Dnieper and other rivers, and for developing the irrigation facilities. It is estimated that the annual output from hydro-electric stations will eventually reach 4,800,000,000 kw.h., the equivalent of 3,000,000 tons of fuel.—*Engineering.*

CORRESPONDENCE

To The Editor of the "Journal,"
Engineering Institute of Canada,
2050 Mansfield Street,
Montreal, Que.

Dear Sir:—

Now that the period has expired during which essays on the "Consolidation" problem may be submitted for the Past-Presidents' Prize, I would like to present to the membership, through the medium of The Journal, a memorandum on this question which I have prepared after much thought and much consultation with members throughout the country. This memorandum is also being presented in a spirit of co-operation to the Committee on Consolidation for their study but is being sent to The Journal in order that it may reach the whole membership and prove to them that alternative schemes to that broadcast by Mr. G. M. Pitts are not only possible but have been present in the minds of members in various parts of the country and are actually expressing themselves in simultaneous and unconnected movements in the different provinces. While I can connect no names other than my own with the following remarks, they do certainly arise out of numerous discussions with individuals of all shades of opinion in as many of the Branches as it has been my privilege to visit.

Yours very truly,

(Signed) P. L. Pratley, m.e.i.c.

Memorandum

Any serious effort to solve the problem presented by the existing duplication of engineering organizations in Canada must be based upon the recognition of certain fundamental facts which may perhaps be expressed for present purposes as follows:—

1. It must be recognized that only to a very limited extent is engineering a profession in the proper sense of that word, and that comparisons with the other vocations where the degree of professionalization is very different, are at least misleading and are potentially dangerous. Admittedly the meaning of "profession" may be revised or redrafted or stretched to various degrees, depending on the object in view, but basically, everybody knows that the essence of the idea is the personal contact between the "professor" and his client, whether he be lawyer, doctor or dancing-master. A considerable percentage, probably a large majority and possibly an increasing majority of engineers, particularly in the cities, are and will remain employees of corporations and industrial firms. These represent what might be termed the capitalistic edge of the wide field of engineering. On the other hand, in the provinces as distinct from the cities, an increasing percentage, under the socialistic tendencies of the times, are becoming employees of the state. To the former the provincial organizations have no appeal whatsoever and the licensing idea is totally inapplicable. By the latter the provincial organizations are regarded, whether consciously or not, as a type of trade union in no sense valuable to the public and only useful to the engineer as they limit the number of entrants or applicants for employment.

2. It must be recognized that at least two very different and distinct motives operate toward the formation and continuance of engineering societies, namely:—(*a*) service to and among engineers themselves—and (*b*) service to, and responsibility toward the public or private client. Item (*a*) postulates an organization of engineers which is mutually educative, which by means of meetings, papers, lectures and other forms of collaborative effort can increase the circulation of technical information, make available to the many the experience of the few and so raise the general standard of knowledge and ability. Item (*b*) postulates a system of protecting the public from incompetent or inexperienced individuals seeking their confidence upon false or insufficient claims to qualification: a system whereby the public are assured, as far as is humanly possible, that the engineer with whom they are dealing and upon whose advice or ability they are relying, is qualified by training and experience to assume responsibility for engineering works which involve public safety or which minister to public needs.

3. It must be recognized that while item (*a*) above may well be a national affair calling for a Dominion-wide organization, item (*b*) is by force of circumstance provincial in its strictly legal aspects. There is every advantage in making (*a*) national and no advantage in overemphasizing by undue or deliberate differentiation the necessity of a legal provincialism in (*b*).

4. It must be recognized as desirable that the element of compulsion be as far as practicable removed. Engineers must be attracted, not compelled, to join the National Institute and only a certain few whose responsibility to the public may be regarded as demanding it should be compelled to apply for a license to practise and show qualifications therefor.

Before dealing specifically with the existing state of affairs and the possibility of its transformation, there will be first presented in a general way the organization which from a practical viewpoint seems nearest to the achievable ideal. By practical viewpoint is meant that viewpoint which recognizes instead of disregards the four statements above written. The organization herein set forth involves the minimum of disturbance within the existing societies, the least seeking for new powers, the removal of the undesirable feature of 'compulsion' indiscriminately applied, the opportunity for a definite raising of the standard and status of the licensed engineer, a policy of encouragement for younger engineers to fit themselves for advancement, and most important perhaps, the elimination of the double set of fees.

For the national organization, concerned with the dissemination of knowledge, the welfare of the engineer technically, socially and to some extent financially, and with the wider contacts between engineering and public policies, the present E.I.C. seems logically to be the best fitted medium, subject probably to some interior development in the way of decentralization. This body would endeavour to enrol within its membership all persons employed or employing themselves in technical engineering work insofar as all such could either help, or be helped by, others of similar or related interests within the broad field of engineering. The general requirements for admission to the various grades of membership or associateship would be set up by the members themselves acting through their elected national council, leaving some leeway possibly for interpretation by the provincial divisions of the

National Institute who would be the active operating units and who would thus control admissions and elections. Each provincial division under its vice-president and its provincial council would include a licensing committee, either appointed or elected as may be arranged and which would administer the local act, serving exactly as the council of the present Provincial Association or Corporation. This Licensing Committee would deal, not only with members of the National Institute, but with all other engineers who by law or by choice came under its jurisdiction in respect to licensing, just as the existing provincial councils do. Under this Provincial Licensing Committee would come, as part of the duty of administering the act, the matter of issuing licences to engineers wishing to practise in direct contact with the public, i.e. consulting engineers in private practice, chief engineers of corporations selling materials, machines, facilities or services to the public, chief engineers of public service bodies, commissions, or boards, and heads of departments doing engineering work for municipal, provincial and federal governments (as far as the law permits). Such engineers and *only such* should be required, in consideration of their direct responsibility to the public to be licensed by law and such licences should be a real assurance that the possessor is trained and qualified by experience to practise in some definite field or fields of the profession. The qualifications should definitely include corporate membership in the national institute, or at least an acceptance from that institute that the engineer in question is fully qualified therefor, or in the case of a foreigner, seeking a temporary licence, equal standing in his own national body. The holding of this provincial licence by an engineer in such practice or positions as those just outlined would be the *only compulsory* feature in the whole organization.

Other fully qualified engineers wishing to do so would be allowed to register with the Provincial Licensing Committee, which procedure would save both time and trouble to themselves in the event of their being promoted or moved to a position requiring a licensed incumbent, or setting up in private practice.

Similarly, young graduate engineers wishing to do so, would be allowed to register with the Provincial Licensing Committee as having qualified in part, and having commenced to acquire experience. Such graduates, having ambitions toward private practice or advancement to positions requiring licensed engineers, would thus also save themselves time and trouble later on.

Both Registered Engineers and Graduate Engineers would be voluntary listees with the Committee and would only be charged nominal rates, and would enjoy a certain status possibly useful in applying for employment. When in the course of events either a registered engineer or a graduate engineer applied for a licence in some special field, such licence would be issued as a matter of course to the former and after investigation to the latter, when they would become liable for the extra fee as a Licensed Engineer. The graduate engineer might reasonably be required to become a corporate member of the national body, if not already one before being eligible for a licence, but certainly should be required to show that he was so qualified, as none but corporate members and those able to qualify for corporate membership should be licensed.

There would thus appear under the Provincial Licensing Committee lists of Licensed Engineers, Registered Engineers, and Graduate Engineers. It is not intended that these titles should be used as letters after the names of individuals, although they should appear on letterheads and possibly on plans, and the lists should at all times be accessible to the public. As to fees, the Licensed Engineer would, naturally, have to pay annually in addition to his regular Institute fees an amount set by the Provincial Division, but preferably uniform all over the country, and not likely in excess of ten dollars. The merely registered engineer and the graduate engineer could only be charged nominal additional sums as the service is only slight and the advantage more a matter of personal opinion. Possibly two dollars would be reasonable. Fees would be paid to the Provincial Division of the National Institute, the part belonging to the Licensing operation being retained by the Provincial Division together with a certain proportion of the Institute membership fees, and a pre-determined portion being remitted to National Headquarters. Fees from licensed engineers who are not corporate members of the National Institute should be substantially higher than the additional amount charged to members, but should not be more than the total fees payable by corporate members, and no part of this fee should find its way to the National Institute headquarters.

As to the accomplishment of this new consolidation and the transition from the existing conditions, and the transformation of the existing Societies, the principal requirement is the "will." If the "will" be reasonably unanimous and be founded on sound conceptions of the purpose and basis of consolidation, then the "way" will become relatively easy. There may undoubtedly be certain difficulties in some quarters. There may be entailed in some provinces a certain surrendering or realignment of present powers possessed, or apparently possessed, by the existing Provincial Corporations. For instance, those Corporations which hold that no one can be an engineer apart from the possession of a provincial licence will, of necessity, surrender this extreme and logically untenable position in favour of the logical attitude that a certain well defined group of engineers should definitely qualify for and receive licences as a protection to the public. Furthermore, the idea must be definitely discouraged that any association of engineers whatsoever may be used as a means of increasing financial remuneration at the public expense, on a power basis rather than a merit basis. It is also possible that the question of mining engineers will become serious in some provinces, but the provisions above outlined do not necessarily demand that all licensed engineers belong to the National Institute, and it would be quite practicable to permit mining engineers to substitute the C.I.M.M. for the National E.I.C.

Many details, naturally, are not referred to in this brief presentation, and some important matters still remain to be worked out, but the machinery exists for setting up the Provincial Divisions of the E.I.C. Some development of the E.I.C. in the direction of decentralization and provincial autonomy has already been acknowledged as overdue by most of the committees and thoughtful students of the Institute's future; in some provinces the councils of the Provincial Associations are at present almost identical with the elected officials of the E.I.C. from the province, and furthermore a spontaneous movement is noticed toward identity of personnel as between the Association Council and the representative committee of the Institute in that province. Arrangements could readily be made for non-interruption of existing activities, non-interference with existing lists of licensees, retention of provincial balances in the hands of Licensing Committees acting as successors to the present Association councils. It is quite possible that alterations to some of the existing acts would ultimately be required, but with the co-operation of the present associations there would not seem to be any overwhelming reason why the scheme of consolidation could not be implemented provisionally and the alteration in the acts delayed until two or three years of experience had been obtained. In any case, the difficulties of transition are bound to be much less than in some of the schemes which have been presented for consideration. The fact that so much of the idea of compulsion would be removed and that one fee only would be exacted from any engineer, would assist greatly among the great body of engineers in making it not only possible but easy to overcome the seeming difficulties, the existence of which is bound to be referred to by those not initially favourable to this present proposal.

The proposal, as here outlined, has in addition to these two advantages the further value that the Institute as a national body can retain its primary function, which is the dissemination and interchange of technical knowledge, and keep open its doors to all those worthy contributors to the progress of engineering who may never reach the professional status, and yet provide fully for all reasonable demands regarding licensing, but definitely on the basis of protection to the public.

P. L. P.

OUTLINE OF PROPOSED ORGANIZATION

NATIONAL E.I.C.
General Council, and Headquarters
Pres., Secy., Editor, Hon.-Treas.

- Hon. Members
- Provincial Division
  Provincial Council
  V.P., Prov. Secy.-Treas. and Registrar*
  - Licensing Committee**
    Lists of Licensed Engrs.
    Registered "
    Graduate "
  - Other Committees
  - Branches in Prov.
    - Members
    - Assoc.M.
    - Jrs.
    - Students
    - Affil.

*The Provincial secretary-treasurer will be registrar.

**The committee, if elected, chosen from and by licensed engineers, whether members of Institute or not.

BRANCH NEWS

Border Cities Branch

C. F. Davison, A.M.E.I.C., Secretary-Treasurer.
F. J. Ryder, S.E.I.C., Branch News Editor.

New Ford Foundry

On Friday evening, March 29th, 1935, members of this Branch were guests of the Ford Motor Company of Canada. Dinner was served to about eighty persons, including newspapermen and members of Ford's staff.

H. J. Coulter, A.M.E.I.C., chairman of the Branch, extended his thanks to the Ford Motor Company for its kind invitation.

Mr. Wallace Campbell, president of the Ford Motor Company of Canada, spoke a few words welcoming the engineers and commented on the benefits to the automobile industry derived from this profession.

Mr. Coulter introduced Mr. J. S. Beaumont, chief chemist for Ford Motor, who presented a short paper on the "New Ford Foundry."

This foundry is designed for the casting of Ford crank shafts. The metal making up the charge is all very carefully weighed and dumped into the electric arc furnace, where it is kept at a temperature of 3,000 degrees F. for eighty-two minutes. The entire furnace which is built on a cradle is then tipped and the molten metal is run off into ladles and then into specially prepared moulds. Each mould is made up of sixteen separate moulds, which when locked together will form four complete crankshafts. In the making of these moulds the variance permitted is thirty thousandths or approximately 2/1000 per unit mould.

This new crank shaft of cast alloy steel is better than the old type, because like cast iron it absorbs some of the vibration. It will withstand a twisting strain of 88,000 pounds which is ten times that actually used. In a test run to destruction with the centre bearing 1/32 inch out of line, the new cast shaft ran seventy hours as against forty-five hours for the forged one. There are fewer machining operations on the new shaft as only nine pounds of metal has to be removed as against twenty-four pounds on the forging.

Mr. Beaumont explained that this theory for the better qualities in the new cast crank had to deal with the "fluidity" of the crystal about which very little is understood at the present time.

The group then adjourned to the foundry where they had the opportunity of seeing the metal poured from the furnace and the detail connected with the making of the cores.

Lakehead Branch

Geo. P. Brophy, A.M.E.I.C., Secretary-Treasurer.

The Lakehead Branch of The Institute expressed its appreciation of one of its oldest members and the high esteem in which he is held as a citizen and a member of the engineering profession when it tendered a complimentary dinner to its chairman, J. Antonisen, M.E.I.C., on Friday, April 12th last.

J. Antonisen, M.E.I.C.

The dinner was given in the Garrison Officers' Mess at Port Arthur through the courtesy of the Commanding Officer and Officers of the Lake Superior Regiment, and our forty members and Branch guests enjoyed an excellent dinner in surroundings which combined to make the occasion one which peculiarly suited the purpose of honouring the guest of the evening. Altogether it was an enjoyable event and one which marked a spontaneous tribute to the engineering services rendered by Mr. Antonisen for many years as city engineer of Port Arthur, a service which was terminated at a loss to the city on March 1st, 1935.

Representatives of the Law Society, the Dental and Medical Associations, the Surveyors, Public Utilities, Power and Paper Interests, Railways and the Architects were among the guests of the Branch and all of these, in addition to engineering members, united in paying their respects to the man, the citizen and the engineer, and in wishing him continued success in his next field of endeavour.

P. E. Doncaster, M.E.I.C., as vice-chairman of the Branch, presided, and outlined the broad academic and engineering foundation on which Mr. Antonisen's professional career was based. He expressed the sentiments of all present in the statement that Canada would always welcome engineers from Norway or any other land who brought with them the high cultural and ethical standards which the guest of the evening combined with a sound engineering training and practice.

Mr. Antonisen replied to the many complimentary references to him in his own inimitable way and manner and, if possible, heightened the feeling of loss which the community and the engineering circle of the Lakehead Branch has sustained in the breaking of a long and happy association.

The annual meeting and election of Branch officers is scheduled for June 4th, 1935, at Fort William, and there is much promising timber in the younger members of the Branch from which to choose a strong executive.

Hamilton Branch

A. Love, M.E.I.C., Secretary-Treasurer.
A. B. Dove, Jr.E.I.C., Branch News Editor.

Bulk Handling

The Hamilton Branch of The Institute held their regular meeting at McMaster University on May 14th, 1935, to hear Mr. J. Farley, of the Link Belt Company, discuss the important subject of "Bulk Handling."

Mr. Farley stated that, with the development of the anti-friction idler, designers have reduced the power required in horizontal drives and belts to 3/5 the figure formerly necessary; the direct outcome, of course, was lighter belts, faster drives, etc. Distributing ploughs, shuttles, and trippers will now place belt-carried materials exactly where required.

He described in some detail uses of various types of general handling equipment including ship hoists, elevators, screws and chain belt equipment. Ship hoists, he stated, are now in large measure replacing elevators. Screws are extremely useful in handling non-abrasive materials. Some modifications in the former design of chain link conveyors have greatly improved their efficiency and lowered maintenance charges.

Mr. Farley then showed a motion picture of the operations at the Marblehead Lime Company of Chicago which was enjoyable in that the audience could view the interesting operations of crushing, screening and calcining without the atmospheric dust disturbances usually so troublesome in visiting the scene of such operations. Several technical points discussed by the members were explained by Mr. Farley.

A hearty vote of thanks was accorded Mr. Farley for his kindness in preparing so interesting a paper upon a broad subject. The meeting adjourned, and refreshments were served in the McMaster Chemical Laboratory.

Attendance, 40.

Quebec Branch

Jules Joyal, A.M.E.I.C., Secretary-Treasurer.

Newsprint Paper Machines

This was the subject of a talk given by Mr. James O'Halloran, A.M.E.I.C., of the Anglo-Canadian Pulp & Paper Mills Limited, Quebec, at a meeting of this Branch held on March 4th, 1935.

Mr. O'Halloran's lecture was illustrated and for that reason the subject cannot be easily summarized; however, the main purpose of the speaker was to outline some of the principal operating and mechanical features of a modern high speed newsprint machine. This was done in a very able manner and the audience was greatly interested.

Short mention was made of mechanical and chemical pulp processes, attention was drawn to the fact that it requires approximately 1¼ cords of wood to produce one ton of newsprint paper.

The speaker then described a complete paper machine, and in concluding said that the last few years have been such difficult ones for the Canadian paper industry, that they have caused very careful studies to be made of the paper machines with the idea of increasing their operating efficiency and their speeds. Increased production without increased investment in equipment is a definite means of lowering production costs and this has been accomplished in a great many cases. Machines which five years ago had a maximum speed of 900 feet per minute can now successfully operate at 1,200 feet per minute due to careful study and adjustment with only minor changes in equipment.

Every part of the machine is receiving the closest attention at the present time, and it is hoped that the results will be faster and more efficient machines will help to lower manufacturing costs to a point where a profitable operation may be expected.

Saguenay Branch

J. W. Ward, A.M.E.I.C., Secretary-Treasurer.

PAPER MAKING

On Friday evening, May 10th, 1935, S. J. Fisher, M.E.I.C., gave a paper on the subject of "Paper Making, Ancient and Modern," before a meeting of fifty-two members and guests.

The speaker commenced his address by giving a brief history of the art of paper making. Before the first paper was made by the Chinese about 120 B.C. stone and bronze tablets were used, followed by parchment made from the skins of animals, and papyrus which was made by moulding or pressing the pith of a reed.

Paper may be described as a web, formed of strands of vegetable fibre first separated then recombined. This process was performed by the first paper makers, by breaking down wood or other vegetable matter under water. After obtaining a sufficient quantity of the mixture of fibre and water, a screen or mould was dipped into it, brought up and allowed to drain. A mat of interlocked fibre was left on the screen which was allowed to dry. The surfaces were smoothed by rubbing with stones.

The art spread slowly from China, reaching Bagdad about 793 A.D. and Morocco in 1100. It was introduced to Europe about 1390, reaching England by 1494 and America in 1690.

The hand mould process with improvements to moulds and fibre processing, continued to be the only manner of paper making until 1800 when the first developments were begun on continuous sheet machines.

Present day newsprint consists of 20 per cent to 25 per cent of sulphite pulp and the remainder ground wood pulp. Sulphite pulp gives the paper the strength required and the ground wood pulp gives it the high speed printing qualities. The best wood for newsprint is spruce with the addition of a small percentage of balsam.

The paper which was well illustrated with slides proved to be very interesting, and a hearty vote of thanks was tendered the speaker.

* * *

Immediately following the reading of the above paper, the members of the Branch held a meeting to discuss the proposal of G. McL. Pitts, A.M.E.I.C., regarding the amalgamation of The Institute with the various provincial associations of professional engineers. After some discussion a committee consisting of Messrs. H. R. Wake, A.M.E.I.C., G. F. Layne, A.M.E.I.C., J. Shanly, A.M.E.I.C., and H. B. Pelletier, A.M.E.I.C., was formed to make a further study of this proposal, and to prepare a motion to be placed before the next meeting. This motion, subject to the approval of a majority of the members, will take the form of an expression of opinion of the Saguenay Branch regarding the proposed amalgamation.

There being no further business the meeting adjourned.

The Late D. N. Dunlop, O.B.E.

Mr. D. N. Dunlop, O.B.E., founder of the World Power Conference, died on May 30th, 1935, after a short illness.

Born in Ayrshire, Scotland, in 1868, Mr. Dunlop served his engineering apprenticeship in Glasgow, and in 1896 became connected with the Westinghouse Company, retaining this connection until 1911 when he was appointed the first organizing secretary of the British Electrical and Allied Manufacturers' Association (B.E.A.M.A.), holding the position of director of that body until his death.

Soon after the war Mr. Dunlop conceived the idea that the engineers and scientists whose inventions had been so powerful in destruction, should lend their great talents in the rebuilding of the world.

As a result of his efforts, on June 30th, 1924, the Prince of Wales opened the first World Power Conference in the presence of representatives of about forty countries. From this conference grew a permanent organization continuing the work begun in 1924, so that during the past eleven years the second plenary World Power Conference has been held in Berlin and sectional meetings in Basle, London, Barcelona, Tokyo and the Scandinavian capitals, while the Chemical Engineering Congress of the World Power Conference will take place in London next year.

The World Power Conference has now become a highly important international body with forty-nine member countries, and a central office in London, and bids fair to realize Mr. Dunlop's vision of a meeting place between scientists and engineers on the one hand and statesmen and economists on the other. The success attained is in no small measure due to his personality and organizing gifts.

The McCharles Prize

The fifth award of the McCharles Prize has recently been made to Harold W. Price, B.A.Sc., professor of electrical engineering in the University of Toronto.

The McCharles Prize was established by the Board of Governors of the University of Toronto through a bequest by the late Æneas McCharles, and provides for an occasional award of the value of $1,000. The award is made for distinction in scientific research, the discovery or invention of processes of benefit to Canada and applicable on a practical scale.

The present award is for the invention and application of devices for improving the control and quality of electric power service in large systems. Its application to the Hydro-Electric Power Commission of Ontario has already produced a marked benefit to electric power users.

Six Ways to Figure Radiation, edited by Harold L. Alt (*Domestic Engineering Publications*).

Jones' Estimating Tables on Air Requirements and Duct Sizes for Heating and Air Conditioning (*Domestic Engineering Publications*).

The Principles of Electric Power Transmission, by H. Waddicor (*John Wiley and Sons, Inc.*)

BOOK REVIEWS

Six Ways to Figure Radiation

Edited by Harold L. Alt. Published by Domestic Engineering Publications, Chicago. 1935. $2.00. 3¾ by 6½ inches. Imitation leather.

In this small book the author describes six recognized methods of figuring the radiator surface for a house and explains how to use them. Their application is illustrated by a practical example.

Jones' Estimating Tables

By Ernest F. Jones. Published by Domestic Engineering Publications, Chicago. 1935. $2.00. 5¾ by 8¾ inches. 68 pages. Imitation leather.

This book is of interest to those who have to estimate for forced air heating for residences and other small buildings. Four sets of tables (degree difference of 90, 80, 70 and 60) are given with multiplying factors for c.f.m. requirements on nine different factors of heat loss.

The book also contains charts of duct sizes and tables for determining register and riser sizes. An example shows the application of the tables and factors.

The Maiden Voyage of the S.S. "Normandie"

The s.s. *Normandie* of the Compagnie Générale Transatlantique, has secured for France the coveted Blue Riband of the Atlantic on her maiden voyage. The vessel left Le Havre at 5.20 p.m. g.m.t. on Wednesday, May 29th, and proceeded at between 28 knots and 30 knots to Spithead, picking up passengers from England in Cowes Roads. Leaving there in the early hours of Thursday, May 30th, she proceeded down Channel, being at first somewhat delayed by mist. She, however, passed Bishop's Rock, off the Scilly Isles, at 11.48 a.m. g.m.t., and passed the Ambrose Light at 2.50 p.m. g.m.t. on Monday, June 3rd, having thus steamed the intervening distance of 2,971 miles in four days three hours and two minutes, at an average speed of 29.98 knots. Notable as this performance is, it would have been improved upon but for the fact that the speed had to be reduced for a period of about eleven hours on Saturday, June 1st, owing, we understand, to the failure of a condenser tube. It may be of interest to recall here that the Blue Riband was previously held by the *Rex*, with an average speed for the voyage between Gibraltar and New York of 28.92 knots. Before that the *Bremen* made a run between Cherbourg and New York at 28.51 knots, and the *Mauretania*'s record was 27.22 knots between Ambrose Light and Plymouth. The *Mauretania*, it may be remembered, was twenty-two years old when her record was made.—*Engineering.*

Archaouloff System of Fuel Injection in Diesel Engines

The M/S *Calgarolite*, a vessel of 17,000 tons deadweight owned and operated by Imperial Oil, Limited, Toronto, Canada, has recently had the fuel injection system of her main engines converted from air injection to solid injection.

The *Calgarolite* is equipped with twin Krupp six-cylinder, two-stroke cycle single acting diesel engines, each developing 2,450 b.h.p. at 90 r.p.m. Commissioned in July 1929 the vessel's engines were operated under the air injection system till January 1934 when the Archaouloff system of solid injection was installed. This system of fuel injection is easily fitted and does not necessitate any considerable amount of alteration to the engines. The basic idea of the scheme devised by Professor Vadim Archaouloff and further developed by Krupp engineers consists in utilizing the compression pressure in the engine cylinder to operate the airless fuel-injection pump. Briefly, all that is required to convert from air injection to solid injection is to fit in place the Archaouloff injection pump, replace existing fuel valves by different type valves and make a few piping alterations, all of which can be and have been done by the ship's personnel at sea with negligible interruption to the vessel's regular schedule.

Each engine cylinder has its individual injection pump (Fig. 1) which consists of a vertical water cooled cylinder having a bottom but no cover or head and fitted with a piston. This gas or power cylinder is open to the atmosphere at its upper end and at its lower end is connected to the compression space of its respective engine cylinder by means of a pipe. Connected by suitable means to the piston of this cylinder is a second piston or plunger extending upward and working in a fuel cylinder. The fuel cylinder is open to the atmosphere at the lower end and closed by means of a removable head at its upper end. A horizontal duct through the cylinder wall together with a high pressure pipe forms the connection between the fuel space of the fuel cylinder and the fuel injection valve of its respective main engine cylinder. The head of the fuel cylinder is fitted with a spring loaded fuel inlet valve and an escape valve, the latter used for priming purposes when starting up.

The diameter of the gas cylinder is 86 mm. and of the fuel cylinder 25 mm. stroke of each 38 mm. The gas piston is fitted with rings in the usual marine manner while the fuel plunger is of the solid lap fitted type.

The Archaouloff apparatus, gas and fuel components is a compact unit and to install it on the *Calgarolite* all that was necessary was to remove a "U" bend which formerly led the cooling water from the main engine cylinder jacket to the main engine cylinder head, fit a special

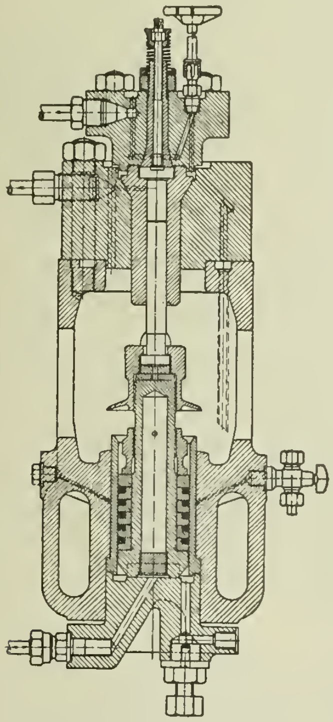

Fig. 1—Section through the Injection Pump—Archaouloff-Krupp Diesel Engine.

elbow to the jacket cooling water outlet in place of the "U" bend, connect the apparatus to this elbow and make a return water pipe from the Archaouloff gas cylinder to the main engine cylinder head. By this means the cooling of the gas cylinder was taken care of and a convenient method afforded of securing the whole apparatus in place without affecting the circulation of the cooling water of the main engines. In addition to above there were necessary alterations to existing fuel piping and the provision of some extra piping and fittings.

Figure 1 shows diagrammatically the Krupp arrangement of the Archaouloff device. *A* is the air cylinder of the injection pump; *B* the fuel-injection pump; *C* the fuel valve; *D* the pipe taking the gas from the combustion chamber to the injection pump which may be shut off by means of cock *E*. The fuel passes at *F* from the fuel pump into the injection pump and into the pressure chamber through valve *G*, then through the pressure pipe *H* to the fuel valve. *J* is a lever connected with the fuel valve in order to vary the tension in the valve spring.

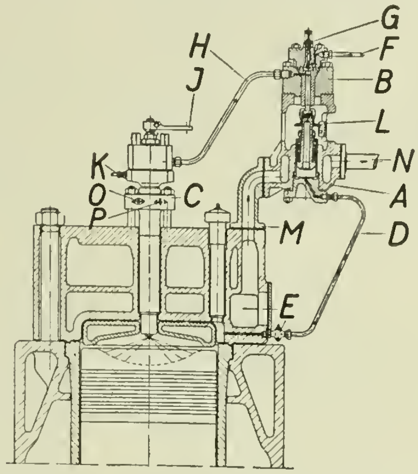

Fig. 2—Section through the Cylinder Head.

K is the connection for a leakage pipe, which provides an outflow for the fuel, which runs in droplets along the valve needle. *L* is a scale showing the lift of the piston.

The cooling water from the cylinder cover used to cool the air cylinder of the injection pump comes in at *M* and leaves at *N*. *O* and *P* are the corresponding cooling-water connections for the fuel valve.

The fuel pumps used on the main engines using air injection system remain unaltered but instead of delivering fuel direct to an air injection cam-operated fuel valve on the main engine cylinder head they now deliver the quantity of fuel necessary for the desired speed of the engine through the spring loaded valve in the fuel cylinder head, the piston being at this time free to move downward to accommodate the amount of fuel delivered. The fuel having been thus delivered compression in the main engine cylinder commences and the under side of the gas piston being in communication with the main engine cylinder by means of a pipe as previously mentioned, a pressure is exerted on this piston, transmitted by it to the fuel plunger and thus to the fuel oil previously delivered to the top of the plunger. The diameter ratio of the gas piston to the fuel plunger being approximately 3.4 to 1 a point is reached at which the pressure on the fuel is sufficiently high to open the automatic fuel injection valve on the main engine cylinder head and the process of injection commences. This process terminates when the fuel plunger closes the horizontal delivery duct in its cylinder wall. The main engine fuel pumps at the proper time again deliver the required quantity of fuel to the fuel cylinder ready for the next revolution, driving the fuel plunger and gas piston downward, a distance according to the amount of fuel delivered.

The Archaouloff system of fuel injection differs from usual methods in both air and solid injection engines in that the timing of injection is not controlled by a cam-actuated fuel injection valve as in an air injection system or by a fuel pump driven by a cam as in other solid injection systems. The timing of injection is controlled by the pressure on the fuel in the fuel cylinder and is not governed by a predetermined crank angle. Injection commences as soon as the pressure on the fuel is sufficient to lift the needle of the spring loaded fuel injection valve on the main engine cylinder head so that beginning of injection is variable with the load of the spring. As combustion commences the pressure on the gas piston increases and the process of injection is accelerated.

The Archaouloff apparatus is purely an injection pump. The amount of fuel delivered to the various cylinders of the engine is controlled by the supply pump, in this case the fuel pumps used in the former air injection system.

Provision is made against overcharge of fuel delivery, for thorough priming previous to starting up and for cutting out any one injection pump for overhaul or repair without stopping the engines.

The system has operated very satisfactorily on the M/S *Calgarolite*. Compared with the former air injection system manoeuvring qualities have been greatly improved, engines start promptly from cold and the quantity of starting air required has been greatly reduced. Since installation of the system the vessel has covered 60,479 nautical miles at an average speed of 12 knots with a fuel consumption of 146.6 bbls. per day. With air injection system for 58,883 nautical miles distance covered the average speed was 12 knots and fuel consumption 159.25 bbls. per day. The reduction of fuel consumption with the solid injection system is 7.94 per cent and further improvement is expected as the period of operation shown includes time spent in making adjustments necessary to obtain efficient operation of the system. Some trouble was at first experienced with leakage in inlet valves on fuel cylinder heads and rings in gas cylinder pistons but these difficulties are being overcome. No trouble is experienced in timing the fuel injection. Adjustment of the fuel injection valve spring can be made easily and accurately and the pressure at which the fuel valve opens is approximately 300 atmospheres.

In September 1934 Imperial Oil, Limited completed installation of the Archaouloff system in their M/S *Victolite*, a twin screw vessel of 16,500 tons d.w., with four cylinder engines of type similar to the *Calgarolite* and the system has now been installed on the M/S *C.O. Stillman* owned by International Petroleum Company, Limited. This vessel is of 24,000 d.w. tons and is engined by twin, six-cylinder, two-stroke cycle, single acting M.A.N. Diesel engines developing a total of 4,300 b.h.p. at 90 r.p.m.

NOTE:—The two illustrations are reproduced from the January, 1935 issue of *Mechanical Engineering*.

Share the Wealth

Abstract of an address given on April 28th, 1935, by W. Cameron of the Ford Motor Company, Detroit.

"Share the wealth" plans usually begin with the assumption that wealth is money. Just share the money and you have shared the wealth! That is a fallacy. Money, being merely part of the bookkeeping system of society, is, or ought to be, the sign of wealth, but it is not and never can be wealth itself.

It is further assumed that wealth can be "shared" by taking it away and giving it away. There is a "catch" here also, for wealth is never wealth in the taking but in the using and the making, and to think of "sharing" as taking is only a half truth. Practically all of the actual wealth under Ford management consists in productive plants and machinery and what goes with them. They are wealth because under proper management they produce what people can use in living or in getting a living. How that machinery could be confiscated, and bit by bit distributed, and still be wealth;—or, if not distributed, how it could be managed by politicians or any other group of theorists and still remain a source of national wealth, no one takes the trouble to explain.

Up to the present time the most effective mechanism that experience has devised to "share the wealth" is industry. Industry is a market where people bring what they have, to get what they need. It is a trading centre where materials, labour, skill and science are changed into commodities useful to life. The farmer brings his produce to get industrial products in return. The miner brings his ore; the weaver his textiles, the millman his steel; the workers in rubber, oil and glass bring their products; railroad men and sailors bring their services and so on through a hundred lines of work that focus in every great industry. Everyone shares in the making in order to share in the taking. He brings goods or work, which is real wealth; he receives dollars which give him a claim on the equivalent of the wealth he has contributed. How this natural process works may be illustrated by what occurred in the Ford Motor Company during the first three months of this year.

The cars we made during those three months consumed more than $48,000,000's worth of labour in our own shops. That labour was rendered in all parts of the country, its equivalent was returned to all parts of the country: more than $3,000,000 in wages for the south, almost $4,000,000 in wages for the west, more than $5,500,000 in wages for the east, nearly $35,000,000 in wages for the great central area of the country. That was for three months in Ford shops only. Now, outside our shops, we bought from other industries more than $214,000,000 worth of materials during those three months. Of this sum those industries paid their employees nearly $72,000,000 in wages, and passed the remaining $142,000,000 along to their suppliers, who in turn paid their employees, and so on back along the whole line of supply until it paid wages to the last producer. So that for those first three months of this year we can count first-hand wage payments of $120,000,000 on work directly done for the Ford industry alone. And we can count an additional $142,000,000 in second-, third- and fourth-hand wage payments for work done for the suppliers of our suppliers all down the line. That is "sharing the wealth." For every car we made, some railroad or other shipping employee received $22 in wages. For every car we made, some worker in a rubber factory received $12.50 in wages. For every car we made, some worker in a steel mill received $12 in wages. And these were repeated 386,326 times over, for that is the number of cars we made during that period. For every ton of coal we burned, some miner received a dollar in wages, and you can multiply that by 600,000 tons. That is sharing. That is not speech-making.

All this in just one industry. Imagine hundreds of industries doing the same thing each in its proportion. Industry can really "share the wealth" because its first concern is to create the wealth. There is no division without creation. Never have creating and sharing been so effectively combined as in industry. There is no other way. The sharing process needs constant improvement, but certainly it does not need introduction. It is already here, and operating.

National Distribution of Electricity, Water and Gas

The striking contrast which existed some time ago between the economists who insisted that individuals should help their country by saving, and the school who considered salvation possible only through spending, was no less notable than that which to-day exists between the advocates and otherwise of public works. It will be remembered that the chief plank of Mr. Lloyd George's last election platform was the expenditure of some £50,000,000 on new roads, at a time when very many thought spending in this direction had already gone further than the actual needs of the country warranted. In this country, the attempt to meet the unemployment difficulty by such means has been spread over many years. Roads have been improved and marine parades constructed at seaside resorts by means of government grants and so on. However, this phase is passed, and there is no doubt that there is quite a body of opinion behind Mr. Runciman and Mr. N. Chamberlain in their contention that further effort in this direction is undesirable at present.

It would be possible, we suppose, to take an example, to compare the effectiveness of the road building schemes of recent years, with that of the grid, as a solution of the unemployment difficulty. The statistics might not be easy to come by, but it would appear to be not at all unlikely that from the employment viewpoint, the country has on the whole spent its money more wisely on the latter than on the former. Both have, of course, involved ancillary industrial activities, but the grid has kept busy many large works all over the country, has kept alive our best designing and business brains, and has employed skilled labour in construction, to say nothing of the industries again behind the makers of plant, added to which, with their works well occupied, many manufacturers have secured contracts which otherwise could not have fallen to them. And, withal, the work has been financed in the ordinary market, with the anticipation of a direct return, whereas road building involves the burden of taxation.

But if electricity is desirable, there is no doubt that water is an essential wherever there are habitations. We can exist without the former, but in the absence of the latter life is impossible. Modern education and sanitary reform have all been in the direction of impressing upon our people, from childhood upwards, the connection between cleanliness and health, and it is manifestly absurd to spend much money in instilling into young minds ideas of life which outside school premises it is impossible to follow. As years have passed, the scale of thought has advanced. A town dweller to-day, always a larger consumer than the countryman drawing from a well, uses far more water than did his father or grandfather. The villager, however, is little better off than formerly.

Any national scheme would, of course, aim at a better use of our resources and a better service to the rural and other areas now ill-supplied. To effect this would mean the opening up of new, and the improved distribution of existing, supplies. While this might mean quite probably relatively long-distance transmission in some cases, it appears to us to be quite beside the point to picture at this stage a very elaborate grid on the lines of the electrical system, merely to prove it to be impossible. Anything in the way of a water grid is clearly to be introduced only where necessary, and after due study and consideration.

As with water and electricity, so with gas. In recent years this industry has had a very well-founded complaint that the weight of the Government has been thrown into the scale in favour of a rival. The two supplies each have their appropriate field, and in some countries, where both are often in the hands of one company, are worked side by side with excellent effect.

At present, the tendency is to absorb companies into larger concerns, to inter-connect between the various works and to work for more efficient production by the use of the best installations of the group. Is it not possible that, taken in hand in the correct way, these might be further welded into a national system of distribution, while retaining, as with electricity, the identity of the actual producers, and, as with electricity, bring to the subject such government backing as would make feasible very great developments of supply. It has even been with some reason suggested that, put upon a similar footing in this respect, the two, electricity and gas, might cease to quarrel and turn their combined weapons on imported fuel.—*Engineering.*

The Canadian Ohio Brass Company Ltd., Niagara Falls, Ont., announces that it has extended the economy of its Universal strain clamp still further by introducing a baby universal clamp. In principle of design this new strain clamp is exactly like the larger O-B universal. The primary snub, in combination with a modified "V" wire-groove and a positive clamping member, makes this smaller clamp applicable to the range of conductor sizes and types used on rural electrification. The only differences in the two universal strain clamps are size and cost. The baby universal will take No. 6 to No. 2 solid or stranded cables.

Sawyer-Massey, Limited, of Hamilton, Ontario, have recently issued an attractive catalogue descriptive of their manufacturing facilities and illustrating the wide variety of equipment produced by the General Contract Department of their Industrial Division at their plant in Hamilton.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situation Vacant

PLANT ENGINEER, required for a modern newsprint mill in the province of Ontario. Give age, experience, education and salary expected. Reply to Box No. 1170-V.

Situations Wanted

SALES ENGINEER, S.E.I.C.; B.Sc. C.E., 1930 (Univ. New Bruns.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ENGINEER AND ACCOUNTANT, Jr.E.I.C., (Capt. Can. Engrs., reserve). Age 35, Canadian. Experienced in mechanical and civil engineering, Diploma; general office, draughting and instrument work; assistant engineer erection Royal York hotel; assistant resident engineer T. & N.O. Ry. const. Desires position in Toronto where combination of technical and business experience will be of value, as have been director and accountant last three years. Apply to Box No. 377-W.

CIVIL ENGINEER, B.A.Sc. and C.E.; A.M.E.I.C., A.M. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.Sc. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

MECHANICAL ENGINEER, B.Sc. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

CONSTRUCTION ENGINEER, age 26, unmarreid, graduate C.E. Experience includes hydro-electric, railroad, highway, and industrial plant construction, both field and office, including cost accounting, estimating, stores, layout, general engineering and supervision, as well as practical work in mechanical trades. Apply to Box No. 567-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

Situations Wanted

ELECTRICAL ENGINEER, McGill '31, desires permanent position in engineering field. Experience includes draughting, designing and testing of induction motors, radio supervision and test, and some construction. Available immediately. Apply to Box No. 626-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL ENGINEER, B.Sc. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box. No. 651-W.

ELECTRICAL ENGINEER, Univ. Grad. 1928. Two years Students' apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660 W.

An Interesting Experiment

Particulars of an interesting venture in endeavouring to assist junior engineers to secure employment in the mining district have been received from Manitoba.

During the past two or three years, the Joint Committee on Unemployment of The Institute and the Association of Professional Engineers made every possible effort to keep in touch with the mines in the province of Manitoba in the hope that young engineers might secure employment as labourers, and thus be on the ground when openings for engineering services should occur. Time after time, the Committee was too late in getting into touch with the mining officials. By the time a letter recommending a man for a job reached the mine, the position had been filled by someone on the site. Consequently the Joint Committee sponsored the idea of a camp to be established in the Rice Lake district, and four men were selected from the unemployed junior engineers to proceed to the central mines area and erect the shack. The cost was met by a grant from the Association of Professional Engineers of the Province of Manitoba to the Joint Committee, and transportation and living expenses were advanced to the four engineers selected, with the understanding that refunds should be made by them in instalments if and when they secured employment.

It is part of the plan that should permanent employment be obtained by the engineers in the camp, other unemployed engineers will be sent up. Provisions will thus be provided for four unemployed men at the camp during the entire summer. The camp was opened in April of this year and it is hoped that several men will be placed as the busy season in the mines opens up.

ELECTRICAL AND RADIO ENGINEER, B.Sc. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc., Elec., '29, B.Sc., Civil '33. Age 27. Jr.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.Sc., '27, Jr.E.I.C. Four years maintenance of high speed Diesel engine units, 200 to 1,300 h.p. Also maintenance of d.c. and a.c. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.Sc., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.Sc. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box No. 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.Sc. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E.Q, married. Desires position, preferably with construction firm Experience includes railway, monument and mil building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

Situations Wanted

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.A.SC., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.SC. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.SC. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.SC., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.SC. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.SC. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, B.A.SC. in C.E., with business and sales experiences, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.SC., JR.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

Situations Wanted

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.SC., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.SC. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.SC., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.SC. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.SC. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.SC. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.SC., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.SC.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.SC. (Univ. of B.C. '29); M.S. Age 27. Single. Four years experience in research work in applied mechanics and materials testing. Desires position involving analytical work in design, development or testing. Available on short notice. Apply to Box No. 1023-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box. No. 1127-W.

Situations Wanted

PETROLEUM CHEMIST, B.SC. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER, B.SC., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.SC., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.SC. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.SC., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Writes and speaks both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211-W.

CIVIL ENGINEER, B.SC. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

COMBUSTION ENGINEER, A.M.E.I.C., with extensive experience in all phases of combustion engineering, including plant layout, piping, etc. Lately connected with prominent firm of automatic oil burner manufacturers. Apply to Box No. 1224-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet tissues. Apply to Box No. 1246-W.

CIVIL ENGINEER, B.SC. '29, JR.E.I.C., age 29, single. Experience in all types of surveying including use of aerial photographs. Three years on hydro-electric power development in field and office. Instrumentman on concrete road construction. Location immaterial. Apply to Box No. 1254-W.

ELECTRICAL ENGINEER, B.SC. '34 (Univ. of N.B.), S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

CIVIL ENGINEER, Univ. Toronto '33, age 24, married. One year as instrumentman with provincial department of highways. Experience in concrete and retread construction grading, culverts, etc. Also draughting, estimating and general office practice. Apply to Box No. 1265-W.

MECHANICAL ENGINEER, B.SC. (Queen's Univ. '29). Age 28. Six years experience in automobile office and plant; two years as supervisor of inspection in body assembly. Good understanding of modern business methods applied to manufacturing. Desires position with production department of smaller Ontario industry. Good references. Interviews anywhere in central Ontario. Apply to Box No. 1270-W.

ELECTRICAL GRADUATE, S.E.I.C., B.SC. '32, M.SC. '34. Experience includes four years as part time operator and announcer for a radio broadcast station. At present employed in radio repair dept. of a large wholesale firm Apply to Box No. 1283-W.

ELECTRICAL ENGINEER, B.SC., E.E., A.M.E.I.C. University of Manitoba '28. Age 32. Married. Experience one year power line construction, five years resident and assistant district engineer on highway construction; two years highway traffic regulation in charge of district office. Good connections in Manitoba and Saskatchewan. Excellent references. Available at once and will go anywhere. Located in Winnipeg. Apply to Box No. 1316-W.

Design of Continuous Reinforced Concrete Arches by the Fixed Point Method
For the Cathedral, at Valleyfield, Que.

E. Nenniger, A.M.E.I.C.,
Associate, Arthur Surveyer and Co., Consulting Engineers, Montreal.

Part I*

SUMMARY.—This paper explains the general theory of the fixed point method and gives in detail an actual application of the method for the design of the reinforced concrete arches of the Cathedral at Valleyfield, Que.

On September 22nd, 1933, a fire destroyed the St. Cecile Cathedral at Valleyfield. As the structure had to be considered a total loss and as the loss was satisfactorily covered by insurance, the owners, "La Corporation Episcopale C. R. de Valleyfield," decided to rebuild the Cathedral entirely and to adopt a type of construction which would be as fireproof as possible.

This article is intended to illustrate the application of what is known as the "fixed point method" in the statical analysis of a continuous reinforced concrete frame which is statically indeterminate in the sixth degree. Although the above-mentioned method of computing continuous elastic frames is not new and is rather commonly used by the European designing engineer, it is amazing how little has been written on this subject in Canadian or American engineering periodicals. With the exception of Hardy Cross's paper and the subsequent discussions which appeared in the proceedings of the American Society of Civil Engineers, little has been published which would give the student in structural engineering a method of statical analysis which would eliminate, at least to some extent, the need of applying the principle of least work, the theory of elasticity or Mohrs' principle of elastic deformations. It is, therefore, understandable why the average engineer shuns calculating anything but the most elementary elastic deformation by the above methods unless he is a wizard in higher mathematics. It is the writer's hope, therefore, that this article will prove to be of interest from a designer's point of view and will start a discussion which is always valuable to the student who specializes in this particular line of engineering.

As already pointed out above, the chief object of the design was primarily to achieve structural economy. This object was obtained by the selection of the materials of the structure best adapted to the specific requirements and by saving no efforts in analyzing the various highly statically indeterminate frames in order to secure maximum efficiency of the materials chosen. In other words, no hinges were assumed or inserted to simplify the calculations, unless an actual saving in construction cost was the result.

The choice of materials to be used was rather limited, on account of the fact that an absolutely fireproof construction was specified. The following types of construction were, therefore, considered:—

(*a*) Structural steel fireproofed with concrete and gunite.
(*b*) Reinforced concrete.

*Part II to appear in September issue of The Journal.

The preliminary cost analysis revealed the fact that structural steel would necessitate a larger space in the roof section than the architect was ready to allow for the supporting structure. Even if the architect would have been ready to make such a concession as to raise the roof to a higher level, the additional cost of the outside walls together with the extra cost of the suspended vaulting would make this type of construction economically impossible.

It was, therefore, decided to execute the structure of the cathedral in reinforced concrete.

In order to eliminate a lengthy description of the layout of the church, the general plan of the ground floor as well as a typical cross-section are shown in the accompanying figure which is self-explanatory.

The standard frame, the general dimensions of which are shown in Fig. 15 and the detailed stress analysis of which is given in this article, was adopted after a comparison of various rigid frames. Two of these alternative frames are shown in Figs. 1a to 1b which were analyzed to obtain the most economical solution.

Such a preliminary study can best be made by using the formulae of Professor Dr. Ing. A. Kleinlogel, which he published in his book "Mehrstielige Rahmen." With the help of these formulae, it was possible to obtain first of all in a very short time the preliminary dimensions of the different members of the frame, and it enables also the designer to obtain a fairly good picture of the economical advantages of one frame over another.

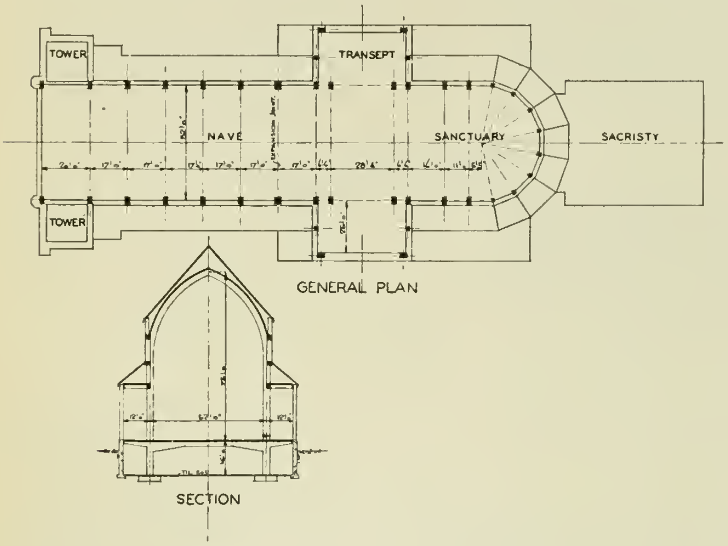
The type of frame as shown in Fig. 1b was found to be superior as far as the cost of the construction is concerned. In addition to this, the depth of the centre beam on the ground floor slab could be reduced considerably, thus meeting with the wishes of the architect, as the head room for the community hall in the basement was rather restricted.

Other advantages were derived by the elimination of the outside wall columns, such as:—

(*a*) The ground floor brackets supported on the inner column and reaching to the outside wall tend to reduce the large negative bending moment at the head of the basement column and also help to reduce the positive bending moment of the centre beam.

(*b*) In case of an uneven settlement of the footings supporting the two main columns, the extra moments due to such settlements are reduced to a very great extent, due to the fact that all exterior walls are independent of the frame and can move in a perpendicular direction without producing any additional stresses in the frame. The joint between walls and brackets are so arranged that only horizontal forces such as wind loads will be transmitted upon the frame.

The final stress analysis of the rigid frame which was found to be the most economical was made according to the fixed point method originally developed by Professor Dr. Wilhelm Ritter, and which was presented in a more useful



Schematic Sketch of Church Framing.

form for the practising engineer by Dr. Ing. Ernst Suter, who extended the method, so that the principle can also be applied to continuous arches as well. (See "Methode der Festpunkte" by Dr. Ing. Ernst Suter.) The method enables the designer to analyze in a clear and simple way any statically indeterminate structure composed of arches, beams and columns joined monolithically together at any angle. Among the many advantages of this method over an analytical stress analysis, are the following:—

(*a*) All complicated formulae are eliminated.

(*b*) The procedure of the analysis can be followed graphically and the calculations can easily be checked at any time during the analysis. It is, therefore, not necessary to complete the entire analysis before a check can be made of the result.

(*c*) The fixed point method is shorter than any analytical method when highly statically indeterminate structures with variable moments of inertia, have to be analyzed, especially if a great number of various loads have to be considered, in order to obtain the possible maximum stresses at any point of the frame.

Although it would be quite possible with the help of the theory of virtual displacements, method of least work, or the general theory of elasticity, to write down the six equations necessary for every type of loading applied to the frame in question, the time required to do all this mathematical work would be impossible, economically and practically, as slide rule calculations would not be accurate enough.

The fixed point method also makes available without much extra work certain information about a given frame such as:—

1. The extent to which the moments are affected due to a partial or total restraining effect of the ground floor slab to prevent the horizontal displacement of the joints, or what is known as side-sway.

2. The extent to which the moments are affected due to an assumed uneven settlement of the foundation of the frame.

The theory of fixed points.

The method is based generally on Mohr's principle, namely, that the angular deformations of elastic lines at supports are equal to the reactions of the member, loaded by its moment area divided by the product of the moment of inertia times the coefficient of elasticity of the material of which the member consists.

The analysis is divided into two stages.

Stage I deals with the determination of the moments and shear diagrams, under the assumption that the joints of the frame cannot sway-sideways, in other words, temporary imaginary supporting forces are applied at any joint which would ordinarily move sideways. These imaginary supports are called by Suter "holding forces." (See Fig. 2a to 2c.)

Stage II deals with the determination of the moments and shears due to the removal of the holding forces. These moments and shears can easily be obtained by loading the frame with each of the holding forces in the opposite direction in which they act as supports. (See Fig. 2b.) The magnitude of the holding forces is already known from the analysis of the frame in Stage I.

When both calculations under Stage I and Stage II are finished, the results are superimposed to obtain the final result of moments and shears. (See Fig. 2.)

To obtain the moments for both Stages I and II, the location of the fixed points have to be determined first. But before going any further, an explanation seems to be in order as to what exactly the so-called fixed point is, and what can be done with it.

Fixed point is called the zero moment point, when the end of a restrained beam (assumed to be without dead weight) is caused to rotate to a certain angle. (See Fig. 3.)

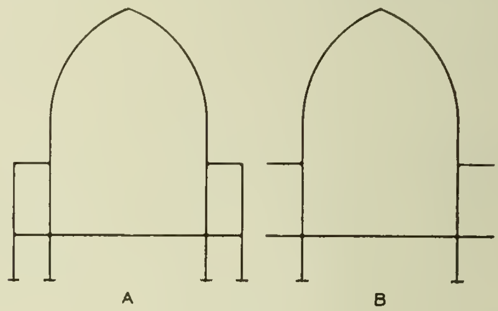


Fig. 1.

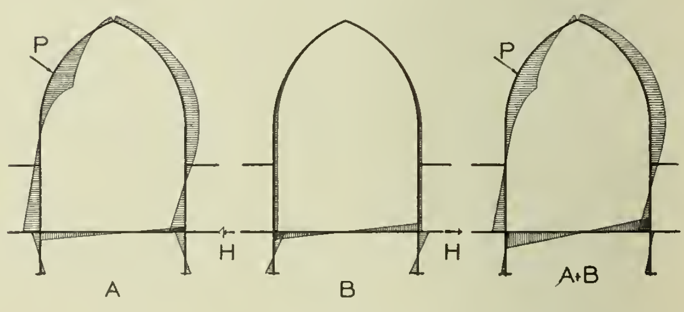

Fig. 2.

Thus, if the right end of the beam is angularly turned, we determine the left fixed point, and if we turn the left end of the beam, the right fixed point is obtained. The moment line is, in both cases, a straight line, and intersects the axis of the beam at the fixed point.

There are always two fixed points to each member of a frame, provided both ends are restrained by adjacent members, or by the characteristics of the support. If one end of a member has a hinged support, the fixed point is located at the support itself, the distance from support to fixed point becomes, therefore, zero.

The formula for the distance of the fixed points from the support of the member of the frame takes the following into consideration:—

(*a*) The elastic deformation of the member itself due to the rotating moment applied at the support. In this case, the modulus of elasticity of the material of the frame is assumed to be uniform.

(*b*) The elastic deformation of the support opposite the end where the rotating moment is applied.

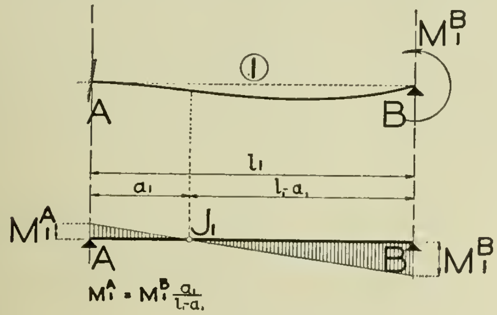

Fig. 3.

It can be seen from the above therefore that the location of the fixed points is solely dependent on the relative stiffness of the member under consideration and the proportional stiffness of the support, or adjacent members of the frame. This is one of the main characteristics of the fixed point, that no matter to what kind of a load each member is subjected, the locations of the fixed points are not changed at all, hence the name fixed point.

In order to illustrate the simplicity of the method in general, the procedure is shown in the following example and explained step by step.

1. Determine location of fixed points.
2. Determine the negative moments of the loaded span. $M_4{}^D$ and $M_4{}^E$ solved by simple graphical method.
3. Plot line from support E through fixed point K_5.

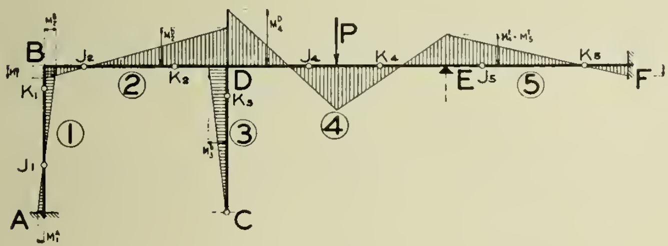

Fig. 4.

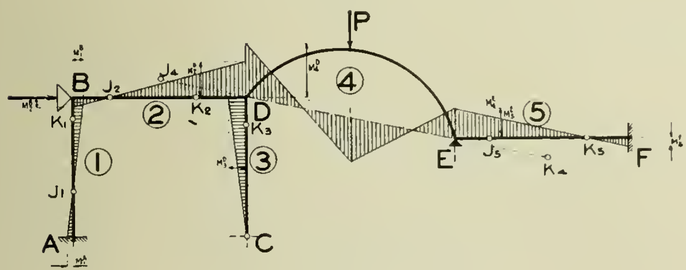

Fig. 5.

4. Split moments $M_4{}^D$ into moments $M_2{}^D$ and $M_3{}^D$ (use carry-over coefficients), draw a line from D with $M_2{}^D$ as ordinate through J_2, and continue from B, with $M_2{}^B$ as moment through J_1 to A.
   Draw a line starting at D, with $M_3{}^D$ as moment at the head of column 3 to the foot C of column 3.
5. With all the moments known, the shear diagram and all reactions at points A, C, E and F can be determined with the ordinary laws of statics.

To obtain the few values mentioned in steps 1 to 4, such as the location of the fixed points, the end moments at the supports D and E of the loaded span and the carry-over coefficients with which $M_4{}^D$ has to be multiplied to obtain $M_2{}^D$ and $M_3{}^D$, ready made formulæ can be applied which have been worked out by Ritter, Strassner and Suter. The application of these formulæ will be shown in detail later when discussing the actual analysis of the church frame.

In case one member of the frame shown in Fig. 4 has not a straight axis, the procedure would be exactly the same as before, except that the final moment of the arch would have to be corrected, by deducting the value of the product of the horizontal thrust multiplied by the height of the arch axis above the base line of arch (See Fig. 5.)

A temporary holding force would have to be assumed at point B or D (it is immaterial which), to prevent the joints B and D from swaying sideways. The extra moments

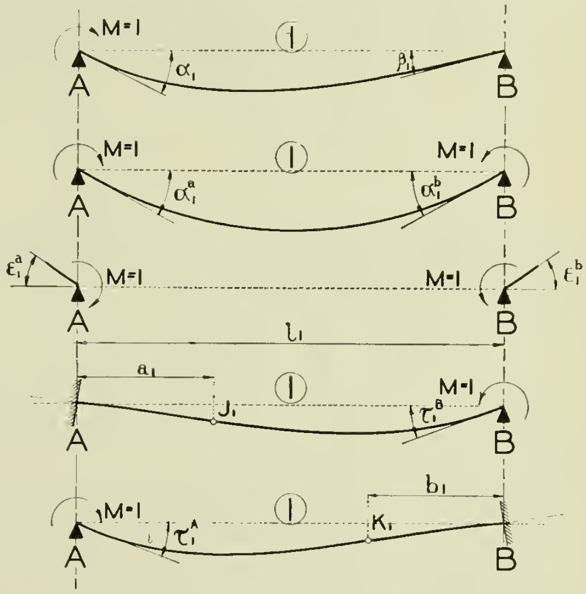

Fig. 6.

due to the release of point B would then have to be determined in the manner as explained previously. (Stage II.)

The following calculations give a detailed analysis of the standard frame of the Valleyfield Cathedral. Most of the calculations are illustrated, so as to make it easy to follow the application of the method adopted.

Determination of fixed points.

The general formula for the distance a and b of the fixed points J and K respectively is as follows:—

$$a_1 = \frac{l_1 \times \beta_1}{\alpha_1{}^a + \epsilon_1{}^a} \qquad b_1 = \frac{l_1 \times \beta_1}{\alpha_1{}^b + \epsilon_1{}^b}$$

for notations used see Fig. 6.

l_1 = length of span in feet of member 1.

β_1 = angular deformation of member 1 at support B, due to an external moment $M = 1$ foot-pound applied at support A.
(*Note.* The value of β at the support A, in case $M = 1$ foot-pound is applied at support B, is the same according to Maxwell's theorem of reciprocal displacements.)

$\alpha_1{}^a$ = angular deformation of member 1 at support A due to $M = 1$ foot-pound applied at both supports.
(*Note.* $\alpha_1{}^b$ has not the same value as $\alpha_1{}^a$ if the moment of inertia of the member is not uniform throughout.)

ϵ_1^a = angular deformation of the elastic support A due to a unit moment $M = 1$ foot-pound applied at the support A.

The latter angle varies between zero, in case of full restraint, and infinity in case of no restraint. In the first case, the distance a_1 becomes 1/3 of the span if the moment of inertia of the member is uniform and in the second case a_1 = zero.

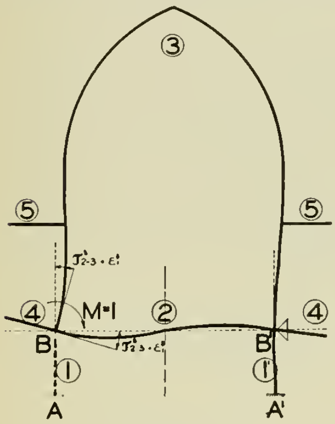

Fig. 7.

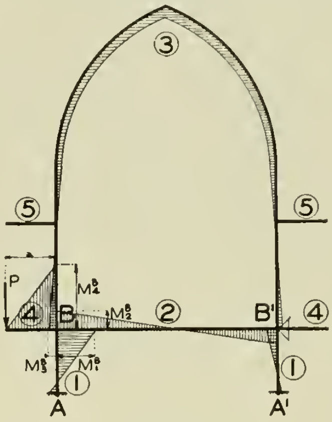

Fig. 8.

The value ϵ^a at joint B of member 1 is equal to the combined angular deformation of the members 2 and 3 due to a moment $M = 1$ foot-pound applied at B. (See Fig. 7.) This angle is expressed thus:

$$\epsilon_1^B = \tau^B{}_{2-3} = \frac{1}{\frac{1}{\tau_2^B} + \frac{1}{\tau_3^B}}$$

In this case, member 1 is assumed removed. The angle $\tau^B{}_{2-3}$ is derived as follows:—

The moment M_1^B at the head of the column 1 produces an angular displacement of both ends of the members 2 and 3 at joint B, and consequently the two rotating moments M_2^B and M_3^B. As the original angle between members 1, 2 and 3 remains unchanged, we can write:

(a) $M_1^B \times \tau^B{}_{2-3} = M_2^B \times \tau_2^B$

(b) $M_1^B \times \tau^B{}_{2-3} = M_3^B \times \tau_3^B$

We know also that

(c) $M_1^B = M_2^B + M_3^B$

therefore

(d) $M_2^B = M_1^B \times \frac{\tau^B{}_{2-3}}{\tau_2^B}$

(e) $M_3^B = M_1^B \times \frac{\tau^B{}_{2-3}}{\tau_3^B}$

and by entering the values d and e in equation c we obtain

$$M_1^B = M_1^B \times \frac{\tau^B{}_{2-3}}{\tau_2^B} + M_1^B \times \frac{\tau^B{}_{2-3}}{\tau_3^B}$$

or,
$$M_1^B = M_1^B \times \tau^B{}_{2-3}\left[\frac{1}{\tau_2^B} + \frac{1}{\tau_3^B}\right]$$

by eliminating M_1^B we obtain

$$\tau^B{}_{2-3} = \frac{1}{\frac{1}{\tau_2^B} + \frac{1}{\tau_3^B}} = \epsilon_1^B$$

as indicated above.

In a similar way value ϵ_2^B can be expressed:

$$\epsilon_2^B = \tau^B{}_{1-3} = \frac{1}{\frac{1}{\tau_1^B} + \frac{1}{\tau_3^B}}$$

and
$$\epsilon_3^B = \tau^B{}_{1-2} = \frac{1}{\frac{1}{\tau_1^B} + \frac{1}{\tau_2^B}}$$

With the help of the above indicated angles of deformation τ, the carry over coefficients μ are obtained.

In the case shown in Fig. 8, the bending moment $M_4^B = P \times a$ is divided into the moments M_1^B, M_2^B and M_3^B. These moments are all smaller than M_4^B. The carry-over coefficients μ with which we want to multiply the moment M_4^B to obtain the three moments M_1^B, M_2^B and M_3^B are, therefore, all smaller than 1 and the sum of three must be = 1.

$$M_1^B = M_4^B \times \frac{\tau^B{}_{1-2-3}}{\tau_1^B} = M_4^B \times \mu^B{}_{4-1}$$

(The subscript of μ denotes the carry-over coefficient at joint B with which the moment of the member 4 at B has to be multiplied to obtain the moment of member 1 at joint B.)

$$M_2^B = M_4^B \times \frac{\tau^B{}_{1-2-3}}{\tau_2^B} = M_4^B \times \mu_{4-2}$$

$$M_3^B = M_4^B \times \frac{\tau^B{}_{1-2-3}}{\tau_3^B} = M_4^B \times \mu_{4-3}$$

The values μ are therefore

$$\mu^B{}_{4-1} = \frac{\tau^B{}_{1-2-3}}{\tau_1^B}$$

$$\mu^B{}_{4-2} = \frac{\tau^B{}_{1-2-3}}{\tau_2^B}$$

$$\mu^B{}_{4-3} = \frac{\tau^B{}_{1-2-3}}{\tau_3^B}$$

A moment of member 1 at joint B to be carried over to the members 2 and 3 would have to be multiplied by:

$$M_1^B \times \mu^B{}_{1-2} = M_2^B$$
$$M_1^B \times \mu^B{}_{1-3} = M_3^B$$

in which

$$\mu^B{}_{1-2} = \frac{\tau^B{}_{2-3}}{\tau_2^B}$$

$$\mu^B{}_{1-3} = \frac{\tau^B{}_{2-3}}{\tau_3^B}$$

Thus we obtain in a similar manner for a moment of beam 2 at joint B to be carried over to column 1 and arch 3

$$\mu^B{}_{2-1} = \frac{\tau^B{}_{1-3}}{\tau_1^B}$$

$$\mu^B{}_{2-3} = \frac{\tau^B{}_{1-3}}{\tau_3^B}$$

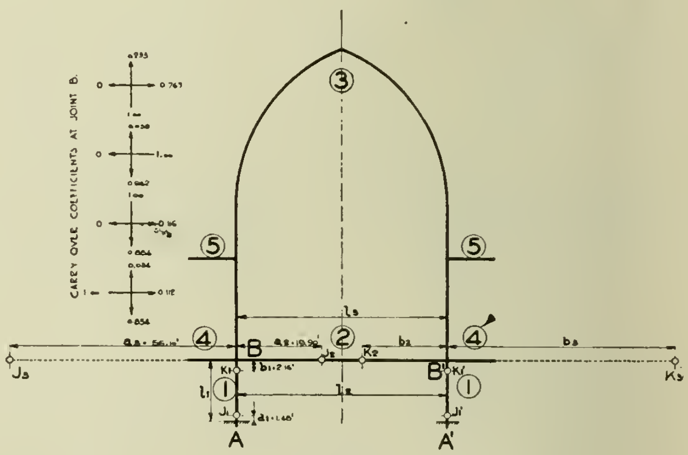

Fig. 9.

and for a moment to be carried over from the arch 3 at joint B to member 1 and 2

$$\mu^B{}_{3-1} = \frac{\tau^B{}_{1-2}}{\tau_1^B}$$

$$\mu^B{}_{3-2} = \frac{\tau^B{}_{1-2}}{\tau_2^B}$$

It can be seen that altogether three angular displacements of each end of every member in the frame have to be determined in order to obtain the location of the fixed points J and K of each member. These angular displacements are α^a or α^b (in case of unsymmetrical members), β and ϵ^a or ϵ^b which latter angle is a combination of the angles τ. As the frame to be analyzed is a so-called closed frame, the procedure to obtain the location of the fixed points is as follows (see Fig. 9):—

Start at the foot of column 1 and obtain a_1 by estimating the degree of restraint the spread footing will exert on the foot of the column. Determine the angle τ_1^B according to formula

$$\tau_1^B = \alpha_1^b - \frac{l_1}{l_1 - a_1} \times \beta_1$$

In order to calculate $a_3 = \dfrac{l_3 \times \beta_3}{\alpha_3^a + \epsilon_3^B}$ of the arch, the value

$$\epsilon_3^B = \tau^B{}_{1-2} = \frac{1}{\dfrac{1}{\tau_1^B} + \dfrac{1}{\tau_2^B}}$$

is needed which in turn requires the angle τ_2^B. But as the formula

$$\tau_2^B = \alpha_2^a - \frac{l_2}{l_2 - b_2} \times \beta_2$$

contains the distance b_2, which is not yet known, it is necessary to assume b_2 temporarily to proceed with the calculations. This assumed distance b_2 is obtained later directly and if the result does not check with the estimated value, the calculation has to be repeated by using the corrected value b_2. A designer familiar with the method usually needs only one correction, in order to obtain the final check of the assumed distance. Finally with τ_2^B known, the angular deformation ϵ_3^B is obtained, which in turn is entered in the equation.

$$a_3 = \frac{l_3 \times \beta_3}{\alpha_3^a + \epsilon_3^B}$$

with a_3 known, the angular displacement $\tau_3^{B'}$ is determined by the equation

$$\tau_3^{B'} = \alpha_3^b - \frac{l_3}{l_3 - a_3} \times \beta_3$$

and as the value τ_1^B is already known which is on account of symmetry equal to $\tau_1^{B'}$ the angular deformation $\epsilon_2^{B'}$ can be determined by the equation

$$\epsilon_2^{B'} = \tau^{B'}{}_{3-1} = \frac{1}{\dfrac{1}{\tau_3^{B'}} + \dfrac{1}{\tau_1^{B'}}}$$

and finally the distance of the fixed point b_2 can be obtained by the formula

$$b_2 = \frac{l_2 \times \beta_2}{\alpha_2^b + \epsilon_2^{B'}}$$

As indicated above, this value b_2 must equal the b_2 temporarily assumed previously. If the two values are the same, the procedure can be continued to obtain b_1 by the formula

$$b_1 = \frac{l_1 \times \beta_1}{\alpha_1^b + \epsilon_1^B}$$

in which $\epsilon_1^B = \tau^B{}_{2-3} = \dfrac{1}{\dfrac{1}{\tau_2^B} + \dfrac{1}{\tau_3^B}}$

All the locations of the fixed points for each member are now known, because, on account of symmetry,

$$a_2 = b_2$$
$$a_3 = b_3$$

The following calculations are now given to illustrate the actual application of the method.

A. *Determination of the angles α and β.*

1. The angles α_1^a, α_1^b and β_1 for column 1 are obtained by the following equations. (See also Fig. 10 for notations.)

$$E\,\alpha_1^a = \frac{1}{l_1} \sum_0^{l_1} wz'$$

$$E\,\alpha_1^b = \frac{1}{l_1} \sum_0^{l_1} wz$$

$$E\,\beta_1 = \frac{1}{l_1^2} \sum_0^{l_1} wzz'$$

of which $w = \dfrac{\Delta s}{I}$ = the elastic weights of the member.

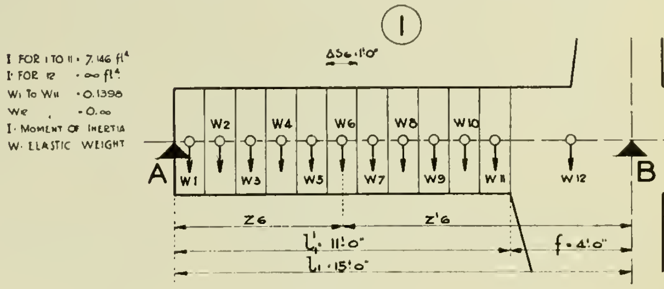

Fig. 10.

The moment of inertia from the footing to the start of the haunch of the beam is constant and amounts to

$$I = \frac{b \times d^3}{12} = \frac{2 \times 3.5^3}{12} = 7.146 \text{ ft.}^4$$

The moment of inertia from beginning of the haunch of the beam to the intersection of axis of members 1 and 2 becomes infinitely large and therefore the elastic weight for this distance is equal to zero.

$$E\,\alpha_1^a = \frac{l_1'}{I} \times \left[\frac{l'}{2} + f\right] \times \frac{1}{l_1} = \frac{l_1'\,[l_1' + 2f]}{2\,l_1\,I_1}$$

$$E\,\alpha_1^b = \frac{l_1'}{I} \times \frac{l_1'}{2} \times \frac{1}{l_1} = \frac{l_1'^2}{2\,I\,l_1}$$

in a similar manner

$$E\,\beta_1 = \frac{l_1'^2 \times [l_1 + 2f]}{6\,l_1^2\,I}$$

therefore

$$E\,\alpha_1^a = \frac{11\,[11 + 2 \times 4]}{2 \times 15 \times 7.146} = 0.974$$

$$E\,\alpha_1^b = \frac{11^2}{2 \times 15 \times 7.146} = 0.564$$

$$E\,\beta_1 = \frac{11^2[15 + 2 \times 4]}{6 \times 15^2 \times 7.146} = 0.288$$

2. *Angular deformations α_2^a, α_2^b and β_2 of beam 2.*

In Fig. 11 are shown all values which are needed to solve the equations for the three angular deformations. The diagram also shows how these angles can be obtained graphically.

The procedure to obtain these angles graphically is as follows:—

1. Divide the span into a number of small sections and determine the moment of inertia for each section.
2. Draw a line representing the moment which is applied at the support to cause the angular deformation, and divide the area of the moment belonging to each section of the span by the moment of inertia of that section.
3. Draw a funicular polygon by using as loads the reduced moment area of each section. The reactions obtained with this polygon represent the angular deformations required.

The following table shows the analytical method of obtaining these angular deformations.

TABLE I

Section	I	Δs	w	z	z'	wz	wzz'
1	13.900	2.125	0.1529	2.8125	49.1875	0.430	21.12
2	10.750	2.125	0.1976	4.9375	47.0625	0.976	45.95
3	8.160	2.125	0.2605	7.0625	44.9375	1.840	82.70
4	6.020	2.125	0.3530	9.1875	42.8125	3.242	138.80
5	4.290	2.125	0.4955	11.3125	40.6875	5.610	228.00
6	2.930	2.125	0.7250	13.4375	38.5625	9.740	375.50
7a	3.635	2.875	0.7905	15.9375	36.0625	12.590	454.00

7d'	3.635	2.875	0.7905	27.4375	24.5625	21.700	533.00
7c'	3.635	2.875	0.7905	30.3125	21.6875	23.980	520.00
7b'	3.635	2.875	0.7905	33.1875	18.8125	26.220	493.00
7a'	3.635	2.875	0.7905	36.0625	15.9375	28.500	454.00
6'	2.930	2.125	0.7250	38.5625	13.4375	27.950	375.50
5'	4.290	2.125	0.4955	40.6875	11.3125	20.150	228.00
4'	6.020	2.125	0.3530	42.8125	9.1875	15.110	138.80
3'	8.160	2.125	0.2605	44.9375	7.0625	11.710	82.70
2'	10.750	2.125	0.1976	47.0625	4.9375	9.300	45.95
1'	13.900	2.125	0.1529	49.1875	2.8125	7.520	21.12
		52.000				277.988	5784.14

$$E\,\alpha_2^a = E\,\alpha_2^b = \frac{277.988}{52} = 5.35$$

$$E\,\beta_2 = \frac{5784.14}{52^2} = 2.14$$

3. *Values of α_3^a, α_3^b and β_3 for Arch 3.*

The formula for the distance a_3 and b_3 of the fixed points for the arch is again

$$a_3 = \frac{l_3 \times \beta_3}{\alpha_3^a + \epsilon_3^a} \quad ; \quad b_3 = \frac{l_3 \times \beta_3}{\alpha_3^b + \epsilon_3^b}$$

The angular deformations at the supports of the two-hinged arch (as shown in Fig. 12) due to a moment $M = 1$ foot-pound applied at the support of the arch have to be determined. But before the formulæ for these angles can be obtained, the horizontal thrust due to the moment

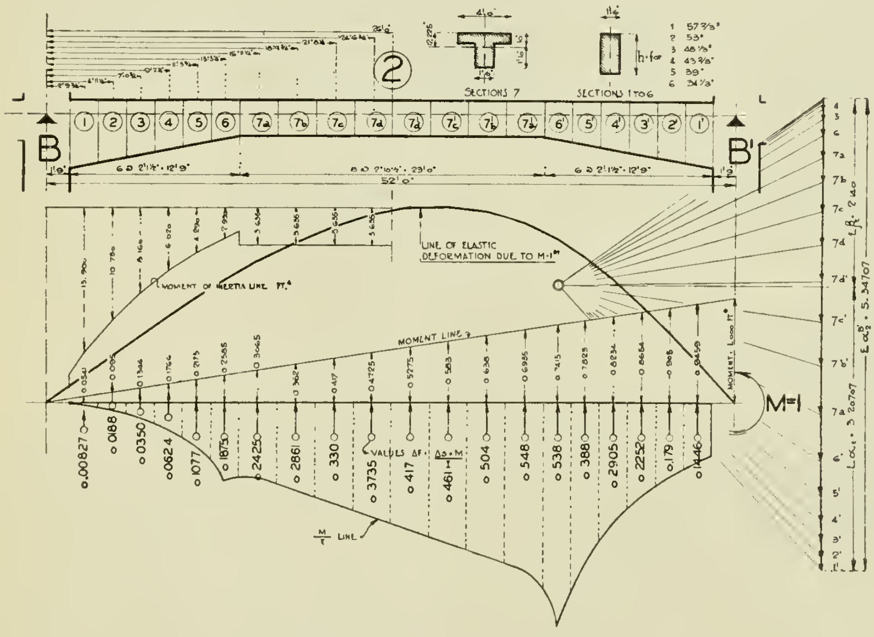

Fig. 11.

causing those angular deformations has to be known. This horizontal thrust can best be determined by means of the principle of least work. According to Müller-Breslau, the general equation based on the theorem of least work is, if the rib shortening due to direct stress and the influence of temperature changes is neglected,

$$L_a = \int \frac{M\,M_a\,ds}{EI}$$

in which

L_a = the virtual work of the reactions at the support for the condition $X_a = 1$ (see also Fig. 13).

M = Bending moment due to the external loads applied on the statically indeterminate frame.

M_a = Moment in statically determinate frame due to $X_a = 1$.

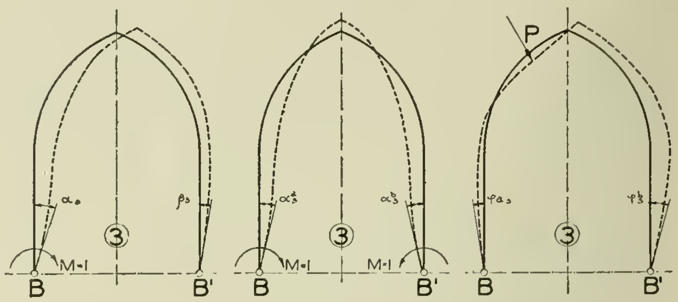

Fig. 12.

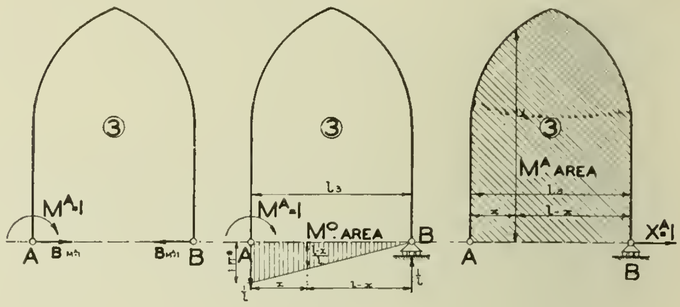

Fig. 13.

As the virtual work L_a must be zero, because the supports cannot move from their original position, the above equation becomes

$$0 = \int \frac{M\,M_a\,ds}{EI}$$

If the value M is now substituted with the value

$$M = M^0 - X_a \times M_a$$

of which M^0 = represents the bending moment of the statically determinate frame, due to the external loading (see Fig. 13), the above equation reads then

$$o = \int \frac{M^0\,M_a\,ds}{EI} - X_a \int \frac{M_a^2\,ds}{EI}$$

or in other words, $\int \frac{M^0\,M_a\,ds}{EI}$ expresses the value of the displacement of the support of the principal frame, or statically determinate system, due to the exterior load applied on the frame, and the value $X_a \int \frac{M_a^2\,ds}{EI}$ represents the displacement of one of the arch supports of the principal system due to the application of the wanted horizontal thrust at the support.

The horizontal thrust is therefore

$$X_a = \frac{\int \frac{M^0\,M_a\,ds}{EI}}{\int \frac{M_a^2\,ds}{EI}}$$

According to this formula, the horizontal thrust due to the application of a bending moment of 1 foot-pound at support A is therefore as follows. (See Fig. 13.)

$$M^0 = \frac{l-x}{l} \qquad M_a = y \qquad \frac{ds}{I} = w$$

$$E\int M^0\, M_a \frac{ds}{I} = \sum_0^l y \frac{l-x}{l} w$$

$$E\int M_a^2 \frac{ds}{I} = \sum_0^l y^2 w$$

therefore

$$X_a = \frac{\sum_0^l y \frac{l-x}{l} w}{\sum_0^l y^2 w} = \frac{1}{l}\, \frac{\sum_0^l y\,[l-x]\,w}{\sum_0^l y^2 w}$$

The notation used by Suter for this thrust is $B_{(M^A=1)}$ of which the subscript denotes that the thrust is due to a moment = 1 foot-pound applied at support A.

The thrust $B_{(M^B=1)}$ due to a moment equal to 1 foot-pound applied at the support B can be derived in a similar manner and amounts to

$$B_{(M^B=1)} = \frac{1}{l}\, \frac{\sum_0^l yxw}{\sum_0^l y^2 w}$$

and the thrust B due to the application of a moment of 1 foot-pound simultaneously at both supports of the two hinged frame amounts to

$$B = \frac{\sum_0^l yw}{\sum_0^l y^2 w}$$

It can be seen that all values B are only dependent on the dimensions and shape of the frame, and are not influenced by the external loads applied on the arch.

The derivation of the formula for the angular deformations α and β, as given by Suter, is rather an intricate application of the theorem of least work. The following derivation of the angular deformation, as shown in Fig. 12, gives a considerably simpler illustration of the application of the principle of least work.

If a rotating moment = 1 foot-pound is applied at the support B, thereby causing an angular deformation β at support B' (see Fig. 12), then the bending moments at any point of the frame amount to

$$M = M^0 - B_{(M^A=1)} \times y \qquad \text{(See Fig. 14)}$$

the angular deformation can therefore be obtained in two easy steps, by computing first the angle β^0 due to M^0 of the statically determinate system, and secondly, by deducting the angle β_B due to the horizontal thrust $B_{(M^A=1)}$, also of the statically determinate system. For each step, the general equation based on the theorem of least work reads in this case

$$\beta^0 = \int \frac{M^a\, M ds}{EI}$$

$$\beta_B = \int \frac{M^a\, M ds}{EI}$$

$$\beta = \beta^0 - \beta_B$$

In the case of β^0 the following values can be placed under the integral.

M^a = Loading group: Applied at that point of the frame where the deformation is wanted. As an angular turn of joint B' is wanted, a rotating moment $\overline{M}$ = 1 foot-pound is applied there and the value M^a becomes therefore

$$M^a = \frac{\overline{M}x}{l} \text{ or } = \frac{x}{l}.$$

M = Displacement group: Influence of the load which actually causes the wanted deformation. It is therefore

$$M = M^0 = \frac{l-x}{l}.$$

These values entered into the above equation, gives

$$\beta^0 = \int \frac{\frac{x}{l} \times \frac{l-x}{l} \times ds}{EI} = \frac{1}{El^2}\int x\,[l-x]\,\frac{ds}{I}$$

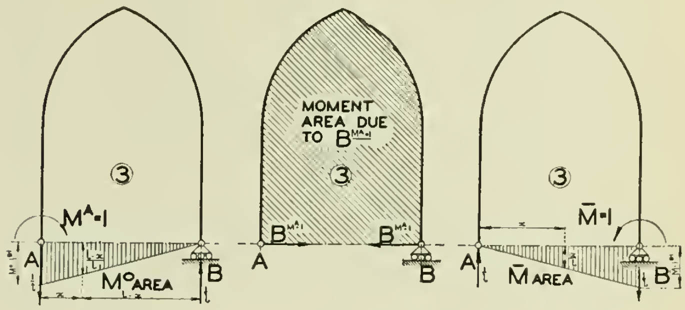

Fig. 14.

As the moment of inertia I in the integral is variable, it is not possible to solve the integral, and it is necessary to subdivide the arch into a number of small sections. At the same time, the values $\frac{ds}{I}$ can be replaced by the elastic weights. The equation reads therefore

$$\beta^0 = \frac{1}{El^2} \sum_0^l x\,[l-x]\,w$$

To obtain β_B the procedure is again as follows:

M^a = Loading group: load $\overline{M}$ = 1 applied at B' where deformation is wanted.

M^a is therefore again $= \frac{\overline{M}}{l}x$ or $\frac{x}{l}$

M = Displacement group: Influence of load actually causing required angular deformation β_B therefore

$$M = B_{(M^A=1)}\, y$$

these values entered in equation for β_B give:

$$\beta_B = \int \frac{\frac{x}{l} \times B_{(M^A=1)}\, y\, ds}{EI} = \frac{1}{El} B_{(M^A=1)} \int \frac{xy\, ds}{I}$$

or again $\qquad \beta_B = \frac{1}{El} B_{(M^A=1)} \sum_0^l xyw$

and finally if the two values are entered in the equation

$$\beta = \beta^0 - \beta_B$$

$$E\,\beta = \frac{1}{l^2} \sum_0^l x\,[l-x]\,w - \frac{1}{l} B_{(M^A=1)} \sum_0^l xyw$$

With the same method of procedure the angles α^a and α^b are obtained, thus

$$E\,\alpha^a = E\,\alpha^b = \sum_0^{l/2} w - B\sum_0^{l/2} yw$$

The following Table II gives the computation of the above angular deformations for the church frame. The general dimensions and division of the arch are shown in the accompanying Fig. 15.

			20.6710		976.267	57156.842			144.1995	5146.939

Note.—All calculations were made with a 20-inch slide rule. The computations need, on account of symmetry, be made only for half of the frame.

$$B_3 = \frac{\sum_0^{l/2} yw}{\sum_0^{l/2} y^2w} = \frac{976.267}{57156.842} = 0.01708$$

$$E\,\alpha_3{}^a = E\,\alpha_3{}^b = \sum_0^{l/2} w - B \sum_0^{l/2} yw = 20.671 - 0.01708 \times 976.267 = 3.991$$

$$E\,\beta_3 = \frac{2}{l^2} \sum_0^{l/2} x\,[l-x]\,w - \frac{B}{2} \sum_0^{l/2} yw = \frac{2}{52^2} \times 5146.939 - \frac{0.01708}{2} \times 976.267 = -4.535$$

With these values, the locations of the fixed points can now be determined.

As far as the column of the frame to be analyzed is concerned, the restraint at the foot of the column depends on a number of factors, such as the size of the footing on which the column rests and the quality of the soil supporting the footing. It is clear that the angular displacement of such a support cannot be determined mathematically and must be estimated. In this case, the degree of restraint was taken at ⅓ of full restraint and, therefore, a_1 becomes:—

$$a_1 = \frac{l_1 \times \beta_1}{\alpha_1{}^a} \times \frac{1}{3} = \frac{1}{3} \times \frac{15.0 \times 0.288}{0.974} = \mathbf{1.48} \text{ foot}$$

$$\tau_1{}^B = \alpha_1{}^b - \frac{l_1}{l_1 - a_1} \times \beta_1 = 0.564 - \frac{15.0}{15.0 - 1.48} \times 0.288 = 0.245$$

assume $b_2 = 20.00$ feet

$$\tau_2{}^B = \alpha_2{}^a - \frac{l_2}{l_2 - b_2} \times \beta_2 = 5.35 - \frac{52.0}{52.0 - 20.0} \times 2.14 = 1.870$$

$$\epsilon_3{}^B = \tau^B{}_{1-2} = \frac{1}{\frac{1}{\tau_1{}^B} + \frac{1}{\tau_2{}^B}} = \frac{1}{\frac{1}{0.245} + \frac{1}{1.870}} = 0.2168$$

$$a_3 = \frac{l_3 \times \beta_3}{\alpha_3{}^a + \epsilon_3{}^B} = \frac{52.0 \times [-4.535]}{3.991 + 0.2168} = -\mathbf{56.10} \text{ feet}$$

$$\tau_3{}^{B'} = \alpha_3{}^b - \frac{l_3}{l_3 - a_3} \times \beta_3 = 3.991 - \frac{52.0}{52.0 - [-56.10]} \times [-4.535] = 6.171$$

$\tau_1{}^{B'} = \tau_1{}^B = 0.245$ (see above)

$$\epsilon_2{}^{B'} = \tau^{B'}{}_{1-3} = \frac{1}{\frac{1}{\tau_1{}^{B'}} + \frac{1}{\tau_3{}^{B'}}} = \frac{1}{\frac{1}{0.245} + \frac{1}{6.171}} = 0.2358$$

$$b_2 = \frac{l_2 \times \beta_2}{\alpha_2{}^b + \epsilon_2{}^{B'}} = \frac{52.0 \times 2.14}{5.35 + 0.2358} = \mathbf{19.90} \text{ feet}$$

This value is so close to the previously assumed value of 20 feet, that the calculation does not have to be repeated. The remaining values can therefore be computed.

$$\epsilon_1{}^{B'} = \tau^{B'}{}_{2-3} = \frac{1}{\frac{1}{\tau_2{}^{B'}} + \frac{1}{\tau_3{}^{B'}}} = \frac{1}{\frac{1}{1.87} + \frac{1}{6.171}} = 1.435$$

$$b_1 = \frac{l_1 \times \beta_1}{\alpha_1{}^b + \epsilon_1{}^{B'}} = \frac{15.0 \times 0.288}{0.564 + 1.435} = \mathbf{2.16} \text{ feet}$$

The carry over coefficients are obtained directly, as all τ values are already known from the calculation of the position of the fixed points.

$$\left.\begin{aligned} \mu_{1-2} &= \frac{\tau^B{}_{2-3}}{\tau_2{}^B} = \frac{1.435}{1.87} = 0.767 \\ \mu_{1-3} &= \frac{\tau^B{}_{2-3}}{\tau_3{}^B} = \frac{1.435}{6.171} = 0.233 \end{aligned}\right\} = 1.000$$

$$\left.\begin{aligned} \mu_{2-1} &= \frac{\tau^B{}_{1-3}}{\tau_1{}^B} = \frac{0.2358}{0.245} = 0.962 \\ \mu_{2-3} &= \frac{\tau^B{}_{1-3}}{\tau_3{}^B} = \frac{0.2358}{6.171} = 0.038 \end{aligned}\right\} = 1.000$$

$$\left.\begin{aligned} \mu_{3-1} &= \frac{\tau^B{}_{1-2}}{\tau_1{}^B} = \frac{0.2168}{0.245} = 0.884 \\ \mu_{3-2} &= \frac{\tau^B{}_{1-2}}{\tau_2{}^B} = \frac{0.2168}{1.870} = 0.116 \end{aligned}\right\} = 1.000$$

To obtain the carry over coefficient, with which the moments of bracket 4 have to be multiplied to obtain the balancing moments of members 1, 2 and 3, the value $\tau^B{}_{1-2-3}$ has to be obtained first.

$$\tau^B{}_{1-2-3} = \frac{1}{\frac{1}{\tau_1{}^B} + \frac{1}{\tau_2{}^B} + \frac{1}{\tau_3{}^B}} = \frac{1}{\frac{1}{0.245} + \frac{1}{1.87} + \frac{1}{6.171}} = 0.2095$$

$$\left.\begin{aligned} \mu_{4-1} &= \frac{\tau^B{}_{1-2-3}}{\tau_1{}^B} = \frac{0.2095}{0.245} = 0.854 \\ \mu_{4-2} &= \frac{\tau^B{}_{1-2-3}}{\tau_2{}^B} = \frac{0.2095}{1.870} = 0.112 \\ \mu_{4-3} &= \frac{\tau^B{}_{1-2-3}}{\tau_3{}^B} = \frac{0.2095}{6.171} = 0.034 \end{aligned}\right\} = 1.000$$

The location of all fixed points and the values of all carry over coefficients are shown in Fig. 9.

Moment due to Dead Loads of centre beam 2. (Fig. 16.)

The uniformly distributed dead load on beam 2 is:—

Slab. "Floortyle," 8″ + 2″	= 13 × 50 lbs. =	650 pounds
T-beam	= 4 × 0.833 × 150 lbs. =	500 "
	= 1.5 × 1.833 × 150 lbs. =	412 "
Suspended ceiling	= 17 × 10 lbs. =	170 "
Tile floor finish	= 17 × 25 lbs. =	425 "
		2,157 pounds per lin. foot of beam.

The procedure of distributing the bending moments due to the above dead load as given analytically below can

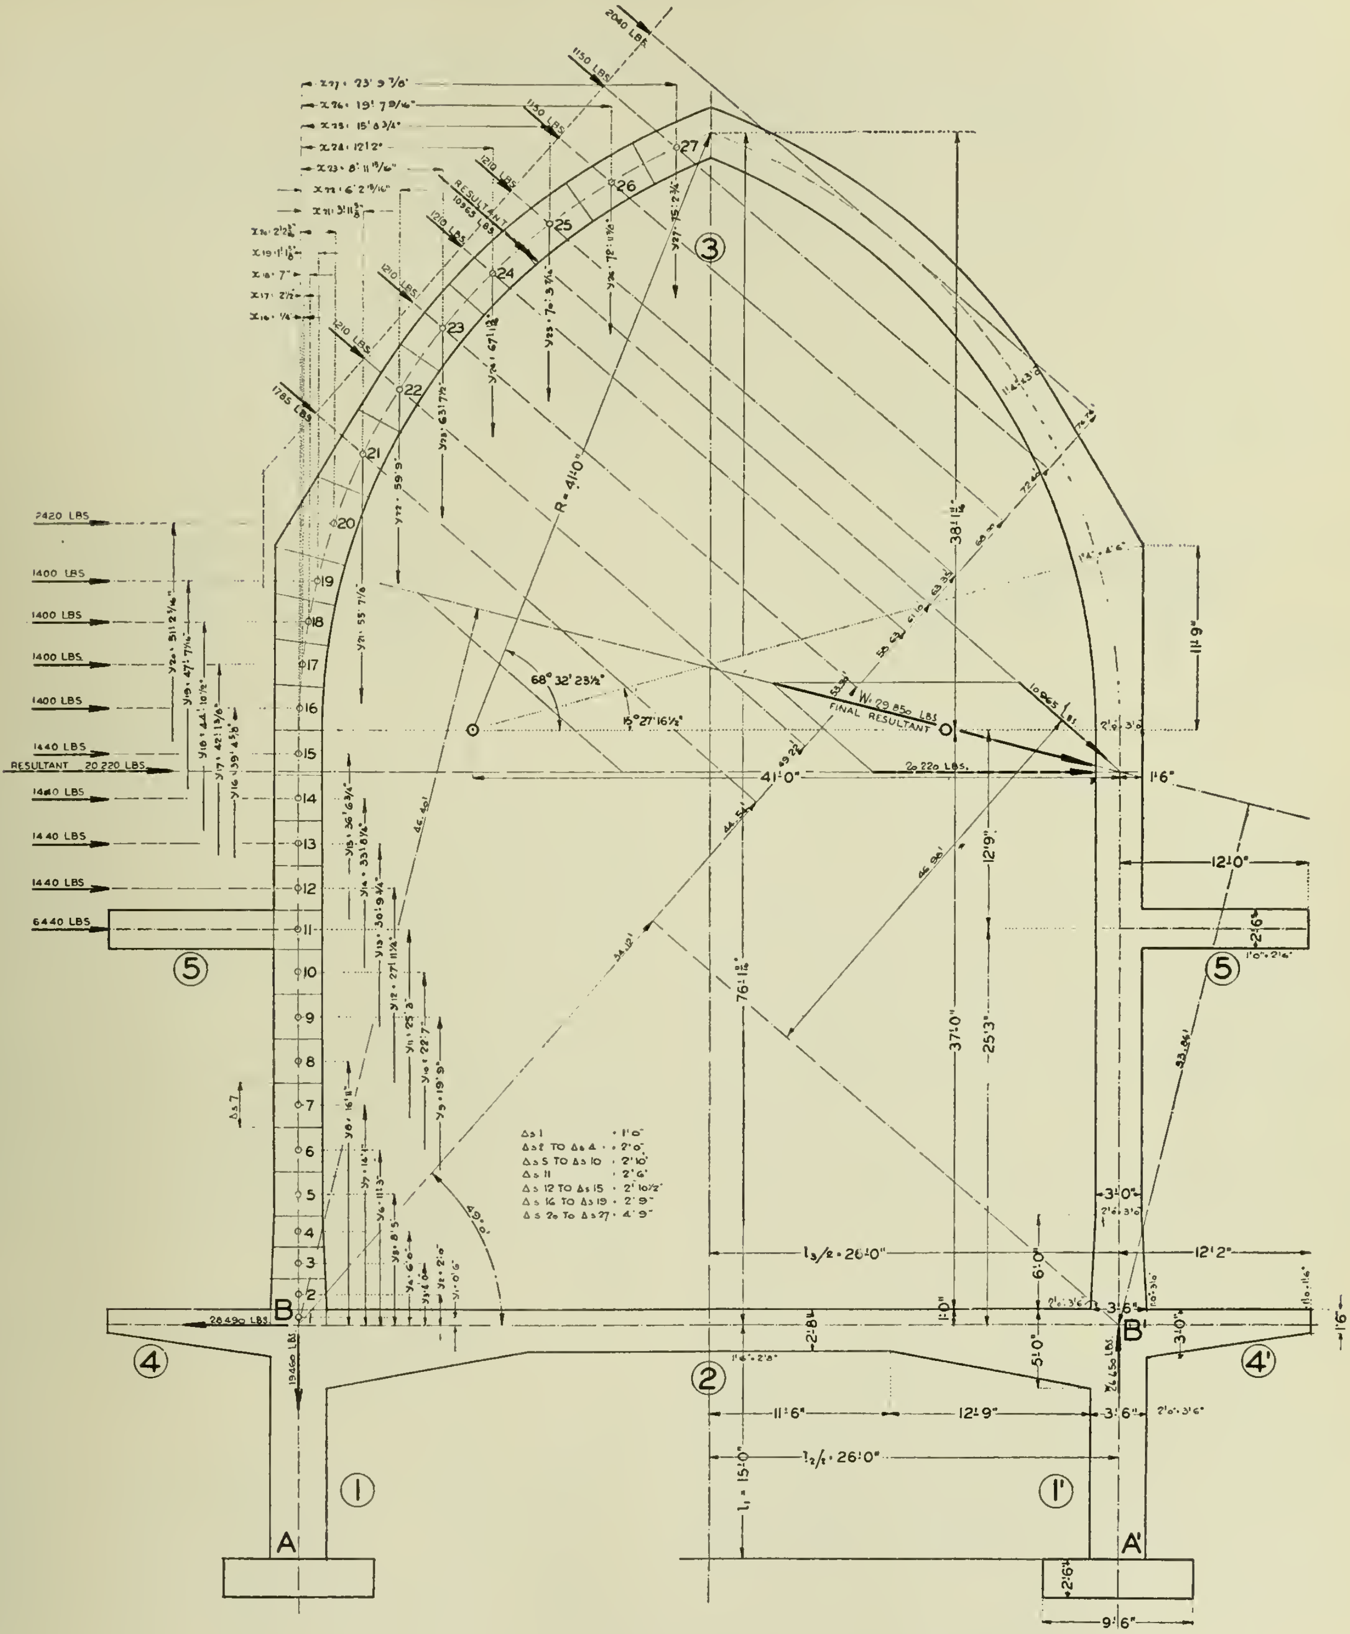

Fig. 15.

easily be followed step by step in Fig. 16 which illustrates the graphical solution.

Assume member 2 freely supported at both ends and compute the maximum bending moment due to the dead load, thus

$$M^0 = \frac{2157 \times 52^2}{8} = 730{,}000 \text{ foot-pounds}$$

To obtain the negative moments due to the restraint at both supports of member 2, a line is drawn from the support to the point of maximum moment (centre of beam) and the intersection of this line with a perpendicular drawn through the fixed point indicates the extent to which the closing line of the moment polygon is lowered (see line 1), or analytically

$$M_2^B = \frac{M^0 \times a_2}{\frac{1}{2}\, l_2} = \frac{730{,}000 \times 19.90}{26.0}$$
$$= -\,558{,}000 \text{ foot pounds} = M_2^{B'}$$

These two moments have to be carried over to members 3 and 1, and from joint to joint of the frame, until the remaining moments are so small as to be negligible. This process can be carried out graphically or analytically. It is usually best to do it in both ways to obtain an independent check of the figures. The analytical procedure is as follows:

(In Fig. 16, the moments are always indicated on the side of the frame axis where tension would be caused by

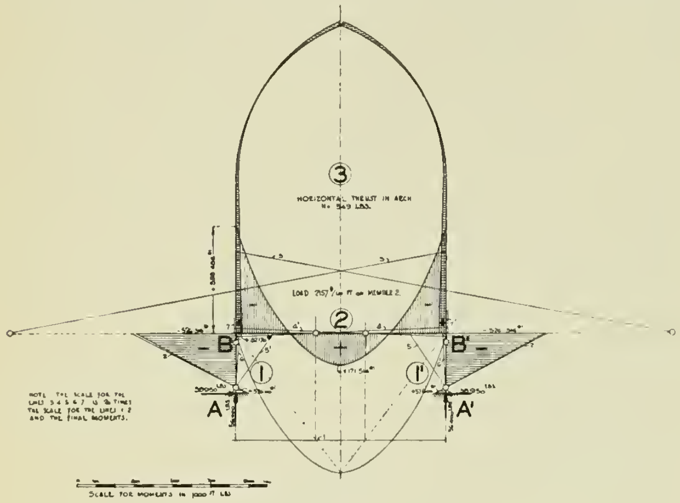

Fig. 16.

such moment). Take moment $M_2{}^B$ at point B and obtain $M_1{}^B$ and $M_3{}^B$ thus

$$M_1{}^B = M_2{}^B \times \mu_{2-1} = 558{,}000 \times 0.962 = 536{,}800$$

$$M_3{}^B = M_2{}^B \times \mu_{2-3} = 558{,}000 \times 0.038 = 21{,}200$$

Moment $M_3{}^B$ is carried over to B' and reduced to $M_3{}^{B'}$ (see line 3).

$$M_3{}^{B'} = \frac{M_3{}^B \times b_3}{l_3 - b_3} = \frac{21{,}200 \times 56.10}{52.0 - [-56.10]} = 11{,}000 \text{ foot-pounds}$$

The result is carried over to members 1 and 2 again thus:—

$$M_1{}^{B'} = M_3{}^{B'} \times \mu_{3-1} = 11{,}000 \times 0.884 = 9724 \text{ foot-pounds}$$

$$M_2{}^{B'} = M_3{}^{B'} \times \mu_{3-2} = 11{,}000 \times 0.116 = 1276 \text{ foot pounds}$$

The moment 1276 foot-pounds is carried over beam 2 by drawing a line through fixed point J_2 and we obtain (see line 4)

$$M_2{}^B = \frac{1276 \times a_2}{l_2 - a_2} = \frac{1276 \times 19.90}{52.0 - 19.90} = 790 \text{ foot-pounds}$$

This moment is carried over to members 1 and 3 again thus

$$M_1{}^B = 790 \times \mu_{2-1} = 790 \times 0.962 = 760 \text{ foot-pounds}$$

$$M_3{}^B = 790 \times \mu_{2-3} = 790 \times 0.038 = 30 \text{ foot-pounds}$$

The latter moment is small enough to be negligible. The process has to be repeated now for the end restraint of beam 2 at point B' or $M_2{}^{B'}$, and after this, all moments can be added to obtain the final moments in the frame due to the dead load on beam 2. The easiest way to sum up these moments is to use the diagram as a basis, and to tabulate the values thus:

$$M_1{}^B = -536{,}800 + 760 + 9724 = -526{,}316 \text{ foot-pounds} = M_1{}^{B'}$$

$$M_2{}^B = -558{,}000 - 1276 + 790 = -558{,}486 \text{ foot-pounds} = M_2{}^{B'}$$

$$M_3{}^B = +21{,}200 - 30 + 11{,}000 = +32{,}170 \text{ foot-pounds} = M_3{}^{B'}$$

As a check, the two moments $M_1{}^B$ and $M_3{}^B$ have to balance the moment $M_2{}^B$ and we should have

$$M_2{}^B - [M_1{}^B + M_3{}^B] = 0$$

or

$$+558{,}486 - [526{,}316 + 32{,}170] = 0$$

The horizontal thrust in the arch, due to the bending moments at both supports amounts to

$$H = M_3{}^B \times \frac{B}{2} + M_3{}^{B'} \times \frac{B}{2} = 32{,}170 \times 0.01708 = 549 \text{ pounds}$$

The final bending moments at any point of the arch is

$$M_x = 32{,}170 - 549\,y$$

Dead Load Moments in Arch. (Fig. 17.)

To determine the moments in the frame due to the dead loads of the arch, it is necessary first to calculate the bending moments of these loads applied on the principal system, or statically determinate system, for every section of the arch. (See M^0 line in Fig. 17.)

The loads applied at each point of the arch are as follows:—

Table III

Dead Loads Member 3

Points 1 to 15	34,200 pounds
Point 16	2,575 pounds
17	2,490 pounds
18	2,540 pounds
19	2,635 pounds
20	8,775 pounds
21	8,175 pounds
22	8,135 pounds
23	8,240 pounds
24	8,340 pounds
25	8,440 pounds
26	8,540 pounds
27	9,060 pounds
	112,145 pounds

To obtain the M^0 moments for each point, a time-saving method is to use the formula

$$M^0_{20} = A\,x_{20} - \overbrace{[M^P_{19} + Q_{19}\underbrace{[x_{20} - x_{19}]}_{a}]}^{M^P}$$

The above formula gives, for instance, the moment required for point 20. The notations used are illustrated in Fig. 17, and are self explanatory. The main advantage of this method is that for each subsequent moment to be computed, the moment previously determined can be used again. In the following Table, A is taken as 77,945 pounds representing the dead loads 16 to 27. The loads 1 to 15 can temporarily be neglected as they do not contribute to the moments to be computed.

Table IV

M^0 Moments in Arch (Member 3)

A = 77,945 pounds is constant

Point	x	Ax	M^P	Q	a	Qa	M^P	M^0
1 to 15	0	0	0	0	0	0	0	0

25	15.7297	1250000	348435	51905	3.5617	184900	533335	716665
26	19.6303	1530000	533335	60345	3.9006	235000	768335	761665
27	23.8203	1855000	768335	68885	4.1900	288500	1056835	**798165**
27′	28.1797	2195000	1056835	77945	4.3594	339500	1396335	**798665**
					28.1797			

For a check, the sum under column "a" must be equal to $x_{27'}$, $Q_{27'}$ must be equal to A, and M^0_{27} must be equal to $M^0_{27'}$ on account of symmetry. The difference between the two latter moments is only 0.06 per cent which is accurate enough.

In order to obtain the moments of restraint at both supports of the arch, the following equations have to be solved.

$$k_3{}^a = -\frac{\phi_3{}^b}{\beta_3} \qquad k_3{}^b = -\frac{\phi_3{}^a}{\beta_3}$$

in which β is already known, and both values $\phi_3{}^b$ and $\phi_3{}^a$ represent the angular deformations of both supports of the two-hinged arch due to the external loading (see Fig. 12).

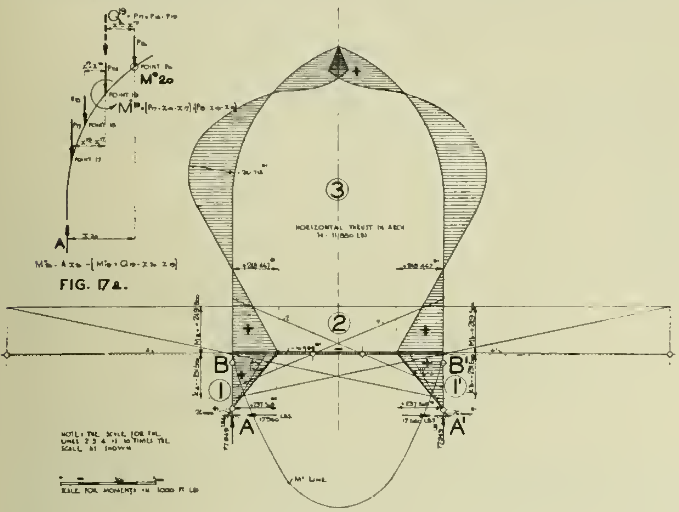

Fig. 17.

When both values k^a and k^b are known, the moments of restraint are easily obtained as shown in Fig. 17 in the following manner: indicate the distance k^a and k^b below joints B and B' respectively. Draw from the two points thus found a line through the opposite joint until the line intersects with a perpendicular drawn from the fixed points of the arch. Connect these two points of intersection with a line which in this particular case happens, on account of symmetry, to be horizontal. This latter line cuts off, at the supports, the moments of restraint $M_3{}^B$ and $M_3{}^{B'}$ which are measured in the same scale as used to plot the values k^a and k^b.

The formulae for the above angular deformations ϕ^a and ϕ^b are derived in exactly the same way as was shown previously for the value β and are

$$E\,\phi_3{}^a = \frac{1}{l_3}\sum_0^{l_3} M^0\,[l_3 - x]\,w - \frac{H}{2}\sum_0^{l_3} yw$$

$$E\,\phi_3{}^b = \frac{1}{l_3}\sum_0^{l_3} M^0\,xw - \frac{H}{2}\sum_0^{l_3} yw$$

in which H represents the horizontal thrust of the two-hinged arch due to the external loading.

$$H = \frac{\sum_0^{l_3} M^0\,yw}{\sum_0^{l_3} y^2 w}$$

The computation of these values to obtain k^a and k^b is given in the following table.

TABLE V

Point	M^0	yw	M^0yw	xw	$[l-x]w$	M^0xw	$M^0[l-x]\,w$
0-15	0						
16	1790	23.080	41300	0.0130	30.410		54500

24	598565	106.250	63600000	19.2500	63.050	11520000	37710000
25	691665	111.300	76800000	24.9000	57.400	17200000	39650000
26	761665	115.500	87950000	31.1000	51.250	23650000	39000000
27	798200	119.250	95200000	37.7000	44.600	30100000	35600000
			433726300			94665900	235539500
							94665900
							330205400

$$H = \frac{433{,}726{,}300}{57{,}156} = 7600 \text{ pounds}$$

$$E\,\phi^a = E\,\phi^b = \frac{330{,}205{,}400}{52} - \frac{7600}{2} \times 2 \times 976.26 = -1{,}070{,}000$$

$$k^a = k^b = -\frac{-1{,}070{,}000}{-4.535} = -236{,}000 \text{ foot-pounds}$$

$$M_3{}^B = M_3{}^{B'} = \frac{k_3{}^a}{l_3} \times b_3 = \frac{-236{,}000 \times [-56.10]}{52.0} = +254{,}500 \text{ foot-pounds}$$

Both these moments have to be carried around the frame again in a similar manner as shown for the moments due to the dead loads of the beam. It is best to begin again at joint B.

$$\left.\begin{aligned} M_1{}^B &= M_3{}^B \times \mu_{3-1} = 254{,}500 \times 0.884 = 225{,}000 \\ M_2{}^B &= M_3{}^B \times \mu_{3-2} = 254{,}500 \times 0.116 = 29{,}500 \end{aligned}\right\} = 254{,}500$$

$$M_2{}^{B'} = \frac{M_2{}^B \times b_2}{l_2 - a_2} = \frac{29{,}500 \times 19.90}{52.0 - 19.90} = 18300 \qquad \text{(see line 2)}$$

$$\left.\begin{aligned} M_1{}^{B'} &= M_2{}^{B'} \times \mu_{2-1} = 18{,}300 \times 0.962 = 17{,}604 \\ M_3{}^{B'} &= M_2{}^{B'} \times \mu_{2-3} = 18{,}300 \times 0.038 = 696 \end{aligned}\right\} = 18{,}300$$

$$M_3{}^B = \frac{M_3{}^{B'} \times a_3}{l_3 - a_3} = \frac{696 \times 56.10}{52 - [-56.10]} = 361 \qquad \text{(see line 4)}$$

$$\left.\begin{aligned} M_1{}^B &= M_3{}^B \times \mu_{3-1} = 361 \times 0.884 = 319 \\ M_2{}^B &= M_3{}^B \times \mu_{3-2} = 361 = 0.116 = 42 \end{aligned}\right\} = 361$$

The remaining value of $M_2{}^B = 42$ foot-pounds is small enough, so that the distribution of the original moment $M_3{}^B = 254{,}500$ foot-pounds can stop here. The moment $M_3{}^{B'} = 254{,}500$ foot-pounds has also to be carried around the frame until the remaining moment is so small that it can be neglected. On account of symmetry, this distribution gives identical values as the moments distribution shown above for $M_3{}^B$.

The result can be added up to obtain the final moments at the joints B and B'. This summation can best be done by using the diagram No. 17 as guide in order to eliminate a possible error of signs.

$$M_1{}^B = M_1{}^{B'} = 225000 + 17604 - 319 = 242285 \text{ foot-pounds}$$

$$M_2{}^B = M_2{}^{B'} = -29500 + 18300 - 42 = -11158 \text{ foot-pounds}$$

$$M_3{}^B = M_3{}^{B'} = 254500 - 696 - 361 = 253443 \text{ foot-pounds}$$

The two moments $M_2{}^B$ and $M_1{}^B$ have to balance the value $M_3{}^B$ if the result is correct, thus $242285 + 11158 - 253443 = 0$. In order to obtain the bending moments at any point of the arch, it is necessary that the final horizontal thrust be known. To the thrust of 7,600 pounds previously computed, which represents the thrust due to the dead loads of the two hinged arch, has to be added the thrust due to both end moments of restraint $M_3{}^B$ and $M_3{}^{B'}$. This additional thrust is very easily obtained by multiplying both moments by half the value of B. Therefore:

$$H \text{ final} = H + \frac{B}{2}\,(M_3{}^B + M_3{}^{B'})$$

or H final $= 7600 + 0.01708 \times 253443 = 11930$ pounds.

The following Table VI indicates the method of computing the final bending moments for the various points of the arch.

Table VI

Dead Load Moments in Arch

Point	$+M^0$	$+M_3{}^B = M_3{}^{B'}$	$-Hy$	M final

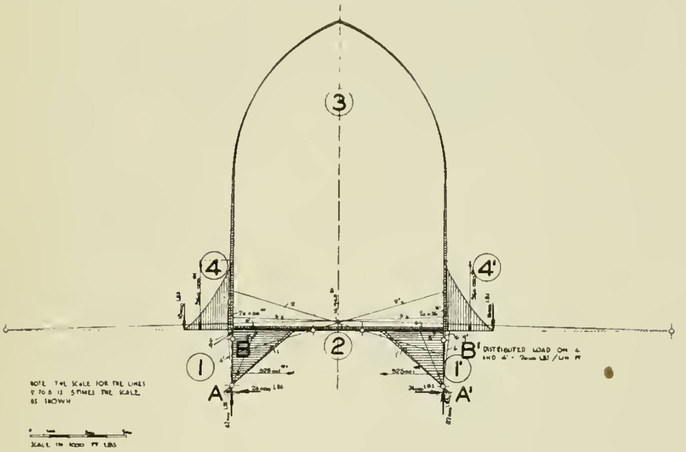

Fig. 18.

Moments due to dead loads on brackets 4. (See Fig. 18.)

The bending moment at the support of the bracket 4 due to the dead loads amounts to:

$$18000 \times 12.0 = 216000$$

$$2000 \times \frac{12^2}{2} = 144000$$

$$\text{Total } M_4{}^B = M_4{}^{B'} = 360000 \text{ foot-pounds}$$

This moment is carried over into the members 1, 2 and 3, and around the frame (as shown previously). See the following table:—

Table VII

	$M_1{}^B$	$M_2{}^B$	$M_3{}^B$	$M_1{}^{B'}$	$M_2{}^{B'}$	$M_3{}^{B'}$	See Fig. 18

	+306573	−40701	−12726	+ 18428	+25738	− 7310	
Bracket 4'	+ 18428	+25738	− 7310	+306573	−40701	−12726	
Total moments	+325001	−14963	−20036	+325001	−14963	−20036	

Verify

$$M_1{}^B = M_1{}^{B'} = 325001$$
$$M_2{}^B = M_2{}^{B'} = 14963$$
$$M_3{}^B = M_3{}^{B'} = 20036$$

$$M_4{}^B = M_4{}^{B'} = 360000 \text{ foot-pounds}$$

The horizontal thrust $H = 0.01708 \times 20036 = 342$ pounds. The bending moment at any point in the arch amounts to

$$M_x = M_3{}^B - Hy$$
$$M_x = 20036 - 342\,y.$$

Moments due to dead loads on brackets 5 and 5'. (Fig. 19.)

The uniformly distributed load on the brackets is

Slab	= 50 × 17′ 0″ =	850
Roofing	20 × 17′ 0″ =	340
Beam		300
Ceiling	10 × 17′ 0″ =	170
		1,660 pounds per lin. foot of bracket.

The bending moment at the support of the bracket

$$M = 1{,}660 \times \frac{12^2}{2} = -119{,}500 \text{ foot-pounds}$$

The moments in the statically determinate system are zero for all points from the arch support B and B' to point 11, and 119,500 foot-pounds for the points 11 to 27 inclusively. The following table indicates the computation of all values required to obtain the end moments at both supports of the continuous arch.

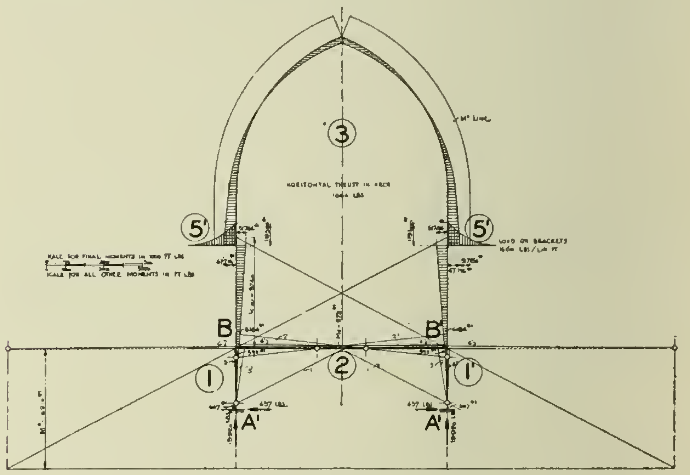

Fig. 19.

Table VIII

Point	yw	xw	$(l-x)\,w$
1 to 10 neglected as $M^0 = 0$			
11	0.00	0	0
12	17.850	0	33.200
13	19.700	0	33.200
14	21.500	0	33.200
15	23.350	0	33.200
16	23.080	0.0130	30.410
17	23.110	0.1150	28.400
18	18.980	0.2455	21.750
19	14.440	0.3450	15.450
20	34.200	1.4560	33.300
21	69.400	4.9550	60.000
22	94.500	9.8900	72.450
23	100.800	14.2300	68.050
24	106.250	19.2500	63.050
25	111.300	24.9000	57.400
26	115.500	31.1000	51.250
27	119.250	37.7000	44.600
	$\sum_{11}^{27} yw = 913.21$	$\sum_{0}^{27} = 144.1995$	$\sum_{11'}^{27'} = 678.910$
			144.199
			$\sum_{11}^{11'} = 823.109$

$$H = \frac{\sum_0^l M^0 yw}{\sum_0^l y^2 w} = \frac{-119{,}500 \times 913.21}{57{,}156} = -1910 \text{ pounds}$$

$$\varphi^a = \varphi^b = \frac{\sum_0^l M^0 xw}{l} - \frac{H}{2}\sum_0^l yw$$

$$= \frac{-119{,}500 \times 823.109}{52} - \left[\frac{-1910}{2} \times 2 \times 976.26\right]$$

$$= -26{,}000$$

$$k^a = k^b = -\frac{\varphi^a}{\beta} = -\frac{-26{,}000}{-4.535} = -5740 \text{ foot-pounds}$$

$$M_3{}^B = M_3{}^{B'} = \frac{-5740 \times [-56.10]}{52} = +6210 \text{ foot-pounds}$$

These two moments are again carried around the frame to obtain the final moments at each joint. The process can easily be followed on Fig. 19. The resulting moments are

$$M_3{}^B = M_3{}^{B'} = +6184 \text{ foot-pounds}$$
$$M_2{}^B = M_2{}^{B'} = -273 \text{ foot-pounds}$$
$$M_1{}^B = M_1{}^{B'} = +5911 \text{ foot-pounds}$$

The final horizontal thrust in the arch is

$$H = -1910 + 6184 \times 0.01708 = -1804 \text{ pounds}$$

The final bending moments at any point of the arch are now as follows:—

$$M_1{}^B = M_1{}^{B'} = +6184 \text{ foot-pounds}$$

The moment at point 11 immediately below the brackets (5)

$$= +6184 - (-1804 \times 25.25) = +51784 \text{ foot pounds}$$

The moment at point 11 immediately above the bracket 5

$$= +6184 - (-1804 \times 25.25) - 119500$$
$$= -67716 \text{ foot-pounds}$$

For the moments at points 12 to 27 and 12′ to 27′ the following formula applies:

$$M = +6184 - (-1804 \times y) - 119500.$$

The table below gives all bending moments for the points 12 to 27.

Table IX

Point	M in foot-pounds	Point	M in foot-pounds	Point	M in foot-pounds
12	−62800	18	−32300	24	+ 7700
13	−57700	19	−27300	25	+13700
14	−52500	20	−20900	26	+18200
15	−47300	21	−12700	27	+22480
16	−42200	22	− 5500	centre	+24180
17	−37200	23	+ 1700		

These final moments due to dead loads on brackets 5 and 5′ are shown in Fig. 19.

(To be continued)

Design and Application of Gears

W. P. Muir,
Mining, Metals and Plastics Machinery Department,
Dominion Engineering Works, Limited, Montreal.

Paper presented before the Montreal Branch of the Engineering Institute of Canada, December 6th, 1934.

SUMMARY.—In the following paper the general problems encountered by the designer of gears are discussed and also the best methods of overcoming these with the present empirical and theoretical data available.

While apparently a pair of gears making conjugate action and transmitting power appears to be one of the simplest forms of mechanism, the satisfactory power drive through gearing is an intricate problem in machine design.

The gear designer first of all has to determine the load to be transmitted. From a straight horsepower formula the direct load can be simply determined but other loads occur on the gear teeth which, although they bear a relation to the transmitted load, are due to dynamic forces, and are not so readily estimated. The dynamic loads are of possibly greater importance in the design of gears than the actual transmitted loads. Considerable research has been done within the last five years on the magnitude of these loads and information is now available which has not been in the past. The designer, therefore, has first to determine the probable loads on the gear teeth, which involves a study of theoretical dynamics, and next to consider the materials which are available to carry these loads. This involves a study of metallurgy because the failure of the material on the surface of the teeth is usually due to structural failure in the material itself due to fatigue in shear.

The gear designer next investigates the solid geometry of the gear teeth to study the effects of tooth shape proportions, as the solid geometry of the gear teeth has a direct bearing on their ability to carry loads. He then considers the methods to be used in the machine shop to reproduce the conclusion arrived at, and this requires a thorough understanding of the practical side of gear cutting. The conditions under which the gear will operate must be considered, such as the accuracy with which it will be held in its relationship to the mating gear; the ability of the supporting structure to carry the loads imposed on the gearing without too much distortion, which would affect the tooth contact and the ability of the gear to satisfactorily transmit the predetermined loads. Further, he must also consider the protection to be given the gears from what might be termed outside interference. They must be enclosed in a case which will prevent foreign matter, both large and small, from interfering with the proper action of the contacting surfaces. Finally, he must consider the problem of lubrication between the gear surfaces themselves and its relationship to loads imposed.

It will be seen from the foregoing that the designer of gears must have a thorough basic knowledge in a good many normally unrelated branches of mechanical engineering, and the success of his design will be governed largely by his ability to handle the mathematical and practical tools at his disposal. While the general machine designer uses, and always will use, gears in his design which he will feel free to choose and install according to his own judgment, nevertheless, in its highest development, gearing is a subject for the specialist, and the most economical and satisfactory service will be obtained from gearing which has been designed by engineers with an adequate background of knowledge and experience.

In the past, gearing has been regarded by machine designers as a nuisance to be avoided wherever possible or to be handled with resignation. In recent years the development of gear design, and, more particularly, the development of machinery to reproduce the design accurately has resulted in gears being used to a much greater extent than previously and for more particular requirements. It is possible to interconnect machines by means of gearing which normally, for reasons of their own efficiency, should run at different speeds, to make a more satisfactory and economical overall installation than would be possible if a compromise in speed had to be effected between the driver and the driven machines. As an illustration of this, marine propulsion by means of steam turbines is today almost exclusively done through gearing. The large and costly low speed turbine has been replaced by a high speed turbine operating at its normal speed. The high rotative speeds used in propellers driven by direct connected turbines have also been abandoned and the propellers today operate at their economical speed regardless of the speed of the turbine. Gearing is used to interconnect water wheels to generators and pumps so that the two individual machines can be operated at their most economical speed.

In view of the extent of the subject this paper will be confined to a study of gearing with parallel shafts as the general problems involved are common to other types.

Gear Tooth Forms

The first problem in the design of gearing is the tooth form which the gear will have when it is installed. A thorough discussion of the various curves which could be used would take too much time; however, an attempt will be made to point out the high points in the various systems used without going into detail. The problem in gearing is to transmit rotary motion from one shaft to another, usually with a reduction or increase of speed, but at all times in such a manner that the angular velocity as against time is a constant regardless of the actual teeth in the gear. The ideal, of course, would be two cylinders running in contact with gear teeth so small that they will practically be the molecular surface of the two cylinders. Such an arrangement would give a high degree of accuracy but would transmit little load.

Gear tooth forms can be subdivided into two types, those having symmetrical action on each side of the pitch point, which is the point of tangency between the two pitch circles, and those in which the action is all on one side of the pitch point. In the first category lie practically all gears with which the average engineer is familiar, and only a few special forms are now made of the other type. All systems of tooth curvature can be referred back to a theoretical rack shape, such a shape being the ideal rack which would mesh with the gear in question. The theoretical rack in the case of the cycloidal gear would have curved surfaces which would be complements of each other above and below the pitch line. This rack would generate a form of gearing which would have perfect conjugate action only under such conditions that the pitch circles were truly tangential. The cycloidal form of teeth is definitely limited to its designed centre distance and any departure from the exact centre distances for which the gears are constructed will result in irregular action, noise, and rapid wear of the gears. The involute curve, however, which is generated by a rack having a straight side will operate under varying conditions of centre distance and give a perfectly regular tooth action at varying centres. The involute curve is the only curve having this property and it is for this reason that it is so widely used in modern gearing. It is possible to get involute gearing which will operate correctly on any centres from the point where the teeth interfere on the back faces out to the point where the teeth barely touch. The regular involute action and the theoretical constant transmission of angular velocity will not be lost. It is possible to cut involute gearing of widely varying shapes with the same cutter and operating with widely varying pressure angles which will be perfectly interchangeable and will operate with each other giving perfect tooth contact and angular transmission of load. As an illustration of this, Fig. 1 shows four gears, all of which are of the same outside diameter and cut with the same cutter, the numbers of teeth varying from 18 to 21 inclusive, and all of which will mesh and operate perfectly with each other.

In the unsymmetrical group, the best known example is the Vickers-Bostock type of gear tooth, which is widely used in turbine reduction gearing in England. This type of gear, due to the concave shape of the teeth in the gear, and to the fact that the pinion teeth gain a more complete contact with such a gear tooth shape, is widely used where the horsepower to be transmitted is high. This type of tooth is generated by a rack having a curved surface, all of which is on one side of the pitch line. The curved sur-

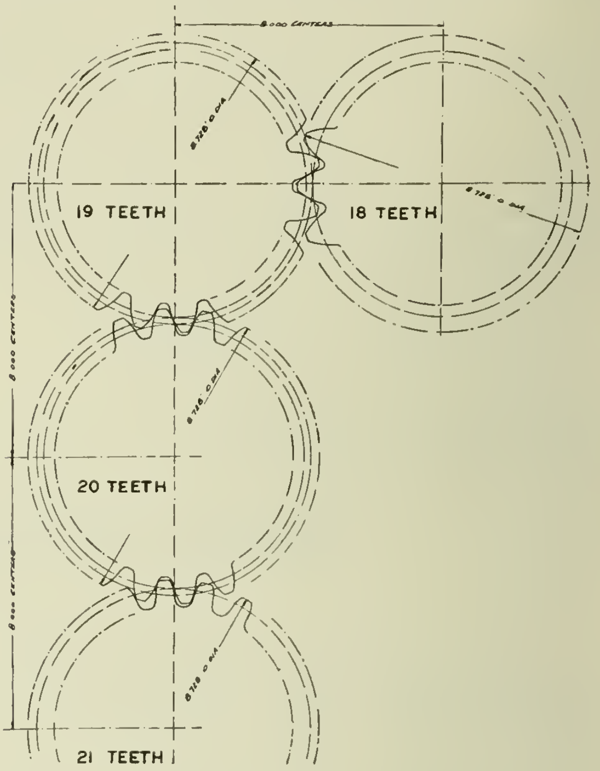

Fig. 1.

face of the rack is a combination of involute and cycloidal curves, and theoretically it requires two racks, one of which is a complement of the other, to generate the surfaces of the two gears. Due to these requirements, this system involves excessive tool cost. It also suffers from the disadvantage that the gears must be operated on exactly fixed centres for perfect tooth action, and is not generally adopted for what might be called commercial gear reducers.

The load carrying capacity of gears depends largely on the curvature of the tooth surfaces in contact. It will be obvious that, while the actual contact takes place on a line which is the point of tangency of the two curves, due to the elastic deformation of the materials used, the contact is actually spread over an area, the width of which bears some relation to the degree of curvature on each tooth and to the load. As the involute curve alters its radius from the base circle out, the rate of change of curvature is more rapid adjacent to the base circle, and this is called the "sensitive" part of the involute. Not only is the rate of change of curvature sensitive but the actual radius of curvature at this point is much smaller than further out from the base circle. For this reason there has been a tendency in recent years to depart from the old fashioned 14½-degree pressure angle and to adopt a pressure angle of 20 degrees and sometimes more, with the object of achieving contact on a less sensitive part of the involute and where the radius of curvature is greater. Of course, the use of a larger pressure angle increases the actual contact load due to the fact that the actual load contact between the teeth is proportional to the diameter of the base circle from which the involute is struck and for any given pitch diameter the base circle will be smaller as the pressure angle increases. It would seem to be poor practice to increase the load by the use of a larger pressure angle but actually it is advisable to do so to obtain a much greater increase in the load carrying capacity of the gear teeth themselves due to a larger average radius of curvature. Another consideration which is of importance is the strength of the teeth themselves. The greater pressure angle gives the pinion a stronger tooth and this has led to the use of higher pressure angles.

Stronger pinion teeth can also be obtained by modification of the addendums of the gear and pinion. It is quite a common practice among gear manufacturers today to make the addendum of the pinion longer than the addendum of the gear. This results in a stronger pinion tooth and utilizes the involute curve further away from the base circle, resulting in a greater average radius of curvature at the points of contact. From practical considerations, however, considering the relationship between the sliding and rolling contact, the modified addendum systems should only be used with gears having efficient lubrication, because the average sliding contact as compared to the rolling contact will be greater with the enlarged pinion than with the older type of symmetrical gear. For this reason, it is common practice to recommend the symmetrical type with equal addendums on the gear and pinion for exposed gearing where the lubrication tends to be inadequate, and to use the modified addendum ratio only in cases where the lubrication will be perfect.

Now to consider the various forms of gears such as spur, helical, double helical, etc. The great advance in load carrying capacity and quietness in modern gearing is undoubtedly due to the development of the machinery for generating the various forms of helical gears. A pair of spur gears with teeth parallel to their axes can be generated to give an absolutely regular transmission of angular velocity. Theoretically, however, this condition can only be obtained at no load because as soon as the gear is loaded the teeth themselves deflect and, due to the fact that in spur gears of this type the transmission of load takes place from tooth to tooth with sometimes only one on contact, tooth deflection makes it impossible to

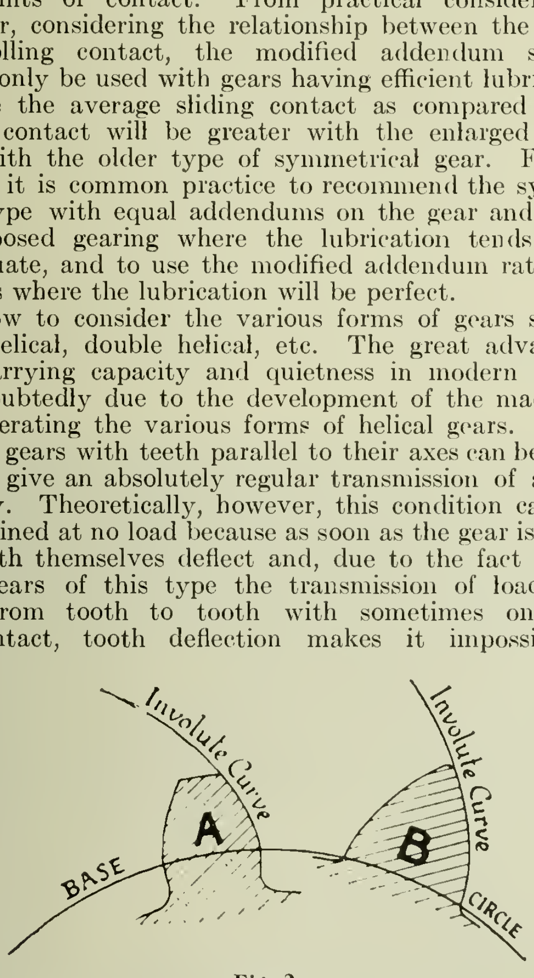

Fig. 2.

Both these teeth are for a 12-tooth pinion, generated to the involute curve from a common base circle.
A is the usual shape, and 14½ degrees pressure angle.
B has increased addendum and increased pressure angle, and uses more of the involute curve than does tooth A.
Both teeth are cut by the same cutter.

obtain the theoretical perfect angular transmission of power with any reasonable loading on the gear teeth.

In some of the more highly developed types of spur gears forms of teeth are used today having a modified tooth shape to make up for the tooth deflection, but such forms are a compromise and can only be generated to transmit power uniformly under definite set conditions of load. It is for this reason that the helical gear has come into its own in recent years, although high grade spur gears are still used, and always will be used, for specific purposes.

Due to the fact that the load per tooth varies on a spur gear as it is transmitted from one tooth to another, the wear also varies and the tendency for the spur gear is to lose its perfect tooth shape from wear. The old idea of running a pair of gears together to run them in was wrong, the only wear which can take place on a spur gear will be in the direction of destruction of the perfect tooth form and

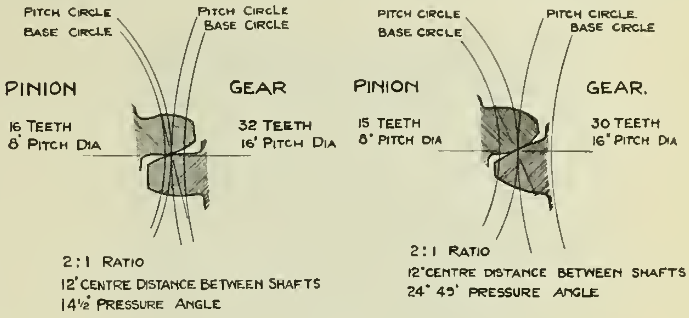

Fig. 3.

it is much better to use a form of gearing which has not this disadvantage.

Contrary to the above, helical gearing, when properly designed and cut, transmits its load from tooth to tooth with practically no change of the number of teeth in contact. As a result, the helical gear is quiet and the wear from operation shows little tendency to depart from the true generated shape.

There is really little difference in action between the single helical and the herringbone type of gear. The tooth overlap, due to the helix, will be the same with the single helical as with the double helical if the helix angle on the first is half that on the latter, assuming, of course, that the face widths, tooth proportions, etc. are the same. The essential difference between these types, however, is that for practical helix angles, the single helical gear develops thrust which must be taken up externally to the gears. The double helical or herringbone gear counteracts its own thrust, introducing no thrust forces to be taken care of in the gear mounting. It would appear, therefore, that the only practical type of gearing is the double helical. This is not the case, however, because the problem must be considered in its entirety and often the designer has good reasons for using the single helical gear so as to give the shafts axial freedom to take care of external thrusts or movements outside the two gears themselves. It is often more convenient to take care of these thrusts externally to the gears and allow some axial freedom in doing so.

As an instance to the above, there is the case of a rolling mill drive where several stands are to be driven from tandem gears by a single motor. The various roll stands are usually coupled by rather crude flexible couplings and any or all of these stands may throw considerable end thrusts back to the shafts carrying the gears. Often this thrust would be sufficient to cause severe damage if transmitted through the gears themselves. In the case of a double helical gear acting under heavy thrust, the load may frequently be many times the transmitted load due to the axial thrust operating to push one helix against the other, causing contact on the front face on one side and on the back face on the other, the transmitted load in this case being the difference between the loads. Occasionally the herringbone gear will set up axial vibration under these conditions which has been known to cause rapid destruction of the gears. Single spiral gears under these conditions have stood up perfectly, if proper provision has been made to take the thrust in the bearings.

There are three types of herringbone gears in common use. The first is the end milled gear, as made by Citroen in France. This gear suffers from the disadvantage that it must be cut with a form cutter and is not generated. The form cutter loses its shape with use and great care must be exercised in the grinding and in using the cutter to obtain a perfect gear. This type also has the disadvantage that at the apex contact between the two gears is lost, due to the difference in curvature of the surfaces of the teeth in changing from one helix to the other.

Fig. 4—Single Helical Ring Gear for Suction Roll Drive.

A more common type of herringbone cut on a hobbing machine is the Wuest gear. This gear is cut by hobs working at opposite angles and usually on opposite sides. This produces a gear which, on account of the necessary clearance between the hobs at the centre, has a gap in the middle, this gap ranging from 1 to 2½ inches or more, depending on the pitch. This type of herringbone was the first type for which generating machinery was built and came into general use about 1905.

The third type of herringbone gear is the continuous tooth with a closed apex, the two helices meeting in a plane which leaves the corners of the teeth sharp. This gear is the more modern type of generated herringbone and has the advantage of a greater effective face width and a certain amount of buttressing of the teeth in the middle, due to the angle at which the helices meet. It can be generated on several machines of modern manufacture and be cut with great accuracy.

The foregoing mentions several different types of gear cutting systems and some of the advantages and disadvantages of each system will be mentioned. End milling will not be again referred to because this type of gear is not generated and is being abandoned where more accurate systems are available. It is still used, however, on some pitches which are too large to be cut by ordinary generating machines.

The first system used for generating gears was the hobbing system. This system uses a hob with straight sided teeth to cut the involute curve, and is equivalent to generating an involute with a rack. It produces a high grade gear. The proponents of the hobbing machine point to the fact that the indexing on their machine takes place continuously and that the backlash in the indexing mechanism has very little effect on the accuracy of the gear. This undoubtedly is true but the hobbing system suffers from a few disabilities. The circular pitch of the gears can not be so readily controlled. The hob has a fixed pitch and whenever the helix angle is changed by shifting the hob to a different angle relative to the axis of the gear, the pitch of the gear is also changed. In cutting high helix angles, this is a considerable disadvantage, as is also the fact that with the higher helix angles the cutting action of the hob becomes imperfect, due to the teeth of the hob travelling in the same direction as the surface of the gear. There is therefore a limit in hobbing to the useful helix angles which can be obtained. The hobbing process is not as adaptable as some of the other gear generating systems to changes in centres which are often very useful in obtaining the exact ratio desired.

The other system is the shaping or planing system in which the action of the cutter is reciprocating. This system uses two different types of cutters, one of which is roughly in the shape of a rack and the other in the shape of a pinion. The first mentioned type of machine suffers from some of the disabilities of the hobbing process in that the amount the gear can be cut differing from standard centres to obtain adjustment in the ratio is quite limited. It, however, has the advantage of cheap cutters and will generate a satisfactory gear using normal centres and helix angles. The type of machine using a pinion-shaped cutter has the great advantage that gears can be cut of a wide range of pressure angles with the same cutter. The four small gears in Fig. 1 were cut with this type of cutter. This latitude of cutting is not possible with the rack type of cutter. This feature in design is extremely useful and makes possible gears of a wide range of strengths and adaptability from the same machine with the same cutters.

A word should be said at this point as to the various helix angles employed. The very common helix angle of

Fig. 5—Generating Double Helical Gear 20-Tooth No. 2½ D.P. 18-inch face in Sykes machine.

22½ degrees was principally used due to its usefulness on the hobbing machine as producing a gear with a normal diametral pitch with the design of hob then in use. If the problem of the thrust developed by the helix angle is neglected, which can be done with the herringbone gear, the highest helix angle makes the smoothest running gear. There are cutting difficulties, however, in using a helix angle of much more than 30 degrees because the actual pressure angle at which the teeth contact changes with the helix angle without changing the contact pressure in the plane of rotation. For a practical purpose, 30 degrees appears to be the one most generally used and is a good compromise between the wide helix angle for smooth operation and the smaller helix angle for ease of cutting. This angle of 30 degrees has been adopted by several larger manufacturers of gears as a standard and is coming into still more general use. In the case of single spiral gears one large manufacturer has adopted a helix angle of 7½ degrees, claiming that at this angle the axial thrust is negligible. However, this does not give as good a tooth action as a wider angle and for small gears a compromise is often adopted of 15 degrees. There are many considerations when deciding on the helix angle for any particular installation.

Materials

Cast iron and semi steel is still used to a large extent for gearing carrying relatively light loads. In recent years alloy irons have been developed and have been found serviceable in some gearing installations to replace steel castings. It is possible to produce an alloy iron having a tensile strength equal to mild steel, a Brinell hardness of 300 to 350, and yet which can be cut at ordinary cutting speeds and which finishes to a high finish. This is an excellent iron for many types of gearing installations.

Cast iron has one advantage in gearing over steel which has not been sufficiently exploited. The modulus of elasticity of iron is about half that for steel. This means that under the same load the teeth on an iron gear will deflect twice as much as the teeth on a steel gear. This becomes of great importance when dynamic forces are considered, which are mainly due to inaccuracies in cutting of the gear teeth, and which must be taken up by the gear tooth deflection because, at ordinary speeds, the inertia forces of the interconnected loads are so high that practically speaking the gear tooth must deflect the amount of its own inaccuracy. For this reason iron gearing will stand up longer than steel under certain conditions.

However, where care is taken in the manufacture of the gear and the teeth are generated with a high degree of accuracy, the use of steel becomes imperative to obtain the maximum load carrying capacity of the gear teeth. It is quite common to use .40 to .50 carbon forged steel in the pinion and somewhat lower carbon cast steel for the gear. It is a bad practice to run wheels of the same grade together and many failures have occurred for this reason, the failure always taking place in the pinion.

In recent years there has been a tendency to develop higher load carrying capacities in gearing by the use of alloy steels; a useful combination being an S.A.E. 3140 nickel chrome steel in the pinion, heat treated to the hardest condition that can be cut on the gear generating machine, running with a cast steel of approximately .40 carbon content and using a small amount of manganese in the steel casting. This combination is common and produces a pair of gears of about the highest load carrying capacity which it is possible to get unless the gears are hardened after they are cut. This type of gearing is called the heat treated gearing.

Several systems of hardening are in vogue, case hardening being probably the most used and an oil or water hardened high alloy being a close second. Both these systems produce a hard, tough gear but one which suffers from a certain amount of distortion in the hardening. This distortion can be quite serious in large gears.

Quench hardening of high carbon or alloy steels suffers from the same disadvantage. In helical gears there is a tendency for the helix angle to change in hardening due to the tension developed in the gear teeth themselves twisting the blank while in a plastic state. It is a common procedure for automobile manufacturers to generate their gear blanks of a modified helix angle which, when it is distorted in the hardening operation, produces the required helix angle to mesh with the other gears in the gear set. This, of course, has to be done by trial and error and is only practical as in the case of automobile gears where a large number are to be made from one design and one specification.

It can be seen, therefore, that the hardened gear is not the cure-all for gear troubles. It is extremely useful in the case of such gears as can be produced in quantities or for some types of speed reducers which are produced in sufficient quantities to make the correction of the hardening troubles feasible. A great deal can be done in this connection with tooth form grinding and lapping and various systems of lapping and grinding are being used in gear manufacturers plants to correct tooth distortion of this kind.

Fig. 6—Torch Hardening Machine.

A hardening system has recently been developed which for certain classes of work has none of the disadvantages mentioned above. This is the torch or flame hardening process, where the surfaces of the teeth themselves are hardened but the main body of the gear and even the core of the teeth are not affected. With this type of hardening, distortion can be held to a minimum, and it is doubtful if any distortion at all is present. It is possible to get a hardness with the torch hardening process utilizing suitable steels of 600 Brinell, which is somewhat higher than the generally considered useful maximum hardness. The problem in tooth hardening of gears is not, as has been generally supposed, to obtain the hardest possible surface. The failure of a gear usually takes place from fatigue below the actual surface of the tooth. This is due to the rolling action of one tooth on the other and results in pitting of the surface of the teeth. This has been investigated from a theoretical standpoint and has proved to be due to fatigue in shear of the material itself below the surface of the teeth. It is well known that the hardest materials are not those possessing the highest fatigue values and, as in this case fatigue strength is of more value than actual hardness, it is coming to be recognized by gear specialists that a hardness for the individual steel above the maximum fatigue value is useless and is actually detrimental.

Professor Buckingham in his tests on gears under running conditions at the Massachusetts Institute of

Technology has reported that while his test results are incomplete, he finds that gears hardened to the extreme, such as nitrided gears, have a lower load carrying capacity than gears hardened by a process which gives a lower Brinell value but more toughness.

Load Capacity

Until a few years ago the most common formula used in determining the horsepower carrying capacity of a pair of gears was the Lewis formula, which was developed to determine the strength of the gear teeth. This formula has been abandoned, however, for purposes of determining horsepower, as the strength of the teeth usually has little to do with the failure of the gear. Formulae have been developed based on a wear life only and neglecting the tooth strength. Tooth strength will always be a factor, however, and the Lewis formula is still used in checking the strength of the teeth where conditions of abnormal shock or heavy momentary loads have to be encountered.

In considering the wear life of gears, one must first know the actual loading. A valuable contribution on the actual loading taking place between the teeth of a pair of gears has been published by a Committee of the American Society of Mechanical Engineers and is based on a series of tests extending over a period of five years on actual pairs of gears run to destruction. From the results of these tests the committee has developed a formula from which can be estimated the actual dynamic loading which a pair of gears is capable of transmitting. Tests have been run on spur gears exclusively and the gear industry is awaiting with much interest the results on further tests on the same machines utilizing helical gears.

Dynamic loading is always present in the case of spur gears but it is generally considered that the use of helical gearing reduces the dynamic forces to such an extent that they can be neglected. No accurate data is available, however, to support this contention and the dynamic loads to be met with helical gearing are still indeterminate.

An interesting paper was read by Mr. W. P. Schmitter before the A.G.M.A. Annual Convention* last spring on the theoretical considerations of contact between the surface of the teeth of a pair of helical gears entitled "Helical and Herringbone Speed Reducer Ratings." This is a step forward in the available data on the subject, but the formulae developed are rather cumbersome to utilize in everyday work. Formulae have been developed, however, from actual known cases of success and failure extending over many years and which are serviceable for every day use. Practically all manufacturers of herringbone and helical gearing use these simple formulae. The following is a formula very generally used for the horsepower capacity of helical gearing.

H.P. Formulae

$$H.P. = \frac{D^2 \times W \times N \times B \times S \times C}{1260} \quad \text{or} \quad \frac{P}{WD} = 100 \times B \times S \times C$$

D = Diam. of pinion in inches.
W = Face width in inches.
N = R.P.M. of Pinion.
P = Total pitch line load.
B = Velocity factor.
S = Material factor.
C = Service factor.

Velocity Factor

Pitch Line Speed	"B"	Pitch Line Speed	"B"
0 Feet per minute	1.8	2000 Feet per minute	.9
200 " " "	1.5	3000 " " "	.85
500 " " "	1.25	4000 " " "	.8
1000 " " "	1.15	8000 " " "	.7

*American Gear Manufacturers Assn., Meeting May 3-5, 1934.

Material Factor

Spur gear rating....... .8
Open gear rating...... .8
Speed increasers.......Special

In the development of this formula it has been assumed that the horsepower capacity of a pinion is directly proportional to the diameter and face width. While this may not be strictly true in all cases, it is approximately true in the great majority of gear designs and has good theoretical backing to recommend it. The modification factors for velocity service and material are important. The velocity factor is introduced to take care of dynamic loads which are accentuated by higher speeds. The service factor is introduced to take care of applied loads exterior to the gear and, to a certain extent, of the endurance capacity of the gears. The material factor is self-explanatory. The service factor is the most important one to be considered in the use of this formula. The reason for this is that the other factors such as velocity, material, etc. can generally be determined by the gear designer but he must use his judgment to estimate the service the gear has to meet in use. The practical horsepower capacity of a gear set may vary over a range of 500 per cent, from extremely severe service conditions such as a rolling mill drive to light intermittent duty such as the operating gear of a valve. To rate a gear set for a given horsepower at a stated ratio and speed and neglect the service factor, is just as foolish as to say that an athlete who can run 100 yards in ten seconds can keep up the same rate of speed all day. In either case fatigue is neglected which, while it would not occur as quickly in a gear set as in the case of the athlete, will be just as certain. It is interesting to note that automobile gearing, which is probably the most highly developed gearing in general use, is designed to be adequate without being unnecessarily large. It is rarely called upon to transmit full engine power for more than a few seconds at a time and in fact the gearing in common use on trucks has a life of only about five hours at full engine power with low gear engaged yet failures in normal service are exceedingly rare. It would be uneconomical, in view of the low percentage of failures, to build such gears with a full load life expectancy of even a week on continuous running because this condition would never occur.

The service factor in the design of gearing is of prime importance and the factors shown on the attached chart can be used as a guide but, however, could be extended or reduced at the discretion of the designer within certain limits. Those shown are for the ordinary run of commercial gearing but for high speeds, and particularly for speed increasers, the factor will generally be below the .45 shown as the minimum. For intermittent duty, or where the life is not important, the factor can be extended beyond the value of 2 shown.

For a quick check on horsepower capacity of gearing, the simplest formulae is the following:

$$\frac{P}{WD} = 100 \times B \times S \times C$$

This formula means that the total pitch line load divided by the face width and the diameter of the pinion is equal to 100 times the various factors shown. The value P/WD should be not more than 50 for high speed gears, increasers, and heavily loaded drives; 100 for the ordinary type of commercial speed reducers and all the way up to 1500 for such gears as the drive gears for the propellers of an airplane which are made of extremely good material, hardened to the extreme, and lapped to the maximum accuracy possible, and where the life, in any case, is limited to a certain number of hours of engine operation.

Any formula or expression is proposed for guidance only, and to assure that the recommendations of the designing engineer will be consistent and conservative. The specification covering the gear set must be tempered by his experience, his sense of proportion and his good judgment, just as with the design of any other piece of equipment.

An attempt has been made to put, in their simplest form, the two most useful formulae used today in designing gears. Many other considerations, however, have to be borne in mind. These formulae are generally based on the assumption that the ratio would be about 5:1, and it will be found that for low ratios such as a 1:1 drive, considerable modification would have to be made because the assumption that the horsepower capacity is proportionate to the diameter of the pinion would obviously not hold good in this case. It is usual to assume that spur gears have approximately 80 per cent of the value shown on the above formulae which have particular reference to herringbone and helical gears.

Consideration must also be given to lubrication and these formulae should not be used for anything but gears operating under perfect conditions. For exposed gears a considerable modification would have to be made.

Gear Mounting

The mounting of the gearing is another important subject as for best results gearing must always be mounted on fixed centres and by means of bearings and shafts which will not deflect and throw the gears out of line under load. It will be obvious that if one of the shafts deflects, the tooth contact will be made on the corners of the teeth and the surface in contact will be rapidly destroyed from overloading. The highest development of gearing utilizes the enclosed gear cases with high grade sleeve or roller bearings mounted on the shafts as close as possible to the gears and with adequate lubrication for the teeth.

The use of roller bearings is becoming general in gear mountings even in the case of large rolling mill drives on account of the benefits from such mounting in that the gears are always held to exact fixed centres and that the axes of rotation of the two gears is always held parallel. Roller bearings are an extremely useful type of bearing and the writer knows of only one application where a sleeve bearing would be preferable, namely, in extremely high speed gearing where the noise due to a roller bearing mounting transmitting the gear vibration to the case becomes extremely annoying. Theoretically it is possible to cut a pair of gears which will operate noiselessly but practically speaking all commercial cut gears will make a certain amount of noise in operation. This noise is accentuated by high speed operation and where roller bearings, with their metal to metal contact, are used under these conditions, the whole set, although it may be a perfectly satisfactory machine from a life point of view, is likely to be extremely noisy. For this reason it is usual to use high grade self-aligning sleeve bearings for these conditions.

Lubrication

The subject of lubrication is one that can be treated in several different ways. The object, of course, is to maintain an oil film between the teeth of the gear at all times so that actual metal to metal contact does not take place. The design of the teeth has some bearing on the ability of the oil to lubricate the gears properly.

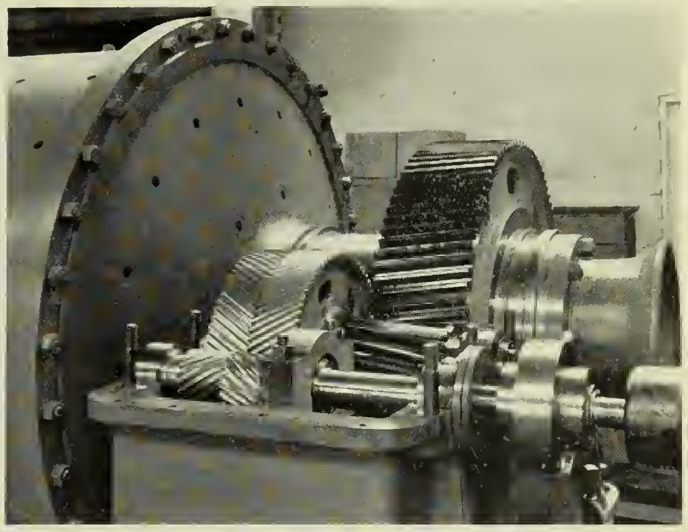

Fig. 7—Drive Gears for a 6-foot by 5-foot Ball Mill.

As mentioned previously one of the reasons for the use of the modified addendum for enclosed gearing is to increase the contact on the arc of recession, that is, where the teeth are drawing apart, and to decrease the contact on entrance. The reason for this is that where the teeth are entering, the tip of one tooth has a tendency to scrape off the oil from the flank of the mating tooth. This occurs up to the point where the pitch point is crossed. After the pitch point, the direction of slide of one tooth on the other is reversed and the slide takes place with more of a wiping action, which has a tendency to retain the oil between the surfaces rather than scrape it away. For this reason the teeth of the pinion are usually lengthened and the teeth of the gear shortened, or, as it may be termed, the addendum ratio of pinion to gear is increased.

If you will observe the Vickers Bostock gear you will note that the contact is all on the recession side of the pitch point, the lubrication is very efficient and this accounts to a large extent for the excellent operating characteristics of these gears. For this reason also it is usual in the case of a stepped up ratio, or an increaser, to reverse the ratio of addendums, making the addendum of the gear greater than the addendum of the pinion, which has the effect of increasing the arc of recession again at the expense of the arc of entrance.

Many different types of oils are utilized in the lubrication of gears. In general it can be said that the heaviest oil which can be carried into the tooth mesh without excessive heating from churning will be the best for the lubrication of the gears. Some special oils have been developed having a greater stickiness than normal oils of the same body for gear lubrication and these are undoubtedly extremely useful. In the past few years another grade of oil has been developed called the E.P. (extreme pressure) oil. This oil is usually combined with some compound which produces a very hard coating on the surface of the teeth themselves due to a combination of the oil with the steel of the gear. This oil has been extremely useful and was developed to increase the load carrying capacity of automobile gears, where the whole tendency seems to be to make the engines of more and more power while keeping the gears of approximately the same size for purposes of road clearance. To date, however, this oil has not been used to any great extent in commercial gearing. It has no value whatever in increasing the resistance of the pair of gears to pitting from fatigue, and as this type of failure is usually the first sign of failure from overloading, the use of the E.P. oils, with an increase in load carrying capacity, does not seem to be advisable, at least until more is known about the subject.

In lubricating a speed reducer it is usually necessary to use an oil which will also be suitable for the bearings. In the case of roller bearings this presents no difficulty because any oil which is satisfactory for gearing will be satisfactory for the roller bearings, provided they are fed with the required amount regularly. In the case of plain bearing speed reducers, however, the heavy oil suitable for the gears is not always suitable for the bearings, which might be ring or collar oiled, and it becomes necessary to provide a gear case with two different oiling systems which must be kept apart to prevent the contamination of one oil by the other. This presents considerable difficulty in the use of such bearings for heavy duty gearing. As to lubricating systems, it is generally considered that up to a pitch line speed of 2,500 or 3,000 feet, splash lubrication is perfectly satisfactory. Above this range of speed, spray lubrication becomes necessary, involving the use of an oil pump with sprays to feed the mesh of the gears with an adequate supply of lubricant. Generally speaking, for the higher speeds, a cooler is also essential because the heat radiating capacity for all gear boxes of extremely high speeds will be inadequate to dissipate the heat generated. In utilizing splash lubrication, it is advisable not to dip the gears too far into the oil. Cases have occurred where a gear case was running hot and the user kept adding oil with the result that the gear case ran hotter, due to churning of the oil. No definite rules can be laid down as to the amount the gears should dip into the oil because this will vary considerably with the speed and with the body of the oil. It is only necessary to dip the gear sufficiently to carry an adequate supply of oil into the mesh. Anything more than this results in a useless waste of power in churning the oil.

In considering the advisability of cooling in speed reducers, it is interesting to note that the modern gearing utilizing herringbones or spiral types of gears cut on a generating system with extreme accuracy and adequate lubrication operates at efficiencies of about 98 per cent. Cases have been known on actual test where gears of this type have developed an efficiency of over 99 per cent. The amount of heat to be dissipated is, of course, proportional to the drop in efficiency in the gear set, and this must be dissipated into the surrounding air by the surface of the gear case.

Conclusion

The statements made in the foregoing are what are generally conceded to be the best conclusions that can be drawn from empirical and theoretical data available. There is no doubt, however, that with the furthering of the knowledge on gearing, and with more tests, considerable modification will have to be made in the various conclusions drawn. In any case there is no question but that modern gearing is an extremely efficient and useful mechanism. The various uses to which it is being put are ever being extended and engineers in general are coming to have more confidence in this type of mechanism.

DISCUSSION

C. D. Bailey, A.M.E.I.C.[1]

This paper is of great interest, because of its broadly informative character and the intensive development proceeding in gear engineering.

Our present conception of gear teeth is that of an elastic mechanism, sustaining and transmitting loads of orders and at speeds which permit of only the most refined geometric forms.

In the area of the overlap of the pinion on the gear, which may be called the mesh, there is a balanced system of forces caused by the total dynamic load. This dynamic load has two components:—

(*a*) The useful transmitted load;
(*b*) The increment load.

This increment load is the sum of the effect of the vibrations system of the mechanism and the resistance of the inertia forces to changes of velocity induced by errors of the gear tooth forms.

It is proposed to outline the development of a gear system wherein this increment load has been reduced by greater potential accuracy of form, and whose transmission capacity has been added to by a reasoned selection of that portion of the involute curve which forms the working profile.

Description of System

A review of conditions existing five years ago revealed that while the standard systems had excellent properties in certain ranges, the effects and appearance of undercut teeth were objectionable; that gears were noisy and that they showed excessive wear.

A decision to improve matters determined that a replacing system would include shapely tooth forms of

[1]Dominion Bridge Company Limited, Lachine, Que.

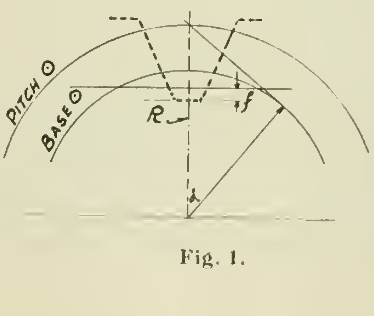

Fig. 1.

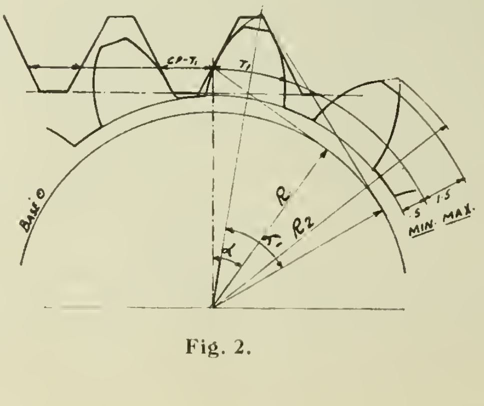

Fig. 2.

balanced strength, with favourable rolling and sliding action, and that the tooth form would be modified to preclude interference.

The principle of universal interchangeability was abandoned. Centre distances proportional to the number of teeth in a pair were retained.

Tooth forms would be involute and would all be generated from the same basic rack. The number of teeth in the smallest pair would be 42, infrequent smaller pairs being embraced by a subsequent extension of the system. The smallest pinion would have 10 teeth and the maximum ratio of addendum to dedendum would be 3 to 1.

The operating pressure angle of 20 degrees, constant by virtue of standard centre distances, was selected when comparative analysis indicated its greater possibilities.

The critical 10-tooth pinion for the smallest pair of 42 teeth was then designed by including the most suitable portion of the involute between the limits of undercut radius $R \cos^2 \alpha - f$ and the radius at which the tooth became pointed $R^2 = \dfrac{R \cos \alpha^2}{\cos \alpha_1}$. This was obtained by means of an outward radial shift of tooth profile on the pinion and a corresponding inward radial shift on the gear.

The 10-tooth pinion was then meshed with the next larger gear—33 teeth—then 34 teeth, and so on, and as the gear increased the practicability of increased shift was utilized until the 10-tooth pinion meshed with a 35-tooth gear when the 3 to 1 maximum ratio of addendum to dedendum was reached after which this maximum shift was constant on all succeedingly larger gears. The same method was followed on the 11-, 12-. 13,- 14-, and 15-tooth pinions, meshing them with first their smallest gear, 31 tooth with the 11-tooth pinion, 30 on the 12-tooth, and so on, then with gradually increasing gears until the maximum shift was reached then continuing this shift unaltered for all larger gears. When the 16-tooth pinion meshed with the 40-tooth gear this progressive correction was arrested somewhat before the maximum correction was reached; because of extremely favourable contact conditions. This followed with the other larger pinions—17, 18, 19, 20 and 21 teeth. The 21-tooth wheels were the smallest equal wheels by the minimum limit of 42 and were identical by symmetry.

The corrections or shifts of profile were then averaged using Buckingham's method of arbitary increments, twenty-five steps of .02 giving the maximum correction and the correction of any pair being .02 $(N - n)$, or if the gear had more than 40 teeth, .02 $(40 - n)$, where N = number of teeth in gear and n = number of teeth in pinion.

Quality of Contact

During these selections of profile certain criteria of quality were established to govern judgment and to maintain it consistently.

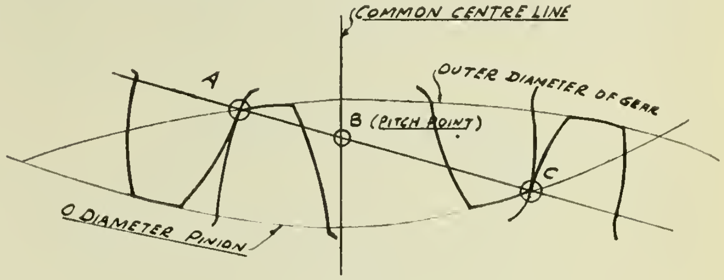

Fig. 4.

They consisted of:

(*a*) Duration of contact.
(*b*) Sliding and rolling properties.
(*c*) Minimum radius of curvature.
(*d*) Strength of form.

Duration of Contact

The common tangent to the base circles of the pinion and the gear is the locus of the point of contact. Theoretically, contact begins at "*A*" and ends at "*C*." If we take the line *AC* and superimpose it on either of the base circles the arc it will cover will be the arc of contact and its length divided by the normal pitch will be the duration of contact expressed in tooth intervals. The arc *AB* will be the arc of approach and the arc *BC* will be the arc of recess.

The value of long duration of contact lies in the condition of distribution of load among a greater number of teeth, in the reduction of load imposed near the root and near the tips of the teeth, and in the consequent smooth-

ness of transfer of load. For any kind of transmission of power, the duration of contact must exceed 1.0 tooth intervals; should exceed 1.35 tooth intervals, and in the system being described is never less than 1.44 tooth intervals.

From Baud and Peterson 1929:—

When D = Duration of contact of 1 − 2 tooth intervals.

One pair of teeth sustain load $\left(\frac{2}{D} - 1\right)$ of time.

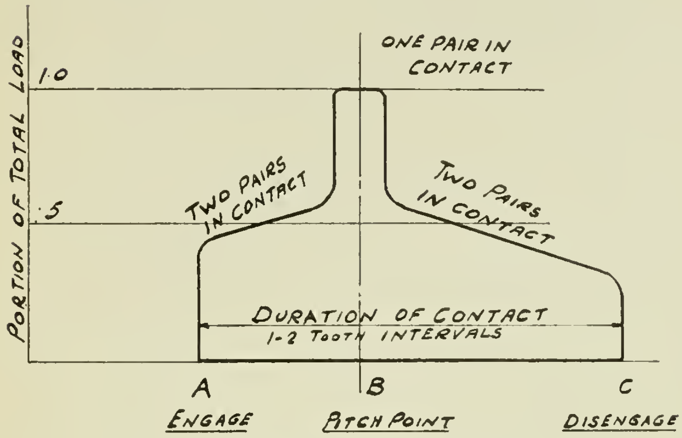

Fig. 5—Typical Variations in Load on Contact Point as it Proceeds Through Mesh.

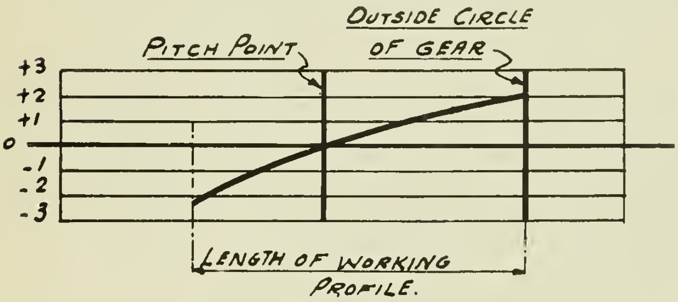

Fig. 6—Graph of Slide.

Two pairs of teeth sustain load $\left(2 - \frac{2}{D}\right)$ of time.

When D = Duration of contact 2 − 3 tooth intervals.

Two pairs of teeth sustain load $2\left(\frac{3}{D} - 1\right)$ of time.

Three pairs of teeth sustain load $3\left(1 - \frac{2}{D}\right)$ of time.

Sliding and Rolling

In involute tooth action when engagement takes place near the pinion base circle, a relatively long arc of the gear tooth contour slides over a very short arc of contour of the pinion tooth. When contact has progressed to the pitch point the radii of the arcs in contact are proportional to the gear ratio and a purely rolling action is simulated. As contact proceeds into the arc of recess the increasingly greater arcs of contour of the pinion tooth slide over the decreasing arcs of the gear tooth so that the direction of sliding changes and its amount increases to the point of disengagement.

The specific sliding is the amount of sliding per unit length of the arc of profile on which the sliding occurs and, while unimportant by itself, it is essential that its change along the tooth profile be gradual. Abrupt change in the graph of the value shows sensitivity of form and may indicate difficulty of lubrication of the tooth form in service.

Minimum Radius of Curvature

This important length is the least radius of the involute of any working profile in the mesh. When engagement takes place near the base circle it is short and rapidly changing, that is, sensitive. This sensitivity is expressed in violent change in sliding and is perhaps productive of the major errors in the tooth form, owing to the inability of the

hob, or cutter, to faithfully reproduce the rapidly varying curvature.

The outward radial shifts of pinion tooth profile postulate an increase in this radius and, therefore, an increase in capacity of the profile to sustain load:—

(*a*) at a point where it is usually most unfitted to take it;
(*b*) at a point where high stress is exceedingly dangerous because of the proximity of the stress concentrations at the fillet of the tooth root;
(*c*) at a point where, because of (*a*) or (*b*), or both, wear and destruction of the tooth form is most evident and troublesome on standard tooth forms.

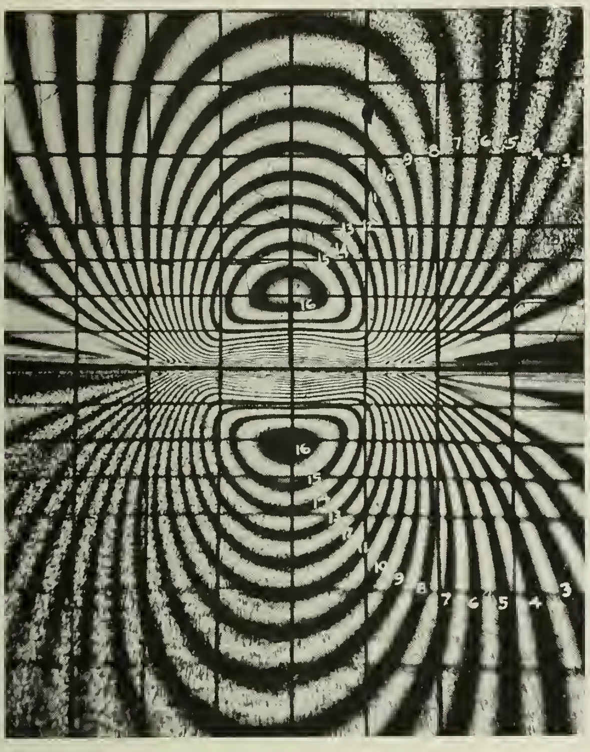

Fig. 9—Stress Distribution in Gear Teeth at Contact Points.

Lewis Factor Y

This is a tooth form factor used in the Lewis formula $W = SPFY$ where S is the stress from primary bending considering the load W applied at the tip of a tooth of circular pitch P. While the formula apparently takes no account of the relieving influence of long contact (Fig. 5) when less than half the load will be applied at the tip and when the full load is only sustained near the pitch line, this is approximately balanced by the existence of stress concentrations at the root fillet (Fig. 7). The figured stress is probably an inclusive approximation of the maximum stress from primary bending in well designed teeth and all gears (especially those whose surfaces have been hardened to resist wear and, therefore, to sustain greater unit loading) must be designed to resist it.

Comparison of Results of Gear Systems

The shifts of tooth profile have resulted in uniformly high qualities of all properties. In Fig. 8 three ratios from the system being described (which is here named the 20 degrees New Standard), are compared with ratios from other important gear systems.

In the 12/30 tooth ratios the 14½-degree standard system has no continuity of contact while the 20-degree stub and the 20-degree standard is apparently good, but this is due to an extensive undercut being present on the tooth which is reflected in the contact, the minimum radius, and in the weakness of the pinion.

In the 15/27-tooth ratio only the 20-degree new standard and the 20-degree standard are suitable for inclusion in a power drive or any responsibility, with the sliding well balanced on both and of moderate magnitude. The minimum radius of 20-degree new standard is three times that of the 20-degree standard.

In the 21/40-tooth ratio the contact is of reasonable duration on all systems except the 20-degree stub. The better sliding, greater minimum radius, and balanced strength of the 20-degree new standard system are evident.

The excellent sliding characteristics of the 20-degree new standard system, which is, of course, a long and short addendum system, are at variance with the views expressed by the author in that section of his paper dealing with tooth forms and are in part responsible for the excellent functioning of these gear teeth.

VOLUME XVIII AUGUST 1935 No. 8

Professional Technical Training

A study of the present membership list of any professional engineering organization, as compared with a list of twenty years ago, will make it evident that engineers as a class are becoming employees rather than employers. The proportion of members of The Engineering Institute, for example, who are in private practice as consulting engineers has dropped steadily, while more and more of our members have become engaged in various salaried capacities in the field of industry, in engineering, supervisory or executive positions; many are concerned with sales or service activities in connection with engineering equipment or products.

To devise educational courses which will prepare for the more responsible positions in such a diversity of occupations is a formidable task; in fact the field of engineering training is full of experiments, the interpretation of whose results gives rise to constant debate. There are, however, certain broad questions which claim attention. To what extent are the higher supervisory and executive positions in the field of industry, including in this term service and construction as well as manufacturing, filled by university graduates in engineering as compared with men trained along other lines? What provision is made for the benefit of technicians, superintendents and foremen in the form of technical training of a less advanced kind than that given in the universities? Are the needs for vocational or apprentice training being met with a view to an adequate supply of skilled craftsmen? What chance of advancement in status is there for a man who has not been able to find the time or money necessary for a college course, and has been trained along more specialized, but possibly less theoretical lines? Such queries as these give food for thought. It must be noted that at the present day the demands on the intelligence and education of men who are leaders in the workshop or on the construction job, are continually increasing. A foreman, besides supervising the work in his department, may have to pronounce on the response of new materials to new methods, or deal with questions of rate setting, economics of handling materials, or the working of cost systems. Modern mass production has called into existence an army of specialists who deal with the design and construction of tools and jigs, or equipment for special processes of treatment or manufacture. In fact, the workshop is, to-day, offering a far wider opening for technically trained men than has ever existed before.

The types of technical training now available in Britain and North America for those who are to be engaged in the engineering industries may be broadly classified as, post-graduate work at the university in preparation for special work or research; the normal four-year engineering courses at schools of university rank; the shorter and less advanced courses of training offered by technical institutes; and the courses given at vocational or apprentice schools. The two latter naturally have closer relationships with specific industries than is possible in the case of university courses. It is interesting to note that in the United States, technical institutes or schools are maintained by a number of the larger industrial companies for the purpose of training new employees.

The General Motors Institute of Technology at Flint, Mich., is a good example of this type of school. Its object, as the president of General Motors Corporation puts it, "is to select men with potentialities for broader responsibilities and attempting to train these men for advancement." It provides a two year course in basic subjects such as mathematics, mechanics, machine design, engineering English and shop practice, followed by a further two years in industrial plant or service subjects. Throughout their courses, students receive pay as employees of the company, but a substantial tuition fee is charged. Almost without exception, high school education is required for admission. A recent report states that over ninety per cent of the young men passing through the school remain in the employ of the Corporation. Many technical institute courses of the United States, like those at Flint, are co-operative, the students spending their time partly in the school and partly in the shops.

As regards the demand for educational facilities of this kind, it has been estimated that in the United States, while ample provision for four-year engineering training is provided by the engineering colleges now existing, about one hundred and fifty in number, industry could absorb some forty to fifty thousand technical institute graduates annually, a number substantially in excess of those now available. A recent survey of industrial education in the eastern states gives for the New York area alone a total of some one hundred and twenty thousand supervisory positions in fifty-three thousand companies, employing one and a half million men. Only a small proportion of these concerns offer instructional courses for their employees, but it must not be forgotten that in all the larger industrial centres there are available well developed programmes of evening instruction. Unfortunately it does not seem possible to extend these facilities to less thickly populated areas, and the courses offered by correspondence schools are only a partial substitute for personal teaching and laboratory work.

The situation in Britain has developed along somewhat different lines, and is more systematically arranged. Engineering instruction of university rank is given in all the main centres of population. There is a well organized system of local technical schools, provided with laboratory facilities and giving both day and evening instruction of a more utilitarian type, in many cases with the co-operation of local engineering firms. There are regular standards for entrance requirements and the universities recognize the work done at a number of the larger technical schools, admitting to their degree examinations students from them who have followed certain prescribed courses. In other cases, the local technical institutes' courses are such as to prepare for the Associate Membership examinations of the Institutions of Civil, Mechanical and Electrical Engineers, or for other like examinations which in England are becoming widely recognized as standards of engineering education. In England the support of industry has been given to this work rather by benefactions from industrial leaders than by the establishment of special schools by the industries themselves. The government and local authorities have been able to spend a good deal of public money on technical education with the result that the classes provided are comparatively inexpensive. Further, in many of these schools, by the aid of scholarships, a boy of capacity, even if his means are small, can obtain an excellent training.

In this country we are well provided with engineering schools of university rank, whose excellence is attested by the careers of their graduates. First rate technical schools exist, like those in Toronto, Hamilton, Montreal and elsewhere, but outside of the main centres of population there are not as yet in Canada adequate facilities for the young man who has to work for his living and at the same time desires to fit himself for advancement in industrial life. We have very few scholarships. It would seem that here, as in the United States, as far as engineering education is concerned, the need is not for a larger number of four-year engineering colleges, but for a higher standard of admission and attainment in those that now exist. It is believed that there are many undergraduates in these institutions whose characteristics and bents are such that they would do better in some more utilitarian type of training, and that the efforts of the university staffs would be more effective if the undergraduate standard were raised. On the other hand, better provision should be made for technical school students of exceptional capacity and force of character who wish to proceed to institutions where they can fit themselves for the higher branches of engineering work.

There is at the present time a tendency to lay stress on the possession of a university degree, as in itself constituting a guarantee of professional capacity as an engineer, and as being alone sufficient to differentiate its possessor from the mere technician. A degree from one of our leading engineering schools is no indication of professional experience, but it does confer a definite status not attainable in any other way; such degrees are therefore recognized by The Institute by-laws and by those of the professional associations. It is noteworthy, however, that The Institute's requirements for admission as corporate member do not close the door on those who have not had the advantages of a university course, provided that they can show that they have received an equivalent training by other means. It is for this reason that The Institute's system of examinations has been established. Many of the candidates who take them have had engineering experience of a kind which makes them invaluable in the modern world of industry and when admitted are able to make substantial contributions to The Institute's work in the interchange of professional knowledge. Any scheme of professional organization which fails to provide for the recognition of such men would be open to objection, as bearing hardly on a class whose exclusion from its ranks would be a great loss to the engineering profession.

New Membership List

It is over three years since the last list of members of The Institute was published, and it has been found necessary to issue a new edition this Fall. This list will appear as a separate section of The Engineering Journal.

Information cards have recently been forwarded to the membership of The Institute, requesting the name, present official position and address of each member that this information may be correctly recorded.

The completeness and accuracy of the list will be greatly increased if the members will co-operate fully and return their cards with as little delay as possible.

The Institute Prizes and Medals

The Sir John Kennedy Medal—a gold medal awarded to corporate members of The Institute as a recognition of outstanding merit in the profession or of noteworthy contribution to the science of engineering or to the benefit of The Institute.

Past-Presidents' Prize—a cash donation of the amount of One Hundred Dollars, or the winner may select books or instruments of no more than that value, for the best contribution submitted to the Council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by the Council at the beginning of the prize year. The subject of the essays to be submitted for the competition for the prize year July 1st, 1935 to June 30th, 1936, is "The Engineer's Contribution to Transportation."

The Duggan Medal and Prize—a prize of a medal and cash to a combined value of approximately $100.00 open to all members of The Institute to be awarded each year from the proceeds of a donation by Past-President G. H. Duggan, D.Sc., LL.D., M.E.I.C., for the purpose of encouraging the development of the branches of engineering in which he practised. Papers to be eligible for this competition shall deal with such subjects as arise in that sphere of constructional engineering which concerns the use of metals in moulded or fabricated shape for structural or mechanical purposes.

The Gzowski Medal—a gold medal awarded to members of The Institute for the best paper of the medal year, provided such paper shall be adjudged of sufficient merit as a contribution to the literature of the profession of civil engineering, but not otherwise.

The Leonard Medal—a gold medal awarded to members of The Engineering Institute of Canada or of the Canadian Institute of Mining and Metallurgy, for papers on mining subjects presented either to The Institute or to the Canadian Institute of Mining and Metallurgy.

The Plummer Medal—a gold medal open to those who belong to The Institute or to non-members if their papers have been contributed to The Institute and presented at an Institute or Branch meeting. The papers to be on chemical and metallurgical subjects.

Prizes for Students and Juniors—technical books or instruments to the total value of Twenty-Five Dollars. Students and Juniors of The Institute only are eligible to compete.

The H. N. Ruttan Prize—The four western provinces;

The John Galbraith Prize—The province of Ontario;

The Phelps Johnson Prize—Province of Quebec (English);

The Ernest Marceau Prize—Province of Quebec (French);

The Martin Murphy Prize—The Maritime provinces.

Sir John Ambrose Fleming Receives the Kelvin Medal

The Kelvin Medal is awarded triennially as a mark of distinction in engineering work or investigations of a kind with which Lord Kelvin himself was especially identified, the award being made by a committee appointed by the principal engineering societies in Great Britain.

This year, on Tuesday, May 7th, the medal was presented to Sir John Ambrose Fleming, F.R.S., at a meeting held at the Institution of Civil Engineers, the presentation being made by the Postmaster-General. In doing so, Sir Kingsley Wood pointed out that engineers were indebted to Sir Ambrose, not only for his own contributions to research, but also for the inspiration he had given to many generations of students. He was glad to have the opportunity of drawing attention to the great debt which the radio industry owes to Sir Ambrose for the development of the thermionic two-electrode valve.

OBITUARIES

Charles Lang Cantley, A.M.E.I.C.

It is with deep regret that we place on record the death of Charles Lang Cantley, A.M.E.I.C., while bathing at Scarboro Beach, Me., on July 14th, 1935,

Mr. Cantley was born at New Glasgow, N.S., on May 4th, 1884, and received his early education at the New Glasgow Public School and St. Andrews College, Toronto, graduating from McGill University in 1909 with the degree of B.Sc.

Following graduation Mr. Cantley joined the staff of the Nova Scotia Steel and Coal Company, and until 1910 was resident engineer in charge at Wabana Mines Limited, Newfoundland. He was later engineer and assistant underground manager. In 1911 Mr. Cantley was appointed engineer at Sydney Mines, N.S.

On the outbreak of war, Mr. Cantley went overseas as a major in the 13th Royal Highlanders of Canada (Black Watch) but due to his outstanding ability in the metallurgical field coupled with executive ability, he was recalled to Canada to reorganize the munitions department of the Nova Scotia Steel and Coal Company.

After the war Mr. Cantley went to the United States and became engineer with the Mutuelle Solvay of America Inc., in New York. Later, returning to Canada, he became general manager of the Nichols Engineering and Research Corporation of Canada Ltd., in Montreal, and a year ago was appointed president of the Company.

Mr. Cantley joined The Institute as a Student on May 2nd, 1907, and on June 10th, 1911, became an Associate Member.

Alfred O'Meara, M.E.I.C.

Members of The Institute will learn with regret of the death at Victoria, B.C., on July 5th, 1935, of Alfred O'Meara, M.E.I.C.

Mr. O'Meara was born at Stoke Prior, Worcestershire, England, on August 4th, 1858, and received his later education in Cork, Ireland, taking a course in civil engineering at Queens College in 1876-1879. Following this he was until 1880 pupil of a Mr. Law of the Ordnance Survey, Southampton. In 1881 he was on the construction of the Nottingham Melton Mowbray railway, and later received practical instruction in underground work at a tin mine in Cornwall.

In 1883 Mr. O'Meara proceeded to Newfoundland, and was for the next three years in charge of prospecting and developing an auriferous quartz mine on the north east coast. In 1886-1888 he was assistant in charge of location and construction of the Placentia Railroad, and in 1888-1890 Mr. O'Meara was in charge of the city sewerage works of St. John's, Newfoundland. In 1888 he was appointed deputy land surveyor for the Island of Newfoundland and Dependencies. In 1892 Mr. O'Meara went to British Columbia, and was in charge of drainage works for the municipality of Chilliwack until 1894, when he returned to St. John's, Newfoundland, and engaged in private practice. In 1898-1903 Mr. O'Meara was in charge of mining work for the British Columbia Rossland and Slocan Syndicate in the Yukon Territory and Northern British Columbia. Returning to Victoria he practiced engineering in that city until 1905 when he joined the engineering staff of the city, retaining the connection until several years ago when he retired.

Mr. O'Meara joined The Institute as an Associate Member on October 8th, 1908, became a full Member on April 13th, 1912, and was made a Life Member in November 1923.

PERSONALS

B. Russell, M.E.I.C., has been appointed chief engineer for the Water Development Committee under the Rehabilitation Board for the Prairie Provinces, and will be located at Swift Current, Sask.

Edwin J. Beugler, M.E.I.C., consulting engineer, Cheshire, Conn., has been appointed a member of the first board of registration for state engineers and surveyors for the State of Connecticut.

Squadron-Leader K. M. Guthrie, Affi.E.I.C., who was formerly at Fort Osborne Barracks, Military District No. 10, Winnipeg, Man., has been transferred to the Department of National Defence, at Ottawa, Ont.

W. G. Hamilton, S.E.I.C., is now connected with the engineering department of Canadian Johns-Manville Company Limited at Asbestos, Que. Mr. Hamilton graduated from the Nova Scotia Technical College in May of this year with the degree of B.E. in mining.

Professor C. V. Christie, M.E.I.C., Department of Electrical Engineering, McGill University, has been elected vice president of the American Institute of Electrical Engineers for the year beginning August 1st, 1935, as announced at the Annual Meeting of that Institute held recently at Ithaca, N.Y.

The Engineering Institute of Canada Prize Awards 1935

Eleven prizes known as "The Engineering Institute of Canada Prizes" are offered annually for competition among the registered students in the year prior to the graduating year in the engineering schools and applied science faculties of universities giving a degree course throughout Canada.

Each prize consists of twenty-five dollars in cash, and having in view that one of the objects of The Institute is to facilitate the acquirement and interchange of professional knowledge among its members, it has been the desire of The Institute that the method of award should be determined by the appropriate authority in each school or university so that the prize may be given to the student who, in the year prior to his graduating year, in any department of engineering has proved himself most deserving as disclosed by the examination results of the year in combination with his activities in the students' engineering organization, or in the local branch of a recognized engineering society.

The following are the prize awards for 1935:

University of British Columbia	John Richardson
University of Alberta	Frank James Hastie
University of Saskatchewan	Arthur Frederick Burke Stannard
University of Manitoba	Eliot Robertson Davis
University of Toronto	William Murray Lawrason, S.E.I.C.
Queen's University	William N. Simmons
Royal Military College	Robert M. Powell, S.E.I.C.
McGill University	Donald Carman McCrady
Ecole Polytechnique	Louis Trudel, S.E.I.C.
University of New Brunswick	Donald D. Cunningham
Nova Scotia Technical College	E. C. Thomas

Committee on Consolidation

The Committee on Consolidation is making no further report on its work this month, pending the submission to the membership of a complete report on the results of the "Questionnaire" which, it is hoped, will be received from all the Branches and Provincial Professional Associations, by the middle of August.

A Presentation of British Columbia Views on the Federation Problem

*P. H. Buchan, A.M.E.I.C.,**
Past-Chairman, the Vancouver Branch of The Institute

Introduction

In the year 1929, The Institute and the provincial associations of professional engineers agreed to the appointment of a Dominion Committee of Four, composed exclusively of members chosen by the associations, one representing the Maritimes, one for Quebec and Ontario, one for the three Prairie Provinces, and one for British Columbia. This body was appointed to discuss the general question of federation. After making a report in 1931, it was resolved into a Committee of Eight, consisting of one representative from each provincial association. The new body adopted the report of the previous committee and was expected to formulate plans for implementing that report. Since its last meeting in 1933, this committee has been inactive while awaiting the outcome of proposals advanced by Institute committees which disregarded the foundations already laid. The following thesis on the problem, as it occurs in British Columbia, aims to demonstrate to all Institute members, that the only practical way to achieve federation will be to insist on action by and through the Committee of Eight. The Institute is favourably placed to give impetus to this movement.

The Federation Problem—1935

During the past fifteen years, there has been a movement among engineers in Canada to obtain legal power to register and regulate their own profession in a manner similar to the sister professions of law and medicine. Progress, evidenced by the rapid growth of bodies incorporated and clothed with this power under special legislation in eight of the nine provinces, has engendered within The Institute a desire for some simple plan whereby any member who has complied with the law, may, by the payment of one combined fee, secure to himself the rights and privileges of both The Institute and the provincial corporation in which he is registered. This sounds like a simple proposition; but the fact is that its complexities have constituted a problem so baffling in its fundamentals, that not only has no generally acceptable plan been forthcoming, but the resulting controversy has tended to discourage all who have devoted time and energy to its solution.

Primarily, we have to devise a means of co-ordinating two distinct types of professional organization, the one, a Dominion society based on the voluntary principle, the other, a provincial corporation based on the compulsory or licensing principle. This situation is complicated by the presence of other voluntary societies, somewhat differently constituted to The Institute, which nevertheless, have many professionally qualified members whose future relations with The Institute must be given full consideration in any scheme which proposes a federation of The Institute with the profession. Besides, there are the eight provincial corporations of the compulsory type, which vary widely in the application of licensing power. Moreover, within either type of organization, we find extensive variation in the qualifications for admission to corporate and junior membership. Again there are the reactions of the individual members of these organizations to be considered. Some are unable to see any need for a registered or licensed engineer to belong to a voluntary society, if voluntary membership requires the payment of additional dues; some employed engineers who belong to one or more voluntary societies, can see no reason why they should be subject to registration law. Others think that membership in a voluntary professional body ought to be sufficient qualification for admission to any licensing corporation without special formalities, or vice versa. And there are those who are unable to see why either type of professional organization should not suffice for all practical purposes.

It is quite apparent that no plan could hope to satisfy so many conflicting opinions and conditions. Modification of some of them is essential; yet whenever proposals have been submitted which run counter to cherished views on the subject, opposition invariably has arisen to forestall any advancement in the direction suggested. Consequently, the only immediate prospect of attaining federation lies in the promotion of that common understanding of the fundamentals of the problem, which is prerequisite to an acceptance of the views of those who, by dint of lengthy study and experience, have gained a practical knowledge of the subject.

The Engineering Profession in British Columbia

The Engineering Act of the Province of British Columbia became law in 1920, followed by amendments in 1924 and 1927. The Association of Professional Engineers of B.C., incorporated in 1920 under the Act, commenced with a charter membership of about three hundred and fifty professional engineers, admitted on credentials. This body has grown in fourteen years, to a corporate membership numbering about eight hundred and twenty-five, with over five hundred enrolled student engineers who are actively qualifying for corporate status under the Association's Student System.

During the past twelve years, admission to corporate membership has been by examination, exceptions being sparingly granted, and only when the credentials of the candidate place his qualifications unquestionably within the standards prescribed by the Examining Board and the By-Laws of the Association. The jurisdiction of the Association covers all branches of professional engineering; and because over ninety per cent of the practising engineers in the province are registered as corporate members, the Association has indisputable grounds for asserting itself to be "The Engineering Profession in British Columbia."

Enrolment of Profession in B.C.
March, 1935

Branch	Member	Engineer-in-Training	Engineering Pupil	
Civil	446	84	—	
Mining	171	62	—	
Mechanical	101	44	—	
Electrical	71	50	—	
Chemical	15	30	—	Total
	824	270	250	1,344

Civil Branch includes Structural, Railway, Forest, Logging, Municipal, Geographical, Irrigation and Hydraulic.
Mining Branch includes Metalliferous, Coal Mining, Placer Mining, Geological and Metallurgical.
Electrical Branch includes Telephone and Hydro-Electrical.

On this continent the term "engineer" has a somewhat casual meaning, being applied broadly to persons possessing superior technical skill, whose occupations are identified with the general field of engineering. It embraces many skilled artisans or mechanics, as well as the professional practitioners. The resulting confusion has led to the adoption in British Columbia of the term "professional engineer," to mean any person qualified to practise engineering, as distinguished from those who, being merely skilled artisans, are not so qualified.

The Engineering Act of B.C. deals exclusively with the professional man. It applies to all grades of assistant engineers above the grade of junior, as well as the chief and consulting engineers, and makes no distinction whatever between employed engineers and those engaged in private practice. It defines the "practice of professional engineering" in considerable detail, and forbids any person who is not duly registered or licensed, to practise in any branch of engineering falling within the scope and meaning of the definition. The Act also forbids the adoption of the title "professional engineer," or any abbreviation thereof, by persons who are not so registered or licensed, excepting only those who are exempted by special provisions of the Act.

The fundamental principle of the Act is the prescribing and developing of a formal system of training and examination for all who would become members of the profession. Graduation from a school of engineering is not in itself a sufficient qualification. The *fundamental purpose* of the Act is to maintain a high standard of engineering practice in British Columbia, and thereby promote public confidence in all persons who by law, are entitled to call themselves "professional engineers." The Act requires the Association to pass by-laws relating to the government, discipline and honour of its members, and the examination and admission of candidates to the *study* and practice of professional engineering.

The Association maintains its headquarters at Vancouver, and a salaried registrar on a full-time basis. The incumbent of this position since incorporation is E. A. Wheatley, A.M.E.I.C., whose diligent researches in the field of professional organization have won for him an ever-widening reputation as an authority on the subject. The faith of the engineering profession in the continued improvement of its status through the agency of the Association, is represented by the expenditure on this venture since incorporation, of a sum in excess of $150,000, contributed in entrance fees and dues by the active membership. It is noteworthy that no part of this amount has been contributed by the voluntary societies operating in the province.

The Institute in B.C.

Having outlined the scope and purpose of the Engineering Profession in British Columbia, let us now discuss the position of The Engineering Institute of Canada. At the time of writing, the total enrolment in the province consists of roughly two hundred and fifty persons, including those on the non-active list.

*B.C. Electric Railway Co. Ltd., Vancouver, B.C.

Summary of E.I.C. Membership in B.C.

Branch	Corporate Active	Corporate Suspended	Juniors and Students	Affiliates	Total
Civil	161	13	41	4	219
Mining	4	1	2	..	7
Mechanical	7	1	7	..	15
Electrical	3	3	2	..	8
Chemical	..	..	1	3	4
	175	18	53	7	253

Comparison with the preceding statement of membership in the B.C. Association, shows that the ratio of Institute enrolment to that of the Association is about 250 to 1,350 or 18.5 per cent. Moreover 86 per cent of The Institute membership is civil, the mining and electrical branches comprising a mere 6 per cent, whereas in the Association, the mining and electrical branches combined, comprise at least one third of its total enrolment. Obviously The Institute has no grounds whatever for considering itself to be the chief representative of the engineering profession in the province, nor is it capable of determining for the mining, mechanical, electrical and chemical engineers in British Columbia any set policy of professional expansion, without their willing acquiescence. Any move of The Institute that might have the appearance of disregarding the opinions of these engineers would scarcely be conducive to the harmonious relations that are so essential for professional solidarity.

The mining and electrical engineers of the province have a preference at the present time for voluntary societies, namely the Canadian Institute of Mining and Metallurgy and American Institute of Electrical Engineers, which minister to their special needs more effectively than The Institute. That such is the case is regrettable from The Institute point of view, but cannot fairly be denied. However, The Institute is distinguished from these societies by its uniformly professional character as measured by the standards of the Association. It is this kinship which has been chiefly responsible for the favoured position it occupies in relation to the provincial body; also because it comprises the largest single group of registered British Columbia engineers, and because its Dominion charter enables it to function as a national society connecting to a large extent, the professional engineers in all parts of Canada. One means of ensuring a continuance of this sympathy between the "Engineering Profession in B.C." and The Institute, has been the annual invitation extended by the Executive Committee of the Vancouver Branch to the president and registrar of the Association to sit as honorary members of the Executive. That this gesture has been appreciated by the Association, is evidenced by the regular attendance of the registrar at the monthly meetings, and the unstinted co-operation given towards furthering the progress of Institute activities in the province.

Compared with the position of The Institute in other provinces, the eighteen per cent minority ratio of its enrolment in British Columbia will probably occasion no little wonder. This circumstance arises from three main causes; firstly, the fact that notwithstanding its altered name, it has continued to be regarded in British Columbia as the Canadian Society of Civil Engineers; secondly, that the electrical and mining engineers naturally gravitate to their favourite societies, the American Institute of Electrical Engineers and the Canadian Institute of Mining and Metallurgy; and thirdly, that the Association has enrolled practically all the professional practitioners and juniors in the several branches of engineering, with the result that those who have not yet joined one of the voluntary societies, are less disposed to join now, except under the strongest of inducements. Moreover, the influence of the financial depression has been particularly unfavourable to The Institute in the last mentioned particular.

Although a somewhat superficial glance at the situation may give many readers of The Journal the impression that The Institute in their own province occupies a premier position, and that comparison with British Columbia would avail them of little else than a feeling of complacency, the real truth of the matter is that the situation in Canada as a whole clearly resembles that in British Columbia. The latest available figures, compiled by the registrar of the B.C. Association in September 1932, will serve to illustrate the fact.

Province	Corporate Members of Association	Being also Members of E.I.C.	Per cent of Assn.	E.I.C. Corporate Members in Province
Nova Scotia	212	110	52	146
New Brunswick	157	85	54	99
Quebec	1188	667	56	927
Ontario	1206	475	39	1179
Manitoba	260	204	78	166
*Saskatchewan	88	52	59	124
Alberta	262	113	43	161
*British Columbia	824	125	15	193
*B.C. Students 220 E.I.T.† 250 E. Pupils	470	43	9	53
	4797	1801	39	3015

*Improved March, 1935.
†Does not include about 50 graduates (1934).

If to the 1,801 joint members we add the 2,996 members of the associations who are not members of The Institute and the 1,214 Institute members who are not registered in any association, we discover that the ratio of Institute corporate membership to the total is 3,015 to 6,011 or about 50 per cent for the whole of Canada. This figure is representative but cannot be taken as complete because of the unknown content of mining, electrical and other branches of engineers. Admittedly there are wide variations in different provinces; but if the national problem of the engineering profession and the problem of Institute development as related to it, are to be solved on the basis of facts as they exist today, British Columbia men have the fruits of fourteen years of experience to offer as a guide to enlightened thought on the subject.

How the Profession in B.C. was Developed

The natural question that the reader now will ask is how the Engineering Profession in British Columbia developed its present strength from such small beginnings, and what part did The Institute play in the process? To answer the question, it will be necessary to refer again to the history of the professional engineer movement in the province.

In 1919 or thereabouts, the desire for some form of legal regulation, translated itself into an effort to procure legislation based on the "Model Act" recommended by The Engineering Institute of Canada. Unfortunately, The Institute, although recognized as being the leading professional body in the province at that time, did not represent more than about twenty-five per cent of the resident practising engineers. In order to gain the co-operation of the majority of these men, it was necessary to form the B.C. Technical Association, which all could join with a minimum of formality. With this new body solidly behind a committee chosen from its own membership and representing all branches of engineering, legislation was obtained at Victoria in 1920, previously referred to as the "Engineering Act." Armed with that somewhat emasculated document, the committee launched the Association, which has carried on since that year. Shortly afterwards the B.C. Technical Association was disbanded. Incidentally it was found that quite a number of the members of that body could not qualify for admission to the Association and therefore were unable to procure certificates of registration as professional engineers.

The Association at once realized that their weakened Act would not permit the unrestrained use of legal power. There certainly was no complete unanimity of opinion among the resident practitioners regarding the matter of registration. Many believed it ought to apply to everyone but themselves. Also employers as a whole viewed the new movement with some uneasiness, although very few showed open hostility to it, most of them believing that the loopholes in the Act would save them from any uncomfortable situations that might arise.

Early Councils wisely adopted an educational policy aimed to accomplish what legal pressure could not do under the prevailing circumstances. This policy visualized a completely registered and regulated engineering profession in British Columbia, animated by a truly professional esprit-de-corps and genuine loyalty to a formally approved code of ethics. It foresaw the willing endorsement of the registration principle by employers and clients alike, provided it could be established in the public mind that registration meant reliability, competence and fair dealing.

Legal compulsion has been studiously avoided, yet undoubtedly there exists today, a strongly developed esprit-de-corps throughout the B.C. profession, and a record of progress which bears witness that the purposes of the Act and the hopes of the originators have been justified. Fourteen years of struggle against economic conditions, apathy, and destructive criticism and inherent weaknesses in the Act have produced the present strong and virile organization.

The most remarkable feature of enrolment is the very high percentage of employed engineers. The educational efforts of past administrations have procured an immense number of voluntary applications from these practitioners, whereas a threat of legal action would have invited sustained resistance and a very disastrous record of failure. Practising engineers of acknowledged standing, who come into the province, readily comply with the regulations, mainly because they feel that it would not be playing the game to refuse. Little or no trouble has been experienced in respect of licences, with any of them. The same applies on the whole to resident engineers, who have evidenced very little real objection to the authority of the Association in the matter of registration. Moreover, it is now quite customary for chief and consulting engineers to insist that their subordinates be registered as members of the Association, or enrolled in one or other of its junior grades according to their individual attainments—a policy which tends to retain appointments and promotions within the ranks of the profession.

The credit for these highly commendable results is attributable principally to wise and tolerant administration and the very sparing use of legal power; also to the carefully framed educational policy aimed to teach the engineer, the client, and the employer, together with the junior aspirants to professional rank, their parents and instructors, the higher duties, qualifications and ethics of professional life. The noticeable improvement in the status of British Columbia engineers rests partly on the maturing strength of the Association, and partly on the power exercised by the Council, to conduct inquiries into all complaints arising from irregularities in professional conduct, or from failures attributable to negligence or lack of professional qualifications.

The thoroughness and impartiality with which these inquiries are conducted, together with the exercise of disciplinary powers when circumstances warrant, is serving to establish in the public mind that the B.C. profession is soundly constituted and stands for a square deal to both the practitioner and the client.

In cases of evasion of the law or of professional misdemeanour, a privately conducted investigation, followed by a forceful presentation to the culprit of the unethical nature of the practice complained of, backed by the power of organized professional opinion, usually has a salutary effect. The potentialities of this method are based entirely on professional esprit-de-corps. The knowledge that such things simply are not done is a powerful deterrent. The odd successful case of evasion, either of the law or the code of ethics, eventually leads the perpetrator into an untenable position.

Although the present administrative practice of the Association is to some extent in advance of the actual letter of the law, further amendment of the Engineering Act would greatly simplify the process of enforcing obedience in recalcitrant parties. Amendments have been under consideration for several years past, but application for legislation has been withheld, pending the adjustment of certain differences of opinion as to the precise intention of some clauses. Considerable progress has been made of late towards ironing out these difficulties.

Admission by Examination and the Student System

The most important requirement of the Engineering Act of B.C. in the practical sense, is the duty laid upon the Association to pass by-laws providing for "the examination and admission of candidates to the *study* and practice of professional engineering." That clause was inserted in the Act because it was recognized that a successful attempt to raise the status of the profession must depend primarily on a strictly enforced standard of qualifications for all persons entitled to the use of the term "professional engineer." Therefore, admission by examination became a cardinal principle of the Association, and early materialized in a carefully prepared system, administered by a competent Board of Examiners. This principle is the real foundation of "The Engineering Profession in British Columbia."

From the beginning it was evident that, quite apart from the eventual registration of every adult practitioner, provision would have to be made for the education and training of the youth of the province to fit them for admission to the profession upon reaching the qualifying age. The resulting by-laws gave effect to the belief that in the course of a few years, the strength of the Association would be maintained not so much by the annual increment of new practitioners taking up residence in the province, as by the annual influx from the ranks of the junior assistant engineers employed therein. The Association has no power to exercise legal compulsion in this regard, but by virtue of its "Student System," the youth are encouraged to enrol in the successive grades of "Engineering Pupils" and "Engineers-in-Training," and are progressed by prescribed courses of study and examination until they finally qualify for admission under the Act. As before stated, over five hundred of these juniors are enrolled under the "Student System."

The non-university applicant may file his name with the Association at the age of 17, on being sponsored by his employer. At 19 he sits for the Preliminary Examination. At 21 or 22, depending on his progress, he can take the Intermediate, which qualifies him as an Engineer-in-Training. At 25 to 27 he may sit for the Final or Professional Examination.

The university undergraduate in engineering is advised and encouraged to enrol as an Engineering Pupil in his third year. Upon graduation he is granted enrolment as an Engineer-in-Training on application, without being required to sit for the Intermediate Examination. The Final Examination takes the form of a thesis, based on the candidate's experience during the four years subsequent to graduation. However if the curriculum of the institution be not approved by the Council of the Association, the graduate may be required to pass the Intermediate, and will most certainly be required to sit for the full Final Examination before being granted a certificate of registration.

By virtue of this system, not only does the Association promote the advancement of the status of the profession, but it ensures from youth, the development and continuance of a proper professional consciousness throughout its membership, based on the principle that what requires effort to obtain, is thereafter the more highly prized and the more jealously guarded.

The Dissemination of Engineering Knowledge

Up to this point, little has been said about the essential functions of professional organization, which are in a measure, complementary to the business of registering and regulating the profession. These functions, selected from the objects of The Institute, are familiar to readers of The Journal.

"To facilitate the acquirement and interchange of professional knowledge among its members; to encourage original research, and the study, development and conservation of the resources of the Dominion; to collaborate with the universities and other educational institutions in the advancement of engineering education.

"To promote intercourse between engineers and members of allied professions; to co-operate with other technical societies for the advancement of mutual interests.

"To advance the professional, the social and the economic welfare of its members and to enhance the usefulness of the profession to the public."

The provincial corporations in general, and the B.C. Association in particular, are not equipped to maintain these objectives as a whole, although their regular activities must necessarily be concerned with the professional and economic welfare of their members, and very properly, with the advancement of engineering education. Most of the field as outlined, is left clear for the voluntary societies, although the B.C. Association has an auxiliary luncheon organization called the "Engineers' Club," which serves as a meeting ground for professional engineers of all branches in the Vancouver area. The fortnightly luncheon meetings, usually addressed on some topic of general interest to the profession, have become a popular institution and are beneficial in breaking down that sectionalism that is so apt to affect the relations of the various branches of the profession. Moreover, the Club, during the past three or four years, has maintained an Engineers' Relief Committee, which has centralized the efforts that otherwise would have necessitated separate committees in each of the voluntary societies. This work has been efficiently handled through the Registrar's office, and even non-registered men have been aided wherever possible, thus indicating that the professional men are at least actuated by a broad-minded spirit.

In recent years it has often been stated that the principal object of The Institute is the dissemination of professional knowledge. If this assertion be true, it is equally certain that The Institute's activities in that direction do not cover, in the practical sense at any rate, the whole field of engineering, even in the province of British Columbia. There are other prominent voluntary societies engaged in the dissemination of engineering knowledge and the promotion of research—in the mining and metallurgical field for one, and the electrical field for another. Moreover, the number of national industrial associations which maintain committees on engineering matters in connection with their own special branches of industry, is very extensive. The personnel of these committees usually are chief or consulting engineers representing large organizations, with plenty of funds to spend on experimental work under the direction of specialist engineers, the result being the production of reports or papers which in many cases are of outstanding value as contributions to engineering knowledge.

The Institute's activities are of interest mainly to civil, structural and hydro-electrical engineers, although some attention is given to the mechanical and aeronautical branches. Broadly speaking however, electrical, mining, metallurgical, chemical, forestry, and many other specialist engineers have to depend on societies other than The Institute for their professional "stock in trade." These bodies vary in character from something approximating The Institute, to the definitely constituted industrial bodies. The latter type has two main varieties; the one, such as the Canadian Institute of Mining and Metallurgy, being composed of individuals and member companies; the other, such as the Canadian Transit Association, being composed of member companies only.

During recent years, some members of The Institute have advocated reorganization as a technical society, open to all ranks of engineering without special regard to professional qualifications, their aim being a great increase in membership from what the B.C. profession terms the "*skilled* artisan class," thereby enlarging the scope of The Institute as a disseminator of general engineering knowledge. Obviously a body of that character would be face to face with a diversification of activity quite beyond practical limits; and moreover, it would immediately be in open competition with the numerous industrial associations now functioning successfully in almost every branch of engineering. For these reasons, if for no other, the proposal appears to be unsound.

The Skilled Artisans

The term "skilled artisan" is used broadly, to distinguish the mass of persons engaged in the field of engineering, from those who are especially grouped as the engineering profession. The former are men without higher educational qualifications, who comprise the routinists of engineering organization, from which stratum emerge foremen, inspectors, supervisors (such as roadmasters, bridge or building masters, etc.), superintendents and contractors. In this stratum the university graduate and the well qualified practically trained engineer carry on without any distinction or recognition as professional men in the making. The system in force in British Columbia reaches out a helping hand to these men by classifying them and offering guidance to their final training as professional engineers.

Before the advent of the provincial corporations of engineers, The Institute was the only body in Canada whose standards of admission enabled the young graduates and the practically trained aspirants to professional rank, to acquire recognition as professional men in the making. The Institute still performs this service in its own way, and that is the reason why the B.C. Association has raised such strenuous objection to the proposal to lower the standards of admission. A flood of "skilled artisans" entering The Institute on terms of equality with professional men, would entirely destroy the advantages of membership to the latter, and would eliminate any possibility of closer relations with the provincial professional bodies.

Moreover, the fact that the public has been educated to regard membership in The Institute as evidence of professional standing, is a further reason why a general lowering of the standards of admission are regarded with keen disfavour by British Columbia engineers, who have been to such pains and expense to impress upon the public mind, the practical advantages of employing the enrolled pupil engineer, the engineer-in-training and the fully qualified professional engineer, in place of the untrained routinist and the partially qualified engineer. Try to picture the confusion in the public mind, if in their own organization, engineers on the one hand deny professional standing to any person who is not qualified under their own standards, and on the other hand, they themselves disregard these standards as being of no consequence. How could the public be expected to learn the lesson we are at such pains to teach, if they were to observe professional men and "skilled artisans" mingling on a common footing in a supposedly professional society. No amount of explanation would suffice to undo the mischief.

The Engineering Profession in Canada

Having made such noteworthy progress with their provincial organization, and having demonstrated the soundness of their policies and methods of administration, is it to be wondered at that British Columbia engineers have an earnest desire to see their system in effect in every province? They are conscious of having pioneered a way to fuller recognition and appreciation of the engineering profession by engineers themselves as well as by the public. They believe that only so long as the composition and policies of the voluntary societies are at one with the interests of the profession, are such societies entitled to a place in the professional organization.

The Institute is one of the voluntary societies, but notwithstanding the superiority of its membership, numerically and professionally, there are numerous engineers qualified for professional status whom The Institute has not enrolled. The engineering profession, however, embraces all of these men. Therefore, if the proposed extension of professional organization is to effect a condition of complete solidarity, the mining and metallurgical engineers, for example, must be given a voice in both the preliminary and final negotiations. Their society unfortunately is of the industrial type. It meets their own requirements, and we have no right to interfere with its organization or its activities. But on account of its composition, the Canadian Institute of Mining and Metallurgy is not admissible as a body, to negotiations involving strictly professional organization. Consequently it was necessary, a few years ago, to exclude all the voluntary societies from the preliminary discussion of national organization of the profession, in order to avoid any appearance of discrimination. By limiting these discussions to representatives of the provincial corporations, which enrol all practitioners irrespective of their specialist qualifications, this principle was maintained. The final outcome was the report of the "Committee of Eight" in 1932.

That report outlined a general plan for co-ordinating the eight provincial corporations under a Dominion Engineering Council, having in view the eventual equalization of engineering acts, standards of admission to practise, student systems, and administration policy.

The report further recommended a Dominion Engineering Body composed of the membership of the provincial corporations, and intended to function along the lines of The Institute, as a society complementary to the registration or licensing organization. The Institute is thus afforded an opportunity to fit itself for acceptance as the Dominion Body of the Engineering Profession in Canada. Now it should be more than ever evident why The Institute would be acting contrary to its own interests, if it resolved itself into a wide-open industrial body, as some members have advocated.

The Institute's Opportunity

It was expected that active steps to implement the report of the Committee of Eight would soon be taken by the provincial corporations. Unfortunately, however, the apparent lack of appreciation of the real intention of the report, coupled with the absence of a central agency to arouse the provincial bodies to action, has resulted in a marked recession of interest in the matter east of the Rockies. If The Institute could be won over to the undivided support of British Columbia principles, it could, through its Journal and the co-operation of its twenty-five branches, conduct a national campaign to get the movement started afresh.

Successful completion of the interprovincial organization under the Dominion Council would pave the way to fulfilment of the ideal presented herein, of the Engineering Profession in Canada fashioned after the Engineering Profession in B.C. Meanwhile, The Institute, by giving leadership to this movement, would be accorded recognition by practitioners in *all* branches of the profession as their potential Dominion body, thereby assuring its eventual acceptance as such by common consent.

Institute Development

In the opinion of British Columbia professional engineers, any broadening of the basis or lowering of the standards of admission to The Institute, whereby any person "fit to associate with engineers" would be allowed to enrol in The Institute and thus receive its official recognition, is contrary to all principles of a professional body and would be a retrograde step. The common sense policy would be to build up the membership exclusively with professional engineers and professional students.

It is believed that the present corporate membership would quickly sanction as an emergency measure, a resolution facilitating the admission of the registered professional engineer with a minimum of formality the same to apply to all students enrolled in the provincial corporations. Meanwhile, The Institute, in its own interests, should set itself to the task of developing in the other provincial corporations, the same professional philosophy that actuates the Association of Professional Engineers of British Columbia.

Regarding the progression of student engineers through the intermediate grade to corporate membership, the extraordinary disparity in the number of Juniors compared to Students in The Institute List of Members, points to the desirability of active remedial measures. When students are allowed to follow their own devices and drop out because they feel that The Institute has lost its appeal, the resulting tendency to become apathetic to professional duties and privileges is apt to dissuade them from ever seeking enrolment as corporate members. Thus they become lost to The Institute altogether. Does it not appear rather incongruous, that anyone who is following the career of a professional engineer, and who once has felt an urge to become enrolled in The Institute, should, in the ordinary course of events, ever desire to drop out? Why are the Juniors shown in the 1932 List of Members, for example, only 9.5 per cent of the total strength, whereas the Students amount to 19.5 per cent? The depression was not wholly responsible for this discrepancy.

By comparison, the Pupil Engineers enrolled in the B.C. Association in 1934 were 18.5 per cent of the total strength, while the Engineers-in-Training (intermediate grade) were 20 per cent. If The Institute, like the Association, had been paying close attention to the younger element in its membership, it might at this time have had roughly three times the present number of Juniors, most of whom would, in due course, become corporate members. The possibilities of this resource are of practical interest, when compared with the net results of the present practice of increasing the corporate membership by trying mainly to induce fully qualified engineers to join.

Joint Development Before Federation

Coming back to the problem stated at the beginning of this thesis, there does not appear to be any genuine prospect of federation other than by the general procedure recommended by the Committee of Eight. A great deal of study will have to be given to detail arrangements, such as the collection of fees, when the relation of The Institute to the group of eight provincial corporations becomes more clearly defined as their Dominion body. British Columbia engineers believe that the rate of progress will depend on the rapidity with which the principles and objectives herein presented become generally understood and accepted. Co-operation based on uniformity of aims is the commonsense procedure to follow, and the only one capable of obtaining success.

Institute members are urged to apply the knowledge gained in British Columbia to the study of each scheme of federation submitted for their approval. Meanwhile the general situation can be improved by a process of joint development initiated in the following ways:

(1) Recognize and employ the Dominion Committee of Eight to discuss all schemes for the consolidation of the Engineering Profession in Canada. The functioning of this Committee can be facilitated through informal discussions between Dr. Gaby, President of The Institute, and Mr. J. M. Robertson, Chairman of the Committee of Eight; also through frequent meetings of the individual members of the Committee with the executive officers of their respective provincial corporations and the officers of the local branches of The Institute.

(2) It would be advisable to abandon all joint committees now functioning, whose members are not active members of their respective executive bodies. It is essential that the individual committee members shall be in intimate contact with the active conduct of affairs in their respective organizations, otherwise they cannot be truly representative of local opinion.

(3) Invite all registered professional engineers to join The Institute as corporate members with minimum formality, sponsorship by the registrar of the provincial corporation being sufficient for acceptance of the application. For this purpose a special short application form similar to that in use by the C.I.M.M. would suffice. Extend a similar invitation to all students enrolled in the provincial corporations.

(4) Promote the adoption of a professional student system by each provincial corporation, similar to if not identical with the British Columbia system; Institute headquarters and branches to co-operate by encouraging student engineers to enrol in both bodies.

(5) By these means, the establishment of a common membership, both corporate and junior, composed exclusively of professional engineers and professional students will eventuate in consolidation as the Engineering Profession in Canada.

(6) We do not feel at the moment, that the present variation in the qualifications for admission to corporate membership in the eight provincial associations provides sufficient grounds for excluding from The Institute any person who has complied with the law and obtained registration, provided he is vouched for by the registrar or other responsible officer. The fact that by so doing, he has attained legally acknowledged professional status, is the really important point after all. If a few improperly qualified engineers were to slip in during the process, their very small minority would have no appreciable bearing on the objective in view. In any case, the operation of the student system, as in British Columbia, would eventually produce uniformity of training and qualifications for all future admissions, and time would do the rest.

(7) It is, of course, essential for The Institute to do everything in its power to persuade its present unregistered resident membership to acquire registered standing at the earliest possible moment. That is a policy which British Columbia has constantly urged, but which The Institute has neglected to follow. By putting it into effect at once, The Institute would not only be building up its own professional strength and influence, but would gain external support and approbation which would go far towards making its path in life an easier and a happier one.

CORRESPONDENCE

The Foundation Co. of Canada Ltd.
Montreal
May 31st, 1935.

The Editor,
The Engineering Journal,

Dear Sir:—

With regard to the Canadian Standard Forms of Construction Contract which have been approved by The Engineering Institute of Canada and the Canadian Construction Association, to which reference is made in the January and March issues of The Engineering Journal,* I desire to offer some criticism as to their applicability to engineering contracts as distinguished from building construction.

I have no particular comments to make on the form for use when the work is being done for a stipulated sum, as I think this should prove quite satisfactory. In my personal opinion the form for the percentage or fixed fee type of contract is open to a good deal of criticism and would hardly be applicable to certain classes of engineering work. I believe this contract form was originally drawn up for building work and it would doubtless be a workable form of contract for the general run of urban building construction, but I doubt if it would be found entirely satisfactory for, say, a large industrial plant located at a considerable distance from the source of labour and materials.

The relations between the owner and the contractor on a percentage or fee contract are basically quite different from the relations of the two under a lump sum contract. When an owner engages a contractor on a fee or percentage basis he is, or should be, buying the services of an organization which he feels is especially competent to handle the particular project in view. He may or may not engage an organization that has the necessary plant and equipment for carrying out the work, as it is quite common on large projects for the plant to be bought for the account of and charged to the cost of the work. Again it is quite common to find cases where the owner is himself supplying a portion of the organization or is supplying certain services to the contractor or is supplying a portion of the plant. Irrespective of how the details are arranged these must of necessity vary to some extent in each case. The basic principle of the contract is that the owner is paying the contractor a fee for the use of his organization and facilities and for services rendered, the engagement being much the same as the engagement of a lawyer, engineer or other expert acting in a professional capacity. In my own experience the relationship as outlined above is the one that actually exists in the great majority of cases under the fee or percentage form of contract, but I do not think that this basic relationship is recognized in the standard form which has been approved by The Institute.

Under the fixed price type of contract the relations between the owner and the contractor are in general quite different, the basic principle being that the owner is buying, not so much a service as a completed structure or piece of work, the details of which have been carefully specified. Under this form of contract, the extent and character of the work, its quality and the method of executing it, must form an important part of the agreement, and machinery must usually be set up for supervision and inspection, and in general for determining whether or not the work as executed is in fact that which the contractor has agreed to deliver. For this work the owner pays a pre-arranged price, irrespective of the cost. If the cost can be reduced in any way the contractor benefits; if it is increased the contractor stands the loss.

Under the fee or percentage contract the contractor is therefore acting in a sense as a trusted employee of the owner, occupying a position of considerable responsibility, and if he performs his functions properly he is bound to give the owner the best and most efficient service he can, and the whole contract of engagement should recognize that the contractor is working solely in the interests of the owner. In this sense I think that the standard form of contract fails to cover what I think should be the true intent of the agreement.

In the actual working out of a cost plus contract it has been my experience that the most important thing is to have a clear understanding as to exactly what is to be included in the cost of the work, and what items of cost are to be paid out of the contractor's fee. I think that the wording of Article IV, which defines the cost, might be materially improved and clarified. It would appear also that two items of cost which are quite important on many engineering contracts, are not covered at all in this article, namely the cost of building, equipping and operating camps and commissary, the question of profit or loss from same and the cost of securing and transporting labour. I think that paragraph (k) of Article IV is entirely impracticable and wrong in principle for the average engineering undertaking, although it might be workable on an urban building contract. Plant rental and overhead bear no even approximately fixed relation to the remainder of the other costs. A contractor figuring on a given piece of work might be willing to take a very low percentage for this item (k), figuring on executing the work without very much machinery, whereas a contractor figuring on a highly mechanized job might have to ask several hundred per cent and the latter might easily be the more economical way of handling the work. The plant charges for making an excavation by hand are nothing, whereas the plant charges for making an excavation using a modern large capacity shovel or dragline constitute almost the entire cost and might be one thousand per cent of the other costs.

In my opinion there are a great many minor items of cost that are not covered by Article IV, among which I might mention drawings and blue prints, telephone service and telegrams, stationery and office equipment, such as adding machines, typewriters, etc. These items are not in the aggregate of great importance but it is these small things that give rise to disputes if they are not properly covered in the first instance. I think it is equally important that there be another article, corresponding to Article IV stating clearly and concisely what items of cost the contractor is to assume out of his fee.

I think the whole question of plant is badly treated in the standard contract, and as I have stated above, I do not think Clause IV (k) is, generally speaking, workable. The standard contract appears to stipulate only in very general terms that the contractor is to supply plant. Usually the question of plant is considered to be of primary importance by both the owner and the contractor, and the possession by the latter of adequate plant and equipment is often the controlling factor of the engagement. In other cases all plant may be furnished by the contractor and the capital cost of same may be a charge against the cost of the work. In yet other cases certain parts of the plant may be furnished by the owner or may be bought as a part of the cost of the work, and certain other parts may be furnished by the contractor. None of these cases, which are all quite common, appear to be covered in the standard contract. I think every cost plus contract should stipulate exactly what classes of plant are to be furnished by each of the parties to the contract, how it is to be paid for and what disposition is to be made of it when it has served its purpose. Our own practice on lump sum work is to charge to the contract cost depreciation or rental on standard construction plant at stipulated rates for each item, assembling and loading same at a fixed rate per ton, transportation to and from the work, and installation, operation, maintenance, dismantling and repairs. We issue a printed schedule that serves to define what items of equipment are considered as standard plant and a monthly rate for each item. We consider that all special plant and equipment is chargeable to the cost of a particular operation and that rented plant is likewise chargeable to the operation at actual cost. Under a percentage contract we naturally prefer to treat plant in exactly the same way that we would under a lump sum contract, but, if the client prefers, we can modify this system to any degree that may seem desirable, and we have on occasion quoted a fixed sum to include all plant charges.

Engineering contracts quite frequently involve the use of very highly specialized and costly items of plant that are built for a particular operation and are virtually scrapped upon the completion of that operation, or, if they are not actually scrapped, are subject to a very large charge for obsolescence. I cite, for example, the large shovel and draglines used at Beauharnois, or the electric shovels which we ourselves used at Masson and which were built to work in a tunnel of a certain size and grade, and could be used elsewhere only with substantial alteration. I might also cite the many cases of engineering contracts that require the use of tugs, barges, lighters, dredges, derrick boats, etc., each of which is usually treated as a separate operating unit subject to various maritime risks which are usually insured against. I do not think the standard form of contract covers any special plant or equipment of this nature.

It has been the writer's experience that insurance is an item that should be very completely covered in a fee or percentage contract, and I would say that the standard form fails in this. It is possible to insure against almost every conceivable kind of risk, and it is usually advisable for the contractor to call the owner's attention to the various classes of risks that can be covered by insurance, and to recommend in each particular case the risks that should be underwritten and those that should be assumed as a part of the cost of the work. The standard form of contract could, I think, cover this question of insurance in general terms and should in some way cite the various classes of insurance which might be carried, leaving it for those negotiating the contract to insert the details. In support of my criticism of the standard form might I call attention to Article VIII of the General Conditions which would require the contractor to insure the work against loss by fire to the extent of 80 per cent of its total value, bearing in mind that the work might consist, for example, of a concrete dam or might be such that a very large proportion of the cost is represented by excavation or earth fill. Article VII of the General Conditions would apparently require the contractor to insure for personal injury without limit, or himself assume the excess risk, which is I think often quite contrary to accepted practice.

On a large cost plus operation I think it is important that the question of salvaged equipment, tools and materials be adequately covered

*Construction Contracts and Contract Forms, Engineering Journal, January 1935, page 42.

Public Works Tenders and Contracts, Engineering Journal, March 1935, page 142.

in the agreement. By salvaged material I mean special equipment, salvage material from temporary structures, salvage material from camps and commissaries, and such items as pipe and fittings, tools and electrical and other supplies that have been purchased as part of the cost of the work and are consequently the property of the owner. The actual cost of these items will have been very substantial, but their value at the completion of the work may be little or nothing except to someone who has a reasonable prospect of being able to use them at a comparatively early date. The standard contract would leave the determination of the value of this salvage in the hands of the engineer who might have little or no knowledge of the practical end of the construction business, and would probably have an exaggerated idea of the real value of the material concerned. I am quite sure that such an arrangement would be found to be unsatisfactory to all concerned, particularly on a large operation, and would lead to endless disputes.

In conclusion I admit that it is difficult to draw up a standard form of contract that will cover such a broad subject as engineering construction, but I do think the present form could be very considerably improved. So far as my own company is concerned, most of our cost plus contracts have simply consisted of a proposal and an acceptance, the former having attached to it a printed circular stating what is to constitute the cost of the work and what items of cost are to be assumed out of the fee, and a schedule that lists the various items of plant and the monthly rates for each.

Yours very truly,

R. E. Chadwick, M.E.I.C.

R. J. Durley, Esq., Editor,
The Engineering Journal,
Montreal.

30 Howard Street, Toronto,
July 15th, 1935.

Dear Sir:—

The writer does not remember ever reading a more interesting article on a public work than that so ably given in the July, 1935, issue of The Journal by Mr. Alphonse Paradis, M.E.I.C., chief engineer, Department of Highways, Quebec, Que. Apart from the fund of information on Canadian highways, the fittingly interspersed descriptions of great undertakings in foreign countries add colourful value to a good work.

The article is well worthy of intensive study by young engineers for its highly informative and pleasing eloquence in the field of engineering.

Yours very truly,

(Signed) W. P. Chapman, M.E.I.C.

1010 St. Catherine Street West,
Montreal, Que.
July 10th, 1935.

The Editor,
The Engineering Journal,
Montreal, Que.

Dear Sir:—

I have read with interest the article of Mr. D. J. Emrey, A.M.E.I.C., in the June issue of The Journal, and wish to make the following comments on the formulae which Mr. Emrey uses in connection with the design of the curved rib.

May I point out that the formula $H = Pl/8f$ would only be correct if the arch were supported by two hinges on a solid foundation and the load were uniform over the entire span. Such an assumption is really not admissible in this case.

Mr. Emrey does not explain how the formula on page 302 was derived, but it presumably represents the maximum stress at a certain section of the arch. In my opinion that particular formula should not be applied to reinforced concrete sections unless the moment is so small that the section is under compression over its entire area. In other cases than this the result obtained by its use would be quite misleading.

Yours very truly,

E. Nenniger, A.M.E.I.C.

Tilting Test Stand for Bristol Aero Engines

Modern aero engines, and more particularly those employed on military machines, are often required to operate for considerable periods with the axis at a large angle with the horizontal, as for example during climbing and diving, looping the loop and other manœuvres. The conditions of operation are particularly severe during terminal nose dives, and to ensure uniform operation of the engine in all such circumstances, Messrs. The Bristol Aeroplane Company, Limited, Filton, Bristol, have now installed a tilting test stand in their line of test hangars in the engine department. This allows the engine on test to be tilted either up or down to simulate climbing or diving conditions. The stand is a stiff structure built up from rolled-steel sections, the engine mounting being incorporated in a trunnion carried in bearings in the two end frames. This trunnion can be revolved from the test cabin beside the stand through an angle of 180 degrees, so that if required, the engine under test may be made to assume a vertical position to simulate vertical climbing or diving. The feed lines for the lubrication system are actually mounted on the trunnion arm and therefore move with the engine, but the remaining feed lines, together with all the controls, are made with flexible connections so that the movement of the engine shall be as unrestricted as possible. The controls are actuated by means of Arens cables.—*Engineering.*

BOOK REVIEW

The Principles of Motor Fuel Preparation and Application, Volume I.

By A. W. Nash and D. A. Howes. John Wiley and Sons, New York, 1935. 6¼ by 10 inches. Diagrams, Tables. 538 pages. Cloth. $8.00.

Reviewed by Dr. J. B. Phillips, A.M.E.I.C.*

The subject of petroleum and its treatment has already received considerable attention from various authors, and a new book on the subject requires some very sound justification. The authors have turned out the most exhaustive and comprehensive work on the subject of motor fuels that has yet been published. Rapid advances in petroleum technology in recent years to keep pace with the constant demand for new kinds of products make it essential that a new work like this be brought out to bring the subject up to date. This is a task of no small magnitude, and the authors have performed a wonderful service in making available this noteworthy contribution which will unquestionably rank as one of the standard reference works on the subject of motor fuels.

Volume I, which has been received, takes up distillation, heat transfer, cracking, hydrogenation, natural gasoline, refining, storage and distribution; also benzol, alcohol, synthetic and auxiliary fuels. Volume II, in the press, will treat of analysis and examination, sulphur and gum in motor fuels, internal combustion and Diesel engines and fuels, knock ratings, aviation fuels, and specifications in different countries.

The two important unit operations—distillation and heat transfer—are discussed clearly in a fundamental way and their relation to the whole process shown. Heat transfer might well make a chapter in itself, and the references should include "Heat Transmission" by McAdams, and "Industrial Heat Transfer" by Schack, the two most important works on the subject. A very useful problem in the design of a bubble-cap column is completely worked out. Thermodynamics and reaction velocities are introduced briefly but clearly in appropriate places. The Cross, Dubbs, and Gyro processes for cracking are discussed in detail as typical examples.

The chapter on hydrogenation of coals and oils, and on methods of producing hydrogen, is one of the best expositions of this subject available. One of the most interesting chapters is that concerning shale oil, tar sands, creosote, synthetic fuels and carbonization of coal. A great deal of interesting information concerning the recovery of gasoline from natural gas is also given.

In view of the many predictions of early depletion of the world's petroleum reserves, the chapters on benzol, alcohols, and synthetic fuels are of great interest. The discussion of the utilization of grain alcohol as motor fuel is of particular interest to Canadians.

A very long chapter is devoted to refining methods. The use of caustic soda and other bases is discussed fully, as well as the sodium plumbite and sulphuric acid treatments. The newer hypochlorite, sulphur dioxide and adsorption treatments are also taken up in detail. This chapter in itself is an outstanding contribution.

The authors have made a thorough review of the literature in addition to their own researches, and have presented an extensive bibliography in each chapter which should be of great assistance in the study of any phase of the subject. The references are all very recent, and many new patents are also listed.

This book is not in any sense a collection of abstracts and patent reviews of various processes, but is a very thorough treatise of both the fundamental principles and practical methods in the production of motor fuels in all parts of the world at the present time. It discusses chiefly principles, and avoids too detailed descriptions of apparatus The material is written in remarkably clear style and has been carefully checked, only a few minor errors being noticeable.

This book should be of value to the refinery engineer, research chemist, student, as well as to the automotive engineer. Anyone having to do with motor fuels in any capacity will find something new and enlightening in this book.

**Lecturer in chemical engineering, McGill University, Montreal.*

BULLETINS

Wrenches.—The Canadian Ingersoll-Rand Company Ltd., Montreal, have published a 16-page booklet describing and illustrating the applications of their air-operated impact wrench. This is made in two types, 503, non-reversible for applying and tightening nuts and 533 I-R reversible for both applying and removing nuts.

Transformers.—The Canadian Westinghouse Company Ltd., Hamilton, Ont., have issued a 4-page folder describing their type SK distribution transformers. These are single-phase, 25 or 60 cycles, 2,200 to 220/110 volts.

Pumps.—A 16-page bulletin issued by Darling Brothers Limited, Montreal, describes the company's single-stage centrifugal pumps, Class B, of the horizontally split-case double suction type. These are manufactured in a large range of sizes and capacities.

Compressors.—Two 4-page leaflets have been received from the Worthington Pump and Machinery Corporation, Harrison, N.J., which give particulars of their air compressor units, types VS and VA-2, for general industrial uses and for oil and gas engine starting.

Condensers.—A 4-page folder received from the Worthington Pump and Machinery Corporation, Harrison, N.J., describes their folded tube layer arrangement surface condensers of welded steel shell construction. These are manufactured in 7 sizes.

Lathes.—A 15-page bulletin (No. 171) published by the Monarch Machine Tool Company, Sidney, Ohio, describes and illustrates the various types and applications of the Monarch specially tooled semi-automatic engine lathe.

List of New and Revised British Standard Specifications

(issued during April and May, 1935)

B.S.S. No.

416—1935. *Cast Iron Spigot and Socket Soil, Waste Ventilating and Heavy Rainwater Pipes.* (*Revision.*)
Pipes have been arranged in the different grades according to thickness. Alternative dimensions for short radius bends without access doors and dimensions for equal and unequal double branch pipes are included.

555—1935. *Tungsten Filament Lamps for other than General Service Lamps.* (*Revision.*)
Brings together the various schedules for lamps, other than general service lamps, including those issued during the past three years.

602—1935. *Lead Pipes for other than Chemical Purposes.*

603—1935. *Lead Pipes (B.N.F. Ternary Alloy—No. 2).*
The above two specifications provide for pipes from ⅜″ to 6″ diameter according to purposes for which they are to be used. The weight of each size of pipe is specified together with the chemical composition and a turn pin test.

607—1935. *Reinforced Concrete Poles for Electrical Transmission and Traction Supports.*
Specifies standard lengths and strengths together with constructional requirements.

608—1935. *Dimensions of Varnished Cambric Insulated Annealed Copper Conductors for Electricity Supply including Voltage Tests.*
Gives full dimensions of conductors, insulation and metal sheathing and prescribes the voltage test, bending test and timing test for cables for voltages up to 10,000 volts.

609—1935. *Multitubular Horizontal Boilers (Dryback and Waste Heat).*
Deals with materials, construction and workmanship, scantlings, inspection and testing, exclusive of brick work setting and insulation.

610—1935. *The Rating of Rivers for Power Purposes.*
Gives recommendations regarding the basis for computing, and the units for expressing water-power resources for statistical use and for the purpose of making comparisons between different rivers, river-basins, regions and countries.

Copies of these specifications may be obtained from the Publications Department, British Standards Institution, 29 Victoria Street, London, S.W.1, or from the Canadian Engineering Standards Association, 79 Sussex Street, Ottawa, Ont.

BRANCH NEWS

Border Cities Branch

C. F. Davison, A.M.E.I.C., Secretary-Treasurer.
F. J. Ryder, S.E.I.C., Branch News Editor.

RUBBER AND ITS USES IN TRANSPORTATION

The regular monthly dinner and meeting was held at the Prince Edward hotel on April 12th, 1935. There were twenty-nine persons present to hear the paper presented by Dr. A. W. Bull, B.S., Ph.D. Mr. Horton, friend and colleague of Dr. Bull, introduced him to the members of the Branch.

The subject of the paper presented was "Rubber and its Uses in Transportation." Dr. Bull explained that the word transportation was very general and that he was limiting his paper to automotive transportation.

Rubber is obtained from rubber trees. Originally, the only source was wild trees but now only one per cent comes from this source, while cultivated trees supply the balance.

The tropical regions are the main sources of latex, which is the sap from the rubber tree. It is five years before a seedling is large enough to tap. The tree can only be tapped every other day and will only produce 50 cu. cent. per tree per day. Bud grafting and seed selection have aided production. There are now approximately 5,000,000 acres of rubber trees under cultivation.

Latex is unstable as it ferments easily and creates a very bad odour. The standard practice of removing the rubber is to coagulate it by the use of acetic acid. The coagulate is washed, squeezed and dried. This reduces the weight of the raw product for shipping purposes. A second method of treating the latex, is to spray it into a warm atmosphere. The liquid is volatile and disappears and the crude rubber settles. The price of crude rubber has fluctuated immensely: 1910—$2.00 per pound; 1921—15c. per pound; 1925—72c. per pound; 1931—3c. per pound; and at present is going up. United States has 58 per cent of the world's production. Of this 58 per cent, 80 per cent is used in tires and tubes. Reclaimed rubber is also a source as 25 per cent of crude rubber is reclaimed. Attempts have been made to commercialize the following sources: Shrubs, golden rod and synthetic rubber. Synthetic rubber (Dupreen by Dupont) is not affected by oils or organic solids and is resistant to checking or cracking in the sun light. Crude rubber softens and becomes sticky in the sun light. It is hard and brittle at low temperatures and has a high permanent set. Crude rubber is used for crepe rubber soles, gum and surgical bandages.

Vulcanization of rubber discovered by Charles Goodyear is the heating of rubber (usually 220 degrees F. or approximately 50 pounds steam pressure) mixed with about 1 per cent to 3 per cent sulphur. More than 5 per cent of sulphur added makes the mixture leathery while 25 per cent or over of sulphur makes hard rubber. White lead and litharge accelerates the vulcanizing. Carbon black is used as a filler in the manufacture of tires. Small amounts of fatty acids and zinc oxide are used as an anti-oxident. The rubber mill consists principally of a pair of rolls through which the crude rubber with the added ingredients is worked back and forth. This mixture is placed in the necessary dies and formed. The vulcanizing is done by steam heat while still in the dies.

The good properties of this rubber are:—

1. It stretches and has no yield point.
2. It has hysteresis. That is, it does not return all the energy put into it.
3. Under compression, it will distort if free to expand.

The poor properties are:—

1. It will not stand high temperatures.
2. It deteriorates with age.
3. It will take a permanent set if it is exposed to sun light and repeated flexings.
4. Its hardness and resistance are affected by temperature.
5. It becomes swollen if in contact with gas or oil.

Dr. Bull accompanied his paper by slides and demonstrations. He gave a long list of parts with which the rubber industry supply the automotive manufacturer.

The meeting was thrown open to questions. Dr. Bull stated that rubber paving had been tried but not commercialized. In bonding rubber to steel, the steel is first brass plated in order to obtain high adhesion. Deterioration in rubber lined tanks may be retarded by immersion in water. It is also possible to rubber line ash pumps or sand impellors very effectively.

A hearty vote of thanks moved by T. H. Jenkins, A.M.E.I.C., and seconded by E. M. Krebser, A.M.E.I.C., were extended to Dr. Bull and his colleague, Mr. Horton.

Lakehead Branch

G. R. McLennan, A.M.E.I.C., Secretary-Treasurer.

At the annual meeting of the Lakehead Branch of The Institute held on June 18th, 1935, the results of the election by ballot for the Executive for the coming year were announced.

At the Executive meeting held on June 27th, chairmen for the various committees were appointed as follows:

Membership................P. E. Doncaster, M.E.I.C.
Finance....................J. Antonisen, M.E.I.C.
Programme................J. A. Rogers, S.E.I.C.
Reception..................R. B. Chandler, M.E.I.C.

P. E. Doncaster was appointed chairman of a committee to study the matter of co-ordination of The Engineering Institute of Canada and the Professional Engineering Associations of Canada. This committee will bring in a complete report at a special meeting to be held in the early part of September.

The membership committee of the Branch has already begun work on the matter of increasing its membership, and the programme committee is going into the matter of the purchase of a moving picture machine.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

ANNUAL MEETING

The annual meeting of the branch was held on May 30th, 1935. H. B. Titus, A.M.E.I.C., vice-chairman for the past season, presided. The annual report and financial statement was presented, and approved on motion of James Pullar, A.M.E.I.C., seconded by R. H. Emmerson, A.M.E.I.C. A vote of thanks to the retiring officers was moved by A. S. Gunn, A.M.E.I.C. The incoming chairman, Mr. Titus, addressed the meeting briefly, thanking the members for the confidence they had reposed in him.

The officers for the year 1935-36 were announced as follows:

Chairman	H. B. Titus, A.M.E.I.C.
Vice-Chairman	G. L. Dickson, A.M.E.I.C.
Secretary-Treasurer	V. C. Blackett, A.M.E.I.C.
Executive Committee	F. O. Condon, M.E.I.C.
	T. H. Dickson, A.M.E.I.C.
	A. S. Gunn, A.M.E.I.C.
	Jas. Pullar, A.M.E.I.C.
	C. S. G. Rogers, A.M.E.I.C.
	G. C. Torrens, A.M.E.I.C.
Ex-officio	H. J. Crudge, A.M.E.I.C.
	J. G. MacKinnon, A.M.E.I.C.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

VISIT TO AIRPORT

On Saturday afternoon, June 22nd, 1935, through the co-operation of the Department of National Defence and of Messrs. Canadian Colonial Airways, over one hundred ladies and members of the Branch visited the St. Hubert airport, viewing the meteorological instruments, two-way wireless and mooring tower apparatus, and the new aerial beacon installation.

About seventy-five took advantage of the opportunity to make a fifteen-minute flight in a new eight-passenger transport plane of the Colonial Airways.

Later, through the courtesy of Mr. Passmore, managing director of Fairchild Aircraft Limited, a number of members and friends inspected the Fairchild plant and air harbour at Longueuil.

In spite of the inclement weather those attending spent a most enjoyable afternoon.

JUNIOR SECTION

Through the kindness of the Harbour Commissioners of Montreal, on the afternoon of July 20th, fifty members of this section made an inspection trip of the harbour on the *S/S Sir Hugh Allan.*

Some three hours were spent in viewing the structures and works in the harbour, particulars and technical information being furnished by the representatives of the Commissioners who were on board, Messrs. Frost, Sparkes and Roberts. Refreshments were served during the afternoon, the trip being thoroughly enjoyed by all present.

Niagara Peninsula Branch

P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

The annual meeting was held at the General Brock Hotel, Niagara Falls, on May 31st, 1935, with W. R. Manock, A.M.E.I.C., in the chair, and President F. A. Gaby, M.E.I.C., as the principal speaker.

A number of guests were present, including Chairman W. Hollingworth, M.E.I.C., and Councillor F. W. Paulin, M.E.I.C., of the Hamilton Branch. Vice-President E. G. Cameron, A.M.E.I.C., sent a letter regretting his absence due to unavoidable pressure of official duties.

Councillor Walter Jackson, M.E.I.C., introduced Dr. Gaby as being an acquaintance of old with the residents of Niagara Falls and took occasion to review some of the aspects of engineering consolidation with the Provincial Associations in Canada.

SOME PROBLEMS OF TRANSPORTATION

Dr. Gaby pointed out that our economic structure is based very largely on the development and use of power and transportation, and these are of such importance that our civilization, with present standards of living, could not exist without them. This was recognized at the time of Confederation by our governments of that day, when they wrote into the Agreement of Confederation many matters providing for the creation and maintenance of adequate transportation facilities between the east and west, which, along with power, have become most important factors in the growth and development of our country, and the establishment of large industrial centres such as exist in the southwestern portion of Ontario.

In Canada, many miles of railways were built which are yet maintained upon social and political grounds rather than as being justified by the financial return they produce. British Columbia made her entry into Confederation dependent upon the construction of a transcontinental route which was only built after tremendous obstacles had been surmounted. Between the years 1900 and 1916 came an era of competition and expansion between the railway companies, aided by various Governments, during which period the existing mileage of 17,500 was more than doubled.

Dr. Gaby then illustrated the rapid advance in the development and use of motor vehicles and aeroplanes in commerce, and pointed out that free-for-all or unregulated competition is not economic and results in wasteful duplication and multiplication of services.

Attention was also drawn to water transport, and the necessity that those responsible for railway economics should keep this competitor in mind.

To meet these varied forms of transportation, the railways must also progress; better service, higher speeds, air-conditioning of passenger cars and many other improvements must be planned. Under the present conditions of strict economy, particularly regarding capital expenditures, these problems will call for statesmanlike forethought in their solution.

At the conclusion of this address our new chairman, Paul E. Buss, A.M.E.I.C., proposed the vote of thanks, which was heartily applauded, and the meeting adjourned.

Quebec Branch

Jules Joyal, A.M.E.I.C., Secretary-Treasurer.

Le 8 mai dernier, environ quarante-cinq convives assistaient à un déjeuner-causerie au Château Frontenac. Le conférencier, M. A. O. Dufresne, M.E.I.C., Directeur du Service des Mines de la Province de Québec, nous fit une très intéressante causerie intitulée "Les risques de la prospection."

Au début de sa conférence, M. Dufresne souligna l'importance qu'a prise l'industrie minière dans notre province et dit qu'au cours des derniers douze mois, les articles tirés su sous-sol ont fourni 27 pour cent de la valeur totale des produits exportés par notre pays. La prospection dans notre province a commencé en 1922, lors de la découverte de la mine Horne dans le canton de Rouyn; cinq ans plus tard, la compagnie Noranda expédiait les premiers lingots de cuivre. Par la suite, plusieurs compagnies ont entrepris des travaux, et en 7 ans, cette région avait produit pour une valeur de $90,527,000 de métaux.

Le conférencier affirme, avec chiffres à l'appui, que cette industrie a rapporté plus qu'elle n'a coûté, puis, en comparant le nombre de claims enrégistrés avec le nombre de ceux qui possèdent des gisements exploitables déterminés par des travaux souterrains, il en arrive aux probabilités de deux claims profitables pour 1,000 claims jalonnés, un claim en exploitation pour 1,000 jalonnés et deux sur 10,000 payant des dividendes après 13 années de prospection. En terminant, M. Dufresne démontra que la prospection entre dans le domaine de l'ingénieur à qui il appartient de la diriger et de l'organiser.

Le conférencier fut présenté par M. Hector Cimon, M.E.I.C., alors président de notre section, puis M. Adrien Pouliot, I.C., professeur à l'Ecole Supérieure de Chimie le remercia.

ASSEMBLÉE ANNUELLE

L'assemblée annuelle de notre section fut tenue au Palais Montcalm le 20 mai dernier.

Au début, l'assemblée était présidée par M. Hector Cimon, président sortant de charge, et pendant que les scrutateurs dépouillaient les bulletins de votation, l'on procéda à la lecture des minutes de l'assemblée précédente, du rapport du conseil et du trésorier; les divers comités furent formés puis la proclamation des officiers élus fut faite comme suit: Président, Alex. Larivière, M.E.I.C.; vice-président, J. T. F. King, A.M.E.I.C.; secrétaire-trésorier, Jules Joyal, A.M.E.I.C.; conseillers, L. P. Methé, A.M.E.I.C., J. G. O'Donnell, A.M.E.I.C., et J. B. Dunbar, A.M.E.I.C.

M. Cimon invita alors M. Larivière à monter sur le fauteuil présidentiel. Un vote de sincères remerciements au président sortant de charge est proposé et adopté à l'unanimité, puis le président élu fait une courte allocution à l'assistance pour remercier ses confrères de l'honneur qu'ils lui font, et de la confiance qu'ils mettent en lui; il les assure de son plus entier dévouement pour travailler au bien-être de notre association en général et de chacun de ses membres en particulier.

Saint John Branch

F. A. Patriquen, Jr.E.I.C., Secretary-Treasurer.
H. P. Lingley, S.E.I.C., Branch News Editor.

On May 9th, 1935, the Saint John Branch held its annual dinner and meeting at the Riverside Golf and Country Club. Reports of the various committees were read and the election of officers held. Reorganization was also discussed. It was moved and seconded that the Saint John Branch go on record as favouring reorganization and that a committee of two be appointed to study the matter and to meet with like committees from the Moncton Branch and the Provincial Association. During the dinner, in response to a toast to The Institute, Mr. Roland Bustin sang Kipling's "Sons of Martha," which has been set to music by Mrs. A. J. Collins of Walkerton, Ont.

Preliminary Notice

of Applications for Admission and for Transfer

July 29th, 1935

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in September, 1935.

R. J. Durley, Secretary.

---

*The professional requirements are as follows.—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, whicb period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of tbe Council, be reduced to ten years in the case of a candidate for election wbo bas graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member sball be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a scbool of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by tbe Council. The candidate shall be examined on the theory and practice of engineering, with special reference to tbe brancb of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners tbat he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if tbe candidate bas held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at tbe discretion of the Council if the candidate for election has graduated from a scbool of engineering recognized by the Council. He sball not remain in tbe class of Junior after he bas attained the age of thirty-three years, unless in tbe opinion of Council special circumstances warrant the extension of this age limit.

Every candidate wbo has not graduated from a scbool of engineering recognized by the Council, or bas not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to tbe examiners that be has attained an equivalent standard.

A Student shall be at least seventeen years of age, and sball present a certificate of baving passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He sball eitber be pursuing a course of instruction in a scbool of engineering recognized by the Council, in which case he shall not remain in tbe class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in whicb case be sball pass an examination in sucb of the subjects set fortb in Scbedule A of tbe Rules and Regulations relating to Examinations for Admission as were not included in the higb scbool or matriculation examination which he has already passed; be shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant tbe extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but wbose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give tbe names of certain members as reference does not necessarily mean tbat their applications are endorsed by such members.

FOR ADMISSION

BAKER—JAMES DAVIDSON, of Edmonton, Alta., Born at Charlton, Kent, England, Feb. 20th, 1883; Educ., Boissevain Public Schools, Man., 1895-1901; 1902-03, inspr. (Winnipeg), 1903-05, inspr. (Calgary), and 1905-07. chief inspr. (Calgary), Bell Telephone Company; 1907 to date (except 1916-19, overseas, Lieut., Can. Signal Corps), with Alberta Govt. Telephones as follows: 1907-08, constrn. foreman; 1908-10, local mgr., Macleod; 1910-13, district plant mgr., Calgary; 1913-16, asst. to plant supt., Edmonton; 1919-20, constrn. engr.; 1920-29, plant supt., in charge of constrn. and mtce. of all physical property; 1929 to date, Deputy Minister of Telephones and General Manager, Alberta Govt. Telephones.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situations Vacant

CHEMICAL ENGINEER, for a large organization, with five to ten years operating experience in heavy inorganic chemical processes. An opportunity for a capable man. Apply giving full information regarding experience to Box No. 1177-V.

MECHANICAL ENGINEER—Manufacturer of steam power plant equipment and accessories has opening for man with experience in sales, power plant operation and a thorough knowledge of combustion problems. Position will lead to sales engineering but applicants need not necessarily have sales experience. Reply stating full details of education and experience to Box No. 1178-V.

CHIEF CHEMIST. Capable man with approximately ten years experience in routine analyses and having the ability to supervise the work of others. Opening is with large Canadian company. Apply giving full particulars to Box No. 1179-V.

Situations Wanted

SALES ENGINEER, S.E.I.C.; B.SC. C.E., 1930 (Univ. New Bruns.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.SC., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ENGINEER AND ACCOUNTANT, JR.E.I.C., (Capt. Can. Engrs., reserve). Age 35, Canadian. Experienced in mechanical and civil engineering, Diploma; general office, draughting and instrument work; assistant engineer erection Royal York hotel; assistant resident engineer T. & N.O. Ry. const. Desires position in Toronto where combination of technical and business experience will be of value, as have been director and accountant last three years. Apply to Box No. 377-W.

CIVIL ENGINEER, B.A.SC. and C.E.; A.M.E.I.C., A.M. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.SC. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

MECHANICAL ENGINEER, B.SC. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

CONSTRUCTION ENGINEER, age 26, unmarried, graduate C.E. Experience includes hydro-electric, railroad, highway, and industrial plant construction, both field and office, including cost accounting, estimating, stores, layout, general engineering and supervision, as well as practical work in mechanical trades. Apply to Box No. 567-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

Situations Wanted

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

ELECTRICAL ENGINEER, McGill '31, desires permanent position in engineering field. Experience includes draughting, designing and testing of induction motors, radio supervision and test, and some construction. Available immediately. Apply to Box No. 626-W

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL ENGINEER, Univ. Grad. 1928. Two years Students' apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660 W.

Employment Service Bureau

This bureau is maintained by The Engineering Institute of Canada for the benefit of members and organizations employing technically trained men.

An enquiry addressed to 2050 Mansfield Street, Montreal, will bring full information concerning the services offered. Details can also be obtained from Branch secretaries who are located in the larger centres throughout Canada.

Brief announcements of men available and positions vacant will be published without charge in The Engineering Journal and the Bulletin. Replies addressed in care of the required box number will be forwarded to the advertiser without delay.

An additional service also offered those who are unemployed or wish to change their positions, is the opportunity of placing their names and records on file at 2050 Mansfield Street for consideration by employers wishing to employ engineers. This is of great assistance as many employers will not advertise or wish to locate a suitable man on short notice. If desired the information contained in these records can be kept confidential.

Forms for registration purposes may be obtained from The Institute Headquarters or Branch secretaries.

ELECTRICAL AND RADIO ENGINEER, B.SC. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC., Elec., '29, B.SC., Civil '33. Age 27. JR.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.SC., '27, JR.E.I.C. Four years maintenance of high speed Diesel engine units, 200 to 1,300 h.p. Also maintenance of d.c. and a.c. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.SC., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.SC. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.SC. (McGill Univ.), O.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box No. 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.SC., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

RADIO AND ELECTRICAL ENGINEER, B.SC. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.SC. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, S.E.I.C., B.SC. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.SC., '25, JR.E.I.C., P.E..Q, married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

Situations Wanted

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, B.A.Sc. in C.E., with business and sales experiences, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

Situations Wanted

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.Sc. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.Sc., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C. '29); M.S. Age 27. Single. Four years experience in research work in applied mechanics and materials testing. Desires position involving analytical work in design, development or testing. Available on short notice. Apply to Box No. 1023-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box. No. 1127-W.

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

Situations Wanted

ELECTRICAL ENGINEER, B.Sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.Sc., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.Sc., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Writes and speaks both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211-W.

CIVIL ENGINEER, B.Sc. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

COMBUSTION ENGINEER, A.M.E.I.C., with extensive experience in all phases of combustion engineering, including plant layout, piping, etc. Lately connected with prominent firm of automatic oil burner manufacturers. Apply to Box No. 1224-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet tissues. Apply to Box No. 1246-W.

CIVIL ENGINEER, B.Sc. '29, Jr.E.I.C., age 29, single. Experience in all types of surveying including use of aerial photographs. Three years on hydro-electric power development in field and office. Instrumentman on concrete road construction. Location immaterial. Apply to Box No. 1254-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

CIVIL ENGINEER, Univ. Toronto '33, age 24, married. One year as instrumentman with provincial department of highways. Experience in concrete and retread construction grading, culverts, etc. Also draughting, estimating and general office practice. Apply to Box No. 1265-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '29). Age 28. Six years experience in automobile office and plant; two years as supervisor of inspection in body assembly. Good understanding of modern business methods applied to manufacturing. Desires position with production department of smaller Ontario industry. Good references. Interviews anywhere in central Ontario Apply to Box No. 1270-W.

ELECTRICAL GRADUATE, S.E.I.C., B.Sc. '32, M.Sc. '34. Experience includes four years as part time operator and announcer for a radio broadcast station. At present employed in radio repair dept. of a large wholesale firm. Apply to Box No. 1283-W.

ELECTRICAL ENGINEER, B.Sc., E.E., A.M.E.I.C. University of Manitoba '28. Age 32. Married. Experience one year power line construction, five years resident and assistant district engineer on highway construction; two years highway traffic regulation in charge of district office. Good connections in Manitoba and Saskatchewan. Excellent references. Available at once and will go anywhere. Located in Winnipeg. Apply to Box No. 1316-W.

ENGINEER AND DRAUGHTSMAN, Jr.E.I.C., age 33, Diplomas from Mtl. Tech. Inst. in R.C. and Structural Design. 11½ years experience in civil engineering, draughting and instrument work. This includes 7 years with M.L.H. & P. Cons. as field engineer on construction and maintenance. Present location Montreal. Available at once. Apply to Box No. 1326-W.

VOLUME XVIII — MONTREAL, SEPTEMBER, 1935 — NUMBER 9

Timber for Structural Use

Its Design, Working Stresses and Preservative Treatment

W. H. Greene, M.E.I.C.,
Chief Engineer, Canada Creosoting Company, Toronto, Ont.

Paper presented before the Calgary Branch of The Engineering Institute of Canada.

Wood preservation can be defined as the art of protecting structural timber from destructive agents, the most common of which are decay, insects, marine borers, mechanical abrasion and fire.

In the three prairie provinces, luckily, one is not concerned with insects or marine borers, therefore they will not be referred to except to state that their destructiveness can be prevented for many decades by creosoting.

Actual examples of untreated piling have been found being destroyed by teredo in ten months, and by limnoria in less than one year. In the same water creosoted piling was still sound after thirty to forty years. This is illustrated in the case of the Santa Monica long wharf which was built in 1891. Changes in freighters made the wharf obsolete, so between 1916 and 1921 it was dismantled. The creosoted piles and timbers, after more than twenty-five years service in water abounding with marine borers, were salvaged and re-driven and are still in service and still sound.

In the prairie provinces, the greatest enemy, after timber has been built into a structure, is decay which is caused by a low form of plant life known as fungi. The spores or reproduction bodies of the fungi are blown about by the wind and find lodgment on the surface or in cracks in the timber. They are very tenacious of life, can remain dormant for long periods of time and then germinate and grow. When fungi starts to grow they send out mycelia (minute roots) which penetrate into the sound wood. By the secretion of enzymes or ferments by these mycelia, the wood fibre is dissolved and its substance serves as food for the fungus. All fungi do not possess the same capacity to cause decay, it is only those forms which vigorously attack cellulose and lignin that affect the durability of timber to any serious degree. But give them a favourable temperature, and proper moisture and air supply and decay will proceed rapidly.

Preservative processes by injecting into and impregnating the wood with poisonous chemicals cause these enemies to commit suicide as soon as they attempt to gain nutrition. Thus decay and destruction is prevented.

Hundreds of chemicals and compounds have been advocated and tested for the preservation of wood from decay but only a few of them possess the necessary qualifications. A preservative must have the following qualities:

1. Toxic qualities that will positively kill all organisms that are destructive to wood. A chemical can be extremely poisonous to some and not affect others.
2. The chemical must have ability to penetrate the wood.
3. It must not affect the strength of the wood.
4. It must not corrode metal because the failure of the fastenings such as bolts, spikes, etc., used would destroy the structure even though the timbers remained sound. This qualification eliminates many chemicals that otherwise are efficient preservatives.
5. It must possess durability—that is, it must not evaporate, wash or leach out, or otherwise be lost for a long period of time.
6. The chemical must be reasonable in cost, safe to handle and readily available in large quantities.

To date, there are only two chemicals that have proved themselves, in accordance with these qualifications, by the test of time and exposure and these are creosote oil and zinc chloride.

Creosote oil is the best preservative discovered to date. It is reasonable in price, has a high toxic value and will positively kill all plant and insect enemies of wood, can be uniformly and effectively injected into any species of wood and exceeds all other chemicals in durability whether exposed to tropic or arctic temperatures, alkali or acid soils, fresh, stagnant, or salt water, wind and weather. It has no deleterious action on iron, steel or any other metal, in fact it will protect metals from corrosion.

Zinc chloride, while not suited to as many varied conditions of exposure as creosote oil, is an efficient and valuable preservative. Wood impregnated with it cannot be used in running water because the salt is water soluble and will leach out. Perhaps its most valuable asset is that it makes wood highly resistant to fire—the wood will char but will not readily ignite and burn. Wood treated with this preservative is odourless and can be painted the same as untreated wood which makes it suitable for use in buildings.

A modern wood preserving plant with a medium capacity will cost, for land, buildings and equipment, from $500,000 upwards and then half as much more for stocks of preservatives, lumber, etc. When operating to capacity it will employ about two hundred men, so such a plant is an asset to any community.

The plant will consist of a retort house containing two or more cylinders (from about 130 to 160 feet in length and 7 feet in diameter) made of heavy steel plates, equipped with heating coils, and complete with Rueping, measuring and storage tanks, vacuum and pressure pumps, condensing

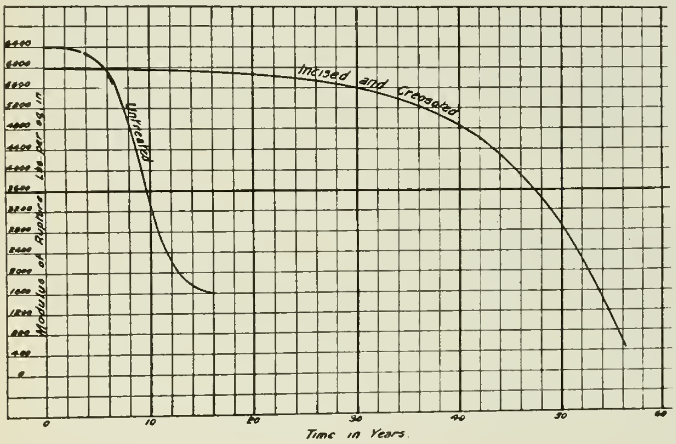

Fig. 1.

and vapour drums, recording gauges, etc. Then there must be butt-treating plant complete with dipping and storage tanks, pumps, derrick, scaffolds, skids, inciser, live rolls, heaters, etc.; boiler plant; framing plant (planer, inciser, borer, saws, etc.); boring, adzing and incising plant, gasoline dinkeys; locomotive crane; cylinder buggies; and several miles of both standard and narrow gauge tracks.

The actual preservative process is more or less the same for any chemical used. The timber is loaded on the cylinder cars, narrow wooden strips being placed between the rows thus leaving a space between each piece of timber so that the preservative can reach every surface. The cars are then run into the cylinder and the end is sealed. Then the moisture and sap are extracted either by boiling in the creosote oil under a vacuum, or, with some woods, by means of moist steam. If the Rueping empty-cell process (the one almost always used except where the timber will be in salt water) is to be used the cylinder is then emptied of oil and air pumped in and compressed. Without releasing the air pressure, the preservative at a temperature of from 180 to 220 degrees F., depending on the species of wood, is pumped in and the pressure increased and maintained until sufficient preservative has been forced into the wood. More preservative than is to be left in the wood is always put in. The cylinder is then emptied of oil and a vacuum pulled to remove the excess oil. An expansion bath (the timber is boiled in creosote oil at atmospheric pressure) is usually given before the vacuum to dry the surface of the wood.

The difference between the "full-cell" and "empty-cell" processes is that in the former the cell-walls and the cells themselves are left full of oil while in the latter all free oil is removed from the cells and only the cell-walls left saturated with creosote.

In using zinc chloride this salt is first dissolved in water, then the solution is injected into the wood in a similar manner by pressure and heat and the water then evaporates and leaves the cells filled with the dry salt.

In general, when wood is preservatively treated the chemical does not impregnate the timber through and through, but the unimpregnated core is amply protected. Maximum benefit and economy are obtained when the timbers are framed before being treated and in the vast majority of cases this is entirely practicable. Where cutting and boring on the job must be done care must be taken to protect any exposed raw wood—it is feasible to do this.

The treating process will also sterilize the wood and destroy the organisms of incipient decay that may have obtained a foothold even during logging operations.

The loss of creosote from wood follows a well established law which applies to loss by both evaporation and leaching. By means of this law it is possible to predict with considerable accuracy the probable life of such material in any installation. Tests, consisting of the extraction of creosote oil remaining in the timbers of different types of structures after they had been in service for from forty to fifty years, show that there has been little or no loss of the preservative up to that time. As the most volatile fractions would be lost first and as these comprise less than 25 per cent of creosote oil it will be seen that the rate of loss per annum will decrease as time goes on.

The Lake Pontchartrain trestle, near New Orleans, built during 1882-83, was the first treated timber bridge on this continent. It is about six miles in length, the timbers and piles being treated with creosote oil.

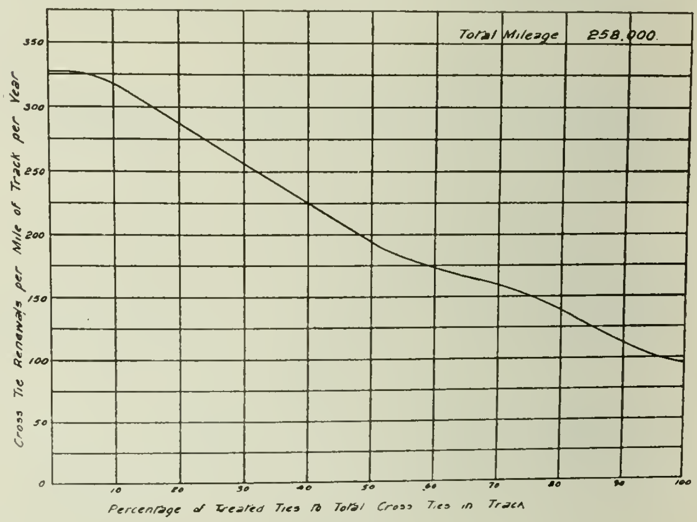

Fig. 2.

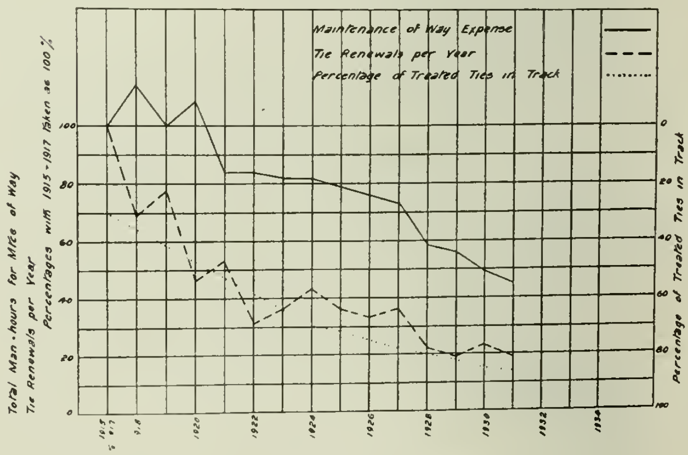

Fig. 3.

This bridge is still in service and the United States Commerce Commission places its useful life at seventy years or more. Some five years ago tests were carried out at Tulane University, New Orleans, which showed that the original strength of the timbers had not been reduced more than 6½ per cent which is negligible considering the factor of safety used in timber design.

The ability of the two present-day recognized preservatives, creosote oil and zinc chloride, to resist decay and retain the original strength of the wood is of the greatest economic importance—that ability has changed untreated timber structures, rightly classed as "temporary construction," into "permanent construction."

There is a further economic advantage that may be secured by using timber that is treated with creosote oil

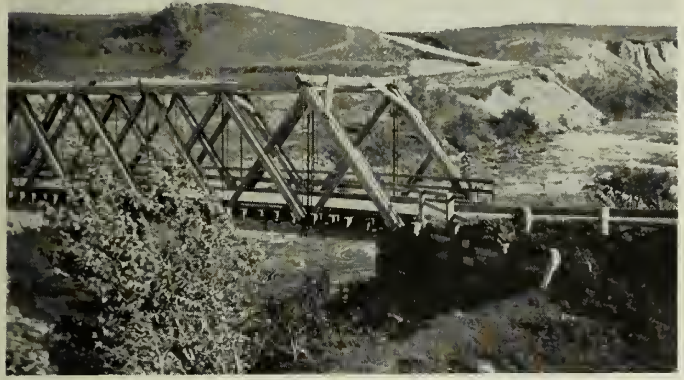

Fig. 4—Wooden Bridge Built of Untreated Timber.

and is thus made waterproof. It concerns the working stresses used in designing any structure.

When a timber structure is designed the working stresses used are only a fractional part of the actual strength of the new timber. In the determination of working stresses both the strength at the elastic limit and the breaking strength have been considered but as the former is more variable and less definite than the latter, the ultimate or breaking strength is taken as the more dependable basis for the determination of safe working stresses.

Modern timber technology considers it good practice to take the fibre stress at the elastic limit at not more than 56 per cent of the modulus of rupture and the working stress at 60 per cent of the fibre stress at the elastic limit. Or in other words the working stress is 39 per cent of the modulus of rupture.

The following figures are for coast type Douglas fir—those for other species of wood will be different but the ratios will remain approximately the same.

The modulus of rupture for coast type Douglas fir in "green condition" is 8,100 pounds per square inch but if in "air-dry condition" it is 14,800 pounds, or 83 per cent stronger.

First, consider a structure of untreated timber. The recommended working stresses are based on "green condition" and these will also be reduced to provide for considerable loss of strength due to decay. The initial strength of the wood will be much greater than that used in arriving at the working stresses and this is necessary because immediately after being built into the structure, or even before it, if the timber is kept in storage for some time, exposure and decay will start to weaken the wood. It would be entirely feasible to use seasoned timber but nothing would be gained because the timber would soon absorb moisture from the air, rain and melting snow and return to the "green, or unseasoned, condition." As a matter of fact the use of seasoned timber would be a mistake and detrimental because if, after being seasoned, wood reabsorbs moisture to above the "fibre saturation point" its strength will be less than the original green strength. As untreated timber in outside locations will nearly always have a moisture content, for part of the year at least, above the "fibre saturation point" it would be unsafe to use working stresses higher than those for green timber.

However, this is not the case with creosoted timber because the creosote oil waterproofs the timber and for structures not continuously, or nearly so, immersed in water will keep the moisture content at, or below, the "fibre saturation point," This has been proved by tests made by the Canadian Forest Products Laboratories. In making comparative strength tests on creosoted versus untreated ties they first submerged the treated ties in water for seven months and only raised the moisture content less than one per cent. It would be impossible for creosoted timber in service, and as specified not constantly submerged, to absorb even this small amount of water—so higher working stresses can safely be used, based on "air dry condition." The use of these higher working stresses simply means that a creosoted timber structure can be built with timber of smaller dimensions and this saving in cost will assist in paying for the creosoting. Also the creosoted structure will last from 3 to 5 times as long (see Fig. 1.)

Figure 1 is for timber having a safe working stress of 1,400 pounds per square inch and the condition of exposure is for a bridge in western Canada. The modulus of rupture cannot safely fall below 3,600 pounds and the untreated timber is reduced to that in just under ten years while the creosoted timber takes forty-seven years.

Figure 2 shows the average annual tie renewals per mile of track for the railways in Canada and the United States—it is complied from the average figures for 258,000 miles of track. The saving per year for each tie that does not have to be renewed varies widely in different localities

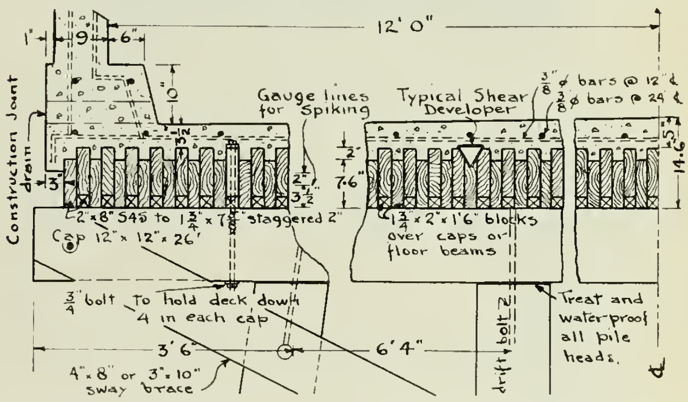

Fig. 5—Timber Substructure and Stringer System Supporting Concrete Deck.

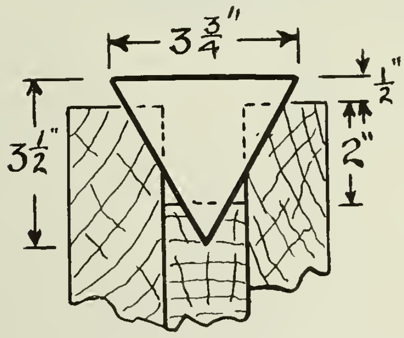

Fig. 6—Shear Developer.

but will average $1.37 per tie in place. There are very nearly 3,000 ties in a mile of track so the saving per mile will be $4,100 or more.

Wooden bridges in some form or other have been used for thousands of years. These bridges, being built of untreated timber and thus being more or less "temporary" in character, were strictly utilitarian in design and construction. Usually there was no effort made to erect an architecturally pleasing structure. They were low in cost, easy to erect, carried the traffic safely and thus sufficed for the need at that time.

But now that preservative treatment has raised timber construction into the "permanent" classification more attention is being given to the appearance of the finished structure.

Fig. 7—Composite Type Bridge of Oregon State Highway Department.

In a highway system anywhere from 60 to 90 per cent of the bridges will have a span of less than 40 feet so the development of an artistic type of reasonable cost is of interest to all highway departments.

Up until little over a year ago a choice had to be made between:

1. Creosoted pile or framed bent trestle with creosoted timber superstructure.
2. Creosoted pile trestle with steel I-beam stringers and concrete deck.
3. Reinforced concrete structure.

There is very little difference in cost between Nos. 2 and 3, each being about two to two and a half times higher in cost than No. 1.

The new composite slab or beam types, wherein creosoted timber and concrete are made to work in conjunction, provide an intermediate type of reasonable first cost, beauty of appearance and long life.

Essentially, the type consists of a creosoted timber substructure and stringer system with integrally supported concrete deck. For spans up to 30 feet a continuous timber deck is used, this being built up of vertical laminations of 2-inch plank spiked or bolted together. The upper edges of alternate laminations are raised 2 inches thus forming longitudinal grooves. Into these longitudinal grooves are driven thin triangular steel plates called shear developers, which mortise into the corners of the raised laminations as well as into the top of the intermediate depressed ones. Three-sided support from the wood is thus secured for these keys, the top of which project into the concrete deck.

For spans from about 24 to 40 feet an individual stringer system is used. It will be noted that the two types are interchangeable for spans of between 25 and 30 feet, the decision depending on which costs the least. In this type the shear developers are usually of pipe, thus combining strength and bearing area with lightness, and the tops of the stringers are usually dapped.

The laminated type does not require any forms for the concrete deck as the wood portion alone develops adequate strength to support loads which may be placed on the deck during construction. A concrete paver could be run over this deck and thus do away with transportation of the concrete in buggies.

Figure 7 shows one of fifty composite type bridges built or under construction by the Oregon State Highway Department.

The sub-structure possesses all the economic advantages of creosoted timber but the appearance when compared with standard designs of the past is so vastly improved as to be almost unrecognizable. This class of architectural design does not add much to the cost and the slight increase is justified in many structures where the aesthetics of the site must be considered and conserved.

Design of Continuous Reinforced Concrete Arches by the Fixed Point Method

For the Cathedral, at Valleyfield, Que.

E. Nenniger, A.M.E.I.C.,
Associate, Arthur Surveyer and Co., Consulting Engineers, Montreal.

Part II*

Live Load Moments.

As far as the bending moments due to the live loads are concerned, it is advisable to determine the moments separately for each member, so that any combination of loading can be analyzed at the end, by adding the different results together to obtain the most unfavourable stresses at any point of the frame. The moments due to the live loads on beam 2, brackets 4 and brackets 5 present no difficulty, as they are simply proportional to the dead load moments in each particular case as computed above.

In the case of the live load (wind load) applied on the arch, it is necessary to subdivide the calculations into two stages in order to account for the side sway of the frame. It is assumed that a temporary force is applied at point B of the frame to prevent side sway, and all moments due to wind are determined in the usual manner. The magnitude of this temporary force is then obtained with the help of the bending moments. This force is then reversed, and applied at point B. The bending moment in the frame due to this force is added to the result of the computation under stage one. The following gives an example of the procedure as applied to the frame of the Valleyfield cathedral.

*Part I appeared in the August, 1935 issue of The Engineering Journal.

Moments due to wind load on Arch 3. (Figure 20.)

The wind load acting against the frame was taken as 30 pounds per square foot of wall area, and 15 pounds per square foot applied on the roof area measured perpendicular to the slope of the roof. The resulting wind loads acting against the frame at each point of the arch are shown in Fig. 15, together with the reactions at both supports of the principal system or the frame made statically determinate by assuming one of the supports resting on a roller bearing (in this case support B').

Table X gives in detail the calculations for the M^0 values for each point of the frame. In this case, the values M^0 represent the bending moments due to the wind loads applied on the principal system. The values used in this table are:

H_B = 28,490 pounds = horizontal reaction at joint B

V_B = 19,460 pounds = vertical reaction at joint B

$V_{B'}$ = 26,650 pounds = vertical reaction at joint B'

W_1, W_2, W_3, windloads at point 1, 2 and 3 respectively.

Table XI shows the values necessary to obtain the horizontal thrust in the arch and the end moments at the joints B and B' due to the wind loads.

$$H = \frac{1{,}159{,}628\,000}{114{,}312} = 10{,}150 \text{ pounds}$$

$$\varphi^a = \frac{1}{52} \times 810{,}985{,}380 - \frac{10{,}150}{2} \times 2 \times 976.26 = +5{,}690.000$$

$$\varphi^b = \frac{265{,}600{,}700}{52} - \frac{10{,}150}{2} \times 2 \times 976.26 = -4{,}800{,}000$$

With the above values, both items k^a and k^b can now be determined and they are obviously no more identical than in the former cases, as the external loading is not symmetrical.

$$k^a = -\frac{\varphi^b}{\beta} = -\frac{-4{,}800{,}000}{-4.535} = -1{,}057{,}500 \text{ foot-pounds}$$

$$k^b = -\frac{\varphi^a}{\beta} = -\frac{+5{,}690{,}000}{-4.535} = +1{,}255{,}000 \text{ foot-pounds}$$

The graphical method to obtain the end moments is as follows: Plot value k^a from joint B upwards in the scale as adopted for the moments. Draw a line through joint B' until it intersects a perpendicular drawn through the right hand fixed point of the arch, thus cutting off the value S^b. Proceed in a similar manner with the value k^b, which, however, has to be plotted from joint B' downwards, as it is a positive value. By drawing a line from k^b through joint B, the distance S^a is obtained at the left hand fixed point of the arch. Analytically S^a and S^b are,

$$S^a = -\frac{56.10}{52} \times 1{,}255{,}000 = -1{,}355{,}000 \text{ foot-pounds}$$

$$S^b = -\frac{56.10}{52} \times -1{,}057{,}500 = +1{,}142{,}000 \text{ foot-pounds}$$

Both end moments are now easily obtained by drawing a line from S^a to S^b.

This line cuts off the magnitude of both moments $M_3{}^B$ and $M_3{}^{B'}$ above joint B and below joint B'. Analytically these moments amount to:

$$M_3{}^B = -\frac{1.355000}{89.20} \times 33.10 = -503{,}000 \text{ foot-pounds}$$

$$M_3{}^{B'} = \frac{1.142000}{75.00} \times 18.90 = +288{,}000 \text{ foot-pounds}$$

		79017			69553		
		503073			288967		

The final horizontal thrust in the arch is

$$H = 10,150 + \frac{1}{2} 0.01708 (-503,073 + 288,967) = 8,320 \text{ pounds.}$$

The bending moments for every point of the arch due to the wind loads acting from the right to the left on the frame are shown in Table XIII.

Correction of moments for side sway. Stage II. (See Fig. 21.)

The temporary holding force supporting joint B to prevent side sway has to be determined first. For this purpose, it is assumed that the horizontal reactions acting from right to left are negative and the horizontal reactions acting from left to right positive. The reactions for every member of the frame due to the wind load moments are indicated in Fig. 20. The holding force is therefore.

Influence of arch 3 at B...........	−28,490 (W')	+8,320 (H)
Influence of arch 3 at B'..........	0	−8,320 (H)
Influence of beam 2...............	0	0
Influence of column 1 = − Q_4......	−31,350	0
Influence of column 1′ = − Q_5......	−16,240	0
Total holding force at B'.......	−76,080 pounds	0 pounds

Before proceeding any further, a preliminary verification of the moments and reactions should be made to see if the result of the calculations for the wind load moments for Stage I is correct. For this purpose, the three basic formulae are applied, namely:

1 = ΣH = 0 or the sum of all horizontal forces is equal to zero

2 = ΣV = 0 or the sum of all vertical forces is equal to zero

3 = ΣM = 0 or the sum of all moments around any pole is equal to zero.

The application of these formulae gives the following result:

(*a*) Horizontal forces.

Wind load	=	+ 28,490 pounds
Support A	=	+ 31,350 pounds
Support A'	=	+ 16,240 pounds
Support B'	=	− 76,080 pounds
ΣH	=	0000 pounds

(*b*) Vertical forces.

Wind load	−	7,190 pounds
Support A	−	7,085 pounds
Support A'	+	14,275 pounds
ΣV	=	0000 pounds.

Table XIII

Wind Load Moments Stage I

The moments at any point of the arch are:

$$M = -M^0 - \underbrace{503073 \times \frac{52-x}{52}}_{a} + \underbrace{288967 \times \frac{x}{52}}_{b} - \underbrace{8320\,y}_{c}$$

(*c*) Moments around joint *B*.

Due to wind	= + 1385750	= 29450 × 47.00
Due to horizontal reaction at A	= − 470250	= 31350 × 15.00
Due to horizontal reaction at A^1	= − 243600	= 16240 × 15.00
Due to moment at A	= + 46400	
Due to moment at A^1	= + 24050	
Due to vertical reaction at A^1	= − 742350	= 14275 × 52.0
ΣM at joint B	= 0000	

In order to obtain the additional moments due to the holding force amounting to 76,080 pounds, it is assumed that the joints B' and B are displaced in the direction from left to right by an assumed amount of, say, one one-thousandth of one foot. Such a displacement of the joints B and B' causes an elastic deformation of both columns and therefore bending moments in both columns amounting to

$$M_1{}^B = \frac{E \times \Delta \times b_1}{l_1 \times \beta_1 [\, l_1 - a_1 - b_1 \,]} = \text{moment at joint } B \text{ of column 1}$$

$$= \frac{432{,}000{,}000 \times 0.001 \times 2.16}{15 \times 0.288 \times 11.36} = +\ 19{,}000 \text{ foot-pounds}$$

$M_1{}^{B'}$ = moment at joint B^1 of column 1′ $= -\ M_1{}^B$ due to symmetry

$$M_1{}^A = \frac{E \times \Delta \times a_1}{l_1 \times \beta_1 [\, l_1 - a_1 - b_1 \,]} = \text{moment at support } A \text{ of column 1}$$

$$= \frac{432{,}000{,}000 \times 0.001 \times 1.48}{15 \times 0.288 \times 11.36} = -\ 13{,}000 \text{ foot pounds}$$

$M_1{}^{A'}$ = moment at support A' of column 1′ $= +\ 13{,}000$ foot-pounds due to symmetry.

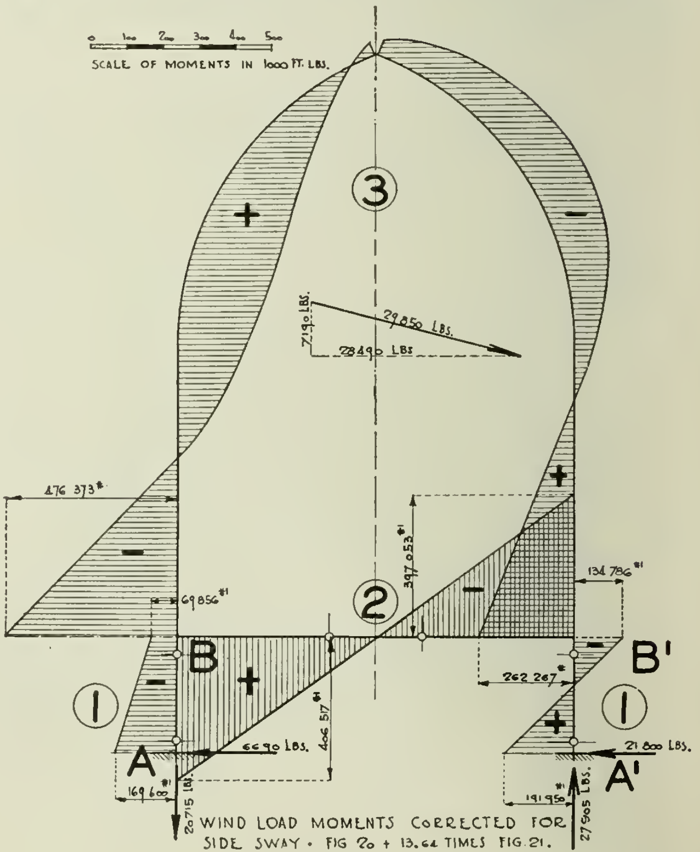

Fig. 22.

The moments $M_1{}^B$ and $M_1{}^{B'}$ have to be distributed around the frame in the usual manner. In Fig. 21 is shown the distribution of these moments by the graphical method. The following table indicates the analytical method.

Table XIV

	$M_1{}^B$	$M_2{}^B$	$M_3{}^B$	$M_1{}^{B'}$	$M_2{}^{B'}$	$M_3{}^{B'}$

		+ 1959			− 1959	
		+25981			−25981	

Moments at joint A and A^1 = due to displacement = 13,000 foot-pounds

$$\text{due to } M^B = \frac{25{,}981}{13.52} \times 1.48 = \frac{2{,}845}{15{,}845} \text{ foot-pounds}$$

With these moments known, it is possible to obtain the force necessary to cause a displacement of joints B and B' of 1/1000 of one foot.

Horizontal thrust of arch = zero

$$\text{Thrust of column 1} = \frac{25{,}981 + 15{,}845}{15.00} = +\ 2{,}790 \text{ pounds}$$

Thrust of column 1′ = + 2,790 pounds

Total displacement force at B' + 5,580 pounds

The above result has to be multiplied by a factor of 76,080 ÷ 5,580 = 13.64 to obtain the final moments for Stage II. These moments due to side sway of the frame subjected to the wind loads are as follows:—

$$M_1{}^A = M_1{}^{A'} = 15{,}845 \times 13.64 = 216{,}000 \text{ foot-pounds}$$
$$M_1{}^B = M_1{}^{B'} = 25{,}981 \times 13.64 = 354{,}200 \text{ foot-pounds}$$
$$M_2{}^B = M_2{}^{B'} = 24{,}022 \times 13.64 = 327{,}500 \text{ foot-pounds}$$
$$M_3{}^B = M_3{}^{B'} = 1{,}959 \times 13.64 = 26{,}700 \text{ foot-pounds}$$

Vertical reaction at A or A'
= 999 × 13.64 = 13,630 pounds

Horizontal reaction at A or A'
= 2,790 × 13.64 = 38,040 pounds

The final moments in the frame due to wind loads, and taking into consideration the side sway, are obtained by adding together the results of Stage I and Stage II. These moments are shown in Fig. 22.

The final verification of the result shows that

(a) $\Sigma H = +\ 28{,}490 - 6{,}690 - 21{,}800 = 0$

(b) $\Sigma V = +\ 7{,}190 - 27{,}905 + 20{,}715 = 0$

(c) ΣM around point B

due to wind =	+1,385,750	foot-pounds
due to A' = 21,800 × 15 =	+ 327,000	foot-pounds
27,905 × 52 =	−1,451,100	foot-pounds
− 191,950 =	− 191,950	foot-pounds
due to A = 6,690 × 15 =	+ 100,350	foot-pounds
− 169,600 =	− 169,600	foot-pounds
M =	− 450	foot-pounds

The difference in the case of ΣM is only 450 foot-pounds which represents an error of only 0.025 per cent. Considering that all calculations are made by slide rule, it can be said that the result is satisfactory.

An examination of the diagrams showing the moments for Stage I, and the combination of Stages I-II, reveals the tremendous importance of correcting the bending moments due to side sway. It is possible, of course, that the ground floor slab which is anchored into the front wall has a somewhat restraining effect upon the frame, and reduces the moments due to side sway to a certain extent. The arches located close to the expansion joint, are, however free to move, and have to be dimensioned accordingly. It was found advisable, therefore, for the purpose of dimensioning the frame, to take both extreme cases into consideration and use those bending moments in combination with the corresponding thrusts whichever produced the higher stresses. It can also be seen how valuable the analysis of such a frame according to the fixed point method is, as the influence of side sway can be computed so easily, without much additional work.

The maximum moments for any point of the frame are now found by tabulating the following cases:

Case I no side sway. Moments due to dead loads of entire frame.
Live loads on beam 2, arch and brackets 4 and 5.

Case II with side sway. Moments due to dead loads of entire frame.
Live loads on beam 2, arch, and brackets 4 and 5.

The following table shows the moments for the above two cases. For this purpose, the live load moments for the beam and the brackets were taken directly in proportion to the moments due to dead loads on these members. All moments causing tension at the intrados of the arch were taken as positive and all moments causing tension at the bottom of beam 2, brackets 4 and 5 and at the inside face of the columns also as positive.

Table XV

Recapitulation of Dead Load and Live Load Moments.

Point	Total Dead Loads	L.L. 2 59.2 per cent of D.L.	L.L. 4 25½ per cent of D.L.	L.L. 5 50 per cent of D.L.	Wind no side sway left half	Wind no side sway right half	Wind with side sway left half	Wind with side sway right half

27	pos.	+185340	pos.	+185340

In these tables, the values of the moments for the points 1 to 10 have not been indicated. These values can easily be determined, however, as the moment line is a straight line between these points for any type of loading.

In order to determine the reinforcing necessary for the frame, and also to find the stresses to which each of the members of the frame is subjected, it is necessary that the magnitude of the thrust at any point be known. The shortest way to obtain these values when all moments are already known, is the graphical method of plotting the funicular polygon for all loads applied on the frame. This

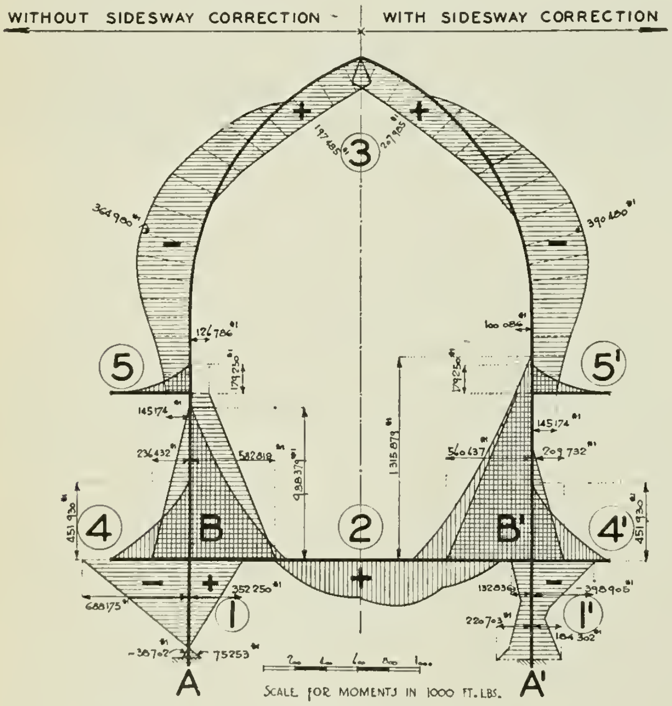

Fig. 23.

method gives at the same time the value of the shear for each section and also a verification of the analysis, as all points of zero moments have to coincide with the points of intersection of the frame axis with the line of the polygon. Figure 24 shows an actual illustration of this graphical method to obtain the direct stresses and shears for the church frame with live loads on beam 2, brackets 4 and 5 and wind on arch 3, in addition to the dead loads of the entire frame.

The following gives an example of determining the influence of an uneven settlement of the footing to illustrate the application of the fixed point method in regard to arbitrarily assumed deformations of any member of the frame.

Influence of an uneven settlement of the footings of the frame.

It is assumed that one of the two footings settles one inch. In order to obtain the bending moments in the entire frame due to such a settlement, it is necessary again to assume that joint B is held temporarily in place to prevent side sway. The moments due to the displacement are then computed, and with the help of these moments the magnitude of the temporary holding force is determined. To obtain the final moments, a load equal to the size and direction to this holding force is then applied at the same point B, but in the opposite direction. The moments due to this load can readily be obtained as they are in direct proportion to the moments which are already calculated to correct the side sway for the wind load moments. (See Fig. 21.)

If the footing A' sinks below the level of footing A by one inch, both beam and arch have to follow this settlement, and are subjected to certain bending moments. These moments are easily obtained with the fixed point method, as all values appearing in the formulae for these moments are already known.

(*a*) *Moments Stage 1.*

Moment at support of beam due to a vertical settlement of one support by one inch.

$$M_2^B = M_2^{B'} = \frac{E \times \Delta \times a_2}{l_2 \times \beta_2 \, [\, l_2 - a_2 - b_2 \,]}$$

$$= \frac{432{,}000{,}000 \times 1/12 \times 19.90}{52 \times 2.14 \, [52 - 19.90 - 19.90]}$$

$$= 527{,}000 \text{ foot-pounds.}$$

Moments at the supports of the arch due to a vertical settlement of one support by one inch.

$$M_3^B = M_3^{B'}$$

$$= \frac{B \left[\frac{l_3}{2} - b_3 \right] \times \Delta \times E \times a_3}{l_3 \times \beta_3 \, [\, l_3 - a_3 - b_3 \,]}$$

$$= \frac{0.01708 \times (52/2 + 56.10) \times 1/12 \times 432{,}000{,}000 \times 56.10}{52 \times [-\,4.535] \times [52.0 + 56.10 + 56.10]}$$

$$= 73{,}100$$

These moments are again distributed around the frame in the manner as shown previously. This distribution is indicated in detail in the following table:

Distribution of end moments of beam:

	M_1^B	M_2^B	M_3^B	$M_1^{B'}$	$M_2^{B'}$	$M_3^{B'}$
527000 × 1.00		−527000				
527000 × 0.962	−507000					
527000 × 0.038			+20000

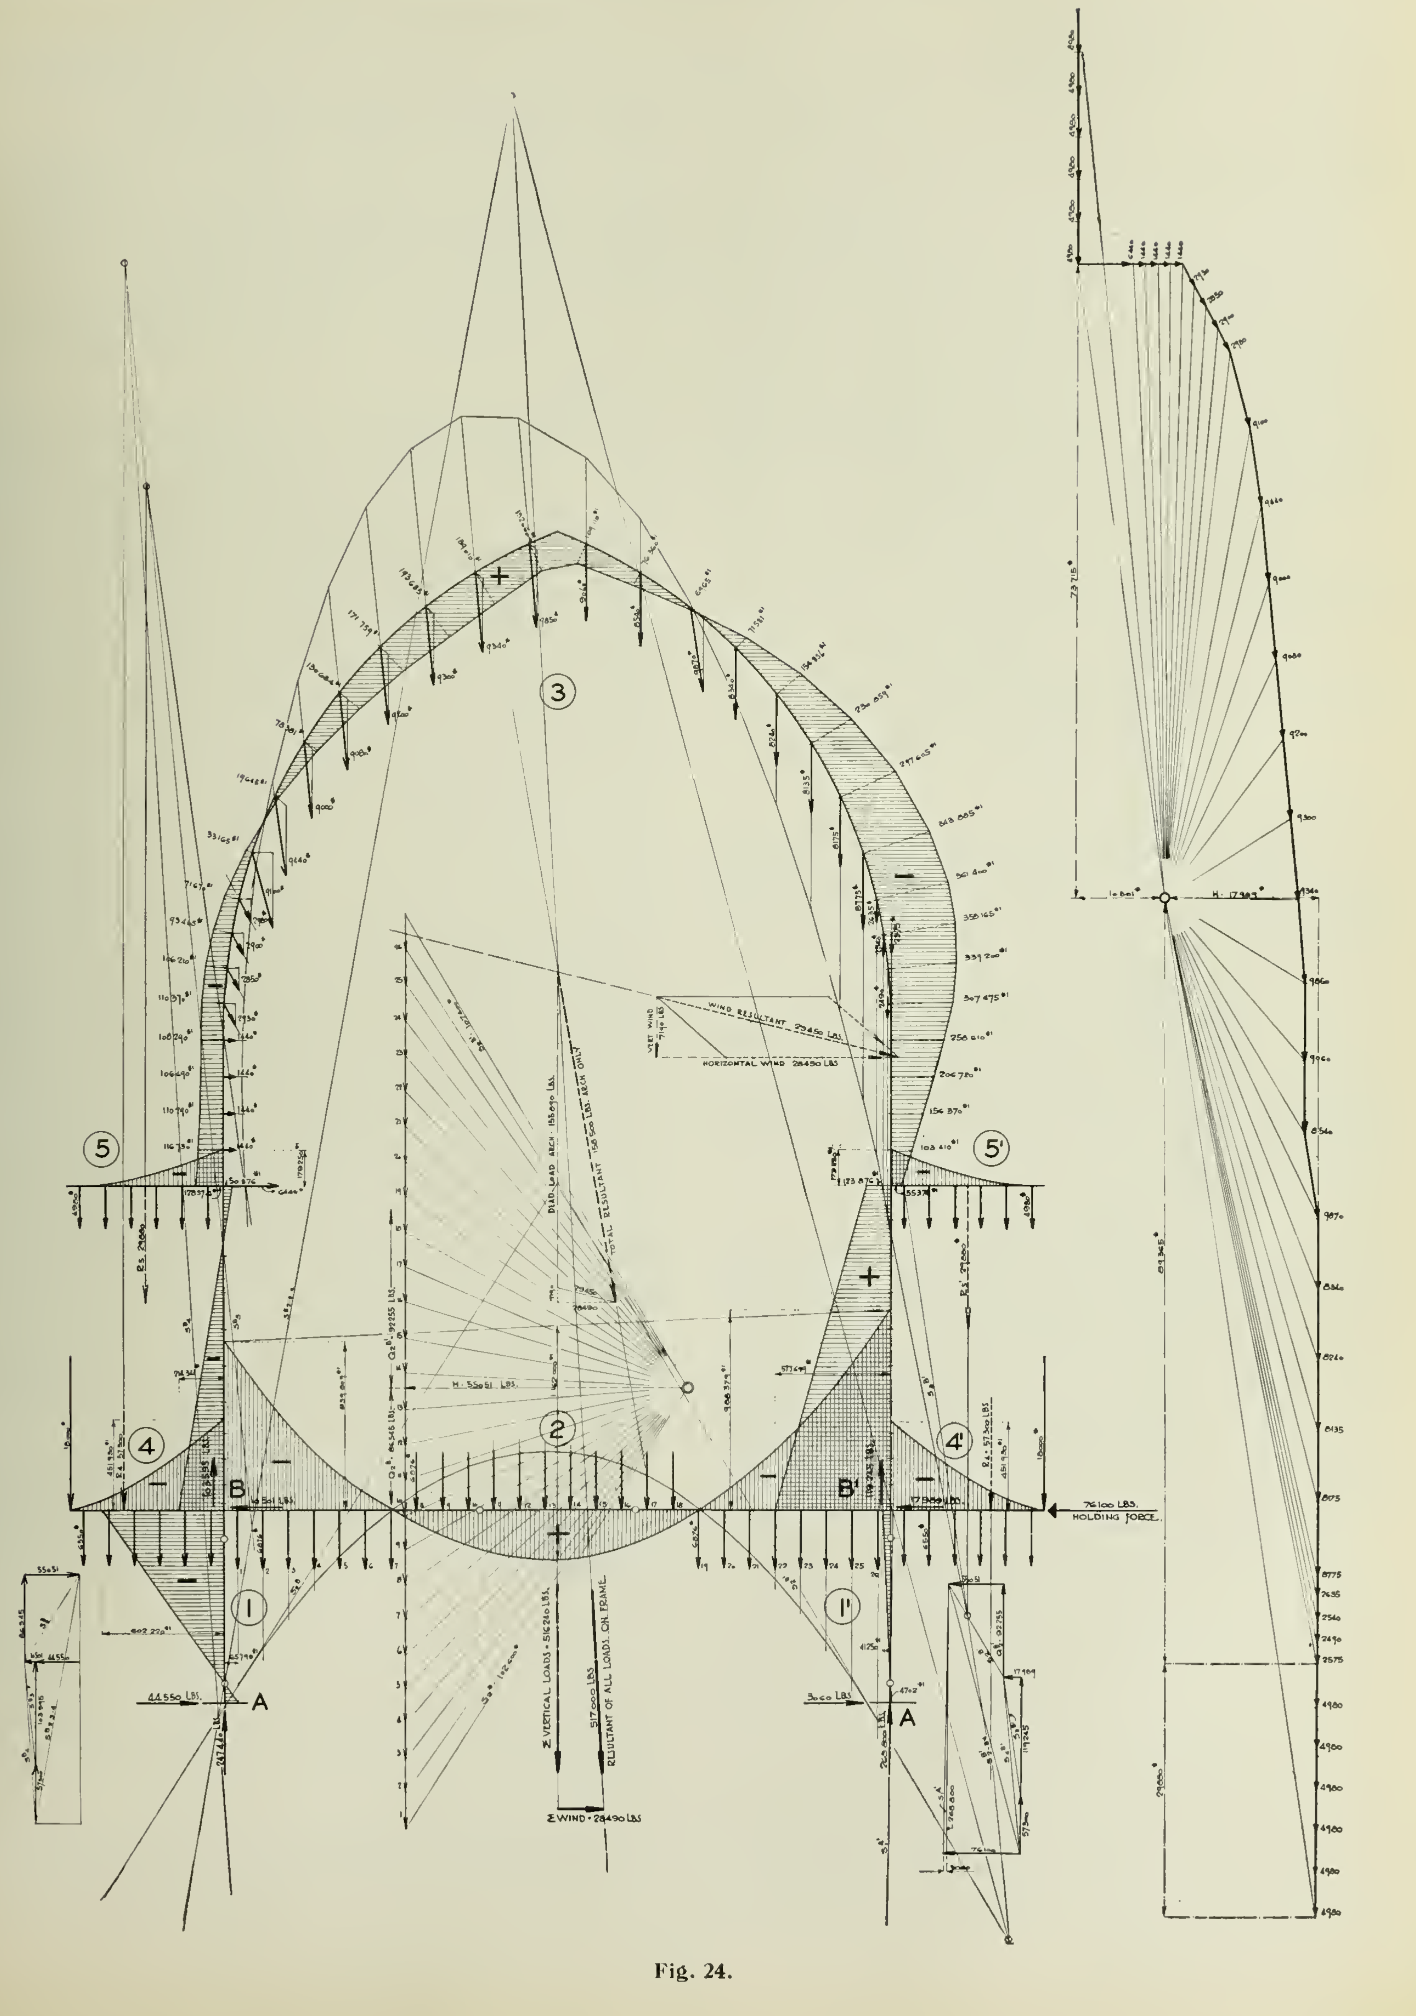

Fig. 24.

Distribution of end moments of arch:

	M_1^B	M_2^B	M_3^B	$M_1^{B'}$	$M_2^{B'}$	$M_3^{B'}$
73100 × 0.884	− 64620		−73100			
73100 × 0.116		+ 8480				
8480 × 19.90					− 5260	
32.10						
5260 × 0.962				− 5060		
5260 × 0.038						+ 200
200 × 56.10			+ 104			
108.10						
104 × 0.884	+ 92					
104 × 0.116		− 12				
Total for end moment at B	− 64528	+ 8468	−72996	− 5060	− 5260	+ 200
Total for end moment at B'	+ 5060	+ 5260	− 200	+ 64528	− 8468	+72996
Total Arch	− 59468	+ 13728	−73196	+ 59468	− 13728	+73196
Total Arch and Beam	−574915	−511321	−63594	+574915	+511321	+63594

The moment at the foot of both columns is

$$\frac{574{,}915}{13.52} \times 1.48 = 63{,}000 \text{ foot-pounds}$$

Horizontal reaction of either support A

$$= \frac{574{,}915}{13.52} = 42{,}500 \text{ pounds}$$

Vertical reactions at both supports A or A'

$$= \frac{511{,}321 + 63{,}594}{26} = 22{,}100 \text{ pounds}$$

(*b*) *Stage II side sway.*

The temporary holding force to keep the frame from swaying sideways at the points B and B' is equal to the shear acting on both columns 1 and 1′. This force is therefore obtained directly thus:

$$H = \frac{M_1^B + M_1^{B'}}{l_1 - a_1} =$$

$$H = \frac{574{,}915 \times 2}{15.00 - 1.48} = 85{,}000 \text{ pounds}$$

This force has to be applied at joint B' in the direction from left to right. The moments due to this force are obtained by multiplying the moments shown in Fig. 21 by the following coefficient.

$$\alpha = \frac{85{,}000}{5{,}580} = 15.23,$$

as Fig. 21 shows all moments in the frame due to a force = 5,580 pounds applied at joint B'. The moments due to side sway are therefore as follows:

$$M_1^A = M_1^{A'} = 15{,}845 \times 15.23 = 241{,}000 \text{ foot-pounds}$$
$$M_1^B = M_1^{B'} = 25{,}981 \times 15.23 = 396{,}000 \text{ foot-pounds}$$
$$M_2^B = M_2^{B'} = 24{,}022 \times 15.23 = 366{,}200 \text{ foot-pounds}$$
$$M_3^B = M_3^{B'} = 1{,}959 \times 15.23 = 29{,}800 \text{ foot-pounds}$$

Reactions

Horizontal reaction at A or A'

$$= 2{,}790 \times 15.23 = 42{,}500 \text{ pounds}$$

Vertical reaction at A or A'

$$= 999 \times 15.23 = 15{,}200 \text{ pounds}$$

The final moments and reactions are obtained by adding the results of Stage I and Stage II, thus

$$M_1^A = M_1^{A'} = 63{,}000 - 241{,}000 = \pm\ 178{,}000$$
$$M_1^B = M_1^{B'} = +574{,}915 - 396{,}000 = \pm\ 178{,}915$$
$$M_2^B = M_2^{B'} = 511{,}321 - 366{,}200 = \pm\ 145{,}121$$
$$M_3^B = M_3^{B'} = 63{,}594 - 29{,}800 = \pm\ 33{,}794$$

Reactions at B horizontal = 85,000 − 85,000 = 0

at A horizontal = 42,500 − 42,500 = 0

at A vertical = 22,100 − 15,200 = 6,900 pounds.

Conclusions.

The result of this analysis shows how dangerous it is for the designer to subdivide the structure into secondary frames by assuming hinges in order to simplify the calculations. In the case of the frame analyzed in this article, it would have been easy to either assume full restraint or two hinges at the base of the arch in order to obtain a frame which is statically indeterminate in the third or second degree. The lower frame could then have been assumed to be a portal frame with only one redundant. Both assumptions would have given misleading results, as it is practically impossible to execute the hinges in a reinforced concrete structure in such a manner, so that they actually work as assumed. On the other hand, the assumption of full restraint would have given an entirely wrong result as far as the distribution of the bending moments are concerned. The fact cannot be ignored any more that those engineers who want to be able to give entire satisfaction to the architect in charge of the design of the building, both from an economical and aesthetic point of view, have to get rid of the old arbitrary and illogical rules and interest themselves in modern statics.

In this article, it has been the intention, after outlining a general explanation of the theory on which the method is based, to give the reader as complete an illustration of the application of the method as possible. By doing so, probably a great number of computations will prove to be superfluous to the experienced designer. On the other hand, it was considered worth while to spend a little more time on the presentation of the text for the benefit of those designers who are probably not very familiar with semi-graphical short-cuts, and who are more at home with analytical methods. The length of this article and the great number of diagrams used for illustrations of the method may give the impression that the method involves rather a considerable amount of time to obtain the final result. But such is not the case, as only one diagram was actually made for the original design of this particular frame embodying all those shown in this article. This saving of time is easily possible for one who is familiar with the method.

Messrs. H. S. Labelle, J. E. Perron, J. M. Lafleur and L. N. Audet were the architects entrusted with the design of the cathedral. The writer, as designing engineer of Arthur Surveyer and Company, was responsible for the structural design.

The Winter Operation of Aero Engines*

Squadron Leader A. Ferrier, A.M.E.I.C.,
Aeronautical Engineering Research, Department of National Defence, Ottawa, Ontario.

Paper presented before the Aeronautical Section of the Ottawa Branch of The Engineering Institute of Canada, February 1st, 1935.

SUMMARY.—The author describes the conditions of aircraft operation in Canada during the winter and after outlining the laborious technique pursued for several years emphasizes the need for improvement in lubrication and starting technique.

Elimination of cold weather lubrication difficulties is based on the proposition that oil temperature is in itself immaterial and that its only real importance is the effect on viscosity which is regarded as a state rather than as a property. In consequence a variation of oil grade and a premeditated variation of oil operating temperature under adequate control is advanced as the solution and the results of two years practical trial are offered as proof. A brief specification of a desirable oil system is given, together with a forecast of possible developments in the near future to deal with existing lubricants.

Although the author is an officer of the Royal Canadian Air Force, this paper deals only very incidentally with problems peculiar to military aviation. The control of civil aviation in Canada is vested in the Minister of National Defence and the members of the Aeronautical Engineering Division of the Department of National Defence are in close touch with civil aviation whether operated by the government or by private enterprise.

That a clear idea may be gained of the particular problems confronting the operator in Canada it is necessary first of all to describe briefly the fundamental characteristics of most Canadian flying. It is essentially a pioneering activity. All commercial undertakings of whatever nature are designed to fill a need—and the less competition the better. One of Canada's crying needs was better facilities for communication in the immense areas of undeveloped territory to the north of the main transcontinental railway lines. The airplane just naturally slipped in to fill this need in competition against the canoe and dog team rather than entering into the expensive development required to compete against the well organized and efficient east-west communication systems.

Transcontinental aviation is not by any means being ignored but the great bulk of activity is now and will for some time remain in the bush and wilderness territory, and a vast majority of customers is among those whose enterprises are of the pioneering sort such as mining corporations, prospectors, timber cruisers, surveyors, fur traders and so on. The very nature of the operations implies mobility and flexibility and consequently the establishment of elaborate bases is impossible. The home base may be moderately comfortable, although it may itself be some hundred miles from the nearest railway, but the outer terminus will as likely as not be a sand bar or beach or a flat patch of snow in the lee of some sheltering trees or rock. Under these circumstances every airplane must be self-sufficient and must carry all the equipment necessary for its own service and maintenance. It must also carry emergency rations and clothing and fuel for the preservation of the lives of its occupants in the event of a forced landing. It is obvious that the necessity for inflicting all this weight on the poor flying machine makes serious inroads on its pay load.

When winter flying operations started seriously in Canada shortly after the World War, the technique at the commencement and at the termination of a flight was terribly laborious. The author's chief, Group Captain E. W. Stedman, R.C.A.F., M.E.I.C., vividly describes the efforts to start a four-engined Handley Page bomber in quite moderately cold weather in Nova Scotia. He tells of hordes of assistants "chain-ganging" buckets of boiling water into the radiators until the outlets on the far end of the water manifolds ran hot; of pouring hot oil into the tanks; of warming at least 48 spark-plugs on a shovel over a fire and then putting them in; and of the fourth engine sulking and the other three having to be shut down for fear of overheating on the ground; and then of starting the whole process over again. The heart-rending thing was that with one engine running its available horsepower could not be harnessed to start the other three. Later, at a government air station at High River, Alberta, where Liberty-engined D.H.4's were in use, a volatile anti-freeze was employed and each aircraft was fitted with an elaborate still for the recovery of the anti-freeze and its subsequent return to the radiator. The coming of the air-cooled radial engine certainly reduced the difficulties, but even at that they remained very formidable. Oil had to be drained from motor and tank with the engine still running, a risky and most undesirable process. Then it had to be heated all over again and poured into the tanks before the commencement of the next flight, with some likelihood that by the time the motor actually started the oil had become cold and the first few moments of running were done with little or no lubrication.

To ensure a start it has been and still is the practice to warm the motor by encasing it in a heavy canvas cover or a nose tent supported on the vertical propeller and applying heat under the cover by means of a blow lamp, gasoline stove, or even a wood-burning stove. This process takes from half an hour to an hour and the cover has to be removed before an attempt is made to start. The oil was poured in at the last possible moment. If for any reason the engine refused to start the whole process of draining and reheating the oil, replacing the engine cover and warming the cylinders had to be repeated. The mere manhandling of 50 to 100 pounds of oil with its container, and of the heavy bulky engine cover is a labour not to be despised and by the time an aircraft is ready to take off, the crew has already done a goodly part of a day's work and, if it is required to take full advantage of the short daylight hours, a great proportion of the preparatory work and the after-flight work has to be done in the dark. The weight and bulk of the oil containers, engine warming bag or tent, and stove are formidable and if the operation is in a treeless district, such as the barren lands of the Northwest, the difficulty is increased by the necessity for carrying fuel for warmth as well as fuel for power. Incidentally, leaded fuel is not suitable for burning in stoves so special fuel in separate containers must be carried.

For several years these arduous conditions were accepted as the inevitable accompaniment of winter. This sounds like rather a weak admission, but Canadian aviation has no great resources either in spare cash or in engineering personnel to devote to experiment and research and we were for some time quite fully occupied with winter landing gears and allied problems. Commercial operators were busy trying to survive and, having settled on a workable technique, had little time or money to devote to research which was not immediately productive.

Attack on the Lubrication Problem

The urge to reopen the attack on the engine problem arose only a few years ago and came to this individual in a manner which may be worth relating. One trouble encountered was that the oil temperature could never be worked up to the degree recommended by the engine manufacturers. This was countered by an elaborate system

*Paper presented at the annual meeting of the Society of Automotive Engineers, Detroit, January 15th, 1935, and published in the April 1935 issue of the S.A.E. Journal. Reprinted by permission of the Society of Automotive Engineers.

of lagging pipes and tanks, shielding crankcases and plugging up all sorts of cowling openings. This involved a great deal of work which had to be done every fall and undone again every spring, and, from some over-worked maintenance man, the suggestion arose that the lagging and so on be retained as a permanent feature and that large oil coolers be fitted to look after summer requirements. This was too much like asking a man to wear his winter overcoat all the year round and to carry an ice pack with

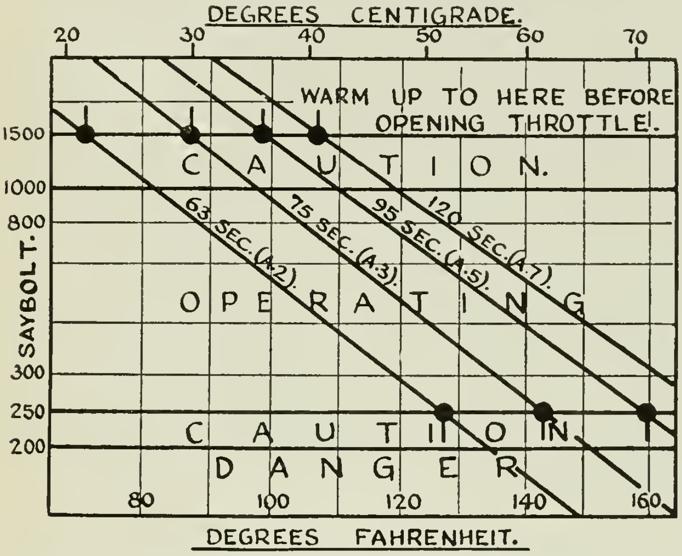

Fig. 1—Viscosity-Temperature Chart. Posted in a Visible Position on every Aircraft in the Royal Canadian Air Force.

him for relief when needed. One's gorge rose in sympathy for the poor overloaded airplane. The objectionable suggestion contained, however, the germ of an old idea and after considerable thought and discussion the Department proceeded to put it to work—in reverse.

Why not work a step or a couple of steps lower on the temperature scale, and use oil coolers in *winter time* to make sure that we remain on the chosen step? After all, a given quantity of fuel burning with a given quantity of oxygen will produce approximately the same amount of heat no matter what the original temperature of the oxygen. Some of this heat is converted into useful energy, a good share is dissipated to the atmosphere through the cylinder walls, directly or through a cooling liquid, some more goes away with the exhaust and a fair proportion is imparted to the oil and thence to the atmosphere. The atmosphere therefore acts as a direct cooling medium for a very considerable proportion of the dissipated heat and, though the exhaust gases will probably be at much the same order of temperature summer and winter, it is quite reasonable to suppose that the general temperature level will be lower in winter than in summer. This supposition is definitely supported by the existence of elaborate shutter systems installed with the sole idea of keeping the temperature up. Any one who has shovelled coal into a furnace during a northern winter can argue this out for himself.

The next supposition is admittedly assailable. Here it is: "If an oil has the proper 'oiliness' and all its other physical and chemical properties are satisfactory, then the physical characteristic which finally determines its suitability as a lubricant under a certain set of conditions is viscosity. Furthermore, viscosity should be regarded as a *state* rather than as a *property* because it varies with temperature."

If this proposition is accepted then a 63 sec. oil at 120 degrees F. is in the same *state* and therefore has the same lubricating qualities as a 120 sec. oil at about 165 degrees F. (See Fig. 1.) If the viscosity indices of the oils are of the same order, then the same deduction could be made if we add a couple of hundred degrees of temperature to each side. The weak point of the chain comes right here.

Is the temperature rise of a 63 sec. oil entering an engine at 120 degrees F. and working in winter of the same order as the temperature rise of a 120 sec. oil entering the engine at 165 degrees F. and working in summer?

Basing our opinion on the established fact of a lowered general temperature level we in Canada decided the point was well worth putting to the test.

Fortunately for our requirements a Wright R975E engine had just completed full type trials for a Type certificate of airworthiness on the test dynamometer of the National Research Council of Canada. The engine had been carefully calibrated for power and had then been torn down, very thoroughly inspected and "miked," and then reassembled for use. Its exact condition, therefore, was well established. This engine was installed in a Bellanca Pacemaker fitted with a controllable oil cooler and with the usual run of measuring instruments for a test of this nature. The aircraft was operated for 200 hours during the winter of 1932-33, observations being made of consumption of fuel and oil, cylinder head temperature, oil pressure, inlet temperature, and all relevant conditions which might have significance; 75 and 63 sec. oils were used and no mercy was given, the aircraft doing a considerable number of full throttle climbs. At the end of the 200-hour period, and incidentally of the winter, the engine was removed from the Bellanca and put on the dynamometer where the power was calibrated again, after which a complete stripping, inspection and "miking" was done. The results, an abstract of which is contained in Appendix I, were sufficiently encouraging to warrant further trials the next winter. Consequently, arrangements were made to fit several aircraft, powered by Pratt & Whitney, Wright and Armstrong Siddeley engines, with the necessary oil coolers, and service trials were done by pilots untrained to test work performing ordinary service functions. No unusual trouble was experienced and we felt satisfied that a lot of the grief of winter flying was being eliminated and that the engines were certainly getting their oil during the first few revolutions—which was a matter of considerable doubt in the old days.

Last winter a Rolls-Royce Kestrel was tackled. This was a different proposition altogether as, being a liquid-cooled engine and the aircraft being fitted with a controllable radiator, the cylinder temperature should be the same winter or summer. To be strictly consistent, the cooling liquid temperature should have been stepped down to a lower figure than that used with the summer oil, but this was not done. The airplane was left exposed out of doors all winter and was started up every day, a number of dead cold starts being effected with no great difficulty at sub-zero temperatures down to as low as −20 degrees F. No real trouble was encountered.

As a result of all this experimentation, the Department felt that the right track was being followed, especially as the automobile industry seemed to be thinking along much the same lines. Consequently, a technical memorandum was published to impart to commercial and private operators the benefit of our experiences. This memorandum, which was written mainly for operators and maintenance men, is contained in Appendix II.

Installation of the lubrication system in an aircraft required to operate in widely varying climatic conditions should include an oil tank or tanks well protected from such external influences as warm air from the cylinders or the cold external atmosphere, and also should include a generous controllable oil cooler in the scavenge line. It is quite a good idea to have the oil feed and return pipes enter the oil tank within the confines of a central enclosure dividing off a gallon or so of oil in the middle of the tank. This enclosure must have feed holes communicating with the main body of oil in the tank, and, if desired, a manually operated bypass in the scavenge line can be arranged to return to the outer section of the tank. The bypass cock must in no position close off both return passages. When the motor is started up, the central body of oil is warmed much more rapidly than would be the whole body in a simple tank and consequently the proper lubrication is effected at an earlier moment. This definitely saves on running up time and on wear and tear at the start.

The oil cooler should bear the whole responsibility for the oil temperature and should therefore be of sufficient capacity to permit overcooling on the hottest summer day. Conversely, if it is completely cut out, overheating should occur on the coldest possible winter flight. Only in this way can the pilot have complete control throughout the four seasons without resort to seasonal modifications, such as shutters and lagging. Thermostatic oil temperature control would be quite satisfactory provided that the thermostat can be set to the correct temperature for the particular grade of oil being used. Our experience with aircraft having common types of air-cooled radials up to 425 h.p., and controllable oil coolers is that 63 sec. oil remains fluid at −20 degrees F. and can safely be used up to an atmospheric temperature of 32 degrees F. and that 95 sec. oil is satisfactory for the upper range except for really abnormal hot weather. Three grades of oil ought to cover the whole year north of the 40th parallel.

Admittedly, people who operate north-south air lines from the 40th to the really low parallels will have to think a bit, but that worry can be left to them. As the development has only been carried down to −20 degrees F. for cold oil starts, and aircraft are quite consistently operated at between −60 and −70 degrees F., the necessity for really rapid oil drainage has not been eliminated. Consequently the drain cock and pipe should be of generous proportions, very easily accessible and should discharge vertically downwards when the aircraft is resting normally on the ground so that there is no necessity to keep on moving the can as the head decreases. The oil filler arrangements should likewise be very large and easily reached. One can't get people to filter oil at −40 degrees F. nor do they want to stand pouring oil out of a can above their heads or in a cramped position at that sort of temperature. The same remarks apply to refueling arrangements but to a lesser degree. To be really safe, filters should be oversize and the oil filters should be duplicated, one on the inlet and one on the scavenge pipe. Great care is required in locating the oil temperature thermometer if provision has not already been made by the engine manufacturer for a thermometer pocket. The measuring element of the thermometer must be well surrounded by the moving stream and must not be in a pocket or back eddy, because quite serious errors of temperature measurement may occur. The present instruments for supervision of the oil condition are the thermometer and the oil pressure gauge. It has been suggested that, as viscosity is the real criterion, a viscometer should be included in the system. Investigations now are under way at the National Research Council laboratories to determine whether a viscometer can be made to tell the truth and, if so, whether the information is of value, and whether the instrument can be used to replace the thermometer and pressure gauge.

Engine and Oil Warming

Three general types of shelters for engine warming have been in general use in Canada: (1) the engine cover, (2) the nose tent, and (3) the nose hangar. The first two are completely mobile while the third is semi-mobile in that it can be knocked down and transported by air if it is found necessary to move a sub base.

The engine cover (Fig. 2) is merely a bag tailored to fit as closely as possible round the engine, vented at the top and provided with a sort of trunk or flue at the bottom into which the chimney of some heating device can be inserted. The bag does not cover the airscrew. Its main drawback is that no maintenance work can be done on the engine while the bag is in place.

The nose tent (Fig. 3) is merely a wigwam shaped affair supported on the tip of one blade of the airscrew and laced around the body of the aircraft. It is usually made of two ply of durable, close-woven canvas. The heating element is placed right inside the tent, provision being made for air inlet and venting. The skirt is spread out and held in place by snow piled on it. The nose tent is necessarily heavier than the simple engine cover, but has the advantage that a limited amount of servicing and maintenance may be performed under it and, in emergency, its shelter may be used for human beings.

The nose hangar (Fig. 4) is a collapsible framework of light metal tubing covered with canvas. It is built of sufficient height to permit turning the airscrew and a split curtain is laced tightly round the body of the aircraft behind the engine. This equipment permits the execution of field maintenance work to the fullest degree but is not intended to be carried as part of the routine winter gear of the aircraft. It is mounted on skids or skis to facilitate placement.

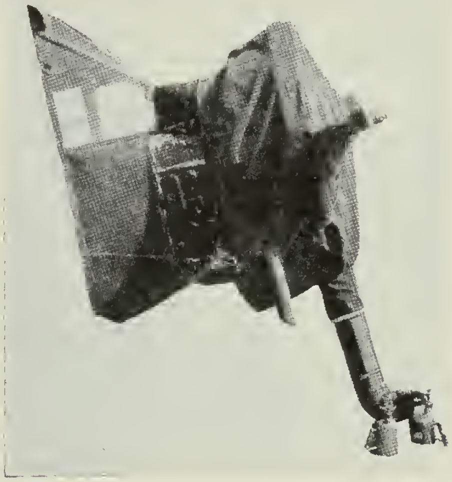

Fig. 2—The Engine Cover. A Bag Tailored to fit as closely as possible around the Engine.

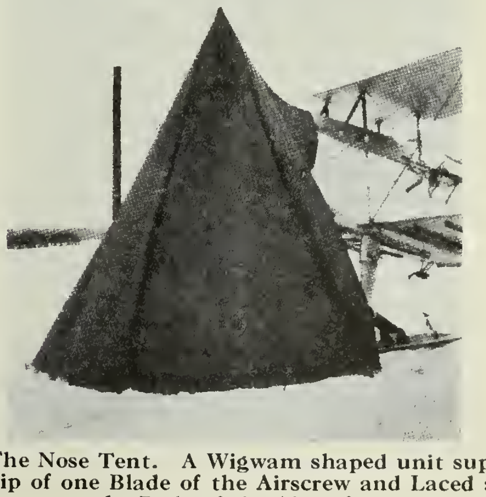

Fig. 3—The Nose Tent. A Wigwam shaped unit supported on the Tip of one Blade of the Airscrew and Laced around the Body of the Aircraft.

Where supplies of wood may be obtained, use is made of a sheet metal stove for warming purposes, but the most usual source of heat is gasoline burnt in a Primus stove or plumber's pot suitably shrouded and flued to take the heat where it will do the most good. As mentioned previously, leaded fuels are not good to burn in these stoves and are definitely forbidden for cooking. Hence a supply of special fuel in separate containers has to be carried. The heat from a large gasoline burner is quite fierce and precautions should be taken to avoid damage to soldered radiators and other vulnerable items, and to avoid danger of fire by providing some sort of control, preferably an automatic one by thermostat. This is most applicable in the case of the simple engine cover and where the metal flue enters the bag, a non-inflammable connection with asbestos is essential.

Fig. 4—The Nose Hangar. A collapsible Framework of Light Metal Tubing covered with Canvas.

None of these equipments make satisfactory provision for warming the oil. On many aircraft the oil tank is situated behind the fire bulkhead and this adds to the difficulty. All sorts of attempts have been made to overcome the trouble. One of these which has some merit is the introduction of a water boiler in the flue of the stove. Steam can then be led through flexible piping to an immersion heater thrust into the oil tank through the filler neck. This is not very efficient as oil does not warm up readily in bulk from a local source of heat. An improvement might be effected by using a built-in steam heating element of efficient design with very thin, closely-spaced fins.

Another suggestion for which a preliminary investigation has already been made in the laboratories of the National Research Council is as follows: The oil tank to be fitted with an internal pierced enclosure surrounding about a gallon of oil as mentioned before but located so that an accessible portion of the outside wall of the tank forms one side of the enclosure, the feed and scavenge pipes to lead through this portion of the wall, and finally a hand pump and three-way cock is to be fitted on a by-pass pipe short circuiting the motor as close as possible to the inlet and outlet connections. (See Fig. 5.) The application of local heat by means of chemical pads, such as the "Thermat" pad made by Bauer & Black, applied to the outer wall of the tank will raise the temperature of a portion of the oil sufficiently to permit it to flow when the hand pump is operated. If in the meanwhile heat from the apparatus which is being used to warm the motor is conducted through the oil radiator, sufficient warm oil for a safe start may be accumulated in a reasonable time without any need to drain the oil, which is one of the main bugbears of the winter operator. The weight of the extra piping, pump and "Thermat" pads may be balanced against the eliminated oil container and the extra fuel required to warm the oil separately. The feasibility of this process has been demonstrated, but practical trials have not yet been made, though it is the Department's intention to make such trials this winter. It will of course occur to every one that the steam immersion heater idea could be applied to this process, thus making one independent of chemical pads.

Ignition and starting

Getting the first kick out of the engine is a ticklish problem and has been the subject of numerous experiments. An organized attack on the problem was commenced under the auspices of the Air Research Committee of the Research Council of Canada by Professor C. H. Robb of the University of Alberta at Edmonton in 1920. Professor Robb continued his experiments for about three winters and forecasted several developments which only now are really being put into practical use, in particular the use of an oil cooler in winter. He used a Liberty engine and the problem was presented to him in this way: "The engine is in an airplane forced to spend a night in the open away from a base. It has been assumed that while the engine was still hot the cooling system has been drained or that an efficient antifreeze mixture is available. It is also assumed that the battery has been removed from the machine and kept at ordinary room temperature and that a supply of commercial ether is available."

Some of Professor Robb's technique would be objected to today as being too brutal. For instance, he recommended supplying the engine by injecting about ½ pint of gasoline and turning the crankshaft over with switches off until the engine worked freely. In extenuation it must be remembered that the starting handle of a Liberty engine took some pretty heavy heaving to get results. The following table gives his recommendations:

Temperature	Gasoline Per Cent	Ether Per Cent
20 degrees F. and warmer.....	100	Nil
0 degrees F. to 20 degrees F. .	75	25
−15 degrees F. to 0 degrees F....	66	34
−30 degrees F. to −15 degrees F.	50	50
Below −30 degrees F...	Nil	100 (warm)

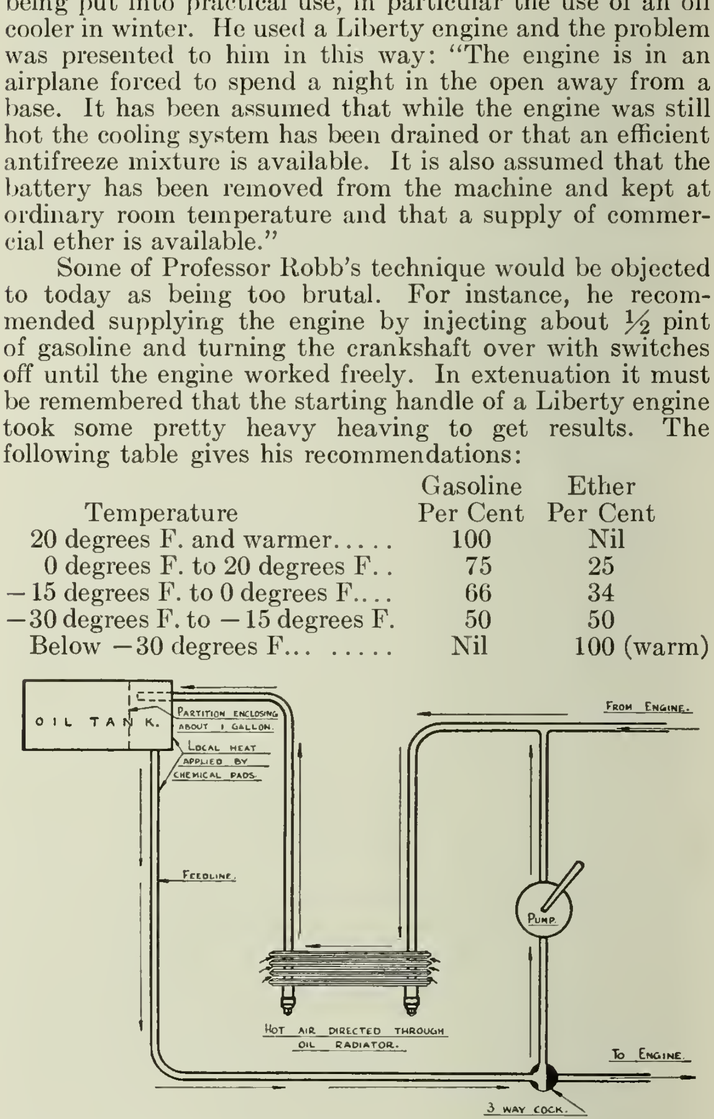

Fig. 5—Suggested Method of Warming Oil in Cold Aircraft Engines on which Canadian National Research Council has made Preliminary Investigations.

About ¼ pint of the appropriate mixture was injected into the intake manifolds and as soon as the engine kicked an additional ¼ pint was shot in. This generally sufficed for the engine to begin to feed on gasoline from the carburetor which had in the meanwhile been flooded. Large capacity priming pumps and nozzles were found to be essential.

It will be noted that under the conditions it was assumed that the battery could be kept at room temperature. This is a concession that we would not care to allow today as the object is to eliminate all possible manual labour. The loss of capacity of storage batteries at low temperatures is a very serious objection to the use of battery ignition in cold climates especially in these times when the poor old battery is asked to do so many things. This is one of the considerations that has led the Department to turn down the booster coil in favour of the hand starting magneto. The aircraft and its crew must be self-supporting and in the final analysis the energy for starting may have to be derived from the calories in the emergency rations supplied for the men. This is not far fetched. Many a pilot in the North has taken the spark plugs to bed with him in the eiderdown bag so as to be sure that they would be warm and dry when required for use the next morning. Incidentally it is quite common technique to warm at least one plug out of each cylinder on a shovel over the engine warming stove. This is not so convenient when a simple engine cover is being used.

To insure lubrication at the start, Professor Robb tried both "Mobil A" and "Mobil Arctic" and decided definitely in favour of the latter. A little "Arctic" was left in the crankcase overnight and the tank was short circuited by means of a bypass with a relief valve leading to the tank so as to control the pressure on the suction side of the oil distributing pump. This idea is similar to that of the segregation of a portion of the oil tank but it has the disadvantage that some one might forget to cut in the main tank.

Experiments were also made at this time with jets of various sizes larger and smaller than the standard high-speed jet. As might be expected, because cold air has more oxygen per unit volume than warm air, the standard jet was inclined to give a lean mixture and the engine was found to take the throttle better with a slightly oversize jet (070 as against 065 on the Liberty).

The danger of vapour lock at high altitude or at high temperature definitely precludes aviation gasoline from being a really easy starter, at least in the present stage of the art. To achieve the ideal of dead cold starts, therefore, it will be necessary to resort to a starting fuel such as ether or some gaseous fuel compressed into a bottle and injected into the intake manifolds. It must be confessed that the lead given by Professor Robb has been somewhat neglected for a long time, but some of the blame can be attributed to the engine manufacturers who were, to say the least, reluctant to tolerate the use of low viscosity oils. So long as the necessity for warming the oil and the motor was accepted, so long was the methodical development of easy starting retarded.

Valve and Accessory Lubrication

There is a fairly strongly supported opinion that much of the difficulty of getting the first kick can be attributed to poor compression caused by sticky valves. This immediately brings up the question of valve lubrication and it is a fact in Canadian experience that liquid-cooled engines start more easily than the air-cooled type. In the effort to get a clean engine which does not foul the windscreen, there is a suspicion that we in Canada, at least, have gone a step too far in packing the valve rocker boxes with over heavy grease. The winter grease is, of course, lighter than that used in summer, but even at that it is probably unnecessarily viscous. The introduction by Pratt & Whitney of pressure lubrication to the valve gear will probably prove to be of definite advantage in cold weather operation, though the drainage of the oil from the lower cylinders through the exposed manifold of apparently rather small dimensions may be attended by some trouble unless low-viscosity low-pour-point oil is used. It is, however, encouraging to relate that in a certain engine with which we had to deal a low pressure lubricating pipe leading forward outside the crankcase to the reduction gear case was looked upon with considerable suspicion and a special pressure gauge was fitted to supervise it and yet no untoward events happened.

It may be taken as axiomatic from the point of view of the cold weather operator that all lubrication of the motor and its accessories should depend on one single supply of oil under pressure with the possible exception of the starter which begins to turn before the pressure pump gets going. So far as the author knows the problem of cold weather lubrication of packed bearings, such as are installed in electrical machinery, has not been tackled seriously and probably needs some attention. It does not appear to be vital.

The inertia starter is the most commonly used kind in Canada and it is absolutely essential to prepare it for winter use by cleaning it thoroughly and repacking with a low viscosity lubricant. This applies whether the starter is electrically energized or wound up by hand.

Icing of Carburetor

One of the worst bugbears of cold weather flying is the danger of icing up in the choke of the carburetor. Many carburetors are furnished with a special heating jacket round the choke housing to forestall this evil. In Canada we probably suffer less from this than most countries in the northern temperate zone, because, with the possible exception of the coastal regions, the relative humidity of the atmosphere is comparatively low for the greater part of the winter. Trouble is definitely experienced in the fall and spring. The accepted method for combating the evil is to reduce the relative humidity of the intake air by warming it. The cheapest way is to use the air that has just finished cooling a nice hot cylinder or two, but if this device entails an air intake inside the cowling it is wise to fit a flame trap as an ordinary precaution against fire. The air intake positively must drain to the outside of the cowling. Heat from exhaust gases is frequently employed to warm the incoming air, but this involves extra complication and expense in the exhaust system and especially careful inspection and maintenance to insure that the engine will not be fed through leakages with some of its own exhaust.

Future Ambitions

Although much of this paper is devoted to describing methods for warming motors and oil tanks, emphasis should be placed on the efforts to eliminate all this unproductive labour. Our proposals for engine warming and oil heating are merely made with a view to finding good expedients to carry through until the ideal is reached. So far, as implied before, the stage has been reached where a 63 sec. special low pour oil can be used dead cold for a start at −20 degrees F. Unfortunately not all motors will start at this temperature and the immediate problem is to get the technique for cold motor starting into line with the progress on lubrication. When that has been achieved it is proposed to aim at a figure of some −40 degrees F. It nearly all depends on the wonderful efforts of the petroleum technologists who are certainly learning to weave their molecules into newer and more pleasing patterns every day. A lot of people will consider that 63 sec. oil is beyond the pale of reason already but there is little cause to doubt that there will soon be available a 53 sec. oil with a remarkably good viscosity index and in the meanwhile we can make sure of the ground where we stand. The ultimate aim to be achieved is dead cold starts at temperatures just above the freezing point of gasoline, namely, around −70 degrees F., which is about the limit of human endurance. Before we ever reach this point, however, there is quite a possibility that the internal combustion motor will be displaced by a steam powerplant, which has many attractive possibilities for winter operation, and that gasoline as a fuel may give way to something else altogether.

APPENDIX II

Technical Memorandum No. 104

Issued by

Aeronautical Engineering Division
Department of National Defence

LUBRICATION OF AERO ENGINES

1. The wide range of climatic conditions which are encountered in different parts of the Dominion of Canada has necessitated extensive experimental work by the Department of National Defence with the object of developing a general technique to meet the requirement of aero engine operation under extreme temperature conditions, with particular reference to extreme cold.

2. For the purposes of this memorandum it will be assumed that the chemical properties of lubricants are not under discussion and that the physical properties including the elusive property best described as "oiliness" are acceptable. The physical characteristic known as viscosity then stands out as having a ruling influence on lubrication.

3. In explanation of viscosity the following quotation from Glazebrook's Dictionary of Applied Physics will serve admirably:

> "When relative motion exists between neighbouring portions of the same fluid, a measurable resistance to the relative motion can be observed and affords a proof that actual fluids are capable of sustaining shearing stresses; the fluid is said to exhibit the property of viscosity or internal friction."

The relation between the shearing stress in a fluid and the rate of distortion (or flow) of the fluid is known as the coefficient of viscosity and it is useful to regard this coefficient as a state rather than as a property or characteristic because it varies with temperature. It is then easy to understand that a lubricant must not only possess the right properties, but must be in the right state in order to perform its functions satisfactorily.

4. In any given aero engine the oil feed pump and relief valve are designed to work within fairly well defined limits, that is to say the applied shearing stress which creates the flow of lubricant is approximately fixed and consequently for a given range of flow the coefficient of viscosity must also remain within fixed limits. If the coefficient of viscosity is too high the flow will be too small and though the oil film in the plain bearings may be strong enough to take the bearing pressure there will not be enough oil spilt to lubricate the cylinders and pistons. Conversely if the coefficient of viscosity is too low there will be too much spillage and the plain bearings will be starved. Departure from the range of viscosity accepted in general practice would necessitate alteration of the oil feed pump and of the clearances in the engine.

5. As correct lubrication depends on rate of flow at a given pressure and as the rate of flow depends upon the coefficient of viscosity which in turn depends on temperature it will be clear that the oil pressure gauge and temperature gauge provide approximate but quite adequate means of supervision of the state of the lubricant in the engine.

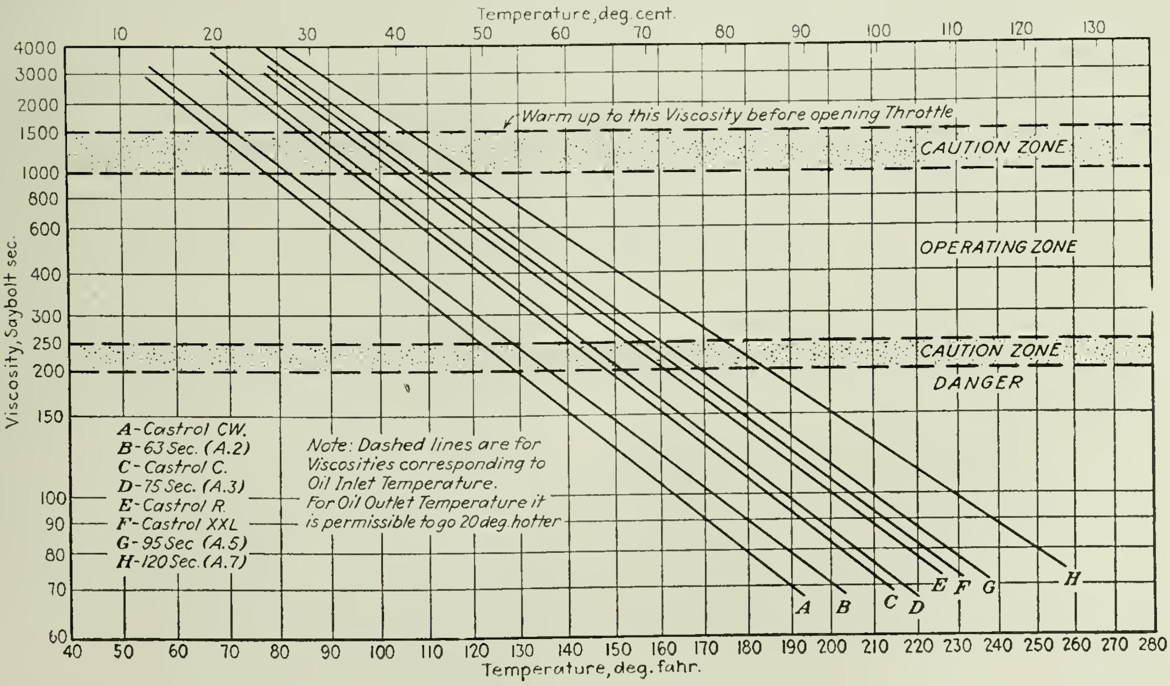

Fig. 6.—Viscosity and temperature for various oils.

6. Nearly all engine manufacturers issue recommendations concerning the grade of oil and the corresponding temperature and pressure found by experience to be suitable for their engines. It must be borne in mind that a statement of recommended oil temperature means nothing at all if it is not accompanied by a complementary statement of the grade of oil, but if the whole information is given the correct state of the lubricant in the working engine can be inferred, and the inference may be used with intelligence and discretion in the deliberate variation of temperature with grade to meet different atmospheric conditions.

7. The accompanying chart A.S.S. 138 (Fig. 6) shows the relationship between Saybolt viscosity and temperature for a number of well known oils. A Centigrade scale is given at the top and a Fahrenheit scale at the bottom. Study of the chart will show that the permissible range of viscosity is wide, and that the oil for curve "*A*" will have the same state of viscosity at 120 degrees F. as the oil for curve "*H*" at 172 degrees F. Actually it will be found that most aero engines work very near the lower boundary of the operating zone, and it is quite possible, and even probable, that this boundary will be lowered, but the Department has no experience so far to justify such action immediately. The modern automobile works much lower down, but seldom works continuously at high throttle openings. The chart has been prepared for oil inlet temperatures, and the preferred position for the oil temperature gauge is in the inlet line, as this gives a more direct indication of the state of the oil entering the lubrication system. A rough assumption has been made that the outgoing oil is 20 degrees F. hotter than the ingoing oil, but this may not be even nearly correct in some installations, and it is strongly recommended that owners should check this for themselves if their aircraft happen to be fitted with a temperature gauge on the outgoing oil line only.

8. During periods of abnormally high atmospheric temperature the cooling of the whole oil system will be reduced and the temperature of the oil stream increased. The drop in viscosity corresponding to the increased temperature increases the flow through the engine with a further increase in the temperature of the oil stream. Provided that a stable condition of oil temperature and viscosity within the limits of the chart is obtained without appreciable loss of oil pressure the engine may be operated safely though an increase of oil consumption is to be expected. Recourse may be had to an oil of higher viscosity if 120 sec. oil Ref. No. 34A/15 is not already in use. It is not considered desirable to use oil of viscosity greater than 120-125 secs. as any advantage gained during full throttle operation or when climbing will be more than offset by a sudden change from the abnormal atmospheric conditions, and during warming up. Failure to obtain stable conditions of temperature, within the limiting temperature range, in the oil stream even in abnormal high atmospheric temperatures may be taken as an indication of defect in the installation and should be reported as such.

9. Extensive warming up periods, during cold weather may be accompanied by excessive wear of cylinder walls and pistons with a certain amount of "scuffing" of the surfaces which will result in further wear when the engine is placed on load and reduction in the life of the engine to a greater extent than occurs during summer flying operations. Several methods, which may be used separately or together, are available for preventing this trouble; viz.:

(*a*) Change of oil to a lighter grade, when the normal cooling effect of the system is such that the desired viscosity of the oil going into the engine can be maintained.

(*b*) Similar to (*a*) but to a lesser degree by addition of oil of a lower viscosity, to that already in the system. This method should be confined to oils of the same brand as it is not desirable that castor or castor compounded oils be added to mineral oils.

(*c*) On training aircraft operated in the vicinity of an aerodrome the minimum quantity of oil permitted by the engine manufacturer plus the amount of the estimated consumption for a convenient period of flight may be used to provide a more rapid flow with correspondingly shorter time required for warming up.

(*d*) Preheating the oil.

10. Outside the engine a good lubrication system should include an oil tank, or tanks well protected from the warm air from the engine and from the cold atmosphere, and a controllable oil cooler in the scavenge line. The cooler should be of such a capacity as to keep the oil temperature under the pilot's control over a considerable range of atmospheric temperature. In this way two or three grades of oil may be made to do for the entire climatic variation in Canada throughout the year. On aircraft not fitted with oil coolers it will probably be necessary to use a greater number of grades of oil. On wet sump engines the variation of grade from that recommended by the manufacturer must be done with great caution, for though it is most desirable in cold weather to use a low viscosity oil for starting, it must be remembered that when running the wet sump engine is not affected by outside conditions to the same extent as a dry sump engine, and the upper temperature limit of the oil is not controllable.

11. The Department's experience with aircraft having common types of radial air cooled engines up to 425 h.p. and controllable oil coolers is that 63 sec. oil (curve "*B*" on the chart) remains fluid at 20 degrees F. below zero, and can be safely used up to an atmospheric temperature of 32 degrees F., and that the 95 sec. oil (curve "*G*") is satisfactory for the upper range of atmospheric temperatures, except for really abnormal hot weather. In radial engines without oil coolers it is thought to be advisable to change to 75 sec. oil (curve "*D*") for the atmospheric range 0 degree F. to 32 degrees F. For temperatures below −20 degrees F. 63 sec. oil should be warmed before starting up, but as it is probably necessary to warm the engine anyway to get a start, the one source of heat may be enough to heat the oil in the tanks as well as to heat the engine.

12. The primary reason for oil changing is to remove the solid matter which accumulates in the oil system. A portion of this material will settle out while the remainder is held in suspension. It is doubtful if the particles which are fine enough to be held in suspension are sufficiently large to cause damage to the bearing surfaces, but the sediment is agitated by circulation of the oil and may contain particles of considerable size though sufficiently small to pass the oil strainer screen. The most serious result of this sediment is its precipitation in the crank pins by centrifugal action and the possible sealing of the oil channels to the connecting rod big end bearings which also cuts off the supply to the cylinders and pistons. Oil changing, when necessary, should take place immediately after the engine has been run, to minimize the quantity of sediment remaining in the system. Twenty (+ −5) hours flying is a safe period between oil changes for present engine installations, based on normal operation. It is reasonable to use a shorter period when conditions of operation have been abnormal, that is, long periods of full power, overheating, etc., and on training aircraft operated from sandy or dusty aerodromes.

E. W. Stedman, Group Captain,
Chief Aeronautical Engineer, R.C.A.F.

Addendum

1. With reference to paragraphs 6, 9, 10, and 11, of this Memorandum, it is desired to emphasize that they are in no way intended to prompt any departure which would not meet with the full approval of the engine manufacturers. Operators are, on the contrary, advised to maintain the closest touch with the manufacturers of their engines concerning the problems under discussion, and they should understand clearly that the full benefit of the use of lighter grades of oil cannot be achieved without the use of an adequate controllable oil cooler.

APPENDIX III

Weights of an Existing Engine Warming Equipment

Engine cover	28 pounds
Chimney and thermometer	19
Chimney base and primus stove	8
Lighting stand	5
Flexible piping	3
Auxiliary primus burner	4
Gasoline container (pressure vessel)	18* (empty)
Methylated spirit	1
Oil container	17*
	103 pounds

*Capable of reduction by redesign.

VOLUME XVIII SEPTEMBER 1935 No. 9

Winter Landing Gear for Aeroplanes

Winter flying in Canada has now increased to such an extent that there is probably no other country in the world to-day where adequate equipment for flying in the winter season is a greater necessity. Accidents, it is true, have been comparatively few, but many practical difficulties are encountered and aircraft operators are interested in any means for improving the winter performance of their machines.

In this country special precautions have of course to be taken in engine operation under low temperature conditions, but serious trouble may also arise in landing or taking off from snow or ice, not only in the depth of winter, but also in the spring, when the ground is bare and perhaps soft in some places, and in others still covered with snow. Some form of landing gear incorporating skis in place of wheels is therefore necessary, and it is difficult to devise landing gear of this type which will be equally serviceable in all snow conditions.

As a result of prolonged experiments, these difficulties have been largely overcome. With any form of ski, however, it is found that the air resistance due to such landing gear is high, and a very considerable decrease in performance results when wheels are replaced by skis.

Elsewhere in this issue there appears a paper on the winter operation of aero engines. It would therefore seem appropriate to comment on a report* recently issued by the National Research Laboratories on the Aerodynamic Characteristics of Aircraft Skis.

This report covers systematic tests carried out in collaboration with the Department of National Defence, the Ontario Provincial Air Service and companies operating aircraft in Canada, which have measured these aerodynamic losses and have also indicated that the pitching moments of the skis now in use give rise to serious problems in trimming gear design.

It is apparent that the present practice of incorporating a heavy trimming gear in the form of shock cords and check cables attached to the front and rear of skis entails extra air resistance. In fact, this alone is responsible for some thirty-three per cent of the total minimum drag of the ski and its trimming gear.

The difficulties to be overcome in developing an improved design of ski were many, as it was necessary not only to reduce air resistance but also to reduce the magnitude of the unstable pitching moments in order that some form of internal trimming gear might be used and thus avoid the use of exterior cables. So well have the investigators succeeded, however, that a new design of stream-lined ski has been developed which allows an eighty-two per cent reduction in drag and has greatly improved pitching moment characteristics.

The result of these investigations has been that definite recommendations have been made with regard to the design of winter landing gear, in order that the full advantage offered by the new stream-lined ski may be realized. The main points of these recommendations are that the ski pedestal should be of the rigid type and should be used in conjunction with a specially designed ski undercarriage. If this special carriage is not possible the shock absorbing unit of the under carriage in use should be capable of a double range adjustment, and finally the ski trimming gear should be enclosed in the ski itself.

The results of the actual service tests to be carried out on the Department of National Defence Hawker *Audax* plane using the improved design of ski will be awaited with interest.

*The Aerodynamic Characteristics of Aircraft Skis and the Development of an Improved Design, by J. J. Green and G. J. Klein.

Subsurface Exploration at Shallow Depths

In the extensive programme of highway construction which is being carried out in the United States the need has arisen for a rapid method of determining subsurface conditions without the expense and delay caused by boring or sinking test pits. The location of gravel deposits, the classification of material likely to be encountered in excavation along the proposed route, and the depth at which consolidated rock will probably be found, are examples of the kinds of problem which occur, and marked progress has recently been made in the application of geophysical methods to their solution. The highway engineer has to deal with the materials existing at shallow depths, and it has been found that the technique employed in deep geophysical work can be considerably simplified.

Experimental work on geophysical methods of determining earth character at shallow depths has been under review by the United States Bureau of Roads during the past two years and progress has now been reported.*

Two methods have been under test; the electrical resistivity method and the seismic method and the practicability of the latter for normal foundation operations has been demonstrated.

Though well established for deep geological determinations, the seismic method has been handicapped for highway work and the planning of foundations for bridges and other structures by the heavy equipment commonly used. It has now been found possible, however, to simplify this equipment and make it easily mobile and adaptable to rapid work.

*Subsurface Exploration by Earth Resistivity and Seismic Methods, Division of Tests, U.S. Bureau of Public Roads.

In the seismic method of exploration the wide difference in the acoustic properties of plastic and granular matter and rigid or consolidated matter is utilized. Sand, clay or gravel transmit wave disturbances, sound waves, at velocities of 1,000 to 6,000 feet per second, while rigid materials such as rock, transmit disturbances at 16,000 to 20,000 feet per second. Here, therefore, is a means of measuring directly that property, namely rigidity, with which the engineer is concerned, while the resistivity method measures this property indirectly, or through its relation to electrical resistivity.

The seismic method would appear more definite in the identification of solid rock than is the resistivity method, but cannot readily be used to distinguish between clay and coarse sand or gravel as can often be done with the latter method.

While experimental and limited to one locality, the results of work with the seismograph have proved so promising that there would appear to be little doubt as to its ultimate value in the study of subsurface formations.

The Duggan Medal and Prize

George Herrick Duggan, D.Sc., LL.D., M.E.I.C., the donor of the recently established Duggan medal and prize, graduated from the University of Toronto in 1883, and commenced his engineering career with the Canadian Pacific Railway Company. In 1886 he joined the staff of the Dominion Bridge Company, and was appointed chief engineer in 1891. In 1901 Mr. Duggan became assistant to the president of the Dominion Iron and Steel Company and the Dominion Coal Company, and was promoted to second vice-president and general manager of the Dominion Coal Company in 1904. In 1910 he returned to the Dominion Bridge Company as chief engineer, and later became general manager and vice-president, being appointed president in 1918, which office he still holds.

Mr. Duggan joined the Canadian Society of Civil Engineers as an Associate Member in March 1888 and

G. H. Duggan, D.Sc., LL.D., M.E.I.C.

was elected a Member in 1890. He served on Council for nine years, was vice-president for five years, and President in 1916, and was the recipient of the Sir John Kennedy Medal in 1931.

He is vice-president of the Royal Bank of Canada, and director of numerous Canadian organizations, including the Steel Company of Canada, the Dominion Steel and Coal Corporation, the Montreal Trust Company and the Wayagamack Pulp and Paper Company.

Mr. Duggan is a Doctor of Science, and received the honorary degree of LL.D. from both McGill and Queen's Universities.

Rules Governing the Award

A prize of a medal and cash to a combined value of approximately $100.00 will be given each year, from the proceeds of a donation by Past-President G. H. Duggan, D.Sc., LL.D., M.E.I.C., for the purpose of encouraging the development of the branches of engineering in which he practised.

The prize shall be awarded for the best paper presented to The Institute in accordance with the following rules:—

1. Competition shall be open to all members of The Institute.
2. The papers shall be presented to The Institute either at the regular meeting of a branch or at a professional meeting of The Institute, or directly to Headquarters. They shall not have been presented previously to any other body or meeting.
3. Papers to be eligible for this competition shall deal with such subjects as arise in that sphere of constructional engineering which concerns the use of metals in moulded or fabricated shape for structural or mechanical purposes. Without limiting the generality of the foregoing, it is suggested that papers describing works should deal with the economic and theoretical elements of design, fabricating, machining, transporting, erecting, problems solved, methods of overcoming difficulties and other interesting features.

   There will also be admitted to the competition papers describing new methods or the recording of important tests that add to engineering knowledge.
4. Papers shall be the bona-fide production of the author and proper credit shall be given for any assistance received from other parties, partners or reports. The relation of the author to the work shall be clearly stated. Papers shall be compiled and arranged with proper regard to literary value and shall constitute worthy contributions to the records of the engineering profession.

   In judging the competition consideration will be given to the personal knowledge and appreciation of the problems and processes involved and the joint application of theoretical and practical considerations to the execution of the subject which are displayed on the part of the author.
5. The papers shall be judged by a committee of three corporate members, eminent in the corresponding branch of the profession, appointed for the purpose by Council as required.
6. The award shall be made only when a paper of sufficient merit is presented. The prize year shall be from July 1st to June 30th and papers must be presented to Headquarters of The Institute by the 30th day of June.
7. The prize shall be awarded at the Annual Meeting.

Annual Meeting 1936

At the meeting of Council held on June 18th, 1935, the invitation of the Hamilton Branch to hold the Fiftieth Annual General and General Professional Meeting of The Institute at Hamilton in February, 1936, was accepted with appreciation.

OBITUARIES

Reginald Walter Brock, M.E.I.C.

Widespread regret will be felt at the death of Reginald Walter Brock, M.E.I.C., which occurred in an aeroplane crash at Alta Lake, B.C., on July 30th, 1935, when the plane nose-dived shortly after a take-off.

Dean Brock was born at Perth, Ont., on January 10th, 1874, and graduated from Queen's University, Kingston, in 1895, with the degree of M.A. He later did post graduate work at Heidelberg University. From 1902 until 1907 he was a professor at Queen's University, and in 1907 he was appointed director of the Geological Survey of Canada. In collaboration with F. L. Congdon, Dean Brock prepared the draft which forms the basis of Canadian mining laws. In 1914 he served as deputy minister of Mines at Ottawa, and resigned from that office to become Dean of Applied Science at the University of British Columbia, at Vancouver, which appointment he held until the time of his death. He had been on leave of absence from the University since December, 1934, when he was appointed chairman of the Vancouver Board of Harbour Commissioners.

Dean Brock organized the 196th Battalion, known as the Western Universities, and served under General Allenby in Palestine and Syria with distinction, bearing the rank of Major. At the time of his death he was Lieutenant-Colonel, and officer in command of the 72nd Highlanders, Vancouver.

For more than ten years, Dean Brock and his associates at the University were engaged in making a geological survey of the Island of Hong Kong for the British government, and in 1933 he had leave of absence from the University to complete the task.

He possessed the degrees and honours of LL.D., (Queen's University, 1921), LL.D., (Hong Kong), F.G.S., and F.R.S.C. He was internationally known as one of the greatest geologists in the history of Canada.

Dean Brock held at various times the following offices: vice-president of the American Society for the Advancement of Science, general secretary of the International Geological Congress, and royal commissioner for the Frank, Alta., landslide. In May of this year he was elected president of the Royal Society of Canada.

He became a Member of The Institute on June 7th, 1924.

Frank Henry Pitcher, M.E.I.C.

Deep regret is expressed in placing on record the death at Montreal on August 21st, 1935, of Frank Henry Pitcher, M.E.I.C.

Mr. Pitcher was born at Montreal on December 21st, 1872, and graduated from McGill University in 1897 with the degree of M.Sc.

In the years 1894-1899 Mr. Pitcher was a demonstrator and lecturer in physics at McGill University, and in the latter year he joined the staff of the Montreal Water and Power Company as engineer. In 1900 he was appointed chief engineer of the company, holding that office until 1903 when he became general manager and chief engineer. He retired in 1926.

Mr. Pitcher joined The Institute (then the Canadian Society of Civil Engineers) as an Associate Member on October 9th, 1902, and on October 24th, 1924, became a Member.

PERSONALS

Lieut.-Colonel J. P. B. Dunbar, A.M.E.I.C., formerly engineer officer of Military District No. 5, Quebec, Que., has been appointed to Military District No. 6, Halifax, N.S., as A.A. and Q.M.G.

Lieut.-Commander A. C. M. Davy, R.C.N., A.M.E.I.C., formerly engineer officer (D) Western Division, H.M.C.S. *Skeena*, at Esquimalt, B.C., is now attached to H.M.C.S. *Stadacona*, at the Naval Dockyard, Halifax, N.S.

G. R. Davidson, S.E.I.C., has received his commission as lieutenant in the Royal Canadian Army Service Corps, and is stationed at Wolseley Barracks, London, Ont. Mr. Davidson graduated from the Royal Military College, Kingston, this year.

R. H. Reid, A.M.E.I.C., has joined the staff of Brunner Mond, Canada, Limited, at Toronto, Ontario. Mr. Reid was formerly on the engineering staff of the Beauharnois Construction Company at Beauharnois, Que.

J. C. Aitkens, Jr.E.I.C., who graduated from the University of Manitoba in 1933 with the degree of B.Sc., is with the Water Development Committee at Swift Current, Sask.

J. H. Wallis, A.M.E.I.C., is now manager of the Dominion Engineering Company Limited. He retains the position of general manager of Dominion Hoist and Shovel Company Limited, as well as his interest in Dominion Welding Engineering Company Limited, as director. Mr. Wallis has been engaged in engineering work in Canada since 1910, his early work being land surveys, railway surveys and construction. In August 1914 he enlisted for overseas service as a private with the British Expeditionary Force, and throughout the war served overseas with distinction In July, 1915, he received his commission as lieutenant, in 1916 that of captain and in the following year that of major. Following his return to Canada in 1919, Mr. Wallis entered the service of the Canadian Pacific Railway Company on maintenance-of-way on the International of Maine division. In June, 1920, he was appointed assistant with the Department of Railways in connection with the Grand Trunk arbitration, and later in that year joined the engineering staff of the Canada Creosoting Company in

J. H. Wallis, A.M.E.I.C.

Toronto. Subsequently he was appointed supply engineer with the Riordon Pulp Corporation Ltd., at Temiskaming, Que., and following the acquisition of this company by the Canadian International Paper Company, he was transferred to the construction department in charge of the purchase of equipment and materials for the extension of the mill. Mr. Wallis was later manager of purchasing for the St. Anne Paper Company Limited, and the Murray

Bay Paper Company Limited, resigning that position in 1928 to take over the management of the newly organized Dominion Welding Engineering Company Limited. In 1931 he became general manager of Dominion Hoist and Shovel Company Limited.

H. A. Crombie, A.M.E.I.C., has been appointed assistant manager of the Dominion Engineering Company. Mr. Crombie was educated at Westmount Academy and

H. A. Crombie, A.M.E.I.C.

McGill University, his university course being interrupted by service in France with the Canadian Engineers. He was invalided home in 1917, and resumed his studies, graduating with the degree of B.Sc. in 1918. Mr. Crombie then spent a year on the staff of the Canadian Allis Chalmers Ltd., in Toronto, and was also, for a short time in the service of the Canadian National Railways. He joined the staff of the Dominion Engineering Company when that company was formed in 1920, and in 1933 was appointed sales manager.

Chemical Engineering Congress

The Chemical Engineering Congress of the World Power Conference is to be held in London, England, on June 22nd to 27th, 1936. The holding of an international congress of chemical engineering has been in contemplation for several years, and it has now been made possible by the co-operation of the World Power Conference organization.

The Congress has the support of practically all organations in Great Britain associated with chemical engineering, which substantial support should enable the Congress to be conducted with efficiency and success.

The Canadian Committee of the World Power Conference, of which the chairman is Dr. Charles Camsell, M.E.I.C., will be pleased to facilitate the participation of The Engineering Institute of Canada in the Congress.

This programme is being brought to the attention of the leading chemical industries in Canada with a view to securing appropriate papers. The technical programme may be classified under the following main headings, which, however, does not necessarily indicate the scope of the Congress: Chemical Engineering Projects; Chemical Engineering Plant Construction; Fuel, Heat and General Problems in Chemical Engineering; Administration and Works Organization in Chemical Engineering; Trend of Development in Chemical Engineering, and General Aspects.

CORRESPONDENCE

The Editor,
The Engineering Journal,
Montreal.

Toronto, Ont.
July 25th, 1935.

Sir:—

During this autumn and the coming winter there will, no doubt, be many members of The Institute travelling on business or pleasure throughout Canada. Council has suggested that advantage might be taken of this by asking such members to make arrangements to call on as many branches as their itinerary would permit. Those who assisted in this way could discuss Institute matters or present papers. This applies particularly to those branches so situated that interesting papers are difficult to obtain.

It was felt that much benefit would result from such visits and I am taking the liberty, through The Journal, of asking all members who contemplate trips to communicate either with the General Secretary or with me, giving their proposed itineraries so that the different Branch chairmen concerned may be notified and the necessary arrangements made.

I am, yours faithfully,
(Signed) C. S. L. Hertzberg, M.E.I.C.
Chairman, Papers Committee.

Toronto 5, Ont.)

A Triangulation System for Newfoundland*

Noel J. Ogilvie, M.E.I.C., Director of the Geodetic Survey of Canada.

Following a request from the Commission of Government at Newfoundland, the Canadian government has consented to an arrangement whereby the Geodetic Survey of the Department of the Interior will assist the Island government in laying down two main nets of triangulation as the basis for the survey development of Newfoundland. The completion of the final practical details was reached in Ottawa recently, and the work, it is expected, will extend over a period of five years.

The co-operation of the Geodetic Survey of Canada in this work was discussed in an exchange of correspondence between Sir John Hope Simpson, Commissioner of Natural Resources of Newfoundland, and Hon. Thomas G. Murphy, Canadian Minister of the Interior, and the final details were completed at a conference in the Dominion capital between Dr. A. K. Snelgrove, consulting geologist to Newfoundland's Commission of Government, and the author. Sir John Hope Simpson indicated that two main triangulation nets of about 600 miles total length were believed to be essential as a basis for the Island's orderly survey development; it was considered, however, that Newfoundland would scarcely be justified in creating a geodetic organization sufficiently large to handle an operation of the required magnitude. He therefore inquired if the Geodetic Survey of Canada could assist in the direction of the undertaking.

Canada has a direct interest in this work, as it will complete a circuit of about 1,300 miles of triangulation around the Gulf of St. Lawrence, about 1,000 miles of which are in Canadian territory. One of the Canadian nets extends from the Maritime Provinces as far as Cape Ray at the south-west corner of Newfoundland, while another net, partially completed, follows the north shore of the Gulf of St. Lawrence heading for the Strait of Belle Isle at the north point of the Island. A primary net in Newfoundland connecting Cape Ray and the Strait of Belle Isle, while possibly more than accurate enough for the local requirements of the Island, would obviously strengthen the Canadian nets and hence insure Canadian interest. Apart from the value of the triangulation in the hydrographic charting of the Gulf of St. Lawrence waters, the nets have additional importance, since the Canadian system along the north shore of the Gulf of St. Lawrence passes a comparatively short distance south of a 400-mile stretch of the boundary between the province of Quebec and Labrador, which belongs to Newfoundland; this net must eventually be the foundation for any future boundary action between the two governments.

By Order in Council dated 30th March, 1935, the Canadian government authorized the participation of the Geodetic Survey of Canada in the co-operative effort. The system will be in the form of a T lying on its left side. The top of the T will consist of a 300-mile primary triangulation net from south to north from Cape Ray to the Strait of Belle Isle; the shank of the T will be a secondary east-and-west net of approximately the same length from the primary net eastward to St. John's, the Capital. Canada will supply the technical officers required for the operation, in number estimated at three or four, with such additional officers as may be required from time to time for the measurement of base lines and the observation of Laplace stations. Canada also supplies the instrumental equipment and will make the mathematical reductions and adjustments and publish the results. The Commission of Government of Newfoundland, through the Colonial Development Fund, will pay all other expenses and has provided the sum of $75,000 to cover the estimated cost.

Work will commence during the summer of 1935 and will probably

*Reprinted from the *Empire Survey Review* for July, 1935.

comprise an aerial reconnaissance of the whole net, by methods used with great success in hundreds of miles of Canadian triangulation; there will be one or more ground reconnaissance parties and a station preparation party. The observations can then be commenced in 1936. W. M. Dennis, M.E.I.C., of the staff of the Geodetic Survey of Canada, whose theodolite investigations with J. L. Rannie, M.E.I.C., chief of the Triangulation Division, have been dealt with in the *Empire Survey Review*, will have charge of the field work.

Editor's Note.—It is understood that the Newfoundland work has progressed as noted above. J. L. Rannie, M.E.I.C., and F. P. Steers have completed the aerial reconnaissance for the whole triangulation net. This aerial work is now being ground checked, and two station preparation parties are operating to enable angular measurements to be commenced in 1936. The Geodetic Survey staff in the field at present comprise W. M. Dennis, M.E.I.C., engineer in charge, F. P. Steers and E. M. Medlen.

BOOK REVIEW

Engineering Shop Practice—Volume II

By O. W. Boston, John Wiley and Sons Inc., New York. (The Renouf Publishing Company, Montreal) 1935. 6 by 9¼ inches, 485 pages, photos., diagrams, etc. $5.00. Cloth.

Reviewed by PROFESSOR L. M. ARKLEY, M.E.I.C.*

As stated in the preface, this book is a continuation of Volume I, which treats of the basic processes of turning, shaping, planing, drilling, boring, reaming, threading, sawing and milling of metals.

In general the book is well written; each machine and process described is easily understood, especially when reference is made to the very excellent cuts with which the book is generously supplied.

At the end of each chapter is a series of questions designed to test the reader's knowledge of its contents, and in addition to this is a comprehensive bibliography of the subject matter of the chapter.

The headings of the different chapters give a good grasp of the contents of the book. Chapter one treats of screw machines, turret lathes and hand-operated production turning machines.

Chapter two is on automatic turning machines, while chapter three gives an interesting discussion on broaching and the tools required in the process, while chapter four is a comprehensive treatise on the methods of gear cutting.

One of the best chapters in the book is number five on the general subject of surface finishing and describes in detail the processes of grinding, polishing, buffing, honing and lapping.

Chapter six is on the general subject of forming metals into different shapes and includes power and hydraulic presses, punches and dies, and lathes for spinning metals with examples of many processes which may be carried out on these.

The last chapter is devoted to precision measuring instruments including inside and outside micrometer calipers, circular dividing engines, Johansson gauge blocks and many others.

This book has been developed as a text book in connection with the shop courses in the University of Michigan, and as the author states, together with Volume I, they give the background necessary for planning production in machine shops.

The book should be of great value not only to students but to machine-shop superintendents, executives, and anyone connected with the operation of metal cutting machines.

*Professor of Mechanical Engineering, Queen's University, Kingston, Ont.

BULLETINS

Road Maintainers.—The Four Wheel Drive Auto Company, Kitchener, Ont., have issued a 12-page booklet containing particulars regarding the company's models LM and HM road maintainers.

Cement.—A 32-page booklet received from the Portland Cement Association contains data on the cement industry in the United States and also world production.

Pipe Couplings.—A 12-page bulletin issued by the S. R. Dresser Manufacturing Company, Toronto, Ont., contains information on pipe joints manufactured by that company.

Screws.—The Stowell Screw Company, Montreal, have published a 100-page booklet containing a price list of the company's products which include screws, bolts, nuts, rivets, escutcheon pins and metal stampings.

Blowers.—A 4-page folder received from Roots-Connersville Blower Corp., Connersville, Ind., includes information on their Victor-Acme rotary positive blowers for pressure or vacuum service, together with net capacities.

Sheet Piling.—The Canadian Sheet Piling Co. Ltd., Montreal, have issued a 6-page leaflet dealing with the use of steel sheet piling in the construction of the new roundhead, King's dock entrance lock, Swansea, England.

Locomotives.—An 8-page pamphlet received from the Brookville Locomotive Company, Brookville, Pa., describes the company's 2½, 3, 3½, 4, 5 and 6 ton model locomotives, powered with Ford V8 engines.

Compressors.—Four pamphlets received from the Worthington Pump and Machinery Corporation, Harrison, N.J., describe the company's model 105, 160, 210 and 315 gasoline engine driven portable compressors.

Silent Chain Drives.—A 4-page leaflet has been received from the Hamilton Gear and Machine Company, Toronto, Ont., describing and illustrating the "compensation" feature of Hamilton-Ramsey silent chain drives.

The Engineer and His Societies

Extract from an article by Huber O. Croft, appearing in *Mechanical Engineering* for July, 1935.

In any critical examination of the professional responsibilities of an engineer one eventually comes not only to the question of the utility of our engineering societies in promoting the aims and broader aspirations of the individual engineer, but also to the type of engineering organization best fitted to fulfil and satisfy the demands of the individual.

Engineers will be interested to learn that there are at present more than ninety national engineering organizations to represent perhaps two hundred thousand engineers. It should be remembered that practically every one of our national engineering societies has an excellent and extensive organization. It is apparent that there must be an overlapping and duplication of activities of the various groups, not to mention clashes of individual committees attempting to accomplish the identical purpose, but each zealously jealous of obtaining the prestige when the objective has been obtained.

The effect of this confused state of affairs upon the individual engineer is that some societies, such as the Founder Societies have stressed what may be labeled "psychic interest" which may be termed one half of the engineer's circle of activities, paying little attention to the other half, "material interest." Other engineering societies, such as the American Association of Engineers, the National Society of Professional Engineers, and the new born Federation of Architects, Engineers, Chemists and Technicians, have primary interest only in the "material interest" side of his activities.

An engineer knows that if half of the circle of activities is removed the semicircular section remaining is inherently mechanically unbalanced, both statically and dynamically. The same principle may be applied to an engineering organization. No organization which fails to balance psychic or technical interest with professional and material welfare can survive the test of time.

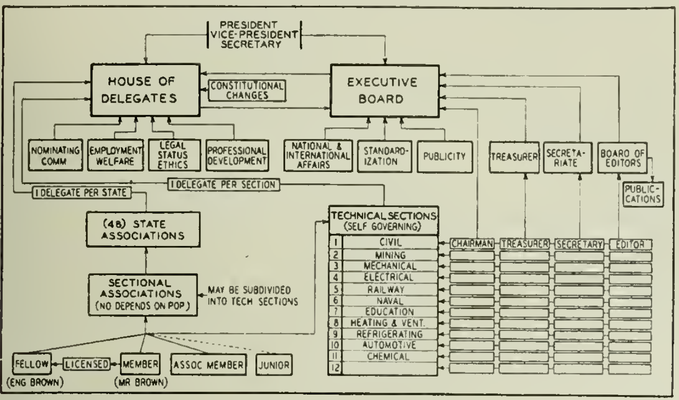
This fact was discovered long ago by the American Medical Association and the American Bar Association. Both of these organizations give suitable attention to both the technical field and the development of professional welfare. The fact that the American Medical Association with a membership of approximately ninety-nine thousand is a flourishing organization should be sufficient stimulus to the engineers of this nation to apply some of their organizing ability to their own profession.

An unbiased engineer considering his societies will recognize two facts: (1) There are too many national engineering organizations, and (2) existing societies should be co-ordinated.

Before suggesting a plan of co-ordination for existing national societies, it is well to consider that steps have been taken to date with this end in view, but so far simplified organization has been confined to the American Engineering Council and the Engineers' Council for Professional Development.

Such co-ordination as these two different groups represent should be supported to the utmost by all members of the profession. It would seem, however, that justified criticisms might be: (1) These organizations are not sufficiently representative, and (2) both the American Engineering Council and the Engineering Council for Professional Development should be branches of the same trunk.

It is with sincere earnestness that a proposed organization chart for a national and rational engineering society is presented below.



The chart is sketchy because it is fully realized that the less appendages attached thereto, the less "deadcats" can be hung thereon.

However it is presented for the discussion and consideration of the engineering profession without comment. Each individual will have his own opinion as to representation, committees, technical sections, and other details.

The four types of membership, "fellow" (a licensed engineer who will be addressed as "Engineer Brown" similar to the custom in Europe and South America), "member" ("Mr. Brown"), "associate member" and "junior" are suggested because of the ease of co-ordination of memberships of existing societies.

Each technical section is self-governing with administrative officers as now exist who become representatives to a committee dealing with the proper interest.

All engineering-society publications pass through the Board of Editors. This in itself might prove of beneficial economic value because of the possible reduced manufacturing costs which might be expected by the proper dispatching of each technical publication through a central plant, either owned or leased by the society to maintain a uniform load curve.

The question of dues is controversial to say the least, but it would seem reasonable to pay dues both to the state group and hence to the national organization, and likewise to as many of the technical sections as might be of interest to the individual.

Steel-Concrete Composite Construction

Steel-concrete composite construction has, during recent years, been applied successfully to numerous buildings and bridges. Since its introduction much valuable technical data has been accumulated, which is now published to assist architects and engineers in preparing designs of composite construction.

In the handbook "Steel-Concrete Composite Construction" recently published by the Dominion Bridge Company Limited, Lachine, Que., and obtainable from that company, the general features of design are discussed and the method of designing composite beams is developed in detail. The uses of special charts and tables which form the body of this handbook are fully explained and are illustrated by typical examples.

Manual of Timber Connector Construction

This manual, published by the Timber Engineering Company, Washington, D.C., presents data on the design and use of connector construction and gives information concerning both toothed and split-ring connectors, and shear plates. Charts and tables of safe working loads for the three types of connectors are given and fabrication and erection notes are developed. Illustrations show a number of interesting examples of modern lumber connector construction. The booklet may be obtained from the publisher at 1337 Connecticut Avenue, Washington, D.C.

Information for 1935 Membership List

Information cards have recently been forwarded to the membership of The Institute requesting the name, present position and address of each member, that the information may be correctly recorded in the new membership list now being compiled.

The completeness and accuracy of this list will be greatly increased if those members who have not already done so will return their cards as soon as possible.

BRANCH NEWS

Peterborough Branch

W. T. Fanjoy, Jr.E.I.C., Secretary-Treasurer.
E. J. Davies, Jr.E.I.C., Branch News Editor.

ANNUAL OUTING

The annual outing of the Peterborough Branch of The Institute was held on Saturday, June 8th, 1935, when forty members motored to Minden, Ont., where they were joined by the members of the Orillia Water Light and Power Commission and the Orillia Town Council. The whole party were the guests of the Dominion Construction Corporation, and the outing consisted of an inspection of Orillia's new hydro-electric power plant at Minden.

This is a half million dollar, two-unit installation, each generator to develop 2,250 kv.a. This plant will replace the present plant at Swift Rapids on the Severn river, which is being supplemented by a block of power from the Hydro-Electric Power Commission of Ontario. When the Minden plant goes into operation Orillia will be one of the few Ontario municipalities with a modern independent power supply. This plant is to go into operation in the very near future.

The guests were welcomed by Mr. A. A. McLaren, A.M.E.I.C., superintendent of the Construction Corporation, who provided every facility for a thorough inspection and enjoyable outing. The visit was concluded by a dinner in the company's dining room provided through the courtesy of the company. Messrs. A. L. Dickieson, A.M.E.I.C., chairman of the Peterborough Branch, and R. L. Dobbin, M.E.I.C., extended the thanks of the guests to Mr. McLaren and his company for their generous hospitality, which made the outing one which would be remembered for a long time.

Saguenay Branch

J. W. Ward, A.M.E.I.C., Secretary-Treasurer.

On Friday evening, June 21st, 1935, G. F. Layne, A.M.E.I.C., gave an interesting paper on "Sugar," dealing particularly with the product obtained from cane.

Sugar is a carbo-hydrate known chemically as sucrose or saccharose. This must not be confused with saccharine, which is a coal-tar derivative.

The refining of sugar was developed by the Egyptians. The Arabs used it in the fourth century, and from them it spread west with the returning Crusaders and East with the various Arab migrations, as far as India and China. Venice was the centre of the sugar trade all through the middle ages.

Spanish and Portugese navigators introduced the cane to the Canary Islands, and to the West Indies about 1525. By 1600 the cane sugar industry was flourishing throughout the West Indies and the demand of this industry for cheap labour was largely instrumental in building up the slave trade.

Sugar cane is a member of the grass family, closely related to the bamboo. It grows only in tropical and sub-tropical countries, and takes about eighteen months to mature. Enormous progress has been made in the improvement of the cane species. Since 1910 the yield has been doubled.

Cane sugar is made by pressing the juice from the ripe cane, the excess water is removed by boiling, until the liquor thickens to the point of crystallization. It is then cooled to form the product known as massecuite, which is shovelled into large hogsheads and allowed to drip. This dripping process goes on for months. Dark crystals remain in the containers, which are known as muscovado. The drippings are known as molasses. The dark crystals are washed with water jets and steam sprays, to produce crystals of much lighter colour known as plantation white. Refinery white sugar is produced from the dark crystals by bleaching with sulphur dioxide or bone coal, and drying in a rotary kiln.

The fuel used to furnish power for the sugar mills consists of the cane after all the juice has been extracted and allowed to dry. This is known as bagasse.

Commercial rum is made from the molasses which contains from 17 to 25 per cent of sucrose. Yeast is used to ferment the sucrose and thereby convert it to alcohol. Great care is exercised in this process, otherwise contamination from the growth of undesirable cultures sets in. Rum comes from the still about 95 per cent pure alcohol and is reduced to about 50 per cent for human consumption. As made rum has a bluish tint. It is coloured by caramel and by storing in burned casks.

Mr. Layne illustrated his talk with a number of slides and diagrams. He also had a number of samples of sugar in its various stages of manufacture, also a section of cane. The sample which aroused the most interest was that of the rum. After the meeting this sample was presented to the chairman, G. E. LaMothe, A.M.E.I.C., who expressed his appreciation in glowing terms.

After considerable discussion the meeting closed with a vote of thanks to Mr. Layne.

Following the address a nominating committee was appointed to make nominations for the new executive for 1935-36. This committee consisted of Messrs. M. G. Saunders, A.M.E.I.C., W. L. Yack, A.M.E.I.C., R. H. Rimmer, A.M.E.I.C., J. W. Ward, A.M.E.I.C., and A. Cunningham, A.M.E.I.C.

The Velox Steam Generator

Abstract of an address given by Adolph Meyer, managing director and engineer in chief of the Brown, Boveri Steam Turbine Works, Baden, Switzerland, in the lecture hall of The Engineering Institute of Canada, Montreal, on July 16th, 1935.

The principal aim in the development of steam producers during the last few years has been to design and manufacture larger units, working at higher pressures and temperatures than in the past.

While new boilers incorporate new and very interesting ideas in the production of steam and the regulation of combustion (the Benson boiler makes use of critical pressure and the Löffler of indirect heating by superheated steam) nothing has been done to improve materially the combustion itself, or the rate of heat transmission.

It is in relation to these last two points that the Velox boiler differs essentially from most boilers which have been in use up to now. Its name, "Velox," refers to the high velocity of the flue gases, which are used to obtain exceptionally high heat transmission. The main features of this new boiler are as follows:—

(1) Combustion takes place under a pressure far in excess of that generally employed.

(2) Partial transformation of the above pressure into velocity, in order to obtain high flue gas speed. This speed may reach the velocity of sound.

(3) The use of a turbo-blower, worked by an exhaust gas turbine, in order to produce the pressure in the combustion chamber referred to in (1) above.

(4) Disposition of the gas turbine between two heat-absorbing parts of the boiler, in order to reduce the temperature of the flue gases so that cooling of the turbine is unnecessary, but also permitting of sufficient heat being left in the gas to provide the necessary energy for driving the turbo-blower. The heat which remains is passed on through the feed-water heater section or sections of the boiler following the gas turbine.

(5) A special device for separating steam from water which consists of a centrifugal separator without moving parts, in which the mixture of steam and water is injected tangentially on to the cylindrical wall of a container at such a velocity that it rotates with sufficient force to separate the steam and water by centrifugal action.

(6) The very small weight of steel and water taking part in the heat transmission which, together with the entire absence of fire bricks and the small storage of water which is necessary, allows for rapid starting of the boiler and gives very flexible operation under variations of load.

(7) Forced circulation in the evaporating part of the boiler.
(8) Entirely automatic governing.
(9) Small weight.
(10) Small space requirement.
(11) High efficiencies over large variations in load.

These advantages have been obtained by the process of "supercharging," which is common practice in diesel work and are even greater when applied to a boiler, for, in addition to reduction in the size of the combustion chamber, the size of the heat transmitting system is reduced twofold; both by higher pressure as well as by higher speed of the flue gases.

In determining the practical range of velocities to be employed in the Velox boiler, it was soon found that to compensate for the higher expenditure on pressure-tight combustion chambers, and the pressure-producing machinery, a radical departure from accepted practice was necessary and velocities ranging from 900 feet per second to 450 feet per second have been adopted for the evaporator tubes: lower, but still unusually high velocities, being used in feedheater and superheater. All these parts have therefore to be built "streamlined" so as to reduce pressure losses as much as possible.

Figure 1 represents a steam generator of the Velox type, and a diagram shows the temperatures and pressures prevailing in its different parts. The combustion of the fuel takes place in the combustion chamber 2 where air and fuel enter through the burner 1, the air under a pressure of about 35 pounds per square inch absolute, the fuel under about 300 pounds gauge. The gases give up part of their heat content by radiation through the external walls of the evaporator tubes 3, which line the wall of the combustion chamber. More heat is transmitted by convection, while the gases pass upwards, through the internal tubes 3A of the evaporators to the exhaust flue gas collecting chamber. Thus the initial temperature of combustion is reduced to about 1,500 degrees F., while the pressure drops to about 33 pounds absolute. With this temperature and under this pressure the gases enter the superheater 5, to leave it cooled down to about 900 degrees F. at a pressure of about 31 pounds. The gas turbine 6, which is then entered, causes the flue gas temperature to drop to about 700 degrees F. while the pressure drops to about 16.5 pounds absolute. The corresponding heat drop is, apart from very small radiation and bearing losses, entirely converted into mechanical energy and transmitted to the blower where it is reconverted into heat with a corresponding rise in the air temperature. Finally, the gases escape through the feed-water heater 7 which forms part of the chimney. From thence they continue, through the chimney 8 itself, to the atmosphere, where they leave cooled down to about 200 degrees F.

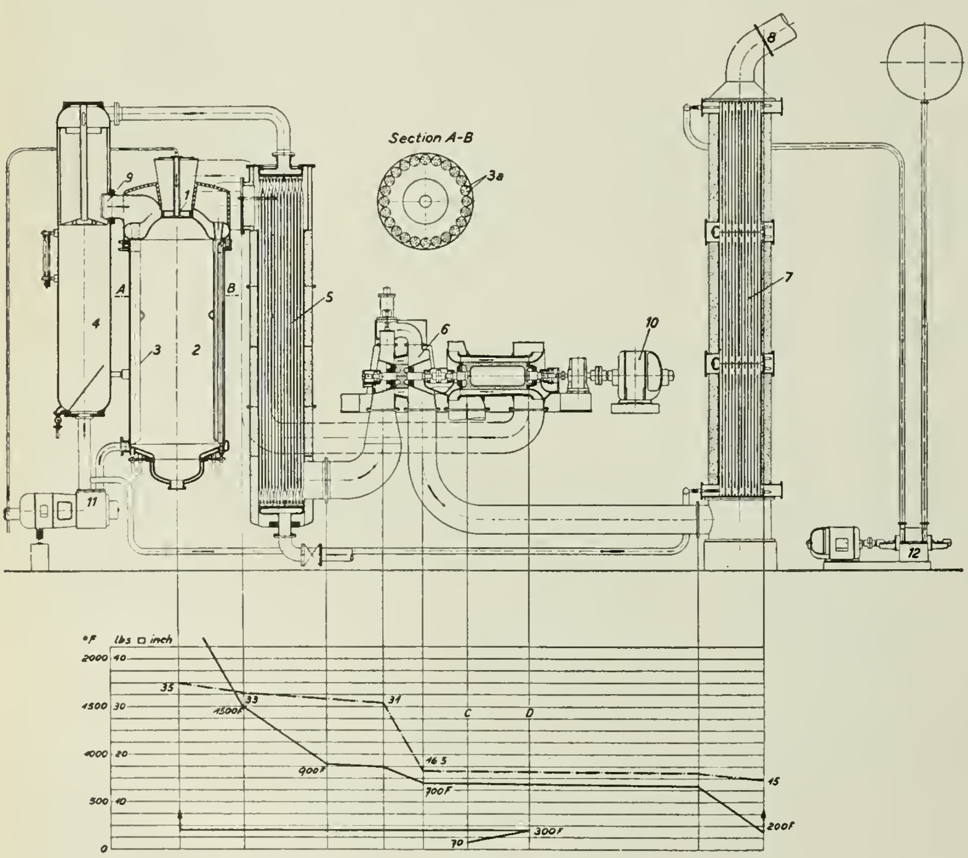


Fig. 1—Diagram of Velox Steam Generator showing Temperatures and Pressures in Various Parts of the Apparatus.

The water and steam circuit is as follows:—

The make-up water is fed by the feed pump 12 through the preheater 7 to the separator 4, where it mixes with the evaporating water. This water is kept in continuous circulation by the circulating pump 11, which pumps it through the combustion chamber 2 and evaporating tubes 3 back to the separator 4, at the rate of about ten times the full load evaporation.

The water enters the separator through the nozzle 9 tangentially to its wall. This nozzle has the smallest sectional area of any tube in the circuit so that a sufficiently high pressure builds up in the tube before the water reaches the nozzle. This pressure is converted into velocity, and the mixture of water and steam spins round on the inside of the cylinder. The water then falls through a small gap in the lower partition of the separator, while the steam is pressed out to the centre and enters the superheater 5, where it is superheated up to the desired amount for use in a steam turbine.

The automatic governing system is shown in Fig. 2. In principle the system is similar to that employed by Messrs. Brown Boveri on their turbines for the last twenty years. The different devices for maintaining the feed-water level, governing the amount of oil and air, are shown respectively by *A*, *B* and *C* of Fig. 2. An oil pump, connected to the motor driving the circulating pump already mentioned, supplies oil through the pipe 13 to the different governors. A plug 12 reduces the pressure in a variable degree according to the position of a leak-off valve 14. In *A* the position of this valve is governed by a water column acting against a spring, so as to keep the water level constant by varying the pressure beneath the piston 15 which governs the feed valve 12.

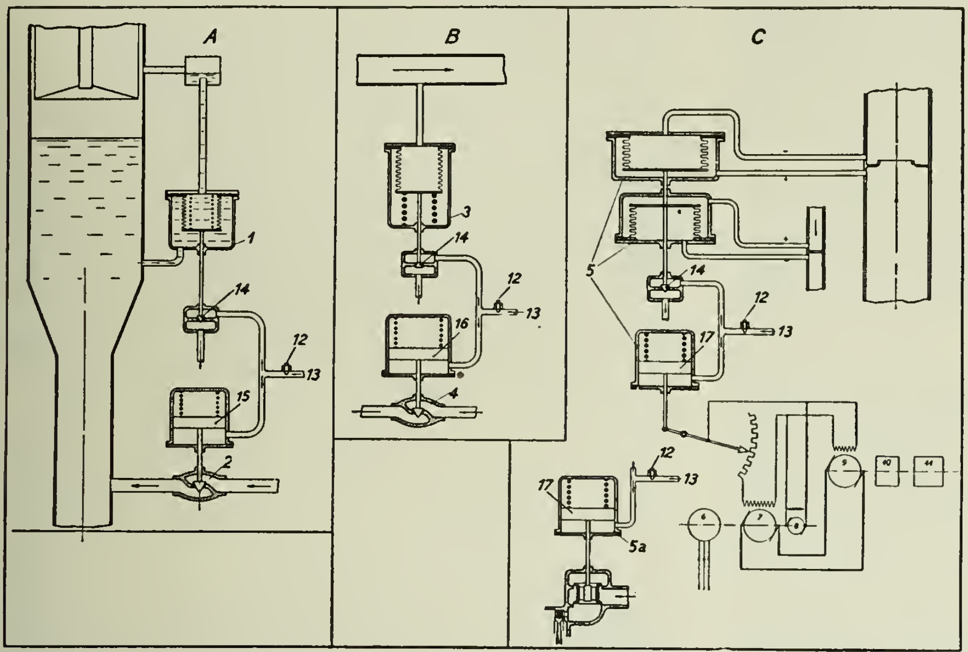

Fig. 2—Outline of Automatic Governing System *A* Quantity of Feed Water and Water Level, *B* Quantity of Fuel and *C* Quantity of Air.

In the governing system *B*, regulating the amount of fuel oil, the leak-off valve 14 is governed by the pressure of the steam in such a way that with a falling steam pressure the valve is shut so as to raise the oil pressure under piston 16, thus opening the fuel valve 14. The governing system *C* tends to establish a constant ratio between the amount of fuel and the amount of air; both the fuel valve and the air valve work on the same leak-off valve 14, and maintain their relative

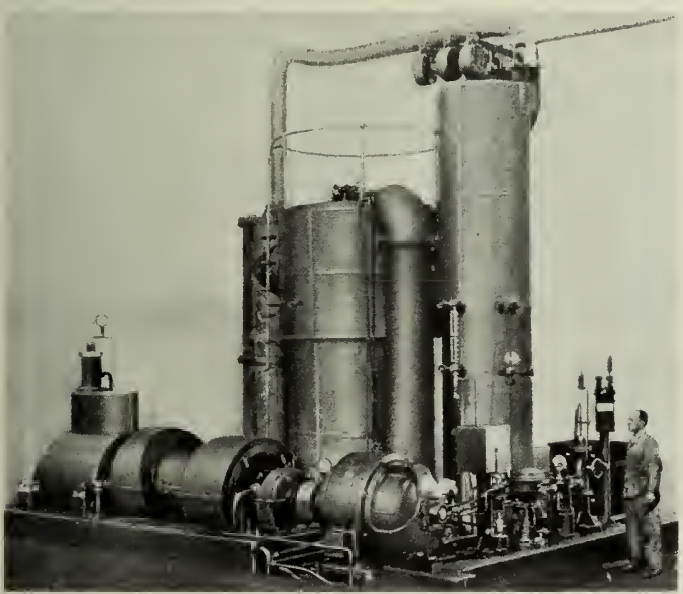

Fig. 3—Velox Steam Generator with Governing System on Test Bed.

positions as long as the ratio of the two is constant. Any deviation from this ratio displaces valve 14 with a corresponding change in the oil pressure beneath the piston 17, adjusting the power of the auxiliary drive which may be an electric motor or a turbine.

If, for instance, more fuel oil is introduced owing to a fall in steam pressure by the system *B*, the auxiliary motor accelerates the supercharging set so as to get more air through. This is only necessary until stable conditions are again established by the increased pressure and temperature at the gas turbine, with a corresponding increase of power from that unit.

Owing to the small amount of material taking part in heat transmission, and to the small water storage capacity, the boiler can be set to work in an unusually short space of time. Steam pressure, temperature and quantity can be raised to full load conditions in less than five minutes. The same applies to load variations, which are so rapidly dealt with by the automatic governing system, that variations from half to full load and vice versa take only about twenty seconds.

As a Velox boiler is more a kind of steam-producing machine than a boiler, the whole unit can easily be erected and tested at the manufacturer's works. This has allowed tests to be made under normal working conditions, of which the following is an example carried out on an oil-fired boiler.

The steam generator, with its governing system, is shown on the test bed in Fig. 3 and gives a good impression of the small space requirements of such a boiler. The boiler was constructed for

A capacity of 55,000 lbs. per hr.
A steam pressure of 284 lbs. per sq. in.
A steam temperature of 700 deg. F.

Particulars of this boiler are as follows:—

Total evaporator heating surface	624 sq. ft.
Superheater heating surface	645 sq. ft.
Economizer heating surface	1,720 sq. ft.
Total	2,989 sq. ft.
Combustion chamber volume	124 cu. ft.
Steam production on test	62,320 lbs. per hr.
Evaporation from evaporator heating surface	100.0 lbs. per sq. ft.
Evaporation from total heating surface	30.0 lbs. per sq. ft.

The boiler efficiency, including allowance for the power absorbed by all auxiliaries exclusive of the feed pump, was 90.85 per cent. The exhaust pipe, being relatively long and of insufficient diameter, caused the back pressure to be 22-inch water gauge instead of 2-inch for which pressure it was originally designed and operated on site. Under normal working conditions the efficiency will approach 92.5 per cent in place of 90.85 per cent achieved. (See Table I.)

Table I

Test Results of 25 Tons Per Hour Velox Steam Generator. Toulon.

Test No.		1	2	3	4
Load		¼	¾	4/4	Overload
Fuel			Mazout		
Calorific value (net)	B.t.u./lb.	17,940	17,820	17,810	17,950
Quantity	lb./hr.	1,078	3,162	4,340	4,578
Air quantity	lb./hr.	19,960	50,600	69,850	71,400
Excess air ratio		1.29	1.10	1.11	1.06
Gas temperature leaving economizer	deg. F.	192	228	257	253
Steam—					
Quantity	lb./hr.	14,690	42,290	57,840	62,320
Pressure leaving superheater	lb./in²g.	276	285	281	283
Temperature leaving superheater	deg. F.	582	673	714	707
Feed-water inlet temperature	deg. F.	140	141	146	143
Electric Power—					
Power absorbed by all auxiliaries	kw.	48.4	73.6	157.6	174.8
Efficiency based on net calorific value—					
Without auxiliaries	per cent	90.3	93.1	93.8	95.0
With auxiliaries	per cent	86.8	91.2	90.8	92.1

The features of the Velox steam generator make it also suitable for use on board ship and for traction purposes, especially if high speeds are aimed at.

In stationary plant its use is somewhat limited owing to the necessity for using liquid or gaseous fuel, but tests which have been made show that the adaptation of the Velox steam generator to pulverized fuel may be possible in the near future.

The Loeffler System of Steam Production

Abstract of a paper by S. McEwen published in the November 16th, 1934, issue of *The Engineer*.

While the combustion engineer is constantly striving to obtain higher furnace temperatures in order to secure the benefit of a high rate of heat transmission consequent with a higher heat head, the steam engineer, pursuing a definite course of development, provides higher internal temperatures so that the result of both these efforts is to subject the material of heating surfaces to conditions of greater severity. The following account of the Loeffler system, however, will show how the new conditions have been effectively met without making exceptional demands on the metallurgist.

Prominent engineers have expressed their views as to highest practical limits of steam temperature and pressure under present-day conditions and it seems to be most generally accepted that considerations of capital cost, maintenance charges and reliability make it unprofitable to employ steam for power generation at pressures above 600 pounds per square inch and temperatures above 800 degrees F. This conclusion is, of course, based on the assumption that water-tube boilers would have to be used for the generation of steam, and ignores the more recent developments in turbine design, which latter have established in commercial practice the complete practicability of the use of pressures and temperatures such as are adopted in the Loeffler system.

Calculations show that with steam at a pressure of 590 pounds per square inch and a temperature of 842 degrees F., the steam consumption per kilowatt generated is 11.7 per cent greater than with steam at a pressure of 1,900 pounds per square inch and a temperature of 896 degrees F. For the purpose of this comparison it has been assumed that with the lower pressure there is no economic advantage in inter-stage reheating, but steam would be bled from the turbine in two stages to heat the feed water to 302 degrees F. Under the Loeffler conditions of higher pressure, reheating is adopted, and steam leaving the first stage of the turbine is reheated by means of a heat exchanger from 537 degrees to 662 degrees F. For preheating the feed water steam is withdrawn from the turbine in three stages, raising the temperature of the feed water to 392 degrees F.

This increased degree of preheating by means of bled steam is warranted by the higher boiling point of the water at the higher pressure. The boiling point of water of 590 pounds pressure is 486 degrees F. whereas at 1,900 pounds pressure it is 623 degrees F. The comparison allows for a higher power consumption for auxiliary plant with the Loeffler system.

Figure 1 is a diagrammatic representation of the Loeffler system. Referring to this diagram, S is a radiant superheater, lining a combustion chamber; N is a convection superheater; B is a boiler drum

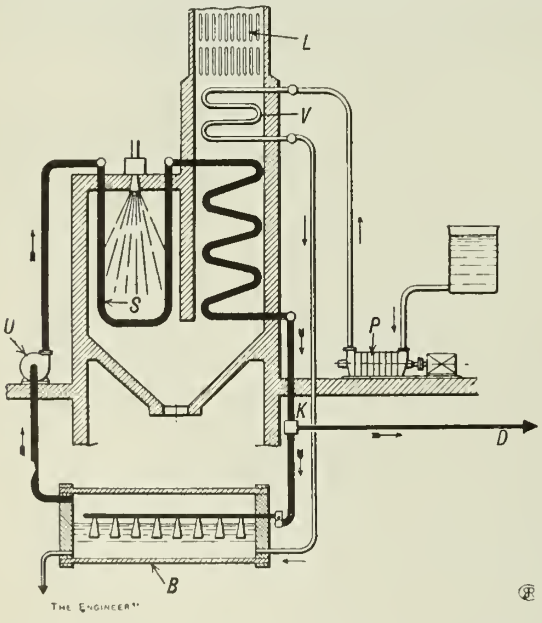

Fig. 1—Diagrammatic Representation of the Loeffler System.

placed in any convenient position outside the setting; U is a rotary pump, the purpose of which is to circulate steam, withdrawn from the boiler drum through the radiant and convection superheaters up to the branch K, at which point a part of the steam passes to the steam mains while the remainder returns to the boiler drum wherein its superheat is utilized to evaporate more water, the amount to be evaporated being equivalent to that delivered to the steam main. P is a feed pump, while V and L represent the economizer and air-heater respectively. It will be observed that one outstanding feature of the system is that all the steam is generated in a drum not exposed to any external heat, while the remainder of the circuit which is exposed to external heat contains only dense, clean and dry steam.

Steam at a pressure of 1,900 pounds per square inch has a specific volume of 0.21; whereas at a pressure of 600 pounds per square inch the specific volume is 0.76; the density at the higher pressure is three and one half times greater than at the lower. It is this low specific volume which makes it economically possible to circulate the steam by means of a pump.

The successful achievement of the commercial generation of steam at high pressures and temperatures by the Loeffler system has been secured in virtue of four main characteristics of the system.

Steam is the only medium for absorbing the heat which is liberated in the furnace, and this steam in a very dense condition is caused to flow through tubes at a velocity which ensures a small differential in temperature between that of the steam and the metal walls of the tubes. This differential, which can be predetermined by calculation, is such that the metal of the tubes of selected quality can suffer no deterioration. The velocity of the steam, which can be predetermined for any installation, is of the order of 65 feet per second at maximum capacity, and, under these conditions, over 40,000 B.t.u. are transmitted per square foot of heating surface per hour through the surface of the radiant superheater without any risk of overheating the metal.

The entire absence of scale or deposit on the interior surfaces of the tubes ensures constant condition for heat transference; no provision has to be made for a progressively reduced rate of transference, as is the case with a water tube boiler, where the maximum allowable rate of transference must be that which is safe when the tubes are dirty and the boiler due for internal cleaning.

There being an entire absence of water circulation problems, the disposition of the heating surface can be arranged with consideration only for heat transmission. The tubes not being subject to the necessity for internal cleaning, can be disposed without regard to provision for cleaning. The high average rate of heat transmission which is actually obtained in practice, results in a material reduction in the area of heating surface which has to be provided for any given duty as compared with that required for a normal water tube boiler. This reduction in area more than balances any extra expense per square foot of heating surface involved, in providing for higher pressures. In comparing modern Loeffler installations with modern water-tube boiler installations, it is found that the latter have from 40 to 50 per cent more pressure heating surface than the former.

It will be readily apparent that by the Loeffler principle of steam generation, the condition of the feed water becomes a matter of minor importance. Thus it becomes possible with the Loeffler system to obtain the economic advantages of high pressure and high temperature steam applied to back pressure turbines furnishing exhaust steam for industrial process. In such cases the make-up water may be 100 per cent, and this presents no difficulty. It is, of course, desirable to deaerate the feed water, and where it is possible it is preferable to subject the feed water to chemical treatment in order to avoid unnecessary blow-down losses. The practicability of operating the boiler with a high concentration of solids has been established by very carefully conducted and complete tests.

In practically every case in which the Loeffler is being examined for the first time, attention is focussed on the steam circulating pump. The pump is quite simple in construction, consisting of a single impeller, which rotates within a heavy steel housing.

Figure 2 shows the complete pump unit. The impeller shaft is fitted with labyrinth gland. This gland is entirely effective and may be seen with the steam channels with which it is provided. If saturated steam from the pump housing were allowed to pass through the gland, some condensation would occur which would cause erosion of the fins of the labyrinth. To obviate this, high pressure steam drawn from the radiation superheater, at a temperature of 770 degrees F. enters at A and passes to the gland near the impeller. Part is withdrawn at B at a pressure of about 190 pounds per square inch, and is conducted to the steam inlet of the turbine driving the pump. The remainder of the steam from the gland escapes at a little above atmospheric pressure, and is used for preheating the feed water.

One of the incidental functions of the pump, which, nevertheless, has a very definite value, is to remove by centrifugal action any moisture which may be carried over with the saturated steam leaving the evaporating drums. Ports provided at the periphery of the housing collect such moisture, which automatically flows back to the drum, the pressure in the housing being greater than that within the drum. The main purpose of the pump, however, is to circulate steam at the desired velocity through the system and by variations in that velocity to maintain a uniform final temperature of steam for delivery to the turbine. The ability of the pump to secure this result by simple speed control may be readily understood when it is appreciated that a given quantity of heat transmitted through the heating surface may be absorbed in a large quantity of steam at a low temperature or in a smaller quantity at a higher temperature. The pump provides the means for varying the quantity at will and instantly so that it is possible to maintain a constant temperature at the expense of a variation in quantity. Variations in demand for total heat must ultimately be met by combustion control. Combustion control is a necessity, owing to the number of factors involved, somewhat low, and the Loeffler boiler, in virtue of the steam-circulating pump, is much more

(*Continued on page 440*)

Preliminary Notice

of Applications for Admission and for Transfer

August 10th, 1935

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in October, 1935.

R. J. Durley, Secretary.

*The professional requirements are as follows.—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

SANDWELL—PERCY RITCHIE, of 139 Brock Ave. South, Montreal West, Que., Born at London, England, Oct. 26th, 1912; Educ., B.A.Sc. (Mech.), Univ. of B.C., 1935; Summers: 1927-28, machine shops, Powell River Co., Powell River, B.C.; 1929, highway survey, B.C. Govt.; 1930-31, timekeeper and surveyor's asst., erection dept., Dom. Bridge Co., Vancouver; 1933, constrn. gang, Powell River Co.; 1934 (4 mos.), dftsman., and at present, dftsman., paper machy. dept., Dominion Engineering Works Ltd., Montreal, Que.

Loeffler System of Steam Production

(*Continued from page 438*)

quickly responsive to variations in load than would be possible by combustion control alone.

The fact that for every pound of feed water supplied to the boiler, about three pounds of steam are circulated, might prompt the fear that so much turbulance in the vaporizer drums would result in a large amount of water being carried out of the drums with the steam. Actually, however, this is not the case.

In comparing the capital costs of complete power stations, taking in one case a low or medium pressure steam station, and the other

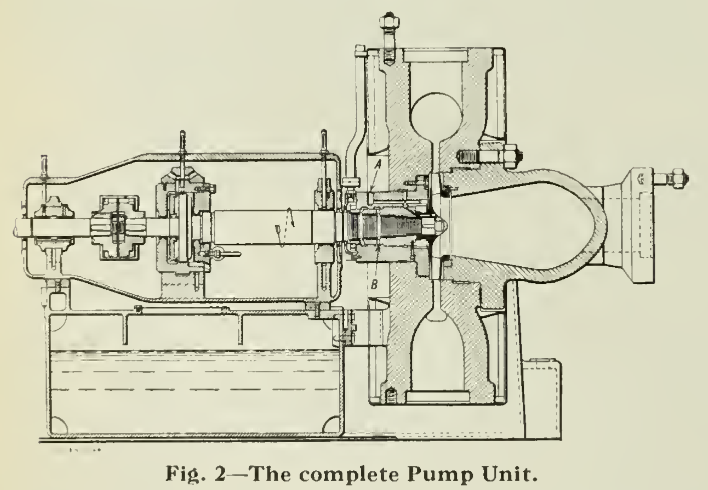

Fig. 2—The complete Pump Unit.

high pressure under Loeffler conditions, so many factors are in favour of the Loeffler system that no additional capital charges need be involved. The reduction in consumption of steam per unit generated, the reduction in fuel to be handled and consumed, the reduced heating surface, the smaller condensers, the lack of necessity for evaporators, the cheaper constructional work owing to reduced space occupied and position of boiler drums, the smaller diameter of steam piping and smaller size of valves, fittings, etc., these items serve to indicate at least that it is reasonably possible to secure the economical advantages of high pressure and high temperature steam without incurring increased capital charges.

The general design and arrangement of the new central power station at Trebovice, Czecho-Slovakia, have been made so that the station in its final form will be able to generate 150,000 kw. The present steam plant consists of three Loeffler boilers each having a capacity at maximum rating of 160,000 pounds of steam per hour at a pressure of 1,900 pounds per square inch, and a temperature of 930 degrees F. The boilers are fired with coal having a calorific value of approximately 12,600 B.t.u. per pound. Two Skoda turbines are installed for an output of 21,000 kw. each. The turbines are bled in three stages for the purpose of heating the feed water to a temperature of 504 degrees F. The steam leaving the first stage of the turbine passes to an intermediate superheater, wherein it is reheated by means of steam from the boiler to a temperature of 645 degrees F.

The following guarantees of performance have been given for this plant:—

Per cent of rated capacity	100	70	40
Kilowatts delivered to consumer	42,000	29,450	17,010
B.t.u. per kilowatt	13,167	12,988	14,553

For the operation of auxiliaries a house turbine has been installed to give a maximum of 3,500 kw. when supplied with steam at 285 pounds pressure per square inch and a temperature of 645 degrees F.

Business Conditions in Canada

Month by month the volume of activity in manufacturing, mining and transportation in Canada shows consistent gain. In each month of 1935 there has been an improvenent as compared with the corresponding month of 1934, and in May the official index of the physical volume of business for the country reached a new high of 103.2. During the first five months of the year the index averaged 98.8 as compared with 91.7 and 69.9 for the corresponding periods of 1934 and 1933 respectively. In terms of volume, the industrial production of the country is half as large again as in 1933.

In view of the prospective improvement in the farmer's purchasing power, a result of generally favourable weather conditions in all parts of the country, there has been less than normal seasonal recession in a number of lines of business this summer. Recently there have been impressive gains in the construction and farm equipment industries.

The agricultural outlook is favourable and without some unforeseen development satisfactory crops should be harvested in many parts of Canada. Damage from rust has seriously reduced prospects for the Western wheat crop. The marketing of a substantial wheat crop would present considerable difficulty, as stocks from last year are still heavy and the carry-over at the end of the present season will show little, if any, reduction from a year ago.

—*Royal Bank of Canada Letter.*

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

Situations Vacant

ASSISTANT SUPERINTENDENT, for shops, consisting of machine, iron foundry, blacksmith, boiler, and pattern, to employ up to 300 men. Must know latest practices and have been engaged in manufacturing and be able to estimate job costs closely. In reply state education, experience, age, and salary expected. Apply to Box 1190-V.

Civil Service Vacancy

JUNIOR STRUCTURAL ENGINEER

2426I.—A junior structural engineer in the Penitentiaries Branch of the Department of Justice at Ottawa at a salary rate of $1,800 per annum.

Duties.—Under direction to assist in the design, inspection or supervision of construction of buildings and other structures of steel, concrete and wood; on occasion to make estimates of cost and to prepare specifications and bills of material and to perform other related work as required.

Qualifications required.—Education equivalent to High School graduation with four years of experience in Structural Engineering, design, inspection and construction; or graduation in engineering from a school of applied science of recognized standing, with two years of experience in structural engineering, design, inspection or supervision of construction; corporate membership in The Engineering Institute of Canada, or membership in a Provincial Association of Professional Engineers, or professional qualifications which would permit of such membership.

While no age limit has been set for this competition, age may be a determining factor.

Application forms properly filled in must be filed with the Civil Service Commission, Ottawa, **not later than September 19, 1935.** Application forms may be obtained from the offices of the Employment Service of Canada, from the Postmasters at any City Post Office, The Engineering Institute of Canada, or the Secretary of the Civil Service Commission, Ottawa.

Candidates must be British subjects, and have resided in Canada for at least five years.

Situations Wanted

ESTABLISHED SALES ENGINEER, Univ. of Toronto '24, with plant and manufacturing experience, wishes to represent manufacturers of technical equipment. Connections with automobile and electrical equipment dealers, throughout Canada. Will make small investment if necessary. Apply to Box No. 1-W.

SALES ENGINEER, S.E.I.C.; B.SC. C.E., 1930 (Univ. New Bruns.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.SC., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ENGINEER AND ACCOUNTANT, JR.E.I.C., (Capt. Can. Engrs., reserve). Age 35, Canadian. Experienced in mechanical and civil engineering, Diploma; general office, draughting and instrument work; assistant engineer erection Royal York hotel; assistant resident engineer T. & N.O. Ry. const. Desires position in Toronto where combination of technical and business experience will be of value, as have been director and accountant last three years. Apply to Box No. 377-W.

CIVIL ENGINEER, B.A.SC. and C.E.; A.M.E.I.C., A.M. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

Situations Wanted

SALES ENGINEER, M.A.SC. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

MECHANICAL ENGINEER, B.SC. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

CONSTRUCTION ENGINEER, age 26, unmarried, graduate C.E. Experience includes hydro-electric, railroad, highway, and industrial plant construction, both field and office, including cost accounting, estimating, stores, layout, general engineering and supervision, as well as practical work in mechanical trades. Apply to Box No. 567-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experiences on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

Employment for Engineers Improved

During the past four months employment for engineers has showed a marked improvement. This has been particularly noticeable in Quebec, Ontario and the middle west.

In Quebec and Ontario very few members are now actually unemployed except in a small number of cases where those with specialized experience have not found a demand for their services.

It is hoped that the improvement already so marked will continue as this should afford an opportunity to place a number of those engineers in other localities or who are in unsuitable positions.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

ELECTRICAL ENGINEER, McGill '31, desires permanent position in engineering field. Experience includes draughting, designing and testing of induction motors, radio supervision and test, and some construction. Available immediately. Apply to Box No. 626-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL AND RADIO ENGINEER, B.SC. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

Situations Wanted

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC., Elec., '29, B.SC., Civil '33. Age 27. JR.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.SC., '27, JR.E.I.C. Four years maintenance of high speed Diesel engine units, 200 to 1,300 h.p. Also maintenance of d.c. and a.c. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.SC., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

CIVIL ENGINEER, B.SC. (Alta. '31), S.E.I.C. Experiences includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.SC., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

RADIO AND ELECTRICAL ENGINEER, B.SC. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.SC. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, S.E.I.C., B.SC. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.SC., '25, JR.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

Situations Wanted

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

SALES ENGINEER, A.M.E.I.C., graduate engineer, age 34, practical experience in the manufacture of power plant equipment, thoroughly conversant with Canadian power plant practice and equipment for the metal working industries. Available on short notice. Apply to Box No. 860-W.

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, B.A.Sc. in C.E., with business and sales experiences, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

Situations Wanted

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.Sc. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.Sc., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C. '29); M.S. Age 27. Single. Four years experience in research work in applied mechanics and materials testing. Desires position involving analytical work in design, development or testing. Available on short notice. Apply to Box No. 1023-W.

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER, B.Sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

Situations Wanted

CIVIL ENGINEER, B.A.Sc., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.Sc., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Writes and speaks both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211-W.

CIVIL ENGINEER, B.Sc. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

COMBUSTION ENGINEER, A.M.E.I.C., with extensive experience in all phases of combustion engineering, including plant layout, piping, etc. Lately connected with prominent firm of automatic oil burner manufacturers. Apply to Box No. 1224-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet tissues. Apply to Box No. 1246-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

CIVIL ENGINEER, Univ. Toronto '33, age 24, married. One year as instrumentman with provincial department of highways. Experience in concrete and retread construction grading, culverts, etc. Also draughting, estimating and general office practice. Apply to Box No. 1265-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '29). Age 28. Six years experience in automobile office and plant; two years as supervisor of inspection in body assembly. Good understanding of modern business methods applied to manufacturing. Desires position with production department of smaller Ontario industry. Good references. Interviews anywhere in central Ontario. Apply to Box No. 1270-W.

ELECTRICAL GRADUATE, S.E.I.C., B.Sc. '32, M.Sc '34. Experience includes four years as part time operator and announcer for a radio broadcast station. At present employed in radio repair dept. of a large wholesale firm. Apply to Box No. 1283-W.

ELECTRICAL ENGINEER, B.Sc., E.E., A.M.E.I.C. University of Manitoba '28. Age 32. Married. Experience one year power line construction, five years resident and assistant district engineer on highway construction; two years highway traffic regulation in charge of district office. Good connections in Manitoba and Saskatchewan. Excellent references. Available at once and will go anywhere. Located in Winnipeg. Apply to Box No. 1316-W.

ENGINEER AND DRAUGHTSMAN, Jr.E.I.C., age 33, married. Diplomas from Mtl Tech. Inst. in R.C. and Structural Design. 11½ years experience in civil engineering, draughting and instrument work. This includes 7 years with M.L.H. & P. Cons. as field engineer on construction and maintenance of gas mains. Present location Montreal. Available at once. Apply to Box No. 1326-W.

GRADUATE ENGINEER, (McGill), in responsible charge of design, construction and operation of hydro-electric plants. Also power design and mechanical maintenance of industrial plants. Apply to Box No. 1328-W.

THE

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

Entered at the Post Office, Montreal, as Second Class Matter.

The Institute as a body is not responsible either for the statements made or for the opinions expressed in the following pages.

Volume XVIII — Montreal, October, 1935 — Number 10

Some Basic Principles in Making Durable Concrete

E. Viens, M.E.I.C.,
Director of Testing Laboratories, Department of Public Works, Ottawa,

and

J. W. Lucas, Jr.E.I.C.,
Testing Laboratories, Department of Public Works, Ottawa.

Paper presented before the Ottawa Branch of The Engineering Institute of Canada on March 21st, 1935, and before the Montreal Branch on March 28th, 1935.

SUMMARY.—The chemical changes which accompany the setting of Portland cement and the relation between water-cement ratio and the quality of concrete are discussed. The paper then considers in some detail the precautions necessary in mixing, placing and curing concrete, if durability and water tightness are to be obtained.

Ordinary concrete is composed of three ingredients: cement, water and aggregates. The simplicity of the materials used tends to make it appear to the average man that it is an easy article to manufacture. No doubt this false view is responsible for much of the inferior and unsightly concrete that one sees. However, these failures of the past have led to much research which has resulted in a fairly well defined science of the art of making economically durable concrete.

A thorough understanding of the science of making durable concrete involves the knowledge of the compounds entering into the composition of Portland cement, their reaction with water, and the function of the aggregates used in the water-cement paste.

The following are the principal components of ordinary Portland cement and their approximate percentages based on several analyses made on cements from five Canadian mills: Tricalcium silicate, 50 per cent; beta dicalcium silicate, 25 per cent; tricalcium aluminate, 11 per cent; tetracalcium alumino ferrite, 8 per cent; in all a total of 94 per cent.

Hydration of Portland Cement

These compounds of Portland cement react with water to form the hard matrix which binds the aggregates into a solid mass. A knowledge of the rate at which water reacts with these compounds is important in the production of durable concrete.

Tricalcium aluminate is the first compound to react chemically with water and imparts most of the early strength of concrete. Its reaction is practically complete in the first twenty-eight days under favourable conditions.

Tricalcium silicate is the next ingredient to contribute to the early development of strength. Tricalcium aluminate and tricalcium silicate are responsible for most of the twenty-eight day strength, although tricalcium silicate continues to impart strength at a diminishing rate after the twenty-eight day period.

Beta dicalcium silicate contributes little to the strength up to twenty-eight days, but is largely responsible for the increase beyond that period.

Tetracalcium alumino ferrite is not an important ingredient and its role is not so well defined. It is known, however, to influence the strength after one day up to a period beyond twenty-eight days.

The significance of the hydration of these compounds will be discussed further under "curing."

Concrete may be thought of as a mixture of inert aggregates held together in a hardened water-cement paste. As will be shown later, the characteristics of the aggregates have an important influence on the properties of the concrete, but concrete derives its main characteristics from the water-cement paste. Then, for the moment, consider the properties of the paste apart from the aggregates.

The water-cement ratio may be defined as the ratio of the quantity of water to the quantity of cement expressed in suitable units. The units most commonly used are: volume, weight, and gallons of water per sack of cement. The latter is, perhaps, the most practical for every day use and can be readily converted to the other units when desired.

The water-cement ratio has been found to serve as an index by which the quality and properties of the paste may be expressed. In fact, a thorough understanding of the considerations involved implies a fairly thorough knowledge of the use of cement.

Compressive Strength of Concrete

Duff Abrams about 1918 discovered that a definite relationship exists between the water-cement ratio employed in concrete and its compressive strength providing that the concrete is plastic and capable of being placed without segregation. That is, the concrete must not be so dry and stiff that it cannot be placed, nor so wet that when placed the ingredients will segregate. Abrams found the relationship between the water-cement ratio and strength to be as given in Table I.

Table I

Compressive strength, Pounds per square inch at 28 days	Water-cement ratio, Imperial gallons per Canadian sack of cement (87½ pounds)	
1000	7.83	
1500	6.63	
2000	5.78	(these results are for average materials cured at a temperature of 70 degrees F. under moist conditions.)
2500	5.11	
3000	4.57	
3500	4.11	
4000	3.72	
4500	3.37	
5000	3.06	

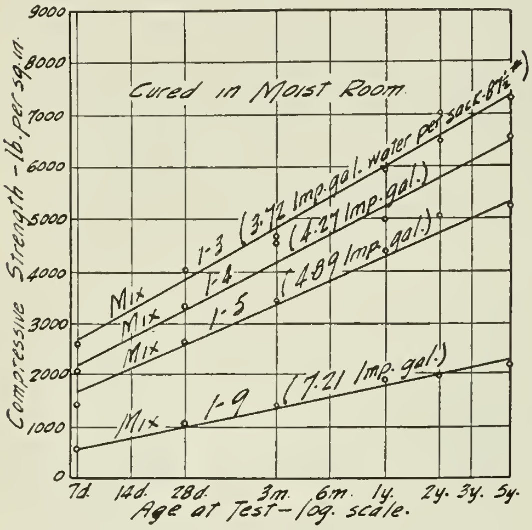

Fig. 1.

Immediately the water and cement are mixed together a chemical reaction commences in which a portion of the mixing water combines with the various compounds in the cement to form hydrates, causing the paste to harden and impart strength to the concrete. This being a chemical reaction the rate at which it proceeds is dependent upon the

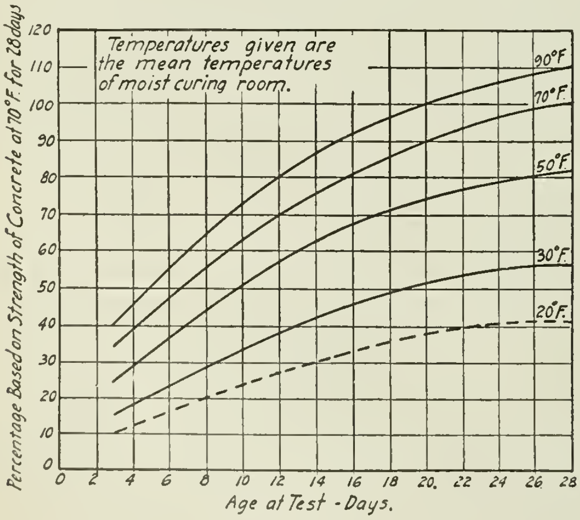

Fig. 2.

temperature and the amount of water available. Therefore, it becomes worth our while to investigate the increase in strength of the paste as related to the temperature and conditions of moisture during the curing period.

The strength of the paste, or concrete containing it, increases rapidly at first and continues to increase indefinitely but at a slower rate. (See Fig. 1.)

The higher the temperature within limits the greater the rate at which the strength increases. (See Figs. 2 and 3.)

Water must be available or hydration cannot take place. If concrete is left exposed to a dry atmosphere, as found in an ordinary room or out-of-doors in summer weather, it will become dry and the gain in strength will be retarded or even stopped. It is interesting in this connection to note that all of the water supplied in mixing concrete is not used in the hydration of the cement. Considerably more than half of the water is only added for the purpose of lubricating the mixture sufficiently so that it can be placed with ease in the forms. This excess of water will eventually evaporate from the concrete which is not in contact with water but it must not be allowed to do so before sufficient hydration has taken place to permit the required strength to be attained. The combination of the water with the cement is one which evolves heat and this heat besides having other effects has a tendency to drive off the water from the mix and hasten its drying. (See Fig. 4.)

Permeability

The rate at which water passes through a piece of concrete will depend upon the water pressure, the thickness of the concrete, and its ability to resist the passage of water. Tests show, for given conditions, that the rate of flow depends upon the water-cement ratio and also that

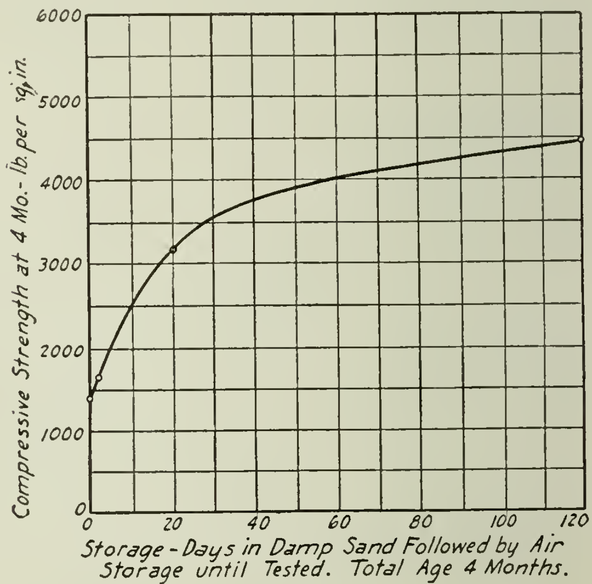

Fig. 3.

concrete can be made watertight. If the water-cement ratio does not exceed four and one-half gallons of water per sack of cement it may be safely said that the concrete will be watertight under all ordinary conditions. This implies that the concrete be uniform throughout and does not mean that it will not leak if the ingredients of the concrete are allowed to segregate and the water-cement ratio allowed to increase in portions of the mass. It does mean, however, that with moderate care watertight concrete may be obtained. (See Fig. 5.)

Volume Changes

With variations in temperature or conditions of moisture, the volume of concrete changes. The thermal coefficient of expansion of the average concrete is for all practical purposes the same as that of the average steel. Usually in the design of concrete structures provision is made for expansion and contraction by the use of expansion joints. Changes in volume in concrete due to changes in moisture are approximately equal in magnitude to the thermal variations but are different due to the fact that they are almost entirely produced within the cement paste. Hence, volume changes in concrete due to this cause are roughly proportional to the richness of the concrete mixture.

One of the advantages claimed for vibration, which will be discussed later, is that the volume changes due to variation in moisture will be greatly reduced. This is because it makes possible the placing of concrete with

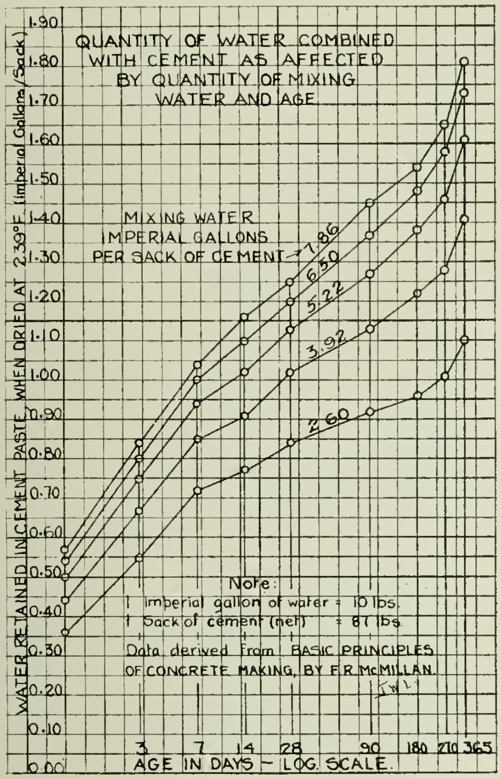

Fig. 4.

smaller amounts of water and hence smaller amounts of cement for a given yardage of concrete.

Aggregates

Aggregates used in concrete may be briefly classified as follows: sand, gravel, crushed stone, slags, cinders, clay and shale products, iron ore and steel mill scrap.

Sand, gravel and crushed stone, are the most commonly used. It is probable that the use of stone-sand (that is, fine crushed stone) will in the future replace a considerable quantity of the natural sand used at present. This will take place with the depletion of the natural supplies, with improvements in machinery and technique, organization, and with an increasing demand on the part of users for a product of better quality.

The use of cinders is quite common in certain types of construction. Aggregates specially manufactured from clay and shale have come to the fore in recent years and although they are in themselves expensive their use makes possible savings in weight which in certain types of structures may warrant their use.

The heavy materials are not commonly used except in special cases where great weight is necessary, such as in counterweights for bascule bridges.

The selection of the aggregates for any particular work requires a knowledge of the type, details and exposure of the structure, along with a knowledge of the properties of the various types of aggregates. In considering the properties of aggregates it may be helpful to do so under the following headings:

(*A*) Structural strength of aggregate particles,
(*B*) Durability of the aggregate,
(*C*) Content of deleterious and extraneous materials,
(*D*) Grading, percentage of voids, maximum size and shape of the particles.

(*A*) *Structural Strength of Aggregate Particles*

The compressive strength of stone varies up to about 25,000 pounds per square inch. When an aggregate of fair strength is used the designed strength based on the water-cement ratio may be expected to control the strength of the concrete. A weak aggregate would, on the other hand, be expected to reduce the strength. The aggregates of very low strength are not difficult to detect in that they are easily broken in handling or with a light blow from a hammer.

(*B*) *Durability of the Aggregate*

At one time all failures of concrete were blamed on the quality of the cement. Since then much has been learned about both cement and aggregates and it is now agreed that most failures are due to the use of poor aggregates, high water-cement ratios, and poor or careless methods of manufacturing, transporting, placing and curing of the concrete. The question of the durability of the aggregate then becomes a real one when considered in the light of present day knowledge and the problem now resolves itself into a study of methods for detecting the aggregates of poor quality.

In general the weaker aggregates are the less durable. It is also true that the more durable aggregates are generally from the stronger rock formations, but it does not necessarily follow that all strong rocks make durable aggregates.

The following procedure is useful in investigating the durability of an aggregate:

(*a*) Mineralogical classification,
(*b*) Inspection of quarry or pit,
(*c*) Inspection of structures containing the aggregates in question,
(*d*) Laboratory tests.

(*a*) From a mineralogical classification it may be possible to determine whether or not the material falls into a class which can be expected to be durable.

(*b*) By inspecting a quarry or gravel pit which has been in use for a number of years one can determine the

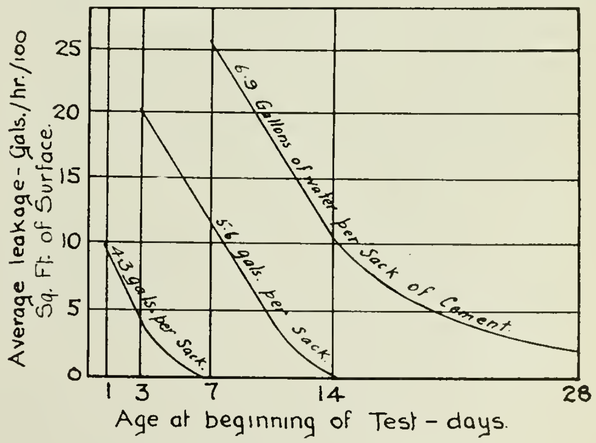

Fig. 5—Permeability of Concrete.

ability of the materials to resist weathering from the open faces and the waste therein.

(*c*) By inspecting structures of a similar type to the one for which the aggregate is being sought and containing the aggregate in question one may determine its durability.

(*d*) Frequently new quarries are opened and there is no opportunity to determine the quality of the aggregates by their past records and in such cases accelerated laboratory tests are particularly useful. These tests usually consist of freezing and thawing or of performing what are known as artificial freezing and thawing tests. These latter consist of alternately immersing the aggregates in a solution of sodium or magnesium sulphate and drying them in an oven. In both cases the number of cycles required to cause the aggregate particles to disrupt is considered to be a measure of the durability of the aggregate.

Fig. 6—Failure due to Inferior Aggregate.

There is some difficulty in determining what weight should be attached to the results of these tests and at best they can only be considered as a guide in the selection of suitable aggregates. However, there is an attempt being made to standardize both the artificial and actual freezing and thawing tests.

(*C*) *Content of Deleterious and Extraneous Materials*

Aggregates should not contain alkalis nor organic matter in sufficient quantity to be harmful. Actual tests of the aggregates with cement in mortar or concrete are perhaps the best way of determining the effect of such materials when present. The percentage of soft, laminated, elongated and thin flaky particles should be kept at a minimum as their presence cannot be beneficial. Frequently an aggregate taken from a river or lake may contain sufficient quantities of wood and bark to cause failure of the concrete in which it is used if it is exposed to the actions of water and frost.

In many cases aggregates are washed in order to remove undesirable materials, but here a word of caution is in order. In a fine aggregate a small percentage of very fine material is desirable, therefore, too much of it should not be removed by washing in order to retain the workability of the concrete.

The form in which a material is present is also important. Clay in the form of lumps can be harmful in that it will contribute to the disintegration of the concrete, while on the other hand, it has been found that small percentages of clay when in the finely divided state, well diffused and free from organic matter, is not detrimental and may be beneficial when fines are lacking.

(*D*) *Grading, Voids, Shape of Particles, Maximum Size*

The grading of aggregates is important but also complicated. There has been much written on this subject and perhaps the only conclusion one can draw is that there is no particular grading which can be considered ideal. On the other hand there are a few points to be watched.

The uniform grading, or that represented by a smooth curve, is generally accepted as being the most satisfactory. Recently some have advocated and used gap grading, that is, a distribution in which a certain size is absent. Gaps are no doubt preferable to humps or excessive quantities of material of one size. Where humps occur on the curve particle interference is indicated. This means that there are too many particles of one size which increase the voids and decrease the workability of the aggregate.

It is a known fact that the finer a material the easier it is to work it. For instance, it is easier to shovel sand than to shovel gravel or crushed stone. Hence, if the grading is such that the particles, when moved, roll around on smaller particles, the workability of the grading should be at a maximum.

When the weight per unit volume and the specific gravity of the aggregate are known it is possible to compute the volume of its voids. The percentage of voids serves as a measure of the quality of the grading and further it can be shown that the quantity of cement required for a unit volume of concrete of a given water-cement ratio is directly proportional to the percentage of voids in the aggregate. (See Figs. 8 and 9.)

The shape of the particles has a bearing on the workability of the aggregate. Flat or elongated particles will increase the voids and decrease the workability. Gravels which are smoothed and rounded produce more workable mixtures than do irregularly shaped pieces of crushed stone. In crushing stone it sometimes happens that a large percentage of flat or elongated pieces are formed. A stone may have a natural tendency to break in this manner, but it can to some extent be remedied by the use of crushers designed to break the pieces into cubical shapes.

The maximum size of the particles has an influence on the cost of the mix, the cost of placing and on the structural properties of the concrete. For economy in mix design the maximum size should be as large as possible. By following this rule the surface area of a unit volume of aggregate will be decreased and the result is an appreciable economy in the amount of cement required for a given water-cement ratio. On the other hand the maximum size should not be greater than that which can be easily handled in mixing, nor should it be greater than that which will easily go through the reinforcing. Further, from a structural point of view, the aggregate should not exceed one-quarter of the least dimension of the member in which it is to be used.

Fig. 7—Fragments of Wood and Bark in Concrete.

Influence of Aggregates on the Compressive Strength of Concrete

The water-cement ratio of a concrete mixture controls its strength but each type of aggregate has also some influence. A structurally weak aggregate, one containing organic impurities, or one with surfaces so smooth that the water-cement paste will not bond to it, can be expected to lower the strength. On the other hand, certain types of aggregates yield strengths above that expected of a given water-cement ratio, and that may possibly be attributed to surface texture. The influence of the aggregate should be determined since it will have an influence on the cost and quality of the concrete produced.

In designing a concrete mixture the following information should be available and from it the necessary decisions made. (See Table II.)

Table II

Information Required and Factors to be Determined when Designing Concrete Mixtures

Information Required	Factors to be Determined
Necessary structural strength of concrete. Conditions of exposure of concrete. Properties of available aggregates.	Water-cement ratio.
Type of structure. Size of members. Quantity of reinforcing. Method to be used in placing concrete.	Maximum permissible size of aggregates. Workability and consistency of the concrete.

Table III will serve as a guide in selecting the correct water-cement ratio for various conditions of exposure.

Table III

A Guide in Selecting the Correct Water-cement Ratio for Concrete Under Various Conditions of Exposure

Class of Structure / Exposure	Water-cement ratio Imperial gallons water per Canadian sack of cement [1]		
	Reinforced piles, thin walls, light structural members	Reinforced reservoirs, water tanks, pressure pipes, sewers, canal linings, Dams of thin sections	Heavy walls, piers, foundations, Dams of heavy sections
Extreme: In severe climates as in Canada, exposure to alternate wetting and drying, freezing and thawing, as at the water line in hydraulic structures. Exposure to sea water and strong sulphate waters.	4½ (3000)	4¼ (3300)	4½ (3000) [2]
Severe: In severe climates as in Canada, exposure to rain and snow and freezing and thawing but not continuously in contact with water.	4½ (3000)	4½ (3000)	5 (2500)
Moderate: Concrete completely submerged and protected from freezing.	5 (2500)	4½ (3000)	5¾ (2000)
Protected: Ordinary inclosed structural members; concrete below ground not subject to action of corrosive ground waters or freezing and thawing.	5¾ (2000)	4½ (3000)	6¼ (1500)

(1) Free water or moisture carried by the aggregate must be included as part of the mixing water.

(2) Figures in brackets indicate the approximate compressive strength of the concrete.

The above table is predicated on the use of materials and methods meeting the requirements of standard specifications and recognized good practice.

When the aggregates have been selected and the water-cement ratio decided on, the actual design of the mix becomes a matter of determining the relative quantities of fine and coarse aggregate and the amount of water-cement paste required per unit volume of concrete, usually a cubic yard.

The object of designing a mix is to secure for the least cost a concrete which will possess adequate workability or placeability, strength, watertightness, durability, etc., from the materials available. The much too common practice of specifying that a concrete mix shall consist of one part of cement to so many parts of fine and coarse aggregate by volume without any knowledge of the characteristics of the aggregates is to be condemned as unscientific and inadequate if either economical or durable concrete is to be secured.

There are methods of computing approximately the quantities of materials required in a concrete mix, notably that developed by Abrams, but these methods require a knowledge of the characteristics of the materials and even then do not account for all the variables and result only in an approximate solution. In fact, the Abrams' method does not claim to do more and the actual mixing of trial batches are considered a necessity.

The procedure in designing trial batches is to assume the quantities of fine and coarse aggregate, cement and

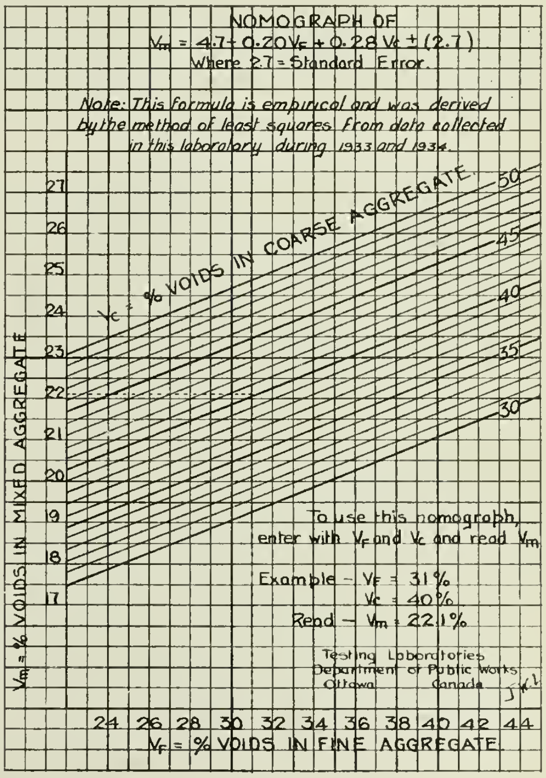

Fig. 8.

water for a trial batch of a convenient volume of concrete, to mix these together and examine the mixture for workability, water-cement ratio and other desired properties. Each individual who happens to be doing this work will develop his own technique and methods of arriving at a satisfactory mix with as few trial batches as possible. One convenient method is to assume slightly less fine aggregate than is likely to be required and to add more when and if it is seen to be necessary for workability and to add the water to the mix a little at a time until the desired consistency is obtained. When a mix of suitable workability is secured the relative amounts of each ingredient may be computed, the volume of the concrete so produced measured or computed from the absolute volumes of the materials and the water-cement ratio determined. With a little practice it will be possible to design a mix of suitable workability with usually one, and not more than two, trial batches. It has been found that for a given aggregate

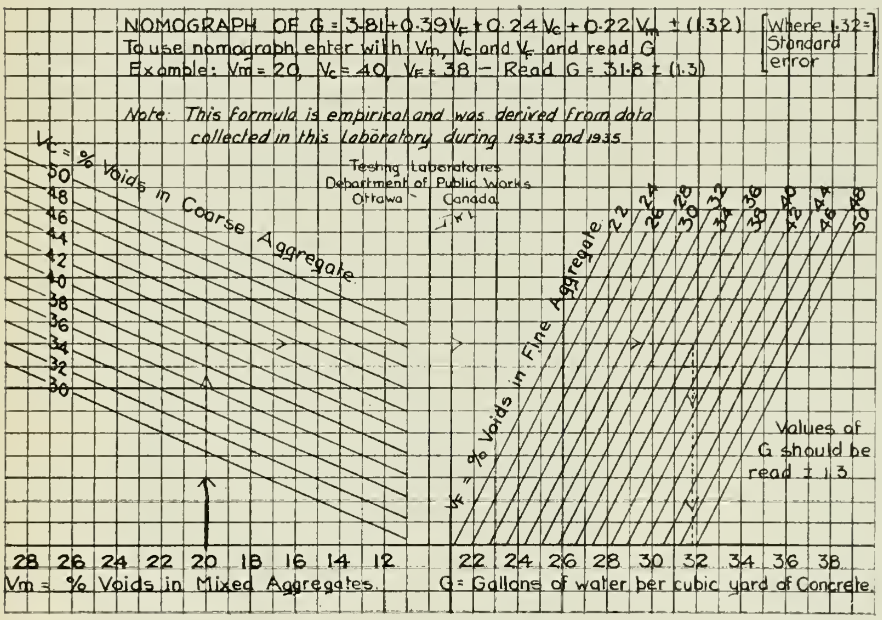

Fig. 9.

combination, and for a given consistency, the quantity of water required per unit volume of concrete will be constant regardless of the water-cement ratio. Hence, knowing the quantity of water required per unit volume of concrete it only becomes necessary to divide the total number of gallons of water in a unit volume of the concrete, by the water-cement ratio in gallons per sack, and to increase or decrease the amount of aggregate, an amount equal to that required to maintain a constant volume of concrete. (See Fig. 10.)

In the case of concrete ranging in strength around 3,000 pounds per square inch, a variation in the water-cement ratio of one-half gallon of water per sack of cement corresponds to a change in strength of approximately 500 pounds per square inch. The reason for stating above that this conversion method should not be used without further trial batches, if the change were greater than the amount indicated, is because when large changes in the cement content of the mix are made a change in the grading of the aggregate may also be desirable. Cement, besides forming the water-cement paste, serves as fine material and increases the workability of the mixture. Hence, the richer the mix, the more workable it should be, and it is often possible to alter the aggregate grading by reducing the sand content and thus securing a more balanced design.

Concreting Operations in the Field

There are many elements which enter into proportioning, mixing, and placing of concrete in the field which are sometimes difficult to control but if economical and durable concrete is to be secured the mixer must produce uniform batches, and the concrete must be conveyed to and placed in the forms without segregation.

Aggregates should be delivered to the job separated into several sizes. In no case should a pit-run material be used without first separating the fine from the coarse by screening and then use them from their separate piles in a definitely established ratio; firstly, because it will be found impossible to secure uniformly graded material from a pit-run aggregate and secondly, the various sizes will separate in transportation and storage. For the same reason it is bad practice to buy ready-mixed aggregate. As a general rule the fine aggregate will pass the ⅜ or ¼-inch screen and in such cases no trouble will be experienced from segregation of the various sizes, also, the fine aggregate usually contains sufficient moisture to prevent any tendency of this nature. Coarse aggregate varies in size from about ¼ of an inch upwards, the maximum size depending upon the nature of the work. When the maximum size is large, much segregation will occur in either stock piles or bins. The lack of uniformity of grading of the coarse aggregate produced in this way is sufficient in many cases to cause wide variations in the consistency of the mix. The obvious solution is to separate this material into two or more sizes and to recombine them as stated above. In cases where the range in size is not too large and conditions permit considerable improvement can be secured by storing the material in low stock piles where the effect of segregation will be minimized. The aggregate should be delivered on a hard clean base from which shovelling is easily performed and should always be shovelled from the bottom of the pile so as to remix it, thus securing uniformity.

The next step in the production of uniform concrete lies in the measuring of the various materials. It has been customary in the past to proportion by volume, but recently the practice of weighing has come into more common use with good results. Weighing has the advantage of being fundamentally a more accurate method of measuring aggregates, and further, the effect of moisture in the aggregates is more easily controlled. Moisture in the coarse aggregate has little effect other than to add to the mixing water, but moisture in the fine aggregates besides adding to the mixing water causes bulking of the sand. This bulking amounts to an increase in volume ranging up to about 40 per cent, depending upon the amount of moisture present and the grading of the fine aggregate. Bulking, of course, is only an apparent increase in quantity and when not compensated for by increasing the amount of fine as measured by the volume method, results in a deficiency of fine which decreases the yield and workability of the concrete. With the moisture content changing from day to day, or even from hour to hour, it is not easy to measure the desired quantities of fine aggregate accurately by the volume method.

The mixer should be of adequate capacity and design to handle the materials being used and to produce sufficient concrete for continuous placing. The rate at which the mixer turns should be sufficient to mix thoroughly, but should not be so great that the centrifugal force will cause the particles of aggregates and cement to be thrown to and remain on the drum of the mixer. The time of mixing should be sufficient to cause a complete mixture of the ingredients and should never be less than one and one-half minutes. The mixer should discharge a homogeneous batch of concrete and not one in which the mortar is first delivered and finally the coarse aggregate.

Two factors enter into transportation of the mixed concrete: time and segregation. The element of time between mixing and placing is usually given adequate recognition and is only a problem in special cases. Recent tests indicate that provided the concrete is placed in the forms within two hours of the time it is first mixed, and provided that no addition of water is added, the strength remains unchanged. Too frequently the methods of conveying the concrete from the mixer to the forms permit considerable segregation. This is to be carefully avoided if durable concrete is to be obtained and the concrete should arrive at the forms in as uniform a state as when it left the mixer. Any method which accomplishes this may be considered satisfactory.

Methods of Placing

Poor methods of placing concrete have been found to account for a greater number of failures than any other single cause. A few simple rules, if observed, should result in a concrete of a homogeneous and durable character.

(*a*) The concrete should be placed where it is to remain and should not be deposited in one spot and allowed to flow to other parts of the form. If permitted to flow, the water and finer materials will find their way to the sides and corners of the forms, resulting in a material of high water-cement ratio and low strength in the parts most vulnerable to attack.

(*b*) Lift planes should be avoided wherever possible. It has been common practice in the past when filling a form to cease operations at intervals to allow the relief of pressure on the forms, or for the construction of additional form work. Considerable difficulty has been experienced in bonding a lift of concrete to the one previously placed and the result is seen in nearly all dams, piers and retaining walls, in the form of horizontal joints or lift planes. A superior practice is to complete the filling of any form in one continuous operation and thus avoid the danger of poor joints. (See Fig. 11.) Figure 12 shows piers 25 feet high placed in one continuous operation making a true monolith.

(*c*) Concrete should be placed in layers not exceeding one foot in thickness. Each successive layer should cover the entire area of the form and should be well worked into the previous layer. Not more than one-half to three-quarters of an hour should elapse between layers. These requirements demand good forms and a mixer of sufficient capacity to supply the concrete at the necessary rate.

(*d*) Water gain should be avoided or taken care of. When concrete is deposited in the forms and allowed to remain undisturbed, as should be done in placing, there is a tendency for the water to rise toward the top of the mass. In its upward travel the water is impeded by the aggregate and reinforcing steel. The result is an increase in the water content of the mortar immediately under the coarse aggregate particles and at or near the top of the mass. Water gain has been found to be a manifestation of the tendency of a cement to "bleed" or to give up the water mixed with it. The "bleeding" tendency of the cement has been found to be reduced as the fineness of the cement is increased and water gain in the mix is reduced as the design of the mix is improved and is less for the dryer than for the wetter consistencies. Frequently water is found to collect on the top of the concrete in the form while placing and this accumulated water can be absorbed by a few batches of dryer concrete provided that the quantity is not too great. Where the quantity of water is too great it is advisable to remove it from the forms.

Vibration

In the past, concrete has been almost entirely placed with the aid of hand tools, but more recently mechanical vibrators have come into prominent use.

Vibration is a new development and undoubtedly is a decided advancement in the art of making concrete, but because it is new our knowledge of its effect is not complete. At present, at least, it should be considered only an aid to the placing and compacting of the concrete in the forms. This will permit the successful placing of dryer and harsher

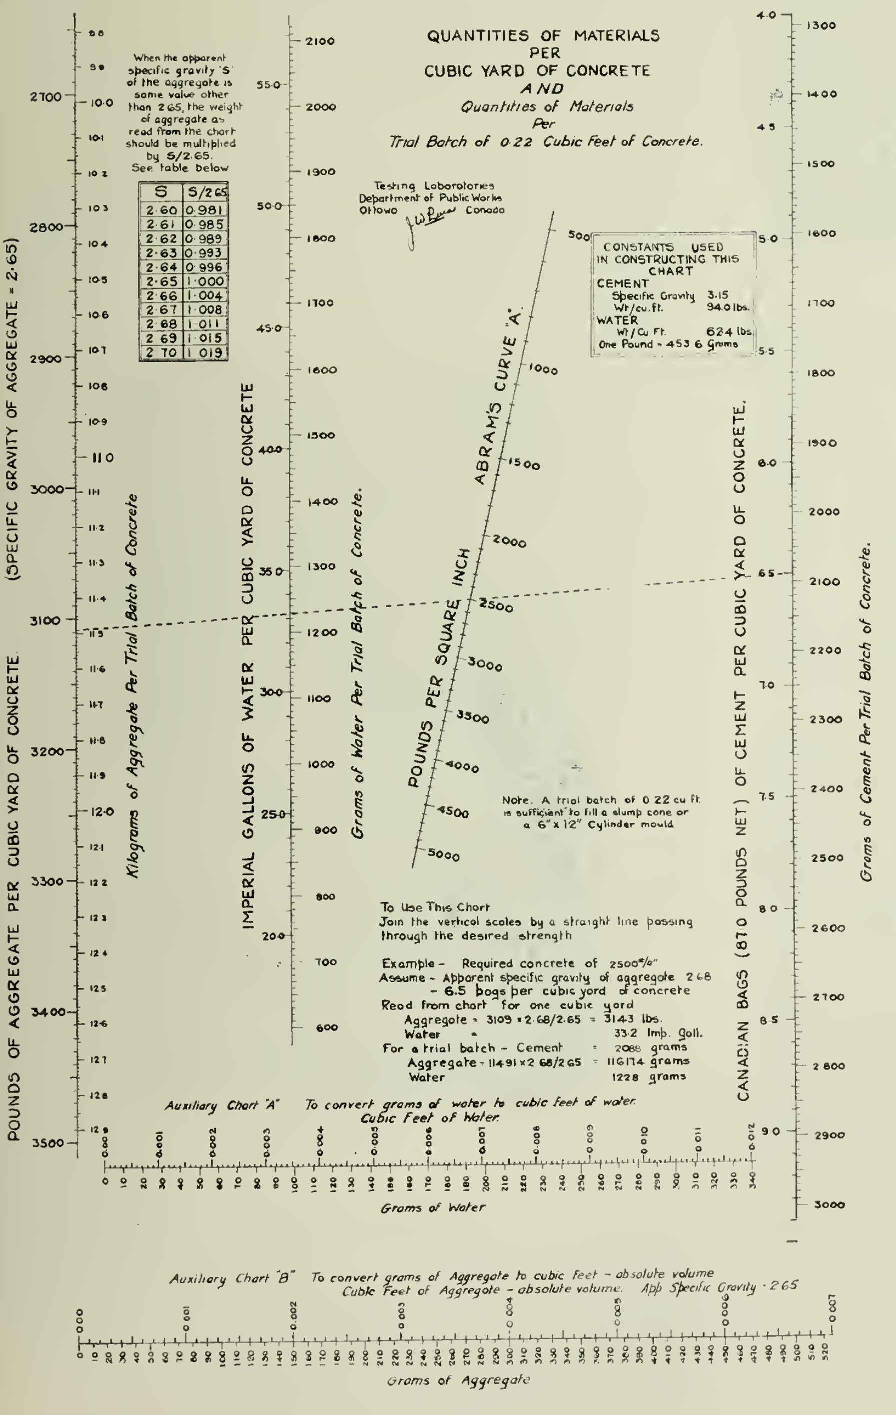

Fig. 10.

mixes than by hand methods. This makes possible either a saving in cement, if a constant water-cement ratio is maintained, or an increase in the strength of the concrete if the cement content is unchanged. Existing data would indicate that a saving in man power in placing the concrete is also possible. Against the saving in cement and labour must be balanced the cost of vibrating but it is generally conceded that an over all saving in cost is secured. In addition to the immediate saving in cost of the concrete

Fig. 11.

the effect of lower cement and water content, increased density, and a lesser tendency towards segregation and water gain, cannot be overlooked in the quality of the concrete produced. It was mentioned above that the design of the mix may be changed to effect a saving and in this connection it has been established that it is necessary to reduce the water and fine aggregate content in the mix to secure satisfactory results. This is so because the effect of vibration reduces the internal friction of the mixed particles to such an extent that if mixes of ordinary workability and consistency are used segregation will result. The amount of vibration required will depend upon the mix and the nature of the work, and care should be taken that it is not overdone to the extent of causing segregation.

Bonding New to Old Concrete

It has been stated that horizontal joints or lift planes should be avoided wherever possible. At times this is impossible and at other times it becomes necessary to bond new to old concrete. Where it is impossible to avoid lift planes the top surface of the concrete should be approximately a smooth surface. It need not, of course, be a plane surface, nor need it be carefully finished, but it should be smooth enough to permit easy and thorough cleaning and an effective glueing of the next lift of concrete to the hardened surface. When water gain takes place in a setting concrete mass the rising water carries to the surface very fine particles of aggregate and hydrated cement, depositing them there as a layer of laitance. This substance has a chalky appearance, having no appreciable strength, and of a porous character. Immediately below the laitance layer the concrete may be weakened and made porous through water gain.

In general, the securing of watertight joints, when bonding new to old concrete, is difficult, but if bonding must be resorted to the following methods may be used with fair success:

First Method:

(*a*) Thoroughly clean and dampen the surface of the concrete.
(*b*) Sprinkle neat cement on the dampened surface to a depth of about 1/16 inch.
(*c*) As soon as the cement becomes wet through from the moisture below, cover it with about one inch of mortar made with one part cement to two parts sand.
(*d*) Proceed on top of this with the regular concrete.

The cement film on the surface of the concrete acts as a cushion to receive the grains of sand of the mortar and the mortar acts as a thicker cushion to receive the coarse aggregate of the regular mix.

Second Method:

This method consists simply of cleaning and dampening the surface of the concrete and covering it with a rich cement grout, generally a 1 to 2 mix, to a depth of about one inch in which the regular concrete is placed.

These precautions are necessary if watertight joints are to be secured and from experience too much care cannot be taken. It will now become obvious that bonding new to old concrete in a satisfactory manner is not an easy matter, is costly, and wherever possible should be avoided by adopting such methods as will permit continuous placing.

Curing

It was pointed out earlier that time and definite conditions of temperature and moisture are necessary for the concrete to develop its required properties. The conditions required are the same in all cases but the method of attaining them may be different on different works.

Fig. 12.

Curing means the hydration of the compounds of the cement. Their hydration is a slow chemical reaction even under favourable conditions. For example, the result of many tests show that concrete under moist conditions at 70 degrees F. acquires during its first seven days about two-thirds of its twenty-eight day strength, and during its first twenty-eight days about 50 per cent of its five-year strength. The percentage of the different components of Portland cement and the time they take to react with water, as mentioned under "Components" and "Hydration of Portland Cement," will be found to be in harmony with these average strengths at these ages. Hence the importance that the average concrete be protected against low temperatures and kept damp for a period of at least ten to fifteen days. However, the service to which the concrete is to be subjected, the size of the members, the thickness of the slabs and the season of the year in which it is laid have to be taken into consideration. The smaller

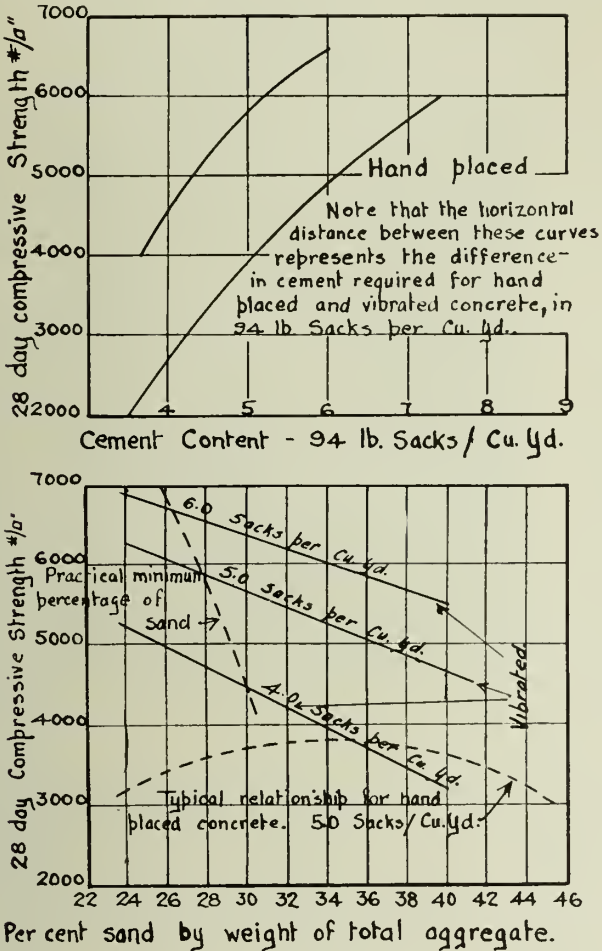

Fig. 13—Vibration Studies.*

the member or the thinner the slab the more protection it should be given.

*Curves taken from a paper entitled "Vibrated Concrete," by T. C. Powers, published in Vol. 29 of the Journal of The American Concrete Institute.

Concrete that is allowed to dry too soon after being laid, especially small members and thin slabs, such as road and floor slabs, will contract due to loss of moisture and will be subjected to stresses that are often greater than the strength developed, thus causing cracks. These cracks may not be visible to the naked eye for days or even weeks, nevertheless, they were developed in that early tender period.

In recent years more and more concreting operations have taken place during the late fall and winter months and there is no objection to that as long as the proper precautions are taken. For instance, no one would think of growing flowers and vegetables in the winter months in this country without doing so under artificial conditions. The growth of these is due to chemical reactions which do not take place unless the conditions are propitious. It is the same with concrete. What the concretor has to do is to learn that he must carry on his winter operations under artificial conditions.

In conclusion it may not be amiss to say that our knowledge of the proper use of cement has not spread as fast as its use. The methods in vogue thirty-five years ago are still in use today and this is true even on works of considerable proportions.

Our city building codes might well afford greater protection to builders and owners by demanding of concretors some proof of their ability and willingness to manufacture and properly place concrete of good quality. By such means the efficient and conscientious contractors would be benefited and the public would be protected against inefficiency and the unscrupulous.

The significance of studies of methods whereby more durable and serviceable concrete may be produced is revealed when one looks into the immense increase in the use of cement in a comparatively short period. In 1900 this country consumed less than 500,000 barrels. In 1920, nearly 6,000,000; in 1925, over 7,000,000; and in 1929, over 12,000,000 barrels of cement were used. Since then the consumption has materially decreased but this can, no doubt, be considered temporary.

12,000,000 barrels of cement represent in round figures 10,000,000 cubic yards of concrete and at an average cost of $10.00 per cubic yard, this would amount to $100,000,000. The annual expenditure of this sum of money indicates the magnitude of the concrete industry in Canada and in the opinion of the authors justifies the expenditure of considerable effort in securing concrete of better quality than much of that produced today. The added inconvenience and cost of repairing or replacing leaking walls, dams, dusting floors, crumbling and unsightly structures of many kinds certainly warrants the study of known methods of producing serviceable and durable concrete.

Electric Heating

As Applied to Hydraulic Control Gates, Buildings and Industrial Processes

Lee P. Hynes,
President, Hynes Electric Heating Company, Philadelphia, Pa.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, April 11th, 1935.

SUMMARY.—The author discusses methods of employing electric heating for the prevention of ice troubles in hydraulic regulating gates and the equipment desirable for this purpose. Notes follow on the use of electrical energy for heating power houses, substations and buildings generally. The paper also deals with some problems connected with industrial heating processes.

Heat is produced in an electric circuit by introducing some conductor which resists the flow of current. This resistor may be a metallic wire or ribbon supported on suitable insulators or embedded in a compacted refractory material. It may be some form of non-metallic conductor, rod, plate, or filament. Some liquids may be used as heat producing resistors, a familiar example being the electrode boiler. Heat may also be produced by induction at high frequency.

In Canada great resources in water power help to offset a lack of certain fuels. An abundant supply of low cost electric power has made possible several developments in electric heating which conditions in the United States have not encouraged. There, the higher cost for electric power and the competition of highly developed automatic fuel heating, have forced an intensive study of ways to apply and control electric heat. Like all new developments, it has suffered somewhat from overzealous promotion and inexperienced planning. However, progress is being made and electrically produced heat is beginning to receive the consideration it deserves.

Electric Heating as a Means of Ice Prevention

The entire field of electric heating is so large that only a few of its phases can be discussed here. One subject of special interest is ice prevention, particularly in relation to hydroelectric projects. In many parts of Canada winter conditions are particularly severe but also in much of the northern portion of the United States there is trouble with ice. This trouble is not entirely proportional to the severity of the climate but depends somewhat upon the characteristics of the river. Large streams, like the Susquehanna river, which have a rapidly changing flow, require careful regulation wherever dams are built. Experience at Conowingo and Safe Harbour has definitely proved the value of electric gate heaters even for the comparatively mild climate of southern Pennsylvania.

Fig. 1—Troublesome Ice Formations with Unheated Two-Leaf Gates.

Wherever freezing occurs, ice must be combatted at seals, guides, gate faces and sills. The ice problems are essentially the same for all types of gates and require similar treatment. Air bubblers help to reduce surface ice formation on the pond but heat is also necessary to keep gates in an operating condition. Electric heat has proved particularly suitable for this service and some methods of applying it will be considered.

When gates are opened any adjacent equipment is subjected to powerful water currents, floating ice and logs, so that any heating structure used must be capable of withstanding such conditions as well as exposure to weather. A practical method for heating seals and guides has been found by providing heater wells in the masonry. In some instances this is done by embedding a 4-inch pipe near the roller bearing guide plates and the seals. An even better method is to form the guides of structural steel members so that the roller track forms one wall of a hollow rectangular well. In any case, it is essential to provide suitable heater wells when designing the masonry structure of a dam. These wells must extend from the surface of the dam down to the sill and have drainage holes at the bottom. They do not need to be waterproof at any point, their function being merely to provide a protected space into which suitable heaters may be inserted.

The heaters themselves must be completely waterproof. They give their heat to the walls of the well and it is conducted through the guide plate and the adjacent masonry so that ice will not form where it can interfere with free movements of the gate. Many types of heater construction have been tried but experience has indicated that one of the most practical methods so far developed is to construct sectional, waterproof heater casings of metal tubing of $2\frac{1}{2}$-inch pipe size. The bottom is sealed and the top is closed by a waterproof fitting arranged for threaded conduit connection.

Inside this waterproof casing is located a long flexible heating element manufactured in convenient sections for shipment and field splicing, and consisting of a series of rigid porcelain blocks mounted on a flexible flat metal bar. These insulators have substantial ribs which guide loosely against the sides of the casing. Flexible Nichrome heating-elements extend through openings in these insulators and are safely spaced away from the metal walls of the casing. This construction permits flexibility and avoids breakage in handling or from expansion and contraction. The glazed porcelain insulators readily withstand heat and moisture and no difficulty is experienced with properly installed heaters on 550-volt service.

The pipe casings are carefully fabricated in convenient lengths, thoroughly cleaned inside, and marked for field assembly. After assembly the complete casings should be tested with air under pressure for loose connections. Each casing can then be lowered into a heater well and permitted to hang freely from its top fitting. All inlet openings should be kept carefully plugged until the heating elements are installed so that water and dirt will not get into the heater casings.

As the heater sections are spliced together the electrical circuits are joined by flexible metal bus bars. They are then lowered into the heater casings through a 3-inch threaded opening in the top fitting. The top heater section is provided with a hoisting hook which engages a shoulder in the top fitting of the heater casing so that the entire heater hangs suspended by this hook. This leaves it completely free to expand or contract without strain or buckling. Each insulator is spaced from its neighbour so that regardless of the length of the assembled heating element no insulator has any strain except its own weight. The flat metal strip acts like a backbone to carry all the insulators. Suitable terminals are provided on the top insulator so that it is a simple matter to connect circuit cables from the conduit. After this is done a 3-inch pipe plug is screwed into the top opening, through which the heater was inserted, thus making a water-tight closure.

Fig. 2—Safe Harbour Dam with Heaters Installed in Masonry.

When the heaters are ready for testing all the top plugs should be removed and the heat be turned on for about thirty minutes to thoroughly dry out any moisture which may have condensed inside the heater casings during construction. Each heater should then be tested for insulation to ground. Forty megohms is easily obtained although readings will often run as high as 100 megohms, depending upon the amount of moisture present. Moisture will not break down the heaters but every precaution should be taken to avoid reduced insulation value, particularly when heater circuits are connected to the station ground-indicator system.

It is seldom advisable to connect several heaters in series as this complicates the wiring and in case of circuit trouble in the conduits may cause an improper voltage to be impressed upon some of the heater sections.

Heaters should be arranged in groups of convenient size with a balanced phase load, each group being controlled by an independent switch and fuses. Remote control is desirable so that heaters at any location can be thrown on from a convenient station in the power house.

The complete heating system should be tested early each fall while the weather is still good, each group being isolated and tested with a megger to locate any insulation fault. A check of the circuit loads should also be made.

In addition to heating the vertical gains it is often necessary to heat the interior of gates. The best method is to close in the downstream side with heavy matched lumber and building paper so as to make a closed air compartment. Heaters are then placed inside of this compartment. Interposing this warm air chamber between the cold air and the face of the gate prevents the freezing of heavy ice masses on the upstream face. By locating a considerable amount of heat as low down as possible, the gate bottom can be warmed sufficiently to reduce ice formation where it rests on the sill. This is important so that when the gate is raised it will not pull the sill timber up from its bed. Where gates are heated internally the top and the face above the water line should be covered with matched lumber and building paper to reduce heat losses.

Large rectangular gates of the Stoney type have numerous partitions which serve as structural braces. These interfere with the installation of heaters. Horizontal waterproof pipe heaters of similar construction to those described for the gains may be installed. Some of these should be located close to the bottom so that some heat will be conducted toward the gate sill. Other heaters can be spaced at higher levels according to local conditions and height of water line.

Another method of applying internal gate heaters to this type of gate is to cut a series of vertically aligned holes through the horizontal partition plates and to insert from the top, vertical heater pipes. This arrangement is completely waterproof, is protected against mechanical damage, and has convenient and readily accessible connection fittings at the top. Heaters can be designed so that any section of the vertical heater will deliver concentrated heat at any desired point.

It is, of course, necessary to have flexible connections to carry the electrical circuit from the stationary dam structure to the movable gate. Cables can be connected with plugs and receptacles if care is taken to house them in a suitable shelter from the weather. In some cases it is thought better to make a splice in the cable. If necessary, this can be disconnected and spliced again.

Fig. 3—Inserting Flexible Electric Heater in Curved Pipe Casing.

Taintor gates can be heated in a similar manner to vertical lift gates by installing curved wells in the masonry at the back of the guide plates. Curved waterproof heater casings of the same radius can readily be inserted and the flexible heating elements will slide freely into this curved casing. Conduit connection can be made at the top exactly as for vertical heaters. For the internal heating of Taintor gates the downstream face should be closed in with timber and building paper and horizontal heater pipes installed in the bottom corner of the gate over the sill. Conduit connection from this heater can be brought out to the pivot point of the gate so that a flexible cable connection will have a minimum movement when the gate is raised or lowered.

Motor driven blowers have been tried for circulating warm air throughout gate interiors. By cutting holes through the partition plates, and erecting suitable baffle walls, a complete air circuit can be arranged. This method does not seem to have any advantage over direct electric heating without a blower and appears to have some disadvantages. A motor driven blower located within a gate is not readily accessible and if it fails for any reason, the air circulation ceases. Where heating elements are arranged in a compact group adjacent to a fan the highly concentrated heat is carried away by the rapidly moving air blast but if this ceases for any reason a thermal protection device must function to cut off the heat energy, and prevent local overheating. It would seem that gate heating is too important to depend upon the operation of any automatic equipment, and that if a fan is to be used at all, the heaters should be distributed throughout the interior of the gate in such a way that they could continue to operate satisfactorily in case of interruption to the air flow.

Fig. 4—Waterproof Gate Showing Top Fitting and Heating Element.

Any heater located within a gate should be fully enclosed so as to be waterproof and protected from mechanical damage at all times. In other words, it is advisable to use the same type and location of heaters in a gate whether fan circulation is used or not and it is to be doubted whether anything is gained by using a fan. It only adds to the first cost of the equipment, to the necessity for inspection, and to upkeep. The fan also has the disadvantage of distributing the heat about equally over the downstream and the upstream faces of the gate whereas direct heating permits a better control of heat application through conduction and local radiation to adjacent gate surfaces.

It has also been proposed to heat gates by means of pipes through which electrically heated oil is pumped. A pump has at least as many chances for failure as a fan and the heating of oil is a more exacting problem than the heating of air. Circulating hot oil is a useful heating medium for some types of industrial process work but there does not appear to be any advantage in using it for gate heating. In fact it would be less satisfactory than direct gate heaters in at least three important respects.

Greater original cost;

Less reliability under all service conditions, particularly on the higher voltages;

Greater maintenance and inspection costs.

Waterproof electric heaters similar to those described can be buried in earth or concrete to combat ice. They can be installed in valve pits, surge tanks, air vents, downspouts, risers to water towers and similar places. Straight or curved sections of any length can be installed as easily as steam pipes. Electric heaters never freeze up and require no drainage connections, and where ample power is available they have many practical uses.

There have been many efforts to combat frazil ice by means of electric heat. Experiments have been made by Mr. C. R. Reid at Shawinigan Falls and somewhat similar work has been done on a smaller scale in the United States. The best method seems to be the one used by Mr. Reid, which was to connect the steel trash-rack bars in series with each other, using wooden timbers for insulating spacers. A high current was passed through these bars so that they served as resistors. It is, of course, impossible to raise the temperature of the river itself but ice is a comparatively good heat insulator. When it starts to form on the surface of the bars it shields them from the cold water and their surface temperature is raised sufficiently to loosen the ice film.

This method requires the installation of large transformers and while in operation may require a considerable proportion of the station output, but it will undoubtedly prevent blocking of the intake bars. Fortunately this type of ice condition occurs for rather short and infrequent periods so that as a matter of insurance against shut-down the installation may sometimes be justified. It is believed there is no other way in which heat can be successfully applied to combat this troublesome ice problem.

The Heating of Power Houses, Substations, Etc.

There is a great deal of waste heat from generators and other electrical apparatus, some of which can be utilized to advantage for heating purposes. Where attendants are always present it is possible to regulate manually the delivery of hot air from electrical equipment for room heating, but this can be more satisfactorily accomplished by automatic regulation. A thorough air circulation is necessary in order to distribute and equalize the heating effect, and in some cases waste heat from electrical machinery can be conveyed to other rooms for heating purposes. When there are periods in which little waste heat is available combination systems can be arranged which normally utilize waste heat but call upon auxiliary heaters when necessary.

Some hydro-electric stations use large portable electric fan heaters, mounted on wheels so that they can be rolled into position, and connected by cable and plug to stationary receptacles. Heaters of this kind should have built-in automatic control, mounted with the motor, on the cool air intake side. These heaters are also useful for emergency heating purposes, such as drying out wet machines. In other stations heaters are mounted on the walls at various locations so that they can be started when needed.

A completely automatic system has recently been designed which will bleed from the generators just enough waste heat for the winter heating requirements, regardless of varying weather conditions and generator loads. This heat will be thoroughly circulated by blowers handling a total of 36,000 cubic feet per minute. Auxiliary electric heating will be installed to take care of certain emergency conditions.

An outdoor supply of fresh air will be introduced under selective automatic control when required for cooling the building. This will vary in volume as required, up to a maximum of 36,000 cubic feet per minute. All of this equipment is completely automatic and will function properly without any manual operation. Both heating and cooling of a large building will be accomplished at an expenditure of about 10 h.p. for driving the blowers.

Unattended substations which do not produce much waste heat can best be heated by fan circulation electric heating units. Automatic control is absolutely essential for economical operation and because no attendant is regularly present, it is not necessary to consider human comfort. The essential thing is to prevent condensation during certain weather conditions. The comfort of inspectors or attendants when they are present can be provided for temporarily. A special form of automatic control known as "dewpoint control" has been devised for this service. It is a type of thermostat having a bulb sensitive to indoor air temperatures and an extension through the wall with a bulb sensitive to outdoor air temperatures. These two bulbs co-operate to produce a resultant indoor temperature which varies, but keeps 15 degrees above the outdoor temperature. If the outdoor temperature is 20 degrees above zero the indoor temperature will be 35 degrees but if the outdoor temperature rises to 45 degrees the indoor temperature promptly goes up to 60 degrees.

Condensation forms on the interior walls of a building and on electrical machinery exactly as dew forms out of doors. This happens when warm, moist air comes in contact with colder surfaces. In a substation the walls and equipment get thoroughly chilled during long cold spells and when these are followed by a sudden warm, damp spell, fresh air entering the building comes in contact with colder surfaces which lower its dewpoint and moisture is deposited. This variable form of dewpoint control is essentially an economy device. Inasmuch as a constant temperature for comfort is not necessary in an unattended station, advantage can be taken during cold weather to make a decided saving in power for heating, by allowing the internal temperature to drop. This would not be possible without some way to raise the internal temperature promptly when the outdoor air grows warmer, but with a variable control a heating system can be safely maintained on a 15-degree temperature difference.

The Heating of Buildings

Electric heat is often suitable for offices and other buildings besides electrical stations, but each project must be studied in relation to rates and to the available power supply. A given installation may be entirely justified in one case and quite unwarranted in another. Large single-phase loads are undesirable but balanced polyphase heaters are available for any voltage.

Many rate schedules include a demand charge based on total connected load. This places a considerable burden upon electric heating if it is only used during a few months of the year. It is not so serious for industrial processes that are used constantly and it actually works in favour of electric heating wherever power can only be used during "off peak" periods when industrial load is at a minimum. Even where rate schedules do not offer direct inducements to use "off peak" power by special low rate steps any user can benefit through avoiding added demand. This can be done by arranging his operating schedule so that the heating load will never be superimposed upon other loads, thus not exceeding at any time the normal demand which other equipment obliges him to pay for. When this is done it is only necessary to pay for the actual cost of the power consumed in heating and at the sliding scale of rates which are customary for industrial plants, this heating load will usually fall into a favourable bracket.

Considerable mistaken effort has been made attempting to sell "off peak" power for electrically heating homes by storing heat in tanks of water. Several factors serve to discourage this method for buildings which normally require a comparatively small power service. While this heat storage method could fit into the generating "off peak" periods, ordinary buildings are not served by distribution lines capable of supplying the heavy power required during the heat storing periods. It is also difficult to adjust the heat storage to suit quick variations in weather. Efficiency may be fairly high on a cold day and exceedingly low on a mild one. This disadvantage is not shared by competing types of modern automatic fuel systems. No way of storing electric energy has yet been found comparable to the energy stored in oil or coal.

However, the principle of utilizing "off peak" power is perfectly sound when properly applied. When studying the economic possibilities of "off peak" electric heating, the existing power service must be considered. Industrial plants with a heavy motor load can often use large amounts of power for heating purposes, during periods when other equipment is shut down. This does not cause any increased demand and considerably improves the plant power factor.

As an example, a large paper box factory in Philadelphia has its own printing room located on the fourth floor. The rest of the building is used for storage or for rough work requiring little heat, but the press room has to be heated at all times. If this room is allowed to cool at night, trouble is experienced in the morning with the printing processes.

Two years ago it was decided to install 50 kw. of auxiliary electric fan heaters in the press room. The motor supply service was ample to carry this load so no extra wiring was needed. The boilers in the basement were shut down at night and over week-ends. The press room was satisfactorily heated at night to 60 degrees F. with a decided saving over the cost for a night fireman and fuel.

Carefully planned "off peak" auxiliary electric heating of this kind deserves consideration from power companies and industrial engineers. Most large plants, if properly surveyed, would reveal possibilities for its economical use.

For large rooms fan circulation electric heaters are usually installed on the walls. Combination steam and electric units are frequently used. Small rooms and offices are usually heated by compact heaters set on the floor to deliver a gentle current of warm air without drafts.

Electric heating is well suited for central fan duct systems of heating and ventilating and numerous installations have been made in moderate size office buildings. The blower can be located in a penthouse on the roof or in the basement. Fresh air supply is taken in through a heating chamber and each branch air delivery duct has its own individual heater. Return ducts to a mixing chamber permit any desired proportion of recirculation.

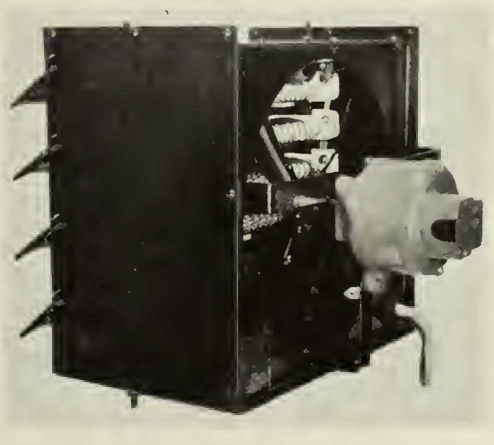

Fig. 5—Fan Circulation Electric Unit Heater.

Special automatic control is necessary for a duct heating system. It is not satisfactory to throw the heat on and off by an ordinary thermostat, because this would produce alternate blasts of hot and cool air. It is absolutely necessary to vary the heat input and accurately adjust it so as to maintain a uniform temperature of air flow regardless of its volume or of weather conditions. In some cases the mixing dampers controlling the volume of fresh air supply are manually adjusted but in other cases they are automatically regulated. When this is done the control must be co-ordinated with the control of the heater input. Heaters are arranged in balanced stages and the control automatically selects the heat stage which most nearly balances the demand for heat.

Electric heaters are often used as auxiliaries to steam heaters in duct systems during mild weather. By properly locating them in local branch ducts, individual rooms can be heated without starting up the boilers.

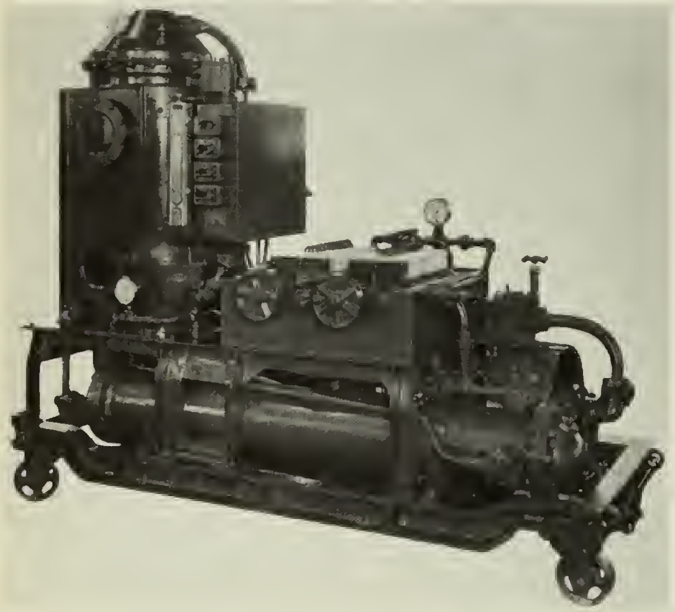

Fig. 6—Electrically Heated Vacuum Oil Purification Machine for Cable Oils.

Duct systems are often designed for heating in winter and cooling in summer. Where a sufficient supply of cool water can be obtained from deep wells a spray chamber will provide adequate summer cooling and complete year-around air washing. Electric heaters installed in the same duct system will provide for winter heating or they can be used as auxiliary to steam heating. Many combinations can be worked out but all require careful engineering and adequate automatic control.

Reverse cycle refrigeration equipment has sometimes been referred to as a form of electric heating but this is not strictly correct, although the heat energy delivered may be as much as two or three times the kilowatt power input required to drive the motor. However, heat is simply pumped from one medium to another and exactly the same result can be obtained by driving the equipment with an internal combustion engine instead of an electric motor. This reverse cycle equipment is an interesting and useful process, which would appear to be most useful in moderate climates where the winter heating requirements are approximately equal to the summer cooling requirements, as the efficiency of the heating cycle falls off rapidly with low outdoor temperature. Equipment of this kind may have a practical use as a means for salvaging low temperature waste heat from industrial processes, thus reducing overall thermal loss.

Industrial Heating Processes

Industrial process work offers a large field for electric heating wherever steam is not available or where temperatures are required outside the range of saturated steam.

Electric heaters have a constant energy input and their surface temperature depends on the rate at which heat is taken away from them. In this respect they are entirely different from steam where the temperature remains constant for a given pressure, but the condensation rate changes according to demand.

Direct applications of electric heaters are difficult to control where demand for heat fluctuates rapidly or for materials of low conductivity. Many materials can best be heated in tanks or vessels by large banks of radiation heaters mounted adjacent to their walls. This gives a uniform input of heat over large areas so as to maintain low heat density and the interior of the vessel is kept free from obstructions. Heaters of this construction are suited for high voltage polyphase circuits and can be arranged in balanced steps to permit variations of heat input. A proper design of vessel with good heat insulation is always necessary.

Pitch is successfully heated by this method in large vertical or horizontal tanks. In coating steel pipe the comparatively thin walls do not require pre-heating. The pipe is dipped cold and is heated by immersion in the hot pitch. This produces a very superior coating as the pitch temperature can be accurately controlled and volatile constituents are not wasted.

Cast iron pipe requires a different process owing to its heavy walls. It should be preheated to approximately the pitch temperature before dipping. A unique installation has recently been made where the pipe is preheated in a gas oven, then dipped in an electrically heated pitch tank. This continuous process permits large production with a very superior quality of coating. Electric heat can often be used for the accurate key part of a process while the bulk of the heat input is obtained from some cheaper and less responsive source.

Large tanks of water are often heated by installing heavy welded tubes with internal heater elements similar to those described for gate heating. The large tube surface permits heavy ratings and the heater design is well suited for high voltages. All electrical parts are easily inspected or renewed without draining the vessel. Large tanks of heavy oil can also be equipped with similar heaters of low surface density, to reduce viscosity and permit flow in cold weather.

For heating oils to high temperatures a more refined method is necessary. Oils have comparatively low rates of thermal conductivity and sluggish convection currents. The temperature gradient of the heater must be kept as small as possible, and a positive uniform flow must be maintained. The heating elements must have a minimum of heat storage capacity to prevent carbonizing the oil from stored heat when flow stops due to shutting down the process.

Uniform flow over all surfaces cannot be secured with ordinary immersion heaters nor with tube heaters as described. A successful method has been found by arranging a series of narrow, flat, staggered passages having walls constructed of thin heater sections. Oil is pumped through these passages so that any desired rate of flow is assured.

This method is widely used in preparing insulating oils for centrifugal purification. It is also used in heating oil baths for tempering steel. Hot oil is a good high temperature medium for heat transfer with coils or jacketed vessels. Special oils are used and pumps, automatic control, expansion tanks and piping must be properly designed, but temperatures up to 600 degrees F. are successfully used with not more than 20 pounds per square inch pressure. This extends the temperature range for jacketed aluminum and copper vessels beyond that permissible for steam, and removes all hazards due to high pressures.

There are many other uses for circulating hot oil. One is for high temperature platens of hydraulic presses, where steam pressures up to 800 pounds per square inch are sometimes necessary. The serious problem of making flexible connections is simplified by using hot oil at 25 pounds pressure.

Sulphur is a poor conductor of heat but large batches can be melted safely by hot oil pipes spaced through the mass. Hot pipes have also been formed into revolving agitators to distribute heat through heavy materials. Vessels heated by steam jackets or coils can often be quite easily converted for oil heating. Hazardous chemical processes are more safely heated by hot oil than by direct firing. Temperature control is also much more accurate.

Electric heat is useful for many drying processes. Radiant reflector heaters can be used above the moving surface of silk and cotton fabrics in dye works and over plate glass travelling from the washer in making laminated safety glass.

Many industrial processes can be improved by using electric heat and automatic control, but in each case careful planning is required. Unless the job warrants being done well, it is usually wiser not to do it at all. There are so many variables in electric heat engineering that successful performance is seldom the result of chance.

Heavy Forgings and the Use of Alloys

M. F. McCarthy, Assistant to the President,
and
E. Voorhees, Chief Metallurgist,
Erie Forge Company, Erie, Penna.

Paper presented before the Niagara Peninsula Branch of The Engineering Institute of Canada, May 2nd, 1935, on the occasion of a visit to the Canada Forge Plant of Canada Foundries and Forgings Limited, at Welland, Ontario.

Forging of metal, in one form or another, is one of the oldest arts known to man and there is evidence that iron was well known to the Assyrians, Chaldeans and Babylonians, long before the time of Christ.

Though the use of iron was widespread, it was considered by the ancients as a rare and precious metal. This was not due to the scarcity of ore but to the difficulty in smelting it. The iron workers of ancient days made iron in a hole dug in a hill-top. A tunnel was then dug through the side of the hill to the bottom of the fire-hole. The wind rushing through the tunnel gave the required draught, but the difficulty with melting in this sort of furnace was that it could be used only on windy days. Finally in Catalonia, Spain, the Catalan forge was made and was the standard furnace for making iron during the Middle Ages.

Steel implements must have been used in the construction of certain of the earliest ancient monuments but little is definitely known of the method of making steels in ancient times.

The famous steels of Damascus and Toledo were made by a crude form of crucible process but this method was lost during the Middle Ages and was not re-discovered until 1842 when Benjamin Dustman, an English watchmaker, found that by breaking or shearing small pieces of "blister" steel and melting them in a clay crucible, he was able to obtain a steel which when worked up into watch springs served in a very satisfactory manner. This was crucible steel and was very popular until the advent of the Bessemer and open hearth processes.

The first open hearth furnace in the western hemisphere was built at Trenton, New Jersey, in 1865 and had a capacity of five tons requiring from seven to eight hours to complete a heat. Five years later a second open hearth furnace was built at South Boston, Mass. All heats were tapped on a fracture test, as laboratories were then unknown. The pig iron and manganese for these early open hearth furnaces were imported from abroad and it was not until the early seventies that steel mills in this country made their own ferro-manganese.

In 1872, the Quebec Steel Company of Quebec had a three-ton open hearth furnace making tool steels. In the early days of the open hearth furnace, twenty-five to forty-eight heats constituted a satisfactory "run" for a furnace while today the modern open hearth furnaces, manufacturing forging quality steel ingots, ranging in capacity from thirty-five to one hundred and fifty tons, turn out from 500 to 800 heats at a "run" without major repairs. The average time required for producing a heat in the modern furnace is from ten to twelve hours.

Fig. 1—Mine Hoist Drum Shaft Forging under 600-ton Hydraulic Press from 48-inch Ingot part Forged at this Point.

The first forging tools known to man were the hand-hammer and the anvil. With the progress of civilization the limitations of these tools were recognized and with the development of uses for heavy iron and steel tools, implements, machinery and equipment, the power-hammer came into being. The first power hammers were of the helve or trip types, usually operated directly from the shaft of a water wheel.

The steam hammer as invented by James Nasmyth in 1842 was direct acting and a decided improvement over the trip and helve types, but was defective in several ways. The valves were operated by hand and it was often difficult to raise the ram immediately after a blow was struck. This had a tendency to chill the metal being worked on the die. The steam hammer remained in this state until Robert Wilson applied a valve motion which enabled the blows to be regulated both in speed and force, thus placing the hammer absolutely under the control of the operator.

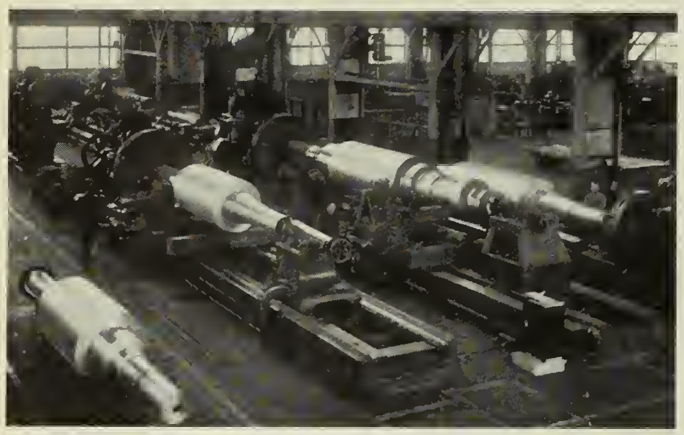

Fig. 2—Steam Turbine Generator Shafts .45 Carbon Steel, Annealed 52-inch diameter of Shaft. Weight 96,000 Pounds Each.

The steam hammer has been a potent factor in the development of the steel industry and today is but slightly different from those made by Nasmyth and Wilson. The improvements made since it was originally invented have been mostly on the valves, the guides for the ram and the general construction of the frames. The smaller sizes are of the single frame type, while those intended for heavy forgings have an arched or double frame.

Later, as further developments in machinery progressed, larger forgings were specified and in order to meet this growing demand the forging press was developed to handle this heavier work.

There are two general types of forging presses in use. First, the regular hydraulic forging press, in which the water pressure is furnished by independent pumps. Second, the steam-hydraulic press in which the hydraulic pressure is produced by means of a steam intensifier. The former type is not now used to as large an extent as the latter, which has a number of advantages over the simple hydraulic type, the principal of which is rapidity of operation.

The power of a hand-hammer is not derived from its weight alone but from weight combined with velocity and the same is true of all kinds of drop-hammers. The power of a drop-hammer depends solely upon the mass of the hammer and its lift, whereas certain types of hammer operated by steam or compressed air obtain additional power by increasing the acceleration beyond that caused by gravity alone.

There is a field for both the drop and the steam hammer as well as the forging press, the former appliances being most suitable for small work, and the forging press for large work. The reason for this is, that small pieces cool quickly and as a rule require a finer surface finish than is demanded in large forgings. Since the hammer strikes a blow, the penetrative force of the impact increases as the forging cools, so that work done on the surface of the forging even when it is quite cool affects the axis of the piece, otherwise the work of a hammer is most effective on the surface. The press, on the contrary, would be powerless to do any work on cold pieces unless the anvil surface was greatly reduced. Thus the hammer will probably always be used for small work and for making tools. However, the features which make the hammer desirable for small work, make it undesirable for large work. The hammer acts upon the surface of the material driving the surface over the core without compressing the latter. The press, on the other hand, exerts a continuous pressure which forces the semi-fluid material at the axis of the forging to flow under compression, which process tends to increase the density of the material. It is thus evident that from the standpoint of improving the quality of the material in forgings, the press is superior to the hammer and would be considered even more useful if under equal conditions it consumed less steam than a hammer. The press is definitely easier on the cranes and other tools used at a forging unit.

There are three means of working hot metal into shape: the hammer, the press and the rolling mill. When speaking of forgings the rolling of the steel is usually overlooked, but the bulk of the steel tonnage used in industry is really turned out by this process.

Alloy Steels

About the end of the nineteenth century alloy steels were developed when it was found that when certain elements were added to ordinary carbon steels a wide range of improved physical properties were obtainable, including much greater strengths. In the majority of cases, heat treatment is necessary to bring out these advantages. Alloy steels untreated are usually brittle and unsatisfactory.

Alloying elements used in steels for forgings may be divided into three groups, based on whether or not the element is completely dissolved by the iron or ferrite, combines with the carbon to form a carbide in the pearlite or is partly dissolved by the iron and partly forms a carbide, thus strengthening both the pearlite and ferrite. Such a classification can at best be based only on the general affinity of the alloying element for carbon, since both the amount of the carbon and the alloying element present determine to a considerable degree whether the alloying element will be dissolved by the iron, combine with the iron or both. Elements which are dissolved by the iron generally increase the strength and toughness of the steel and those

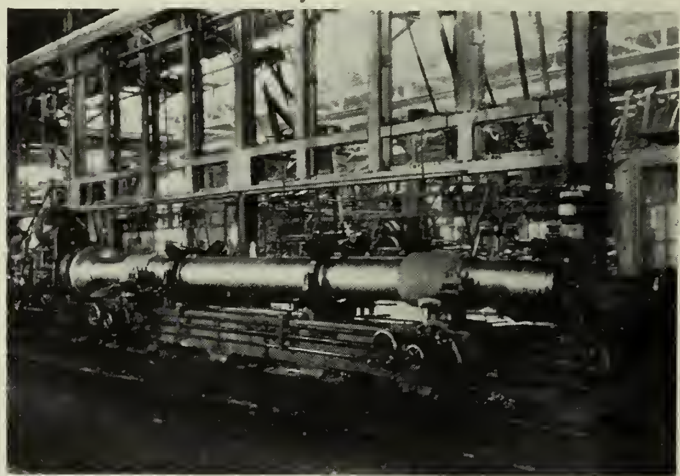

Fig. 3—Noranda Hoist Shaft. Weight 31,180 pounds.

which combine with the carbon to form carbides increase the hardness, therefore elements which are partially dissolved by the iron and also form carbides have the general tendency to increase both the toughness and the hardness. The prevailing practice is to use two alloying elements, one to build up the strength of the iron or ferrite, the other to strengthen the pearlite by the introduction of carbides.

Nickel

Nickel is one of the two most widely used alloying elements in machinery steel, but is little used in tool steels.

Its principal use is in large forgings where toughness and strength are required and is outstanding because of the fact that it combines with or is dissolved by the iron in any proportion and does not normally form a carbide. Therefore, as would be expected, nickel increases the strength and toughness of the steel without materially increasing the hardness. The nickel content of commercial nickel steels in forgings varies and is effective from one-half of one per cent up to about six per cent. Each one per cent of nickel up to five per cent raises the tensile strength about 5,000 pounds over the corresponding carbon steel without loss of ductility or material increase in hardness. In non-magnetic steel, corrosion resisting steel, and heat resisting steels, the nickel content may reach 60 per cent.

Chromium

This element may be used in forging steels in the range from one-half per cent to two per cent. It adds strength and hardness by the formation of carbides. In forgings, it is generally used with nickel, vanadium or molybdenum and gives its best results in material which is to be quenched. Its use in connection with nickel for heat and corrosion-resisting materials has proved to be absolutely necessary.

Vanadium

This is the most expensive of the ordinary elements used in steels. It is used in smaller amounts than the other alloys and the effect of adding as little as .05 per cent is distinctly noticeable. The use of more than .20 per cent vanadium does not appear to be particularly beneficial in machinery steels. Vanadium was first used as a scavenger or cleanser in the molten state but it is now well recognized that the properties it imparts to steel are due chiefly to its effect when present in the steel as an alloy. The presence of vanadium produces fine grain, probably by promoting simultaneous crystallization on many nuclei or centres as the steel passes through the solidification range and the transformations in the critical range. Carbides containing vanadium diffuse less rapidly than when the vanadium is not present; hence steels with this element have to be heated to higher temperatures to obtain diffusion than in the case of plain carbon steels. A mere "pinch" of vanadium in almost any alloy steel so retards the growth of austenite grains that the leeway in heating for annealing or quenching is greatly increased and the danger of brittleness resulting from heating the steel too hot or heating too long is minimized. The benefit from the presence of vanadium is intensified when chromium is present; consequently, excepting in the carbon vanadium steels, vanadium is nearly always supported by chromium. Vanadium itself adds little to the strength of steel except that due to reduced grain size the yield point and elastic limit are higher. From .15 to .20 per cent vanadium is added to straight carbon steels to obtain greater toughness, uniformity, resistance to grain growth when overheated, and to decrease the danger of breakage when water quenched.

Molybdenum

Molybdenum was used as an alloy in some of the old self-hardening crucible steels previous to 1880. In these steels it replaced the tungsten or rather, a part of the tungsten. It is a carbide former, increases the hardness and affects the critical points all in the manner of tungsten and also increases the depth effect of heat treatment. It is used as an alloy in machinery steel in amounts up to .50 per cent and usually in combination with other alloys such as chrome or nickel, or both. The tendency to temper-brittleness so prevalent in most combinations of nickel-chromium steels is retarded or minimized by addition of molybdenum in amounts of .20 to .50 per cent.

Manganese

Manganese is necessary in alloy and carbon steels and is added to all steel because of its effect as a scavenger in removing gases and their products, and in order to combine with the sulphur and obviate the harmful red-short effects of sulphur. Manganese adds toughness and strength to low carbon steels by retarding precipitation when hardened. In large size forgings used in the normalized condition, the so-called intermediate manganese steel (i.e. 1½ to 3 per cent) is somewhat erratic under heat and requires special care in forging. The value of manganese as an alloy is increased by combining with it another element such as vanadium, nickel or molybdenum. With either of these

Fig. 4—Hydraulic Turbine Shafts. Hydraulic End .45 Carbon Steel Annealed.

elements supporting the manganese, very satisfactory normalized and tempered forgings can be produced. Such forgings are used in considerable number for locomotive driving axles, crank pins, connecting rods, etc. Normalizing is the reheating of the steel after forging and subsequent cooling, usually in still air, to refine the grain structure and relieve forging stresses. This improves the quality and strength of the steel as well as its machineability.

Silicon

Silicon is used in practically all commercial steels as a deoxidizer but its use as a true alloying element has been limited in machinery steels. Silicon is not used as an alloy in forging quality steels.

Heavy Forgings

The production of a large forging really starts when the engineer designs the finished machine or tool in which it is to be used. The design of the forging, as well as the dimensions, is thus determined beforehand. In some cases the physical properties required of the finished forging are given to the steel and forging maker, who decides of what class and kind of steel the forging should be made to give the desired results. In other cases only the chemical analysis is supplied the steel maker and he makes the steel and forging to this specification.

After the kind of steel to be used is settled, the next question for the forge man to decide is the weight of steel necessary to make the forging, the size and weight of ingot and the type of ingot mould the steel shall be poured into. After these questions have been decided the actual manufacture of the steel ingot begins.

The rapid development of power plant equipment, the greater size and speed required for propulsion machinery for ships, the increased size of paper mill machinery, mining machinery and parts such as crankshafts for forming presses for the mass production of automobiles, all call for larger forgings of both straight carbon and various alloy steels. Serious accidents such as the bursting of rotor bodies while running at great speeds are of rare occurrence and this is due to the proper selection of the quality of steel and the size and type of ingot used, and to the proper forging, heat-treating and machining of the forgings designed for these jobs. Similar care along the same lines is applied to forgings for service in aero engines, automobiles and locomotives.

Homogeneity as regards the composition of the ingot, freedom from defects and permanence of properties are essential in the case of large forgings and are attained only by following the best metallurgical practices based upon long experience with special forging steels. The manufacture and casting of the ingot is done under complete technical control. This insures proper melting and refining

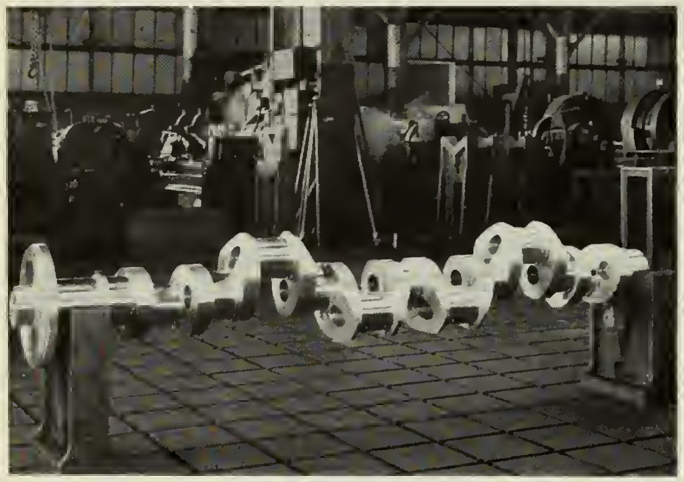

Fig. 5—No. 2 Light Weight High Speed Diesel Engine Crankshafts Chrome Nickel Molybdenum Steel, quenched and drawn to test 115-95-20 and 50.

conditions, casting temperature, teeming speeds and so forth, the metal used being produced from selected scrap materials treated by the basic or acid open hearth processes. The cast iron moulds into which the steel is poured are of special composition and design and these are cleaned, coated with graphite and pre-heated carefully before the steel is poured into them. They also have large refractory-lined hot-tops to prevent the possibility of gas pockets or mechanical troubles due to shrinkage effects located in the utilized part of the ingot. Sufficient material is discarded from the top and from the bottom of the ingot to insure perfectly sound material in the forging and to eliminate the zones of segregation set up during the solidification of the metal. The removal of 30 per cent of the total weight from the top end of ingot is required by many specifications and satisfaction of quality requirements often necessitates discarding as high as 50 per cent from the top and 10 per cent from the bottom of the ingot.

After the ingot has been poured the subsequent processing moves on a pre-determined schedule. Many of the problems of heavy forging manufacture are problems of handling, and extensive equipment such as cranes, manipulators, forging presses, porter bars, cutting tools, soaking pits and forge heating furnaces, heat-treating and annealing furnaces, turning and boring lathes and planers, is required.

When the poured ingot has thoroughly set, it is stripped and placed in an air-tight soaking pit on the pouring floor where it is permitted to soak or equalize for several hours without the addition of external heat and is thus allowed to attain a uniform temperature throughout at about 1,000 degrees F. Entering this pit with the interior perhaps 500 to 1,000 degrees F. hotter than the exterior, the gradual equalizing of the temperature prevents the contraction strains which might otherwise be set up if it were allowed to cool rapidly to atmospheric temperature, or what is even more serious, the development of hot tears or shrinkage discontinuities at the axis of the ingot; thus an ingot is produced which is uniform in structure.

The ingot is then put into an oil-fired soaking pit in the forging department, where it follows a definite pre-arranged schedule of heating in which the specific temperature, hour by hour, is rigidly stipulated. As an example, an ingot is brought slowly to say 1,400 degrees F. and held there for several hours without change. It is then brought up in steps of 75 to 100 degrees per hour to the final forging temperature of 2,100 to 2,300 degrees, depending upon the carbon content. These schedules are all worked out to avoid strains in the steel while passing through the critical temperature range and to assure the axis of the ingot being thoroughly soaked at the prescribed temperature. A medium sized ingot, say of 42 inches cross section, would be fired forty-eight hours, while an 80-inch cross section is fired ninety hours before it is considered ready to forge.

Upon reaching the forging press, the piece again finds a definite schedule of operations awaiting it. A blueprint furnished the head pressman shows exactly the amount of reduction to be made for each heating, while general instructions state the reduction to be made at each impression of the press before the piece is turned around and squeezed in another direction. Observance of these directions prevent the trouble so often experienced in small diameters, of opening up the centre of the ingot into a four pointed star-shaped fissure. The reduction is so gradual and the piece rotated so frequently that it is impossible for the fibres to tear themselves apart as occurs in less careful forging. Under this press, which varies in different plants from 250 tons to 2,500 tons capacity, it is possible to handle ingots ranging in size from 23 inches in diameter and 19,000 pounds in weight to those 80 inches in diameter and 170,000 pounds, while a 12,000-ton press works an ingot 108 inches in diameter and 400,000 pounds in weight.

After large carbon steel forgings of 40 inches or over in diameter and alloy steel forgings under and over 40 inches in diameter, have been finished forged, they are buried in ashes or placed in a warm furnace to protect the piece from draughts, etc., until a temperature under the Ar critical is reached throughout the section. They are then taken to the treatment furnace and uniformly reheated to a temperature sufficiently above the upper critical range to break up the ingot structure, held the necessary length of time and then withdrawn and air-cooled under closely controlled conditions, protected from moisture. Upon being cooled to a black state, the forging is reheated to a low annealing temperature, held the necessary length of time and uniformly slowly cooled. The forging is then given a preliminary rough machining all over, including the rough boring of the axial exploration hole in the case of a bored forging. It is then recharged into a cold furnace and reheated to a temperature above the upper critical range to refine the grain, held the necessary length of time, and withdrawn and air-cooled under closely controlled conditions, protected from moisture. Upon being cooled to a black state, it is reheated to a low annealing temperature, held the necessary length of time and uniformly cooled.

The forging is then rough machined to the dimensions of the purchaser's drawing, after which, to assure stability, it is again charged into a cold furnace, reheated to a temperature of not less than 1,050 degrees F., held for a sufficient length of time and cooled slowly in the furnace to remove surface stresses set up by machining. No further machining other than cutting off test specimens or finishing the bore of the axial hole in the case of bored forgings, is to be performed after this final annealing. Most large diameter forgings are bored along the axis and explored with a periscope to assure absence of discontinuities which might originate at the solidification of the ingot or during subsequent heatings or coolings.

Forgings less than 40 inches in diameter may be treated in the same manner as outlined in the foregoing; or the sequence of heating and machining operations may be varied, depending on the size and shape of the forging.

but in any event, the forging is heated twice to a temperature above the upper critical range and air or furnace-cooled, and after all rough machining has been completed, it receives a final low temperature annealing at a temperature of not less than 1,050 degrees F., and is slowly cooled in the furnace. In the case of a bored forging, the axial exploration hole is bored at any stage before the final annealing operation.

Most of the heavier type of forgings delivered to machinery builders are furnished by the manufacturer in the rough machined state with possibly the exception of large crankshafts, which are more often furnished ready for installation.

There are now Canadian plants capable of producing heavy forgings from ingots up to 42 inches in diameter and 44,000 pounds weight, and to any desired chemical or physical specifications. This range covers ninety per cent of all Canadian requirements, it being only necessary to import a few specially large forgings, for which the demand is so limited in Canada that it would not be economical to provide the expensive equipment necessary for their production.

Canadian steel mills furnish ingots up to 20 inches in diameter, in both carbon and alloy steels, ingots of larger size or special composition being purchased in England or the United States.

VOLUME XVIII OCTOBER 1935 No. 10

Low Cost Housing

In the thickly populated countries of Europe the problems of housing and the removal of slum conditions have been before the public and Legislative bodies for many years, and naturally have received more attention than on this side of the Atlantic. In July of this year the International Housing and Town Planning Congress met in England, where its delegates were able to visit many industrial centres and see the results of long-continued effort on the part of both public and private organizations. The housing estates and cottage homes at Bolton, the slum clearance schemes of Leeds and Manchester, the flats and arterial roads in Liverpool, and the remarkable post-war developments in Birmingham showed the advances which have been made in dealing with these pressing questions. In Britain house construction is being carried on on a very large scale, nearly two and a half million dwellings having been built since 1919. Great progress has also been made in Germany and there has been marked development in the United States, although it has not extended over so long a period as in England. It is estimated that the United States will need ten million homes during the next ten years, and much study has been given to the subject, culminating in an immense housing programme financed by the Government under the Federal Housing Administration.

In Canada the problem has not yet been attacked as a whole, although there have been a number of local schemes. It is encouraging to note the public and governmental interest which has now been aroused, thanks to the efforts of such bodies as the Town Planning Institute of Canada, the National Construction Council of Canada, the Royal Architectural Institute of Canada, and a number of Boards of Trade and similar bodies throughout the country. Surveys have been made of the situation in Toronto (by a commission under Lieut.-Governor Bruce), in Montreal (by the Board of Trade and the City Improvement League), and in Halifax, Saint John, Winnipeg and Vancouver and elsewhere by local housing committees. In this country the number of people affected by improper living conditions is, of course, much smaller than in Britain, Germany or in the United States, but our authorities are agreed that the situation here is a serious one. Recent reports lay stress on the uncoordinated growth of our cities, the overcrowding due to the shortage of dwellings, its effect on the public health, and the unemployment which has resulted from failure to undertake the programme of repairs to existing dwellings and the construction of new ones which is so long overdue.

The need of legislation on this subject has long been realized, and, particularly since the war, a number of provincial and federal housing acts have been placed on the statute books. Definite action was taken this year by the Dominion government, and the latest information in regard to all phases of the question will be found in the final report of the Special Committee appointed to consider and report upon the inauguration of a national policy of housing, which was presented to the House of Commons on April 16th of this year. The Canadian Housing Act followed, under which the Government is prepared to advance part of the cost of homes or apartment blocks. While the provisions of the Act will no doubt facilitate the financing of homes of moderate cost, they do not appear to afford adequate assistance in the case of the lowest paid groups of workers. Wage earners who receive over a thousand dollars a year and who can afford to pay from a quarter to one-third of their income as rent without undergoing serious privation as regards food and clothing, will, it is believed, be able to benefit from the Act, but there exists in every large city a group of workers (largely unskilled), whose annual income is six hundred dollars or less. If the families of these workers are to have adequate food, fuel and clothing, they cannot afford more than about one-fifth of their income in rent. Evidently it is necessary to provide accommodation for them which can be rented at about ten dollars per month and which will replace the unsatisfactory dwellings in which many of them are now living. The Bureau of Statistics has estimated that there is at present a shortage of fifty-five thousand new houses in Canada, to which must be added the number of dwellings required for the newcomers who annually increase our urban population, and the construction needed to put in proper condition otherwise suitable dwellings which have been allowed to deteriorate. Possibly one-third of this total would be needed for the lowest paid group of wage earners.

The difficulty that first arises in this case is that under existing legislation the prospective owner must be prepared to put up twenty per cent of the total cost himself, and pay five per cent interest on the remainder, conditions which cannot be met in the case of the very class whose need for improved housing is the greatest. Further, the problem is more complex than appears at first sight. It is tied up with unemployment, the incidence and amount of taxation, the lack of adequate city planning, land values, construction costs and methods, the habits, standards of living and tastes of the people affected, the public health, provision of the necessary utilities, the requirements of city building regulations, and many other considerations.

The Bruce report found that in Canada, under present conditions, the minimum cost of a suitable dwelling for a family of five is such that if as much as twenty dollars a month rent could be paid, this would only provide a proper return on one third of the total cost of the building and land. Thus, if the present cost of housing cannot be greatly reduced, this difference for the lowest wage groups must be met by a subsidy from federal, provincial or municipal authorities. The need of such financial assistance is generally recognized, and to quote from the Federal Housing Report, "the prevailing opinion would seem to be that the community as a whole has some responsibility for the housing of its people."

In order to reduce the amount of the subsidy required, efforts are being made in all countries to diminish the various items which enter into housing cost, and particularly to find out how to provide a dwelling or an apartment for a family of five which can be rented by the lowest paid wage earner. The matter is not simply one of the construction cost of the building itself. Other items must be considered. For example, the unit cost of land can be reduced by constructing large apartment blocks for those who must live in the city near their work, and by developing economically laid out community sites for those whose work can be transferred to the outskirts of the city. Incidentally, it has been suggested that in many cases suitable areas of land which have reverted to our cities by tax sales, could be replanned and used in this way. Proposals have been made to lessen the tax burden on low cost house property by exempting improvements from municipal taxation, as has been done with great success in England in the garden cities of Letchworth and Welwyn. Again, a properly planned housing area can be provided with facilities and amenities at a much lower cost than if the homes are built on individual lots in different parts of the city. This offers a further possible source of economy.

But even if savings are effected in these and other ways, the stubborn fact remains that the present cost of building construction is so high as to prevent the building of homes for the lowest salaried groups. Attention is therefore being directed to the possibilities of obtaining reduction in cost by the pre-fabrication of houses, the constituent parts or units being factory-made and assembled on the site. It is urged that in this way the benefits of mass production can be obtained, and considerable activity along these lines is being manifested in the United States. It would appear doubtful, however, whether in Canada the possible volume of such work would be sufficient to justify real mass production methods, since these involve so considerable an outlay on factory plant and equipment. It is also a question whether houses can be designed which can be fabricated in this way and which will, at the same time, meet the natural desire of the owner or tenant for a cottage or dwelling which has an individuality of its own. Climatic difficulties in Canada must also be considered, and the increased expense which they entail.

In the United States, where the potential market is, of course, much larger than with us, attempts are being made to utilize the possibilities of fabricated construction in steel, precast concrete, timber, and plywood, and much ingenuity has been devoted to the design of inexpensive central units containing all the household equipment necessary for cooking, heating, bathing and laundry work, such a unit forming a kind of economic core around which the rest of the house can be assembled. Experience gained so far, however, indicates that these pre-fabricated houses are not yet so cheap as to be available for the lowest paid wage earner, partly because those now in the market include many labour saving devices and conveniences which are beyond the means of such families. Dealing with this subject at a recent convention, one speaker stated that the potential market for such houses in the United States must be mainly in the groups with incomes of from $1,500 to $3,000 per annum, in which there are some fourteen million families in the United States.

In Canada this phase of the subject is under consideration by the National Construction Council, and the Royal Architectural Institute of Canada has already appointed a special committee on low cost housing and slum clearance. The question of fabricated housing was brought up at a recent meeting of the Council of The Engineering Institute of Canada, and as a result of discussion it was suggested that a small committee be appointed, to study the possibilities of pre-fabrication and mass production, and work in collaboration with the architects' committee which is dealing with the question of low cost housing as a whole. This matter is now receiving attention. There is no doubt that if some satisfactory solution can be found for this problem under Canadian conditions, a very great advance will have been made in the provision of improved conditions of living for a large number of our citizens who have real need for assistance of this kind.

The Unwin Memorial

The long and active life of the late Dr. W. C. Unwin covered a period of remarkable growth in all branches of engineering, during which theory and experiment gradually gained recognition as bases for actual engineering work. In the nearly sixty years of his professional career he took a leading part in the development of the scientific training of engineers, and was as distinguished for his ability as a consultant on great engineering problems as for his services to engineering education.

With his death in 1933, in his ninety-fifth year, there passed away an engineer of international repute. He was the recipient of many honours. He was a Fellow of The Royal Society, and to him was awarded the first Kelvin Medal. He was President of The Institution of Civil Engineers in 1911, and President of The Institution of Mechanical Engineers in 1915 and 1916. The American Society of Civil Engineers and the American Society of Mechanical Engineers conferred their honorary memberships upon him. His well-known text books on machine design, first published in 1877 (of which 43,000 copies were sold), and on hydraulics (based on his classical article on that subject in the Encyclopedia Britannica), added greatly to his reputation. He was consulted in regard to many major engineering works, and was a recognized engineering authority on such widely diversified branches of engineering as hydraulics, steam power, the design of dams, transmission of energy, the strength and testing of materials, and machine design. He served with Lord Kelvin, Dr. Coleman Sellers and other eminent engineers on the International Niagara Commission, which was formed in 1890 to advise on the best method of developing and distributing Niagara Power. That Commission's decision to select electrical development by alternating current was followed by the adoption of this system in all parts of the world.

Of Dr. Unwin's relations with the many students who received their training from him it need only be said that he was their friend and guide, not only while at college, but throughout the whole of their professional careers. He was indeed an engineer and educationalist of international repute.

On Dr. Unwin's retirement from his professorship in 1904, his students established an Unwin Scholarship, which, however, was not a large one. As a fitting memorial to his life work it is now proposed to raise a sum of £2,500, a portion of this fund to be used to present to the Central Technical College a portrait or plaque of Dr. Unwin, the balance being applied to augment the scholarship in question to a value of at least £60 a year, so as to make it worthy of his name.

The matter is in the hands of an Unwin Memorial Committee, under the chairmanship of Sir Alfred Chatterton, C.I.E., F.C.G.I., K.I.H., and its membership includes many prominent British and American engineers. As Canadian representatives on this committee, Brig.-Gen. C. H. Mitchell, C.B., C.M.G., M.E.I.C., Dean of the Faculty of Applied Science, University of Toronto, Toronto, Dean Ernest Brown, M.Sc., M.Eng., M.E.I.C., Dean of the Faculty of Engineering, McGill University, Montreal, and Group-Captain E. W. Stedman, O.B.E., M.E.I.C., Chief Aeronautical Engineer, Department of National Defence, Ottawa, have been nominated.

A fitting memoir of Dr. Unwin, forming a permanent record of his life work, is being prepared by Mr. E. G. Walker, and will be issued at 10/6 per copy. Subscriptions for this volume, and contributions to the Memorial Fund, are requested from former students of the City and Guilds College, and from Canadian engineers, and they may be sent to the General Secretary of The Engineering Institute of Canada, 2050 Mansfield Street, Montreal.

Meeting of Council

A meeting of the Council of The Institute was held at Headquarters on Tuesday, September 17th, 1935, at eight o'clock p.m., with President F. A. Gaby, M.E.I.C., in the chair, and seven other members of Council present.

The attention of Council was drawn to the fact that the present Canadian Standard Form of Construction Contract, issued by the Canadian Construction Association and approved by the R.A.I.C. and the E.I.C., while entirely suitable for building construction work, appears to require certain modifications to make it applicable to large engineering works. The following committee was appointed to draw up and recommend such modifications as may be thought desirable for this purpose:

R. E. C. Chadwick, M.E.I.C., *Chairman*
J. H. Brace, M.E.I.C.
C. S. L. Hertzberg, M.E.I.C.
J. A. McCrory, M.E.I.C.
J. W. Orrock, M.E.I.C.

It was noted with appreciation that, following a circular letter recently sent out, a considerable number of members on the non-active list have been able to rejoin the active list of The Institute.

The report of the Nominating Committee, containing that committee's list of nominees for officers for the year 1936, was received and examined by Council in accordance with the by-laws.

The Secretary presented a resolution passed by the Moncton Branch protesting against the inclusion in The Engineering Journal of articles in the French language, a copy of this resolution having been sent by the Moncton Branch to each of the other branches of The Institute. After discussion, Council decided not to recommend any change in policy in this matter.

Two resignations were accepted, two Life Memberships were granted, one hundred and forty-six members were replaced on the active list, and a number of special cases were dealt with.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Members	3	Assoc. Member to Member	7
Assoc. Members	4	Junior to Member	1
Juniors	2	Junior to Assoc. Member	5
Students admitted	6	Student to Assoc. Member	2

The Council rose at eleven thirty p.m.

OBITUARIES

Frederick Passmore Gutelius, M.E.I.C.

Widespread regret will be felt at the death at North Bay, Ont., of Frederick Passmore Gutelius, M.E.I.C., on September 12th, 1935.

Mr. Gutelius was born at Mifflinburg, Penna., on December 21st, 1864, and graduated from Lafayette College in 1887 with the degree of C.E.

Early in his career he served the Pennsylvania lines as assistant engineer and supervisor for the region west of Pittsburgh, and from 1892 to 1894 Mr. Gutelius was in charge of a water power electric plant at Butte, Mont., later taking charge of the Butte City water works. Following this he was for a time engaged in general practice in Butte City. In 1895 Mr. Gutelius became general superintendent of the Columbia and Western Railway at Trail, B.C. He joined the staff of the Canadian Pacific Railway Company in 1898 and remained in the company's service, passing from one responsible office to another, and becoming general superintendent of the eastern division in 1912. He was occupying this position when the Dominion Government appointed him as a Royal Commissioner to enquire into the construction of the National Transcontinental line through northern Quebec and Ontario. Mr. Gutelius' ability was so highly appreciated by the government that he was chosen to be general manager of the Intercolonial and Prince Edward Island Railway, being located at

F. P. Gutelius, M.E.I.C.

Moncton, N.B. He was in charge of the government lines until 1917 when he became vice-president of the Delaware and Hudson Railroad Corporation in charge of operations and traffic. Since 1923 Mr. Gutelius has been resident vice-president of the Delaware and Hudson in Montreal.

Mr. Gutelius joined The Institute (then the Canadian Society of Civil Engineers) as a Member on December 18th, 1902.

Gustave Lindenthal, M.E.I.C.

It is with deep regret that we place on record the death on July 31st, 1935, of Gustav Lindenthal, M.E.I.C., at his home in Metuchen, N.J.

Mr. Lindenthal was born at Bruenn in Austria on May 21st, 1850, and received his school and technical education in that city.

In May 1874 he came to the United States as draughtsman and assistant engineer on the buildings for the Centennial Exhibition in Philadelphia, and in 1876 he located in

Cleveland, and until 1881 was bridge engineer of the old Atlantic-Great Western Railroad. Mr. Lindenthal subsequently settled in Pittsburgh, and was consulting engineer for a number of railroads, having designed and executed many large works, mostly bridges.

The works of Mr. Lindenthal were characterized by a daring in conception and execution and by a mingling of artistry with engineering technique which made him one of the outstanding bridge engineers in the United States. The spanning of Hell Gate is the accomplishment with which his name is perhaps most frequently linked. At the time of its completion in 1917, Hell Gate bridge was the largest arch bridge in the world, and both in design features and in construction methods it marked a great forward step in American engineering practice. Another of Mr. Lindenthal's designs which was notable for its æsthetic features was that for the Chesapeake and Ohio Northern Railroad crossing at Sciotoville, Ohio, a remarkable long span continuous-truss structure. Because of a combination of circumstances, the railroad suspension bridge across the Hudson river, designed by Mr. Lindenthal in 1888 for the North River Bridge Company, was never built. It was, however, a remarkably bold and well-conceived plan, calling for the first time for a single span across the river, 2,850 feet long and having a total length between anchorages of more than a mile.

Mr. Lindenthal was a prominent member of the American Society of Civil Engineers, having joined as a Member in 1882, and being elected to honorary membership in 1929. He received the Thomas Fitch Rowland Prize in 1883 for his paper entitled "Rebuilding the Monongahela Bridge at Pittsburgh, Pa.," and thirty-nine years later the same prize was awarded to him for his paper discussing the Sciotoville Bridge. In 1929 he was the first recipient of the Phebe Hobson Fowler Architectural Award. In 1920 Mr. Lindenthal received the degree of Doctor of Engineering from the Polytechnical School in Bruenn.

Mr. Lindenthal was a Fellow of the American Association for the Advancement of Science; a member of the (British) Institution of Civil Engineers and the Verein Deutscher Ingenieure; an honorary member of the Oesterreichischer Ingenieur und Architekten Verein and the Cleveland Engineers' Society.

Mr. Lindenthal joined The Institute (then the Canadian Society of Civil Engineers) on February 14th, 1889, and was made a life member on March 18th, 1932.

PERSONALS

A. E. Foreman, B.Sc., M.E.I.C., has been appointed associate professor of civil engineering by the University of British Columbia, Vancouver, B.C.

Mr. Foreman, who was born in 1878, had a brilliant career at McGill University, from which he graduated in 1903 with the degree of B.Sc., leading his class in each of four years and securing thirty-four first prizes, including the Scott Exhibition and Prize, Mathematical Exhibition and Prize, British Association Exhibition, Canadian General Electric Scholarship, and British Association Medal and Prize. He took an active part in athletics and was president of the McGill Basketball Club.

Following graduation Mr. Foreman spent three years in Toronto, securing business experience, and in 1907 went to Vancouver where he became secretary and manager of the Concrete Engineering and Construction Company. He was for one year, member of the firm of Dutcher and Foreman, consulting engineers, and was appointed supervising engineer for the city and provincial government on the Dallas Road Sea Wall, Victoria, B.C. In 1912, he was appointed assistant engineer of the city of Victoria, and in 1917, chief engineer of the Department of Public Works, which position he resigned in 1920 to become district engineer for the Portland Cement Association.

Mr. Foreman is a member of the Canadian Engineering Standards Association, the American Society for Testing Materials, and the British Columbia Good Roads League.

A. E. Foreman, M.E.I.C.

He is past-president of the Canadian Good Roads Association and the Association of Professional Engineers of British Columbia. He is chairman of the Road and Transit Committee of the Vancouver Town Planning Commission.

J. M. Paquet, S.E.I.C., is now sanitary engineer with the Provincial Board of Health, at Amos, Que. Mr. Paquet graduated from the Ecole Polytechnique in 1934 with the degree of B.A.Sc.

T. L. Hall, S.E.I.C., has joined the staff of the Canadian General Electric Company Limited, at Winnipeg, Man. Mr. Hall, who graduated from the University of New Brunswick in 1928 with the degree of B.Sc., has previously been connected with the same company.

F. Stewart Gumley, A.M.E.I.C., has been appointed designing engineer with Martin and Company at Calcutta, India. He will be in charge of design and construction of bridges, buildings and engineering structures in structural steel. Mr. Gumley, who was formerly works manager with J. and J. Lawrence Limited, in Edinburgh, Scotland, was at one time with the Western Bridge Company Limited, Vancouver, B.C.

J. M. Wardle, M.E.I.C., has been appointed Deputy Minister of the Department of the Interior, Ottawa, Ont.

Mr. Wardle was born at Chilliwack, B.C., and graduated from Queen's University with the degree of B.Sc. in 1912. Following graduation he was assistant to the city and municipal engineer of Chilliwack, and in 1914 he joined the Dominion Parks Branch of the Department of the Interior as assistant highway engineer. From 1915 until 1918 Mr. Wardle was acting chief highway engineer with the Dominion Parks Branch, and in 1918-1920 he was superintendent of the Banff National Park at Banff, Alta. In 1920 Mr. Wardle was appointed chief engineer of the Canadian National Parks Branch, Department of the Interior, Ottawa, which office he has held until the present time.

Charles C. Ross, M.E.I.C., Appointed Minister

The Hon. Charles C. Ross, M.E.I.C., has been appointed Minister of Lands and Mines in the new Alberta administration.

Mr. Ross was born at Ottawa, Ont., and graduated from McGill University in 1909 with the degree of B.Sc. (civil). Following graduation he was with the International Boundary Survey, and was subsequently with the

The Hon. Charles C. Ross, M.E.I.C.

Hydrographic Survey. From 1911 until 1913 Mr. Ross was in private practice, contracting. In 1916 he went to Calgary, and as senior mining inspector and later as supervisory engineer for the Department of the Interior he accomplished noteworthy results in the evolution and harmonious operation of the regulations for the development of the mineral resources of the prairie provinces. In 1928 Mr. Ross was appointed by the Minister of the Interior to set up departmental administrative machinery in northern Manitoba and northern Saskatchewan in connection with the mining development in those provinces, and since that time has supervised and administered all mining regulations affecting Crown lands in Manitoba, Saskatchewan, Alberta, the Railway Belt of British Columbia, the Yukon and the Northwest Territories. Mr. Ross later left the Government service and has been engaged in the development of oil and gas and mining as a consultant.

Mr. Ross is an active member of the Calgary Branch of The Institute.

The following members of The Institute have been appointed by the Executive Committee of the City of Montreal to investigate the waterworks intake at Ville LaSalle, and to report to the administration what amount of money is necessary to equip the aqueduct properly in this connection: R. de L. French, M.E.I.C., Professor of Highway and Municipal Engineering, McGill University, and consulting engineer, A. Plamondon, A.M.E.I.C., consulting engineer, Montreal, J. M. Robertson, M.E.I.C., consulting engineer, Montreal, E. Gohier, M.E.I.C., consulting engineer, Montreal, J. E. Blanchard, M.E.I.C., Director of Public Works, Montreal. C. J. Desbaillets, M.E.I.C., chief engineer of the Montreal Water Board will act as secretary.

Lieut.-Colonel L. N. Seaman, M.E.I.C., received the Order of the British Empire in the King's Birthday Honours List this year, and was invested with the decoration at Buckingham Palace by His Majesty the King on July 10th last. Colonel Seaman was formerly Officer in charge of Timber Testing with the Forest Research Institute, Dehra Dun, India, but has now retired. He is at present visiting Canada, and is staying at Halifax, N.S.

George E. Kent, A.M.E.I.C., has joined the staff of the International Petroleum Company at Talara, Peru, as assistant superintendent. Mr. Kent graduated from the Nova Scotia Technical College in 1928 with the degree of B.Sc., and following graduation was, until 1929, with the Bell Telephone Company of Canada at Montreal. In September 1929 he joined the staff of the Imperial Oil Refineries Limited at Sarnia, being in the draughting department on the design of oil refinery equipment. In 1930 Mr. Kent became assistant mechanical superintendent with the same company, and in 1932 he was assistant to the refinery superintendent.

Elections and Transfers

At the meeting of Council held on September 17th, 1935, the following elections and transfers were effected:

Members

BAKER, James Davidson, Deputy Minister and General Manager, Alberta Government Telephones, Edmonton, Alta.

CALDER, William, 10122-123rd Street, Edmonton, Alta.

FINDLATER, Richard Hamilton, F.I.C., M.Inst.P.T., 74 Highfield St., Moncton, N.B.

Associate Members

DOUGLAS, John Holden Webb, mech'l. supt., Dept. of Public Works Alberta, Edmonton, Alta.

EVANS, Thomas Owen, B.Sc., (McGill Univ.), asst. supt., Back River Plant, Montreal Island Power Co., St. Vincent de Paul, Que.

HARDY, William Gathorne, B.Sc., (N.S. Tech. Coll.), 4879 Patricia Ave., Montreal, Que.

HERR, Arthur George, chief dftsman., Packard Electric Co. Ltd., St. Catharines, Ont.

Juniors

FORTIN, Jean Julien, B.Sc., (Queen's Univ.), tracer and designer, Duke-Price Power Co., Arvida, Que.

*KING, Eric Charles, power house operator, Churchill River Power Co. Ltd., Island Falls, Sask.

Transferred from the class of Associate Member to that of Member

BUCHAN, Percy Halcro, B.A.Sc., (Univ. of Toronto), asst. engr., mtce. of way, B.C. Electric Rly. Co. Ltd., Vancouver, B.C.

DORMER, William John Smylie, B.Sc., (McGill Univ.), district engr., (Montreal Suburban and Three Rivers Districts), Bell Telephone Company of Canada, Montreal, Que.

GILBERT, Gordon Macdonald, B.Sc., (Univ. of Man.), supt. and acting-engr., Vancouver and Districts Joint Sewerage and Drainage Board, Vancouver, B.C.

ROBERTSON, James, B.Sc., (McGill Univ.), engr. Pacific Divn., Dominion Bridge Co. Ltd., Vancouver, B.C.

STUART, Harold Brownlee, B.A.Sc., (Univ. of Toronto), field engr., Hamilton Bridge Co. Ltd., Hamilton, Ont.

THRUPP, Edgar Charles, (Kings College, London, England), 2626-13th Ave. West, Vancouver, B.C.

WHEATLEY, Edward Augustus, M.C. and Bar, (City and Guilds Tech. Coll.), registrar and sec.-treas., Association of Professional Engineers of the Province of British Columbia, Vancouver, B.C.

Transferred from the class of Junior to that of Member

MacNICOL, Nicol, B.A.Sc., (Univ. of Toronto), works commissioner, Forest Hill Village, Ont.

Transferred from the class of Junior to that of Associate Member

FOX, John H., B.A.Sc., (Univ. of Toronto), engr., Minneapolis-Honeywell Regulator Co. Ltd., Toronto, Ont.

LEA, Harry Windsor, B.Sc., (McGill Univ.), designing engr., Montreal Sewers Commission, 1226 University St., Montreal, Que.

McGILLIS, Lester, B.Sc., (McGill Univ.), manager, Beauharnois Divn., Shawinigan Water and Power Co., Valleyfield, Que.

THOMPSON, William Lennox, B.A.Sc., (Univ. of Toronto), sales service engr., Bailey Meter Co. Ltd., Montreal, Que.

*VARLEY, Percy, elect'l. dftsman., Canadian Industries Ltd., Montreal, Que.

Transferred from the class of Student to that of Associate Member

BOSTOCK, William Norman, Capt., R.C.E., B.Sc., (McGill Univ.), (Grad., R.M.C.), Work Point Barracks, Esquimalt, B.C.

MULLIGAN, Henry Ineson, B.Sc., (McGill Univ.), N.B. Electric Power Commission, Newcastle Creek, N.B.

Students Admitted

ALLEN, Richard T. W., B.Sc., (Univ. of Alta.), P.O. Box 891, Vernon, B.C.

DAVEY, Roland Eric, B.A.Sc., (Univ. of Toronto), Dufferin Paving Co. Ltd., Kenora, Ont.

GRIFFITHS, George Henry Rickard, B.Sc., (Univ. of Man.), 212 Forest Ave., West Kildonan, Man.

MILLER, Donald Waters, B.Sc., (Univ. of Man.), 616 Ashburn St., Winnipeg, Man.

WELSH, James Gordon, (Univ. of Toronto), 1078 Valley Way, Niagara Falls, Ont.

WILLIAMS, Stanley Chevers, B.Sc., (Queen's Univ.), 23 Ossington Ave., Ottawa, Ont.

*Has passed Institute's examinations.

BOOK REVIEWS

Working, Heat Treating and Welding of Steel

By H. L. Campbell, John Wiley and Sons, New York. 1935. 6 by 9¼ inches. Photos. Diagrams. 185 pages. Cloth. $2.25.

Contents: Manufacture of iron and steel; composition; classifications; testing; effects of heat treatment and mechanical working; processes and equipment for working; constitution of steel (metallography); processes and equipment for heat treatment; alloy steels; processes and equipment for welding; surface preservation; laboratory experiments (eighteen).

The author's aim has been to present in a concise way the principles and practice relative to the working, heat treating and welding of steel.

All this subject matter, leading up to the experiments, is covered in 148 pages, and it is obvious that the treatment cannot be detailed; however the style is concise and clear, and the halftones and diagrams are, respectively, well chosen and well drawn; there are very few errors.

The book is essentially designed as a laboratory manual for second or third year students in mechanical engineering. It should not, of course, be compared with any of the standard text- and hand-books covering the many phases referred to; but, in addition to its main purpose, it would well serve as an introduction to stimulate interest in the subject on the part of those unfamiliar with the metallurgy of steel. A well-selected list of reference books is included.

The Principles of Electric Power Transmission

By H. Waddicor. John Wiley and Sons Inc., New York. 1935. 5½ by 8¾ inches. Diagrams. 449 pages. Cloth. $6.00. (Renouf Publishing Company, Montreal.)

Reviewed by Edgar T. J. Brandon, A.M.E.I.C.*

In the third edition of this useful book, the author has attempted to bring up to date such parts of it as required revision.

The book is useful in that it brings together in one volume features of electric power transmission heretofore treated separately. As a result, some of the chapters, such as those on "Line Conductors and Supporting Structures" and "Apparatus for the Prevention of Dangerous Currents" are very elementary and cannot be considered as other than presenting a very general outline of the subject matter with which they are dealing.

The book is notable for the originality of treatment of some phases of the subject, and also for the freedom with which the author has given the source of other data.

Chapter XI on "Economic Principles and Calculations" emphasizes the fundamental laws, but makes only very general statements regarding economic principles.

There are some examples of lack of balance in the treatment of various subjects. For example, distance protection is covered in one page, whereas spark gaps of various kinds are given nine pages.

Chapter XIII on "Pressure Rises" deals very clearly with the theory of travelling waves, and the transient voltages appearing on transmission systems. This chapter is of considerable value in a book on power transmission.

Chapter XV on "Power Limits of Transmission Systems" deals with the subject mathematically and may give the wrong impression of this problem to a casual reader. The author is careful to point out, however, that practical considerations modify calculations of power limits to a great degree.

A very valuable bibliography is found at the end of each chapter, and the author is to be commended for including this. He has evidently studied American as well as European practice, so that the book has merit in that it expresses the author's opinion of the best in each, and as such, is of more than ordinary interest to the American engineer.

Chief electrical engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

Mechanical and Electrical Equipment for Buildings

By C. M. Gay and C. De Van Fawcett. John Wiley and Sons, New York. (Renouf Publishing Company, Montreal) 1935. 6 by 9¼ inches. Diagrams, tables. 429 pages. Cloth. $5.00.

Reviewed by E. A. Ryan, M.E.I.C.*

This new work on the subject of mechanical and electrical equipment for buildings is a very complete review of the major problems to be solved in the equipment of a modern building. The authors have purposely prepared the work for members of their own profession, the architects, and with this in mind they refrained from presenting a treatise that is technical in the extreme. They have preferred rather to treat the various subjects in the simplest possible forms but have, nevertheless, given the fundamental technical data governing the solution.

The work treats of water supply, plumbing, drainage, heating, air conditioning, electrical equipment and acoustics, and gives very valuable information on the better known systems and apparatus commercially available.

Chapters are included on water supply equipment and the design and installation of water supply; plumbing fixtures and private sewage disposal; warm air, steam and hot water heating; electrical materials and machinery, wiring systems; elevators, and interior and flood lighting.

It should prove very convenient and useful to all practising architects, or even engineers whose duties do not require a deep knowledge of any of the foregoing branches but who at the same time should have a working knowledge of the underlying principles and facts.

Consulting engineer, 1188 Phillips Place, Montreal.

ANNUAL MEETING 1936

The Fiftieth Annual General and General Professional Meeting of The Institute is to be held at The Royal Connaught Hotel, Hamilton, Ontario on Thursday and Friday, February 6th and 7th, 1936.

BULLETINS

Signal Systems—A 4-page leaflet received from Edwards and Company of Canada, Montreal, gives particulars regarding a number of the company's signals and alarm systems.

Motor Trucks—The Four Wheel Drive Auto Company, Clintonville, Wis., have issued a 12-page bulletin detailing features and uses of their Model HS for high speed hauling.

Graders—A 40-page booklet issued by the Caterpillar Tractor Company, Peoria, Ill., describes their elevating graders Nos. 42 and 48 which are available in either engine-driven or power take-off designs. The first, with a 42-inch carrier belt, requires a 40-h.p. engine; the latter size, with 48-inch carrier belt, requires a 46-h.p. engine. Both sizes can be obtained with carriers of from 14 to 25 feet.

Compressors—A 4-page leaflet received from the Worthington Pump and Machinery Corporation, Harrison, N.J., contains data on the company's steam booster compressors.

Pumps—The Worthington Pump and Machinery Corporation, Harrison, N.J., have issued a 4-page folder describing and illustrating their deep well turbine pumps, types Q and QA, obtainable for installations requiring from 30 to 225 U.S. gallons per minute at heads up to 400 feet.

Aerial Ropeways—A 48-page booklet received from Ropeways Limited, London, England, illustrates types and systems of aerial ropeways, and their general uses and advantages.

List of New and Revised British Standard Specifications

(issued during June and July, 1935).

B.S.S. No.

613—1935. *Components for Radio-Interference Suppression Devices.*
First of a series of specifications dealing with radio interference. Originated in a sub-committee of the I.E.E. Deals with rating, performance, and tests of condensers, inductors and resistors used in the construction of interference suppressors. Appendix gives diagrams of connections and schedules of component values.

618—1935. *Emulsions of Road Tar and of Road Tar-Asphaltic Bitumen Mixtures for Penetration (Grouting and Semi-Grouting) and Surface Dressing.*
First B.S. Specification for a cold road dressing, incorporating tar. Appendices are included giving methods of sampling and testing of the emulsion.

620—1935. *The Dimensions of Grinding Wheels and Method of Attachment.*
Dimensions of generally used shapes and sizes of grinding wheels, and of the flanges and washer plates to be used with the standard method of attachment. Tolerances and fits of the spindle in the wheels are specified, with the quality of the material from which the spindle and flanges are to be made.

621—1935. *Wire Ropes of Special Construction for Engineering Purposes, inclusive of Cranes, Lifts and Excavators.*
Providing for Seale construction, oval and flattened strand and multiple strand wire ropes from 1½ to 6 inches circumference for special engineering purposes including cranes, lifts and excavators.

Copies of these specifications may be obtained from the British Standards Institution, 28 Victoria Street, London, S.W.1, England and from the Canadian Engineering Standards Association, 79 Sussex Street, Ottawa, Ont.

The Institution of Civil Engineers of Ireland Celebrates its Centenary 1835-1935

(*Contributed by N. F. Harrison, A.M.E.I.C.*)

On August 6th of this year, The Institution of Civil Engineers of Ireland celebrated its one hundredth birthday. It was on August 6th, 1835, that a few Irish engineers, animated by the need of a national organization for the engineering profession in Ireland, first met under the chairmanship of Colonel John Fox Burgoyne in the old office of Public Works, Dublin, for the purpose of forming an association to be called "The Civil Engineers Society of Ireland."

In its early years the society encountered many difficulties, but a successful reorganization was effected in 1844, and its title changed to its present form.

The first printed transactions appeared in 1845, the opening paper being one read on November 12th, 1844, by Robert Mallet, F.R.S. (President 1865-67), on "The Artificial Preparation of Turf (Peat) Independently of Season or Weather."

In 1877 a Royal Charter was granted to the Institution by Queen Victoria, and it will be of interest to many Canadian engineers to know that in the charter year, Robert Manning (whose celebrated paper on "The Flow of Water in Open Channels and Pipes" was read to the Institution of C.E.I. on December 4th, 1889) was President.

Two days were given over to the centenary celebrations this year. On August 6th a special meeting was convened at the Engineers' Hall, Dublin, when an address appropriate to the occasion was delivered by the President (Mr. Nicholas O'Dwyer) and delegates, bringing felicitations from the universities and various sister institutions and associations, were received. In the evening a reception and dance was held in the Mansion House.

On August 7th visits were paid to the new stand-by plant of the Electricity Supply Board at the Pigeon House Fort, the Main Drainage Outfall Works of the Dublin Corporation, and an inspection trip, by steamer, of the Port of Dublin.

BRANCH NEWS

Border Cities Branch

C. F. Davison, A.M.E.I.C., Secretary-Treasurer.
F. J. Ryder, S.E.I.C., Branch News Editor.

There were about thirty persons present at the meeting which was held after dinner at the Prince Edward hotel, on Friday, May 17th, 1935. Owing to the continued illness of our secretary, the minutes were not read. B. Candlish, A.M.E.I.C., spoke of a proposed visit to Sarnia and a vote was taken to see how many were interested. Everyone appeared to be in favour of the idea.

F. H. Kester, M.E.I.C., introduced P. L. Pratley, M.E.I.C., of the firm of Monsarrat and Pratley, Montreal, which is very well known for its work throughout the Dominion. The subject of the paper presented was "The Isle of Orleans Bridge." The construction of this bridge was part of the government's plan to aid the unemployed.

The Isle of Orleans Bridge

The major problems in design were (1) to have as large a Canadian content as possible; (2) to overcome political opposition and restrictions. These two problems were overcome by the firm submitting two recommended designs. One which could be constructed under the restrictions and specifications cited; the other was the best design for the conditions existing at the site of the proposed bridge. The latter, a suspension bridge combined with truss spans, was finally chosen.

A good deal of attention was paid to the æsthetics of the design as well as the technical details so that the structure would not mar the landscape.

Mr. Pratley discussed the general details covering substructure and superstructure which have been previously reported upon in The Journal. One of the new innovations on this particular project was the use of the "Truscon Tee Grid" flooring system which lightened the load due to floor stem and also enabled the contractor to use the bridge floor prior to the pouring of concrete.

After a good deal of interesting discussion, it was moved by R. A. Spencer, M.E.I.C., that a hearty vote of thanks be extended to Mr. Pratley, which was seconded by H. J. Coulter, A.M.E.I.C.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

Through the courtesy of the Cunard White Star and Donaldson Atlantic Lines, members of the Montreal Branch of The Institute with their ladies and friends visited the *Ascania* and *Athenia* on Wednesday, September 18th, 1935.

Luncheon was served on board the *Ascania* at 1 o'clock p.m., some one hundred and fifty being present. F. S. B. Heward, A.M.E.I.C., chairman of the Branch, presided and thanked the officials of the Cunard White Star Line for their kindness in arranging for the visit. Eric Reford, of the Robert Reford Company Limited, welcomed the visitors on behalf of the owners of the *Ascania*. Chief Officer H. N. McGill also spoke a few words of welcome. Dr. F. A. Gaby, M.E.I.C., President of The Institute, was among those at the head table.

Both ships were open for inspection from 12.30 to 3.00 o'clock p.m. and a large party took advantage of the opportunity of viewing them, the boiler and engine rooms of the *Ascania* proving of particular interest.

The English Electric Company of Canada, Limited, announces the formation of a new Lighting Division, which will manufacture and sell "Barlux" tubular lamps and fittings. These lamps are of 3-ply opal glass in lengths from 6 inches to 48 inches, bent to any desired curve. The standard sizes are 38 mm. and 40 mm. diameter and consume 35 and 60 watts per foot respectively.

The International Nickel Company of Canada Limited have announced their intention of erecting a chemical and research laboratory at Copper Cliff, Ontario. This will deal with projects leading to improvements in the process for refining nickel and copper, with particular emphasis directed towards the development of new uses for copper.

River Improvement Work in Manchuria

A description of the Training and Protective Work Carried out on the Lower Liao River

E. E. Lord, A.M.E.I.C.,
Estimator, Smith Bros. and Wilson Limited, Regina, Sask.
Formerly Assistant Engineer, Lower Liao River Conservancy, Newchwang, Manchuria.

Paper presented before the Saskatchewan Branch of The Engineering Institute of Canada, March 22nd, 1935.

Manchuria has a climate somewhat similar to that in Regina, the temperature ranging from a maximum of about 98 in summer to 15 below zero in the winter. However, there is a great deal more wind and much of the work seemed to be a continual fight against wind. The yearly rainfall averages about 23 inches but nearly half occurs in a period of about three weeks during July and August. The total drainage area of the Liao river is 80,000 square miles and the greater part is entirely barren of trees with a rather loose sandy soil which is subject to erosion. This meant that the Liao river at some periods of the year carried a tremendous amount of silt.

The Port of Newchwang is situated about 11 miles from the mouth of the river, at which point the river is approximately 2,000 feet wide and 35 feet deep at low water. During the cold weather the river at Newchwang froze over in November and opened some time in March, the port usually being closed for about four and a half months. The main export from Newchwang was soya beans or soya bean oil and at one time it was a thriving port with some 20,000 junks sailing up and down the Liao river. Soya beans were brought from the interior and general cargo and salt, extracted from sea water at Newchwang, carried back. These junks were taxed on the trip down and also on the trip up at a town called Tien Chwang Tai, some 15 miles up river from Newchwang.

There is a branch of the river running from Tan Chia Wo Pu to the sea north of Newchwang (see Fig. 1) this is the Shwang Tai Tzu branch. Originally this was not a branch at all but was a creek which had its source near the Liao at Tan Chia Wo Pu and ran from there to the sea. There was no connection between this creek and the Liao river. However, some junk owners conceived the idea of digging a small canal to connect this creek with the Liao river as they could then go down the canal and the creek to Newchwang and dodge the tax collectors at Tien Chwang Tai. They dug the canal, and as it was only eight feet wide and would only take a small boat, no one worried about it. The distance to the sea via the Shwang Tai Tzu branch is much shorter than via the Liao river and in consequence the water tended to go that way. This tendency gradually scoured out the creek until now it is a large river and robs the Liao of anywhere from 15,000 to 40,000 second-feet of water.

The tidal limit of the Liao river does not reach the point where the Shwang Tai Tzu branch leaves the main river and all the water going down the branch is fresh water. A silt analysis of the water taken at various points on the river shows that the water coming down the main river and in the Shwang Tai Tzu branch is reasonably clean and that most of the silt and sand comes in from the two branches which join further down the Liao river. This silt and sand is gradually carried down river by the ebb tide and the fresh water discharge until it reaches the mouth of the river. There was then no training wall at the mouth of the river and the ebb with its heavy silt content deposited silt and sand to form a bar. There had always been a bar at the mouth of the Liao river with approximately 9 feet of water over it at low water but there was a sufficient fresh water discharge at all times to maintain that depth. However, when the Shwang Tai Tzu branch started robbing the Liao of its fresh water the bar began to silt up and finally in 1914 it had silted up until there was only 6 feet of water at low water.

The tide rises from 10 to 14 feet at the bar, and this added to the original 9 feet of water gave a high water depth of 19 to 23 feet which was generally sufficient for the China coastal steamers, but when the bar had silted up 3 feet steamers had to go out with three feet less draught which meant a loss of considerable cargo. As a result most steamers had to go to another port to fill up. The nearest port was Dairen where there was plenty of water and an excellent harbour and many ships were going there and not calling at Newchwang at all. The upper reaches of the river below the Shwang Tai Tzu branch were also silting up and junks had difficulty in getting down river to Newchwang. In fact, something had to be done.

The Liao River Conservancy Board was formed in 1914 and was composed of various Chinese officials and the managers of shipping companies and any foreign consuls located in Newchwang. A tax was placed on shipping to obtain funds and Mr. Hughes was appointed engineer for the board and Sir John Wolfe Barry & Lister consulting engineers. Mr. Hughes was also carrying out considerable work in other parts of Manchuria for the Chinese government and could not devote all his time to the Conservancy work.

The obvious thing to do to improve the river was to close the Shwang Tai Tzu branch and this was tried on two occasions. However, towns had grown up along the branch and there was considerable traffic on the river, also customs stations had been established to tax the junks. When work was started on the closure there was a great deal of complaint and finally the works were torn out and a few riots staged so that the closing had to be abandoned. The consulting engineers then recommended the dredging of the upper reaches of the river which were silting up, the construction of two training walls at the mouth of the river and the closing of the west channel near the mouth of the river. (See Fig. 2.) The training walls at the mouth of the river were to confine the ebb tide across the bar and thereby scour out a channel over the bar. As the set of the tide on the bar was in a southerly direction the east training wall was essential, but both would be better, if finances permitted.

Mr. Hughes, the engineer for the Board, made surveys of the river and in the years 1916, 1917 and 1918 closed the west channel and started the east training wall at No. 5 beacon and carried it out to Mound Beacon. He died in 1918 and in 1919 Mr. P. N. Fawcett was appointed engineer-in-chief of the Lower Liao River Conservancy and the author was appointed assistant engineer early in 1920. Figure 3 shows the part of the river with which our work was concerned, that is from the entrance up to Swan island, and this article will deal with that section.

The Survey Work

The only way to watch the various changes in a river is by taking frequent soundings if possible in the same places each year. It was decided to do this and permanent sounding lines were established across the river at about 1,000 feet apart. Concrete posts 4 by 6 inches and 4 feet long were placed in the ground on the sounding line, one on either bank of the river, and in all 117 lines were marked in this way from Signal Station to Swan island. These sounding line stones were also used as bench marks and triangulation points.

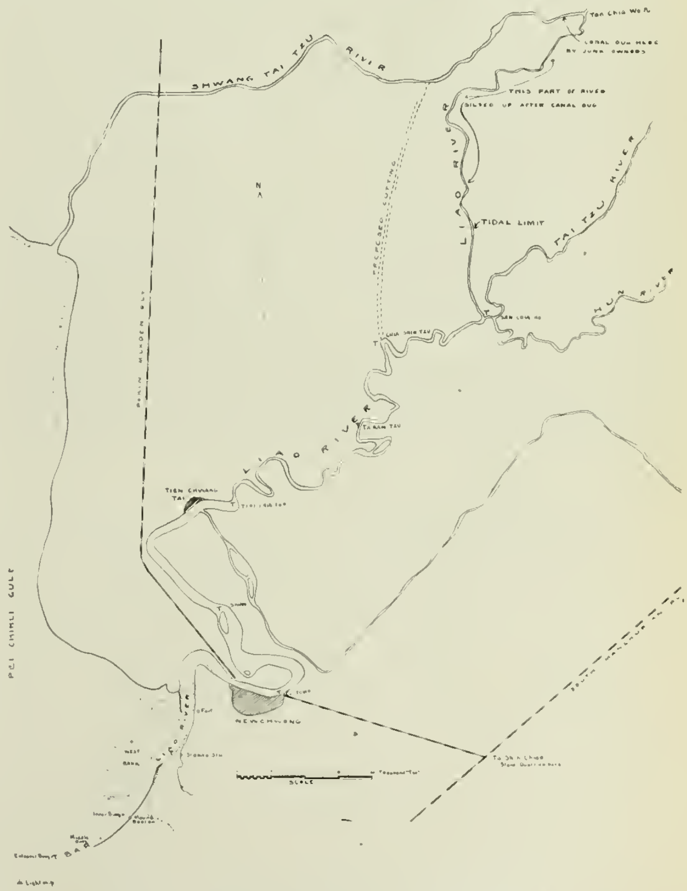

Fig. 1—The Liao River and Tributaries.

The next step was to make a proper triangulation of the whole river from the bar to Swan island. (Fig. 3.) Sides of the triangles were from one to three miles long. Accurate base line measurements had already been made by Mr. Hughes from Fort to Signal Station. All angles were measured six times by trebling the angle then reversing the instrument and again trebling it. The correction of the survey was interesting as all triangles were corrected to 180 degrees and the central angles of each polygon corrected to 360 degrees, also in each polygon the sum of the log sines of right hand external angles was corrected to equal the sum of the log sines of the left hand external angles. With so many triangles being common to two polygons this last correction was complicated but the results were gratifying indeed. When taking angles minor triangulation was made of any prominent chimneys, flagstaffs, etc., which might be useful for sounding work. The angles at East Bank Beacon and West Bank Beacon on the bar were taken with sextants, as these were in about 10 feet of water.

In plotting the surveys and for taking and plotting soundings three draughting boards 4 by 6 feet were used. All points of the triangulation were plotted on these boards, one for work on the bar and two for the river. The banks of the river were then fixed by walking along the bank with a sextant and every two or three hundred feet taking two angles on any three triangulation points.

The next step was to obtain levels, as no levelling had been done along the river. These were started from Signal Station and ran to Swan island with bench marks established where a tide gauge might be placed. It was also necessary to have a level close to the bar for sounding the bar, and as the east training wall had been built from No. 5 Beacon to Mound it was decided to run levels down to Mound. The training wall was only built to a height of about two feet above low water, so concrete blocks 4 by 6 feet and 4 feet high were first poured on the wall and a hole left in the centre to take a beacon, which served to mark the wall when it was covered at high water. The training wall was constructed of hand size rubble stone and was settling slightly all the time so that levels were carried out from Signal Station to Mound every year before any sounding on the bar took place.

The levelling completed, tide gauges were established at seven points along the river. The gauges used were 2- by 8-inch plank nailed to a pile driven in the sand. They were 20 feet and the pile 25 feet long. Owing to shortage of funds a floating pile driver was not available so that all piles were driven by hand. The method was briefly: two junks were taken out on to the bar with their crew of seven men each and about six extra coolies to assist. These junks, about 40 feet long with a 9-foot beam, were anchored fore and aft at the spot where the gauge was to be placed with a foot of clearance between the junks. Two poles 10 feet long were lashed to the pile one on either side at a suitable height and the pile then hoisted to an upright position over the water with the poles forming a large T. Ten men would then scramble up on to the tee pieces and when all set the pile would be let go. The weight of the pile and men on it was sufficient to drive it into the sand enough to make it stick; then four guys were made fast to the top and the driving action would start. This was accomplished by swaying the pile from side to side by the guy ropes and at the same time the ten men on the tee piece would jump up and down, the men all jumping in unison with a song accompaniment and a huge amount of shouting by the remainder of the crew, the foreman shouting the loudest of all. It was a most bizarre method of driving piles but it worked. Large beacons 60 feet in height with a 17-foot diamond on the top were driven in the same way to a depth of ten or twelve feet in hard sand, the only difference being that there were more men, more singing and more shouting. This method was only used where piles or beacons were driven in water. Later a small hand power jetting pump was added to the equipment.

Having erected the tide gauges at the middle and outer buoys it was necessary to obtain their levels. These gauges were in the open sea, the latter being five miles out from Mound Beacon and the only way to obtain their levels was to obtain high water reading, which is always a level plane or nearly so, of the gauges at Mound Beacon Signal Station and the two buoy gauges. The only trouble was that there always seemed to be a wind or a bad sea to contend with and junks anchored at the buoys with tide gauge readers on board would run for shelter when a sea came up, and if the wind died down the junks could not get out to the gauges again against the tide. Finally, after about two weeks' trial, the necessary readings were obtained. These readings coupled with those at the other two gauges gave figures from which the slope of the water on both flood and ebb tides could be plotted. All was now ready to take soundings on the bar, when the gauges at the middle and outer buoy were stolen during the night.

The erection and levelling of the gauges had cost considerable money and it was decided that it was not worth the expense, as when readings of the tides taken at these four gauges were plotted they showed that, for sounding purposes, the gauge at Mound Beacon could be used on most of the ebb tide and obtain from it reductions which would be sufficiently accurate for the whole bar.

When gauges were established and levelled at the other points on the river previously mentioned it was decided to take a series of simultaneous tidal observations on the whole river. The Upper River Conservancy staff established gauges on their section and simultaneous readings were taken every ten minutes over the whole of the tidal part of the river. The tide gauge readers were usually slightly educated coolies who were supplied with watches. These coolies were anxious to see how the watches worked, much to the detriment of the watches, and one could never be sure for any length of time that all watches were going and correct. When the watches stopped the obliging coolies would guess at the time for possibly a twelve hour stretch and it was also found that the readers would go to sleep for two or three hours and then guess at the height of the tide for that period. After a good deal of disciplinary action and patience excellent results were finally obtained and these were of value as they showed the progress of the tidal wave up river and gave the quantity of the tidal charge of the river.

Taking Soundings

The all important work of the survey department and the most interesting was taking soundings. One complete survey was made of the whole bar every year and usually one or two smaller surveys of those parts on which work was to be done. Also one complete survey was made of the river from Mound Beacon up to Swan island. The scouring effect of the training wall on the bar was of interest and the only way to watch it was by taking soundings. Each spring three large survey beacons were placed on the bar at Mound, East Bank and West Bank, the remaining beacons shown on Fig. 2 were placed by the customs service as aids to navigation but were useful as well. Those beacons placed on the training wall were in concrete blocks and did not need to be triangulated but the remainder had to be triangulated as soon as erected in the spring.

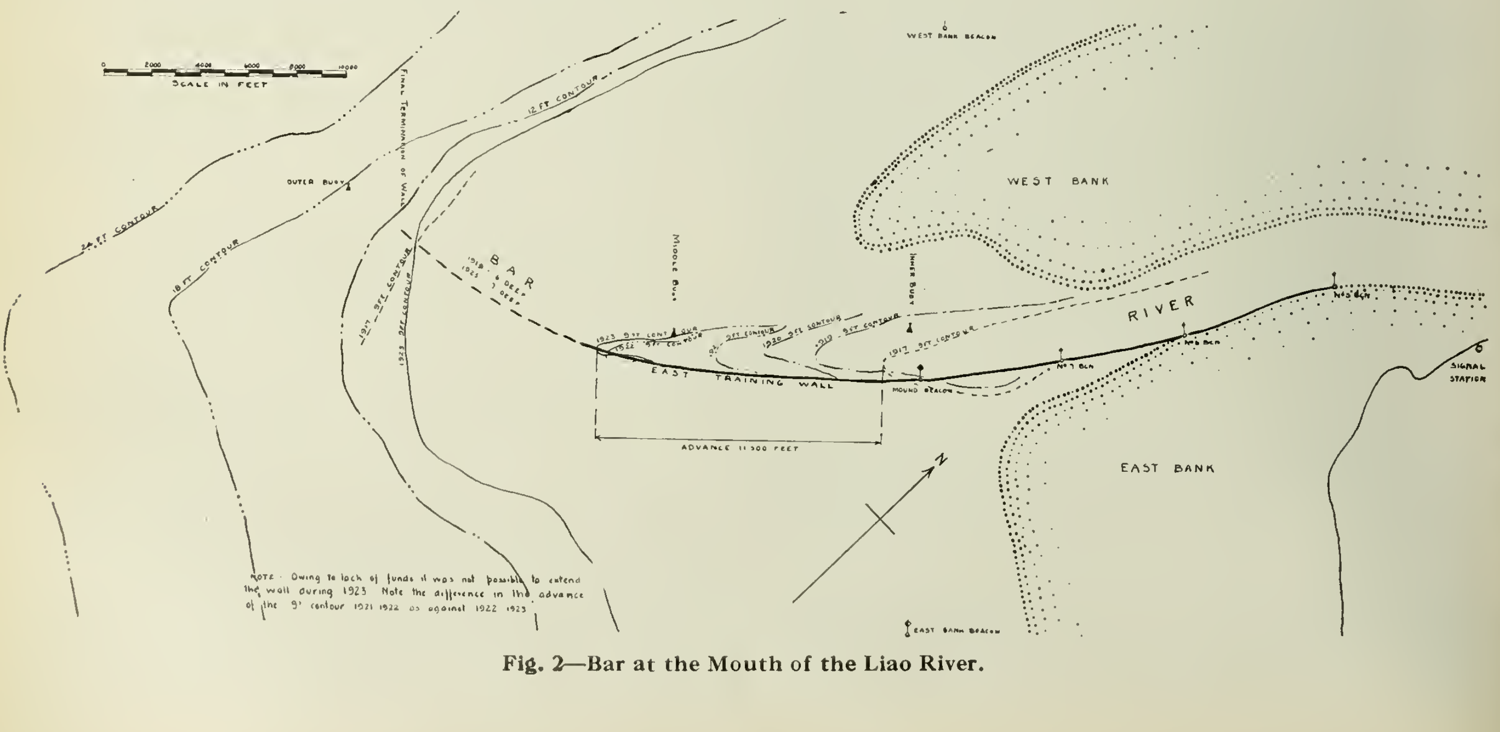

Fig. 2—Bar at the Mouth of the Liao River.

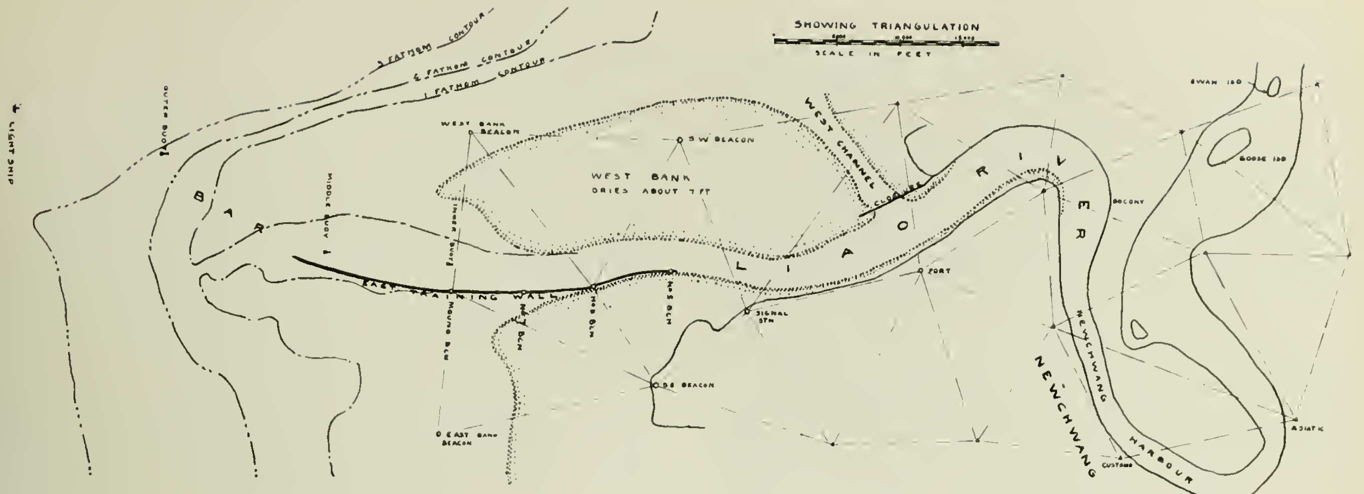

Fig. 3—Triangulation of the Lower Liao River.

For sounding on the bar a 60-foot steam launch with a crew of six men was used. Before starting the survey a series of transit lines that the launch could steam along were laid out and it was arranged so that no two sounding lines were over 1,000 feet apart. All depths were read to 3 inches using bamboo poles for depths up to 16 feet and lead lines for over that depth. Tide gauge readers were placed at Signal Station and Mound Beacon with watches corrected. When sounding the launch ran at a speed of 3 to 4 knots, two sailors, one on either side of the launch, took the depth taking about ten soundings a minute all of which were recorded in the sounding book. The author and his assistant would fix the position of the launch by taking sextant angles on three beacons at the same time. That is, the angle between East Bank Beacon and Mound would be measured and also the angle between Mound and West Bank Beacon. The position of the launch was fixed about once a minute during which time ten soundings had been taken and the launch travelled 400 feet. The time of fix and angles were all entered in the sounding book. A survey of the bar usually took about two weeks. It could have been done quicker but when sounding to 3 inches the sea must be calm and it was sometimes necessary to wait for days before anything could be done.

As the nearest tide gauge to the bar was at Mound Beacon it was necessary to stop sounding as soon as there was a suspicion of flood tide at the outer buoy. All soundings were reduced to the depth at low water of ordinary spring tides which meant that the depth at any one place was reduced by the amount that the gauge at Mound showed above low water, but if there was a slight rise in the tide at the outer buoy it meant that the slope of the water over the bar was in the form of a very flat V with the bottom point of the V gradually coming nearer Mound Beacon until such time as the flood tide started making at Mound. If sounding at that time readings on the gauge at Mound showed low water with no reduction in the soundings whereas actually at the outer buoy the tide may have risen as much as 9 inches and depths would show that much greater than they actually were. On some tides the water would actually rise a matter of 6 inches in ten minutes. No soundings were taken on the flood tide except in places where accuracy was not important.

River sounding was quite different in some respects. A gauge could be driven down in the soft mud quickly at any place where there was a bench mark and thereby sound at any state of the tide and also in most places there was no sea and soundings were only taken to 1 foot. The same launch was used but always with a lead line as the depth ranged anywhere up to 40 or 50 feet. Two men were placed on each bank of the river, each man with a light beacon 15 feet high. A man on either bank would place his beacon on the sounding line stone and his mate would place the other one in line with the stone and the beacon across the river. This gave the launch two beacons on either bank to keep in line. Large flags were also placed at all triangulation points on either bank in the vicinity for fixing the position of the launch. The launch would steam as slowly as possible across river but there was often a tide running at 2 feet per second so that it was not going any too slowly. The greatest difficulty was in getting the sailors to take soundings in 40 feet of water quickly enough. The actual sounding in the river did not take long but the time was spent in getting tide gauge readers to the gauges and placing flags on the triangulation stones. Flags and poles had to be taken down at night as the flags were 4 feet square and were valuable to the natives as clothes for children and any flag left up over night was gone in the morning.

Current observations were also taken at various points on the river and bar with a current meter, but as the direction of the tide was often of more interest than the speed, floats were used most of the time. These floats were made from half of a 5-gallon oil can with a weight made of sheet lead and constructed so as to offer as much resistance to the current as possible suspended from the under side. The floats were followed in a sampan and their position fixed as often as desired.

The object of the Conservancy was to aid shipping to the port of Newchwang and it was realized that one way to assist would be in tide predictions. The tides over the Newchwang bar were a combination of the diurnal and the semi diurnal and the result was to give a large diurnal inequality in the height of high water. This caused the high water that occurred in the late afternoon and evening to be as much as 4 feet higher than the high water occurring in the morning. Therefore if the tides could be predicted reasonably accurately steamers could take advantage of the higher high water at all times and so load more cargo. The Liao river is situated at the head of the Pei Chihli Gulf and forms a bottle neck and with a strong southerly

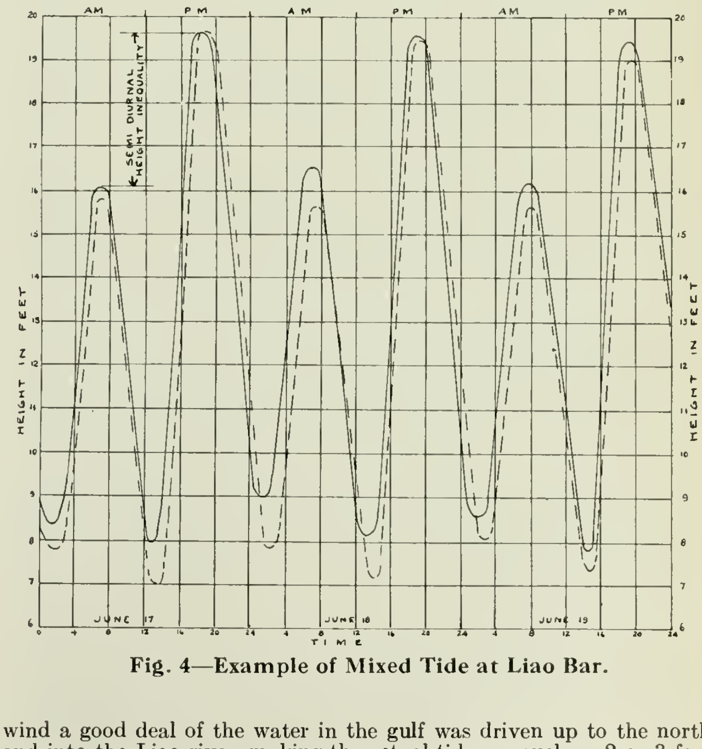

Fig. 4—Example of Mixed Tide at Liao Bar.

wind a good deal of the water in the gulf was driven up to the north and into the Liao river, making the actual tide as much as 2 or 3 feet above normal, and the reverse took place with a north wind. In order to predict tides it is necessary to have one year's tidal records to predict from but with so much wind at Newchwang it was necessary to take two or three years' tides in order to get away from the effect of the wind.

The author was not at the time acquainted with any method of tide prediction but after some study finally predicted tides for the bar. These predictions were issued in small books to the shipping companies and captains of steamers using the port and proved very useful. Figure 4 shows actual tides and predictions with predicted heights as a dotted line.

Work on the Bar

The main work of the Conservancy was the construction of the east training wall and the west channel closure. See Fig. 2. As mentioned previously Mr. Hughes had from 1916 to 1919 constructed the west channel closure and the east training wall from No. 5 Beacon to Mound Beacon. The closing of the west channel had helped to some extent in increasing the speed of the ebb tide over the bar but the main work was to push out the east training wall quickly in order to gain advantage of the increased scouring effect. The wall was carried on from Mound Beacon and in 1925 extended past the middle buoy. The stone used for the training wall was not all that could be desired as regards size. Owing to financial difficulties large plant to handle large sized stone could not be purchased and all stone used was placed by hand, which limited the size, though no stone was to weigh less than 66 pounds. The stone for the wall came by train from quarries at Ta Shih Chiao some 20 miles east of Newchwang. During the summer ten cars of stone arrived daily. The stone was brittle and with the loading on to cars at Ta Shih Chiao, unloading at Newchwang and loading and unloading on the bar, it broke up considerably. For transporting the stone there was a 94-foot sea-going tug and three barges. Two of the barges carried a deck load of 200 cubic yards each and were 110 feet long, 20-foot beam. The third barge was a self-dumping hopper barge 120 feet long, 22-foot beam and carried 220 cubic yards of stone. These barges were loaded by hand at the docks in Newchwang, which took two hours, and towed to the bar. Arrived at the bar the two barges with a deck load would moor, usually one on either side of the wall, and the stone was dumped on the wall by hand again. This also took about two hours. The hopper barge had large doors in the bottom of the hopper and was moored over the end of the wall where there was no stone and the doors opened. As all unloading was done on the ebb tide the arrangement worked out very well as the hopper barge could start the wall and the other two barges finish it to proper height. The wall was built up to 3 feet above low water and was approximately 10 feet high in all. The ice action in the winter and seas in the summer flattened it out a great deal and building was continued until such time as the stone found its own angle of repose. There were also twelve stone-carrying junks with a capacity of 28 to 50 cubic yards of stone. These were used in maintaining the older part of the wall and the west channel closure and filling up any gaps left by the barges.

There was also good stone available at Kaichow which is 13 miles by water south east of the end of the training wall. This stone was of better quality and cheaper than that at Ta Shih Chiao but there was no harbour at Kaichow and no docks. However it was decided to investigate the feasibility of taking the barges there. At low water there was no water at all on the shore, which meant at high water there was from 9 to 14 feet. The tug drew 9 feet of water and at one place there was a small point jutting out which afforded slight protection from the sea. It was therefore decided that it could be done and a wharf was built to accommodate the three barges and also hold a reserve supply of stone. The barges usually unloaded on the bar at low water and as soon as the tide rose a little the tug would pick them up and head for Kaichow. The trip took about three hours and by that time there would be sufficient water at the docks for the barges to go alongside. The tug would steam in at full speed and as soon as the water became too shallow she would swing around and let the barges go and they usually had sufficient way to make the dock. Loading took about two hours and by that time the tide would be sufficiently high for the tug to come in and pick up the barges. This was the schedule but for emergencies a large anchor was dropped out in deep water and a cable run from it to the dock. When the barges were loaded and there was not enough water for the tug the crew took a turn or two of the cable around their own winch and pulled out to the tug. The stone at Kaichow was quarried from the hills in the immediate vicinity and hauled to the dock in two wheeled carts. The carts were made entirely of wood including the axle and were of the same design as used in China some two thousand years ago. These carts carried about one cubic yard of stone, and were drawn by two horses, one mule and a donkey or any other arrangement of animals that the owner possessed.

The work required at times a good deal of ingenuity due to the almost complete lack of mechanical equipment. The only available power was the tug and launches. Everything else was done by hand. Concrete mixed by hand, piles driven by hand and stone loaded and unloaded by hand. The wages for coolie labour were about $4.50 per month and at that without board so that mechanical methods simply could not compete with labour. All lumber used was purchased in logs and sawn and dressed by hand. The dock built at Kaichow was constructed of concrete piles and 3- by 18-inch concrete planks to form a bulkhead. The whole of this work was made in Newchwang by hand, loaded and unloaded by hand at Kaichow and the piles driven by hand. The piles ranged from 18 to 25 feet in length.

In 1927 the east training wall had been constructed to a point well past the middle buoy, the total length being 36,000 feet. 510,000 cubic yards of stone had been placed on this wall and 54,000 cubic yards used on the west channel closure. The wall had been pushed out as quickly as possible to obtain the scouring effect on the bar and still required a great deal of stone to complete it. The cost of the stone laid down on the wall including all charges was $2.00 per cubic yard.

Figure 2 shows some of the results accomplished by the training wall, which were very gratifying. Before the wall was started the depth at low water on the bar was 6 feet but the six-foot contour had not broken through the bar. This contour finally broke through and later the seven-foot contour. In 1917 the nine-foot contour on the inside of the bar ended at Mound Beacon and in 1923 it had advanced to a point past the middle buoy, a total advance of 11,500 feet. In 1917 the distance from 9 feet of water outside the bar to 9 feet inside was three miles and in 1923 this had been reduced to one mile. The length of the bar had therefore been decreased by two miles and the depth increased by one foot. The consulting engineers had recommended the purchase of a dredger when the wall reached the middle buoy so that a channel could be started across the remainder of the bar which would materially assist in cutting through; however, finances at the time did not permit this.

It has been calculated that a total of 18½ million cubic yards of material was scoured off the bar between 1917 and 1925. The total cost of the work was roughly one million dollars or just a little over 5 cents per yard. A dredger could have taken it off much quicker but not as cheaply.

The Association of Professional Engineers of the Province of British Columbia

QUALIFICATIONS

LEADING TO A LICENCE TO PRACTISE

For University Applicants

"Engineering Pupil"—In British Columbia undergraduates enroll as "Engineering Pupils" in the third year of a five year course.

"Engineer-in-Training"—On graduation, graduates enroll as "Engineers-in-Training"; are formally welcomed into the Profession by means of a suitable ceremony held in their honour by the Council of the Association (part of the ceremony being, "The Order of the Calling of an Engineer"). An Entrance Fee of $10.00 becomes payable in the year subsequent to the year of graduation and an Annual Fee of $5.00 in succeeding years.

"The Licence to Practise" constitutes the highest honour at the disposal of the Engineering Profession and this is granted to graduates who, after four or five years of practical work and having paid their fees as Engineers-in-Training for this period, present a worth-while professional thesis of from five to ten thousand words, based on the work that they have enjoyed or been in contact with subsequent to graduation.

The theory or principle underlying the granting of a licence to practise is that which guides all the other professions, namely that those applicants who have successfully passed through the officially prescribed education, the officially prescribed junior experience and the official tests, deserve complete and full recognition. (Entrance Fee $35.00. Annual Fee $10.00.)

For Non-University Applicants

Non-university applicants, who must possess JUNIOR MATRICULATION, can obtain a licence to practise by passing three examinations, Preliminary, Intermediate and Final, together with a professional thesis. Semi-annual Examinations October 28th, 1935 and April 27th, 1936.

Further information can be obtained from:

THE REGISTRAR

The Association of Professional Engineers of the Province of B.C.
930 Birks Building, Vancouver, B.C.
Seymour 1827

The Lachine sheet of the National Topographic series of maps recently issued by the Geographical Section of the Department of National Defence provides a comprehensive view of the southern half of the island of Montreal, showing about one-half of greater Montreal, including Westmount, Montreal West and Bellevue, together with the area south of the St. Lawrence river in which are located Beauharnois, Caughnawaga, Chateauguay, Delson and St. Remi. In conjunction with the Laval sheet issued earlier in the year, the two maps almost completely cover the island of Montreal and a considerable area north and south of the St. Lawrence river.

The sheet is distributed by the Topographical and Air Survey Bureau, Department of the Interior, Ottawa, from which source copies may be obtained for 25 cents each.

Preliminary Notice

of Applications for Admission and for Transfer

September 30th, 1935

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in November, 1935.

R. J. Durley, Secretary.

*The professional requirements are as follows.—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ANDERSON—HOPE VERE, of 102 Fentiman Ave., Ottawa, Ont., Born at Motherwell, Scotland, Dec. 10th, 1890; Educ., 1906-10, Glasgow and West of Scotland Tech. Coll.; 1907-10, premium ap'tice. with Messrs. Alley and McLellan, Glasgow. Pattern-making, fitting, erecting and testing divn., drawing office; 1910-13, designing dftsman., as follows: 1910-11, G. & J. Weir, Glasgow; 1911-12, Mimlees Watson, Glasgow; 1912, International Marine Signal Co., Ottawa; 1913, Dept. of Mines, Ottawa; 1913-24, mech'l. engr., and 1924 to date, senior asst. engr., Dept. of Marine, Ottawa, Ont. Work includes inspection of sites for new projects and reports thereon. Design of lighthouse piers, timber and reinforced concrete, steel towers, protection works, depot wharves and workshops, optic apparatus, etc.

FOR TRANSFER FROM THE CLASS OF JUNIOR

BENJAMIN—ABRAHAM, of 1080 Lajoie Ave., Outremont, Que., Born at Glace Bay, N.S., Dec. 23rd, 1900; Educ., B.Sc., McGill Univ., 1924; 1925-29, with Electrical Commn. of the City of Montreal, in charge of expropriation and contract payments; 1929 to date, electric substation designer, Montreal Light, Heat and Power Cons., Montreal. (*St. 1921, Jr. 1928.*)

References: G. E. Templeman, G. C. Reid, H. Milliken, R. M. Walker, C. V. Christie, G. A. Wallace.

BOWN—CHARLES ROY, of 5404 Clanranald Ave., Montreal, Que., Born at Sydney, N.S., Dec. 10th, 1900; 1918-19, and summers 1920-22, helper in foundry, machine shop, etc., and tracer in drawing office, Dom. Iron and Steel Co., Sydney, N.S.; 1923-24, dftsman., Can. Mead Morrison Co., Welland, Ont.; 1924-26, mechanic's helper on constrn. of power stations for Stone & Webster Inc.; 1926-32, mech'l. inspector for same company on erection of mech'l. equipment in various power houses and industrial plants; 1932 to date, asst. chief engr., Canada and Dominion Sugar Co. Ltd., Montreal, Que. (*St. 1921, Jr. 1925.*)

References: K. G. Cameron, C. M. McKergow, A. W. McMaster, H. M. Black, R. A. Gurnham, D. A. Killam, E. B. Jubien.

HARRIS—ARTHUR CLIFFORD, of 256 Almon St., Halifax, N.S., Born at Halifax, Dec. 7th, 1900; Educ., B.Sc. (C.E.), N.S. Tech. Coll., 1927; 1925-26 (summers), with the City of Halifax; 1927, Dom. Bridge Co. Ltd.; 1928, N.S. Steel and Eastern Car Works; 1928 to date, asst. engr., City of Halifax, N.S. (*St. 1927, Jr. 1928.*)

References: F. R. Faulkner, W. J. DeWolfe, H. W. L. Doane, W. P. Copp, R. M. McKinnon.

HOLDEN—JOHN HASTIE, of Westmount, Que., Born at Westmount, May 20th, 1902; Educ., B.Sc., McGill Univ., 1923; 1922 (summer), dftsman., Shaw. Engrg. Co.; 1923-24, asst. to plant engr., Northern Electric Co. Ltd.; 1924-31, asst. to head estimator and chief dftsman., and 1931 to date, sales manager, in charge of sales and statistics, giving technical information regarding products, Geo. W. Reed & Co. Ltd., Montreal, Que. (*St. 1921, Jr. 1930.*)

References: B. R. Perry, W. G. Hunt, J. F. Plow, A. S. Rutherford, A. T. Bone.

McBRIDE—ERNEST WILLARD, of 86 High Park Ave., Toronto, Ont., Born at Churchville, Ont., July 24th, 1901; Educ., B.A.Sc., Univ. of Toronto, 1923; Summer work: (1) Willis Overland Electric shop; (2) Hollinger Gold Mines; (3) Bakelite Corpn.; 1923 (6 mos.), research work, Canada Paper Co., Windsor Mills, Que.; 1923 (3 mos.), research work, Univ. of Toronto; 1924-30, Abitibi Power and Paper Co., Iroquois Falls, 1 year, engr. on statistics, 2 years, asst. to control engr., 3 years, in charge of control dept.; 1930 to date, technical engr. with same company at Toronto, Ont. (*St. 1920, Jr. 1928.*)

References: F. L. Mitchell, T. R. Loudon, A. M. Reid, J. W. Dyer, E. L. Goodall, H. O. Brown, G. W. Holder.

PINEAU—MAURICE, of 1377 Fleury St., Montreal, Que., Born at Mussidan, France, March 6th, 1902; Educ., 1924-27, Montreal Technical School. Passed Institute's exams. under Schedule "B" for admission as Junior Nov. 1932; 1927-29, heating and engrg. depts., Crane Limited, Montreal. In charge of design of heating systems of all descriptions. Design of boiler plants. Research work in design and testing of boilers and radiators. High and low pressure piping layouts; 1929-32, with McDougall & Friedman, Consltg. Engrs., Montreal. Design and layout of boiler plants. High and low pressure piping layouts. Ventilating, air conditioning and plumbing systems for large public bldgs., hospitals, etc. Specifications, estimates, supervision and inspection during constrn.; 1932-34, doing similar work to above for McDougall & Friedman, Raoul Lacroix, Architect, and L. A. St. Pierre, Consltg. Engr.; 1934 (June-Nov.), with Canada Paper Co., Windsor Mills, Que., in charge of design and erection of a 3,400-ft. outside h.p. steam line; Jan. 1935 to date, heating and engrg. depts., Crane, Limited, Montreal. In charge of engrg. pertaining to the heating dept. Design of pipe bends and fabrication in the engrg. dept. (*Jr. 1932.*)

References: G. K. McDougall, T. E. McGrail, C. P. Creighton, F. J. Friedman, J. D. Fry, J. A. Kearns, H. L. Johnston.

SEVIGNY—JOSEPH ALFRED, of 733 St. Cecile St., Three Rivers, Que., Born at St. Angele de Laval, Que., Feb. 13th, 1902; Educ., 1918-22, Grad., De La Salle Academy, Three Rivers; Passed E.I.C. Exams. under Schedule "B" for admission to class of Junior, 1933; With the St. Lawrence Paper Mills Co. Ltd., Three Rivers, as follows: 1923-25, steam clerk; 1925-26, dftsman.; 1927-28, in charge of control work, control dept.; 1928-32, chief dftsman., and 1932 to date, chief dftsman. and asst. to plant engr. (*St. 1925, Jr. 1933.*)

WILSON—ARCHDALE McDONALD, of 223 Pilgrim St., Sault Ste. Marie, Ont., Born at Hamilton, Ont., Oct. 7th, 1899; Educ., B.Sc., Queen's Univ., 1928; 1918-20 and summers 1922-27, chainman, rodman and instr'man., T.H. & B. Ry., Hamilton, Ont.; 1928 to date, asst. engr., Algoma Central and Hudson Bay Rly., Sault Ste. Marie, Ont. (*Jr. 1929.*)

References: R. S. McCormick, A. E. Pickering, E. M. MacQuarrie, H. B. Stuart, R. L. Latham.

FOR TRANSFER FROM THE CLASS OF STUDENT

BARBOUR—CLARENCE ALLEN, of Saint John, N.B., Born at Saint John, Feb. 14th, 1906; Educ., B.Sc. (E.E.), Univ. of N.B., 1931; Summers: 1929-30, N.B. Telephone Co. Ltd., 1931, Saint John Harbour Commission; 1931-32, asst. engr., Canadian Comstock Co., and journeyman electrn., Sterling Electric Co. Ltd.; 1932 to date, proprietor, Maritime Radio and Electrical Supplies, Saint John, N.B. (*St. 1930.*)

References: W. J. Johnston, A. Gray, A. F. Baird, A. A. Turnbull, J. Stephens.

BENNETT—ARTHUR J., of Montreal, Que., Born at River Desert, Que., April 23rd, 1904; Educ., B.Sc. (E.E.), McGill Univ., 1927; Summers: 1924, rodman on survey, Dept. Nat. Defence; 1925-26, instr'man., Beatty & Beatty; 1927-28, layout and survey of toll lines, Quebec Divn., outside plant, Bell Telephone Co. of Canada; 1929 to date, sales engr., English Electric Co. of Canada Ltd., Montreal, Que. (*St. 1925.*)

References: G. Kearney, C. V. Christie, A. D. Ross, H. M. Black, R. DeL. French, K. O. Whyte, R. H. Balfour.

CUNNINGHAM—GEORGE ALLIN, of 331 Reid St., Peterborough, Ont., Born at Peterborough, May 1st, 1908; Educ., B.A.Sc., Univ. of Toronto, 1929; Summers: 1926, machine shop, Wm. Hamilton Ltd.; 1927, bldg. constrn., A. B. Cunningham, contractor; 1928, asst. to mgr., Peterborough Public Utilities; 1929-31, asst. chief engr., Riley Engineering and Supply Co. Ltd., Toronto, also in charge of design and production of materials handling divn.; 1932 to date, district representative, Imperial Oil Ltd., selection and specification of lubricants and fuels for internal combustion engines, installn. and operation of combustion systems, recommendation of industrial lubricants, and management of operating personnel. (*St. 1927.*)

References: R. L. Dobbin, E. A. Allcut, A. B. Gates, R. H. Parsons, V. S. Foster.

DOBRIDGE—RONALD WEMYSS, of 41 Dobie Ave., Town of Mount Royal, Que., Born at St. Kitts, B.W.I., Sept. 26th, 1905; Educ., B.Sc., 1928, M.Sc. (Physics), 1929, McGill Univ.; 1926 (summer), rodman, C.P.R., Ottawa; 1928 (summer), engr., Northern Electric Co., Montreal; 1929-33, engr., Bell Telephone Co. of Canada, Montreal; Oct. 1934 to date, transformer engr., Canadian Marconi Company, Montreal. (*St. 1928.*)

References: J. H. Thompson, W. H. Moore, E. W. Farmer, J. L. Clarke.

HAMILTON—ROBERT WILLIAM, of 113 Brock Ave. South, Montreal West, Que., Born at Montreal, November 16th, 1907; Educ., B.Sc. (E.E.), McGill Univ., 1929; 1926 (summer), sketching and checking constrn. of paper mill foundations, Fraser Brace Engrg. Co.; With the Dominion Electric Protection Company as follows: 1927 (summer), installing signal systems; 1928 (summer), installing switchboards, generators in central station at Montreal; 1929-30, junior engr in charge of development of new apparatus; 1930 to date, electrical engr. Full charge of engrg. dept. located at Montreal which serves central stations at Winnipeg, London, Hamilton, Toronto, Ottawa, Montreal and Quebec, and factory at Montreal. (*St. 1925.*)

References: D. C. Tennant, C. V. Christie, R. E. Jamieson, C. B. Brown, G. E. Templeman.

HART—WILLIAM O., of 431 Simcoe St. South, Oshawa, Ont., Born at Bowmanville, Ont., June 24th, 1906; Educ., B.Sc., Queen's Univ., 1929; 1925 (June-Aug.), pipe fitting for H.E.P.C. at Hydro, Ont.; With the General Motors Company of Canada, Oshawa, Ont., as follows: 1928 (May-Aug.), reject dept. mechanic; 1929-30, salvage dept.; 1930-33, technical clerk, body plant office, in charge of engrg. and production records in body plant and inspection office; Sept. 1933 to Mar. 1935, inspection supervisor of body shop, mill rooms and garnish moulding inspection; at present, advertising and sales mgr., Oshawa Dairy Ltd., Oshawa, Ont. (*St. 1928.*)

References: F. Chappell, D. M. Jemmett, A. Macphail, L. T. Rutledge, D. S. Ellis.

HUTTON—JOHN R., of 123 Bold St., Hamilton, Ont., Born at Halifax, N.S., June 2nd, 1905; Educ., B.Sc. (E.E.), N.S. Tech. Coll., 1927; With Canadian Westinghouse Co. Ltd., as follows: 1927-29, student apprentice; 1929-32, illumination divn.; 1932-35, correspondence and sales, and at present engr., lamp dept. (*St. 1925.*)

References: F. R. Faulkner, D. W. Callander, W. F. McLaren, J. R. Dunbar, H. U. Hart, G. W. Arnold.

LOCHHEAD—KENNETH YOUNG, of Winnipeg, Man., Born at Lachine, Que., Sept. 26th, 1907; Educ., B.Eng. (C.E.), McGill Univ., 1932; 1930 (summer), student engr., Montreal Harbour Commn.; 1931 (summer), student engr., Dominion Bridge Company; 1932-33, demonstrator, mech'l. engrg. laboratory, McGill University; at present, asst. to supt. of bldgs., Hudson's Bay Company, Winnipeg, Man. (*St. 1931.*)

References: H. M. White, G. J. Dodd, C. M. McKergow, E. Brown.

MacGREGOR—JAMES GRIERSON, of Vegreville, Alta., Born at Dornoch, Scotland, June 2nd, 1905; Educ., B.A., B.Sc., Univ. of Alta., 1929; 1928, smoke testing, etc., Cons. Mining and Smelting Co., Trail, B.C.; 1929, meter testing, line constrn., 1929-31, office work in all branches of electric utility, including rates, valuation, constrn., and from 1931 to date, district supt., Lloydminster-Vegreville district, Canadian Utilities Limited. (Two diesel generating plants, 155 miles transmission line serving 14 towns and villages. In charge of operation, mtce., new constrn., rates, collections and merchandise.) (*St. 1929.*)

References: E. W. Bowness, R. S. Trowsdale, C. A. Robb, H. J. MacLeod, R. S. L. Wilson.

MOLLARD—JOHN ELLIS, of Tisdale, Sask., Born at Grand Bend, Ont., Sept. 1st, 1903; Educ., B.Sc. (M.E.), Univ. of Sask., 1931; With the Dominion Electric Power as follows: Jan. 1926 to Oct. 1927, plant operator, Biggar, Sask.; Oct. 1927 to July 1928, plant mgr., Gravelbourg, Sask.; 1928 (July-Oct.), 1929 (May-Oct.), and 1930 (May-Oct.), line foreman at Shaunavon and Estevan; With the Saskatchewan Power Commission as follows: 1931 (June-Sept.), constrn. dept., Regina; Oct. 1931 to Jan. 1932, operator, operating dept., Humboldt, Sask.; Feb. 1932 to date, supt., Tisdale, and at present, district supt. (Diesel electric plant, distribution systems, and 13 k.v. transmission line). (*St. 1931.*)

References: C. J. Mackenzie, L. A. Thornton, R. W. Jickling, I. M. Fraser, W. E. Lovell.

McINTYRE—DOUGLAS VALLANCE, of Rouyn, Que., Born at High River, Alta., April 28th, 1903; Educ., B.Sc. (E.E.), Univ. of Alta., 1931; 1928, constrn. survey, E.D. and B.C. Rly.; 1931-32, electrn. (constrn.), Gen. Elec. Company; 1933, track relay, C.N.R.; at present, electrn., McWalters Gold Mines, Ltd., Rouyn, Que. (*St. 1930.*)

References: H. J. MacLeod, W. E. Cornish, H. R. Webb, P. F. Poole.

RYDER—FREDERICK JAMES, of 1430 Giles Blvd. East, Windsor, Ont., Born at Holyoke, Mass., June 28th, 1907; Educ., B.Sc. (C.E.), McGill Univ., 1929; Summers: 1926-27, rodman and chainman, C.N.R.; 1928, instr'man., Laurentide Pulp and Paper Co., Grand'Mere, Que.; 1929-32, dftsman., Canadian Bridge Co., Walkerville, Ont.; 1932 to date, with Motor Products Corpn. Ltd., Walkerville, Ont., material dept. and gen. office work. (*St. 1928.*)

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

Situations Wanted

ESTABLISHED SALES ENGINEER, Univ. of Toronto '24, with plant and manufacturing experience, wishes to represent manufacturers of technical equipment. Connections with automobile and electrical equipment dealers, throughout Canada. Will make small investment if necessary. Apply to Box No. 1-W.

SALES ENGINEER, S.E.I.C.; B.SC. C.E., 1930 (Univ. New Bruns.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.SC., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ENGINEER AND ACCOUNTANT, JR.E.I.C., (Capt. Can. Engrs., reserve). Age 35, Canadian. Experienced in mechanical and civil engineering, Diploma; general office, draughting and instrument work; assistant engineer erection Royal York hotel; assistant resident engineer T. & N.O. Ry. const. Desires position in Toronto where combination of technical and business experience will be of value, as have been director and accountant last three years. Apply to Box No. 377-W.

CIVIL ENGINEER, B.A.SC. and C.E.; A.M.E.I.C., A.M.A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.SC. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

MECHANICAL ENGINEER, B.SC. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

CONSTRUCTION ENGINEER, age 26, unmarried, graduate C.E. Experience includes hydro-electric, railroad, highway, and industrial plant construction, both field and office, including cost accounting, estimating, stores, layout, general engineering and supervision, as well as practical work in mechanical trades. Apply to Box No. 567-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

ELECTRICAL ENGINEER, McGill '31, desires permanent position in engineering field. Experience includes draughting, designing and testing of induction motors, radio supervision and test, and some construction. Available immediately. Apply to Box No. 626-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

Situations Wanted

ELECTRICAL AND RADIO ENGINEER, B.SC. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC., Elec., '29, B.SC., Civil '33. Age 27. JR.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

Employment Service Bureau

This bureau is maintained by The Engineering Institute of Canada for the benefit of members and organizations employing technically trained men.

An enquiry addressed to 2050 Mansfield Street, Montreal, will bring full information concerning the services offered. Details can also be obtained from Branch secretaries who are located in the larger centres throughout Canada.

Brief announcements of men available and positions vacant will be published without charge in The Engineering Journal and the Bulletin. Replies addressed in care of the required box number will be forwarded to the advertiser without delay.

An additional service also offered those who are unemployed or wish to change their positions, is the opportunity of placing their names and records on file at 2050 Mansfield Street for consideration by employers wishing to employ engineers. This is of great assistance as many employers will not advertise or wish to locate a suitable man on short notice. If desired the information contained in these records can be kept confidential.

Forms for registration purposes may be obtained from The Institute Headquarters or Branch secretaries.

MECHANICAL ENGINEER, B.SC., '27, JR.E.I.C. Four years maintenance of high speed Diesel engine units, 200 to 1,300 h.p. Also maintenance of d.c. and a.c. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.SC., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

CIVIL ENGINEER, B.SC. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

Situations Wanted

YOUNG CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.SC., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

RADIO AND ELECTRICAL ENGINEER, B.SC. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.SC. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, S.E.I.C., B.SC. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.SC., '25, JR.E.I.C., P.E.Q, married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.A.SC., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.SC. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.SC. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.SC., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.SC. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

Situations Wanted

SALES ENGINEER, A.M.E.I.C., graduate engineer, age 34, practical experience in the manufacture of power plant equipment, thoroughly conversant with Canadian power plant practice and equipment for the metal working industries. Available on short notice. Apply to Box No. 860-W.

CHEMICAL ENGINEER, B.SC. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, B.A.SC. in C.E., with business and sales experiences, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.SC., JR.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.SC., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.SC. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.SC., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.SC. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

Situations Wanted

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.SC. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.SC. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.SC., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.SC.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.SC. (Univ. of B.C. '29); M.S. Age 27. Single. Four years experience in research work in applied mechanics and materials testing. Desires position involving analytical work in design, development or testing. Available on short notice. Apply to Box No. 1023-W.

PETROLEUM CHEMIST, B.SC. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER, B.SC., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.SC., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

Situations Wanted

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.SC. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.SC., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Writes and speaks both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211-W.

CIVIL ENGINEER, B.SC. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet tissues. Apply to Box No. 1246-W.

ELECTRICAL ENGINEER, B.SC. '34 (Univ. of N.B.). S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

CIVIL ENGINEER, Univ. Toronto '33, age 24, married. One year as instrumentman with provincial department of highways. Experience in concrete and retread construction grading, culverts, etc. Also draughting, estimating and general office practice. Apply to Box No. 1265-W.

ELECTRICAL GRADUATE, S.E.I.C., B.SC. '32, M.SC. '34. Experience includes four years as part time operator and announcer for a radio broadcast station. At present employed in radio repair dept. of a large wholesale firm. Apply to Box No. 1283-W.

ELECTRICAL ENGINEER, B.SC., E.E., A.M.E.I.C. University of Manitoba '28. Age 32. Married. Experience one year power line construction, five years resident and assistant district engineer on highway construction; two years highway traffic regulation in charge of district office. Good connections in Manitoba and Saskatchewan. Excellent references. Available at once and will go anywhere. Located in Winnipeg. Apply to Box No. 1316-W.

ENGINEER AND DRAUGHTSMAN, JR.E.I.C., age 33, married. Diplomas from Mtl Tech. Inst. in R.C. and Structural Design. 11½ years experience in civil engineering, draughting and instrument work. This includes 7 years with M.L.H. & P. Cons. as field engineer on construction and maintenance of gas mains. Present location Montreal. Available at once. Apply to Box No. 1326-W.

GRADUATE ENGINEER, (McGill), in responsible charge of design, construction and operation of hydro-electric plants. Also power design and mechanical maintenance of industrial plants. Apply to Box No. 1328-W.

MECHANICAL ENGINEER, recent grad. University of Toronto, B.A.SC. in mech. engrg, 24 years old, S.E.I.C., now managing a chain store, desires engineering work. Present location So. Ontario. Location immaterial. Best of references. Apply to Box No. 1348-W.

Telephones

World telephone statistics recently issued for 1934* will impress all engineers with the growth and development of telephone service during the past sixty years. It is difficult to conceive of such a development taking place in so short a period, but the first record of the use of the term "telephony" only occurred in a lecture delivered before the Physical Society of Frankfort in 1861 by Philipp Reis, the experiments of Alexander Graham Bell taking place only ten years later, between 1874 and 1876. In 1934, 32,495,855 telephones were in use in the world; an astonishing figure, yet only 1.54 telephones for each one hundred of the population. Some 14,300,000 of these are automatic or dial telephones of which 46 per cent are in the United States.

The United States, where the earliest developments occurred, has continued to be the leader in the number of installations, and now has 51.4 per cent of the total instruments in the world, or 13.29 telephones per one hundred population. Canada ranks second with 1,192,330, or 11.15 telephones per one hundred population. New Zealand is third and Denmark fourth. Great Britain is the leader of the major European countries with 4.78, ranking tenth; Germany, which has almost three million telephones and is second to the United States in the number of instruments installed, holds eleventh place with 4.48. In Asia, Japan is the outstanding country with 1.50 telephones per one hundred of population and Argentina in with South American countries with 2.64.

Canada, with 84 per cent of telephones under private management, ranks second to the United States in this respect. As a striking contrast there are the three major European countries, Great Britain, Germany and France with telephone services exclusively operated by the government.

Washington, D.C. is the leader in telephone development among the large cities of the world, with 35.31 telephones per hundred of population. Vancouver in fifth place is the leader of the Canadian cities with 27.51, Toronto ranking ninth with 24.44; Ottawa has 18.88 and Montreal 16.14 telephones per one hundred population. Stockholm, the leading European city, has a development of 31.95, New York 20.83, Paris 14.18, Berlin 10.85 and London 9.07 telephones per one hundred population.

Interesting figures and annual surveys show an unmistakable trend towards still greater usage in every country. This however is not to be wondered at when the recent technical advances in the telephone art are considered, and long distance transmission, radio and carrier current telephony and automatic systems which will no doubt further increase the trend.

*Bell Telephones Quarterly, July, 1935.

TREASURER
J. B. CHALLIES, Montreal, Que.

SECRETARY
R. J. DURLEY, Montreal, Que.

OFFICERS OF BRANCHES

HALIFAX
Chairman, H. FELLOWS
Sec.-Treas., R. R. MURRAY, 87 Cambridge St., Halifax, N.S.
Executive, C. S. BENNETT, R. M. McKINNON, W. H. NOONAN, J. R. KAYE, F. C. WIGHTMAN, E. L. MILES, G. MEDFORTH, J. D. FRASER, J. H. M. JONES
(Ex-Officio) R. L. DUNSMORE, H. S. JOHNSTON

CAPE BRETON
Chairman, W. E. BOWN
Sec.-Treas., SYDNEY C. MIFFLEN, 60 Whitney Ave., Sydney, N.S.
Executive, M. R. CHAPPELL, W. S. WILSON, C. M. ANSON, W. E. CLARKE
(Ex-Officio) C. M. SMYTH

SAINT JOHN
Chairman, V. S. CHESNUT
Vice-Chair., J. R. FREEMAN
Sec.-Treas., F. A. PATRIQUEN, 19 Horsfield St., Saint John, N.B.
Executive, S. HOGG, C. S. MacLEAN, G. H. THURBER
(Ex-Officio) E. J. OWENS, A. GRAY, G. A. VANDERVOORT

MONCTON
Chairman, H. B. TITUS
Vice-Chair., G. L. DICKSON
Sec.-Treas., V. C. BLACKETT, Engrg. Dept., C.N.R., Moncton, N.B.
Executive, F. O. CONDON, JAS. PULLAR, T. H. DICKSON, C. S. G. ROGERS, A. S. GUNN, G. C. TORRENS
(Ex-Officio) H. J. CRUDGE, J. G. MacKINNON

SAGUENAY
Chairman, J. SHANLY
Vice-Chair., S. J. FISHER
Sec.-Treas., L. R. BEATH, P.O. Box 211, Kenogami, Que.
Executive, W. L. YACK, E. LAVOIE, H. B. PELLETIER, M. G. SAUNDERS
(Ex-Officio) G. E. LaMOTHE, J. W. WARD, G. H. KIRBY

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, ALEX. LARIVIERE
Vice-Chair., J. T. F. KING
Sec.-Treas., J. JOYAL, Quebec Public Service Comm., Court House, Quebec, Que
Executive, R. B. McDUNNOUGH, L. P. METHE, L. BEAUDRY, A. G. SABOURIN, J. G. O'DONNELL, A. ROBERGE
(Ex-Officio) A. B. NORMANDIN, HECTOR CIMON

ST. MAURICE VALLEY
Chairman, B. GRANDMONT
Vice-Chair., E. B. WARDLE
Sec.-Treas., J. A. HAMEL, 642 Notre Dame St., Three Rivers, Que.
Executive, J. E. FLEURY, R. MORRISSETTE, J. H. FREGEAU, H. J. WARD

MONTREAL
Chairman, F. S. B. HEWARD
Vice-Chair., J. B. D'AETH
Sec.-Treas., C. K. McLEOD, 1440 St. Catherine St. W., Montreal, Que.
Executive, F. E. V. DOWD, J. A. LALONDE, J. G. HALL, B. R. PERRY, J. H. LANDRY, R. H. FINDLAY
(Ex-Officio) C. B. BROWN, A. COUSINEAU, O. O. LEFEBVRE, F. A. GABY, J. A. McCRORY, P. L. PRATLEY, J. L. BUSFIELD, E. A. RYAN, A. FRIGON, F. P. SHEARWOOD

OTTAWA
Chairman, R. W. BOYLE
Sec.-Treas., F. C. C. LYNCH, Dept. of Mines, Motor Bldg., Ottawa, Ont.
Executive, B. F. HAANEL, A. V. GALE, T. A. McELHANNEY, J. H. PARKIN, G. R. TURNER
(Ex-Officio) A. K. HAY, C. M PITTS, E. W. STEDMAN, C. CAMSELL

PETERBOROUGH
Chairman, A. L. DICKIESON
Sec.-Treas., W. T. FANJOY, 223 Crescent St., Peterborough, Ont.
Executive, V. R. CURRIE, A. L. KILLALY, E. J. DAVIES, E. R. SHIRLEY
(Ex-Officio) J. W. PIERCE, H. R. SILLS, R. L. DOBBIN

KINGSTON
Chairman, R. A. LOW
Vice-Chair., Lt.-Col. N. C. SHERMAN
Sec.-Treas., Major L. F. GRANT, Royal Military College, Kingston, Ont.
Executive, G. G. CARR-HARRIS, S. STEPHENSON, J. E. GOODMAN
(Ex-Officio) W. CASEY, L. F. GOODWIN

TORONTO
Chairman, W. E. BONN
Vice-Chair., O. HOLDEN
Sec.-Treas., W. S. WILSON, Mining Bldg., University of Toronto, Toronto, Ont.
Executive, N MacNICOL, W. G. CHACE, A. M. REID, J. M OXLEY, C. E. SISSON, A. U. SANDERSON
(Ex-Officio) R. E. SMYTHE, A. B. CREALOCK, J. ROY COCKBURN, C. S. L. HERTZBERG

HAMILTON
Chairman, W. HOLLINGWORTH
Vice-Chair., J. STODART
Sec.-Treas., A. LOVE, 40 Paisley Ave. S., Hamilton, Ont.
Asst. Sec., A. B. DOVE
Executive, W. J. W. REID, V. S. THOMPSON, E. G. MacKAY, D. W. CALLANDER
(Ex-Officio) F. W. PAULIN, H. B. STUART

LONDON
Chairman, S. W. ARCHIBALD
Vice-Chair., J. FERGUSON
Sec.-Treas., S. G. JOHRE, 153 Kent St., London, Ont.
Executive, V. A. McKILLIP, E. V. BUCHANAN, W. C. MILLER, H. A. BRAZIER, J. R. ROSTRON
(Ex-Officio) F. C. BALL, H. A. McKAY, J. A. VANCE

NIAGARA PENINSULA
Chairman, P. E. BUSS
Vice-Chair., G. H. WOOD
Sec.-Treas., P. A. DEWEY, 1224 Ontario Ave., Niagara Falls, Ont.
Executive, C. G. MOON, E. P. MURPHY, C. W. WEST, C. S. BOYD, S. HAIRSINE, J. H. JACKSON, J. C. STREET, L. C. McMURTRY, H. WELLWOOD
(Ex-Officio) E G. CAMERON, W. JACKSON, W. R. MANOCK

BORDER CITIES
Chairman, H. J. COULTER
Vice-Chair., T. H. JENKINS
Sec.-Treas., C. F. DAVISON, 32 Indian Road, Sandwich, Ont
Executive, E. M. KREBSER, D. T. ALEXANDER, B. CANDLISH
(Ex-Officio) C. G. R. ARMSTRONG, H. J. A. CHAMBERS

SAULT STE. MARIE
Chairman, F. SMALLWOOD
Vice-Chair., J. L. LANG
Sec.-Treas., H. O. BROWN, Abitibi Power & Paper Co., Sault Ste. Marie, Ont
Executive, C. W. HOLMAN, H. W. SUTCLIFFE, C. J. RUSSELL, A. A. ROSE
(Ex-Officio) E. M. MacQUARRIE, A. E. PICKERING

LAKEHEAD
Chairman, R. J. ASKIN
Vice-Chair., F. C. GRAHAM
Sec.-Treas., G. R. McLENNAN, 80 High St., North, Port Arthur, Ont.
Executive, H. G. O'LEARY, K. A. DUNPHY, G. R. DUNCAN, G. ERICKSEN
(Ex-Officio) G. H. BURBIDGE, GEO. P. BROPHY

WINNIPEG
Chairman, F. V. SEIBERT
Vice-Chair., G. E. COLE
Sec.-Treas., J. F. CUNNINGHAM, 918 Somerset Ave., Fort Garry, Man.
Executive, A. CAMPBELL, H. L. BRIGGS, A. E. MACDONALD, R. W. McKINNON, WM. WALKDEN
(Ex-Officio) A. J. TAUNTON, F. G. GOODSPEED, E. W. M. JAMES, E. V. CATON

SASKATCHEWAN
Chairman, A. P. LINTON
Vice-Chair., W. E. LOVELL
Sec.-Treas., S. YOUNG, 2822 Rae St., Regina, Sask.
Executive, J. W. D. FARRELL, W. E. LOVELL, H. S. CARPENTER, J. J. WHITE, S. R. MUIRHEAD, H. C. RITCHIE
(Ex-Officio) R. A. SPENCER, S. YOUNG

LETHBRIDGE
Chairman, W. L. McKENZIE
Vice-Chair., J. M. CAMPBELL
Sec.-Treas., E. A. LAWRENCE, 207-7th St. S., Lethbridge, Alta.
Executive, G. S. BROWN, R. F. P. BOWMAN, J. HAIMES
(Ex-Officio) C. S. CLENDENING, C. S. DONALDSON, J. B. deHART

EDMONTON
Chairman, F. K. BEACH
Vice-Chair., E. STANSFIELD
Sec.-Treas., R. M. HARDY, University of Alberta, Edmonton, Alta.
Executive, C. E. GARNETT, A. J. GAYFER, R. J. GIBB, H. P. KEITH, C. A. ROBB
(Ex-Officio) H. R. WEBB

CALGARY
Chairman, J. HADDIN
Vice-Chair., J. DOW
Sec.-Treas., JAS. McMILLAN, Calgary Power Co. Ltd., Insurance Exchange Bldg., Calgary, Alta.
Executive, F. J. HEUPERMAN, H. W. TOOKER, J. R. WOOD
(Ex-Officio) G. P. F. BOESE, F. M. STEEL

VANCOUVER
Chairman, JAS. ROBERTSON
Vice-Chair., H. N. MACPHERSON
Sec.-Treas., G. M. GILBERT, 930 Birks Bldg., Vancouver, B.C.
Executive, C. T. HAMILTON, J. P. McKENZIE, P. SANDWELL, E. C. THRUPP, G. L. TOOKER, F. O. MILLS
(Ex-Officio) A. S. WOOTTON, P. H. BUCHAN, A. E. GORDON

VICTORIA
Chairman, D. MacBRIDE
Vice-Chair., J. C. McDONALD
Sec.-Treas., KENNETH REID, 1336 Carnsew St., Victoria, B.C.

Modern Arc Welding

David Boyd,
Dominion Bridge Company Limited, Montreal.

Paper presented before the following Branches of The Engineering Institute of Canada: Toronto Branch, December 13th, 1934; Peterborough Branch, January 10th, 1935; Montreal Branch, January 31st, 1935; Saint John Branch, February 18th, 1935; Moncton Branch, February 19th, 1935; Halifax Branch, February 20th, 1935; Hamilton Branch, March 12th, 1935, and Niagara Peninsula Branch March 13th, 1935.

SUMMARY.—This paper outlines the main considerations affecting the employment of arc welding in steel structures and machine parts. Among the topics treated are the actions occurring in the arc, the selection of equipment for arc welding, the suitability of various types of joint and the precautions to be taken in the design of welded work. Notes are given on residual stress, the training of operators and the inspection of the finished work.

Welding, in its many forms, has become a very important method of joining metals particularly within the last ten years. Despite the widespread use of welding there appears to be more misleading information dispensed in connection with the art than can be fairly excused by reason of its comparative novelty.

A comprehensive treatise on modern welding would be encyclopedic in its proportions and, due to the rapid development of all branches of the art, would be partly obsolete upon completion. This paper will be confined to giving a general résumé of metallic arc welding of mild steel exclusive of all other welding processes. It is not intended to attempt any detailed treatment of design of equipment, joint design, electrodes or methods but merely to outline in a general way the various factors involved in arc welding. It is primarily intended as a guide to those who are faced with the necessity of equipping and operating a shop in which welding will be performed. It is a transcription of notes used by the author in addressing various branches of The Institute during the winter of 1935.

Each of the many other welding processes (such as oxy-acetylene, thermit, electric percussion, electric spot, electric flash, electric resistance, atomic hydrogen and carbon arc) has applications for which it is peculiarly adapted and for which the metallic arc process would not be economical or practicable. Engineers would be well advised to obtain general information on all welding processes.

The metallic arc process, however, is the one which is most widely used in general engineering for the welding of mild steel for buildings, bridges, tanks, machine frames and for repair work in industrial plants, mines and on construction jobs.

Welding is not a new art although modern welding processes have extended the field to which welding is applicable. Forge or smith welding is an ancient art which is in commercial use today in practically its original form. Its application is limited, however, to the welding of simple sections such as rounds, squares and flats although special methods have been developed to allow of its use on longitudinal joints in pipes.

Arc Theory

The properties of the electric arc were first investigated in connection with the arc lamp. This phenomenon of electrical conduction across an apparent air gap in a metallic circuit which is accompanied by the liberation of intense heat is the basis of arc welding.

Arc welding may be defined as that process which utilizes an electric circuit continuously fed with electric current from an adequate source which current is passed through an arc. One pole of the arc is a metallic electrode and the other pole the work. The intense heat of the arc causes the electrode and the work to fuse simultaneously and molten metal from the electrode is added to the work metal to form a welded joint.

There is as yet no full and authoritative explanation of the mechanics of metallic transference in the electric arc. It is known that the bulk of the metal is transferred across the arc into position in the joint by the force of gravity.

Simultaneously there are other forces acting to assist in the transfer of metal across the arc such as the expansive effect of occluded gases in the electrode, the "pinch" effect and, to a degree, electro-magnetic forces in the arc acting on metallic particles of possibly atomic size which are electrostatically charged.

The "pinch" effect is a phenomenon which occurs in plastic or fluid metallic conductors carrying heavy currents. The electro-magnetic forces act to force a small section of the conductor—in this case the end of the electrode at the arc—to assume a spherical shape. These forces then act to repel the globule from the electrode. The force is large in comparison to the mass of the globule and is an important factor in the transfer of metal in the arc.

The relative importance of the forces acting to transfer metal, other than gravity, has not been evaluated and it is believed that their total effect is small.

Once deposited the molten weld metal is held in position in flat welds by gravity and in vertical or overhead welds by surface tension and capillary action.

The welding current crosses the arc partly by metallic conduction and partly by gaseous conduction through the ionization of the air and of metallic materials. Oscillograms of arc welding currents read in conjunction with motion pictures of the arc show that the arc is actually short circuited instantaneously several times per second by globules of molten electrode material. During these periods of short circuit the transfer of current is by metallic conduction. At other times the current flow is entirely by way of the ionized gases in the arc.

The energy of the arc, which is liberated within a very small volume (less than .05 cubic inch), gives rise to extremely high temperatures. These temperatures (over 3,000 degrees C.) are such that the electrode and work fuse simultaneously thus permitting intimate fusion of the added metal with the parent metal.

It was observed when studying the direct current arc lamp that heat distribution was unequal and that the positive carbon fused nearly twice as rapidly as did the negative carbon. Thus in direct current welding there arises the question of polarity. It is the established practice in direct current arc welding with bare electrodes to connect the electrode to the negative terminal of the welding generator and the work to the positive terminal. This practice is based upon the observation of the phenomenon of heat distribution mentioned above and the unequal distribution of heat in the arc is of great assistance in obtaining adequate fusion. By connecting the comparatively heavy "work" to the positive or "hot" pole the fact that the heavier "work" requires a greater quantity of heat to reach fusion temperature than does the lighter electrode is counteracted to a considerable degree. This question of polarity is of prime importance in bare electrode welding as it is not possible to obtain proper fusion or arc stability without using the standard or "straight" polarity described above.

Electrodes

Electrodes are of prime importance in arc welding. Indeed it may be said that it is impossible to obtain good results with inferior electrodes.

There are in current use two main classes of electrode for the welding of mild steel, viz.: bare and flux covered.

Nomenclature is rather loose and vague in connection with electrodes although the trade is agreed that the term "bare electrode" does represent a definite class of material. The confusion arises over the designations to be applied to the various types of flux dipped, lightly coated and heavily coated electrode. The tendency now is to classify the flux dipped or washed electrode along with the bare electrode and the lightly coated and heavily coated together as flux coated electrodes.

A bare electrode is simply a straight 14-inch length of steel wire which is accurately drawn as to size and which is given a very thin coating of "sull," lime, or some other arc stabilizer. These light coatings serve merely to resist rust in storage and to stabilize the arc. It is not possible to weld with a bright finished bare electrode.

A covered electrode is similar, in-so-far as its core of steel is concerned, to the bare electrode but in addition has a coating of flux or gas forming materials, or both, such as when fused in the arc, act to cleanse the weld of impurities, to protect the molten metal with a slag and to protect the metal crossing the arc from atmospheric attack.

An appropriate term has been coined as a general designation for welding with covered electrodes. This term is "shielded arc" welding and hence the covered electrodes are designated as "shielded arc" electrodes. Unfortunately the term was originally coined as a trade name by one particular electrode manufacturer and for a time was usually used in referring to that specific make of electrode. Today, however, the appropriateness of the term is such that it is being applied to all electrodes of that general type.

These coated or heavily covered electrodes are of two types—"universal" or general purpose and "downhand" or groove welding electrodes.

The universal or general purpose electrode is so designed as to permit of vertical and overhead welding while retaining some of the advantages of the more heavily fluxed electrode.

The universal or general purpose electrode produces welds of a tensile strength of from 55,000 to 65,000 pounds per square inch with a ductility of from 15 to 20 per cent elongation in two inches.

The heavily fluxed "downhand" or groove welding electrode is definitely a single purpose electrode designed to make welds in the horizontal or "flat" position only. This limitation in application is due to the fact that the crucible effect obtained at the end of the electrode while welding coupled with the higher currents used with these electrodes gives weld metal of great fluidity. This high degree of fluidity (or temperature) of the molten metal acts in such a way as to prevent the metal being controlled in any other position than the horizontal.

The welds produced by this type of electrode show the following average physical properties:

Tensile strength. . .	60,000-70,000 pounds per square inch.
Ductility.	25-35 per cent elongation in 2 inches.

Electrodes and their metallurgical characteristics are discussed at some length in a paper* which will appear in the December issue of The Journal and this phase of the electrode question will therefore not be treated now.

Before leaving the subject of electrodes, however, it would be well to clear up certain misconceptions. It is generally known that the bare electrode produces welds in many respects inferior to those produced by the covered electrodes. Bare electrode welds have poor resistance to corrosion, low ductility and low impact values. Covered electrode welds have better corrosion resistance than steel plate, have good ductility, high tensile strength and give high impact values.

There remains the factor of cost which is often overlooked due to extravagant claims made by those seeking to sell the various covered electrodes. In Canada, generally, it may be said that the cost of bare electrode welds per pound of metal deposited is from 5 to 15 per cent less than the cost, as deposited, of welds made with the shielded arc electrode.

The engineer may specify bare electrode welds on structures that are not dynamically loaded and where the cost of the welding is an important factor in the total cost. Welding engineers favour the use of the shielded arc process for all work regardless of the cost differential.

Machines and Circuits

The characteristics of arc welding circuits are determined by the characteristics of the arc itself. A high open circuit voltage is required in order to "strike" or start the arc.

The open circuit voltage varies between 50 and 70 volts in machines designed for bare electrode welding and may run as high as 100 volts or more on a.c. transformers or alternators for shielded arc welding.

The arc voltage, as already noted, lies between 18 and 35 volts. Thus the machines and circuits for arc welding must have a comparatively high no load or open circuit voltage coupled with a load voltage of from one third to one half of the no load or open circuit value. In addition, for good welding, the arc current must have a constant average value and this value may be anywhere within the current output range of the unit. The range of current values taken

*The Metallurgy of Metallic Arc Welding of Mild Steel," by C. R. Whittemore, A.M.E.I.C.

from a typical welding generator may well be from 100 to 350 amperes by continuously variable control. From the foregoing it will be seen that generators for arc welding offer a difficult design problem.

Regardless of the inherent stability of the machine proper it is often necessary to incorporate stabilizers in the form of external reactors or special stabilizing windings in the machine in order to obtain the degree of stability and rapid voltage recovery required in the arc circuit.

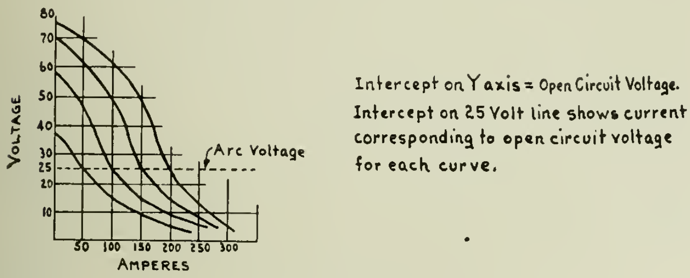

Fig. 1.

Since the arc is short circuited instantaneously several times per second the necessity of rapid voltage recovery characteristics is apparent.

There are two general machine classifications: "Constant Voltage" machines and "Variable Voltage" machines.

Constant Voltage Welding Generators

Machines of the constant voltage type obtain the drooping voltage-load characteristic (see Fig. 1) by means of resistors. Figure 2 shows a schematic diagram of a typical constant voltage type welding equipment.

The generator of a constant voltage type welder is usually designed as flat compound, that is, the generator output voltage is constant over the range from no load to full load. The voltage of the unit is adjusted by the shunt field rheostat to lie between 50 and 75 volts as required. The moment current flows in the external circuit through the electrode and arc the welding rheostat becomes operative and causes the overall circuit characteristics to approximate those shown in Fig. 1. As an example of this assume a typical case:

Electrode size $\frac{3}{16}$ inch, current required 200 amperes, arc voltage 20 volts. The generator open circuit voltage may be assumed as 60 volts. From the data it will be seen 40 volts must be absorbed in the welding rheostat and in the resistance of leads and reactor. Allowing 5 volts drop in leads and reactor leaves 35 volts to be absorbed in the rheostat itself. Suitable adjustment of the rheostat will accomplish the desired result.

It is well to observe that this voltage drop in the rheostat occurs only when current flows and that while the current flows there is a large power loss. In this example the loss is (35 × 200) watts = 7,000 watts. At the same time only (200 × 20) = 4,000 watts is being used in the arc to do useful work. The efficiency of the constant voltage welder is therefore of a low order.

Assuming a conversion efficiency in the motor generator of 80 per cent and knowing the actual welding circuit conditions from the above it is found that (ignoring lead losses):—

$$\text{Efficiency} = \frac{\text{Useful output}}{\text{Total input}} \times 100$$

$$= \frac{4{,}000 \times 100 \times 0.8}{(4{,}000 + 7{,}000)} = 29 \text{ per cent}$$

An overall efficiency of only 30 per cent represents a serious loss of power where power cost is high.

Against this low efficiency must be balanced the lower cost for the machine. Constant voltage welding generators are usually used to serve more than one operator with the welding circuits being connected in parallel. See Fig. 2.

Thus a multiple-operator constant voltage welding generator might be arranged, and often is, to serve ten welders. When this is done the machine of this type is an economical source of welding current particularly for shop use.

It is not uncommon to connect seven welders' outlets to a multiple-operator type machine designed to deliver one thousand amperes and for each welder to use current up to two hundred amperes. This apparent overload is of no consequence since the load factor as between a group of welders is very poor—sometimes as low as 50 per cent.

When this condition obtains and portability is not a prime consideration the low cost per welding outlet of the multiple-operator constant voltage machine is a decided advantage. The cost of equipment per outlet is about half that of single-operator variable voltage type equipment.

Variable Voltage Welding Generators

Variable voltage welding generators are so designed as to obtain the drooping volt-ampere characteristics of Fig. 1 by means of their internal winding arrangement and without the use of external power wasting resistors. These generators are inherently single-operator machines and it is impossible to employ such units to supply welding current to more than one operator.

The single-operator variable voltage welding generators obtain the drooping volt-ampere characteristic of Fig. 1 by means of differential compounding. This method is more economical than the resistance method in that the reduction in voltage from the open circuit value to the welding value is accomplished by demagnetization of the field system which in turn reduces excitation and generated voltage. Machines of this type are very efficient, their overall efficiency including motor being as high as 60 per cent.

Some machines are designed as self excited while others have small exciter generators mounted on the same shaft. The relative merits of the two systems are largely a matter of opinion, the better machines of each type being satisfactory.

Machine Ratings

Rating of welding machines is an important consideration when making a choice between several makes. Most American or Canadian built machines are one hour

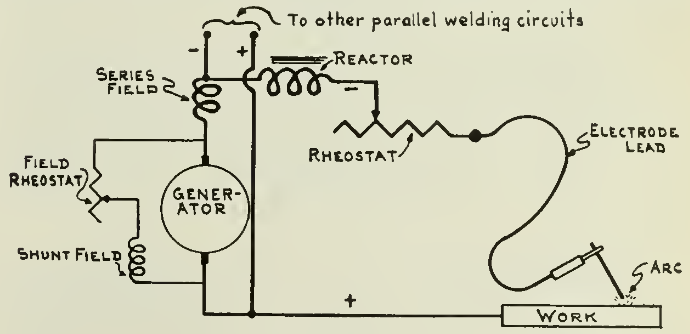

Fig. 2.

rated and built according to National Electric Manufacturers Association standards.

Voltage rating is a point worth attention when purchasing new equipment or when assigning machines to a specific job.

It should be noted by users of welding equipment that the majority of machines now in use are unsuitable for the use of shielded arc electrodes. It is important that machines intended for use with covered electrodes be of 40-volt rating. The older types of machines rated at 25 volts have insufficient capacity for any but the smaller (⅛- and 5/32-inch) covered electrodes and then only those machines which permit adjustment for high open circuit voltages. The common method of rating welding machines is by ampere output, i.e. 200- and 300-ampere machines. The ampere rating alone is insufficient to classify a welding generator and the rated welding voltage should always be given.

This fact will be readily understood when the driving motor sizes of the older 25-volt type and newer 40-volt type machines are compared. The power in the welding circuit of two typical machines delivering the same current will be exemplified as follows:

A 25-volt machine delivering say 300 amperes at 20 volts to a ¼-inch bare electrode has an output of

$$\frac{300 \times 20}{1,000} = 6.0 \text{ kw.}$$

A 40-volt machine delivering 300 amperes at 30 volts to a ¼-inch shielded arc (or covered) electrode has an output of

$$\frac{300 \times 30}{1,000} = 9.0 \text{ kw.}$$

The motor ordinarily applied to a 300-ampere 25-volt generator is 10 h.p. and, while adequate to drive the generator at rated output, cannot drive the generator at the greater rating without overloading and suffering damage. The 300-ampere, 40-volt, generators are normally powered by 20-h.p. motors.

Incidentally the characteristics of the older type 25-volt machines are such that they attempt to keep the arc voltage to the lower values of from 20 to 25 volts and so they are inherently unsuitable for shielded arc welding.

Installation

Installation of welding equipment is a subject worthy of much more attention than is normally given. It should be borne in mind that good welding depends as much upon having a steady dependable power supply to the machines as on any other factor.

The power distribution system to which welding motor generators are connected should be adequate for the load assuming a load factor of 50 per cent for hand welding. All connections should be made in accordance with the regulations of the governing electrical authority and each machine frame thoroughly grounded. If the machines are to be really portable it is advisable to install plug type receptacles on the power distribution system where necessary.

The welding circuit from the generator to the point of welding and back to the generator should be all of extra flexible copper conductor and insulated throughout from ground. The practice of grounding one side of the welding circuit to the steel frame of a building is undesirable from both welding and safety viewpoints and should be discouraged.

Alternating Current Welding

Alternating current has always been used to some extent for arc welding although European practice has been to employ it to a much greater extent than has been the custom on this continent.

One of the reasons for American tardiness in the use of a.c. welding was the widespread use of the bare electrode for welding on this continent until about seven years ago. Alternating current is not suitable for bare electrode welding and thus the development of a.c. welding equipment waited upon the development of the covered electrode. Within the last two or three years this development has proceeded rapidly and a.c. welding equipment of several types is available. It is well to note in passing that European practice involved the use of covered electrodes many years before they became popular in the United States and Canada.

The main advantage, and possibly the only real advantage, of alternating current for welding as compared with direct current lies in the fact that the use of a.c. eliminates the troublesome magnetic effects encountered with d.c.

There are two main types of alternating current welding equipment, viz.: transformer type and high frequency alternator type.

The transformer type is simple and, of course, has no rotating parts and therefore has negligible maintenance costs.

The transformer type of a.c. welder has against it the fact that it is a single phase device and one that generally operates at low power factor. The power factor characteristics of arc welding transformers, however, vary as between the products of different manufacturers. The detailed discussion of this factor is beyond the scope of this paper. Both of these characteristics are objectionable from a plant operating viewpoint.

The high frequency alternator type of a.c. welding equipment has standard three-phase induction motor drive, and thus has characteristics from a distribution system viewpoint similar to those of any standard motor-generator type welding set.

All a.c. welders, however, are inherently comparatively high voltage machines, their open circuit voltage often exceeding 100 volts. The manufacturers minimize this hazard to the welding operator but none the less it is a serious one especially when welding inside tanks or boilers or on high structures. Actually the various manufacturers offer as optional equipment on transformer type welders automatic or semi-automatic control devices which remove the high voltage from the welding circuit either by opening a primary contactor or by reducing secondary voltage afford protection to the operator while changing electrodes.*

Alternating current welding machines, despite some drawbacks, will be used to an ever-increasing extent throughout the welding industry.

Automatic Welding

The term automatic welding is somewhat of a misnomer in that the process is not fully automatic. Automatic welding machines require the attendance of a skilled operator who as well as being a competent welder is also capable of making the many adjustments, electrical and mechanical, required by the apparatus.

Automatic arc welding machines have been in use for about ten years. They are so designed that they strike the arc, move forward along the seam, maintain the arc voltage required and feed the electrode to replace that which has been consumed. They are complicated and costly and their use is only economical where there is a large amount of work of simple form to be welded. Automatic welders have been successfully applied to the welding of small tanks, boilers and pipes. They have never been successfully applied to irregularly shaped parts and the costly nature of jigs and fixtures required limits their use to long runs of similar work

Automatic arc welders have been developed to use the modern flux covered electrode but as yet their success is dubious. Much effort is being expended upon the development of automatic shielded arc welders and there is reason to believe that at an early date the problem will be satisfactorily solved.

Materials

Those steels covered by the Canadian Engineering Standards Association or American Society for Testing Materials Specifications for steel for bridges, buildings, ships, boilers, etc., can all be readily welded. These steels

*"A.C. Arc Welding Transformer and Circuit Characteristics," A. M. Candy, Journal American Welding Society, September 1934

have a tensile range of up to 72,000 pounds per square inch and a carbon range of from 0.12 to 0.30 per cent. The normal manganese range is 0.30 to 0.60 per cent with sulphur and phosphorus not in excess of 0.05 per cent.

With the steels in commercial use ordinarily being kept within the specification limits by modern mill practice the problem of welding is greatly simplified.

It is only with dirty steel or steel containing high sulphur or phosphorus that any difficulty due to parent metal is encountered and that is an extremely rare occurrence. The welding of steels above or below the ordinary carbon range (.10 to .30) offers certain difficulties. The lower carbon steels (below 0.10 per cent), which are not common in industry, are difficult to weld. This difficulty seems largely due to the gas absorption characteristics of the low carbon range. They can be welded to attain full strength but porosity may occur to a troublesome degree.

Steels of greater than 0.30 per cent carbon have been successfully welded using a special technique. It is necessary to employ preheating to about 300 degrees F. while welding and to normalize the finished parts.

The modern low alloy high-strength steels such as chromador, cromansil, etc., can be satisfactorily welded only by employing electrodes designed specifically for the purpose. No modification of welding technique is required, however, and sound welds can be obtained.*

The electric arc may be employed to weld some of the non-ferrous metals but its application to this field is somewhat limited.

Cast iron can be welded with the arc but in the author's opinion the oxy-acetylene process is better adapted for this material.

Joint Design

Very few tools and no machine or structure can be built of one single piece of material. Thus at the outset the designer is faced with the problem of devising connections between the component parts of the structure, machine or vessel.

The ideal joint is one having 100 per cent efficiency, which is perfectly homogeneous in structure and in which there is no break in the continuity of the member or members due to the design or material of the joint. This ideal is one which is unattainable except in isolated cases although modern arc welding provides the most satisfactory means yet devised for obtaining joints in steel that closely approach this standard.

Designers have long been familiar with riveted, pin connected and bolted joints and can predict with complete assurance the performance of any of the three types under a given service condition. This ability to predict performance is based upon results of thousands of investigations of various mechanical (riveted, pinned, bolted) joints extending back over a century of engineering development and of the performance records of hundreds of thousands of structures. While engineers agree that the welded joint is definitely superior in nature to any mechanical joint they have not, as yet, developed confidence in their own ability to design structures employing welded joints. This lack of confidence is not, the author believes, due to their disbelief in the welded joint but solely due to their own caution in using a method of jointing with which they are not thoroughly familiar and upon which there is not, as yet, a wide enough background of experience in service. This natural and wise caution will be readily replaced by enthusiastic adoption of welding as its obvious advantages become more widely appreciated.

With the extended acceptance of welded joints designers will, of necessity, be obliged to give study to the welded joint itself and its mechanical properties such as weld size and arrangement.

The simplest joint possible between two plates or shapes is the butt joint which, when properly designed and executed, can have a very high efficiency.

Figure 3 illustrates the more usual joint types. The single "V" butt joint is the most commonly used although limited, economically, to plates less than half inch thick. In plates of ½ inch or greater thickness the double "V" butt joint is used for economy only and not because of any inherent superiority over the single "V" butt joint.

The "U" groove butt joint has been developed within recent years and is widely used in the butt welding of heavy plates particularly on pressure vessels. It is an economical joint type on plates ⅝ inch and greater in thickness and its economy relative to the double "V" joint becomes more marked in the greater plate thicknesses. The "U" groove type of joint was developed to obtain full advantage of the shielded arc process. Its shape is such that by simple downhand welding in the narrow groove a sound weld is produced.

The partial butt joint illustrated in Fig. 3 is a very common and unsound type. This joint is not truly continuous through the thickness of the section and there will be heavy stress concentration at the roots of the two welds which will raise the stress in those areas to a figure greatly in excess of that assumed as average stress in designing the joint. The total thickness of weld metal when the reinforcements are included is greater than the plate and might therefore lead a careless designer to assume low average stress. The fact remains, however, that a complete joint welded through the full section and having less reinforcement would be not only cheaper but safer and would have no dangerous stress concentration due to lack of continuity. This type of joint is unfortunately too common. While sketched in the figure as having been made in a plate of ⅜ inch in thickness by partial grooving it is often made even in plates of that thickness by simply fusing into the square plate edges from both sides. Such a joint has very porous and dirty metal lying in a seam or pipe through its centre which is, in the author's opinion, simply inviting trouble.

In butt welds the guiding principle is to so prepare the joint as to obtain penetration of weld metal throughout the full plate thickness. On plates of ¼ inch in thickness or less full penetration may be obtained without scarfing or grooving by simply welding from both sides with a quarter inch electrode. On plates of greater thickness the joint should be scarfed either to form a single or double vee joint.

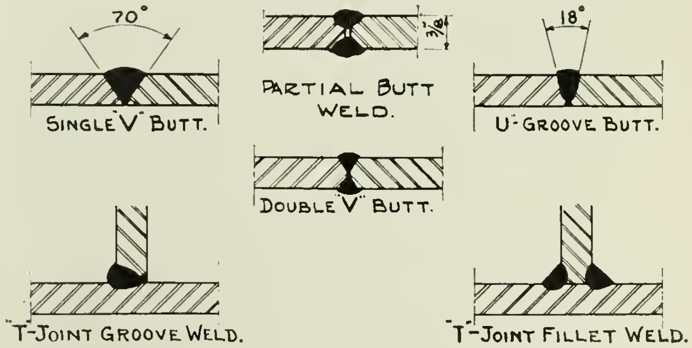

Fig. 3.

On certain classes of work, notably car building, it is common practice to attempt penetration in a butt joint from one side of the plate without grooving. This practice is one which is open to serious question and most welding engineers feel that it should be prohibited.

*"Development and Use of Low Alloy, High Tensile Steel," A. E. Gibson, and "Welding of Low Alloy Steels," J. C. Holmberg, both in Journal of American Welding Society, September 1935.

The most extensive application of the butt joint is to large tanks, pipes and pressure vessels. In this field the welded joint has shown such remarkable savings in cost, reliability and tightness that it is rapidly displacing the riveted joint on all except the smaller pressure vessels.

While the butt joint is the simplest and most efficient joint in-so-far as disposition of metal is concerned nevertheless the most common type of welded joint employs the fillet weld. Indeed about 90 per cent of all welded joints are of the fillet type.

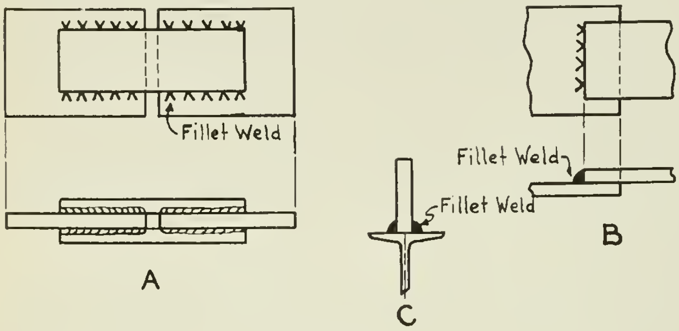

Fig. 4.

Joint "*A*" in Fig. 4 is a very common type of joint. It is simple to fabricate and assemble although not as economical in its use of weld metal as is a plain butt joint. In addition it has the extra material of the splice bars which would be absent in a butt joint.

The lap joint "*B*" is a very common joint in storage tanks where joint efficiency is not a criterion of design. It has severe eccentricity and is never used between members of structures.

The "tee" joint "*C*" is frequently used for details on structural work and is a simple joint to fabricate and weld. It is most frequently used for knee bracing connections to columns and beams.

When considering design of fillet welded joints it is well to so dispose the weld metal around the parts joined as to prevent any tendency to progressive failure due to torsional stresses at the joint. The best example of this point is shown in Fig. 5.

This figure shows a box structure composed of four corner angles and an angle web system in each face. This type of member is encountered in light crane girders, coal bridge structures, transmission towers, crane booms, etc. Note that the welds are placed so as to connect the members together for the figured axial or transverse loadings. These welds however have on some structures shown a tendency to failure when torsion is introduced due to service conditions. The welds fail by tearing progressively and such a structure is unreliable. If, however, the condition is anticipated it can readily be corrected by redistribution of welds. By simply placing part of the total weld required at any intersection at right angles to the remainder, the joint can be stiffened without extra cost of weld metal and a sound and reliable structure be evolved. (See "*X*" in Fig. 5.) In a riveted structure the rivet heads accomplish the same result. Generally these weld failures due to torsion stresses in joints of this type start in craters at the end of welds. It is a fundamental rule that no crater should ever be permitted at the ends of any fillet weld.

If the mechanical nature of the joint is such as to prevent the weld being run partly from each end thus placing the crater in the centre of the length of the weld then the crater should be carefully filled with weld metal. A simple manner of avoiding a crater in the line of a weld is to break the arc on the parent metal out of the line of the weld proper.

Designers in the past have frequently called for single sided or one sided fillet welded "tee" joints.

This joint (Fig. 6) has been a constant source of trouble to welding engineers as it is fundamentally unsound and can be knocked apart with a small hammer. This has often been done and those who witness such a demonstration usually assume that the fault lies in welding as a jointing method whereas the true weakness is one of design. A moment's consideration of the geometry of such a joint will show that there is, as assumed in the sketch, a lever arm of sixteen to one acting when the blow is struck and thus the stress in the root of the weld is much above the ultimate causing failure. Redistribution of the weld metal so as to place half of the total on each side of the plate will resist any attempt to cause failure.

Design precautions may be summarized in six simple headings:—

(1) Place all welds in accessible positions.
(2) Be sparing in the amount of weld specified. Apply only the amount of weld actually required as excess weld metal adds to cost and may even act to give a weaker, not a stronger, joint.
(3) Avoid using fillet welds in tension where the member is liable to encounter torsional stress in addition to pure tension.
(4) Avoid eccentricity just as in riveted work.
(5) Place all welds and joint materials symmetrically if possible. This will limit distortion and residual stress.
(6) Avoid single sided fillet welds or partial butt welds.

Welding Technique or Procedure

Given sound design, suitable materials, electrodes and equipment there still remains the complicated group of interrelated problems of technique and procedure. These problems arise out of the physical nature of the arc welding process—the application of small quantities of molten metal to a comparatively large mass of cold metal. The forces of expansion and contraction set up vary in degree with the relative weight and stiffness of the member, the quantity of weld metal and the rate or speed at which the weld is applied. This variation in relative weight runs from the condition found in small light members with a few small welds in which distortion and stress are negligible to large members of heavy section upon which large quantities of weld metal are deposited.

Welded members and frames must be kept relatively free from distortion and stress and for these reasons an attempt is made to so devise procedures that the stresses due to the process are controlled insofar as their warping action is concerned and limited as to their residual values. One example of correct weld sequence is shown in Fig. 7 and the following description:—

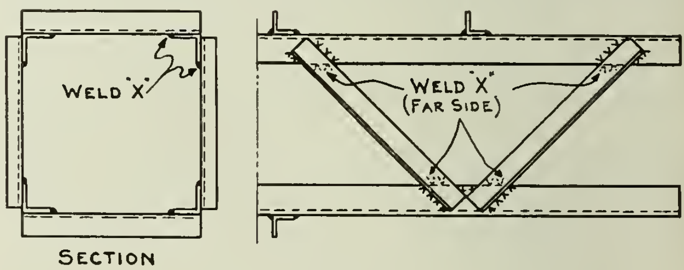

Fig. 5.

(1) In a member such as a plate girder all butt welds or other splices in webs and flanges should be made before the final assembling.
(2) All welds between stiffeners and web should be made either before final assembly or whilst welding the flange plates to the web. If the latter

method is used the welding of the girder should be carried out while lying with the web horizontal and the flanges rigidly guided so as to preclude their deflecting off the square.

The flange welds are started at the centre on both top and bottom flanges. As the welding progresses toward each end along each flange the stiffener welds are made when they are reached.

When all the welds between flanges, web and stiffeners are complete on one side the girder is turned over and the welds on the other side made in a similar way. Such a procedure allows shrinkage to occur freely and there is a minimum of residual stress.

Shrinkages are best evaluated by actual study of a typical joint. The safest procedure to follow if any doubt exists is to make a sample joint and actually evaluate the shrinkage by micrometer measurement. As a general rule the shrinkage in an ordinary section such as a built up beam or girder due to the longitudinal shrinkage of flange to web welds will be in the region of ½ of 1 per cent in length. While not a large percentage it is important if the girder or beam considered is long and has holes for connection purposes at the ends or along its length. When building machine frames or heavy structural details the prime rule is to break the larger and heavier members into sub-assemblies thus obviating cumulative strains. Advantage should be taken where possible of the economies possible when welding in the "flat" position. This involves the exercise of some ingenuity in placing and handling members for welding and in devising fixtures. It will be found possible to obtain a considerable increase in welding speed and more uniformly high quality welds if the work is manipulated into a position, or positions, such that the welder can work straight downhand in what is, in effect, a 90-degree vee formed by the plates at the joint. The speed of deposition in such a "V" will average 20 to 50 per cent higher than when the fillet weld is made in the conventional position with one plate horizontal and one vertical.

Regardless of the procedure or sequence adopted the engineer should carefully watch all heavy and important work while in process with a view to detecting tendency toward distortion and modifying procedure to check or correct the difficulty.

Residual Stresses

Notwithstanding the care used in design and in devising procedures there will still exist residual stresses whose

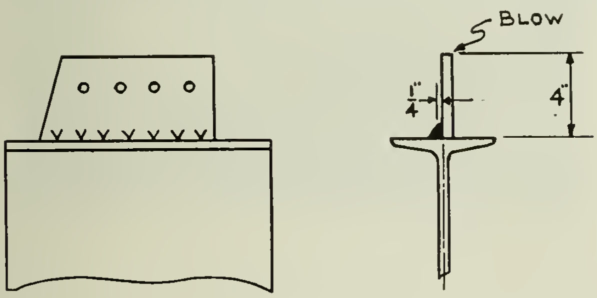

Fig. 6.

magnitude and direction are almost completely indeterminate.

On light work, such as small buildings, where there is considerable structural flexibility; on storage tanks and other very light structures; or on any type of fabrication where the relative amount of weld to the weight of the structure is small, the residual stresses can be disregarded with safety. In the case of large work such as pressure vessels, machine frames and heavy structural details, particularly where subject to dynamic loading, these residual stresses are of a serious nature. The residual stresses act as an unknown degree of pre-loading and therefore must be removed.

Stress Relief

Stresses due to welding in heavy fabrications and pressure vessels may be relieved by heat treatment. This is the only sure method of reducing them to the low values essential to avoid any danger of pre-loading.

Stress relief by heat treatment is accomplished by slow heating of the welded part in a suitable furnace to about

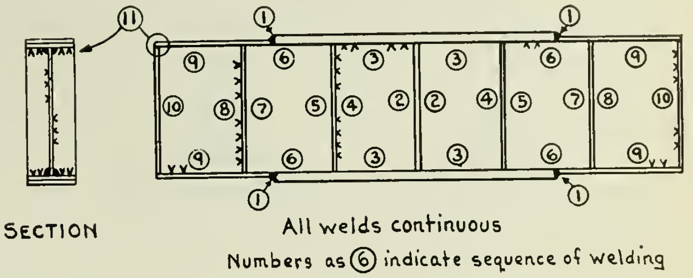

Fig. 7.

1,250 degrees F., soaking at that temperature for a time equal to one hour per inch of thickness of material and slow cooling in the furnace. The relief of the residual stresses is accomplished due to the fact that at the stress relieving temperature of 1,250 degrees F. the yield point of the material is reduced to about 3,000 pounds per square inch and thus any stress existing in excess of this value disappears. This is borne out experimentally and may be readily verified.

As well as removing preloading, stress relief removes the tendency of highly pre-stressed structures toward creep under load in service.

Stress relief by heat treatment is mandatory in the case of many vessels designed for storage of liquids and vapours under pressure. Unfortunately the practice of stress relief has not been carried into other phases of arc welded fabrication and as a result some unfortunate failures have occurred. These failures have not always been actual mechanical breakages but have more often been in the form of warp occurring after the welded part has been placed in service. Welded frames designed to replace castings as component parts of machines or as complete machine frames should be stress relieved after welding is completed and before machining. A properly designed welding which has been carefully stress relieved may be machined and assembled into a machine with the assurance that there will be no further warpage to cause misalignment of parts.

Peening has often been suggested as a means of relieving weld stresses. The difficulty in using peening is to determine how hard to peen and how long and over what areas of weld and parent metal. Peening is useful as a subsidiary method of stress relief on heavy work but is not as yet a sufficiently controllable method to be used for complete relief of weld stresses. While peening is permissible on all weld layers except the top or final layer it is necessary to resort to heat treatment to achieve adequate stress relief of heavy welded frames.

The advantages which accrue from stress relief are two:—

(1) The stress relieving operation alters the physical properties of the weld metal so that the ultimate tensile strength is reduced to about equivalent to that of the parent metal, with shielded arc welds it improves the free bend elongation twenty per cent or better, and most important of all it markedly improves the resistance of the weld

metal to fatigue failure. After stress relief shielded arc welds have physical properties in all respects equal to or better than those of the parent plate.

(2) It produces in a short interval of a few hours the same effect as is obtained by ageing castings to obviate warping.

Stress relief is specified by many designers of welded machine frames for parts of all sizes and weights and it is the author's opinion that the process will eventually become standard practice for all welded parts.

Training of Personnel

All welding should be carried out under the direct supervision of a trained welding engineer. These men are few in number but their numbers must be increased by the training of young engineers in welding. When welding was merely a repair tool any good welder was competent to carry out ordinary work but now that welding is being developed into a large scale production process the technically trained man is indispensable. Therefore the first essential in a large plant employing many welders is a competent welding engineer.

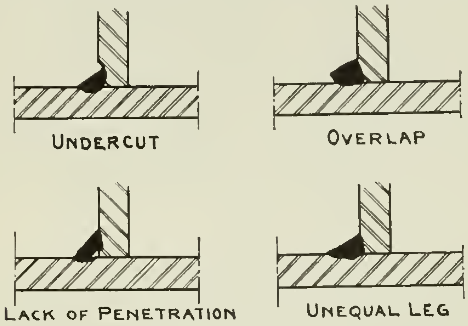

Fig. 8.

A welding engineer should preferably be a civil engineer who has had several years of actual fabricating shop training. He should become a competent welder and be thoroughly familiar with the equipment and processes under his control. He must be patient and resourceful and not afraid of tackling the many perplexing problems that are the routine work of a welding engineer's day.

Welding is a manual art and for best results demands welders possessing a high degree of skill. Such men cannot be picked at random but must be carefully chosen and trained. Due to the nature of the art more responsibility for quality of work is on the welder's shoulders than is the case in many other trades. This indicates that the ideal welder should be trustworthy to a high degree and of such a calm temperament that he can continue to apply himself effectively over long periods to a monotonous and exacting occupation. Welding requires constant application on the part of the welder for a good quality of work.

Training should be of a practical nature, the student taking his place in the shop in an assembling crew and working as a tack welder. As quickly as he develops his skill he should be taught to make welds on actual work rather than be asked to pass long periods of fruitless repetitive practice. During his training period, which should extend over at least one year and preferably two, he should at all times be under the supervision of a competent instructor. This instructor can instill, by example, a pride in good workmanship such that the novice rapidly develops into a true craftsman.

In some plants welders are required to pass qualification tests periodically which are designed to show the man's ability to produce sound welds in any required position. These tests can be very useful in maintaining a high standard of workmanship but should not be employed as a substitute for constant supervision and inspection.

Tests should be made simple and economical in order that they may not be burdensome. It has been the author's experience, and that of many others, that complicated and extensive tensile tests requiring a large expenditure of time and money defeat their own ends by becoming irksome to the production staff and are eventually dropped altogether.

A preliminary qualification test may rightly be comprehensive and include tensile test specimens but all subsequent check tests should consist of simple nick break test specimens which can be quickly and economically performed.

Certain classes of work, such as pressure vessels, are constructed under codes such as the Code for the Fusion Welding of Pressure Vessels formulated by the American Society of Mechanical Engineers and now generally adopted. This code specifies definite tests which must be carried out periodically if the plant in question proposes to fabricate pressure vessels by fusion welding.

Inspection

Many engineers question the susceptibility of welded work to visual inspection without employing destructive tests. It is a fact, however, that a competent welding engineer or inspector is capable of inspecting welding. A good inspector makes a point of observing the welders while they are actually at work and of checking current values and electrode type and size. Having observed the welders at work and being familiar with their test performances the inspector can adequately inspect the finished work by visual methods. Welds which are faulty are readily recognized by their superficial appearance, as is shown in Fig. 8.

Undercut is readily recognizable by the sharp groove in the surface of the vertical plate. This defect can be readily repaired by simply running a further light bead of weld in the groove. While it is a common and dangerous defect it is readily recognized and repaired. The presence of undercut is, however, reassuring as it indicates excellent penetration.

Overlap is a common fault due to incorrect manipulation of the electrode and indicates a possible lack of penetration on that leg of the fillet which is overlapped. The weld should be removed by cutting with a torch or by chipping and rewelded if the overlap is of serious proportions.

Fig. 9—Welded Cable Saddle for Isle of Orleans Bridge. Weight 3,000 pounds.

Lack of penetration is difficult to detect except by using a cutting torch on doubtful welds. The torch flame is directed against the weld surface so as to gouge into the weld with the axis of the flame directed to the root of the weld. By observing the condition at the junction of weld and plate at fusion point the degree of penetration can be determined. When the defect is present it is repaired by increasing the weld size to compensate for the amount by which complete penetration is lacking.

The flat or unequal fillet usually is the result of careless manipulation of the electrode but is not an indication of unsoundness unless the other marks of an unsound weld such as overlap or undercut are also present. If the small side of the fillet is up to the size specified no further work is required. If on the other hand it is undersize it must be built up.

There are other methods of weld inspection such as the electro-magnetic method and the X-ray but neither is applicable to ordinary types of work. The electro-magnetic method is not used in weld inspection in any plant in America to the author's knowledge but X-ray examination is extensively used on pressure vessel welds.

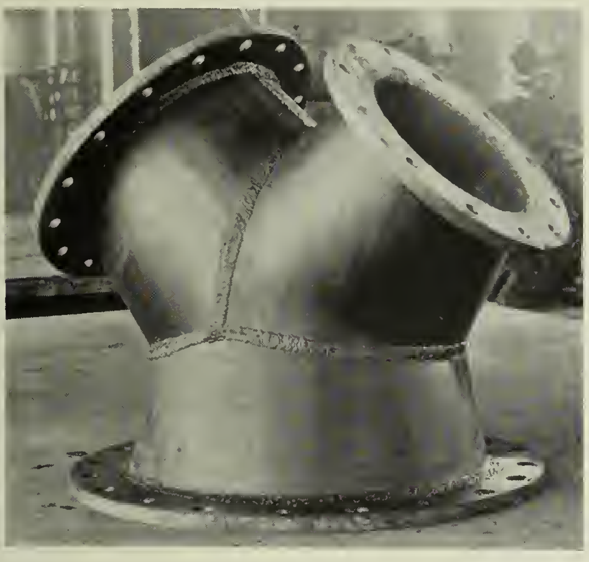

Fig. 10—Welded Pipe Wye, 24 by 16 by 12 inches.

Control

Many individuals in the industry are not fully aware of the importance of adequate supervision in design, fabrication and erection of welded structures.

There exists, as yet, no one authority competent to set up standards of design and workmanship or to adequately supervise the application of such standards in practice. As a result of this absence of control many irresponsible persons undertake to fabricate and erect welded structures, or to repair by arc welding existing structures, who are not competent so to do. They ignore the essentials of sound design and workmanship and employ methods and equipment of types that are obsolete and inadequate. The net result of this is a chaotic condition which cannot but be detrimental to the continued development and application of welding on a sound and proved basis.

The answer to such a condition seems to lie in the institution, co-operatively by those interested, of a governing bureau competent to administer a code of design and fabrication standards for the good of the industry.

Applications

Arc welding as a method of making joints in steel plates and sections has been successfully applied to every type of structure or vessel.

Tanks for the storage of liquids such as oil, water, etc., and hoppers, bins, chutes, etc., are today welded as a matter of general practice. This is due to the simplicity of detail and the tightness of joints possible with arc welding. In most cases in this field the arc welded structure is more economical.

Large storage tanks of greater than 20,000 gallons capacity are usually riveted because of the difficulty of erecting welded tanks in the field when they are shipped in the knocked down form. It is only a question of awaiting development of some method of erection which does not require bolt holes for assembly until even the largest tanks will be of welded construction.

Pressure vessels have been successfully arc welded and welding bids fair to replace riveting in this field. The inherent tightness of the welded joint coupled with the high joint efficiencies obtainable without any special complication have been factors in the rapid adoption of welding in this field. Pressure vessels are in service today under temperatures of from 800 to 1,000 degrees F. and pressures of more than 1,000 pounds per square inch on which all joints are arc welded. Some of these vessels have walls up to four inches in thickness.

From welded boiler drums it was a short step to welded steam headers and branches and several high pressure plants are in operation today in which all piping joints, including those between pipe and fittings such as valves, are arc welded.

Piping of all types is now welded in preference to the use of screwed or flanged fittings with resultant improvement in flow conditions and in freedom from leaks. Most pipe welding is performed by means of the oxy-acetylene process due to its greater flexibility and lower cost on this type of work.

Pressure pipe for water works systems and for penstocks is now being welded in preference to riveting due to the economies possible and the freedom from leaks.

Welding is now being applied successfully to the fabrication of "weldings" replacing steel castings. This is an important field of application and one which is having rapid development. The advantages of the welding over the casting are numerous:—(1) Elimination of patterns. (2) Greater flexibility in design. (3) Rapid deliveries. (4) Freedom from flaws. (5) More economical use of material and consequent reduction in weight. (6) Smaller machining allowances and easier machining due to freedom from sand or hard spots resulting in lower machining costs. (7) Lower cost on large weldings (one ton or greater).

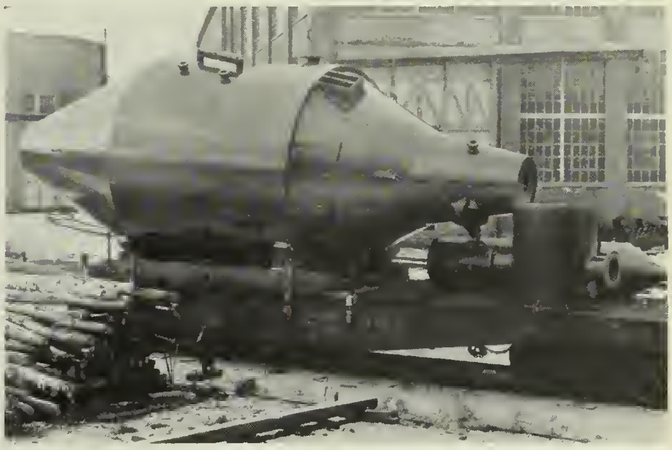

Fig. 11—Welded Salt Evaporator. Length 55 feet, weight 25 tons.

Among the weldings already fabricated are press frames, planer beds, engine frames, gears and many other parts.

The application of arc welding to bridges has, with a few notable exceptions, been restricted to short spans. There is every reason to believe, however, that welding will be applied to an ever greater extent to bridge structures with a consequent reduction in their weight.

Arc welding is being used extensively to reinforce existing bridges and this application is of great importance economically since it will permit older bridges to be reinforced for greater loadings and thus extend their life.

Buildings have been constructed by arc welding in many cities both on this continent and abroad. The welded steel building is lighter and stiffer and the riveting noises usually so objectionable in cities are eliminated when welding is employed.

The illustrations Figs. 9, 10 and 11 show representative types of work that are today being successfully arc welded.

Welding, both by the arc and by other methods, is today not only a useful repair tool but also an effective production process. Its adoption is revolutionizing conceptions of design in all fields and as its advantages become more widely known its applications will multiply. Arc welding indeed marks the beginning of a new age in steel.

Surveying and its Relation to Property

Particularly as regards conditions obtaining in the Province of Quebec

C. C. Lindsay, B.Sc., A.M.E.I.C.,

Lindsay and Bélanger, and M. D. Barclay Inc., Quebec Land Surveyors and Civil Engineers, Montreal.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, January 24th, 1935.

SUMMARY.—In outlining the functions of the Provincial Land Surveyor, Mr. Lindsay describes the system of land registration in the province of Quebec, and explains the principal legal provisions affecting the surveyor's work. Notes follow on the organization and equipment of survey parties whose work lies in unpopulated areas.

Jean Bourdon was the first surveyor to hold his commission as such in Canada, and he received that from the King of France in 1634. He was a civil engineer, like most of the surveyors who followed in his footsteps down the centuries.

The Corporation of Quebec Land Surveyors was founded in 1882 to weld the scattered members of the profession in this province into one body, to ensure uniformity of method in taking measurements, to maintain the necessary standard of education and experience amongst its members, to provide for the safekeeping of their plans and records for future generations, and above all to protect the public from imposition and fraud by ensuring that all works involving the delimitation of property boundaries should be performed only by properly qualified men subject to disciplinary action. With a few exceptions due to different needs, these reasons were the same as prompted the formation of the Canadian Society of Civil Engineers, some five years later.

It is commonly supposed that surveying consists mostly in running an instrument and using a chain, measuring up a number of lines in a mechanical sort of way and making the necessary calculations to ensure an accurate closure of these. Actually land-surveying goes a great deal deeper than that, it goes into the very foundations of property ownership and property rights. Surveyors originally started out as civil engineers, but specializing as surveyors they have gradually leaned more and more towards the legal profession, until they have become as necessary an adjunct to it as is the notarial profession, though in somewhat lesser degree. Quite a large portion of the practice of a surveyor consists in legal matters pertaining to property, and as such he must be an expert in all matters of law pertaining thereto, and be capable of acting in an advisory capacity to the lawyer or notary engaged in the settlement of any boundary dispute or property transaction whatsoever. As an illustration, you go to a notary to have your deed of sale drawn up and signed, but you go to the surveyor either directly, or through your lawyer or notary, to make sure that the property you are buying is properly described in the deed, that its measurements are correct and that there are no trespasses upon its boundaries.

The surveyor is obliged by law to keep an accurate record of all his operations, plans, field-notes, and other information obtained in the course of his practice, and maintain these properly indexed so that copies may be obtained or the originals consulted at any time. After his death if they are not transferred by his executors to another qualified surveyor they must be deposited with the Prothonotary of the district in which he practised, and thus be available for posterity. This obligation is a most important one for the public, and in daily practice it is a common occurrence to consult these old records and plans.

Notwithstanding the comparatively crude instruments of measurement in existence in the early days as compared with present day standards, it is surprising what good records were made, and many points then mentioned can still be retraced at the present time.

In the province of Quebec, there are two systems of measurement both officially recognized, namely the old French or Paris foot and arpent and the English standard foot and acre. The French arpent and foot are used for computation purposes in the seigneuries and land laid out under the French regime, the actual measurements are made with tapes graduated in English measure.

All measurements in the original seigneuries, which for instance include the whole Island of Montreal, are French measure, unless English measure is expressly stated. It is therefore necessary to remember that unless a dimension in a deed or other document is specifically stated as being English measure the law presumes it is in French measure.

Before proceeding further a definition of property should be given. Property is something which may belong to a person through right of ownership. It may be corporeal or incorporeal, principal and necessary, real or personal. But officially the Civil Code of the Province recognizes only two ways of classifying it, namely moveable and immoveable. Corporeal property is that which has substance such as land or merchandise, while incorporeal property is something which has no physical existence like a share in a commercial enterprise. The main thing to remember is that immoveable property may be taxed or hypothecated but moveable property may not be.

Thus it is important to know just what may be classed as immoveables; to give an instance, the transmission lines of power companies were long considered as being moveables, but not many years ago, a decision was handed down by the Privy Council fixing them as immoveables, and taxable.

A building is considered as consisting of more than its walls and roof. Balconies, gutters, shutters, doors, windows and screens, heating and plumbing systems, etc., are considered as forming part of the immoveable once they have become attached thereto. A boiler placed in a building as one of its constituent parts is an immoveable by nature.

Vegetables, crops, fruit, plants and trees which adhere to the ground are immoveables as long as there is adherence; there are numerous modifications of this and in case of dispute it is advisable to seek legal advice.

Land, the most widely-owned immoveable, is held under either one of two tenures in the province of Quebec, either by franc aleu roturier or in free and common socage. The former is the tenure if the land has once formed part of a seigneury, while the latter is the tenure if the land has been obtained through grant from the Crown subsequent to the cession to Great Britain.

During the French regime, most of the land fronting upon the great rivers had been ceded to seigneurs, who in return bound themselves to develop this land, colonize it and supply a stated amount of military service as and when required. Those whom they brought out to settle upon their seigneuries were called concessionnaires or censitaires and were subject to certain feudal servitudes, not least of which was the payment of an annual rent. These censitaires were never the real owners of their land, but merely held it at the pleasure of the seigneur. It is not generally known, that after the cession, the British Crown continued for a little while the system of conceding land to seigneurs, and during that time the seigneuries of Murray Bay, Mount Murray, Shoolbred, and five others were conceded. This system did not prove popular however, and the remaining lands were divided into townships and conceded direct from the Crown, subject only to certain reserves for mineral rights, etc.

Under the seigneurial tenure the censitaires or tenants were not only liable for feudal or seigneurial duties or charges but their annual rental was perpetual and irredeemable. In the middle of the last century this system was enquired into and it was found to be not only unsatisfactory but unfair and injurious. The first acts for the abolishment of this tenure were passed in 1845 and 1849 but these did not meet with general approval and finally in 1854 another and final act was passed which converted the tenure of land in these seigneuries into free tenure of franc aleu roturier, as follows:—

To quote from Marler's book, "The Law of Real Property":

1. From and after the date of the publication in the Canada Gazette of the deposit of the Schedule prepared by the Commissioners for any seigneury, each censitaire therein held his land in franc aleu roturier, free and clear of all cens, droit de banalité, droit de retrait and other feudal and seigneurial duties and charges whatever, except the redeemable constituted rent fixed by the Schedule, which was substituted for all seigneurial duties and charges.

2. Every seigneur held his domain and the unconceded lands in his seigneury, and all water-powers and real estate belonging to him in franc aleu roturier, and the constituted rents payable to him under the Act by his censitaires, free and clear of all feudal duties or dues to the Crown or to any seigneur dominant of whom his fief or seigneury was then held, and he could deal with his unconceded lands in the same manner as land held by other persons under the same tenure might be dealt with.

3. In order that no tenure resembling feudal tenure should ever be charged on lands, whether held in free and common socage or in franc aleu roturier, it was provided that no such lands should ever be charged with a perpetual and unredeemable rent, and if such a rent had been stipulated its capital might be redeemed at the option of the holder who would pay the capital of the rent calculated at the legal rate of interest, and all other feudal duties and charges or servitudes were declared null and void.

When subdividing the townships the system followed in the province consisted in general of lots of narrow width by considerably greater depths. This system has much to recommend it in a new country, it brings the neighbours closer together, reduces to a minimum the amount of road which has to be built and maintained in summer and winter per unit of population and conduces to a denser settlement on fertile soils. In the first days all lots were made fronting upon the rivers, which were then the main arteries of travel.

Since 1884 all lands sold by the Crown are subject to a reserve of three chains in width on all lands bordering upon non-navigable rivers and lakes, which remain the property of the Crown. In lands sold previous to that date, ownership extended to the centre of the non-navigable stream or lake.

In navigable streams or lakes, ownership extends to high-water mark only. This high-water mark is usually called mean high-water and is generally accepted as being the line of limit of growth of land vegetation and the beginning of aquatic vegetation. Spring floods may extend above high-water mark without affecting its authenticity.

Fig. 1—Typical Surveyor's Post and Stone Mound.

A navigable river is one which is floatable and which may be driven by logs in rafts. A non-navigable river is one which may be driven only by loose logs.

Another important point involving property is possession. That old saying that possession is nine points of the law is not far out, in this province at any rate. Possession is defined as the keeping of something in our power either by oneself or by someone holding it for us and in our name, with the intention of holding it as owner.

If a person occupy a piece of property continuously and uninterruptedly, publicly, unequivocally and as proprietor for thirty years he has fulfilled all the requirements of prescription and as such is entitled to possession. From this it follows that if a wall, or a fence, or some other mark of that nature such as a line of blazed trees through the bush, be accepted by two neighbouring proprietors for this period without question or dispute, then this wall or fence or line of blazed trees is their boundary-line, whether it be straight or crooked or in its correct position or not with regard to the original land lines. The law presumes good faith on the part of the occupant, and any claimants to the land occupied must prove the contrary. It will be considered at first sight that this law is all in favour of the squatter. While this is true to some extent it is offset by the fact that every proprietor must protect his own interests by maintaining and correctly establishing his boundaries. This protects the innocent person who may possibly have a flaw in his title through error or discrepancy in description and would otherwise be unjustly evicted.

Originally the term "squatters' rights" was meant to apply to the settler who had pushed out beyond the surveyed areas in his search for good land, and having found it and settled upon it, was improving his holdings. When the surveyor subsequently came along, it was his duty to take note of the area occupied by each squatter, and in his report give each one credit for what he had. The squatter then had first right to file upon that particular area which he was occupying when the district was thrown open for settlement. As no one can prescribe against the Crown, the squatter has no legal right to his land until the Crown has it surveyed or he has it surveyed for himself and files an application for its purchase.

As already stated one cannot prescribe against the Crown, nor can one prescribe against property possessed for the general use of the public such as roads, squares, landing places, etc. Property belonging to municipalities for other uses than the above is subject to prescription.

Land titles in the province of Quebec are recorded by the cadastre system, and all transactions are registered in the Registry Office of the district concerned. By this means the identity of a piece of property is maintained no matter how often it is subdivided or redivided or changes hands. The method used is simple; it consists of hyphenating the numbers of subsequent subdivisions with the number of the original lot in any municipality. When a portion of the country becomes thickly settled and transactions are taking place between the settlers involving portions of lots on the original survey, the provincial government has a cadastral plan made of the township, in which each man's holdings are measured and a book of reference is prepared showing the owner of each piece of land in the township, taken separately, its boundaries upon all its sides, and its dimensions and area. It is given, at the same time, a number which would be a subsidiary number to that given to the lot of which it formed part at the time of the primitive survey. This cadastral plan and book of reference are prepared in triplicate, submitted to the Minister of Colonization, Game and Fisheries for his approval, during which time official notice is given to the public in general, but especially to the inhabitants of this township, that this cadastre has been prepared and that it may be examined at an appointed place, generally the principal town or village in the community, and after all objections, if any, are straightened out, it is formally accepted and comes into force. The original is kept in the archives of the department at Quebec, and a duplicate copy, duly certified, is sent to the Registrar of the district concerned.

Subsequently as the community grows in size, and people gradually group themselves together into towns and villages, it is necessary to make further subdivisions of the lots in these districts. This is done by laying out the boundaries of the lot which it is desired to cut up into building lots and put upon the market, and then designing the same in accordance with the needs of the situation. Unfortunately, the surveyor is not the final dictator of the form which this subdivision is to take, but the proprietor is, and in many cases he wants to get the greatest number of building lots with a minimum of streets and lanes. No streets, in a town or village, can be put in less than sixty-six feet in width unless with the permission of the Lieutenant-Governor in Council.

Engineers frequently express surprise that measurements in a city block do not always conform to what is given for its width or length in the official cadastre. This most frequently is not faulty measurement at the time of the original lay-out, though it sometimes is. In our province there is an article in the Civil Code which specifies that when a man sells a specified area of land he must deliver that exact quantity, and the purchaser may insist upon the exact fulfilment of the contract. Though most deeds of sale are for a determinate thing, and the quantity is qualified by the words more or less, or as it exists at the present time without warranty as to exact content, some are still made stating the actual quantity and the price per unit. If the seller does not have that much land in his lot then he must get out and get the difference from his neighbours. Therefore people who laid out these lots at a time when land was comparatively cheap, were instructed to chain long and leave a surplus in each subdivision so that the vendor would always be upon the safe side.

It must be remembered in deeds of sale that all obscurities are generally construed against the seller, as he is supposed to know better than the purchaser what he has for sale.

Ownership of the soil carries with it the ownership of what is above and below the surface. In the original grants from the Crown prior to 1880 mining rights except for gold and silver were not reserved to the Crown. Since that time all mining rights in all sales of land by the Crown are reserved. Therefore if a prospector discovers a body of ore upon private property he may stake this area under the Quebec Mining Act and mine it; he must however make arrangements with the proprietor of the surface for whatever part of this surface which he shall need. In cases of disagreement as to the value of the land thus taken, the dispute may be submitted to arbitration as provided in the Act. This does not apply to tunnels for transportation purposes, therefore if any such construction is projected it is necessary to acquire right by title from the owner of the surface rights.

In the same way no one can encroach upon the aerial space over another's land by building the eaves of his house in such a way as to permit water to run therefrom upon his neighbours' land, nor have the branches of his trees project thereon. Also any wires or clothes-lines stretched across another person's land may be considered as an encroachment. The passage of an aeroplane would not be, as it is not of a permanent nature.

Land fronting upon running water is subject to increase or decrease in area due to alluvion and erosion respectively. Alluvion is silt carried down by the stream and gradually depositing itself upon the bank through eddies or fluctuations in the current of the river; it becomes the property of the adjacent proprietor. Erosion on the other hand may cut off portions of riparian land and carry it away and deposit it on neighbouring land, to the profit of the owner thereof. If this erosion is gradual the original owner of the land thus washed away cannot recover it but he naturally can endeavour to protect his land as best he may by rip-rap or retaining walls. If this erosion is sudden and caused by a flood or some such agency, and a large and distinguishable portion of land is carried away and deposited upon another property, the owner of the land thus despoiled may have it carried back again to its original site. This is applicable to places where the flood has washed out a portion of a farm down to gravel and boulders and the devastated area has to be back-filled again.

Islands in a navigable stream belong to the Crown, and may be sold or transferred by it. If a piece of riparian property is cut off from the main land so as to form an island, this island still belongs to its former owner. Should an island form in a navigable river through gathering of silt and changing of channels, etc., this island belongs to the Crown and may be disposed of solely by it.

In non-navigable streams, the islands belong to the proprietor of that side of the stream to which it is nearest, provided it is altogether upon one side of the centre line of this stream. If the centre line of this stream cuts through this island, then the two portions of it belong to the riparian owners on each side in accordance with their location.

In the same way, if a non-navigable stream abandons its bed and cuts a new path for itself, the old bed belongs to the proprietor through whose land it has cut its path. In a navigable river the old bed belongs to the Crown and so does the new bed which it has cut.

If a proprietor wishes to construct a dam across a non-navigable stream he must obtain the permission of the proprietor upon the opposite bank. Also no person may take the water away from a non-navigable stream nor interfere with its flow without the permission of the proprietors below him. The Civil Code states that the owner of property through which the stream runs may make use of the water which thus passes through his land for his own use and that of his stock but may not divert any part of its flow to other places or purposes.

A source of interest to engineers in this province is the existence of the mitoyen or common wall between buildings. A proprietor may build a wall altogether upon his own property following along his dividing line. This is a private wall and his neighbour cannot make use of it in any way. He may not lean a building against it, nor train vines upon it, nor even pile earth against it. However the Civil Code states in Article 517 that the adjoining proprietor has the privilege of making the private wall mitoyen in whole or in part, by paying for half of the value of the land of the ground on which it is built plus half the value of the part of the wall which he wishes to render common. It is however recognized that a proprietor may take not more than nine inches of his neighbour's land and construct a wall which would be partly upon his neighbour's land and partly upon his. The neighbour may acquire mitoyenneté in this wall by paying for half of its value, and incorporate it as part of the building which he intends to erect upon his property, but until the transaction involving his payment of his share of the cost of this wall is completed the builder of this wall is absolute owner of it and has the same rights in it as for a private wall. There are various signs used by builders and architects to denote whether a wall is mitoyen or not, and these are as familiar to these professions as to surveyors. These signs are not necessarily final proof however and give way in law before definite evidence to the contrary.

Any proprietor, in a city or town, may oblige his neighbour to share the cost of erection of a fence-wall, ten feet high and eighteen inches thick, between their respective properties. Fortunately for the public this privilege is rarely used, and has never been done so far to our knowledge.

One proprietor cannot make any openings of any kind whatsoever in the mitoyen wall without the consent of his neighbour, not even if these openings are closed with fixed glass and iron grilles. If, however, the city demolishes a house in order to pass a street through the site it occupies, the proprietor of the other portion of this house may make openings in the mitoyen wall in order to permit views out upon the newly opened street.

If a proprietor wishes to raise the common wall he may do so, provided he notifies his neighbour of his intention, and obtains his consent. If the latter refuses the dispute can be settled by arbitration and by experts who

Fig. 2—Cutting Sled Trail around Open Water-course.

determine whether the existing wall is capable of carrying the extra load. If it is not, it must be strengthened by additional supports or thickening placed upon the side of the one who wants to raise it, and he must give the land necessary for this purpose. He must also pay not only all the cost of the erection of this additional height but must also pay to the neighbouring proprietor a sum equal to one-sixth of the value of the new construction as indemnity for the additional load which the common wall must bear.

If the neighbouring proprietor wants to make use of this structure thus erected he must pay half the value of it plus half the value of the land used by the man who raised the superstructure for the additional thickness required.

It frequently occurs, that the examination of the experts reveals that the mitoyen wall as it is built will not stand the additional load designed for it. In this case it must be demolished and rebuilt and during the course of this operation temporary protection works must be put in to support the floors and remaining walls of the buildings. As previously mentioned, if the foundations have to be widened or thickened to carry the additional weight, then the area required must be taken off the land of that proprietor who desired to raise the wall.

Fixing a Boundary or Making a Bornage

Any proprietor may oblige his neighbour to fix the boundary between their contiguous properties. This is a right and the neighbour may not refuse. When the line has never been established or is no longer visible both parties should agree upon a surveyor to establish it for them in accordance with their titles. The costs of the "bornage" are always equally divided but if one proprietor refuses to be called en bornage amicably then an action has to be taken to compel him to do so. The payment of the costs of this action is at the discretion of the court. It is part of the surveyor's role to settle boundary disputes, and he is frequently called upon to arbitrate between rival claimants, generally being both judge and jury.

If the two parties have agreed upon a surveyor, the latter notifies them to be at a certain place near the job, at a certain time, and to bring all documents showing their titles to their holdings with them, and proceeds to draw the line in accordance with these.

If the two parties have not agreed upon a surveyor, then the party desiring the bornage chooses his own surveyor and instructs him to proceed with the necessary formalities to carry out this task. The surveyor then gives the other proprietor official notification to be at a definitely appointed rendezvous nearby at a certain date and time, bringing with him all documents showing his title to the adjoining property, advising him also that he has the right to choose his own surveyor to represent him for the purpose mentioned. These notices must allow three clear days when the domicile of the party concerned does not exceed fifty miles from the property to be bounded, and an additional day for each additional fifty miles therefrom.

If the neighbour refuses to agree to the one surveyor, or to name a surveyor of his own, or does not appear upon the scene at the date and hour specified, then the boundary can only be determined by an action en bornage in the courts. If the neighbour attends upon the ground after having agreed to accept the services of the surveyor suggested by the other party and finds that the line is not drawn in accordance with his liking, he is not obliged to accept it, but may have recourse to the courts.

If the case goes to the courts, the judge appoints one or more surveyors, according to the representations of counsel for the contending parties, as experts to determine the proper position of the line. They are sworn in especially as such. The experts are instructed by the court to make a plan of the locality showing the claims of the various parties, their occupation, and all topographical or other features which may be pertinent to the case.

These expert surveyors proceed in the same manner as if they were working upon an ordinary bornage. They give the usual official notification to the interested parties, examine all the titles, swear in witnesses and take down their testimony regarding the length of time the claimants have been in occupation of their respective areas, etc. The plan is then prepared and filed with the court accompanied by a report, both of which are signed by the surveyor or surveyors thus appointed.

In the cities where land is valuable extreme care must be exercised and measurements taken with great accuracy. However, one is assisted to a great extent by occupational rights and previous notes of surveys in that vicinity.

In the country, especially in the district north of Montreal, the old survey lines have completely disappeared where they have not been maintained by farm-fences, and must be retraced from the notes of the primitive survey. These surveys were made about seventy-five or eighty years ago, with compass and link chains, and the lines are far from straight. However, when one considers the difficulties which these old surveyors encountered, it is surprising that the results obtained were as good as they were. There is considerable local attraction in spots and the compass lines were affected accordingly, but frequent observations with the primitive theodolites used served to keep them fairly well in the right direction. The younger generation are at times disposed to criticize the work of these men harshly, in view of the results which can be obtained with modern instruments. One thing they did excel in and that is their chainage notes. As a rule these were taken with painstaking care and described every important topographical feature clearly and well. It is due to these chainage notes that one is able to retrace these old lines to-day.

As mentioned previously, when an old survey line has disappeared or is no longer visible it must be retraced in its old position. It is not sufficient to measure off the theoretical depth of a range from one that has previously been found, and call the line which would be drawn from the point thus found, the true position of the range-line wanted. The law demands that each line must be retraced in its previous position, and that means that the old survey notes must be obtained and the old line found. If two points are found on the old line a certain distance apart, they may be joined together and the line thus drawn called the proper location of the line, but experience and practice determines with how much latitude the words "certain distance apart" can be taken.

Servitudes

No discussion of property would be complete without mentioning servitudes. Servitude is defined by Marler as being a charge imposed on one real estate for the benefit of another belonging to a different proprietor. That land of which the servitude is in favour is called the dominant land, that land which is subject to the servitude is called the servient land. These separate pieces of land must have separate owners.

Any reserve which is made in the sale of a piece of property can be classed as being a servitude unless it is of a temporary nature. For example, a right of passage, or a right to draw water from a well, or a right to take gravel from a borrow-pit, or the right to cut timber, are all servitudes upon that property where these things exist.

Lower lands are subject to the waters which may flow upon them from higher lands so long as this flow is not increased by the hand of man. This means that these low lands are servient to the high lands to this extent. But the proprietor of the high land cannot drain out a swamp or lake or other body of water upon his land and dump it upon the proprietor of the low land, without compensation or agreement.

Although it has been mentioned previously that the riparian proprietor of any stream cannot divert the flow of this stream, yet there is a special reservation made in the case of springs. A spring is the absolute property of the person who owns the land where it exists and he can dispose of its flow as he sees fit.

There is another servitude which exists upon all riparian property whether this be fronting upon a navigable or a non-navigable stream, and that is the "chemin de halage" or towpath. At one time in the French regime there was a reserve of two French perches in width along both sides of the St. Lawrence river which was to serve for navigation by barge or floating of logs and rafts, and also for vehicles and cattle. This was subsequently abrogated and at the present time, all water-courses whether navigable or non-navigable, lakes, ponds, streams, and islands in navigable rivers are subjected to a servitude whereby the bed and banks of all these may be used for the floating of lumber and for the passage of ferries, boats and canoes engaged in navigation, subject to the repair of any damages which may be caused through these operations. The servitude does not exist for any other purpose however, and does not mean that picnic parties or campers or tourists travelling by canoe can make use of private property without trespassing thereon. It is a very important servitude for lumber companies who have to drive their logs down stream from the piling-grounds to the mills.

In this connection attention should be drawn to the fact that since the limit of private property fronting upon a navigable river is fixed as being at mean high water mark, the beach and low water area extending below that belongs to the Crown. Therefore if any riparian proprietor wishes to build a wharf extending out into the stream it is up to him to secure his possession to the land which he intends to build upon, as well as the beach in front of his residence, by applying to the provincial government for what is called a beach and deep-water lot. These beach and deep-water lots are granted on lease upon presentation of a plan and description prepared by a land-surveyor describing its exact extent and location. The rentals are nominal and the possession of such a beach-lot confirms the land-owner in his possession of the beach between high and low water marks and enables him to protect himself from unwelcome intrusion by the public who use the beach as a highway.

There is another servitude which is of particular interest to residents of the cities and that is the right of view over another's property. According to the Civil Code no proprietor may have windows directly overlooking his neighbour's property unless they are at a distance of six French feet from the mutual dividing line, or 6 feet 4¾ inches English measure. Oblique views from side windows must be at a minimum distance of two feet French measure. The right to put windows or views at a lesser distance than the above has a commercial value, and the proprietor of the neighbouring property may dispose of this as he sees fit, though if he grants this privilege he may diminish the value of his own property.

Lights may be established in a wall fronting over a neighbour's property under certain specified conditions. If these are on the first floor of the building they must be situated at a minimum distance of nine feet from the ground; and not lower than seven feet from the floor if on the upper storeys. These lights must be composed of fixed glass (verre dormant) and provided with an iron grating or grille of not less than four inches between the bars. Moreover these windows must be fastened securely with plaster or cement so that they may not be opened.

A proprietor whose land is enclosed on all sides by that of others and has no outlet upon the public highway, may demand a right of passage over that of his neighbours for the use of his property, subject to an indemnity which would be proportional to the damage which he may cause. This right of passage should usually be taken at that point which is nearest to the public highway; on the other hand it should be taken at that place which would cause the least damage to the land thus traversed. If this land becomes enclosed as a result of a sale, or of a partition or of a legacy, then it is up to the vendor, the co-partitioner or the testator to offer a way out, and not to the proprietor of the shortest possible route, and this without indemnity. If the passage thus given is no longer required, the right to it can be suppressed and the indemnity is refunded or the annual rental ceases to exist.

Servitudes may be extinguished and a servitude ceases to exist when the things subject to them are in such a condition that it can no longer be exercised. It revives when conditions are re-established so it may be used again. If the dominant land and the servient land are united in the same ownership then the servitude of one to the other is extinguished. If a servitude is not used for thirty years it can become extinguished if between persons of full age and privileged. Thus if there is a right of passage over a property, and the proprietor of that property erects a gate or fence which prevents passing thereon, and no objection is made for over thirty years, then the right no longer exists. It is sufficient to perform some public act every once in a while before witnesses whereby the right of passage is exercised, to break any prescription which may have formed up to that time. Any owner of a servitude must exercise vigilance to see that his rights are not curtailed by obstructions, either through his own acts or those of the proprietor of the servient land, otherwise if the curtailed condition exists for thirty years, his servitude becomes limited to this curtailed condition.

Trespass

Before there can be trespass the boundaries of land must have been established and be visible. In settled districts a fence or a wall or a hedge or a line of shrubbery are the most usual signs of ownership and occupation, though a sign or placard placed upon the side of a path or roadway is of the same effect. In unsettled districts where the properties have not yet reached the fencing stage, a surveyor's line well-blazed is easily found and recognized as such by the rural population and woodsmen.

The boundary-line between contiguous timber-limits is marked by blazed trees on each side of the line, the line itself being well cut-out to a minimum width of three feet. It cannot be recommended too strongly that efforts should be made in logging operations to preserve as many of these blazed trees as possible so as to maintain the boundary line. The corners and deflection points are marked by large wooden posts with an iron post alongside it driven deep into the ground, and wooden posts are placed at every mile along the sections of the line.

Of recent years most of the timber-limits of this province have been sold bounded by the height of land of the watershed in which they are located. In the old days limits were frequently sold as being so many miles in depth along the frontage of such and such a river. In rough country it was frequently found uneconomical to log out that portion of the limits thus obtained which were found to be on the reserve side of the adjoining watershed, as all the wood therein would have to be hauled back over the divide.

In obtaining land in unsurveyed townships, the procedure is to call in a surveyor and have him lay off the area required, prepare a plan and description and get it filed with the Department of Lands and Forests, Quebec. In the olden days it was possible to obtain letters-patent to pieces of land of this nature without any difficulty; now it is not usual to sell the land but to grant it on long lease at a nominal sum. Later when the area becomes part of a surveyed township, this area would become part of a numbered lot and it would be possible for the lessee to change his status by filing on the whole lot and obtaining letters-patent. In the meantime his buildings and other improvements are fully protected by the lease.

Mortgages

Mortgages are registered against the lot number affected, in the registry office of the district concerned. Usually a subdivision plan is prepared of the original lot before building lots are put upon the market and this subdivision is registered. In the smaller towns and rural districts regular subdivisions are not always made and lots are sold off piecemeal in accordance with the demand. Therefore any mortgages given to the various proprietors or occasioned by the unpaid balance of the purchase price are registered against this cadastral number as a whole. The description of the land involved is frequently vague, ambiguous, and sketchy, and as the number of transactions increases the registrar finds himself in a position where he cannot commit himself in his Certificate of Search and there is a cloud upon all the properties in the original lot. This cloud can only be dispelled by diligent title examination and subsequent survey. In view of this it is now general practice for a purchaser to insist upon a new subdivision plan being made of the land which he is about to buy so that he may start his occupation with a clean sheet, where this state of affairs exists.

Survey Work in Remote Areas

The surveyor's work in the open is somewhat different from an engineer's. As a rule an engineer comes into the picture when a district has developed enough to permit of solid construction and subsequent advancement. When he goes off into the bush his task consists of a more intensive study of a project, which permits him to spend a longer time in one area for the purpose of concentrating on the information which he is seeking. He has less moving about to do, fewer caches to establish, and is able to erect camps or make himself more comfortable in view of his longer stay and also carry a larger and more varied amount of provisions.

The surveyor on the other hand is still an explorer as well as a surveyor. The surveyor's lines take him anywhere across country where even Indian guides are not totally reliable. This means that personal clothing and paraphernalia must be cut down to a minimum, that food must be rationed to avoid catastrophe, that caches must be built up beyond the reach of depredatory animals, and protected against the elements and destruction by bush fire.

Fig. 3—Well Balanced Portage Train of Men and Dogs.

In cases like these the welfare of men and animals is of the first consideration, and it is well to take upon such a trip only those who have proved themselves capable under similar conditions on previous occasions. The author has found the labouring men best suited for this work are those from the Lower Saguenay, the north shore of the St. Lawrence and Gaspé. The people in those regions are accustomed to hardship, have not yet been spoiled by contact with softening civilization, are exceedingly clever with their hands, are good canoemen and inured to snowshoes and hauling of supplies on sleigh and toboggan. It is not unusual even at the present time to have to plan on expeditions lasting many months.

It must be remembered that parties going off into the hinterland on expeditions must rely altogether upon their own resources. They are complete units in themselves, the regions they will work in are exceedingly remote and difficult of access, and therefore they must look out for themselves.

In the old days, game was plentiful and could be relied on to a considerable extent, but forest fires and indiscriminate hunting have thinned out game and one must plan for all eventualities. A food consumption of 3½ pounds per day per man, of dry, uncooked food is the usual amount. This ration covers meat, flour, dried fruits and vegetables and groceries. Canned goods are avoided owing to the lost weight in the cans and the difficulty in packing. Personal baggage in winter is cut to a maximum of thirty pounds per man exclusive of sleeping gear. Blankets are replaced by sleeping bags and much poundage is gained by this change. Tents are made of silk, and small sheet iron stoves are used. The heaviest item is the cook-stove, but recent improvements in these have permitted the reduction of considerable weight. Now it is possible to get a well-built little stove, with an oven suitable for baking, measuring just the width of a dog-sled, and weighing not more than forty-five pounds.

In the old days, the route into the northern regions was up the great rivers from the end of steel or river-steamboat travel, carrying supplies in canoes in summer, packing them over the portages or lining the loaded craft up through the rapids wheu the banks permitted. This was pretty hard work and progress was slow. If the expedition was for a long period, there would be two men per canoe loaded with close to 1,000 pounds of supplies and baggage.

In the winter the same routes would be followed, sleds replacing the canoes, supplemented by dog-teams bringing up reserve supplies. Since the food expenditure of a party numbering ten men and ten dogs could be based on a daily ration of 3½ pounds each for the men, and 1½ pounds each for the dogs, daily food expenditure would run a total of forty-five pounds per day, it is only a question of arithmetic to figure out the necessary tonnage of food-stuffs required for a trip of several months. It is interesting to know that a man on snowshoes, breaking trail for himself and hauling a sleigh or toboggan, can only convey enough food and baggage to keep himself warmed and fed for a little over one week. Therefore if man is to survive and maintain his energy, it is necessary to organize supplementary means of transportation for the additional supplies required for his stay in the country. These supplementary systems of transportation are the canoe, the dog-sled and the aeroplane.

The coming of the aeroplane simplified matters very greatly. It changed the whole system of communication and transportation and it was a surveyor, Henri Bélanger, of Quebec City, who was the first in this province to organize the transportation of men and supplies into the faraway regions by the use of the aeroplane. Working in conjunction with the late Harry Quigley in 1919 and 1920, they took in all the crews necessary for the survey of the height of land between the Hamilton river and the St. Lawrence in Ungava, which survey was afterwards used for the case submitted by the province of Quebec against Newfoundland for the delimitation of the Labrador boundary. It used to take his men forty-five days travelling by the water route from Quebec via Seven Islands to the site of his work, and the food expenditure during this period made serious inroads in his caches. It was estimated that food landed on the job cost $1.10 a pound, so that a 100-pound sack of flour cost exactly one hundred and ten dollars in addition to its purchase price, before it could be used. By using planes, the journey was made in a few hours from Clarke City or Seven Islands, and caches were made all along the projected route of the work, thus avoiding the re-handling and re-transportation of the supplies from the central cache to the secondary ones.

No article on the outdoors would be complete without mentioning man's good friend the dog. The reasons which make the dog eminently suitable for hauling purposes are that a dog eats the same kind of food as man, and therefore rations for the one are reserve rations for the other; a dog for his weight has a comparatively light tread and can keep a good footing upon a snowshoe trail broken the day before; he does not sweat through his coat and therefore runs no risk of catching cold at the end of the day's travel when he is put into temporary quarters; he has a warm furry coat and when curled up in the den which the dog-man makes for him, blizzards may blow snow several inches over him without making him uncomfortable; and lastly and most important, he is a regular dynamo of energy, a dog can haul twice his own weight with a light sleigh on a well-beaten trail and being intelligent learns to handle his load with almost human care.

In the Arctic regions and along the north shore of the St. Lawrence, dogs are driven in teams of five or more, each one hitched separately by a single trace to the komatik or sled, and as the load gets under way they spread out fanwise and can maintain a good pace for a long time. The conditions there are different from ours however, as almost constant wind packs the snow into hard ridges and affords hard footing without trail breaking being necessary unless after a blizzard. Moreover dog food in the shape of fish, seal or other meat is available and it is possible to support a larger string upon the country. In the northwest, dogs are hitched in tandem, the usual team numbering five dogs, and it is not uncommon for teams thus arranged to make very wonderful runs for distance and time over good trails.

In this province, conditions are different as there is usually rough wooded country to traverse. The snow falls in large quantities and is very soft, lying unpacked through the winter until the warm suns of March put a crust upon it. It is therefore necessary to break trail with snowshoes for every foot of the way, and consequently the pace of the whole party is cut down to the pace of the man breaking trail. This procedure is extremely arduous when snow conditions are bad, and he has to be relieved every few hundred yards. Under these conditions ten or fifteen miles per day is a good day's travel, and when there is a large supply of provisions to be brought up it may average less than that.

From experience the author has found it better to hitch only one dog, or under rare occasions two in tandem, to a sled and this sled is usually loaded with 150 pounds. There are many advantages in using only one dog: If one dog hauls 150 pounds it does not follow that two dogs will haul three hundred pounds, as usually two dogs will only haul about 250 pounds. When two dogs are hitched in tandem in rough country, the lead-dog's pulling has either a tendency to lift the wheel-dog off his feet or to increase the load on the wheeler's back by dragging him down towards the ground; both occasions reduce the leader's pull and increase the wheeler's load; again it is difficult to get two dogs with the same temperament to team together, and anyone who has ever known the term "soldiering" should see how some lead-dogs will just pull enough to keep the traces tight and not an ounce more; if you reverse the dogs and put the energetic wheeler in as leader he will keep up his good work until he falls down exhausted, as now he has to pull his erstwhile leader as well as the whole load.

When a dog is hitched separately to a sleigh he cannot fight; when he is in tandem he often does. When dogs are hitched tandem, it practically requires one man per sleigh, whereas when they are hitched singly, the dogman and one assistant can handle sixteen or seventeen different sleighs with their dogs, and thus leave the balance of the men available for hauling a sled themselves. If you have a party of ten men travelling with ten dogs for a distance of one hundred and fifty miles or so from railhead. you will have a pilot party on in front breaking trail one day ahead of the main body; this party consists of three men, two of them taking turns breaking trail and the third man hauling a light sleigh loaded with their camping equipment and food for a week. Of the seven men remaining with the main body, two of them will be driving and looking after the dogs, helping them over the rough places and keeping them up to the mark, they will be assisted by the cook. The remaining four men will be each hauling sleighs. Allowing 100 pounds per man on each of the man-drawn sleds and 150 pounds per dog, with 75 pounds on the sled drawn by the pilot party, the total amount of food and supplies which can be hauled by the party would be almost two thousand pounds.

As the pilot party move more slowly than the party following their trail, it is possible for the dog teams to make back trips now and again and bring up the reserve supplies, which have been cached behind. As soon as the work is reached, the party breaks up into its component parts, the line-crew go off on line and keep the work moving without interruption, while the dog-man and his helper, who are now known as portageurs, bring up reserve supplies, make caches where needed, explore the country round in the direction which the line is taking and locate suitable camping grounds in advance. Camp is usually moved three times in two weeks, sometimes oftener, depending upon the nature of the work and the amount of cutting encountered. As none of the crews come in to dinner, taking food for the day with them when they leave in the morning, the cook has the day to himself, during which times he must do all the necessary cooking and baking and gathering of wood to provide good warm meals for both men and dogs on their return at night. The dogs are only fed once a day and that in the evening.

These notes refer to a profession closely allied to that of the engineer, a profession which has not dropped behind in the years during which it separated itself from the engineering profession but on the contrary has maintained the traditions which it inherited then and has added to them, until to-day it has become a complete and entire specialty of its own, carrying over the mathematical education and precision of the engineer to a close kinship with the legal profession.

Some Considerations Governing the Undertaking of Hydro-Electric Power Developments

E. D. Gray-Donald, A.M.E.I.C.,
Superintendent Power Division, Quebec Power Company, Quebec, Que.

Paper presented before the Quebec Branch of The Engineering Institute of Canada, January 14th, 1935.

SUMMARY.—The author notes the trend towards the combination of power development with flood control; deals with the respective advantages of steam and hydro-electric development; discusses the effect of various types of load; new uses for electric energy; and the factors affecting the location of power sites and the control of their water supply.

Various estimates have been made of the potential water power available in the world. It is obvious that such estimates must be at the best only guesses, as there are many rivers of which little is known as regards flow, profile, etc. Again the methods of calculation vary, as to whether minimum or six months or average flow is considered, whether total head or only suitable heads are considered, plant efficiency and other features.

A table published in 1933, gives the installed capacity of hydro-electric plants in various countries, and is of interest though it covers only a fraction of the potential power.

Water Power Development in Countries Having an Installed Capacity in Excess of 100,000 Kilowatts

Country	Rating, kw.	Per cent of total
1. United States	11,800,000	30.06
2. Canada	5,256,000	13.39
3. Italy	4,348,000	11.08
4. Japan	3,151,000	8.03
5. France	2,781,000	7.08
6. Germany	2,300,000	5.86
7. Switzerland	1,900,000	4.84
8. Norway	1,850,000	4.71
9. Sweden	1,400,000	3.57
10. Spain	875,000	2.23
11. Soviet Russia	758,000	1.93
12. Austria	725,000	1.85
13. Brazil	525,000	1.34
14. Finland	300,000	0.76
15. India	300,000	0.76
16. Mexico	235,000	0.60
17. Great Britain	228,000	0.58
18. New Zealand	225,000	0.57
19. Jugoslavia	190,000	0.48
20. Czechoslovakia	110,000	0.28
Total	39,257,000	100.00

In 1931 in the United States the total capacity of generators in all power plants both hydraulic and steam, generating electricity for public use was slightly over

36,000,000 kw. Compared with the above table it appears that the hydro-electric power plant installation in the United States was only about one-third of the total installation.

In Canada the greater amount of power is developed by hydraulic means. It is estimated that the minimum water-power possibilities of the Dominion are something over twenty million horse power under ordinary minimum flow and nearly thirty-four million horse power for six months of the year. The installed horse power at the end of 1933 was 7,332,000 h.p. and it has been estimated that the saving in coal, based on the kilowatt-hour output of the plants was nearly 15 million tons.

In a country where the few available coal deposits are far from the centres of industry this is a very important factor.

Trends in Hydro-Electric Power Development

The trend in hydro-electric power development has been interesting. The first sites to be developed were those prominent falls near centres of population; often they were falls which yielded little power, but enough for those days. Then, as the art of transmitting power advanced, more remote sites were developed, gradually increasing in size, but still the really large sites were not tackled. For a while there was talk of developing all available small sites—five hundred or a thousand kilowatts here and there all over the country. With the introduction of automatic and remote control equipment these small developments became popular due to their low operating cost. Then came the development of large low head sites. All the time increasing attention was being given to storage and river flow control. Recently power developments have been combined with navigation projects, as in the St. Lawrence river, and with irrigation and flood control, as the Hoover Dam development on the Colorado river.

In the United States in particular the idea of the combination of power development with flood control and irrigation or with navigation, has taken hold. Such sites are invariably costly to develop from a purely power standpoint, and would not be attempted were not state aid forthcoming. In some cases the state pays a certain amount to cover works done for the public good. In other cases the state has shouldered the whole burden with the intention of profiting thereby. An ambitious plan is now under way in the Tennessee Valley, where the United States government is developing a large water power and establishing flood control, and is endeavouring to improve the lot of the population. This is not the place to discuss the wisdom or otherwise of such a policy. It is certainly true that the United States government has provided the means and given the necessary impetus to these colossal projects which would not have been undertaken by any private corporation.

For any private corporation the undertaking of a hydro-electric power development is a business proposition which must pay its own way. However, when government aid is forthcoming to pay for those features of the undertaking which are for the public good, the development of power sites in conjunction with irrigation, flood control and navigation projects enables power to be obtained at reasonable cost from sites that would otherwise be uneconomical to develop. Some of the figures published with regard to the economics of such developments are not convincing. It is reasonable to assume that, if a site be uneconomical to develop for power purposes alone, but be developed in connection with flood control and irrigation or navigation, the sale of power alone will not pay for the whole project. If, however, the cost be divided in proportion to the value of each feature, the whole matter may be considered intelligently.

Steam Versus Hydraulic Generation

The popular belief that electricity generated by means of water power is always cheaper than that generated in steam plants, is a fallacy. The reason is, of course, the tremendous capital cost of hydraulic works, the cost of storage water as an operating charge, and the long distances over which hydro-electric power usually has to be transmitted, involving high investment in transmission lines, and continuous loss of power. Except in special cases careful analysis must be made to find which is the more economical method of generation.

There are certain conditions under which the development of water power sites is obvious, as there are others under which there is no choice as there are no hydro-electric sites available. There are many cases in which only estimates of the construction and operating costs of the two schemes will reveal which is the cheaper. Given equal cost there are other factors to be taken into account, such as the possibility of increasing capacity, obsolescence, etc.

The various important factors governing the choice of plants are tabulated below. Each type has inherent advantages and disadvantages, and all must be given consideration.

Steam Plants

Advantages	*Disadvantages*
Usually lower cost of installation.	Rapid obsolescence due to improvements in science.
Ease of expansion.	Necessity of transporting large quantities of fuel.
Nearness to load centre.	Less reliability.
	Difficulty in obtaining sufficient condensing water.

Hydro-Electric Plants

Advantages	*Disadvantages*
No fuel charges.	High cost of hydraulic works.
Less rapid obsolescence.	Variable stream flow, usually at minimum when load is greatest.
Perpetual life of hydraulic works.	High cost of storage water.
Greater reliability.	Usual remote locations meaning costly transmission lines and power losses.
	If full capacity of site generated no possibility of increasing capacity.

Many power systems are composed of a number of interconnected power plants, some steam and some hydraulic. There are certain instances of steam and hydro plants being built alongside of one another. One such plant, Holtwood, is worthy of notice.

The Susquehanna river has a great range in flow, and in order to obtain the maximum advantage from the water available at the plants at Holtwood and Safe Harbor a steam station was built alongside the Holtwood station. Coal for the steam plant is dredged from the forebay of the hydro plant. The Susquehanna river flows through the Pennsylvania anthracite deposits and brings down particles of coal which it deposits in the lower reaches of the river. It is estimated that there are over ten million tons of coal deposited in the bed of the river over a distance of eight miles. The steam plant is designed to burn this fuel. In this particular case it was convenient to have the plants together. Nearness to a supply of coal is not always a governing factor in the location of a steam plant. Although it seems almost unbelievable, it has been repeatedly shown that it is cheaper to transport energy in the form of fuel than to transmit the electrical energy that would be generated from the fuel, particularly if a long haul is involved. For large steam stations the availability of an adequate supply of condensing water is frequently a governing factor.

A point that comes to the fore in considering the gigantic power projects being undertaken by various governments is that of obtaining the maximum advantage from the power available. None of the plants will operate at one hundred per cent firm power. That is, with a certain installed capacity only a certain percentage may be considered as being available at all times. Figures for some of these projects are given below.

Hoover Dam, Colorado river....	73	per cent firm power
St. Lawrence projects..........	50	" " " "
Kennett Dam, Sacramento river	15	" " " "

There are two ways of using the surplus power over these percentages—either by providing loads that may be carried only when the power is available, or by providing steam standby capacity to bring up the amount of firm power available.

Now the cost of power in a generating station can be divided into two parts—cost of readiness to give service, and actual cost of service. The former item consists of the capital invested and all fixed charges, and the latter the actual cost of operation, such as fuel, labour, etc. Considering a hydro-electric development with a steam standby to bring the firm power up to the full installed capacity of the hydro plant, the cost of any power over the firm power rating of the hydro plant would be as follows:

> Cost of power above firm power rating of plant equals cost of readiness to give hydro service plus hydro operating plus cost of readiness to give steam service plus steam operation.

Such an expression looks formidable enough but the relationship between the various amounts may be such that the total is less than for straight steam generation.

It must be borne in mind that the cost per horse power of hydro-electric developments is increasing and will continue to increase; whereas the cost of steam generation is decreasing and will probably continue to decrease for some time to come. This gives the steam station an increasing advantage over the hydro-electric station. Steam costs decrease due chiefly to increasing steam efficiencies and use of cheap fuel. An example of this is that in 1917 a plant which burnt 3.5 pounds of coal per kilowatt hour was considered efficient. The present average consumption of coal in the United States is 1.4 pound per kilowatt hour, with a number of plants burning less than a pound per kilowatt hour.

Hydro-electric costs are mounting due to remoteness of sites and corresponding high construction and transmission line costs, and large loss of power in transmission. This latter is being reduced, but slowly. Should developments be undertaken in populated country the cost of property and flooding rights is enormous.

Available and Possible Load

In any undertaking for the supply of electric power there are many factors to be considered. The two fundamentals are of course first, a demand for power, and second, an available source of supply. As some considerable time elapses between the first studies and the completion of the work it is first of all necessary to make a study of the available load and how rapidly it will increase, so as to know what the demand will be when the undertaking is completed, and also to see how long the capacity decided upon will last. It is obviously necessary to anticipate the load for several years.

Having determined what the load will be at various times in the future it is necessary to decide what capacity is to be installed. Just as it is wise to provide for a certain period in advance it is also foolish to build too far in advance. However, if a hydro-electric development is contemplated it may not be economical to build to a certain capacity determined by the load owing to the necessity of building works at one time sufficient for the full capacity of the site. In such cases the turbines and electrical equipment necessary to produce power over and above the initial installation warranted by the available load cost a relatively small part of the total job. Consequently if the load can be increased the unit cost of energy will go down. There are three types of load that can be built up. These are—

(*a*) Firm power, that is power sold at a certain rate which the customer may use whenever he wishes, and which is always available;

(*b*) Off-peak power, that is power sold at a lower rate but which may only be used at certain hours of the day, to fill in between the peak loads and keep up the load factor of the plant.

(*c*) Dump power, which is sold at very low rates, usually in large blocks, and which may be curtailed at any time that the power company wishes. This is surplus power sold to various industries for process work at a rate low enough to compete with their existing means of supply, and yet at a rate sufficient to cover the investment charges on the development. This power can be cut off due to shortage of water or due to equipment being out of service, or when the firm power load builds up sufficiently so that the power may be put to work more profitably. In addition to helping to carry the charges during the time that the firm power load is being built up this sort of load is of great help during bad times when the firm power load falls off appreciably.

New Uses for Electric Energy

Contrary to the general impression, electric power is a commodity for which a market must be found. Potential buyers must be convinced that it is of use to them, and they must be persuaded to buy it. Of course, a certain amount of energy is sold as a matter of course for lighting and sundry purposes, but in order to sell power at a low rate, and at the same time operate at a profit a company must have a fairly concentrated load, and, according to the size of the company, a heavy load. In order to obtain load the public must be educated to the use of electricity, and at the same time devices must be produced that will consume current and be attractive to the consumer. The author will not attempt to enumerate the many new applications, but one such type of equipment, the electric steam generator, which has undergone considerable development in Canada is worthy of mention.

One of the great industries in eastern Canada is the manufacture of newsprint paper. It is an industry peculiarly adapted to the country as two principal requirements are wood and power. The mills are frequently built on rivers, many of which supply sufficient hydro-electric power to operate the mills. Often the wood is cut in the basin of the same river and floated or "driven" down to the mill. The power is used principally in grinding the wood to a pulp, and to drive the machinery in the mill. The usual rule-of-thumb method of calculation allows 50 to 75 horse power per ton of paper per day; that is, a mill producing 200 tons of newsprint a day would use about ten to fifteen thousand horse power. In addition to power a great deal of steam is required for use in various processes and in drying the paper.

The difficulty of finding something to do with the idle capacity in newly-built hydro-electric plants, where there is a large investment not earning anything, has been largely overcome by the installation of electric steam generators which take surplus power at rates which will supply steam at slightly less than by coal, but which may be cut off at short notice. The application of these electric boilers has not been limited to paper mills, but they are installed in a variety of places where a considerable quantity of steam is required.

This type of load is satisfactory because in addition to paying the carrying charges on the investment in hydraulic plant it can be dropped when a more profitable market appears, and from an operating point of view it is good because it is a purely resistance load.

The extent to which this boiler load has been built up in ten years is shown in the following table of the output of Canadian electric stations:

Year	1924	1933
Total output kw.h	8,135,604,000	17,553,001,000
Output less exports and boiler consumption	6,572,798,000	12,955,237,000
Exports	1,302,317,000	989,364,000
Boiler consumption	260,489,000	3,608,400,000

The domestic firm power consumption has doubled, the exported power has diminished, and the boiler power consumption has increased from an almost negligible quantity to over twenty per cent of the total consumption. This result has been obtained by active development and salesmanship by the power companies concerned.

The question as to the practicability of domestic heating by means of electricity has been given attention. As far as the direct use of electricity by space heaters, or by conversion into steam or hot water is concerned it seems unlikely that much will be done in cold climates, except in a few places where power is exceptionally cheap. However in more temperate climates there may be distinct advantages. It is possible that the so-called "heat pump" or reversed refrigeration may be made at a sufficiently low price to make it adaptable to residential heating. In temperate climates where the winter temperatures are not extremely low and the summer temperature is high a combined heating and cooling plant would be of great use. At the present stage of development these heat pumps can supply heat at about one-half the cost of direct electrical heating, and at about twice the cost of heating by use of various fuels, but of course the cost of the equipment is high.

Location of Power Sites

In order to get the maximum benefit from the available head in any river it is often necessary to survey a long section of the stream under consideration, and possibly choose a number of sites with a view to successive development with ultimate use of the total available head. Just picking out a suitable fall and developing it has been done in many cases with the result that the maximum power has not been developed. However the location of a power development does not depend entirely upon the profile of the river and the topography of the surrounding country, but a number of other factors must be considered. An interesting example of what can be done by thorough investigation of a long stretch of river has been described in a paper by C. R. Lindsey, M.E.I.C.*

The St. Maurice river has a drainage basin of approximately 16,000 square miles in area, and over a distance of 188 miles has a fall of 1,138 feet. Of this total drop 636 feet is comprised in ten distinct falls, and the balance is accounted for by various rapids. In the lower reaches of the river four plants had been installed up to 1928, using 380 feet of head. The Shawinigan Water and Power Company controlled 285 feet of this head with an installed capacity of 674,000 h.p. In 1928 the company was granted rights on the upper reaches of the river over a distance of 89 miles, and comprising a total fall of 630 feet. Of this total fall only 150 feet was concentrated in two major falls. The problem was to use as much of this available head as possible in the most economical manner. The scheme finally adopted made use of a total of 623 feet head in six plants, with a total installed capacity of 1,208,000 h.p. With the completion of these plants the water will be used ten times in its course down the river, and a total of 1,003 feet of the theoretical available head of 1,138 feet will be utilized. Apart from using all the available head, the arrangement of having the tailwater of one plant discharge directly into the forebay of the plant below drowns out rapids where in cold weather frazil ice forms. This is an important operating advantage.

The preliminary work for this proposed hydro-electric development necessitated surveys for possible hydro-electric developments at nineteen locations, comprising thirty-nine possible heads, and data relative to such parts of railway location, timber limits, and depots, Indian reservations and fish and game clubs as would eventually come within the flooded areas. In the study of this information fifty-one various schemes were given consideration and comparative estimates made, and as a result, plans for six developments were submitted to the government and given approval.

*"Considerations Governing the Location of Hydro-Electric Power Developments on the Upper St. Lawrence River." The Engineering Journal, July 1933, p. 293.

Water Supply

In the preceding discussion it has been assumed that the river under development has a regular and sufficient flow of water. Such cases are extremely rare, however, and the rivers of eastern Canada, with the exception of the St. Lawrence, have extremely variable flow. Many of the rivers in the province of Quebec have a flood over a hundred times that of the minimum flow. Usually the minimum flow will only supply a small proportion of the normal output of the plant, consequently it is desirable to find some means of increasing the natural minimum flow.

The amount of power which may be generated at any given site depends directly upon the head, and the amount of water available. On most streams or sections of streams that are in populated country river flow and precipation records are available, but when more remote sites are contemplated often the information obtainable is slight.

In considering the flow of any stream there are two things to consider, first, the natural flow, and secondly the possibilities for regulation of flow. The first is obtained either from existing hydrographic records, extending preferably over a long period of years, or from observations taken during the preliminary investigation. Where accurate information over a long period is available for one part of a river, readings taken in another section over a short period can be fairly safely co-ordinated. The natural flow of a stream depends chiefly upon the area of the drainage basin, the precipitation, the geological structure of the ground, natural storage in the form of lakes, and the degree of afforestation. This last has a very pronounced effect, as a sparsely-wooded watershed with a large area of lakes has, other things being equal, a much more regular flow than one that has no lakes.

The St. Lawrence river is an extremely well-regulated stream, as the maximum flow is only about double the minimum. This is accounted for by the fact that the Great Lakes act as shock absorbers and store excessive floods and later give up this water to the lower river. The Great Lakes system forms the greatest natural reservoir in the world. To regulate smaller streams it is necessary to form artificial reservoirs which are allowed to fill during times of flood and from which the impounded water is released when necessary.

By artificial regulation much can sometimes be done to improve the flow of streams, in particular with regard to minimum flow conditions. There are many rivers which have their sources in systems of lakes some of which are suitable for damming for storage of flood water. However it takes a great deal of stored water to make much difference to the flow of a stream. A flow of 1,000 second feet for a period of four months, would require a reservoir twenty-five square miles in area and fifteen feet deep. The ideal place at which to store water is at the place at which it is to be used. If there be sufficient capacity the maximum advantage is then obtained, because advantage is taken of the whole drainage area tributary to the river at the site of the development. This is the condition at the Boulder Dam where two years flow of the river can be impounded, but this cannot always be achieved. Apart from topographical conditions at power sites frequently the cost of flooding rights would be so high as to be prohibitive. Usually the storage has to be done far up the rivers.

Much important work has been done in this way by the Quebec Streams Commission and the power companies. Considering the St. Maurice river watershed again, a reservoir of nearly four million acre feet capacity has been formed by the building of the Gouin Dam, and another large storage basin behind the dam at Toro Rapids. The result has been that plants that would otherwise have had a very limited output during low water are able to deliver all the power required. The actual minimum unregulated flow of the St. Maurice river is in the neighbourhood of 6,000 c.f.s. and the flow can now be regulated to a minimum of 18,000 c.f.s.

The results achieved in many cases are little short of marvellous. It is claimed that at the Gatineau river plants of Paugan Falls, Chelsea, and Farmers Rapids, for several years no water has gone down the river except that which has actually gone through the turbines. However storage water costs money. If the storage works are built by the Quebec Streams Commission the cost of the works is paid in the form of an annual rental, if they are built by the power companies it comes to much the same thing as there is the interest and depreciation to look after as well as the actual operating costs. The existence of large storage possibilities near the head waters of a river may however justify a large expense in making use of these possibilities because the maximum amount of use may be obtained from the water impounded, as it can be used over and over again on its way down the river.

Geological Considerations

In conjunction with other considerations governing the location of a dam comes the important matter of foundations. Without an investigation of the geological features of a river serious errors might enter into the calculations.

As stated by R. F. Legget, A.M.E.I.C., in a recent paper*:

"It is perhaps not generally appreciated that the erection of a dam to retain water causes more interference with natural conditions than does any other civil engineering operation."

"There are three geological problems to be investigated in connection with the design of all dams, namely, the ability of the foundation bed to support the superimposed load proposed, the resistance that the foundation bed will offer to the increased hydrostatic pressure, and the possible effects of the creation of underground hydraulic gradients at the ends of the dam. A fourth problem has to be faced in all cases where earth movement has occurred at any section of the area to be covered by the dam, in determining how far the effects of this extend in the adjacent rock, and in assisting in the selection of the necessary protective features in the design."

In the preliminary work on the Upper St. Maurice river a study was made of the geology of the country, and when suitable dam sites were found an electrical prospecting method was used to determine the depth of bed rock.

In the location of the present Boulder Dam the geology of the canyon had a decided bearing, and it was partly due to the nature of the rock that the dam was built in its present location.

Apart from the dam site and its surroundings, knowledge of the geological features of the area to be flooded is most important. Owing to the presence of pervious formations the leakage from a reservoir formed by damming a stream might be so great as to materially lessen its usefulness.

Construction Organization

Behind all large undertakings there must necessarily be an efficient construction force. Good organization and management of the construction force means speed, economy and dependability of construction, and is therefore an important factor in the success of any enterprise.

The construction organization on a large hydro-electric power development is much like an army in the field, about the only difference being that nowadays living conditions must be better. First of all the force must be housed and fed, after that work must be organized so that there is a minimum of wasted effort. Possibly the most important part of a construction force like an army, is its line of communications. There must be an unfailing supply of rations, and ammunition in the form of materials of construction.

This business of moving in materials is probably the greatest problem in many cases. Sometimes a spur railway line may be run in to the site, but frequently the expense is too great in comparison with the total cost of the job, due to the remoteness of the site, so other means must be resorted to.

In the more remote parts of the provinces of Ontario and Quebec often the simplest way is to bring the material in in winter over snow roads. As in some parts of the country there is a great deal of muskeg, material can often be brought in comparatively easily in winter when everything is frozen solid, whereas in summer it would be impossible without the construction of solid roads. The transformers for the Matachewan substation in Northern Ontario were brought in in winter. Their full weight was twenty-six tons each, but this was reduced to fifteen tons by replacing the oil with nitrogen. Even fifteen tons is a fair weight when it has to be hauled over twenty-six miles of snow roads. Most of the material for the transmission line from Lake St. John to Quebec was taken in in winter, as at the time of construction the present road through the Laurentide Park was nothing but a trail.

For larger jobs more permanent arrangements must be made. For the Rapide Blanc development a road ten miles long was built from the Transcontinental Railway. The road itself was unusual. It was built to a width of twenty-two feet, of which ten feet was concrete and twelve feet gravel. Loaded vehicles kept to the concrete strip. Everything for the construction of the plant with the exception of crushed stone and gravel had to be hauled over that road, the whole amounting to about one hundred thousand tons. During the winter the road was kept open to automobile traffic. The heaviest pieces brought in over this road were the transformers. The normal weight of the transformers was 188 tons each, but this was reduced for shipping purposes to 107 tons by replacing the oil with gas.

Conclusion

The author has endeavoured in this paper to give some idea of the problems to be encountered when any hydro-electric power development is under consideration. The science of hydro-electric power engineering has made great advances in recent years, but the difficulties to be surmounted become greater all the time. The engineering profession has also increased its knowledge and it is hard to conceive of any problem that will remain unsolved for long.

VOLUME XVIII NOVEMBER 1935 No. 11

Modern Welding Methods

The rapid development of electric arc and other fusion welding processes during the last few years has given rise to many interesting technical problems, while the employment of these methods is having a profound influence on many branches of engineering work. The application of the welding art, however, tended at first to run ahead of the advances in theory and research, so that in some cases processes have been used without proper knowledge of their limitations and the underlying principles involved in their employment. This condition, though it existed to a limited extent in the earlier stages, has been and is being corrected, and success is being reached by methods based on increased knowledge of the metallurgy of the materials employed and systematic investigation of their properties and micro-structure. At the same time it has been necessary to work out the radical changes in design which the employment of welding has required in many structures and machines, and which must be based on a working knowledge of the possibilities of the processes employed. The development has further involved the training of a new type of craftsman, the welder, whose skill, while certainly not less than that of the old-time blacksmith, is of quite a different kind. The welder now has to meet the exacting requirements and tests of modern construction. His work must be carried out under rigid supervision, and his manual skill must be of a high order if the results are to be reliable.

It is now realized that in a fusion weld conditions arise which do not occur in any other form of joint. For example, both in the design and assembly of welded work, consideration must be given to the avoidance of distortion, and the relief of any internal stresses that may remain when the welds are finished. Comparatively small variations in the operator's technique may result in quite serious differences in the quality of his joints. The control of the welding current in arc welding depends on his dexterity, as well as on the suitability of the electrical equipment. If good work is expected of an operator he must be properly protected against burns; his comfort must be considered, and he must have the best type of welding screen, since he has to see clearly what is happening in a welding zone whose area is perhaps not more than one-tenth of a square inch. Success in the application of modern arc welding methods involves many other factors, such as a knowledge of how the metallic arc behaves; the reactions occurring between the arc, the parent material, the electrode and its covering; the manner in which the electrode metal is deposited, and the effect of all these on the mechanical strength of the resulting weld. In this connection it has been necessary to call in the physicist and the metallurgist. Without the information obtained by their detailed studies of the metallic arc, and their investigations of the micro-structure of weld metal and the parent material, welders would still be working largely in the dark, and welding methods could never have reached their present stage of reliability. They are now being used successfully for bridges and structural frames and for pressure vessels carrying very high pressures and temperatures. Confidence in their use has been gained through exhaustive tests and by X-ray and electro-magnetic examination of the interior of finished welds.

Thus the sphere of usefulness of modern welding is continually being extended, and an appreciation of its capabilities has become essential for engineers of all branches of the profession. The paper on "Modern Arc Welding," which is printed elsewhere in this issue of The Journal, will therefore be welcomed, for it presents a general view of the present state of the art, and embodies much of the experience of an engineer who has himself been actively concerned in many of the developments of which he writes.

His observations cover the essential considerations which must govern the engineer in selecting the most suitable process and equipment for any given piece of work; the precautions which must be adopted to ensure rapidity and reliability in execution, and the special ways in which welded work must be designed and treated to avoid trouble from residual stress. Warnings are given as to certain pitfalls which await the unwary engineer who is not familiar with the limitations imposed by the nature of the welding process. Many of Mr. Boyd's remarks, while referring specifically to arc welding work, are applicable to welds executed by other methods, as for example, his recommendations regarding the measures to be taken for the relief of stress, the systematic training of welders as craftsmen, and the need for constant supervision and inspection.

The hesitation shown by many structural and mechanical engineers in adopting welded joints and connections is apparently not so much due to lack of faith in the welding process as now carried out, as to a desire to have available records of long experience as to the behaviour of welded structures and machine parts or pressure vessels in actual service. When this experience has been gained—and it is rapidly accumulating—we may look forward to a much wider and more rapid development of welding as a basic engineering method.

Mr. Boyd's article is based on the addresses which he has delivered before a number of the branches of The Institute, and in conjunction with other papers which have already been published in our columns or which will follow, cannot fail to be of interest to a wide circle of our members.

The Third World Power Conference 1936

Invitations on behalf of the President of the United States were issued on September 24th, 1935, by the State Department to the nations of the world to participate in and send delegates to the Third World Power Conference to be held in Washington from September 7th to 12th, 1936, and to the Second Congress of the International Commission on Large Dams to be held concurrently therewith.

The World Power Conference was organized in 1923 for the purpose of serving as a medium for the interchange of data and experience on power resources, their development and use, and for the discussion of the technical, economic and social problems associated therewith.

The proposed subject recommended for consideration at the Third World Power Conference is "The National Power Economy: Physical and Statistical Bases; Technical, Economic and Social Trends; Organization of Fuel Industries and of Gas and Electric Utilities; Public Regulation; National and Regional Planning; Conservation of Fuel and Water Resources; Rationalization of Distribution; National Power and Fuel Policies."

Plenary meetings of the World Power Conference are held every six years. The first was held in London in 1924 and the second in Berlin in 1930. It is the third of these meetings which is scheduled to be held in Washington in 1936.

Sectional meetings within limited geographic areas are held between the larger general meetings. One such sectional meeting was held in Basle in 1926, another in London in 1928, a third in Barcelona and a fourth in Tokyo in 1929. The most recent of the sectional meetings was that held in Stockholm in 1933 under the joint auspices of Sweden, Norway, Denmark and Finland.

In addition to the general and sectional meetings and the publication of their transactions, the World Power Conference, through national committees designated for that purpose and through special committees, engages in certain activities, including the adoption of a system of forms for reporting the statistics of power resources—annual production, consumption, import and export.

The Secretary of the Canadian National Committee of the World Power Conference is Mr. N. Marr, M.E.I.C., Dominion Water Power and Hydrometric Bureau, Department of the Interior, Ottawa.

Highways and Motor Vehicles in Canada

An interesting report, mainly statistical in character, entitled "The Highway and the Motor Vehicle in Canada 1934," has been received from the Transportation and Public Utilities Branch of the Dominion Bureau of Statistics. In that year there were 93,000 miles of surfaced roads in Canada, over half of which were in Ontario, the total mileage of rural roads being over 400,000. Some ninety per cent of the surfaced mileage was gravelled. The expenditure on construction during the year amounted to more than forty-six million dollars, and nearly twenty million dollars were expended in maintenance. Some 10,000 miles of highways were kept open during the winter at a cost of about half a million dollars. The various provincial highway debts totalled four hundred and sixty-two million dollars.

The registration of motor vehicles is given by years, and showed a continuous and rapid growth up to 1931, when the first decline was recorded, an upward turn occurring in 1934. The total registration, now over a million, gives an average number of persons per vehicle of 9.6 as compared with 4.9 persons per vehicle in the United States. Particulars are given of the registrations by provinces and municipalities, there being some 542,000 vehicles in Ontario and 165,000 in Quebec. Montreal, although larger in population, has only 60,000 passenger cars as compared with 100,000 in Toronto.

As regards gasoline consumption, the gross sales of gasoline were over 530 million Imperial gallons, of which 479 millions were taxable, at a rate varying from 8 cents per Imperial gallon in the Maritime Provinces to 6 cents in Quebec and Ontario.

It is difficult to obtain comprehensive statistics as to motor vehicle accidents, but an attempt has been made to get comparative figures by tabulating the average number of deaths per 10,000 registered motor vehicles for the various years from 1926 onwards, this ratio showing a surprising range, from 3.28 in Saskatchewan to over 17 in the case of New Brunswick. The report notes, however, that these figures are of somewhat doubtful value, as they give no weight to differences in use of vehicles, climatic conditions, density of population, roads, character of cars, and other factors which affect the accident ratio.

Some interesting data follow as regards the entry of tourist automobiles, and the motor vehicle regulations of the various provinces are given, together with a summary of the various requirements as regards the licensing of public vehicles. The report will be found of value to everyone interested in motor traffic in Canada.

List of Nominees for Officers

The report of the Nominating Committee was presented to and accepted by Council at the meeting held on October 18th, 1935. The following is the list of nominees for officers as prepared by the Nominating Committee and published for the information of all corporate members as provided by Sections 68 and 74 of the By-laws.

List of Nominees for Officers for 1936 as Proposed by the Nominating Committee

President:	E. A. Cleveland, M.E.I.C.	Vancouver.
Vice-Presidents:		
Zone "B"	H. F. Bennett, M.E.I.C.	Sault Ste Marie.
	R. L. Dobbin, M.E.I.C.	Peterborough.
	F. W. Paulin, M.E.I.C.	Hamilton.
	C. M. Pitts, A.M.E.I.C.	Ottawa.
Zone "C"	A. B. Normandin, M.E.I.C.	Quebec.
Zone "D"	H. W. McKiel, M.E.I.C.	Sackville, N.B.
Councillors:		
‡*Cape Breton Branch*	Y. C. Barrington, A.M.E.I.C.	Sydney Mines, N.S.
‡*Moncton Branch*	T. H. Dickson, A.M.E.I.C.	Moncton.
‡*Quebec Branch*	H. Cimon, M.E.I.C.	Quebec.
††*Montreal Branch*	F. S. B. Heward, A.M.E.I.C.	Montreal.
	F. Newell, M.E.I.C.	Montreal.
‡*Ottawa Branch*	R. W. Boyle, M.E.I.C.	Ottawa.
	A. K. Hay, A.M.E.I.C.	Ottawa.
‡*Peterborough Branch*	A. B. Gates, A.M.E.I.C.	Peterborough.
	B. Ottewell, A.M.E.I.C.	Peterborough.
‡*Hamilton Branch*	E. P. Muntz, M.E.I.C.	Hamilton.
‡*Niagara Peninsula Branch*	W. R. Manock, A.M.E.I.C.	Fort Erie North.
	E. P. Murphy, A.M.E.I.C.	Port Colborne.
‡*Sault Ste Marie Branch*	F. Smallwood, M.E.I.C.	Sault Ste Marie.
‡*Winnipeg Branch*	T. C. Main, A.M.E.I.C.	Winnipeg.
‡*Lethbridge Branch*	G. S. Brown, A.M.E.I.C.	Lethbridge.
‡*Calgary Branch*	T. Lees, M.E.I.C.	Calgary.
	H. J. McLean, A.M.E.I.C.	Calgary.
‡*Victoria Branch*	H. L. Swan, M.E.I.C.	Victoria.

*One Vice-President to be elected for two years.
‡One Councillor to be elected for two years.
††Two Councillors to be elected for three years each.

Additional Nominations

Section 68 provides also that "Additional nominations for the list of nominees for officers signed by ten or more corporate members and accompanied by written acceptances of those nominated, if received by the Secretary on or before the first day of December, shall be accepted by the Council and shall be placed on the officers' ballot."

OBITUARIES

J. E. Noulan Cauchon, A.M.E.I.C.

Members of The Institute will learn with regret of the death at Ottawa, on October 28th, 1935, of J. E. Noulan Cauchon, A.M.E.I.C.

Born at Quebec, Que., on March 4th, 1872, Mr. Cauchon was educated at St. Boniface College, Manitoba, Point Levis College, Quebec, and privately.

Mr. Cauchon commenced his career with the Quebec and Lake St. John Railway at an early age, but remained

J. E. Noulan Cauchon, A.M.E.I.C.

only a few months before joining the staff of the Canadian Pacific Railway Company in Montreal. He stayed in the service of the Railway for more than twenty years, rising to the position of assistant to the chief construction engineer during the road's great expansion period. He ended this service in 1907 and spent the next two years as assistant engineer to the Board of Railway Commissioners. Mr. Cauchon then became actively interested in town planning, and subsequently devoted more than twenty-five years to that subject, becoming an internationally known authority.

As chairman of Ottawa's Town Planning Commission, Mr. Cauchon sought to make Ottawa a scientifically landscaped city of beauty and efficiency. He was an advocate of the hexagonal system of town planning and from the first realized that his science was not concerned merely with beautifying towns but also had sociological implications. In 1916 Mr. Cauchon went to Hamilton and evolved a scheme for a joint railway entrance and union station for the Grand Trunk and Canadian Pacific Railways. In 1917 he proposed an irrigation and cultivation scheme for Ontario from the Grand River to the Niagara, and offered it as the basis for soldier settlement schemes, self-contained garden cities and industrial decentralization; in the same year he undertook the valuation of the Canadian Northern Railway terminals across Canada.

In 1924 and 1925 Mr. Cauchon drew up zoning laws for Ottawa designed to be models for the Dominion. The next year he was appointed technical adviser to the Montreal Town Planning Commission, working with Professor P. E. Nobbs, of McGill University, and drafting a town-planning and zoning act for Quebec. During most of 1929 Mr. Cauchon was in Europe lecturing, returning there in 1931 as a delegate to the International Town Planning and Housing Congress in Berlin. In 1934 Mr. Cauchon served as an honorary technical adviser and expert witness before the Parliamentary Housing Committee.

Mr. Cauchon was a past-president of the Town Planning Institute of Canada and an honorary member of the Royal Architectural Institute of Canada. He was Canadian corresponding member on the general committee of the Town and Country Planning School of Welwyn, England.

He took an active interest in Institute affairs, and was chairman of the Ottawa Branch in 1927 and represented that Branch on Council in 1930 and 1931.

Mr. Cauchon joined The Institute (then the Canadian Society of Civil Engineers) as an Associate on April 14th, 1904, and became an Associate Member on April 17th, 1909.

George H. Davis, M.E.I.C.

It is with deep regret that the death of George H. Davis, M.E.I.C., at Toronto, Ontario, on September 6th, 1935, is placed on record.

Born at Toronto on February 28th, 1881, Mr. Davis' entire professional career was with the Canadian Pacific Railway Company. Joining the service in 1905, he was engaged on the preliminary and final location of the Georgian Bay and Seaboard Railway; and in 1906-1907 on the preliminary location of the Campbellville, Lake Ontario and Western Railway. From 1907 until 1909 Mr. Davis was occupied on the construction of the Georgian Bay and Seaboard Railway, including Port McNicoll terminal, docks and elevators, and later in 1909 became draughtsman for the division engineer of construction, at Toronto; in 1909-1910 he filled the same position with the district engineer of the Ontario district. In 1910-1912 Mr. Davis was in charge of construction of double track work, and later was assistant engineer of terminals at Toronto. In 1912 he was appointed division engineer, Toronto Terminals, Ontario District, and from 1913 until 1915 was assistant district engineer of Ontario District, being made division engineer, Toronto Terminals, on February 1st, 1915. In May, 1915, Mr. Davis became assistant district engineer, Quebec District, at Montreal which position he held until 1918 when he was appointed division engineer, Toronto Terminals. From August 1918 until 1920 Mr. Davis was assistant district engineer, Quebec District, at Montreal, and in 1924 he became assistant district engineer, Ontario District, at Toronto, which position he held until the time of his death.

Mr. Davis joined The Institute as a Member on March 25th, 1925.

PERSONALS

S. J. Hayes, Jr.E.I.C., has been appointed lecturer in engineering at the Memorial University College, St. John's, Newfoundland. Mr. Hayes was formerly located in Toronto, Ont.

J. W. Gathercole, Jr.E.I.C., has joined the staff of Price Brothers Limited at Kenogami, Que., as steam plant engineer. Mr. Gathercole was formerly with the Canada and Dominion Sugar Company Ltd., Montreal.

J. L. Pidoux, Jr.E.I.C., assistant highways engineer, Department of Public Works, Alta., Calgary, who graduated from the University of Alberta with the degree of B.Sc., in 1934, has been awarded the John Bonsall Porter Scholarship for 1935-1936. The scholarship is open to graduate students proceeding to the degree of Master of Engineering in civil engineering at McGill University.

D. L. McLean, A.M.E.I.C., was recently appointed assistant chief engineer of the Greater Winnipeg Sanitary District, in direct charge of the construction of $4,000,000 worth of intercepting sewers and a disposal plant. Mr. McLean graduated from McGill University in 1909 with the degree of B.Sc., and following graduation became assistant to J. B. McRae, M.E.I.C. consulting engineer, Ottawa, and later was assistant chief engineer for the International Commission. He was then appointed chief engineer in connection with the water power surveys of the Winnipeg rivers, being carried on by the Dominion Water Power Branch, Department of the Interior. Later Mr. McLean became chief engineer of the Manitoba Drainage Commission, and in 1922 he was appointed deputy minister of public works for the province of Manitoba. In 1929 he became Manitoba Power Commissioner. In 1932 Mr. McLean was appointed chairman of a Hydro-Electric Power Commission appointed by the Manitoba government, in addition to being general manager of the city of Winnipeg Hydro-Electric System. Mr. McLean has taken a prominent and active part in the affairs of the Winnipeg Branch of The Institute and represented it on the Council of The Institute in 1926 and 1927.

E. G. Cullwick, Jr.E.I.C., has returned to the University of British Columbia, Vancouver, as associate professor of electrical engineering. Mr. Cullwick graduated from Cambridge University in 1925 with the degree of B.A. in engineering, and following graduation was for a time connected with the Canadian General Electric Company Ltd. at Peterborough, Ont. He was then appointed assistant professor in electrical engineering at the University of British Columbia, and early this year resigned to join the professional staff of the Military College of Science, Woolwich, England, as lecturer in electrical engineering.

C. D. Howe, M.E.I.C., managing partner of C. D. Howe and Company, Port Arthur, Ont., who was elected to Parliament as Liberal member for Port Arthur in the elections held recently, has been appointed Minister of Railways and Canals and Minister of Marine.

Mr. Howe graduated from the Massachusetts Institute of Technology in 1907 with the degree of B.Sc., and was subsequently assistant in the structural engineering department of the same university. From 1908 until 1913 he was professor of civil engineering at Dalhousie University, Halifax, and also acted as a consulting engineer on important factory and warehouse structures. From 1913 until 1916 Mr. Howe was chief engineer of the Board of Grain Commissioners of Canada and was in charge of the design and construction of terminal grain elevators at Saskatoon,

The Hon. C. D. Howe, M.P., M.E.I.C.

Moose Jaw, Calgary and Vancouver. In 1916 Mr. Howe established the firm of C. D. Howe and Company, consulting engineers, at Port Arthur, Ont., and since that time has designed and superintended the construction of many large grain elevators. He also surveyed the grain handling situation in the Argentine for the government of that country. In the past few years Mr. Howe has travelled extensively, studying world trade, particularly factors affecting the grain business.

Burton M. Hill, M.E.I.C., was elected Member of Parliament for Charlotte county, New Brunswick, in the general election recently held.

Mr. Hill graduated from the University of New Brunswick with the degree of B.Sc. in 1907, and was

Burton M. Hill, M.P., M.E.I.C.

subsequently engaged in civil engineering work; ten years in railroad work in various capacities as resident engineer, divisional engineer and chief engineer on location and construction work. In 1917 he took over the organization of the permanent highway department for the province of New Brunswick, and occupied the position of chief highways engineer until 1925 when he was taken into the provincial cabinet of New Brunswick as minister of public works. In 1929 he was made one of the commissioners of the Saint John Harbour. Since 1931 Mr. Hill has been managing director of Consolidated Diversified Standard Securities, Montreal.

In connection with Mr. Hill's election it is interesting to note that his grandfather, the Hon. George S. Hill, was a member of the legislature of New Brunswick from 1830 to 1848, and a member of the Legislative Council from 1848 to 1858. His uncle, the Hon. George F. Hill, represented Charlotte county in the legislature of New Brunswick from 1865 to 1908, twenty-five years of which he was a member of the Legislative Council, and was president of this Council at the time of its dissolution.

Elections and Transfers

At the meeting of Council held on October 18th, 1935, the following elections and transfers were effected:

Associate Member

HUDSON, Arthur Magennis, equipment engr., Dept. of Northern Development, Toronto, Ont.

Junior

SANDWELL, Percy Ritchie, B.A.Sc., (Univ. of B.C.), dftsman., Paper Machy. Dept., Dominion Engineering Works Ltd., Montreal, Que.

Transferred from the class of Junior to that of Associate Member

BEAM, Donald Carleton, B.A.Sc., (Univ. of Toronto), struct'l. engrg., bldg. dept., City of Toronto, Ontario.

JACKSON, Charles H., B.A.Sc., (Univ. of Toronto), production mgr., ammunition divn., Canadian Industries Ltd., Brownsburg, Que.

MOORE, Alexander Glydon, B.Sc., (N.S. Tech. Coll.), asst. supervisor, underground elect'l. distribution, Montreal Light, Heat & Power Cons., Montreal, Que.

WILLIS, Reuben Wesley, B.Sc., (Queen's Univ.), designing engr. of bridges, dept. of works, City of Toronto, Ontario.

WRANGELL, Kjell Frederick, (Horten Tekniske Skole), mech'l. engr., The E. B. Eddy Co. Ltd., Hull, Que.

Transferred from the class of Student to that of Associate Member

LEGG, John Herbert, B.Sc., (McGill Univ.), mill supt., Aldermac Mines Ltd., Niagara Falls, N.Y.
MOFFAT, Thomas Stuart, B.Sc., (McGill Univ.), supt., Provincial Wood Products Co., Saint John, N.B.
NICOLAISEN, Juncker Zelo, B.Sc., (Univ. of Durham), Villa Egemaes, Espergaerde, Denmark.
PEEBLES, Archibald, B.A.Sc., (Univ. of B.C.), instructor, dept. of civil engrg., University of British Columbia, Vancouver, B.C.
RHODES, Donald, B.Sc., (McGill Univ.), district engr., Bell Telephone Company of Canada, Sherbrooke, Que.
ROSS, William Bruce, B.Sc., M.Sc., Ph.D., (McGill Univ.), lecturer in mathematics, McGill University, Montreal, Que.
SHEARWOOD, Alexander Perry, B.Eng., (McGill Univ.), asst. engr., National Steel Car Corpn., Montreal, Que.

Transferred from the class of Student to that of Junior

ELLIOTT, Lisgar Webster, B.Sc., (Univ. of Alta.), engr., receiver development dept., Canadian Marconi Co., Montreal, Que.
McKAY, Robert Donald, B.Sc., (N.S. Tech. Coll.), Graduate School of Engineering, Harvard University, Cambridge, Mass.
SKELTON, Cecil Hastings, B.Sc., (McGill Univ.), research engr., Consolidated Paper Corpn., Three Rivers, Que.
THOMPSON, Frank Lawrence, B.Sc., (N.S. Tech. Coll.), tech. service engr., Imperial Oil Ltd., Dartmouth, N.S.
TREMAIN, Kenneth Hadley, (Grad. R.M.C.), B.Sc. (McGill Univ.), asst. sales mgr., The Elias Rogers Co. Ltd., Toronto, Ont.

Students admitted

BLOOM, David, B.Eng., (McGill Univ.), 660 Querbes Ave., Outremont, Que.
FRIGON, Rosario, B.A., (Ecole Polytechnique, Montreal), 169 Sherbrooke, St. East, Montreal, Que.

RECENT ADDITIONS TO THE LIBRARY

Proceedings, Transactions, etc.

Institution of Naval Architects: Transactions 1935.
Society for the Promotion of Engineering Education: Proceedings of 42nd Annual Meeting.
Highway Research Board, National Research Council: Proceedings of 14th Annual Meeting, 1934.

Technical Books, etc. Received

Industrial Electronics, by F. H. Gulliksen and E. H. Vedder. (*John Wiley and Sons, New York.*)
Elements of Machine Design, by D. S. Kimball and J. H. Barr. (*John Wiley and Sons, New York.*)
Materials of Testing, J. H. Cowdrey and R. G. Adams. (*John Wiley and Sons.*)

BULLETINS

Gear Motors—A 16-page bulletin has been received from the Dominion Engineering Company Ltd., Lachine, Que., describing and illustrating the line of gear motors manufactured by that company. These are available in ratings from ½ h.p. to 40 h.p. at ratios giving output speeds from 5,000 r.p.m. down to 10 r.p.m. These are drive units in which enclosed gearing and an electric motor are so arranged that for purposes of installation the assembly may be considered as a single piece of equipment. Tables indicating correct sizes of units for given horse powers and ratios are included.

Flashers and Controls—An 8-page booklet issued by Betts and Betts Corp., New York, N.Y., gives particulars of their high speed type flashers and controls designed to operate neon tube and bulb signs.

Tube Fabricating Equipment—The Parker Appliance Company, Cleveland, Ohio, have issued a 24-page bulletin describing the equipment used in the fabrication of tubes.

Bearings—A 110-page completely indexed catalogue has been received from Ransome and Marles Bearings Canada Limited, Montreal, which includes types and sizes of bearings not listed in the older editions. Engineering data is furnished on ball journals, double purpose bearings, motor cycle bearings, roller journals, thrust bearings, mounting, housings, lubrication and tolerances for shafts and housings. Prices are given. Copies furnished on request.

BOOK REVIEWS

Elementary Structural Problems in Steel and Timber

By Professor C. R. Young, M.E.I.C. John Wiley and Sons Inc., New York, 1935. 6 by 9¼ inches, 315 pages, diagrams. $4.00. Cloth.

Reviewed by P. L. Pratley, M.E.I.C.*

The present reviewer finds it practically impossible to describe with the aid of one adjective the impressions raised by a perusal of the compilation made by Professor Young under the above title. To the engineer continuously engaged in the solving of such problems, the book may almost be classed as fascinating, and it was with difficulty that the reviewer refrained from attacking all the exercise problems given at the end of each section.

To the young graduate engineer interested in his profession and starting out in a designing office the book should surely be useful, while to the student still in college it should serve as a most valuable link between theory and practice and also as a stimulant encouraging the reader to master the fundamental principles by means of which the various problems are solved.

There is, perhaps, a certain latent danger in suggesting to such a student that all problems can be solved as simply and as straightforwardly as those in the book, and by the application of standard formulæ. It is manifestly impossible to combine with such a selection of practical problems the theory upon which the solution is founded, and references are accordingly given in the book, at certain places, to standard texts where the interested student may find the demonstration or derivation upon which the quoted formulæ are built. Nevertheless, it is, in the reviewer's opinion, somewhat risky to include without explanation such formulæ as number 23, article 72, page 75, as the necessity and effect of such a correction factor are not readily appreciated. The present reviewer, in his own career, has never before seen such a factor and is rather inclined to regret its introduction.

Generally speaking, the problems are very plainly stated and the solutions very clearly demonstrated, and insofar as the word "elementary" enters into the title of the book, the number and nature of the problems would appear to be very wisely selected. Naturally, there are features where a legitimate difference of opinion may arise as to the validity of assumptions and even as to the resulting detail, but these are very few considering the scope of the work. In problem 94, for example, the references to the initial stress in the tie-rod might well be disputed, and the same question arises in problem 186. In problem 122, the author works out the moment of inertia of a plate girder by two methods and finds a resulting divergence of 19.4 per cent. Although his closing paragraph refers in a casual manner to the shape of his plate girder, it would have appeared more logical to have made a similar comparison for the more usual type where the divergency is nothing like 19.4 per cent. This comparison might have been effected in the succeeding problem, 123, where in spite of the assertion made toward the end of problem 122, the so-called approximate method is used. On page 176, the detail of the roof truss at panel point U1 is decidedly at variance with good shop practice and even at U5 a top cover plate would normally be used instead of the eight rivets on the 4-inch leg.

The odd misprint will persist in appearing in such technical script, but very few came to the reviewer's notice while reading this work. That on page 71 in the third line where the "multiplication" sign is used for the "equals" sign might be a little troublesome to the less experienced reader. On page 91, in figure 52, it would be to some advantage if the dimensions from the neutral axis to the back of the angles and to the toes, namely: 1.14 inch and 2.36 inch, were incorporated in the figure.

As is undoubtedly the author's intention, the book will find its greatest field in the hand of the young engineer just beginning to apply his theory to practice; but the reviewer feels that a good many ex-graduates might do worse than tackle some of the exercise problems as a means of keeping themselves in touch with the principles which have a universal application but which are sometimes violated by those who should know better. In this manner, Professor Young's book might perform a very useful service in the maintenance field by preserving the engineer's acquaintance with the fundamental theories upon which his formulæ are based. In the reviewer's opinion the acquaintance with the principles is of much more importance than the memorizing of formulæ or extracting them from a textbook, and one of the best methods to maintain an appreciation of the principles is to apply them to such problems as Professor Young outlines.

*Monsarrat and Pratley, Consulting Engineers, Montreal.

Practical Designing in Reinforced Concrete Part III

By M. T. Cantell. E. and F. N. Spon, Limited, London. 1935. 5½ by 8¾ inches, 221 pages, photos, diagrams, tables. 12/6. Cloth.

Reviewed by J. F. Brett, A.M.E.I.C.*

The book begins with an elementary chapter on tall chimneys, seven pages being devoted to this subject. Then follows a six-page chapter on dams, where the author gives some historical data and briefly discusses the principal features of gravity and Ambursen dams without attempting to go into design.

Beam bridges is the title of the next chapter, and here the author elaborates a little more, the data given being still elementary. There is a worked-out example of a 30-foot bridge. On page 20 it is stated that bridge sidewalks are generally designed for a live load of 150 pounds per square foot, an erroneous assumption.

Over one hundred pages are devoted to the treatment of arches and arch bridges. The graphic and elastic methods are both given and elaborated by worked-out examples: the data given here are in general sufficiently thorough to be of value in designing. The reviewer, however, wishes to draw attention to page 28, where it is stated that "the centre line of arch is called the neutral axis or neutral surface curve" and would emphasize that the arch axis is not the neutral axis in a reinforced concrete arch.

In the chapter dealing with temperature shortening and moisture stresses in arches, page 43, the now well-known phenomena of time flow should have been described in connection with shrinkage and other volume charges, since the influence of the former is perhaps the most important.

There is a chapter on hinged arches, where some forms of hinges and temporary hinges are mentioned, but no design data are given.

The author then touches on skew arched bridges, devoting less than five printed lines to the subject. Besides the mere statement that they are designed in the same way and by the same formulæ as square arched spans, the reviewer feels that the reader's attention should have been drawn to the important stresses caused by the condition of skew, neglect of which has been the cause of many failures.

Arch abutments, unsymmetrical arches, arched conduits and box culverts are then discussed, sufficient data being given in these chapters for designing the simpler cases.

Influence lines for fixed arches are next dealt with in a separate chapter. The method here used is based on the general method of analysis by the elastic theory as developed by Turneaure and Maurer which the author explains when dealing with concentrated loads. A short treatment of the arched conduit and the box culvert follows.

The author then passes on to what he calls "rigid structures" including under this item continuous beams and rigid frames. Some thirty-four pages are devoted to the subject, several worked-out examples being given. The methods of analysis employed are the elastic theory and the moment distribution method of Professor Hardy Cross. The data here presented may serve as a good introduction to the study of monolithic structures.

There is a chapter on concrete dome design well worth reading, and another one, the last, on earthquake resisting structures, which includes valuable data from direct observation and a rational method of design. Basic formulæ pertaining to arches are given in the appendix, some eleven pages being devoted to these.

It is certainly no easy task to attempt to cover the structural features of so many different types of structures within the compass of a demy 8vo book of some two hundred pages. This explains the rather short treatment of some of them. Many of the chapters, however, contain a great deal of valuable practical information and in any case the volume will serve as a useful introduction to the subject.

The reproduction of a number of working drawings showing the general arrangement of reinforcing steel would add to the value of the book.

Division Engineer, Montreal Water Board, Montreal.

The Story of the Tunnelling Companies R.E.

by Captain W. G. Grieve

The investigation carried out during the past three years of the activities of the Tunnelling Companies during the War has now been completed.

This story will be published in the next few months and the Committee of the Tunnellers' Old Comrades Association wish to draw the attention of mining engineers to this unique publication, entirely connected with the work during the War of members of their own profession.

Copies may be reserved on the understanding that the cost will not exceed one guinea per copy, by writing to the Hon. Secretary, T.O.C. Association, c/o The Institution of Mining and Metallurgy, Salisbury House, Finsbury Circus, London, E.C.2.

Province of Quebec Association of Architects

A booklet containing its Charter, By-laws and Code of Ethics has been issued by the Province of Quebec Association of Architects. The publication is of interest to Institute members at this time, since the President of the Association, Mr. Gordon McL. Pitts, A.M.E.I.C., under whose auspices it was prepared, is also chairman of The Institute Committee on Consolidation.

It gives the text of the Architects' Act, incorporating the Association, with the most recent amendments, together with the By-laws of the Association, which regulate such matters as the requirements for membership; the professional examinations; the duties of officers, Council and committees; the relations of the Association with The Royal Architectural Institute of Canada and the fees payable to the Association. The regulations governing professional practice and discipline and proceedings at meetings are followed by the Association's Code of Ethics as adopted in 1935.

Requests for copies may be addressed to The Honorary Secretary of the Association, 627 Dorchester Street West, Montreal.

List of New and Revised British Standard Specifications

(Issued during July and August, 1935)

B.S.S. No.

617—1935. *Identification of Pipes, Conduits, Ducts and Cables in Buildings.*
Intended to be applicable to buildings other than those used for industrial processes but the provisions of the specification can be taken as a basis by factories or industries adopting schemes of identification. Represents general practice, and consists of a distinguishing colour and a specially shaped identification plate for each service.

618—1935. *Emulsions of Road Tar and of Road Tar-Asphaltic Bitumen Mixtures for Penetration (Grouting and Semi-Grouting) and Surface Dressing.*
Specification for a cold road dressing, incorporating tar. Appendices give methods of sampling and testing of the emulsion.

620—1935. *The Dimensions of Grinding Wheels and Method of Attachment.*
Dimensions of the most generally used shapes and sizes of grinding wheels, and of the flanges and washer plates to be used with the standard method of attachment. The tolerances and fits of the spindle in the wheels are specified, together with the quality of the material from which the spindle and flanges are to be made.

621—1935. *Wire Ropes of Special Construction for Engineering Purposes, inclusive of Cranes, Lifts and Excavators.*
Providing for Seale construction, oval and flattened strand and multiple strand wire ropes from 1½″ to 6″ circumference for special engineering purposes including cranes, lifts and excavators.

622—1935. *Cyanide (Classes A and B) suitable for Electro-plating.*
The adoption of this specification when ordering cyanide for electro-plating will remove to a large extent the risk of damage to electro-plating baths, and the consequent loss to the plater.

623—1935. *Colours for Signal Glasses for Railway Purposes.*
(Issued 2-9-35) Covers the colorimetric and photometric properties of the glasses and methods of measurement of colour and transmittance.

Copies of the new specifications may be obtained from the Publications Department, British Standards Institution, 28 Victoria Street, London, S.W.1, and from the Canadian Engineering Standards Association, 79 Sussex Street, Ottawa, Ont.

The Chemistry of Cement and Concrete

The Chemistry of Cement and Concrete, by F. M. Lea and C. H. Desch, published by Edward Arnold and Company, London, and costing $7.50 in Canada, gives a general survey of the Chemistry of cement and concrete, interpreting the title in a broad sense. The constitution of cements, the nature and properties of the compounds they contain, the properties of set cements and of the hydrated compounds present in them are fully described. The importance of cementing materials other than Portland Cement is now so great that considerable space is devoted to a description of Portland blast-furnace and other slag cements, aluminous cement and pozzolanas.

The testing of cement is only discussed in general outline, as this subject has been dealt with fully in various other works. For the same reason no mention is made of the methods of operating a cement plant, the general principles of concrete mixing, nor of the machinery employed.

The nature of various concrete aggregates, and any special properties inherent in them which favour or militate against their successful use, are critically discussed. The behaviour of concrete in use is dealt with at length. Such topics as its resistance to sea water and to soils containing soluble sulphate salts or acid water and its use for factory floors and in pipes for sewage effluents are all considered. An attempt has been made to outline the conditions which may be expected to affect concrete deleteriously. The survey made is based both on practical experience and on the results of the many large-scale trials and exposure tests which have been published. It represents the most ambitious survey of this type which has been attempted, and it is hoped that it may prove of real value to engineers.

Erratum—October Journal, page 459—in line 23 of the paper "Heavy Forgings and the Use of Alloys" by Messrs. M. F. McCarthy and E. Voorhees, for "1842" read "1742" and for "Dustman" read "Huntsman."

Returns on the "Questionnaire" of the Committee on Consolidation to October 24th, 1935

QUESTIONNAIRE OF THE COMMITTEE ON CONSOLIDATION

1. Are you in favour of the broad principle of Consolidation of the Engineering Profession in Canada?
2. In your opinion, should the corporate membership of the Provincial Professional Associations and of the National organization be identical?
3. Are you in favour of The Engineering Institute of Canada being accepted as the National body of the consolidated engineering profession in Canada?
4. Under Consolidation, would you be willing to pay a single annual membership fee which would include a uniform subscription from each member of the profession throughout Canada to the National organization?
5. In view of the fact that discipline and legal action are at present a function of the Provincial Associations, are you in favour of the administration of admission to membership and collection of fees also being made the responsibility of the Provincial organizations?

Province of Nova Scotia

*Cape Breton Branch (38)**

The Cape Breton Branch answered the "Questionnaire" as follows:
Question No. 1—Yes.
Question No. 2—Yes.
Question No. 3—Yes.
Question No. 4—Yes.
Question No. 5—(held pending information as to any alternative suggestions which may be forthcoming).

Halifax Branch (106) and Association of Professional Engineers of the Province of Nova Scotia (204)

The Halifax Branch of The Institute and the Professional Association of Nova Scotia appointed a special Joint Committee whose members were:—Messrs. R. L. Dunsmore and C. S. Bennett, representing the Branch, and Messrs. C. M. Smyth, L. H. Wheaton and Professor F. R. Faulkner representing the Association. This Committee considered the "Questionnaire" and their findings, as the official expression of the Branch and of the Association, are as follows:
Question No. 1—Yes.
Question No. 2—No, not necessarily.
Question No. 3—No, not as at present constituted.
Question No. 4—Yes.
Question No. 5—Yes.

Questions Nos. 1, 4 and 5 are answered in the affirmative in view of the recommendations of the "Joint Committee of Eight" last January. "In answering Question No. 3 the fact that only about 50 per cent of the members of the Association of Professional Engineers in Nova Scotia are also Corporate Members of The Engineering Institute of Canada was taken into account."

Province of New Brunswick

Moncton Branch (27)

The "Questionnaire" was issued to the members of this Branch for an expression of their individual opinions and the results were as follows:
Question No. 1—Yes, 20; No, 0.
Question No. 2—Yes, 20; No, 0.
Question No. 3—Yes, 18; No, 2.
Question No. 4—Yes, 20; No, 0.
Question No. 5—Yes, 12; No, 7.

Three members also sent in suggestions, explanatory remarks or questions.

Saint John Branch (53)

The "Questionnaire" was issued to the members of this Branch for an expression of their individual opinions and the results were as follows:
Question No. 1—Yes, 28; No, 0.
Question No. 2—Yes, 27; No, 1.
Question No. 3—Yes, 27; No, 1.
Question No. 4—Yes, 26; No, 2.
Question No. 5—Yes, 23; No, 5.

Association of Professional Engineers of the Province of New Brunswick (141)

The Association has prepared and issued to its members a special bulletin and questionnaire on Consolidation, a report on the results of which appears herewith. At the same time, a Special Provincial Committee has been formed in New Brunswick composed of two representatives from the Moncton Branch of whom Mr. H. J. Crudge is one; two representatives from the Saint John Branch, Mr. Gilbert G. Murdoch and Mr. A. A. Turnbull; and four representatives from the Professional Association, Professor A. F. Baird, Mr. Geoffrey Stead, Mr. L. L. Theriault, and Mr. C. S. MacLean. The Commission of this Committee is: "To act with two members appointed by the Saint John Branch of The Engineering Institute of Canada and two from the Moncton Branch as a Committee to consider Consolidation in all its aspects; to take steps to prepare a scheme whereby it may be brought about; to co-operate with Mr. Kirby and the Committee of Eight (Dominion Council) and with the central committee of The Institute headed by Mr. Pitts, and with other bodies of The Institute or of the Provincial Associations working toward this end."

Special Questionnaire on Consolidation issued by the New Brunswick Association

(Note:—It is not suggested that the National Corporation shall exercise any of the powers now exercised by the Provincial Corporations such as "Admission to Membership" or "Disciplinary Action," etc.).

(1) *Do you favour a National Body?*
Yes, 51; No, 3.
(2) *Do you favour a form of amalgamation with The Engineering Institute of Canada under a revised constitution for the latter?*
Yes, 41; No, 10.
(3) *Do you favour an independent new Corporation composed of Registered Professional Engineers only?*
Yes, 10; No, 39.
(4) *Would you be willing to pay a higher annual fee than that at present set by the Provincial Association for the support of a National Corporation up to say:*
$5.00 per year
or 10.00 per year
or 15.00 per year.
Yes, $5, 3.
Yes, $10, 9.
Yes, $15, 21; No, 1.

Twenty of the above members submitted suggestions, explanatory remarks or questions.

Province of Quebec

Saguenay Branch (27)

The "Questionnaire" was issued to the members of this Branch for an expression of their individual opinions and the results were as follows:
Question No. 1—Yes, 20; No, 1.
Question No. 2—Yes, 15; No, 5.
Question No. 3—Yes, 20; No, 0.
Question No. 4—Yes, 18; No, 2.
Question No. 5—Yes, 14; No, 5.

Quebec Branch (91)

At a Special General Meeting this Branch considered and discussed the "Questionnaire" and reported as follows:
Question No. 1—Yes.
Question No. 2—Yes, *eventually;* but, at the beginning and for some time to come we feel that some members of the E.I.C. may not necessarily become members of the Provincial Association of their province.
Question No. 3—Yes.
Question No. 4—It would be desirable to pay a single fee which would include all privileges available to the profession. However, it is premature to agree that the single fee should include a *uniform subscription* from each member of the National organization without knowing whether the benefits to accrue to each member will be almost uniform or widely different as at present, due to the location of Headquarters and Branches.
Question No. 5—Yes.

Note:—We again wish to go on record as recommending that the present grade of E.I.C. Affiliate be abolished.

★*Saint Maurice Valley Branch (27)*

No communication has been received from this Branch.

Montreal Branch (735)

At the direction of a Special General Meeting the "Questionnaire" was circulated to all corporate members of the Branch for an expression of their individual opinions and the replies were as follows:
Question No. 1—Yes, 295; No, 13.
Question No. 2—Yes, 246; No, 10.
Question No. 3—Yes, 298; No. 10.
Question No. 4—Yes, 273; No, 21.
Question No. 5—Yes, 193; No, 52.

There are 48 of the above members who submitted suggestions, explanatory remarks or questions. Three members of this Branch answered all five questions in the negative.

Corporation of Professional Engineers of the Province of Quebec (990)

At its Annual Meeting of March 27th, 1935, the Corporation adopted the following report of a Special Committee on Affiliation. Resolved:

(1) That the Corporation of Professional Engineers of Quebec is ready and willing to co-operate immediately with the other Provincial Engi-

neering organizations in an attempt to develop with The Engineering Institute of Canada a suitable and adequate basis of co-ordination of the Engineering profession in the Dominion.
(2) That the lines along which such co-ordination should proceed be generally similar to those which have governed the organization of sister professions.
(3) That The Engineering Institute of Canada should rightfully be the national co-ordinating body, its corporate membership to consist solely of members of the Provincial Professional Associations
(4) That in order to overcome a serious obstacle existing at present, it be suggested that any corporate member of The Engineering Institute of Canada, at the time of such change, who is not qualified to belong to his local Professional body should remain a corporate member of the National body but shall not, by reason of such change, become a member of the Association or Corporation in the province in which he resides.
(5) That The Engineering Institute of Canada should, after the date of such change, admit no person to corporate membership who is not at the time of application a member of his own local Provincial body.
(6) That a copy of this resolution be immediately referred to the Corporation's representative on the Committee of Eight for transmission by him to the other members of this Committee for consideration, the intention being that the Committee of Eight shall at the earliest possible moment present to The Engineering Institute of Canada a suggested basis for co-ordination. In view of the inexpediency of holding a meeting of the Committee of Eight at this time, such negotiation shall be conducted by correspondence.

The "Questionnaire" of the Committee on Consolidation is being considered by the Corporation but the results of its deliberations thereon have not yet been received.

Province of Ontario

Ottawa Branch (297)

The Ottawa Branch made the following returns on the "Questionnaire":

Question No. 1.—Yes.
Question No. 2—Yes. If this is impossible of attainment at the present time we would not be in favour of allowing it to prevent or delay steps toward consolidation. Further, provided that some provision will be made for those members of The Institute residing outside of Canada or those whose official position does not require affiliation with a provincial organization.
Question No. 3—Yes.
Question No. 4—Yes. With variable fee according to the extent which the individual member would require a provincial license.
Question No. 5—Yes. But the function of admission to membership in the National organization might be taken over not at once but gradually, by the Provincial organization as a common understanding of the standard necessary for membership will become more generally comprehended in the various provinces. The collection of fees might be taken over by the Provincial organizations from the beginning.

Peterborough Branch (43)

This Branch answered the "Questionnaire" as follows:
Question No. 1—Yes, 17; No, 0.
Question No. 2—Yes, 17; No, 0.
Question No. 3—Yes, 17; No, 0.
Question No. 4—Yes, 17; No, 0.
Question No. 5—Yes, 13; No, 4.

Kingston Branch (29)

This Branch made the following return on the "Questionnaire":
Question No. 1—Yes.
Question No. 2—Yes, but with exceptions for
(*a*) Engineers from other countries.
(*b*) Engineers now members of The Institute who do not wish to join their Professional Association.
Question No. 3—Yes.
Question No. 4—(How much would the fee be?)
Question No. 5—Dues—Yes. (If a single fee is adopted.)
Admission—No.
Discipline—No — insofar as the rules of Ethics are concerned.

Toronto Branch (317)

The Toronto Branch has issued the "Questionnaire" to its members for an expression of their individual opinions. This Branch favours a Joint Committee of the Branches of The Institute in Ontario to meet a Joint Committee of the Association of Professional Engineers of Ontario to discuss the question of "Consolidation of the Engineering Profession in Canada."

The Branch has appointed the following Special Committee—Messrs. O. Holden, W. E. Bonn, and C. E. Sisson, Chairman.

The following are the results of the "Questionnaire" issued to the members of this Branch for an expression of their individual opinions:
Question No. 1—Yes, 128; No, 3.
Question No. 2—Yes, 117; No, 10.
Question No. 3—Yes, 119; No, 5.
Question No. 4—Yes, 122; No, 3.
Question No. 5—Yes, 109; No, 15.

Fifteen of the above members submitted suggestions, explanatory remarks or questions.

Hamilton Branch (79)

The Hamilton Branch has made the following return on the "Questionnaire":
Question No. 1—Yes.
Question No. 2—Yes.
Question No. 3—Yes, if reorganization takes place.
Question No. 4—Yes.
Question No. 5—Yes, if approved by the National Governing Body.

Mr. H. A. Lumsden is chairman of the Special Committee on Consolidation and representative of the Branch on the Provincial Committee on Consolidation.

London Branch (38)

The "Questionnaire" was issued to the members of this Branch for an expression of their individual opinions and the results were as follows:
Question No. 1—Yes, 19; No, 0.
Question No. 2—Yes, 18; No, 0.
Question No. 3—Yes, 17; No, 1.
Question No. 4—Yes, 18; No, 0.
Question No. 5—Yes, 16; No, 3.

Niagara Peninsula Branch (75)

The Niagara Peninsula Branch has replied to the "Questionnaire" as follows:
Question No. 1—Yes.
Question No. 2—Yes.
Question No. 3—Yes.
Question No. 4—Yes.
Question No. 5—Yes.

Border Cities Branch (50)

The Border Cities Branch made the following return on the "Questionnaire":
Question No. 1—Yes.
Question No. 2—Yes.
Question No. 3—Yes.
Question No. 4—Yes.
Question No. 5—(Left unanswered)

Sault Ste. Marie Branch (55)

The Sault Ste. Marie Branch issued the "Questionnaire" to its membership for an expression of their individual opinions and the results are as follows:
Question No. 1—Yes, 28; No, 1.
Question No. 2—Yes, 28; No, 1.
Question No. 3—Yes, 28; No, 1.
Question No. 4—Yes, 29; No, 0.
Question No. 5—Yes, 18; No, 11.

Lakehead Branch (34)

The replies to the "Questionnaire" from this Branch are as follows:
Question No. 1—Yes.
Question No. 2—Yes.
Question No. 3—Yes.
Question No. 4—Yes.
Question No. 5—Yes.

Association of Professional Engineers of the Province of Ontario (1,119)

The Association appointed the following Special Committee to consider the Problem of Co-ordination:—Messrs. Archie B. Crealock, E. M. Wood, E. R. Frost and J. Clark Keith, Chairman.

The report of this Committee was accepted by the Association with some minor reservations:
Question No. 1—Yes.
Question No. 2—Yes.
Question No. 3—Yes.
Question No. 4—Yes.
Question No. 5—Yes.

Province of Manitoba

Winnipeg Branch (131)

The Winnipeg Branch of The Institute has appointed the following Special Committee on Consolidation:—Messrs. C. H. Fox, C. H. Attwood, J. W. Sanger, Fred. V. Seibert, E. V. Caton, Secretary, and A. J. Taunton, Chairman.

The "Questionnaire" was issued to the members of the Branch for an expression of their individual opinions and the results are as follows:
Question No. 1—Yes, 57; No, 0.
Question No. 2—Yes, 53; No, 4.
Question No. 3—Yes, 55; No, 2.
Question No. 4—Yes, 53; No, 4.
Question No. 5—Yes, 49; No, 8.

Eight of the above members submitted suggestions, explanatory remarks or questions.

Association of Professional Engineers of the Province of Manitoba (*203*)

The Association has a Special Committee co-operating with the Special Committee of the Winnipeg Branch, forming a Joint Committee on Consolidation in this Province. In view of the progress of the deliberations of the Joint Committee, and the proposals relative to Consolidation within the Province, which it has drawn up for submission to both organizations, the Association has refrained from answering the "Questionnaire" until these proposals have been passed upon by the engineers of Manitoba. It is anticipated that a decision will be made in the near future.

These proposals are as follows:

1. The Council of The Institute will recognize registration with the Association as constituting full and satisfactory qualifications for admission to the grade of member in The Institute.
2. The Association will acquire a group membership in The Institute by virtue of which each and every individual shown on the register of the Association will be a member of The Institute.
3. The Association will pay annually to The Institute a group membership fee.
4. The annual fee for members may, if necessary, be increased to cover the increased activities of the group membership.
5. The Association of Professional Engineers of the Province of Manitoba shall assume the functions of the Winnipeg Branch of The Institute.
6. Individuals who are not practising engineering within the meaning of the Act may, if they are qualified and accepted, obtain or continue membership in The Institute and pay their fees direct to headquarters. The Association will extend to such members the privilege of attending and participating in all meetings, but they will not be qualified to vote in such meetings.

The above proposals were approved by the executive of the Professional Association on September 16th and by the executive of the Winnipeg Branch E.I.C. on September 26th, 1935.

A joint General Meeting of the members of the Winnipeg Branch and the Association of Professional Engineers of the Province of Manitoba, will be held at the University of Manitoba on Thursday, November 7th, to receive and discuss the above recommendation of the Joint Committee, after which a letter ballot will be sent out to the members of both organizations.

Province of Saskatchewan

Saskatchewan Branch (*64*) *and Association of Professional Engineers of the Province of Saskatchewan* (*89*)

The consideration of the problem of Consolidation is well advanced in this Province under a Special Joint Committee of the Branch and the Association of which Mr. D. A. R. McCannel is Chairman. The engineers of this Province were the first to make a return on the "Questionnaire" and the results were as follows:

Question No. 1—Yes.
Question No. 2—Yes.
Question No. 3—Yes.
Question No. 4—Yes.
Question No. 5—Yes.

A General Meeting of the engineering profession in Saskatchewan was held as an open meeting of the Professional Association of that Province in Regina, on October 26th, 1935. At this General Meeting the following Resolutions were passed without a dissenting vote:—

1. Resolved that this General Meeting of the Engineering Profession in Saskatchewan endorses the general principle of Consolidation of the Engineering Profession in Canada, and urges the Executive of respective Engineering societies to overlook minor details and make every effort to consummate Consolidation.
2. Resolved that this General Meeting of the Engineering Profession in Saskatchewan hereby goes on record as considering National Consolidation the objective of the Profession, but if a National scheme is not formulated within six months, that we consider it the duty of National societies to take immediate steps to permit Consolidation in any Province desiring such action.
3. Resolved that this General Meeting of the Engineering Profession in Saskatchewan, from reports received, deplores the apparent lack of action by the Dominion Council of Professional Associations, and hereby goes on record to request the Council of the Association of Professional Engineers of Saskatchewan to take the necessary steps to urge such Associations to arrange for a National meeting at an early date to give consideration to the Consolidation of the Engineering Profession in Canada.
4. Resolved that this General Meeting of the Engineering Profession in Saskatchewan further requests that the Council of the Association of Professional Engineers of Saskatchewan notify all interested parties of the foregoing resolutions and further, that they supply Saskatchewan Engineers with a digest of the Papers presented at this meeting, and a copy of the Resolutions adopted.

Province of Alberta

Lethbridge Branch (*24*)

While this Branch of The Institute has gone on record as being in favour of Consolidation, they did not fill in the "Questionnaire" as they feel this matter should be dealt with through the "Dominion Council of Engineering."

Edmonton Branch (*45*)

The Edmonton Branch issued the "Questionnaire" to its members for an expression of their individual opinions with the following results:

Question No. 1—Yes, 12; No, 0.
Question No. 2—Yes, 11; No, 1.
Question No. 3—Yes, 12; No, 0.
Question No. 4—Yes, 11; No, 0.
Question No. 5—Yes, 7; No, 3.

Certain of the answers carried qualifications. This Branch has suspended further action on this matter, pending consideration of a proposal by the Calgary Branch for a provincial conference of representatives of the Branches of the E.I.C. and the Provincial Professional Association.

Calgary Branch (*73*)

The Calgary Branch appointed the following Special Committee on Consolidation:—Messrs. John Haddin, Lieut.-Colonel F. M. Steel, G. P. F. Boese, S. G. Porter and R. S. Trowsdale, Chairman. The Calgary Branch made the following reply to the "Questionnaire":

Question No. 1—Yes.

Question No. 2—Yes; (*a*) Providing the present corporate members of the E.I.C. should continue to be corporate members of the national organization. (*b*) We suggest that the members of the Provincial Association of Professional Engineers be admitted to the E.I.C. and that all E.I.C. members be admitted to the provincial Association. (*c*) That those members of the E.I.C. who do not wish to be registered be allowed to remain as corporate members of the National Association.

Question No. 3—Yes.

Question No. 4—Yes, providing as in question 2 (*c*) E.I.C. members may continue to pay fees to the national association in the event that they do not see fit to register with the provincial association.

Question No. 5—Yes.

Association of Professional Engineers of the Province of Alberta. (*253*)

The whole question of Consolidation and the "Questionnaire" will be considered by this Association on November 2nd, 1935.

Province of British Columbia

Vancouver Branch (*127*)

This Branch has submitted a Report prepared by Mr. P. H. Buchan, past-chairman of the Vancouver Branch, as representing views of that Branch on Consolidation. This Report has been printed in full in the August issue of The Journal. The Committee on Consolidation has not attempted to interpret the Report in the terms of the "Questionnaire."

Victoria Branch (*45*)

The Victoria Branch submitted a "Questionnaire" to its members for an expression of their individual opinions. The results are as follows:

Question No. 1—Yes, 18; No, 0.
Question No. 2—Yes, 17; No, 1.
Question No. 3—Yes, 17; No, 1.
Question No. 4—Yes, 18; No, 0.
Question No. 5—Yes, 16; No, 2.

Two of the above members submitted suggestions, explanatory remarks or questions.

The Branch strongly favoured the Consolidation of The Engineering Institute of Canada and the Provincial Associations of Professional Engineers and the appointment of a Joint Committee of the Branches of The Institute in British Columbia to discuss Consolidation with a Committee of the Association of Professional Engineers in that Province.

Association of Professional Engineers of the Province of British Columbia (*808*)

This Association has previously decided to refer the whole matter (of Consolidation) to the Committee of Eight and to leave any action until the advice of the Committee of Eight has been received. It is reported that the Council of the Association is at present considering what further action may be taken. It might be noted that the Committee of Eight held its last meeting in February of 1933.

*Note:—The figures in parentheses give the approximate number of active corporate members of The Institute in the branches concerned and the membership of the various Professional Associations.

Gordon McL. Pitts, A.M.E.I.C.,
Chairman, Committee on Consolidation.

BRANCH NEWS

Hamilton Branch

A. Love, M.E.I.C., Secretary-Treasurer.
A. B. Dove, Jr.E.I.C., Branch News Editor.

An Engineer's Experiences in Russia

The Hamilton Branch of The Engineering Institute of Canada were guests of the Ontario Chapter of the American Society for Metals at their regular meeting, October 11th, 1935, at the Royal Connaught hotel.

The speaker of the evening, Arthur G. McKee of the McKee Construction Company, chose as his subject "An Engineer's Experiences in Russia" and was introduced by Prof. O. W. Ellis of the Ontario Research Foundation.

Mr. McKee's company was under contract with the U.S.S.R. to build, at Magnetogorsk in the mid-southern territory, a complete steel works from blast furnaces to rolling mills. It was typical of Russian phsychology that their constant theme was "haste" and "hurry," with a constant check on schedules set up for the work.

The plant was a huge affair and the coal and necessary ore were separated by 1,500 miles of single track of 70 pound rail—and it may be imagined that deliveries were slow. It was necessary to dam the Ural river to provide adequate water for plant operation during the whole year and to build a skid dam 34 feet high on silt.

Blast furnaces had 25-foot hearths, were 100 feet in height, stoves 28 feet by 140 feet high, with as much as 200,000 square feet of heating surface and blowers producing 115,000 cu. ft. at 30 pounds per square inch. The Russians did not follow instructions implicitly, and redesigned the hearths of the blast furnaces and would not use the proposed switching designs.

In Russia there is a natural inertia to change whether it be living conditions, working conditions, or social life. Cranes provided for erection of steel and concrete work were discarded for great forests of timber erection. In Russia "Everybody lifts, and everyone sweats." Women as well as men must work to eat. The children are brought up to believe in no god but themselves and Russia. What effect this teaching will have upon the new generation can only be guessed.

Mr. W. Hollingworth, M.E.I.C., made a motion of a vote of thanks to Mr. McKee, but the applause of the assembly showed that no seconder or voting was necessary to show their approval.

About 200 were present, many from out of town, and prior to the meeting there was an informal dinner. Mr. A. B. Oram, chairman of the Ontario Section A.S.M., presided at both dinner and meeting.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

Smoker

A well-organized and exceptionally well-attended informal smoker held in the Rose Room of the Windsor hotel on Friday evening, October 4th, 1935, ushered in the nineteenth season of activities of the Montreal Branch. F. S. B. Heward, A.M.E.I.C., chairman of the Branch, acted as chairman, and Dr. F. A. Gaby, president of The Institute, was the guest of honour.

Songs, music and choruses enlivened the proceedings while the programme also included recitations and sleight-of-hand tricks, the contributors being D. C. Tennant, M.E.I.C., who led the community singing, F. Cleal, orchestra conductor, Noble Birks, R. Eric, Crawford, A.M.E.I.C., J. L. Heald, W. J. Langston, J. G. Caron, A.M.E.I.C., R. H. Findlay, M.E.I.C., F. J. McHugh, A.M.E.I.C., Professor C. M. McKergow, M.E.I.C., and others. Many of the artists were members of The Institute.

During the course of the evening refreshments were served, and Mr. Heward made a brief address, as did Dr. Gaby, and introduced a number of guests including four Past-Presidents of The Institute who were present: Messrs. G. H. Duggan, M.E.I.C., H. H. Vaughan, M.E.I.C., Dr. O. O. Lefebvre, M.E.I.C., and F. P. Shearwood, M.E.I.C.

The attendance of 325 almost equalled that of the smoker held last spring.

Niagara Peninsula Branch

P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

For the first meeting of the season this Branch visited the McKinnon Industries of St. Catharines, a branch of the General Motors, where small parts are manufactured for Canadian and Empire trade.

This factory exemplifies the evolution in business during the last fifty years. Started about the year 1880, by Messrs. L. E. McKinnon and F. F. Mitchell of St. Catharines, as a saddlery and waggon hardware factory, the business was extended to cover carriage dashes and fenders. The malleable iron foundry was constructed in 1901 and a drop forging department opened in 1905 when the manufacture of chain was undertaken. A separate factory was built at Tonawanda, N.Y., and, in 1917 the chain company was merged with the Columbus Chain Co., of Columbus, Ohio.

At the outbreak of the war the St. Catharines plant secured large contracts from the British and French governments for military harness hardware. In 1916 the plant was extended to provide for the manufacture of shrapnel bullets, time fuses and H.E. shells.

After the war, machinery was installed to manufacture automobile radiators, differentials and transmission gears, the first venture of that nature in Canada.

Late in 1928 the General Motors opened negotiations for the purchase of the plant and, on March 1st, 1929, that corporation assumed control and became owners of the McKinnon Industries Limited through an exchange of stock.

Since then the plant has been extended and improved. A pulverized coal system has been installed and a modern building erected to manufacture Delco-Remy equipment which, up to that time, had been imported from Anderson, Indiana.

The chief products of the plant are now as follows: malleable iron castings, steel forgings, differentials, shock absorbers, steering gears, starting motors, generators, ignition coils, spark plugs, rear axle shafts, fractional h.p. motors for electric refrigeration, and various tools. Units for six hundred cars a day can be supplied. Some twelve hundred men are employed with a yearly payroll of about three quarters of a million dollars. A modern foundry lay-out, with a system of travelling conveyors for the moulds and continuous pouring, is now being designed.

After a well attended dinner at the Welland House, Mr. Orwell Brown, factory manager, explained that the automotive industry is not only seasonal but has large yearly fluctuations. The effect of a poor season is less noticeable in a community with diversified manufacturing interests than it would be if all work were concentrated in a single city such as Oshawa.

A lengthy discussion followed and the skeleton sections of various products were examined with great interest.

Walter Jackson, M.E.I.C., proposed the vote of thanks to Mr. Brown, his assistants and the General Motors for their kindness in providing an instructive afternoon and evening session. Chairman Paul Buss, A.M.E.I.C., then declared the meeting adjourned.

Quebec Branch

Jules Joyal, A.M.E.I.C., Secretary-Treasurer.

Le Cout d'Exploitation des Centrales Diesel

Tel fut le sujet traité à une réunion générale des membres de la section de Québec, par M. Jean St-Jacques, S.E.I.C., assistant ingénieur au Quebec Power.

L'étude du conférencier s'est limitée aux petites centrales de 500 chevaux ou moins localisées dans la ville de Québec; une série de résultats obtenus dans 18 centrales établies aux Etats-Unis fut d'abord présentée, puis leur coût d'exploitation fut ramené aux conditions existant à Québec quant au prix du combustible.

Ces exemples ont montré jusqu'à quel point le coût d'exploitation dépend du facteur d'utilisation et que l'on doit bien se garder de parler de résultats moyens. Il fut aussi démontré que le moteur Diesel a un bon rendement économique quand il est chargé à sa puissance normale mais que ce rendement baisse rapidement quand on le surcharge ou qu'on le charge seulement à une fraction de sa puissance nominale; de cette dernière constatation le conférencier conclut qu'il y a nécessité d'établir avec précision la puissance requise dans un projet quelconque.

Le conférencier montra ensuite une analyse des résultats obtenus dans une centaine de centrales Diesel établies en Angleterre et en Amérique; de cette analyse il est possible d'établir des courbes du coût des divers éléments qui entrent dans le coût total d'exploitation. Ces divers éléments sont ensuite combinés de manière à obtenir un coût total pour toute une série de facteurs d'utilisation en supposant que la centrale fonctionne à pleine charge aux heures de pointe. Ces résultats s'expriment sous forme de courbes en regard desquelles il est possible de mettre d'autres courbes donnant le coût d'achat de l'énergie électrique au réseau de distribution à Québec.

Comme conclusions générales le conférencier démontre qu'à des facteurs d'utilisation réduits le prix de production de l'énergie par groupes électrogènes se rapproche beaucoup du prix d'achat de l'énergie au réseau de distribution. De même pour des facteurs élevés le coût unitaire au kwh. est bas et il augmente à mesure que le facteur d'utilisation diminue. Enfin il est démontré par l'écart de prix entre le coût à l'utilisation élevée et le coût à utilisation réduite que tout projet de centrale Diesel nécessite une étude approfondie des conditions d'exploitations afin d'établir le facteur d'utilisation de l'installation.

A Philosophical View of the World Today

On October 3rd, 1935, Professor Rupert C. Lodge, M.A., Professor of Logic and History of Philosophy of the University of Manitoba, presented a paper, "A Philosophical View of the World Today," at the initial fall meeting of the Branch.

Professor Lodge stated that there are three major viewpoints of philosophy, realism, idealism and pragmatism, each of which to some extent contradicts the others. The realist thinks of the world of physical reality as being primary. The idealist believes that man's mind transcends the physical. The pragmatist believes that the two preceding types go well beyond the facts, that the proper attitude is to stay rooted in experience. The present day realist regards the mind as the interaction of the physical senses with environment. He looks out on the world today expecting the worst, and believing that present tendencies confirm his idea that the world is barbaric as ever. The idealist looks on the present world and is pessimistic, for he wishes to see his ideals realized. The pragmatist believes that we are biological and social organisms. He claims he is more real, more concrete, than the realist. His gaze is on the problems of the moment, he has no use for history, he minds his own business.

These three viewpoints are tendencies within ourselves which come into conflict when we form our judgments, though usually one of them is stronger than the others. It has been said that Goethe is the best example of a happy combination of all three.

Those taking part in the discussion which followed included T. C. Main, A.M.E.I.C., W. D. Hurst, A.M.E.I.C., G. E. Cole, A.M.E.I.C., and W. F. Oldham, A.M.E.I.C. A vote of thanks was moved by Professor A. E. McDonald, A.M.E.I.C., after which the meeting adjourned for light refreshments.

The Consolidation Problem

Comments on the Memorandum by P. L. Pratley, M.E.I.C. (published in the July issue of The Journal, pages 359-360), prepared by E. A. Wheatley, M.E.I.C., Registrar, Association of Professional Engineers of British Columbia.

(*Underlining by Mr. Wheatley*)

Quotation

"Any serious effort to solve the problem... must be based upon the recognition of certain fundamental facts..."

"Admittedly the meaning of 'profession' may be revised or redrafted or stretched... but basically... the essence of the idea is the personal contact between the 'professor' and his client whether he be lawyer, doctor, or dancing master."

Comment

Definitely inaccurate. Consideration of all the other professions will prove its inaccuracy. The young priest when ordained, the young lawyer on being called to the Bar, the young doctor, the young architect, the young chartered accountant, on receiving their licences, may and invariably do continue in an employee capacity for many years before making "personal contact" with clients. In law lawyers continue for many years in an employee condition and officially and authoritatively quite 40 per cent of the legal profession continue indefinitely in an employee condition. Making personnal contact with clients is but accidental and secondary, and is not the fundamental idea of what constitutes a professional man which is:—

Originally, a professional man was one who 'professed' a special education and special training. By the passage of time and the seal of custom, it is now one who has passed through an *officially* prescribed education, an *officially* prescribed junior experience and passed official tests, and thus is one who is *officially* authorized "to profess." Personal contact is nowhere stipulated.

The official authorization in all professions on this continent is the licence to practise.

One can visualize or recognize the inaccuracy of Mr. Pratley's proposals by contemplating imaginatively the lot of an engineer brother amongst a group of brothers belonging to the other professions. At a young age of from 25 to 30, the oldest brother is ordained as a priest, the second brother is called to the Bar, the remaining brothers have received a license as a doctor or as an architect or chartered accountant. At a reunion of the family all will be congratulating those other brothers on having received formal official recognition by their respective professions, but the engineer son, a graduate and an engineer of many years junior experience, one who in British Columbia, would have passed the final test and would have written a book or thesis (of all mental tests the most difficult), to this young professional man, the brothers and parents would turn and inquire why he should not have received the highest honour at the disposal of his profession. He could only reply. "Oh no. I have gone through an officially prescribed disciplinary period as my brothers have, but Mr. Pratley states that 'it is totally inapplicable' for me to receive a license to practise. I must wait until I 'make personal contact with clients' before I can receive my license."

Quotation

"A large majority... of engineers... in cities are... employees of corporations and industrial firms, [(to these)] the licensing idea is totally inapplicable." "In the Provinces, the provincial organizations are regarded [(by engineers)]... as a type of trade union, in no sense valuable to the public and only useful... as they limit the number of entrants or applicants for employment."

Comment

The number of industrial engineers who have sacrificed their time to work on the Councils of the Association in B.C. and on the other hand the number of leading Government and municipal engineers who have also worked as presidents and on the Councils of the Association in B.C. proves the injustice and inaccuracy of these words and condemns them and their author.

Industrial engineers in B.C. prove that it is *not* "totally inapplicable" to licence the young assistant engineers. In B.C. *they delight* to reward merit by confining employment or granting a strong preference to the young licensed engineer and to the young enrolled student—no compulsion, whatsoever,—the young engineer *longs* for his license, and the industrial employer *delights* to reward him and *give value* to the license, by employing or promoting him.

Quotation

"And only a certain few should be compelled to apply for a license."

Contrast this with the quotation

"The qualification should definitely include corporate membership in the national Institute."

Comment

In B.C. we should have to reduce our members from 824 to possibly 206 requiring the remaining 618 to list merely their names ("both registered engineers and graduate engineers would be voluntary listees with the Committee"), also too, our 520 students would be expected presumably to leave the Association and to join The Institute.

One can justifiably criticise Mr. Pratley for selecting a passion-raising word such as "compelled" or "compulsion"—it is provocative.

Note:—He would use the very powers of the Associations which he tacitly condemns by his use of the word "compulsion," to compel professional engineers to seek membership in The Institute, but he uses the much quieter terms of "definitely include"—and later he uses even the non-provocative terms "reasonably be required."

Quotation

"The graduate engineer might reasonably be required to become a corporate member of the national body."

"As to the accomplishment of this new consolidation... the principal requirement is the 'will'."

Comment

It is required of the Association to have the "will" to degrade the Associations, not so much to merge them, but to submerge them, and in B.C. we must have the "will" to give up 618 members,—to lose our name, etc. etc. Would any organizations of any type whatsoever agree to negotiations leading almost to such complete submerging?

Quotation

[(Associations will)] "of necessity surrender this extreme and logically untenable position in favour of the logical attitude that a certain well-defined group of engineers who... receive licenses," a chosen few.

Comment

There is no need for further comment on this. Such an idea is totally contrary to the philosophy of *all* registration acts (already dealt with on Page One of this memorandum.)

Quotation

"It is quite possible that alterations to some of the existing acts would ultimately be required but... there would not seem to be any overwhelming reason ... and the alteration in the acts delayed until two or three years."

Comment

The administrators of the Acts have a duty to perform to the Governments who granted their Acts and any Association which contemplated operating their Acts *illegally* for two or three years, would deserve to have the Act repealed.

Quotation

"The proposal... has the further value that The Institute can keep open its doors to all those worthy contributors to the progress of engineering who may never reach professional status."

Comment

Does the Canadian Medical Association grant membership to orderlies, because they are "worthy contributors to the progress of medicine?" Does the Canadian Bar Association open its ranks and grant membership to hack law clerks or male stenographers on the plea that they are "worthy contributors to the progress of law?" Does the Architectural Institute of Canada open its doors to draftsmen on the same fallacy? No. The national body of all of the professions is and must be a *rigidly strictly professional body.*

Vancouver, B.C. E. A. W.
September, 1935.

(*Note:*—The above analysis was accompanied by a proposal to hold a meeting of the Presidents and Secretaries of all the Provincial Professional Associations and the members of the Committee of Eight in Montreal, in January 1936, to determine the basic principles on which Consolidation can be effected from the point of view of the Provincial Professional Associations.)

Preliminary Notice

of Applications for Admission and for Transfer

October 31st, 1935

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in December, 1935.

R. J. Durley, Secretary.

*The professional requirements are as follows.—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BOYD—DAVID, of 6-36th Avenue, Lachine, Que., Born at Belfast, Ireland, Sept. 15th, 1902; Educ., B.Sc. (E.E.), McGill Univ., 1928; With Dominion Bridge Co. Ltd., as follows: 1923-29, dftsman and checker; 1929-33, mtce. supt.; 1933 to date, asst. works manager.

FOR TRANSFER FROM THE CLASS OF JUNIOR

MIDGLEY—GEORGE HENRY, of Montreal, Que., Born at Glasgow, Scotland, Oct. 19th, 1901; Educ., B.Sc. (Mech.), N S. Tech. Coll., 1924; 1918-22 (summers), mine and land survey works, wharf constrn., dfting., etc.; 1923-24 (summers), mach. shop; 1924-26, dfting, field work, etc., on mill constrn., Riordon Pulp Corpn., and International Paper Co. (Canadian); With Dodge Manufacturing Co. as follows: 1926-34, sales engr., Toronto and Montreal offices, looking after engrg., estimating, sales and erection works in Prov. of Quebec and the Maritime Provinces; May 1934 to date, sales manager, Divn of United Steel Corpn. Ltd., in charge of all Montreal office works, including engrg., sales and office management (Prov. of Quebec, Maritimes and Nfld.). (*Jr. 1928.*)

References: K. H. Marsh, W. S. Wilson, E. A. Ryan, F. O. White, W. S. Kidd, A. N. Ball, J. H. M. Jones, R. Ford, L. S. Dixon.

SINCLAIR—ARCHIBALD BEAIRSTO, of Kenogami, Que., Born at Truro. N.S., Apr. 3rd, 1902; Educ., B.Sc. (E.E.), Univ. of Man., 1927. Grad., National Radio Institute; 1922-23, field engr., Manitoba Power Co., Grand Falls; Summers: 1924-25-26, electrn., material checker and dftsman.; 1927-28, student, Canadian Westinghouse Co., Hamilton, Ont.; 1928-31, asst. to gen. elec'l. supt., Price Bros. & Co. Ltd., and 1931 to date, chief operator, Kenogami substation, for same company. (*St. 1927, Jr. 1928.*)

FOR TRANSFER FROM THE CLASS OF STUDENT

BROWNIE—FRANK AUSTIN, of Edmonton, Alta., Born at Montreal, Que., Apr. 16th, 1908; Educ., B.Sc. (Civil), Univ. of Alta., 1934; Summer work; 1928-29-30, chainman, rodman, instr'man., C.P.R. townsite surveys; 1931, rodman, constrn. of Glenmore water supply, Calgary; 1934, instr'man on Seismic Survey, for Dominion Gas Service Ltd., Calgary; Nov. 1934 to date, with assessment branch, dept. of municipal affairs, Edmonton, at present as inspector of assessment. (*St. 1932.*)

References: R. S. L. Wilson, F. K. Beach, M. L. Gale, H. R. Webb.

CRAIN—HAROLD FOWLER, of Ottawa, Ont., Born at Ottawa, Feb. 28th, 1908; Educ., B.Sc., Queen's Univ., 1932; 1927-31 (summers), pressman, Crain Printers, Ltd.; 1931, dftsman, E. B. Eddy Co. Ltd.; 1932 to date, with Crain Printers Ltd., estimating, lithographing dept., and from Feb. 1933, vice-president in charge of production. (*St. 1932.*)

References: W. S. Kidd, C. M. Pitts, L. T. Rutledge, G. Stephenson, L. M. Arkley.

CRAWFORD—JAMES MERRILL, of 3427 Harvard Ave., Montreal, Que., Born at Howick, Que., May 3rd, 1907; Educ., B.Sc., 1929, M.Eng., 1932, McGill Univ.; 1928-29 (summers), elect'l. installn.; 1929-30, demonstrator in electr'l. engrg., McGill University; 1930 to date, elect'l. engr., Shawinigan Water and Power Co., Montreal, Que. (*St. 1928.*)

References: C. V. Christie, G. R. Hale, S. C. Hill, C. R. Reid, B. C. Hicks.

DONNELLY—WILLIAM DAVID, of Asbestos, Que., Born at Deseronto, Ont., Sept. 15th, 1904; Educ., B.Sc., Queen's Univ., 1925; 1925-26, stock layout man, 1926-30, plant engr. dftsman and surveyor, Hudson Motor Car Co., Detroit, Mich.; 1930-32, dftsman. and estimator, schedule dept., Canadian Locomotive Co. Ltd., Kingston, Ont.; 1934 to date, asst. foreman, and at present foreman, friction materials dept., Canadian Johns-Manville Co., Asbestos, Que. (*St. 1924.*)

References: L. M. Arkley, D. M. Jemmett, L. T. Rutledge, C. G. R Armstrong, W. A. Dawson.

GAUER—EDWARD, of 275 Evanson St., Winnipeg, Man., Born at Winnipeg, Apr. 29th, 1904; Educ., B.Sc. (C.E.), Univ. of Man., 1926; D.L.S., 1930, M.L.S., 1931; 1928-32, highway location and surveys, Good Roads Board, Winnipeg, Man.; 1932 to date, private and govt. surveys, at present in private practice as land surveyor and municipal engineer. (*St. 1924.*)

References: G. H. Herriot, S. E. McColl, J. N. Finlayson, A. E. MacDonald.

JACOBSEN—ERIC RIVERS, of Montreal, Que., Born at Calgoorlie, Australia, Sept. 18th, 1906; Educ., B.Sc. (C.E.), 1929, M.Eng., 1932, McGill Univ.; 1924-25, shipping clerk and asst. to acct., Maple Leaf Asbestos Mine; Three summers, one as instr'man., two as field party chief, McClare & McClare, Borough Engrs., State of New Jersey; 1929 to date, designer, Dominion Bridge Co. Ltd., Montreal, Que. (*St. 1928.*)

References: D. C. Tennant, F. P. Shearwood, E. Brown, H. R. Montgomery, A. T. Bone, R. E. Jamieson.

STOREY—THOMAS EDWARDS, of Pointe du Bois, Man., Born at Brockville, Ont., Feb. 17th, 1906; Educ., B.Sc., (E.E.), Univ. of Man., 1928; 1927 (summer), instr'man., survey party, City of Winnipeg Hydro; 1928-29, test course and engrg. office, Can. Gen. Elec. Co. Ltd.; With the City of Winnipeg Hydro-Electric System as follows: 1929-31, elect'l. layouts, including equipment lighting and control wiring; 1931-35, senior operator, Slave Falls; Feb. 1935 to date, chief operator at Slave Falls in charge of operation and mtce. (*St. 1926.*)

References: J. W. Sanger, R. H. Andrews, H. L. Briggs, C. T. Barnes, E. P. Fetherstonhaugh, A. E. MacDonald, N. M. Hall, W. M. Cruthers.

VINCENT—PAUL, of 837 Hartland Ave., Outremont, Que., Born at Montreal, Dec. 8th, 1906; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1934; 1927 (summer), quantity and report clerk, Wayagamack Pulp and Paper Co.; asst. supervisor in bldg. constrn., and summers 1930-31, asst. constrn engr., Heroux & Robert Ltd., Montreal; 1935 (June-Aug.), asst. constrn. engr., Aluminum Co. of Canada, Arvida; Aug. 1935 to date, junior engr., Water Levels Investigation Board, Dept. of Marine, Ottawa, Ont. (*St. 1934.*)

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

Situation Vacant

SALES ENGINEER. Applications will be received for the position of sales engineer with a steel fabricating company. Applicants must have at least ten years experience in detailing and design of steel structures and preferably some experience in estimating and selling. Graduate engineer and member of E.I.C. preferred. State fully, qualifications. Apply to Box No. 1208.

Civil Service of Canada

JUNIOR ENGINEERS

24466.—Two junior engineers in the Airworthiness Branch, the Aeronautical Engineering Division, Department of National Defence, Ottawa, initial salary $1,800 per annum, which may be increased at the rate of $120 per annum, until a maximum of $2,160 has been reached.

Duties.—Under direction, to make computations in connection with engineering work, and to perform other related work as required. Under direction to make detailed calculations in connection with determining the airworthiness of aircraft; to assist in making mechanical tests to determine the strength of aircraft components; under direction to examine drawings of aircraft and aircraft engines to see that they comply with the requirements for airworthiness.

Qualifications Required.—Graduation from a university of recognized standing in Applied Science; two years of engineering experience, which should, if possible, be in conjunction with aeronautical engineering; aptitude for making difficult mathematical calculations; the department will not accept candidates who have passed their twenty-eighth birthday on the date of examination.

Application forms properly filled in must be filed with the Civil Service Commission, Ottawa, **not later than November 28, 1935.** Application forms may be obtained from the offices of the Employment Service of Canada, from the Postmasters at any City Post Office, The Engineering Institute of Canada, or from the Secretary of the Civil Service Commission, Ottawa.

Candidates must be British subjects, and have resided in Canada for at least five years.

Situations Wanted

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ENGINEER AND ACCOUNTANT, Jr.E.I.C., (Capt. Can. Engrs., reserve). Age 35, Canadian. Experienced in mechanical and civil engineering, Diploma; general office, draughting and instrument work; assistant engineer erection Royal York hotel; assistant resident engineer T. & N.O. Ry. const. Desires position in Toronto where combination of technical and business experience will be of value, as have been director and accountant last three years. Apply to Box No. 377-W.

CIVIL ENGINEER, B.A.Sc. and C.E.; A.M.E.I.C., A.M. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

CONSTRUCTION ENGINEER, age 26, unmarried, graduate C.E. Experience includes hydro-electric, railroad, highway, and industrial plant construction, both field and office, including cost accounting, estimating, stores, layout, general engineering and supervision, as well as practical work in mechanical trades. Apply to Box No. 567-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

ELECTRICAL ENGINEER, McGill '31, desires permanent position in engineering field. Experience includes draughting, designing and testing of induction motors, radio supervision and test, and some construction. Available immediately. Apply to Box No. 626-W.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL AND RADIO ENGINEER, B.Sc. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering For further information apply to Box No. 680-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc., Elec., '29, B.Sc., Civil '33. Age 27. Jr.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

Mechanical Engineers

During the past month there has been considerable improvement in the demand for mechanical engineers both for men experienced in design and for sales work.

All inquiries have originated in the provinces of Quebec and Ontario and are for recent graduates with a year or two of experience, or for men with some five or six years experience.

Unfortunately a number of these positions are not permanent but any young mechanical engineers unemployed and not registered with the Employment Service Bureau, or not suitably located, should communicate with Institute headquarters.

MECHANICAL ENGINEER, B.Sc., '27, Jr.E.I.C. Four years maintenance of high speed Diesel engine units, 200 to 1,300 h.p. Also maintenance of d.c. and a.c. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.Sc., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

Situations Wanted

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

CIVIL ENGINEER, M.Sc., A.M.E.I.C., R.P.E. (Ont.), ten years experience in municipal and highway engineering. Read, write and talk French. Married. Served in France. Will go anywhere at any time. Experienced journalist. Apply to Box No. 737-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.Sc. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

MANAFACTURERS' REPRESENTATIVE, at present doing business with leading industrial organizations in Canada, wishes to represent manufacturers of mechanical equipment. Such work as would involve technical data, and the preparation of plans where necessary, would be handled by an engineer whose experience with outstanding firms and projects, would be valuable to those seeking representation. Apply to Box No. 764-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

Situations Wanted

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

SALES ENGINEER, A.M.E.I.C., graduate engineer, age 34, practical experience in the manufacture of power plant equipment, thoroughly conversant with Canadian power plant practice and equipment for the metal working industries. Available on short notice. Apply to Box No. 860-W.

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, B.A.Sc. in C.E., with business and sales experiences, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.Sc. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.Sc., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C. '29); M.S. Age 27. Single. Four years experience in research work in applied mechanics and materials testing. Desires position involving analytical work in design, development or testing. Available on short notice. Apply to Box No. 1023-W.

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER, B.Sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.Sc., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.Sc., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Writes and speaks both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211-W.

CIVIL ENGINEER, B.Sc. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet tissues. Apply to Box No. 1246-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

CIVIL ENGINEER, Univ. Toronto '33, age 24, married. One year as instrumentman with provincial department of highways. Experience in concrete and retread construction grading, culverts, etc. Also draughting, estimating and general office practice. Apply to Box No. 1265-W.

ELECTRICAL GRADUATE, S.E.I.C., B.Sc. '32, M.Sc. '34. Experience includes four years as part time operator and announcer for a radio broadcast station. At present employed in radio repair dept. of a large wholesale firm. Apply to Box No. 1283-W.

ELECTRICAL ENGINEER, B.Sc., E.E., A.M.E.I.C. University of Manitoba '28. Age 32. Married. Experience one year power line construction, five years resident and assistant district engineer on highway construction; two years highway traffic regulation in charge of district office. Good connections in Manitoba and Saskatchewan. Excellent references. Available at once and will go anywhere. Located in Winnipeg. Apply to Box No. 1316-W.

ENGINEER AND DRAUGHTSMAN, Jr.E.I.C., age 33, married. Diplomas from Mtl Tech. Inst. in R.C. and Structural Design. 11½ years experience in civil engineering, draughting and instrument work. This includes 7 years with M.L.H. & P. Cons. as field engineer on construction and maintenance of gas mains. Present location Montreal. Available at once. Apply to Box No. 1326-W.

GRADUATE ENGINEER, (McGill), in responsible charge of design, construction and operation of hydro-electric plants. Also power design and mechanical maintenance of industrial plants. Apply to Box No. 1328-W.

MECHANICAL ENGINEER, recent grad. University of Toronto, B.A.Sc. in mech. engrg, 24 years old, S.E.I.C., now managing a chain store, desires engineering work. Present location So. Ontario. Location immaterial. Best of references. Apply to Box No. 1348-W.

South African Empire Exhibition

During the period from September to December 1936, a South African Exhibition, which will include displays from all parts of the Empire, will be held in Johannesburg, and in view of the anticipated number of visitors from overseas scientific, engineering and technical institutes, the Associated Scientific and Technical Societies of South Africa have agreed to arrange that the headquarters of the Societies, i.e., Kelvin House, Fox Street, Johannesburg, together with the organization of the Associated Societies, will be placed at the disposal of duly accredited visitors.

In general, it is proposed that all visitors from overseas institutes and societies could regard Kelvin House as their headquarters during their stay in Johannesburg, and avail themselves of the facilities provided by that organization to ensure that, in addition to visiting the Empire Exhibition, they would be able to meet members of the local Institutes, and be assured that they will be welcomed by their corresponding professional colleagues in the Union and be able to obtain all information and facilities during their visit.

All information regarding travelling and the facilities to be provided in Johannesburg are obtainable from the London Secretary of the South African Empire Exhibition at 21, Tothill Street, Westminster, London, S.W., or direct from the Head Office, P.O. Box 114, Johannesburg, Transvaal.

Special travel facilities will be afforded to exhibition visitors from overseas, of which the offices named above will be able to supply particulars in due course.

"Silver Jubilee" Train

The "Silver Jubilee" train of the London and North Eastern Railway was put into service as arranged recently. On the up journey running proved to be well inside the schedule, the train arriving at King's Cross three minutes ahead of time. On the down journey in the afternoon, the times were not quite so good, arrival at destination being two minutes late. The maximum speeds are said to have been 90 m.p.h. and 91 m.p.h. for the respective journeys. Prior to the first run on regular schedule, the train was given a special trial on Friday last, when a large number of special guests were on board. This only extended as far as Grantham, but this distance was, of course, ample for the purpose of showing what could be done. The whole run to Grantham (105 m. 37 ch.) was covered in 88 min. 15 sec. The highest speed attained was 112 m.p.h. at Sandy. A speed of 100 m.p.h. was first reached 30 miles out of London and for 25 miles subsequently over 100 m.p.h. was recorded. The distance over which a speed of more than 100 m.p.h. was averaged worked out at 43 miles, 25 miles averaging 107.5 m.p.h. From Wood Green to Fletton (at which the slack for Peterborough commences) the speed worked out at 91.8 m.p.h., and on the continuous up grade of 1 in 200 for 8 miles from Wood Green to Potters' Bar, the train accelerated from 70 m.p.h. to 75 m.p.h. So far as is known, the performances at over 100 m.p.h. constitute record runs, and Mr. Gresley and the railway company are to be heartily congratulated on the performance, more especially as it is understood there was still something substantial in hand, to meet vicissitudes of weather, etc.

—*Engineering.*

LIST OF MEMBERS

OF

THE ENGINEERING INSTITUTE OF CANADA

CORRECTED TO OCTOBER 15TH, 1935

(Names of members temporarily on the Non-Active List have not been included)

In the following list (†) prefixed to a name indicates the contributor of a paper published in the Transactions of The Institute; (*G*) prefixed to a name indicates the award of the Gzowski medal; (𝔎) prefixed to a name indicates the award of the Sir John Kennedy medal; (*L*) prefixed to a name indicates the award of the Leonard medal; (*P*) prefixed to a name indicates the award of the Plummer medal; (𝔓) prefixed to a name indicates the award of the Past-Presidents' prize; (*q*) prefixed to a name indicates admission under the special provisions of the Quebec Act; (♂) prefixed to a name indicates Service with Allied Armies.

HONORARY MEMBERS

HIS ROYAL HIGHNESS EDWARD, Prince of Wales, K.G. (*Hon.M. 1919*)

H.R.H. ARTHUR, Duke of Connaught, K.G., P.C., G.B.E. (*Hon.M. 1912*)

ADAMS, Frank D., Ph.D., D.Sc., F.G.S.A., F.R.S., 1173 Mountain St., Montreal, Que. (*Hon.M. 1922*)

BESSBOROUGH, The Right Hon. the Earl of, P.C., G.C.M.G., Stansted Park, Rowlands Castle, Sussex, England. (*Hon.M. 1931*)

CLARK, Arthur L., B.Sc., Ph.D., Dean of the Faculty of Applied Science, Queen's University, Kingston, Ont. (*Affil. 1920*) (*Hon.M. 1922*)

DEVONSHIRE, His Grace the Duke of, K.G., G.C.M.G., Chatsworth House, Derbyshire, England. (*Hon.M. 1917*)

WILLINGDON, His Excellency The Right Hon. the Earl of, P.C., G.C.S.I., G.C.M.G., G.C.I.E., G.B.E., Viceroy and Governor-General of India, Viceregal Lodge, Delhi, India. (*Hon.M. 1927*)

MEMBERS

ABBOTT, A. C., B.Sc., (McGill '26), Shawinigan Water & Power Co., Three Rivers, Que. (*H*) 677 St. Ursule St. (*S. 1925*) (*A.M. 1931*)

ABBOTT, Harold F., B.Sc., (McGill '28), Beauharnois Construction Co., Box 50, Beauharnois, Que. (*H*) Prince George, B.C. (*S. 1926*)

ABBOTT-SMITH, H. B., B.Sc., (McGill '23), Asst. Meter Engr., Shawinigan Water & Power Co., Power Bldg., Montreal, Que. (*H*) 3475 University St. (*S. 1923*) (*Jr. 1931*)

♂ABBOTT, Wm. Hamilton, Capt., M.C., address unknown. (*A.M. 1920*)

GEOGRAPHICAL LIST OF MEMBERS

CORRECTED TO OCTOBER 15th, 1935

(Names of Members temporarily on the Non-Active List have not been included)

ZONE A

(*The four Western Provinces.*)

Victoria Branch District

(*Vancouver Island and the Gulf Islands Tributary to Vancouver Island.*)

Albert Head (Br. Res.), MEMBER, J. H. Gray.

Cadboro Bay (Br. Res.), ASSOCIATE MEMBER, A. W. Ferguson.

Duncan (Br. Non-Res.), ASSOCIATE MEMBER, R. H. Vaughan.

East Sooke (Br. Res.), ASSOCIATE MEMBER, W. F. Wilson.

Headquarters (Br. Non-Res.), ASSOCIATE MEMBER, H. E. Stevens.

Nanaimo (Br. Non-Res.), ASSOCIATE MEMBER, A. G. Graham.

Saanich (Br. Res.), MEMBER, A. L. Ford.

Victoria (Br. Res.), MEMBERS, R. A. Bainbridge, A. L. Carruthers, E. Davis, J. S. Dennis, G. M. Duncan, C. W. Gamble, F. C. Green, J. E. Griffith, A. E. Hodgins, H. T. Hughes, G. M. Irwin, J. C. MacDonald, K. Moodie, G. P. Napier, F. J. O'Reilly, G. L. Stephens, H. L. Swan; ASSOCIATE MEMBERS, J. N. Anderson, I. C. Barltrop, J. H. Blake, W. N. Bostock, H. F. Bourne, E. C. G. Chambers, R. F. Davy, W. S. Drewry, M. J. Evans, R. C. Farrow, S. H. Frame, H. N. Gahan, A. J. Gray, E. I. W. Jardine, F. W. Knewstubb, D. MacBride, J. H. McIntosh, G. Phillips, L. W. Toms, G. M. Tripp, N. A. Yarrow; JUNIORS, W. M. Davidson, K. Reid, C. D. Schultz; STUDENTS, J. O. Johnson, W. S. B. Latta, M. C. Nesbitt, V. Wiebe.

Vancouver Branch District

(*The balance of British Columbia, except that allocated to Lethbridge Branch.*)

Atlin (Br. Non-Res.), ASSOCIATE MEMBER, A. M. Ross.

Bridge River (Br. Non-Res.), ASSOCIATE MEMBER, S. H. Davis.

Britannia Beach (Br. Non-Res.), ASSOCIATE MEMBER, G. W. Waddington.

Choate (Br. Non-Res.), ASSOCIATE MEMBER, H. L. Cairns; STUDENT, E. J. Merrett.

Deer Park (Br. Non-Res.), ASSOCIATE MEMBER, C. S. Moss.

Fort St. James (Br. Non-Res.), ASSOCIATE MEMBER, W. M. Ogilvie.

Kamloops (Br. Non-Res.), ASSOCIATE MEMBER, C. Varcoe.

Kelowna (Br. Non-Res.), MEMBERS, F. W. Groves, G. Stirling; ASSOCIATE MEMBER, D. K. Penfold.

Ladner (Br. Res.), ASSOCIATE MEMBER, C. E. Cooper.

Likely (Br. Non-Res.), ASSOCIATE MEMBER, W. B. Young.

Nelson (Br. Non-Res.), MEMBER, A. L. McCulloch; ASSOCIATE MEMBERS, J. P. Coates, H. R. Younger.

New Westminster (Br. Res.), MEMBERS, L. B. Elliot, J. P. Forde; ASSOCIATE MEMBERS, G. D. Dixon, W. E. Keyt, J. B. Lambert, G. MacLeod, F. O. Mills, C. Raley, E. Smith, G. N. Stowe; STUDENT, F. E. Ladner.

Ocean Falls (Br. Non-Res.), ASSOCIATE MEMBERS, H. M. Lewis, A. S. Mansbridge.

Oliver (Br. Non-Res.), ASSOCIATE MEMBER, D. G. McCrae.

Penticton (Br. Non-Res.), MEMBERS, F. H. Latimer, A. McCulloch, T. E. Naish; ASSOCIATE MEMBER, R. A. Barton.

Pouce Coupe (Br. Non-Res.), ASSOCIATE MEMBER, H. L. Hayne.

Powell River (Br. Non-Res.), MEMBER, W. Jamieson; ASSOCIATE MEMBERS, N. Beaton, R. Bell-Irving.

Prince Rupert (Br. Non-Res.), ASSOCIATE MEMBERS, W. L. Stamford, F. S. Walton.

Premier (Br. Non-Res.), JUNIOR, A. I. E. Gordon.

Rossland (Br. Non-Res.), MEMBER, A. E. Wright.

Salmo (Br. Non-Res.), ASSOCIATE MEMBER, I. M. Marshall.

Salmon Arm (Br. Non-Res.), ASSOCIATE MEMBER, V. J. Melsted.

Smithers (Br. Non-Res.), ASSOCIATE MEMBER, R. C. Davidson.

Squamish (Br. Non-Res.), ASSOCIATE MEMBERS, C. L. Bates, D. W. Hodsdon.

Trail (Br. Non-Res.), MEMBER, L. A. Campbell; ASSOCIATE MEMBERS, S. C. Montgomery, A. C. Ridgers, H. Vickers; JUNIOR, C. A. Broderick; STUDENTS, J. E. Craster, W. N. Papoff, R. J. Whitehouse.

Vancouver (Br. Res.), MEMBERS, W. Anderson, W. R. Bonnycastle, C. Brakenridge, P. P. Brown, P. H. Buchan, E. E. Carpenter, E. F. Carter, C. E. Cartwright, E. A. Cleveland, A. D. Creer, C. R. Crysdale, A. C. Eddy, A. E. Foreman, H. W. Frith, A. S. Gentles, G. M. Gilbert, H. Gisborne, J. R. Grant, J. P. Hodgson, N. J. Ker, W. L. Ketchen, F. Lee, D. O. Lewis, W. O. Marble, J. G. MacGregor, F. L. Macpherson, H. B. Muckleston, W. G. Murrin, W. H. Powell, H. Rindal, J. Robertson, W. Smaill, F. C. Stewart, L. Stockett, W. G. Swan, S. H. Sykes, E. C. Thrupp, G. A. Walkem, C. E. Webb, E. A. Wheatley, T. H. White, A. S. Wootton, A. C. R. Yuill; ASSOCIATE MEMBERS, H. P. Archibald, T. V. Berry, R. T. Blair, W. W. Brumby, J. E. Buerk, F. P. V. Cowley, A. W. G. Clark, W. R. Duckworth, W. P. Ferguson, H. C. Fitz-James, C. B. Freeman, W. B. Greig, C. T. Hamilton, J. B. Holdcroft, W. E. Jenkins, R. J. Lecky, J. McHugh, A. H. Macfarlane, J. P. Mackenzie, R. G. MacKenzie, H. N. Macpherson, F. O. Orr, J. B. Parham, A. Peebles, T. E. Price, R. Rome, P. Sandwell, P. M. Smith, W. O. Scott, G. L. Tooker, D. P. Urry, J. A. Walker, S. F. Workman, G. R. Wright; JUNIORS, C. R. Cornish, E. G. Cullwick, F. A. Forward, W. A. Madeley, R. C. Robson, W. H. Sparks; STUDENTS, E. Abernethy, D. E. Bell, E. R. Carswell, C. W. Deans, C. W. E. Locke, J. E. Macdonald, F. R. Phillips, J. A. Pike, A. G. Raue, J. M. Rothwell, H. L. Thorne, R. Walkem; AFFILIATE, G. E. Herrman.

Vernon (Br. Non-Res.), STUDENT, R. T. W. Allen.

Wells (Br. Non-Res.), STUDENT, T. H. Munn.

Williams Lake (Br. Non-Res.), ASSOCIATE MEMBER, W. Ramsay.

Woodfibre (Br. Non-Res.), ASSOCIATE MEMBERS, W. A. Bain, C. C. Ryan.

Yahk (Br. Non-Res.), STUDENTS, G. Eckenfelder, F. A. Lazenby.

Calgary Branch District

(*The territory in Alberta included between the north boundary of township thirteen from Saskatchewan to the British Columbia boundary, northerly on the interprovincial boundary to the north boundary of township forty-two; east to the east boundary of range twelve (west of the fourth meridian); south to the north boundary of township thirty-seven; east on the north boundary of township thirty-seven to the Saskatchewan boundary; and south on the interprovincial boundary to township thirteen.*)

Alexo (Br. Non-Res.), ASSOCIATE MEMBER, E. F. Pullen.

Banff (Br. Non-Res.), MEMBER, P. J. Jennings; ASSOCIATE MEMBER, C. K. LeCapelain.

Brooks (Br. Non-Res.), ASSOCIATE MEMBERS, H. G. Angell, C. C. Elliott.

Calgary (Br. Res.), MEMBERS, P. T. Bone, E. W. Bowness, M. P. Bridgland, F. G. Cross, A. S. Dawson, J. Dow, W. S. Fetherstonhaugh, A. Griffin, J. Haddin, R. C. Harris, D. W. Hays, O. H. Hoover, T. Lees, G. H. N. Monkman, J. H. Parks, S. G. Porter, F. M. Steel, J. S. Tempest, B. L. Thorne, J. R. Wood; ASSOCIATE MEMBERS, W. Anderson, E. Avery, F. G. Bird, G. P. F. Boese, R. L. Bonham, W. H. Broughton, A. S. Chapman, S. J. Davies, A. Dickson, F. S. Dyke, P. A. Fetterley, R. H. Goodchild, L. Green, J. J. Hanna, F. J. Heuperman, J. M. Ireton, M. W. Jennings, H. B. LeBourveau, A. W. P. Lowrie, A. T. McCormick, H. J. McEwen, W. T. McFarlane, R. Mackay, H. J. McLean, J. McMillan, W. St.J. Miller, H. H. Moore, V. A. Newhall, P. F. Peele, J. W. Reid, F. N. Rhodes, J. H. Ross, H. B. Sherman, G. H. Thompson, H. W. Tooker, D. T. Townsend, A. L. Tregillus, R. S. Trowsdale, J. H. Walshaw; JUNIORS, D. F. Becker, H. W. Becker, W. R. Davis, R. W. Dunlop, J. S. Neil, R. G. Paterson, W. A. Smith; STUDENTS, J. Blair, F. A. Brownie, A. C. Davidson, D. C. Fleming, A. W. Howard, E. Hulbert, C. L. Ingles, G. D. Kellam, G. G. D. Robertson.

Canmore (Br. Non-Res.), ASSOCIATE MEMBER, C. S. Dewis.

Didsbury (Br. Non-Res.), STUDENT, W. G. Sharp.

Exshaw (Br. Non-Res.), ASSOCIATE MEMBER, V. C. Hamilton.

High River (Br. Non-Res.), STUDENT, T. D. Stanley.

Nordegg (Br. Non-Res.), ASSOCIATE MEMBER, A. Cox.

Okotoks (Br. Non-Res.), STUDENT, D. V. McIntyre.

Patricia (Br. Non-Res.), ASSOCIATE MEMBER, H. B. Miller.

Seebe (Br. Non-Res.), JUNIOR, I. A. Abramson.

Strathmore (Br. Non-Res.), MEMBER, E. N. Ridley; ASSOCIATE MEMBERS, G. H. Patrick, T. Schulte.

Turner Valley (Br. Non-Res.), MEMBER, S. G. Coultis; STUDENT, J. E. Beach.

Edmonton Branch District

(*All the Province of Alberta north of the northern boundary of the Calgary Branch.*)

Alcomdale (Br. Non-Res.), JUNIOR, P. Hargrove.

Edmonton (Br. Res.), MEMBERS, J. D. Baker, F. K. Beach, J. Callaghan, L. C. Charlesworth, W. J. Dick, J. Garrett, A. J. Gayfer, R. J. Gibb, H. J. MacLeod, W. R. Mount, A. I. Payne, C. A. Robb, E. Stansfield, R. S. L. Wilson; ASSOCIATE MEMBERS, J. M. Anderson, H. A. Bowden, T. W. Brown, J. W. S Chappelle, W. E. Cornish, R. M Dingwall, J. H. W. Douglas, J. M. Forbes, M. L. Gale, C. E. Garnett, A. W. Haddow, D. A. Hansen, H. P. Keith, E. Nelson, V. Pearson, A. Ritchie, R. W. Ross, R. H. Stevens, W. G. Stuart, H. H. Tripp, H. R. Webb, T. H. White; JUNIORS, H. R. M. Acheson, R. M. Hardy, J. W. Porteous; STUDENTS, J. E. Cranswick, J. C. Dale, L. J. Ehly, E. R. Gayfer, W. J. Gold, W. G. Hole, H. L. Hurdle, K. A. Jackson, W. L. Kent, J. F. McDougall, R. C. McPherson, B. W. Pitfield, W. L. Redmond, G. Sinclair, E. L. Smith, R. L. Stevens, N. O. Weston, J. Woznow, F. J. Wyllie.

Jasper (Br. Non-Res.), MEMBER, A. C. Wright.

Manola (Br. Non-Res.), ASSOCIATE MEMBER, H. J. Whittaker.

Mayerthorpe (Br. Non-Res.), ASSOCIATE MEMBER, E. Hughes.

Peace River (Br. Non-Res.), ASSOCIATE MEMBER, J. H. Johnston.

Spedden (Br. Non-Res.), JUNIOR, J. P. Svarich.

St. Paul de Metis (Br. Non-Res.), MEMBER, M. W. Hopkins.

Sterco (Br. Non-Res.), ASSOCIATE MEMBER, W. F. Stevenson.

Vegreville (Br. Non-Res.), STUDENTS, J. G. MacGregor, E. H. Perlson.

Vermilion (Br. Non-Res.), ASSOCIATE MEMBER, B. E. Bury.

Lethbridge Branch District

(*The territory in Alberta and British Columbia included between the United States boundary from Saskatchewan to the 117th degree of longitude in British Columbia; north to the 50th parallel; east to the Alberta boundary; northerly on the interprovincial boundary to the north boundary of township thirteen in Alberta, east to the Saskatchewan boundary, and south on the interprovincial boundary to the United States boundary.*)

Coal Creek, B.C. (Br. Non-Res.), STUDENT, W. R. Workman.

Coaldale (Br. Res.), ASSOCIATE MEMBERS, R. S. Lawrence, H. W. Rowley.

Coalhurst (Br. Res.), ASSOCIATE MEMBER, D. H. Quigley.

Diamond City (Br. Res.), ASSOCIATE MEMBER, C. S. Clendening.

Etzikom (Br. Non-Res.), STUDENT, R. C. Davis.

Fernie, B.C. (Br. Non-Res.), ASSOCIATE MEMBER, G. E. Elkington.

Kimberley, B.C. (Br. Non-Res.), ASSOCIATE MEMBER, A. B. Ritchie; JUNIOR, G H. Morrison.

Lethbridge (Br. Res.), MEMBERS, J. B. deHart, G. N. Houston, R. Livingstone, P. M. Sauder; ASSOCIATE MEMBERS, R. F. P. Bowman, N. H. Bradley, G. S. Brown, J. M. Campbell, C. S. Donaldson, J. Haimes, W. L. McKenzie, S. F. McLeod, W. Meldrum, A. Thomson, J. T. Watson; STUDENTS, J. A. Burke, W. R. Craig, J. E. Hawkins, E. A. Lawrence, R. B. McKenzie.

Magrath (Br Res.), ASSOCIATE MEMBER, M. F. R Lloyd.

Medicine Hat (Br. Non-Res.), ASSOCIATE MEMBERS, A. C. Gardner, C. M. Moore; STUDENT, H. R. Hayes.

Monarch (Br. Res.), STUDENT, A. P. Alexander.

Picture Butte (Br. Res.), ASSOCIATE MEMBER, A. J. Branch.

Rainier (Br. Non-Res.), JUNIOR, W. Crook.

Saskatchewan Branch District

(*The Province of Saskatchewan.*)

Borden (Br. Non-Res.), STUDENT, D. Lazorka.

Carlyle (Br. Non-Res.), ASSOCIATE MEMBER, W. E. Denley.

Claybank (Br. Non-Res.), ASSOCIATE MEMBER, S. Matthews.

Dunblane (Br. Non-Res.), STUDENT, C. R. Forsberg.

Dundurn (Br. Non-Res.), Associate Members, W. P. Dempsey, C. J. L. Sanderson; Student, C. F. Dobson-Smith.

Hillmond (Br. Non-Res.), Student, W. C. Newman.

Indian Head (Br. Non-Res.), Student, A. H. Douglas.

Island Falls (Br. Non-Res.), Junior, E. C. King; Affiliate, H. T. Olson.

Kamsack (Br. Non-Res.), Associate Member, J. M. Bloomfield.

Lloydminster (Br. Non-Res.), Associate Member, S. E. Durant.

Lydden (Br. Non-Res.), Student, C. C. Schnedar.

Maple Creek (Br. Non-Res.), Member, W. W. Meadows.

Melville (Br. Non-Res.), Associate Member, H. M. Bailey.

Moose Jaw (Br. Non-Res.), Member, H. R. Miles; Associate Members, H. J. A. Bird, H. C. Ritchie; Junior, N. R. Crump.

Nipawin (Br. Non-Res.), Associate Member, N. A. Link.

North Battleford (Br. Non-Res.), Member, A. E. Sharpe.

Pelly (Br. Non-Res.), Student, W. Trischuk.

Prince Albert (Br. Non-Res.), Members, W. Christie, J. G. Reid.

Punnichy (Br. Non-Res.), Associate Member, S. Harding.

Regina (Br. Res.), Members, H. S. Carpenter, J. N. deStein, J. W. D. Farrell, A. C. Garner, A. P. Linton, D. A. R. McCannel, M. H. Marshall, P. C. Perry, L. A. Thornton, S. Young; Associate Members, R. W. Allen, E. S. C. Carpenter, D. C. M. Davies, E. A. Duschak, W. G. Dyer, G. G. Fitzgerald, R. J. Fyfe, P. R. Genders, W. H. Hastings, R. W. Jickling, H. A. Jones, E. E. Lord, P. G. McAra, C. J. McGavin, H. R. MacKenzie, J. C. Meade, S. R. Muirhead, R. H. Murray, J. M. Patton, J. H. Puntin, F. B. Reilly, H. L. Roblin, J. K. Sexton, M. J. Spratt, T. G. Tyrer, J. J. White; Juniors, A. F. S. Fuller, L. W. Llewellyn; Students, A. W. Braine, N. I. Fraser, G. B. Greene, L. M. Howe, W. N. McCann, J. E. Thom, J. Walter.

Ridgedale (Br. Non-Res.), Student, Z. Levington.

Rosetown (Br. Non-Res.), Associate Member, J. C. Todd.

Saskatoon (Br. Non-Res.), Members, A. R. Greig, C. J. Mackenzie, W. G. Worcester; Associate Members, I. M. Fraser, W. E. Lovell, A. M. Macgillivray, R. A. Spencer, G. M. Williams; Juniors, E. J. Durnin, F. J. E. Martin, E. K. Phillips.

Swift Current (Br. Non-Res.), Member, B. Russell; Juniors, J. C. Aitkens, F. L. Grindley.

Theodore (Br. Non-Res.), Student, G. S. Anderson.

Tisdale (Br. Non-Res.), Student, J. E. Mollard.

Weyburn (Br. Non-Res.), Associate Member, H. J. deSavigny.

Yorkton (Br. Non-Res.), Associate Member, M. Sinclair.

Winnipeg Branch District

(*The Province of Manitoba.*)

Ashern (Br. Non-Res.), Student, L. J. Marshall.

Boissevain (Br. Non-Res.), Associate Member, J. A. Wakefield.

Brandon (Br. Non-Res.), Member, W. H. Shillinglaw; Associate Members, J. P. Fraser, T. J. Pounder, S. C. Wilcox.

Brunkild (Br. Non-Res.), Associate Member, F. E. Umphrey.

Churchill (Br. Non-Res.), Associate Members, G. Coutts, G. Kydd, W. L. Mackenzie.

Cranberry Portage (Br. Non-Res.), Member, W. T. Thompson.

Dauphin (Br. Non-Res.), Associate Member, R. C. Robinson.

Flin Flon (Br. Non-Res.), Juniors, W. L. Bunting, L. W. McClure; Students, R. H. Moore, M. K. T. Reikie.

Fort Whyte (Br. Res.), Associate Member, C. W. Edmonds.

Garson (Br. Non-Res.), Associate Member, C. H. Blanchard.

God's Lake (Br. Non-Res.), Associate Member, W. M. Reynolds.

Lydiatt (Br. Non-Res.), Member, W. A. James.

Lyleton (Br. Non-Res.), Junior, W. G. Reekie.

Morden (Br. Non-Res.), Junior, R. A. Emerson.

Norwood (Br. Res.), Associate Member, F. B. Hazel; Student, R. P. Fraser.

Pointe du Bois (Br. Non-Res.), Junior, T. E. Storey.

Reston (Br. Non-Res.), Associate Member, D. A. Livingston.

St. Boniface (Br. Res.), Junior, W. R. C. Taylor.

Selkirk (Br. Res.), Student, C. H. Martin.

Seven Sisters Falls (Br. Non-Res.), Associate Members, V. W. Dick, A. S. Williams.

The Pas (Br. Non-Res.), Associate Members, F. P. Fuller, J. G. MacLachlan.

Transcona (Br. Res.), Student, L. E. Jones.

Virden (Br. Non-Res.), Associate Members, H. D. Brydone-Jack, G. R. Hill.

Winckler (Br. Non-Res.), Student, H. F. Peters.

Winnipeg (Br. Res.), Members, F. W. Alexander, W. P. Brereton, W. Burns, E. V. Caton, C. H. Dancer, J. A. Douglas, L. L. Doupe, C. Ewart, E. P. Fetherstonhaugh, J. N. Finlayson, A. W. Fosness, C. H. Fox, F. G. Goodspeed, N. M. Hall, H. B. Henderson, G. H. Herriot, J. C. Holden, T. Kipp, D. A. MacDougall, W. M. Macphail, W. A. Mather, V. Michie, E. R. Millidge, J. W. Porter, D. A. Ross, W. M. Scott, F. V. Seibert, D. N. Sharpe, A. J. Sill, J. G. Sullivan, F. B. Tapley, J. Woodman; Associate Members, G. Affleck, R. H. Andrews, C. H. Attwood, C. T. Barnes, E. A. Beman, H. B. Brehaut, F. M. Brickenden, H. C. D. Briercliffe, H. L. Briggs, A. Campbell, G. W. Campbell, V. H. Campbell, A. L. Cavanagh, J. L. Charles, G. Clark, C. A. Clendening, G. E. Cole, J. F. Cunningham, H. A. Dixon, J. E. Duncan, J. H. Edgar, E. G. Eggertson, F. S. Fowler, W. Fulton, J. Gordon, J. L. Gordon, F. F. Griffin, C. H. Gunn, C. P. Haltalin, S. G. Harknett, B. Henderson, W. E. Hobbs, B. B. Hogarth, L. M. Hovey, W. D. Hurst, E. W. M. James, V. C. Jones, C. E. Joslyn, E. S. Kent, T. H. Kirby, A. M. Kirkpatrick, H. C. G. Ligertwood, C. R. Lys, G. B. McColl, S. E. McColl, G. McDermid, A. E. Macdonald, J. A. MacGillivray, W. J. MacKenzie, R. W. McKinnon, D. L. McLean, H. W. McLeod, T. C. Main, R. W. Moffatt, W. F. Oldham, A. W. Paterson, E. B. Patterson, G. M. Pearston, J. D. Peart, W. D. Pender, B. L. Reid, E. M. Rensaa, J. T. Rose, J. D. Ruttan, J. W. Sanger, G. L. Shanks, H. L. Sherwood, D. M. Stephens, D. G. Sutherland, A. J. Taunton, A. Taylor, J. C. Trueman, J. Veitch, W. Walkden, A. S. Weekes, H. M. White, J. Young; Juniors, E. W. R. Butler, H. D. Cluff, J. L. McMahon, H. Payne, W. F. Riddell, J. B. Striowski, C. J. Timleck; Students, C. V. Antenbring, G. S. Baldry, E. S. Braddell, N. S. Bubbis, W. A. Capelle, A. B. Connelly, A. G. Courtney, B. H. Darwin, D. M. Dunlop, E. Gauer, G. H. Griffiths, T. L. Hall, E. L. Hartley, R. P. Henderson, W. C. Houghton, J. Howorth, M. Levin, K. Y. Lochhead, E. R. Love, G. M. Lyon, J. R. Mathieson, D. W. Miller, W. R. Mitchell, H. Nelson, L. G. Scott, H. G. Seybold, C. G. Wallman, D. H. Watson, F. Willows, T. L. Woodhall; Affiliate, W. Hurst.

ZONE B

(*The Province of Ontario*)

Lakehead Branch District

(*The Counties of Kenora, Thunder Bay, Rainy River, Patricia.*)

Dryden (Br. Non-Res.), Member, J. S. Wilson; Junior, H. J. Petursson.

Fort Francis (Br. Non-Res.), Associate Member, W. B. Hutcheson.

Fort William (Br. Res.), Member, P. E. Doncaster; Associate Members, G. P. Brophy, G. R. Duncan, K. A. Dunphy, H. G. O'Leary, C. B. Symes; Students, J. I. Carmichael, G. G. DeMocko, G. R. Duncan.

Gold Pines (Br. Non-Res.), Associate Member, F. C. Rust.

Hawk Lake (Br. Non-Res.), Associate Member, F. Petursson.

Hudson (Br. Non-Res.), Associate Member, G. G. McEwen.

Ignace (Br. Non-Res.), Associate Member, F. D. Austin.

Kenora (Br. Non-Res.), Members, E. A. Kelly, C. D. MacKintosh; Associate Members, J. F. Lester, J. A. McCoubrey, J. R. Paget; Junior, R. O. Paulsen.

Nakina (Br. Non-Res.), Associate Member, W. E. Harry.

Port Arthur (Br. Res.), Members, J. Antonisen, G. H. Burbidge, R. B. Chandler, C. D. Howe; Associate Members, R. J. Askin, E. J. Bolger, B. A. Culpeper, G. Eriksen, J. M. Fleming, E. L. Goodall, F. C. Graham, G. R. McLennan, H. Os; Students, W. H. Peach, J. A. Rogers.

Red Lake (Br. Non-Res.), Student, G. L. Hood.

Root River Portage (Br. Non-Res.), Associate Member, C. M. Low.

Schreiber (Br. Non-Res.), Associate Member, W. W. Benny; Student, W. R. Benny.

Sioux Lookout (Br. Non-Res.), Associate Member, H. A. Oaks.

White River (Br. Non-Res.). Associate Member. W. J. Bishop.

Sault Ste. Marie Branch District

(*The Counties of Algoma, Cochrane, Nipissing (north of the Mattawa River), Sudbury (including Manitoulin Island), Timiskaming, Ont., and the area in the United States within a radius of twenty-five miles of Sault Ste. Marie.*)

Burlington (Br. Res.), Associate Members, C. E. Hogarth, E. L. Zealand.
Dundas (Br. Res.), Member, H. G. Bertram; Junior, M. W. Huggins; Students, J. E. Gordon, L. S. Lauchland, W. M. Robinson; Affiliate, J. F. Crowley.
Fergus (Br. Non.Res.), Student, J. A. Fisher.
Galt (Br. Res.), Student, E. B. Hymmen.
Guelph (Br. Non-Res.), Members, L. E. Jones, F. MeArthur; Associate Members, E. P. Bowman, W. H. Keith, H. S. Nicklin; Student, D. R. McQueen.
Hagersville (Br. Non-Res.), Student, J. S. Green.
Hamilton (Br. Res.), Members, W. D. Black, J. B. Carswell, G. A. Colhoun, E. H. Darling, L. W. Gill, H. U. Hart, W. G. Hewson, W. Hollingworth, F. I. Ker, R. L. Latham, A. Love, H. A. Lumsden, J. A. McFarlane, W. L. McFaul, J. J. Mackay, W. F. McLaren, C. D. Meals, W. G. Milne, E. P. Muntz, R. K. Palmer, F. W. Paulin, A. T. Perrin, H. S. Philips, H. A. Ricker, J. Stodart, H. B. Stuart, J. W. Tyrrell; Associate Members, G. W. Arnold, G. M. Bayne, R. E. Butt, D. W. Callander, E. M. Coles, W. H. Collins, E. D. W. Courtice, J. R. Dunbar, H. M. Fletcher, W. B. Ford, T. S. Glover, J. P. Gordon, E. Haggas, A. R. Hannaford, F. W. Hubbard, F. R. Leadley, O. E. Leger, E. G. MacKay, W. L. Miller, G. Moes, J. C. Nash, W. J. W. Reid, A. G. Riddell, F. L. Smith, V. S. Thompson, W. W. Van Every, N. Wagner, C. W. Webster, C. F. Whitton; Juniors, W. E. Brown, A. B. Dove, G. G. Gates, W. A. T. Gilmour, A. F. McPherson, A. Pottinger, C. C. Smith, W. J. Thomson, J. T. Thwaites; Students, S. M. Baker, G. M. Bell, D. E Bridge, L. S. Collison, H. G. Conn, H. P. Dickey, J. L. Donaldson, R. A. Harvie, E. C. Hay, J. R. Hutton, A. E Hyde, E. P. N. Innes, G. W. Jarvis, D. B. Leightner, J. E. McClung, W. L. McKiel, H. F. McLachlan, G. Pilkey, W. W. Preston, R. W. Price, A. G. Scobie, R. N. Tucker, A. J. Turner, D. W. Wood; Affiliate, J. A. M. Galilee.
Kitchener (Br. Non-Res.), Members, W. H. Breithaupt, S. Shupe; Associate Members, C. L. Breithaupt, P. W. Breithaupt, E. L. Dilworth, D. J. Emrey, M. Pequegnat; Juniors, G. R. Beavers, W. M. Prudham; Students, J. H. Gregory, L. D. McGee, J. M. Pequegnat.
Preston (Br. Non-Res.), Member, F. H. Midgley.
Simcoe (Br. Non-Res.), Associate Members, C. H. Donnelly, J. F. LaPlant, G. R. Marston.
Waterloo (Br. Non-Res.), Associate Member, A. M. Snider.

Niagara Peninsula Branch District

(The Counties of Lincoln, Welland, and the area in the United States within a radius of twenty-five miles of Niagara Falls, Ontario.)

Buffalo, N.Y. (Br. Non-Res.), Member, N. R. Gibson; Associate Members, J. D. Burbank, H. D. Fyfe.
Chippawa (Br. Res.), Associate Member, G. C. Mountford.
Fort Erie (Br. Res.), Member, C. H. Scheman.
Fort Erie North (Br. Res.), Associate Members, C. S. Boyd, L. C. McMurtry, W. R. Manock.
Grimsby (Br. Non-Res.), Associate Member, G. F. Hanning.
Niagara Falls, N.Y. (Br. Res.), Member, C. J. H. Moritz; Associate Member, J. H. Legg; Student, A. C. Knapp.
Niagara Falls, Ont. (Br. Res.), Members, H. G. Acres, H. L. Bucke, R. L. Hearn. J. H. Jackson, W. Jackson, H. M. King; Associate Members, T. A. Barnett, J. R. Bond, W. D. Bracken, C. G. Cline, G. H. E. Dennison, P. A. Dewey, A. M. Fennis, L. L. Gisborne, M. F. Ker, J. M. Kilkenny, A. A. McLaren, A. W. F. McQueen, J. L. Miller, W. B. Musgrave, G. H. Wood; Junior, A. M. MacDonald; Students, K. L. Bellamy, F. S. Durdan, G. D. Durham, L. A. Hilton.
Port Colborne (Br. Res.), Associate Members, C. N. Geale, E. C. Little, E. P. Murphy; Junior, A. C. Harvie.
Port Robinson (Br. Res.), Associate Member, J. E. Sears.
Ridgeway (Br. Non-Res.), Student, A. C. Ellsworth.
St. Catharines (Br. Res.), Members, M. B. Atkinson, A. J. Grant, L. P. Rundle, F. E. Sterns, W. H. Sullivan, G. F. Vollmer; Associate Members, A. C. Blue, R. A. Bradley, E. G. Cameron, H. M. Campbell, W. Campion, H. S. Clark. J. V. Fahey, E. Grummitt, S. Hairsine, A. G. Herr, F. C. Jewett, M. H. Jones, R. V. H. Keating, J. B. McAndrew, A. L. McPhail, H. C. Maguire, C. G. Moon, J. C. Moyer, A. H. Perry, W. T. Porter, C. W West; Junior, J. F. Shelton; Student, D. D. Hall.
Thorold (Br. Res.), Associate Members, S. Bowen, P. E. Buss, G. E. Griffiths, C. B. Shaw.

Welland (Br. Res.), Members, F. L. Haviland, G. Morrison, J. C. Street, H. Wellwood; Associate Members, C. H. M. Burns, N. K. Cameron, E. P. Johnson, J. Stephenson; Student, R. T. Sawle.

Toronto Branch District

(The Counties of Ontario, York, Peel, Halton East (Townships of Trafalgar and Esquesing), Dufferin, Grey, Simcoe, Muskoka, Parry Sound, Nipissing (south of Mattawa River).)

Aurora (Br. Res.), Student, C. G. Southmayd.
Barrie (Br. Non-Res.), Associate Member, J. Walker.
Birch Cliff (Br. Res.), Associate Member, R. Harrison.
Brampton (Br. Res.), Associate Member, W. P. Dale.
Burk's Falls (Br. Non-Res.), Student, W. V. Rintoul.
Camp Borden (Br. Non-Res.), Associate Member, D. C. M. Hume; Juniors, W. O. Peffers, W. S. Wishart; Students, C. R. Dunlap, H. B. Godwin, M. M. Hendrick, A. C. Herbert, E. A. McGowan, D. E. McIntosh, D. G. Williams.
Clarkson (Br. Res.), Member, A. S. Cook.
Emsdale (Br. Non-Res.), Associate Member, J. H. Ings.
Forest Hill Village (Br. Res.), Associate Member, G. Alison; Student, B. B. Puddy.
Lakeview (Br. Res.), Member, H. M. Cawthra-Elliot.
Leaside (Br. Res.), Member, H. Horsfall; Associate Member, J. R. Roberts; Junior, W. H. Hooper.
Long Branch (Br. Res.), Associate Member, J. S. Galletley; Junior, J. A. C. Bowen.
Mono Road (Br. Res.), Associate Member, J. E. Hinchliffe.
Mount Dennis (Br. Res.), Member, A. B. Cooper.
Nobel (Br. Non-Res.), Student, R. B. Carpenter.
Oakville (Br. Res.), Member, C. Johnston; Associate Member, C. Connell.
Orillia (Br. Non-Res.), Associate Member, L. G. McNeice.
Oshawa (Br. Non-Res.), Associate Member, F. Chappell; Student, W. O. Hart.
Owen Sound (Br. Non-Res.), Associate Members, N. Bowman, T. D. Kennedy, R. McDowall, R. C. McKnight.
Pickering (Br. Res.), Member, W. A. McLean.
Port Carling (Br. Non-Res.), Student, K. W. MacDermott.
Port Elgin (Br. Non-Res.), Junior, C. G. E. Feick.
Sheridan (Br. Non-Res.), Student, S. N. Lawrence.
Stouffville (Br. Non-Res.), Student, M. R. Lemon.
Sundridge (Br. Non-Res.), Associate Member, T. J. Paget.
Toronto (Br. Res.), Members, A. Aeberli, E. A. Allcut, J. R. W. Ambrose, R. W. Angus, H. W. D. Armstrong, T. S. Armstrong, R. A. Baldwin, J. H. Barber, F. J. Bell, A. E. Berry, A. W. K. Billings, H. Modern Sewage Treatment

With Particular Reference to Conditions in the City of Winnipeg

W. D. Hurst, A.M.E.I.C.,

Assistant Engineer, in charge of Waterworks, City of Winnipeg, Man., and Secretary, Board of Engineers, Greater Winnipeg Sanitary District.

Paper presented before the Winnipeg Branch of The Engineering Institute of Canada, April 18th, 1935.

SUMMARY.—The sewage problem in the city of Winnipeg is now being dealt with, and the author, after outlining the existing conditions and the possible means of treatment, describes the progress made to date on the construction of the new secondary sewers, interceptor and pumping and treatment plant.

In 1932 Mr. S. W. Lea, M.E.I.C., consulting engineer, of Montreal, reported to the city of Winnipeg on the problem of sewage disposal, and the need of a proper system of disposal is covered in his first report, hence its desirability will not be discussed here. In this paper Greater Winnipeg refers to the cities of Winnipeg and St. Boniface, the towns of Tuxedo and Transcona, and the rural municipalities of East and West Kildonan, Fort Garry, St. Vital and St. James. Greater Winnipeg has a population of roughly two hundred and seventy-five thousand inhabitants, and the sewage from this population is discharged without treatment by forty-nine public outlets into the Assiniboine and Red rivers. In addition to this there are a dozen private industrial outlets.

Sewage

Sewage usually consists of the spent water supply of a community containing solids of animal and vegetable origin from the kitchens and bathrooms, and in some systems surface water from the streets, as well as wastes from industrial and commercial establishments. The wastes from industrial establishments are usually considerably stronger than domestic sewage, and are more difficult to handle at the treatment plant.

There are two general systems in use for the handling of wastes—

(1) The dry carriage system.
(2) The water carriage system.

The dry carriage system has largely disappeared on this continent except in isolated dwellings and villages.

The water carriage system is sanitary, and removes household wastes quickly and economically to the point of disposal.

Reasons for Treatment.

One reason why sewage is treated is because it may and usually does contain the germs of serious intestinal diseases such as typhoid fever, dysentery, both amoebic and bacillery, cholera, etc. In one million pounds of sewage (100,000 gallons) there is contained 800 pounds of solids (dry weight) 400 pounds of which is organic matter, and it is this 400 pounds of organic matter that gives rise to the main problem of sewage disposal.

This organic matter is eventually broken down by bacteria and micro-organisms into inert matter. When the decomposition takes place in contact with oxygen, nuisance is not caused, but in the absence of oxygen putrefaction is set up.

The discharge of sewage into a body of water may be objectionable for two main reasons:—

It may constitute a menace to health through bathing, and through the use of ice and by drinking water from the polluted waters. It can also result in the destruction of fish life.

It may constitute a nuisance for aesthetic reasons, due to the decomposition of the sewage, resulting in foul odours and discoloration of the waters, as well as the unsightly appearance of sewage solids floating on the surface.

The solids referred to above may be classified as follows:

(1) *Floating solids.* These solids are apt to be strewn on the shores, or be entangled in aquatic plants near shore, and form a decomposing slime objectionable to sight and smell.

(2) *Settling solids.* If the velocity of the receiving stream is low enough the heavier organic solids will settle and form sludge banks which decompose, forming gas which carries the rotting sludge to the surface, the process repeating itself over and over.

(3) *Solids in solution.* The solids referred to above represent less than one-half of the organic matter. The remainder is in solution, and it can neither be screened nor settled out of the sewage, and because of its finely divided state has proceeded further toward decomposition than the floating or settling solids, and is a heavy consumer of the oxygen held in solution in the receiving body of water.

Oxygen Content of Water.

The whole problem then resolves itself as follows: If there is sufficient oxygen in solution in the receiving body of water, or if it can be replenished fast enough by atmospheric reaeration, no nuisance will result. The nuisance incidence is determined by four factors:—

Volume and character of the sewage discharged.

Volume and character of the water available for dilution.

The velocity of the receiving body.

The temperature of the receiving body of water.

Now to consider these factors as they apply to the local situation.

There are discharged from the sewers of Greater Winnipeg each day roughly eighteen million gallons of sewage into the Red and Assiniboine rivers. The sewage from several of the outlets is in a septic condition when it is empt'ed into the rivers, and contains large quantities of industrial wastes.

There has already been much said of the decreasing flow of these rivers, and any determination as to whether the river or receiving body is capable of handling the sewage delivered is a complicated problem, but an approximate way of getting at this important factor is by the so-called dilution ratio. This is expressed in terms of c.f.s. per one thousand of the contributing population. Modern practice states that if the flow of a stream is less than 3.5 c.f.s. per one thousand persons discharging into it, a nuisance more or less widespread is the rule rather than the exception.

Dilution Ratios c.f.s. per 1,000 Population for Various Months from 1913 to Date for the Red River at Louise Bridge

	Jan.	Feb.	Aug.	Sept.	Oct.	Dec.
1913	4.8	3.4	24.0	16.4	12.4	5.4
1914	4.6	4.4	9.8	8.9	9.7	4.6
1915	4.5	4.3	17.2	10.7	11.0	7.8
1916	5.0	4.5	33.5	25.8	20.7	10.0
1917	7.2	6.1	9.2	5.8	6.5	4.2
1918	1.6	1.6	7.2	6.7	4.4	3.9
1919	3.4	3.0	23.7	11.2	9.0	4.0
1920	4.6	4.9	11.9	8.3	8.5	6.1
1921	4.4	4.1	8.9	9.9	13.0	7.8
1922	4.5	3.0	10.2	7.8	6.7	4.2
1923	3.2	3.1	19.4	10.5	8.9	6.3
1924	2.8	2.7	7.0	5.7	7.9	3.2
1925	1.9	1.9	7.6	5.9	7.8	5.0
1926	3.2	3.3	4.6	5.4	8.7	4.5
1927	3.5	3.1	19.8	15.6	16.2	6.3
1928	4.9	4.6	20.2	18.0	13.4	6.3
1929	5.4	4.8	3.6	2.7	3.4	2.5
1930	1.8	1.5	3.5	2.4	2.5	1.8
1931	1.6	1.6	1.7	1.6	1.9	4.9
1932	1.1	0.9	1.6	1.5	1.9	1.0
1933	0.8	0.7	2.0	1.3	1.2	1.1
1934	1.0	1.0	1.0	0.8	1.2	0.7
1935	0.4	0.6	...	...	...	...

This table shows that during the months of August, September and October, from 1913 to date, the dilution afforded by the rivers has for sixteen months been less than that required to prevent nuisance. Curiously enough these sixteen months are all after 1928. They also show that during the months of December, January and February from 1913 to date, the dilution afforded by the rivers has for thirty-one months been less than that required to prevent nuisance. Sixteen of these thirty-one months are after 1928.

The following criteria have been established regarding the character of the water available for dilution.

If the free ammon'a exceeds one-half part per million, the receiving body is likely to cause nuisance. Similarly if the dissolved oxygen falls below 50 per cent of the saturation value, nuisance can also be expected.

The British Royal Commission on Sewage Disposal stated that if the stream water could take more than 4 p.p.m., dissolved oxygen nuisance would likely be caused. In this country this is referred to as bio-chemical demand, abbreviated b.o.d.

In 1931 Mr. Archibald Blackie, city chemist, made determinations of these and other factors affecting the situation and the McCrady Memorandum tabulated them. These results have been prepared in graph form in order that they may be visualized more easily.

The third important consideration is the velocity of the receiving body of water. Velocities of the order of 0.15 foot per second will reduce by sedimentation 50 per cent of the suspended solids of average sewage in twelve hours. During the period July-September 1931, the velocity of the Assiniboine river averaged 0.25 f.p.s. while the Red averaged but 0.07 f.p.s. It took thirty-three hours to transport the sewage from Aubrey street to the junction of the Assiniboine and Red and one hundred hours additional to carry it to St. Johns Park. Two hundred and ninety-five hours were required to transport sewage from the civic hospitals

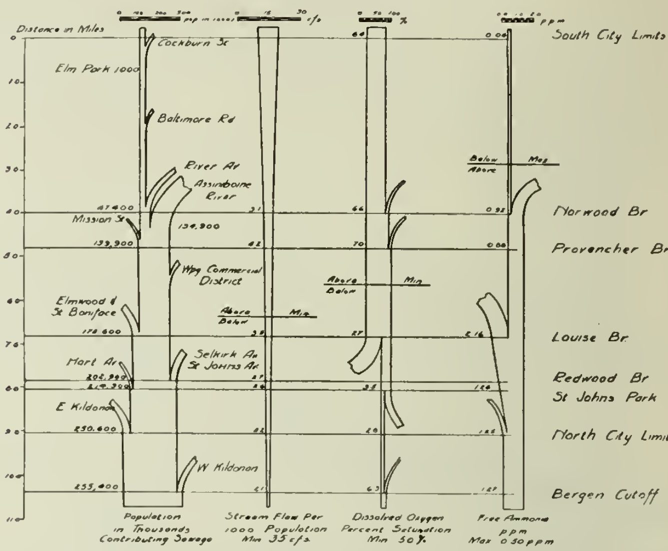

Fig. 1—Population Contributing Sewage and Extent of Pollution of Red River.

to St. Johns Park. Hence one can fully expect to have somewhere in the vicinity of 50 per cent of the suspended solids in the sewage deposited on the river bottoms before it gets out of Winnipeg.

The temperature of the receiving body of water governs the speed of the biological action of bacteria and other organisms on the organic matter contained in the sewage. It is also a fact that water is capable at low temperature of holding more oxygen in solution than at high temperatures, and hence nuisance is not so readily set up if the water is cold. However as the water freezes, the ice cover prevents the water from taking up oxygen from the air, and hence putrefaction starts again when the oxygen is exhausted.

Dr. McCrady has summed up the local situation very well. He states in his memorandum:

"The condition of the rivers may be described as follows:—

Gross pollution, during the late summer, prolonged in duration until the latter part of the month of October.

Reduced pollution, during the period of change from summer to winter conditions, by reason of autumn rains and falling temperatures. This stage was completed about the first week in December.

Increasing pollution under winter conditions of resumption of restricted stream flow, and prevention of reaeration by the ice cover."

General Means of Treatment.

There are two general methods of treatment where outlets are scattered along many miles of river bank:

(1) Individual treatment plants at trunk sewer outlets.

(2) One or more large treatment plants with intercepting sewers leading to them.

(3) A combination of these methods.

Mr. Lea reported on this subject in September 1934, and recommended the interceptor and single treatment plant.

The city then is faced with the design of a proper interceptor. Here, too, there is the choice of three general types:

(1) Gravity interceptor.

(2) Pressure interceptor with pumping stations at each outlet.

(3) A combination of both types.

The engineers are considering what scheme will be the most economical to build and operate as well as be the most practical.

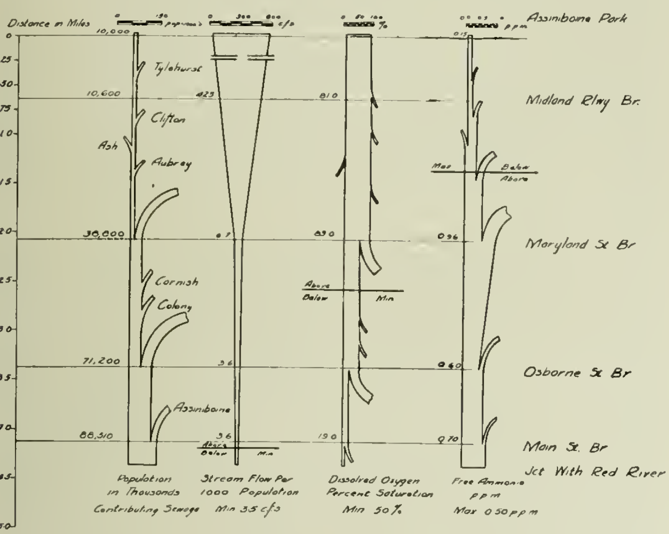

Fig. 2—Population Contributing Sewage and Extent of Pollution of Assiniboine River.

The interceptor according to the present proposal starts near Aubrey street, picks up Ash street sewer discharge by inverted syphon, follows east on Wolseley avenue to Furby street, picks up Cornish sewer discharge, runs up Furby street to Broadway, runs east on Broadway, picks up Colony street sewer discharge, at Main street picks up sewer discharges from Assiniboine avenue, River avenue, Jessie avenue and Marion street sewers.

The route then follows Main street to beyond the north city limits of Winnipeg picking up the discharge from the following sewers:

Bannatyne, Robert, Mission, Orleans, Boyle, Syndicate, Selkirk, St. John's, Hart avenue and Polson avenue. The secondaries from Mission, Orleans and Hart avenue sewers cross the river by inverted syphons.

The depth of the interceptor at Aubrey street is twenty feet from surface of ground to invert, and at the plant forty-eight feet. At this depth provision has been made for the extension of the sewer westward into St. James municipality of such a size as to amply take care of the increase in population. At Aubrey street the interceptor is four feet diameter, it increases in diameter to seven and a half feet at the treatment plant.

It is not proposed to extend this system further south than Jessie avenue.

PART II

Sewage treatment is in reality a problem in classification. The following solids are found in sewage:

Class I Rags, skins, wood, paper, hair.
This class can be incinerated or disposed of without nuisance or odour.

Class II Coal, sand, grit and other inert matter.
These cause no odour troubles.

Class III Organic solids, consisting of fecal matter, kitchen wastes both of animal and vegetable origin, and usually of small size.
This matter is apt to cause nuisance, and cannot be detained long in the vicinity of human habitation.

Sewage practice may vary in detail of application, but the basic principles are the same, and are universally accepted. Purification of sewage can be correctly regarded as artificial adaptation of natural processes. Modern treatment has been so thoroughly developed that if the treatment units are properly selected, and the sequence is proper any desired degree of treatment may be obtained.

This all sounds very simple, but such is not the case. The degree of refinement to which the process should be carried is a matter of great importance. This usually depends on the following things among others:

Danger to health of persons using the receiving body.

The value of the stream for ice harvesting, oyster beds, fisheries.

The water supplies taken from the stream below the point of discharge.

The sites available for treatment plants.

The type of sewage and its condition.

The Provincial or State Board of Health usually decides after thorough study of the problem what strength of effluent they will permit to be discharged into the receiving body.

To obtain a plant that will be economical in first cost and in operation, free from operating troubles, and will produce a thoroughly satisfactory effluent requires the judgment of the specialist in sewage treatment. This branch of sanitary science is changing so rapidly from day to day that the average engineer cannot hope to keep abreast

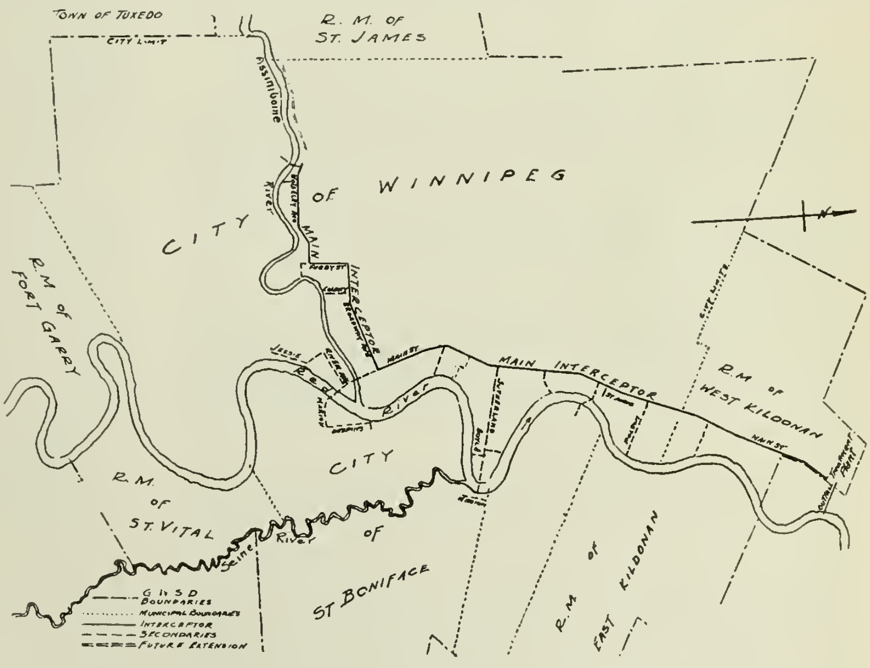

Fig. 3—Proposed Sewerage System for Greater Winnipeg Sanitary District.

of the changes in the biological, chemical, bacterial and mechanical factors.

PRIMARY TREATMENT

The first piece of mechanism usually encountered in a sewage treatment plant is the coarse bar screen. This consists of bars usually placed from ½ inch to 2 inches apart, and is simply a barrier placed in the flow of the sewage to intercept large solids. These racks may be fixed or movable, and either cleaned by hand or mechanically. The material taken from these screens may be burned or hauled away. The screenings usually amount to from 1 to 6 cubic feet per million gallons.

Grit Removal.

The next problem in classification is the removal of sand, grit, and other inert solids. If the velocity of flow is reduced sufficiently, these solids will settle out. The velocity usually adopted is one foot per second. This will allow the grit to settle, but is not low enough to cause the organic matter to settle out. It is only necessary, therefore, to widen out the sewer into tank form. The length of the chambers is governed by the amount of grit to be stored, but is usually fixed by making the detention period one minute.

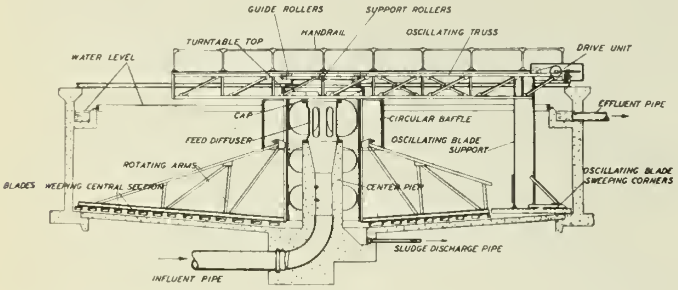

Fig. 4a—Dorr Siphon Feed and Traction Drive Clarifier.*

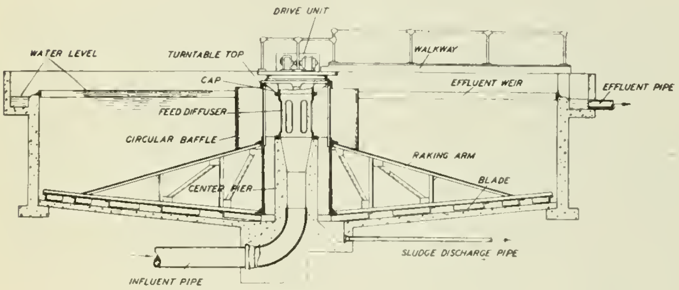

Fig. 4b—Dorr Siphon Feed and Central Drive Clarifier.*

Grease Catchers.

With the advent of the motor car more oil and grease have been discharged into municipal sewers. The oil and grease have a bad effect on treatment processes, and therefore should be removed. Tanks with skimming mechanism and provided with air agitation are now widely used, and solve the problem very well.

Detritors.

The Dorr detritor is an ingenious mechanically cleaned grit chamber. The movement of the grit is outward, and ploughs mounted on four revolving radial arms carry the grit to the inclined channel along one side of the chamber. Here it is picked up by a reciprocator which washes the grit, and at the same time it is pushed up an incline and out of the tank. While passing up the incline any organic solids are separated from the grit and carried back to the basin through a special opening. It is claimed that the discharged grit contains less than 5 per cent of organic matter, in which state it remains free from odour and can be used for filling without risk of offence.

Clarification.

The next step in the process of classification is the removal of the settleable organic solids in the sewage. These are the most difficult to remove due to their small size and their tendency to decompose, and to cause odours. A few years ago one popular method to remove these organic solids was that of fine screening, but this method is rapidly disappearing in favour of settling tanks which are much more effective and efficient.

Fine Screening.

Fine screens consist of perforated metal plates or wire mesh with opening of 3/64 inch to 3/32 inch, and are practically all of the movable type, and are either machine cleaned or self-cleaning. One advantage of screens is the small space required for screening works, but the most important disadvantage is the character of the screenings. Objectionable odours are almost inevitable if the screenings are not buried or incinerated. Another method of getting rid of them is to mix them with ripe sludge, and allow them to digest in sludge digesting tanks.

Settling Basins.

Better than screens is a reduction of velocity causing settlement in tanks where the organic solids may be removed mechanically or by hand. The principle is the same as in the grit chamber, namely, an enlargement of the sewer into tank form where the bulk of the solids which are of a higher specific gravity than water will settle. In order to assist the very fine solids and those in solution to settle, chemicals which form a floc are sometimes added. Before this is resorted to careful study should be given to the whole problem as there may be more economical means of attaining the same end.

The settlement in the bottom of the tank is called sludge and is in a form that will decompose rapidly unless attended to and removed. The velocity of flow through these tanks usually varies from 0.15 inch per second to 2 inches per second and the detention period varies from one-half to eight hours, an hour and a half being common.

The continuous mechanical removal of the sludge is desirable from many standpoints, among them being the following: Storage space does not have to be provided for the sludge. It provides easy means of returning a portion of the fresh settled sludge to the influent.

Septic Tanks.

It was learned years ago that if the solids in sewage were allowed to undergo natural decomposition they would eventually reach a stable and inert state. The first unit to use this principle was the septic tank developed by Cameron in Exeter, England. Collection and decomposition were carried out in the same tank, sludge being removed only after long periods. Many of the important claims advanced in favour of this system have failed to stand the test with the result that it is now practically obsolete.

The septic tank still has its uses for treatment of sewage from institutions, but most boards of health will not permit its use in municipal treatment plants.

After the process had been studied Travis in England and Imhoff in Germany recognized the impracticability of carrying on two separate and distinct processes in a single storey tank. They developed tanks which provided an upper compartment in which the solids were removed by settling and a lower or digestion compartment where they were allowed to undergo digestion. These tanks, too, had their faults, foaming being the principal operating fault. The gas that is generated is either collected in gas collectors or discharged into the atmosphere, the latter method sometimes resulting in odours around the plant.

Another disadvantage of the Imhoff or Travis tanks is the heavy cost of construction due to their depth.

Separate Sludge Digestion.

The next logical step was to arrange to have the processes of sedimentation and digestion carried on in separate

*Courtesy of the Dorr Company.

tanks, the process being known as the "separate sludge digestion" process. It eliminated the disturbance of quiescent settling due to gas being given off in the lower compartment and allowed the operator to control the contents of the digestion unit. As it was shallow it was of course, cheaper to build.

When the separate sludge digestion tanks were first used they had all the faults of their predecessors, foaming, odours, and a small yield of gas mostly hydrogen sulphide. However, they were amenable to study and research, and it was soon discovered that bad conditions only existed when acid conditions were prevalent in the tanks. When reagents were added changing the contents to an alkaline condition an immediate improvement was noted. No foaming, no odours, a large quantity of gas, and a 50 per cent reduction of organic matter. This gas contained 75 per cent of methane by volume, which is odourless, and had a heat value of 650 B.t.u. per cubic foot. Well-digested sludge is black, gritty and has a tarry odour. It was found that in the cold winter months the digestion tanks became merely storage tanks and very little digestion went on. However, if the tanks were artificially heated normal conditions were resumed. This, would be expensive but for the gas yield from the digesting sludge which was more than adequate.

Temperature is a particularly important factor in alkaline fermentation. Gas production begins at 42 degrees F. and increases uniformly up to 77 degrees F. after which it falls off. In well operated digestion tanks the ratio of digested sludge to fresh sludge is usually greater than 1 to 1. It was also found that it was desirable to maintain contact between the digesting solids and the daily addition of fresh solids. For good digestion the *pH* value should run from

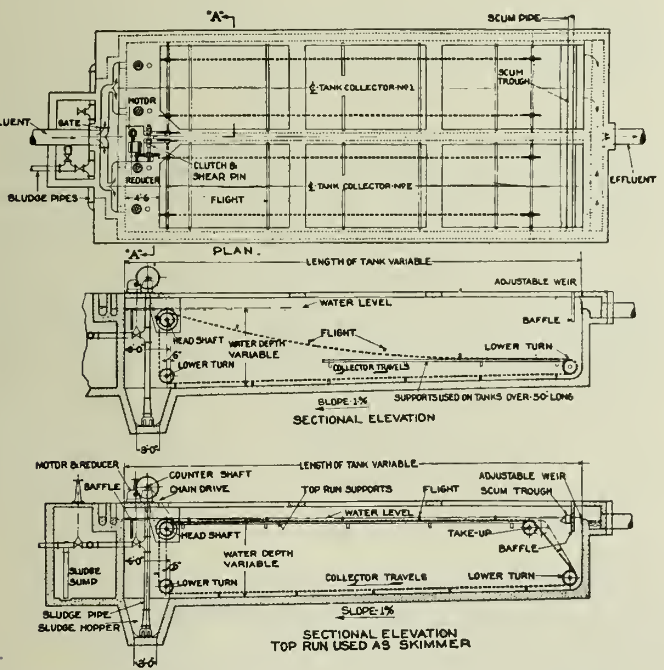

Fig. 5—Arrangement of Link-Belt Straight Line Sludge Collectors.*

7.0 to 7.6. One cubic foot per capita is usually provided in digestion tank design corresponding to an effective digestion period of two months.

A new development in digestion tank design embodies a two stage principle involving two tanks. The first tank is provided with high speed agitation, breaking down solids rapidly, the sludge then automatically passing to the second tank where quiescent conditions and gas collection are accomplished. It is claimed that 90 per cent of the total possible gas is produced in ten to twelve days. If this is a fact the tank sizes can be reduced and a larger volume of gas obtained.

Gas production varies from 0.4 to 0.8 cubic foot per capita per day and averages 650 B.t.u. Many plants in Europe use the gas for supplying power for the plant especially where the cost of electric energy is high. In most American plants the gas is used to heat the digestion tanks and to incinerate screenings and sometimes to heat the plant. Where current is cheap some plants sell the surplus gas to the local gas company.

The disadvantage of this form of digestion is the accurate and constant control required.

*Courtesy of the Link-Belt Company.

Secondary Treatment

All the solids that can be removed by purely physical means have now been removed. However, there is still left in the sewage liquid (the effluent) now leaving the clarifiers, 200 p.p.m. of dissolved organic solids that must or at least should be removed before the effluent is sent to the receiving body. For this purpose oxidation is required causing an irreversible chemical change. Air must now be naturally or mechanically supplied for the cultivation of bacteria that will convert the organic matter into stable inoffensive compounds.

Land Irrigation.

The first method used was the application of the effluent to land properly treated. The sewage was allowed to overflow on to the land in thin films, the percolated sewage being collected in shallow trenches or ditches. It was rare that land could be found that would absorb sewage without being first underdrained at considerable expense. Even then prolonged droughts caused the clayey soil to crack which allowed the sewage to short circuit to the drains without material reduction of its degree of pollution. Hence sewage farming was abandoned due to economic, administrative and sociological factors.

Land Filtration.

The next method tried was to run the sewage on to sand beds through which it percolated to underdrains. An acre of land was required to take care of 120,000 gallons a day and for large cities this was quite impractical.

Contact Beds.

The next step was the introduction of the contact bed which usually consisted of a concrete basin 5 to 6 feet deep filled with broken stone. Sewage was then applied filling it nearly to the top of the stones and allowed to remain in the basin for two or three hours and then released. A slimy biological film formed on the stones after the beds matured destroying the organic matter in the sewage. This filter was capable of treating 325,000 gallons per acre per day which made it still out of the question for large cities. The bed soon clogged up reducing its capacity with the result that the aggregate had to be removed, washed, screened and replaced, and the process is now obsolete.

Trickling Filters.

The contact bed was replaced by the trickling filter which consisted of fixed sprinkler nozzles or distributors spraying the sewage over beds consisting of stone 6 to 8 feet deep which is underdrained. This was a great improvement over the contact bed especially as 300,000 gallons per acre per day per foot depth could be treated. However, this type of treatment is still widely used and results are good, but for larger cities the land required was a stumbling block.

Activated Sludge Process.

Development in England of the activated sludge process by Ardern and Lockett has largely solved the problem of secondary treatment when area is limited. The sewage is aerated in tanks either by agitation by paddles or by forcing compressed air through it. The air serves three purposes, first providing oxygen to maintain bacterial conditions existing only in its presence, secondly to cause the sludge so activated to move through the sewage maintaining contact between the gelatinous surfaces of the sludge and the putrescible organic matter in the sewage and thirdly to prevent the sludge depos ting and becoming septic, upsetting the process. As in other biological processes two to four weeks must elapse after the tank is put in operation to produce activated sludge which is very flocculent and has a golden brown colour. Once the tank is broken in the sludge will retain its action under favourable conditions, sludge being withdrawn daily of which an amount of 20 per cent to 25 per cent of the sewage flow is returned to the influent in order that it may become activated in a short period. If the sewage is properly activated it will settle rapidly and to accomplish this secondary clarifiers are provided. One hour's detention usually suffices.

One of the chief difficulties with the activated sludge process is the immense volume of sludge produced. As activated sludge has a moisture content of from 98.5 per cent to 99.5 per cent. Another disadvantage with the process is the large volume of compressed air required and the cost thereby entailed.

However, the results are good and the suspended matter in the sewage is often reduced 90 to 95 per cent by the process and the bacteria reduced 90 per cent.

Thirty horse power are required for furnishing 1.5 cubic feet per hour per gallon of sewage for the treatment of 1,000,000 gallons per day.

Chemical Precipitation.

It has been recognized for many years that a process somewhere between sedimentation and complete treatment was desirable. As was stated previously the oxidation processes are very delicate and not flexible and often produce an effluent of greater purity than necessary and at a high cost. On the other hand sedimentation does not do enough. During the past seven years intense study has been given to this phase and there has evolved what is known as the chemical-mechanical processes. One of the best known, the Laughlin process, was operated as a pilot plant in Coney Island, N.Y. and later as a full size plant built at Dearborn, Michigan. The incoming sewage passes through screens and then flows to the mixing chamber. Here is added a mixture of grit, screenings, lime and waste paper and ferric chloride. This mixture is than delivered to a clarifier equipped with a magnetic cleaner. The effluent goes to the river while the sludge is sent to vacuum filters and then for final disposal.

The clarifiers are the most interesting part of the installation. In the Dearborn installation the tanks are 60 feet in diameter, 10 feet deep at the outside and 12 feet deep at the centre.

Around the inside circumference of the tank is a shelf-like arrangement 8 feet wide. This supports a coarse grating on which is placed a phosphor-bronze screen with 1 mm. openings.

On this screen is placed 3-inch magnetite graded between No. 10 and No. 16 screens. Sewage enters the tank at the centre through a 7-foot circular baffle wall and flows radially outward to and upward through the magnetic filter. It then passes over weirs into an effluent channel that completely surrounds the tanks. The filter is provided with a bronze cleaner case suspended from a truss as long as the filter bed is wide and itself 4 feet 6 inches in width, the top being just a few inches above the surface of the liquid. In the bottom is a longitudinal opening over which is mounted a long bronze solenoid wound about a vertical axis. The solenoid is as long as the cleaner case, about 18 inches wide, and covers a narrow sector of the filter bed. As the cleaner travels over the surface of the filter it is periodically energized by direct current and when so energized it picks up violently a narrow sector of magnetite. The uprushing liquid from beneath the screen scrubs and cleans this magnetite and then overflows into the cleaner case into a side compartment from where it is pumped back to the centre of the tank. When the solenoid is demagnetized the magnetite drops and is trowelled down by the cleaner case. The solenoid operates at 16.9 cycles per minute and the cleaner travels completely around the filter in thirty-three minutes.

The following results were obtained with this plant in 1932:

Per cent total solids removed	63
Per cent suspended solids removed	97.5
Per cent b.o.d. reduction	87

Experiments are going on at the present time and the results so far are meagre but promising. Several cities are considering chemical precipitation and hope thereby to reduce both capital and operating costs.

Sludge Disposal

Sludge disposal always has been and still is one of the most difficult problems of sewage treatment. Sludge before drying is a thick, syrupy liquid having a moisture content of from 94 to 98.5 per cent depending on the process producing it.

Primary treatment produces 2,000 gallons per million gallons of sewage and from activated sludge process 11,000 gallons per million gallons of sewage. Digestion will reduce this by 50 per cent but there still remains a great mass requiring disposal.

Wet sludge is still commonly run on to specially prepared sand beds and air dried. In order to reduce the amount of land required the sand beds are often covered with a greenhouse structure which of course raises the capital cost considerably.

Fig. 6—Dorr Multidigester System. General view of Unit at Cedarhurst, L.I., with primary tank at right and secondary tank at left.
Courtesy of The Dorr Company

At the present time probably the most successful method of dewatering sludge is by using the vacuum filter. Before reaching the filter the sludge must first be conditioned with ferric chloride or chlorinated copperas as this makes the filter rate higher and thus reduces the cost of filtration.

Milwaukee has produced a high grade fertilizer by heat drying vacuum filtered activated sludge and adding to it other chemicals, but due to the cost this has not met with favour elsewhere.

Ordinary sludge is usually put on barges and dumped at sea, is used for filling up low land or is sometimes sold to farmers as a low grade fertilizer. Filtered sludge may be incinerated if mixed with other fuel but incineration is still in the experimental stage

A reference should be made to costs as this has been the bugbear of sanitary engineers. Some plants do not include capital charges in their published costs, others do not include cost of pumping and some do not include interceptor costs and cost statements are therefore often misleading. Certain cost data have here been abstracted from a recent article by Besselievre but as he does not give operating costs these have been taken from the author's files to supplement the information. It is believed to be substantially accurate. Perhaps, too, it should be mentioned that the capital cost of the treatment plant and interceptor for Greater Winnipeg has been estimated as follows:

1. Interceptor, pumping plant, clarification plant for 200,000 connected population and land and administration and incidentals—$3,250,000.00.
2. Interceptor, pumping plant, activated sludge treatment for 200,000 connected population and land and administration and incidentals—$4,000,000.00.

In closing, the following quotation from the first report of Mr. W. S. Lea to the City of Winnipeg on sewage disposal is of interest:

"In summary it may be said that sewage treatment plants are imperative where needed as a public health measure. They are of great worth also as a cure for nuisances in rivers. On the other hand the community which has to resort to them, is often left with something of a nuisance on its hands on shore. Moreover, the capital and operating costs of sewage treatment plants entail a substantial annual expenditure from which there is no direct monetary return. It follows, therefore, that the minimum which will suffice, is the maximum which should be recommended to a community, which has to operate and pay for sewage treatment plants."

Cost of Sewage Treatment

Treatment Process	Area Req'd. per m.g.d	Per cent Removal Suspended Solids	Per cent Removal b.o.d 5 Day	Construction Costs per m.g. (U.S.)	Operating Costs per m.g. Treated (Capital charges not included)
1. Fine screening....	½ acre	16 per cent	...	$20,000	....
2. Sedimentation...	1 acre	65 "	30 per cent	30,000	$10
3. Sedimentation and chemical precipitation..............	1¼ acres	90 "	80 "	40,000	....
4. Sedimentation with trickling filters..............	6 acres	96 "	80-90 "	60,000	$6 to $12
5. Activated Sludge	2 acres	96 "	90 "	80,000	$16 to $27

Note:—After Besselievre with exception of operating costs and b.o.d. per cent removal (authors). Cost of land and incineration of screenings not included.

Supplementary Notes*

Historical

During the years 1930 and 1931, the condition of the Red and Assiniboine rivers had become exceedingly bad owing to extremely low flows and increasing sewage pollution. Accordingly in August 1931, the City Council of Winnipeg appointed a committee to enquire into the necessity or otherwise of a sewage disposal plant for the city of Winnipeg. This committee recommended that Mr. W. S. Lea, M.E.I.C., consulting engineer of Montreal, be asked to make a report on the situation. This recommendation was concurred in, and Mr. Lea made his report in February 1932. During the interval, a sanitary survey of the rivers was carried out by the City Engineer's Department. Mr. Lea recommended in his report:

(1) That the sanitary survey be continued throughout the summer of 1932.
(2) That the city of Winnipeg continue the investigations outlined in the report, requisite to the adoption of a practically complete scheme for its future sewage treatment needs.
(3) That the necessary lands be acquired for the interceptor and treatment plant.

No action was taken on this report, but Mr. Lea was retained to go further into the scheme.

Conditions grew worse during 1932 and 1933, and in September 1933, the Manitoba government called together representatives of the municipalities surrounding Winnipeg for a conference on sewage treatment.

This inter-municipal conference went on record as "approving of a scheme for the disposal of raw sewage, and of providing for Winnipeg and suburban area, a sewage disposal system."

The committee also appointed an Engineering Committee consisting of the municipal engineers, and engineering representatives of the Dominion and Provincial governments. The engineers were instructed to examine the existing data on the subject and to prepare estimates of cost. This committee together with Mr. W. S. Lea made a very complete study of the project throughout 1933 and 1934. In March 1935, a bill to create the Greater Winnipeg Sanitary District was introduced in the Provincial Legislature. The bill was passed and came into effect in June 1935. Meanwhile negotiations had been carried on with the Dominion government with a view of giving financial assistance to the project as an Unemployment Relief Measure.

In July 1935, an agreement was signed by the Dominion government and the Provincial government in which the Dominion undertook to assist the project financially.

Following this, the Administration Board of the Greater Winnipeg Sanitary District with Mayor John Queen of Winnipeg as chairman, came into being. This Board appointed a Board of Engineers consisting of the engineers of Winnipeg and the municipalities comprising the district, together with engineers representing the Dominion and Provincial governments. This Board was charged with the construction of the sewage disposal project. Mr. Lea was named consulting engineer. The personnel of this Board is as follows:

W. P. Brereton, M.E.I.C.,
Chairman and Chief Engineer
R. W. McKinnon, M.E.I.C.
J. W. Battershill
Chas. F. Gray
W. D. Hurst, A.M.E.I.C.,
Secretary.

*The following notes are not intended to constitute part of the paper but merely to indicate the progress which has been made in the construction of the greater Winnipeg intercepting sewer and sewage disposal project.

A technical staff was engaged and D. L. McLean, A.M.E.I.C., was named assistant chief engineer and J. F. Muir, office engineer. This staff at the present time numbers seventy.

Gravity System

The first contract was for one mile of 7-foot 6-inch circular monolithic concrete sewer with a wall thickness of 12 inches constructed in tunnel. This was awarded to the Nelson River Construction Company Limited of Winnipeg at a tender price of $40.00 per lineal foot.

The second contract was for approximately two miles of 7-foot 6-inch circular sewer of monolithic concrete in tunnel and was awarded to the Mutual Contractors Limited of Winnipeg, at a tender price of $36.00 per foot.

The third contract for 1,936 lineal feet of 7-foot 6-inch circular sewer, for 6,936 lineal feet of 6-foot 6-inch circular sewer, and for 4,146 lineal feet of 5-foot 6-inch circular sewer, all built of monolithic concrete in tunnel, was awarded to the Nelson River Construction Company Limited at tender prices of $30.00, $30.50 and $21.00 per lineal foot respectively.

In addition to the above the district has awarded four other contracts comprising the outfall sewer from the plant, and the secondary sewers. The approximate value of these contracts is $130,000.

Contracts covering the balance of the interceptor and practically all of the secondary sewers are now being tendered upon and it is expected that they will be let by December 15th, 1935. To date the value of the contracts awarded amounts to $1,080,000.

The Interceptor

The route of the interceptor is shown in Fig. 3 and it will carry to the main treatment plant the sewage from twenty sewer outlets now being discharged into the Red and Assiniboine rivers. This interceptor is designed to carry 245 million U.S. g.p.d. from an ultimate tributary population of 585,000. This is based on 247.5 U.S. g.p.c.p.d. being two and three-quarter times the average ultimate dry weather flow. The sewer was designed using a value of $C = 110$ in Hazen and Williams formula, this value being chosen because it was not known at the time whether brick would be a material of construction. It will be seen that by "crowding" the interceptor it can be made to carry considerably more sewage.

Types of Construction

Tenders were called for on the interceptor using four different types of construction:—

Type "A"—Monolithic alkali-resisting cement concrete.

Type "B"—Alkali-resisting cement concrete segmental tile jointed with alkali-resisting cement mortar.

Type "C"—Portland cement steam cured concrete segmental tile, jointed together with alkali-resisting cement mortar.

Type "D"—Hard burned brick jointed with alkali-resisting cement mortar.

It will be noticed that three of these types require alkali-resisting cement. This is the first large scale construction job using alkali-resisting cement as sold in Canada by the Canada Cement Company Limited under under the trade name "Kalicrete." This cement was specified owing to the rapid disintegration of Portland cement concrete in alkali soils. Accelerated tests extending over three years had been carried out by Mr. Archibald Blackie, F.C.I.C., consulting city chemist, and the alkali-resisting cement stood up exceptionally well while similar tests made on Portland cement showed rapid disintegration. The necessity for developing a concrete resistant to alkali action was recognized in Western Canada about the year 1920 when a committee consisting of engineers and chemists was appointed by The Engineering Institute of Canada to investigate the problem.

Tunnelling

Shafts have been put down at intervals and progress of work has been rapid.

Contract No. 2—The average progress in a typical week has been 10.0 lineal feet per day of three eight-hour shifts per heading (completed sewer).

Contract No. 3 and No. 4—The average progress in a typical week has been 6.33 lineal feet per day of two eight-hour shifts per heading (completed sewer).

The material that has been encountered so far is stiff blue clay having a weight of approximately 113 pounds per cubic foot. Excavation so far has been free from water trouble.

In contract No. 2, the earth is brought up the shaft by a hoist and bucket. In contract Nos. 3 and 4, a dumping elevator has been used. It is expected that these contracts will be completed by March 31st, 1936.

Treatment Plant

Specifications for the treatment plant equipment are now underway. The pumping station at the treatment plant initially will be provided with a capacity of 87 million U.S. g.p.d. against a 60-foot total dynamic head.

It is expected that clarifiers and sludge dewatering equipment will be provided in the initial plant.

The consulting engineer is making a very complete study of the chemical precipitation processes which have gained great favour in the United States in the past three years.

The treatment plant site in Old Kildonan has an area of 61.0 + acres.

DISCUSSION

T. C. Main, A.M.E.I.C.(1)

Mr. Main asked the following questions:—

As bacterial action practically ceases at 38 degrees F. and as ice cover in winter prevents absorption of oxygen by the river water, would it not require considerably more than 3.5 second feet per 1,000 population to prevent serious pollution under winter conditions?

Is not the land irrigation method of sewage treatment quite unsuitable for cold climates like ours?

About what proportion of Greater Winnipeg's spent water supply comes from wells?

How do you propose to take care of storm water?

E. V. Caton, M.E.I.C.(2)

Mr Caton inquired as to whether the pollution at Selkirk was greater than in the city or whether the rivers had started to recover before reaching that point.

N. M. Hall, M.E.I.C.(3)

Mr. Hall asked what should be done in the case of very small towns where the large scale methods would not likely be applicable.

L. Ostrander(4)

Mr Ostrander inquired as to whether two treatment plants and two interceptors, one serving, say, St. Vital,

(1) Assistant Engineer, Water Supply, Canadian National Railways, Winnipeg.

(2) Manager, Electric Utility, Winnipeg Electric Company, Winnipeg.

(3) Professor, Mechanical Engineering, University of Manitoba, Winnipeg.

(4) Assistant Engineer, Canadian National Railways, Winnipeg.

St. Boniface and Elmwood, on the east side of the river, and the other serving the municipalities on the west side of the river had been considered.

George Cole[5]

Mr. Cole outlined Dr. Dorr's early work in South Dakota and how he had come to develop the clarifiers for use in the cyanide process. This work had extended from the mining field to many others and went to show that developments in one field may be of advantage when applied to others.

W. M. Scott, M.E.I.C.[6]

Mr. Scott reviewed briefly the advance that had taken place in sewage treatment over the past twenty-five years. He thought that the engineer would do well to consider methods of treatment that had been recently developed on the Continent, especially Germany.

D. L. McLean, A.M.E.I.C.[7]

Mr. McLean congratulated the author on his paper and read the following remarks submitted by Mr. Aldridge by letter.

W. Aldridge[8]

(By letter.)

In discussing the virtues of sewage treatment for Winnipeg with a medical man, the writer was asked if all the pathological germs would be destroyed. What would be the right answer?

At the outset Mr. Hurst had stated that the reason why sewage is treated is because it may contain the germs of disease. By this he probably meant that the only really vital consideration urging treatment should be one of health.

However, actually this is not the case either historically or in practice. When the water closet was introduced in London a little better than one hundred years ago it resulted in over-charging of the family cesspool, which the householder was led to connect to the street gutter, or the closet itself was connected to the gutter. This led to covering the gutter or laying underground pipes and so the water carriage system was born. This pollution, buried from sight under the streets, only appeared in the small rivers and streams into which the pipes discharged. This water carriage idea led to the presence of all sorts of filth in the rivers. The government issued numerous regulations, and a great deal was done to "purify" the sewage. Germany followed England very closely. From then on a good deal is read about "disinfection of sewage." Sterilization, or complete removal of bacteria was not attempted.

On examination of the effluents it was found that the methods in use resulted in a large reduction of organisms as compared with the incoming sewage. Hence, since disinfection proved difficult and expensive, attention was given to reducing to a minimum the pathological germs in the effluent, but this was a side issue. The results attained were something like this:—

Sand filters: a reduction of	99.6 per cent
Sprinkling filters: a reduction of	86.6 per cent
Contact filters: a reduction of	40.0 per cent

Only sand filters reached 99 per cent under especially expert operation. However, Prescott & Winslow showed that "All these processes produce a certain reduction in bacterial numbers, but the decrease is not sufficient to be of very great sanitary moment. With a material containing so many bacteria as sewage, a reduction of 99 per cent may be satisfactory, but a reduction of 90 per cent is certainly not satisfactory." Hence, the effluent is chlorinated and all is assumed to be well. It may be good religion to overlook the ninety and nine and worry about the one, but what about the ninety and nine? They have gone into the sludge; but are they rendered harmless? Only Dr. Dunbar as far as the writer knows mentions this point. He found that typhoid bacilli remained active for thirty-three days in septic tanks, that bacilli in effluents spread throughout an irrigation farm area and that the draining from sludge beds acted similarly. However, he is satisfied to leave the subject there as no epidemic has been traced to this source.

He states that, "A complete separation or destruction of pathogenic germs is not, however, possible with any of the methods of purification which have been successfully adopted on a practical scale. Methods depending on heat and chemicals alone can be effective. Thermal disinfection can scarcely assume practical importance so one is left with chemical disinfection and this is not the same as chemical purification. Chlorine, as stated above, is the principal element used for this purpose but it is now applied for many other purposes, as for instance: controlling odours, relieving pooling of filters, reducing oxygen demand, correcting disturbances in activated sludge tanks and controlling fly breeding.

The disinfection factor has again assumed a secondary place and one must search closely to find any mention of disinfection or bacterial efficiency in such a book as T. P. Francis, on "Modern Sewage Treatment," for example.

From the practical side, as opposed to the historical development, Kinnicut, Winslow and Pratt, 1919, state: "The primary object of sewage purification is the oxidation of organic matters, its conversion into a stable form, so that it will not putrefy and create a nuisance. This end can often be attained by methods which do not effect a very notable reduction in the number of bacteria present."

And Metcalf and Eddy, after dealing with all the methods of purification covered by the paper state: "In all the processes of treatment previously outlined, the purpose has been mainly to prevent sewage causing a nuisance. If it is desirable to reduce the danger of transmitting disease by sewage-contaminated water to a minimum, the bacteria in the effluent must be killed before it is discharged into the water. This can be done by disinfection."

Again, "In the methods of sewage treatment, previously described a change in the character of the organic matter originally present is the main object sought, whereas in disinfection and sterilization the main object is to kill the bacteria in the liquids treated." But all this applied to effluents.

What about the ninety and nine not in this effluent? London sludge dumped into the sea contained 100,000,000 b. per c. c., one-half of which was assumed to be intestinal.

Drying beds are made over porous ground or are underdrained and a large amount of the water content drains off and travels long distances, and typhoid and dysentery germs will live three months in soil.

Experiments at the Chicago north side plant reported on last November showed that B. Typhosus persisted in sludge after eighty-three days and led to the conclusion that activated sludge at times may be very infectious. Caution should be observed when it is used as a fertilizer for truck gardens.

Fair and Wells in a paper on "Measurements of Atmospheric Pollution by Sewage Works" presented before the New Jersey Sewage Works Association last fall stated that "Trickling filters, activated sludge, pre-aeration tanks and aerated skimming tanks afford a relatively large measure of opportunity for contamination of air through the medium of evaporating droplets" and go on to give results of tests. Then what about flies?

The ordinary filter fly "psychoda alternata" is a poor weak body who never ventures far away. But the stable y, "stomoxys calcitrans," infested the filters at Green-

(8) Assistant City Engineer, City of Winnipeg.

ville, S.C., last July and plant farmers had to cover their mules three miles away so as to protect them from bites. Milk production of cows fell off 50 per cent and even residents considered moving. All that was necessary was the proximity to the plant of cattle and sheep which acted as hosts for the breeding. Of course modern sanitation has reduced the chances of trouble, but when it does come, what? The question arises, does modern sewage treatment destroy the pathogenic bacteria?

W. D. Hurst, A.M.E.I.C.[9]

In reply to Mr. Main's questions the author stated that experiments elsewhere had indicated that considerably more dilution was required when ice cover prevented reaeration.

Land irrigation was undergoing a revival in Texas but he believed it was not suitable for conditions in Western Canada.

Surveys indicated that about 10 per cent of Greater Winnipeg's water supply came from wells.

The interceptor would carry up to 2.75 times the average dry weather flow to the treatment plant and regulators would by-pass the excess to the river.

In answer to Mr. Caton he remarked that the sanitary survey had not been carried any further north than Lockport as it was carried out with funds supplied by the Corporation of the City of Winnipeg and it was felt that a wider survey of the rivers was a problem that should be handled by the provincial government. However, as a matter of information, the survey was carried as far south as Emerson, Manitoba, and very bad conditions were found to obtain there, indicating pollution from the American side of the boundary. The pollution at Lockport was less than that at the Bergen cut-off just outside the city limits and it was thought that the river was beginning to recover at this point. It had not been deemed advisable to complain to the International Joint Commission concerning the pollution at the boundary as their obvious answer would be that the city and municipalities should clean up their own mess before complaining about someone else.

In reply to Mr. Hall he observed that in the past septic tank installations had been installed but modern practice considered that small mechanically cleaned sedimentation tanks provided with digesters would serve the purpose better, even though the initial cost might be higher.

In respect to Mr. Ostrander's inquiry, two separate plants had been considered but estimates made showed that a single interceptor and treatment plant with inverted syphons taking care of the municipalities on the east side of the river would be cheaper.

Mr. Aldridge's comments force the sanitary engineer to wonder whether the most important reason for the treatment of sewage is that of removing danger to health, or that of removing nuisance from the community affected. A community that is dumping raw sewage into a river from which another community down-stream takes its water supply is certainly creating a health hazard. If the condition of the water is such as to overload a municipal filter plant situated down-stream the second community may well insist that the first community construct a sewage treatment plant and the reason for its construction is primarily a health reason. The effluent from the plant may be sterilized with chlorine and the waters reach the second community in a sterile state at least as far as the first community is responsible for their being polluted.

If there are bathing beaches down-stream, the reason for sewage treatment is again a health reason or if there are valuable oyster fisheries and ice harvesting the reason is the same.

However, Mr. Aldridge suggests that the bacteria have been removed from the liquid and transferred to the solids, and still the danger to health remains. This may well be true and a discussion of this feature appears in the Sewage Works Journal for November, 1934, by C. C. Ruch-hoft, Bacteriologist, The Sanitary District of Chicago. He concludes that wet activated sludge cannot be considered innocuous and at times may be quite infectious. He also believes that caution should be observed when it is used as a fertilizer for truck gardens. However, sludge can be entirely freed from bacteria at a price. Milwaukee accomplishes this by vacuum filtration of the sludge, by heat drying it and making commercial fertilizer.

Great progress is also being made on the incineration of sewage sludge, and two plants are at present in operation, one at Dearborn, Michigan, the other at Chicago, Illinois.

If the supplementary fuel costs can be sufficiently lowered this process is likely to find widespread use.

The results on droplet infection from trickling filters, activated sludge pre-aeration tanks and aerated skimming tanks are still under study and judgment on their danger should be reserved.

The filter fly and the stable fly are troublesome when the trickling filter process is used and where apprehension is felt concerning this danger other processes should be given study.

The medical man can be safely told that all the pathogenic germs in sewage can be destroyed — at a price. It is the sanitary specialists' function along with the medical and other allied professions to appraise the value both social and economic of the complete removal of pathogenic organisms in sewage.

Both health and aesthetic reasons for the treatment of sewage are equally important where the receiving body is used for water supply, bathing, fisheries and ice-harvesting.

The Metallurgy of Metallic Arc Welding of Mild Steel

C. R. Whittemore, A.M.E.I.C.,
Metallurgist, Dominion Bridge Company, Montreal.

Paper presented before the Junior Section of the Montreal Branch of The Engineering Institute of Canada, March 25th, 1935

SUMMARY.—A discussion on the difficulties of welding mild steel is followed by notes on the characteristics of the arc, the choice and suitability of various types of electrodes and the examination and structure of the weld metal in some actual welds, as shown by photomicrographs.

The metallurgical aspects of welding involve the consideration of the chemical and physical properties of the deposited weld metal and the effect of conditions of deposition on the parts joined. The properties of the welded joint depend upon the proper selection of equipment, materials and the control of the process to effect the joining of the parts.

The weld is composed of metal from two sources, viz., metal from the material being welded and metal from the electrode. The resultant weld is, therefore, affected by the parent metal, the electrode core and its coating or covering and to some extent by the procedure followed.

An ideal welded joint is one in which the properties of the weld metal and the base metal are similar in chemical composition and physical properties. A joint of this type is readily attainable if the structure demands it. Joints subjected to dynamic stress, e.g., pressure vessels, require weld metal of the highest quality, whereas in a structure subjected to static loads only, the weld metal will not require the same degree of ductility and resistance to impact. It will, however, be necessary to develop full tensile strength and a sound weld.

Materials

In the metallic arc welding of mild steel nearly every one at some time or other has experienced difficulty in its welding and to overcome this attempts have been made to define by specification the quality of steel suitable for welding. To date, such a specification has not been evolved but it is the opinion, based on practical experience, of those concerned with the choice of materials that steels conforming to those enumerated under American Society for Testing Materials Serial designation A151-33 are suitable for fusion welding being mindful of the fact that welding technique is of fundamental importance. This specification lists some twenty separate A.S.T.M. specifications and includes those for structural steel for bridges, buildings, ship plate, locomotive boiler and firebox steel, etc.

Plate meeting these specifications will have a tensile strength of 45,000 to 72,000 pounds per square inch with a carbon content of 0.12 to 0.30 per cent, depending on requirements and plate thickness. Steels up to 0.35 per cent carbon have been welded with satisfactory results under usual commercial practice.

Other steels may be metallic-arc welded with satisfactory results when suitable fluxes and filler metal are used in conjunction with correct technique.

Steels having a carbon range of 0.10 to 0.35 per cent, with a manganese content of 0.30 to 0.60 per cent, sulphur and phosphorus each 0.05 per cent maximum and made by good, basic or acid open-hearth practice, will present no difficulty in metallic arc welding. Such steel will be free from detrimental amounts and types of non-metallic inclusions, gases and segregations. There is no reason why steels below 0.10 per cent carbon cannot be welded if due care has been observed in the manufacture of the steel but it has been our experience that steel under this carbon content contains more non-metallic inclusions and absorbed gases, than steel higher in carbon.

The surface condition of the plate is also important from a welding viewpoint. A plate with a heavy red oxide scale is not as satisfactory as one with a light blue scale, as the heavy red scale offers more resistance to the arc.

The effect of segregation or lamination in plate on the deposited weld metal is shown in Fig. 1 (lower half). Note the small hole at the line of fusion where sulphur segregation is shown by the dark lines.

Electrodes

A metallic arc welding electrode is a metal wire of definite diameter, length and suitable composition used as a terminal in an electric circuit to produce an arc through which the filler material (the electrode) is carried in the molten state and fused between the parts to be joined. In metallic arc welding it is necessary that the surface of the electrode be coated or heavily covered with suitable metal fluxing materials for the purpose of stabilizing the arc and protecting the metal from atmospheric contamination during transfer and upon deposition.

Theories of Metal Transfer

Whether the deposited metal passes through the arc as vapour, mist or globules, has long been under discussion, as has also the driving force.

One of the first theories advanced was that the metal was transferred as vapour which formed at the tip of the electrode and condensed in the crater of the work. Others have pointed out that this may be only partially true since a large amount of energy would be necessary to vaporize the metal, and it was concluded that the larger part of the metal must be transferred as mist or globules of molten metal. This has been found to be the case.

As to the method of transfer, some have attributed the driving force to the evolution of gas within the melting tip, which carried particles of metal with it; others to the forces of adhesion and surface tension between the molten metal on the tip and that in the crater.

A comparatively new theory as applied to electric welding is the "pinch effect" which accounts for the force necessary to separate the globules. The "pinch effect" is the local contraction of the cross-section of a liquid resistor through which electric current is passing and in which heat is being generated. In an open path this contraction results in complete rupture. This contraction is caused by an electromagnetic force that acts from the circumference to the centre of the conductor and in a direction perpendicular to the axis. The ejecting force increases as the square of the current and diminishes with an increase in the cross-section of the conductor. In the filament formed, as the

Fig. 2.

globule is about to be separated, there is a tremendous current density producing a high pressure of vaporized and ionized metal which propels the globule.

It seems that all the above factors combine to effect the deposition of metal. To weld in the vertical and overhead positions it would appear that the explosive force of the gas formed and the "pinch effect" are necessary to overcome the force of gravity.

Arc Voltage

The voltage drop across the arc is influenced by the arc length and by the resistance of the incandescent vapour forming the arc. The arc voltage, which is a function of the arc length, is one of the major variables influencing the deposited metal. The effect of arc length on the chemical composition of weld metal deposited by a 3/16-inch diameter "bare" (sull-coat) electrode is shown by Fig. 2.

Figure 3 shows the effect of arc voltage on the nitrogen content and ultimate strength of weld metal deposited by a 3/16-inch diameter "bare" electrode.

Arc Stability

The significance of arc stability may be summarized as follows:

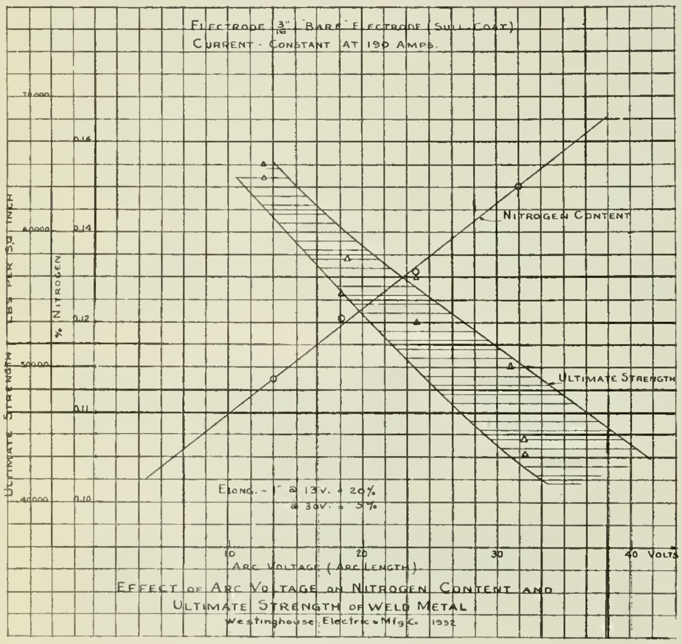

Fig. 3.—Effect of Arc Voltage on Nitrogen Content and Ultimate Strength of Weld Metal.

(1) Ease of operation.
(2) A regular flow of small particles across the arc.
(3) A shorter arc resulting in a sounder weld (less slag inclusion, less porosity and less contamination from oxide and nitride).
(4) Less loss of metal from sputtering.

Arc Current and Electrode Size

It is difficult to give definite figures covering current, speed, etc., on account of the conditions under which the work is done, the character of the work and skill of the operator.

The following tables give the current range, consistent with good results, for "bare" and lightly coated metallic electrodes and for heavily covered electrodes for downhand welding of mild steel.

Current and Arc Voltage—Heavily Covered Electrodes

Electrode Diameter in Inches	All Mineral Coating		Braided Type		Mineral and Cellulosic Compound	
	Amperes	Arc Voltage	Amperes	Arc Voltage	Amperes	Arc Voltage
5/32	125-160	25-28	150-180	30-35	110-170	21-25
3/16	160-240	25-28	180 225	33-38	150-200	30-34
1/4	240-375	28-32	225-300	35-40	225-275	33-37
5/16	375-500	28-32	300-400	38-42	325-375	36-40
3/8	500-650	30-33	400-500	38-42	425-475	43-47

Bare and Lightly Coated Electrodes

Electrode Diameter in Inches	Amperes Hand Welding	Arc Voltage	Amperes Automatic
1/8	120–150	15–17	130–175
5/32	150–175	17–19	175–225
3/16	160–220	19–22	225–275
1/4	200–275	19–22	275–325

Fig. 4.

It will be noted that a higher arc voltage is required for heavily covered electrodes. This is due, in part, to the gas around the arc and partly to the actual increase in arc length which is necessary to keep the coating from touching the metal pool and causing porosity.

Polarity

In general, heavily coated electrodes are connected to the positive pole, and the work to the negative pole, usually referred to as "reversed polarity." Bare wire or lightly coated electrodes are connected to the negative pole and the work to the positive pole, "straight polarity."

Factors Governing the Performance of Mild Steel Electrodes

It was previously stated that the deposition of electrode metal takes place in the form of drops. Investigators have also shown that satisfactory electrode performance is conditioned upon the regularity of the drops. During the brief existence of each drop two periods may be noted, namely, the formation period and the transfer or short circuit period.

The difference in performance of two electrodes of the same diameter and surface finish, but of different composition, is found in the relationship of the formation and transfer periods. The relationship is a function of the volume, temperature and surface tension of the individual drops.

The ability of the electrode to perform depends upon the following factors:—

(*a*) Chemical composition.
(*b*) Freedom from impurities.
(*c*) Grain structure.
(*d*) Surface finish.

Electrode Coatings

As previously stated it is very essential that all metallic electrodes have some type of coating or covering in order to obtain stabilization of the arc for protection of the arc stream from the atmosphere.

Electrode coatings may be conveniently divided into four types according to their respective thicknesses.

(a) Surface finish—so-called "bare" electrode.
(b) Light coatings (dipped) .001 inch to .02 inch.
(c) Medium coatings (dipped and extruded) .025 inch to .035 inch.
(d) Heavy coverings (extruded, wrapped, or braided) .035 inch to .060 inch.

Mild Steel Welding Wire and Weld Metal Analysis

	C	Mn	Si	S	P	O_2	N_2
1. Electrode (Base Rod.)...	0.11	0.45	.03	.04	.03	Nil.	Nil.
2. Base Rod......	.13-.18	.40-.60	.06 max.	.04	.04	Nil.	Nil.
1. Deposit (Bare)........	0.03	0.04	.005	.03	.02	0.20	0.13
2. Deposit (Bare)........	.03-.08	.10-.20	.03 .05	.04	.04	.20-.30	.10-.14
Deposit (Covered).....	.08-.17	.30-.50	.10-.15	.04	.04	.025-.04	.014-.02
Boiler Plate...	.15-.20	.35-.60	....	.05	.04	....	.009

Fig. 5.

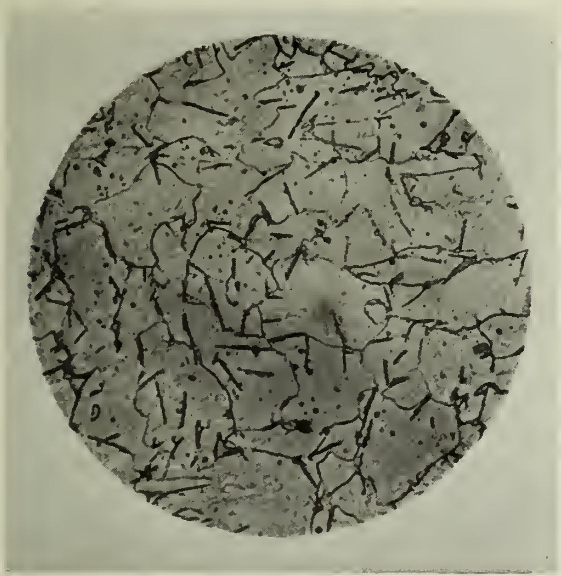

Fig. 6.

The above thickness values, for any one type, vary with the diameter of the core wire and to some extent with the composition of the coating or covering and the application of the electrode.

Effect of Electrode Coatings and Coverings on the Chemical and Physical Properties of Deposited Metal

During the melting of an electrode, it was pointed out that the metal crossing the arc was in a finely divided form

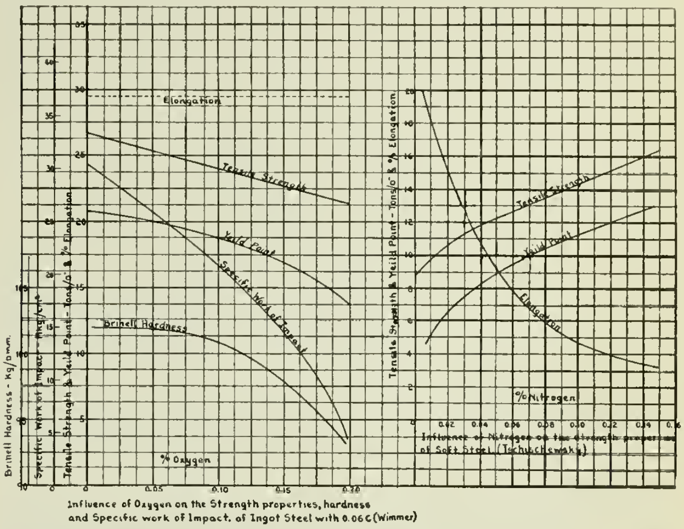

Fig. 7—Influence of Oxygen on the Strength Properties of Steel.

and at an extremely high temperature (3,700 degrees C.). In this condition the metal undergoes considerable chemical change, first, through volatilization and oxidation of some of the constituent elements of the steel core; second, the properties of the deposited metal are affected by the introduction of atmospheric gases in combination with elements of the former and also in solid solution.

The degree to which chemical and physical changes occur will vary with the type and efficiency of the coating or covering.

Typical analyses of deposits made with the so-called "bare" electrode and covered electrode will demonstrate the advantage attached to adequate protection.

The bare electrode weld metal is low in carbon, manganese and silicon due to oxidation and volatilization of these elements.

The contaminating influence of the atmosphere is indicated by the high oxygen and nitrogen contents. The

Fig. 8.

nitrogen often appears as needles within the crystal. Figure 6 shows the presence of nitrogen needles at a magnification of 500 diameters.

At the grain boundary a dark constituent is evident which is probably an oxide-nitrogen-carbide compound of extreme brittleness. The presence of such a material would cause low impact strength and low ductility which is characteristic of "bare" wire welds.

Molten metal in the presence of oxygen forms its corresponding oxide which dissolves and causes brittleness on solidification. The effect of oxygen on "bare" wire weld metal is extremely active as shown by the fact that the electrode wire has a carbon content of .13 to .18 per cent and the resulting weld metal 0.02 to 0.04 per cent carbon. The iron oxide reacts with the carbon forming carbon monoxide, bubbles of which are entrapped to some extent during solidification, resulting in a porous weld.

Welds made with heavily covered electrodes are practically free from nitrogen and oxygen.

The influence of oxygen and nitrogen on the physical properties of low carbon steel are shown in Fig. 7.

The physical properties of weld metal deposited by "bare" or lightly coated electrodes and heavily coated electrodes are shown in Fig. 8.

Bare and lightly coated electrode weld metal has low ductility, low specific gravity, low impact resistance and low corrosive resistance because of the presence of oxides and nitrides.

An important function which can only be fulfilled by the use of flux-covered electrodes is the control of chemical analyses and physical properties of the deposited metal. Increase in carbon, manganese and silicon content with a decrease in the nitrogen and oxygen content account for the improved physical properties of weld metal. The density or specific gravity, indicative of porosity, of covered electrode weld metal is practically equal to that of the best grade of boiler plate.

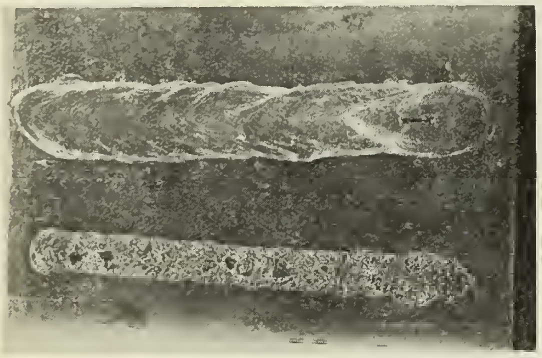

Fig. 9—Corrosion Test on "Bare" and Covered Electrode.

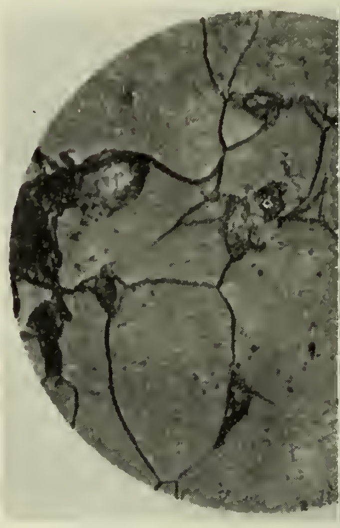
The resistance of covered electrode weld metal to corrosion is comparable to that of the parent metal whereas the resistance of bare wire weld metal is quite inferior. The specimen shown in Fig. 9 was immersed in hot 1:1 hydrochloric acid for twenty-four hours.

Weld Structure

The deposition of metal by the metallic arc process is somewhat analogous to electric melting and casting. The fundamental principles governing good or poor metal in the molten condition are essentially the same. If in an electric furnace the metal was melted down under oxidizing conditions and had a slag of unsuitable viscosity, quantity, and was somewhat inactive, the resultant ingot would be porous, segregated and of little value. In the case of the welder he may obtain weld metal of the same poor quality by non-observance of the proper current, arc voltage, manipulation or by the use of an unsuitable electrode.

Since the greater percentage of welding is on steel having a carbon range of 0.10 to 0.35 per cent, we shall consider the structure of welds made on material of this class.

The deposition of metal in a single layer is essentially a cast structure but in multiple layers complex metallurgical effects result. The factors of current, arc voltage and of time control the temperature gradient of the plate from the melting point downwards and thereby produce pronounced changes on the weld structure and metal adjacent to the weld.



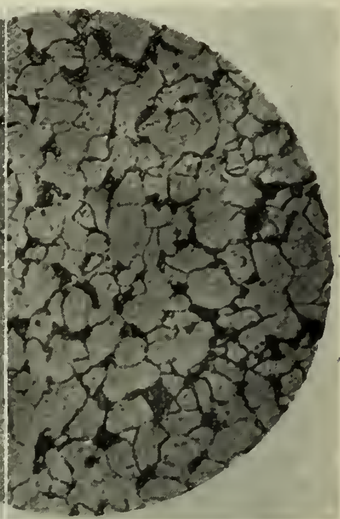


Fig. 10—Mag. 500X. **Fig. 11—Mag. 500X.**

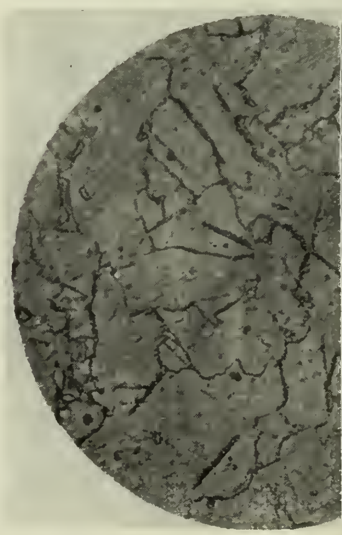
Structural Examination

The structure of weld metal may be determined by the application of micrography and macrography which are supplementary to each other.

Micrography is the examination by means of a microscope of a specially prepared and representative specimen, which is necessarily confined to a small area.



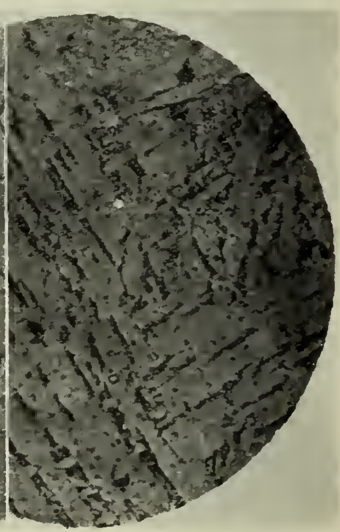


Fig. 12—Mag. 500X. **Fix. 13—Mag. 500X.**

Macrography is the examination of a properly prepared specimen under a very low magnification or with the naked eye, as for example in Fig. 1.

Macro examination of a weld will reveal the following conditions:—

(*a*) The number of layers of metal and manner in which they have been deposited.
(*b*) Excessive, or lack of, penetration of weld metal.
(*c*) Lack of fusion along the side walls and between runs.
(*d*) Porosity.
(*e*) Inclusions of slag, oxide, etc.

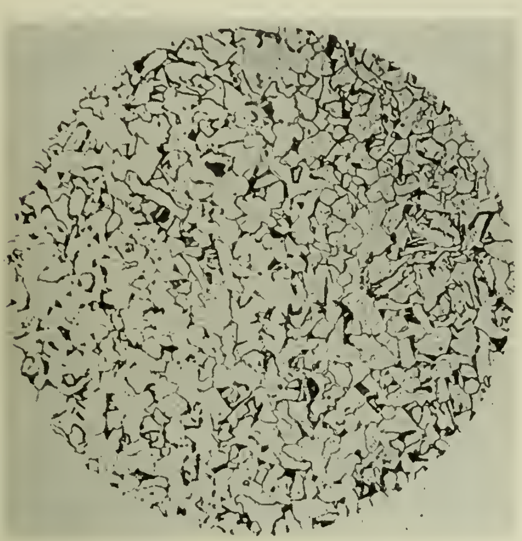

Fig. 14—Mag. 100X.

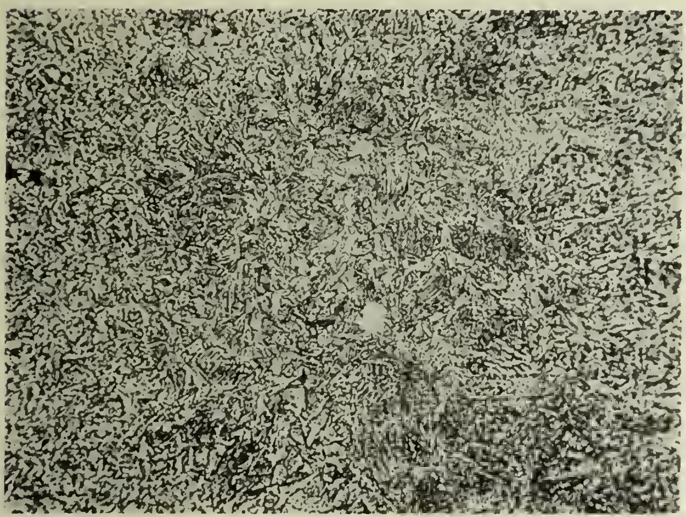

Fig. 15—Mag. 100X.

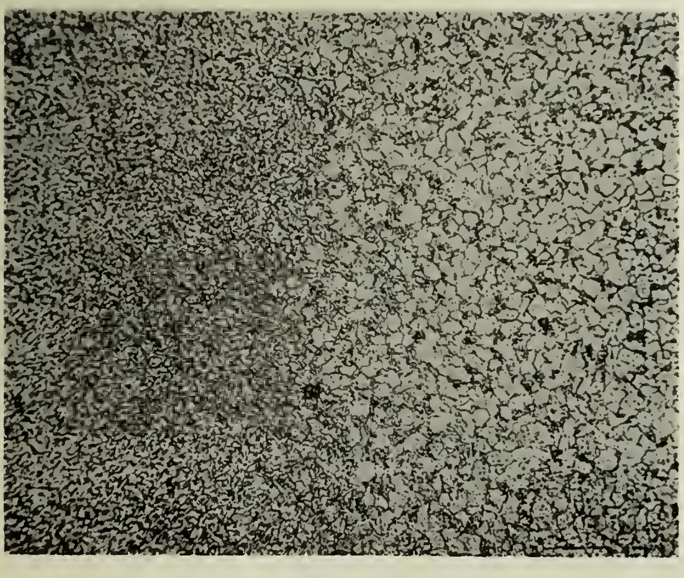

Fig. 16—Mag. 100X.

Micro Structure of Low-Carbon Metallic Arc Welds

The solidification of weld metal results in the formation of a "columnar" structure due to rapid cooling when the metal is deposited in a single layer. In multiple layer welding each layer modifies the structure of the preceding and a knowledge of these changes and factors contributing to them is of fundamental importance in the deposition of weld metal as also the degree to which the parent metal is affected.

The structure typical of weld metal deposited by the metallic arc process is illustrated by the following examples.

"Bare" Wire Weld Metal (see Figs. 10 to 13).—The weld metal was deposited in a 90-degree Vee on a ⅜-inch plate having a chemical analysis of 0.25 per cent C., Mn. 0.377, P. .028. The joint was made in three layers with a ⅛-inch diameter sull-coated electrode, .18 per cent C. and operated at 125 amperes and arc voltage 17. The electrode was negative. The tensile strength of the weld metal was 61,000 pounds per square inch.

Figure 10 shows the structure of the parent metal which is that of ordinary hot rolled steel finished at a high rolling temperature.

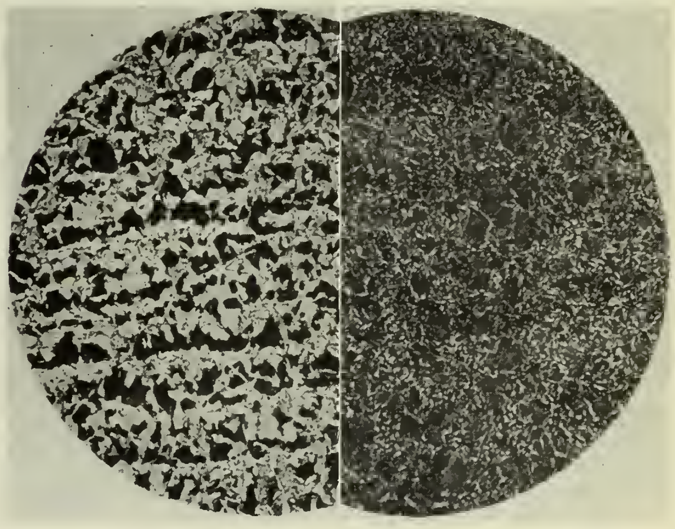

Fig. 17—Mag. 100X. **Fig. 18—Mag. 100X.**

Figure 11 shows the structure adjacent to the weld metal deposited in the first pass. The grain size has actually been refined and indicates a temperature of 1,525-1,550 degrees F. within the thermo-critical range.

Figure 12 represents the structure of the first pass which has been altered by the heat effects of subsequent layers. The structure shows the so-called nitride needles and segregation along the grain boundaries.

Figure 13 is the characteristic structure of a single pass weld. The grain structure is coarse and greater segregation of impurities result.

Covered Electrode Weld Metal (see Figs. 14 to 20). —Figure 14 represents the structure of blue annealed 12 gauge sheet having an analysis of C. 0.17 per cent, P. 0.013 per cent, Mn. 0.45 per cent, S. 0.032 per cent, with physical properties of 41,340 pounds per square inch elastic limit, 58,470 pounds per square inch ultimate and 22.5 per cent elongation in 8 inches.

The grain structure and distribution of pearlite (dark areas) are uniform, the light areas are ferrite in excess of that required to form pearlite.

Figure 15 represents the weld structure formed by automatic butt welding of this material with a heavily covered electrode at 160 amperes, an arc voltage of 25 and speed of 14-16 inches per minute.

The structure is Widmanstatten in character, typical of single layer deposition and indicative of primary crystallization.

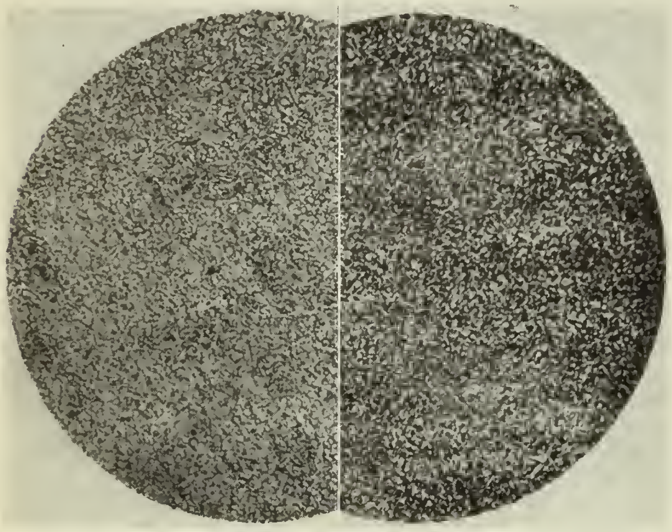

Fig. 19—Mag. 100X. Fig. 20—Mag. 100X.

The weld metal analyzed 0.10 per cent C., 0.47 per cent Mn., 0.02 per cent Al_2O_3.

Figure 16 shows the transformed area adjacent to the weld. In this area a recrystallization has taken place and the grain structure is somewhat smaller than that of the parent metal.

Figure 17 represents the structure of 1¼-inch plate having an analysis of C. 0.33 per cent, Mn. 0.49 per cent, P. 0.029 per cent, S. 0.019 per cent, Si. 0.20 per cent, with physical properties of 45,330 pounds per square inch, elastic limit, 79,300 pounds per square inch ultimate, 30 per cent elongation in 2 inches, reduction of area 48 per cent and Brinell hardness 163.

A U-type of groove was used and the weld metal deposited in eleven layers, using a 3/16-inch diameter electrode and 220 amperes for the first pass and ¼-inch diameter electrode and 360 amperes for subsequent passes. The back was chipped out and two passes laid down using a 3/16-inch diameter electrode.

After welding the structure was stress relieved at 1,200 degrees F. for one hour per inch of thickness.

Figure 18 represents the transformation zone next to the parent metal.

Figure 19 is the area adjacent to the weld and has a sorbitic structure.

Figure 20 shows the structure of the weld metal which is typical throughout the cross-section except for the top and bottom passes.

From the photomicrographs shown it is apparent that the conditions of heating and cooling, which are produced in the material adjacent to the welding zone, give rise to an infinite number of structural forms as the temperature gradient ranges from normal to the melting point of steel.

The Boulder Dam - Los Angeles Transmission Lines

O. W. Titus,
Chief Electrical Engineer, Canada Wire and Cable Company Limited, Toronto, Ontario.

Paper presented before the Niagara Peninsula Branch of The Engineering Institute of Canada on October 22nd, 1935.

SUMMARY.—After giving engineering particulars of this 270-mile, 287-kv. transmission line, the paper discusses the concentric type of conductor employed, with respect to manufacture, corona loss, vibration and jointing.

The Colorado river is one of those rivers which have been both a curse and a blessing. Boulder dam is intended to remove the one and to add to the other. It drains approximately 240,000 square miles with an average annual run-off of about 16,000,000 acre feet (varying from 4,000,000 to 24,000,000 acre feet). Couple this tremendous variation with a great seasonal variation (there being but little natural storage and a consequent sudden run-off) and the necessity for some control is apparent. The serious floods and the tremendous silting up of the channel in the lower reaches, with the resultant dyke expense, demanded some action.

The Black Canyon of the Colorado, where the Boulder dam is being built, is located about 150 miles down stream from the Grand Canyon. It is on the border of Nevada and Arizona near the south-west corner of Utah and quite close to one corner of California. The project is for the purpose of water storage for (*a*) river control, (*b*) water supply and irrigation, (*c*) electric power.

The Boulder dam must be considered in conjunction with the Colorado river aqueduct fed from the Colorado river about 150 miles downstream at the Parker dam. This aqueduct is a larger project than the Boulder dam (some $225,000,000 as compared with $185,000,000) but does not receive the same publicity. The necessity of the aqueduct is due to the water situation in Southern California, particularly in the metropolitan water district in and around the city of Los Angeles. As the population of the Southern California Pacific slope is growing, the existing water supplies are proving increasingly inadequate. Nature even now (with only 15 inches annual precipitation) is not replacing water as rapidly as man is withdrawing it. The Boulder dam's 30,000,000 acre feet capacity will compensate for the smaller capacity of the Parker dam, about 700,000 acre feet. It is a necessary factor in the Parker dam and Colorado river aqueduct project.

With these thoughts in mind it will be appreciated that the Boulder dam involves a great deal more than the development of cheap hydro-electric power, and those in the electrical industry must not judge this immense project purely from their own viewpoint.

Fig. 1—Location of Boulder Dam in Southern California.

However, this article deals particularly with the electrical side. The United States government sells the water in the penstocks to the generating interests at 1.63 mills per kilowatt hour for firm power and 0.5 mill for secondary power, also installing the generating apparatus but recovering the cost thereof in instalments.

The site eventually will be able to develop 1,800,000 h.p., four machines of 115,000 h.p. each now being under construction.

The first block of power is 240,000 kv.a. contracted for by the City of Los Angeles Department of Water and Power and it is the transmission of this power from the dam to Los Angeles that is to receive attention in this paper.

Later blocks of power will be taken, one to pump the water over the mountains in the aqueduct project mentioned above, the Metropolitan Water District of Los Angeles (not to be confused with the Department of Water and Power) being the purchaser. A third lot will go to the Southern California Edison.

In neither of these latter cases is absolute continuity of service so essential as with the Department of Water and Power, the Southern California Edison block being supplementary to steam and local hydro-electric developments, and the aqueduct having large water reservoirs close to Los Angeles which would render even a comparatively long power interruption not serious.

In the case of the Department of Water and Power, however, absolute dependability is of utmost importance and pains have been taken toward ensuring only the best of constructions.

Due to the magnitude of this project and the conditions involved large sums of money and time have been spent on research to see that the right thing is done and that continuity of service is ensured.

The dam itself will rise 730 feet above bed rock and will be 1,180 feet long by 43 feet wide at the crest. It is keyed into slots cut in the rock on each side of the canyon although due to its 650-foot thick section at the base it will be stable of itself even against the relatively great head of water involved.

During construction, the river is being diverted through four 50-foot diameter by one-mile-long tunnels cut in the solid rock. These tunnels, or rather the lower ends of them, will be used later for spillway and discharge outlets.

Spillways, one on each side of the river, will be for flood control and will connect through 50-foot tunnels to the down-stream ends of the diversion tunnels mentioned above. It should be noted that water will not flow over the crest of the dam, the dam being designed on that basis due to the high temperature to which the concrete is subjected on the down stream face. It is feared that if water were to flow over the face of this concrete it would result in destructive stresses at the surface of the concrete.

The power houses will lie at the bottom of the downstream face of the dam and on both sides of the river.

The Boulder dam is 271 miles from Los Angeles, the intervening country being desert and low mountains as far as Cajon Pass, a distance of 231 miles, and thence 40 miles of coastal slope to the city. The characters of these sections have resulted in different types of transmission line construction as will be shown later.

As mentioned before, the block of power under present discussion is 240,000 kv.a. This is to be transmitted 271 miles at 287,000 volts sending end, 275,000 volts (grounded neutral) receiving end on two three-phase lines of 512,000 c.m. copper. It is said that this would be equivalent to three 220-kv. lines. Overhead ground wires and counterpoises are used throughout, average spans 1,000 feet.

Transmission Lines

The transmission line will cost $13,700,000 or a cost of about $25,300 per circuit mile.

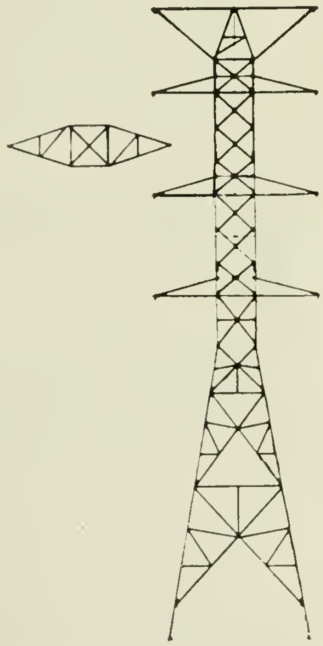

Fig. 2—Double Circuit Tower, Coastal District.

In the 40-mile coastal district a single line of double circuit towers will be used. These towers are of standard construction and of the following dimensions.

Each tower:
- Height—144 feet 2 inches.
- Conductor spacing—24 feet 6 inches vertically in a plane.
- Circuit spacing—40 feet 6 inches.
- Height to lowest cross-arm—75 feet.

Weight—23,000 pounds.
Insulator strings—approx. 12 feet long.
Ground wires—2 lines 7/16 inch e.h.t. copper-weld steel on 40-foot 2-inch centres.

There will be two hundred and seventy-one towers in this district.

In the desert section, of 231 miles, a double line of single circuit towers is being employed. Switching stations

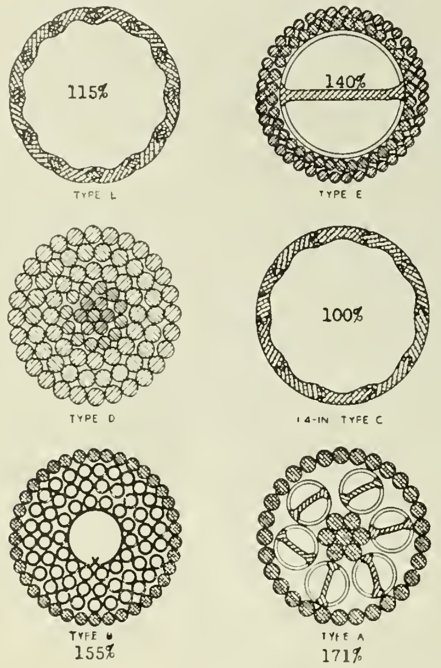

Fig. 3—Comparison of Weights for some Outside Diameters. Weights Expressed in Per Cent of 1.4 inch Type C (Type HH).

are being set up at about 90-mile intervals to permit cutting out sections of either line for maintenance or emergency purposes.

Each tower:
Height—109 feet 2 inches.
Conductor spacing—32 feet 6 inches horizontally.
Circuit spacing (tower line, centres)—265 feet standard.
Height to cross-arm—90 feet.
Weight—18,000 pounds.
Number—2,530.
Ground wires—2 per line (4 total).
—½-inch galvanized steel on 50-foot centres.

The base is rotated 45 degrees from the normal which results in an approximate saving of 10 per cent in weight.

Counterpoise systems normally are either of the crowsfoot type or parallel type. This is a combination of both, a double line of ½-inch black copper rod extending along each tower line and cross connected at each tower. It is just another evidence of extreme factors of safety in design on account of the importance of 100 per cent service from the line. About 4,000,000 pounds of copper were used in this counterpoise system.

Conductors

A highly important element in the transmission line is of course the conductor. On account of breaking new ground in the voltage range, and due to the amount of material involved, a variety of conductors have been studied.

In selecting a conductor in the upper voltage ranges one must consider two factors from the viewpoint of losses:—

1st—The cross-sectional area must be sufficiently large to keep the $I^2 R$ losses within proper limits but should not be larger than that amount or the best economy in use of metal is not attained. Cost of power and cost of metal are the determining elements in this first division of the problem.

2nd—The outside diameter must be such that for the voltage, spacing, altitude and kind of conductor surface the corona loss does not become excessive. Corona is that pale blue discharge accompanied by a rustling sound developed around a conductor if the voltage stress in the surrounding air rises above a certain critical value, the critical value depending on conditions. The production of this corona absorbs an appreciable amount of power and must be given proper consideration when designing a line.

Increasing conductor diameter (other conditions being equal) is the common method of reducing excessive corona loss.

So long as condition "one" (economical resistance loss) results in condition "two" (economical corona loss) being fulfilled one has an economical design without waste of metal. If, in order to meet corona loss consideration, more metal is employed than resistance loss necessitates one does not have the most economical design and good engineering requires a better metal efficiency.

This search for the efficient use of the conductor metal led the Los Angeles engineers to study a wide variety of conductor designs, from the conventional concentric stranded and the internally supported expanded sections to the finally selected type HH. (See Fig. 3.) With this construction one can engineer properly the conductor design for resistance loss and corona loss independently of each other between quite wide limits; this by increasing the thickness of the wall while maintaining the same outside diameter; or by adjusting the wall thickness while maintaining the same cross-sectional area and varying the outside diameter.

This design of conductor has an important characteristic from the corona viewpoint of which full advantage was not taken in this particular transmission line. It is well known that a smooth cylindrical surface is the most resistant to the formation of corona. Any unevenness on such a surface aids the formation of corona. An inspection of the surface of the type HH conductor shows it approximates very closely to a smooth cylinder whereas the conventional stranding has a large number of serrations.

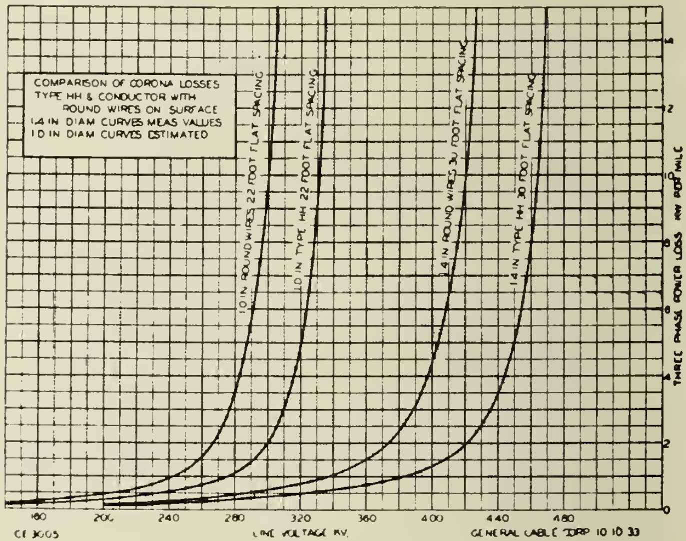

Fig. 4—Comparison of Corona Losses.

It has been proved by extensive experiments that for a given diameter the type HH loss is much lower than that of the conventional. (See Fig. 4.) Or if the economical corona loss has been determined a smaller diameter conductor may be chosen for HH than for conventional. In the case of Los Angeles this would have permitted a still smaller cross-sectional area for HH than was used if it had been so desired. This would have reduced the conductor weight to about 83 per cent of the chosen value.

In examining a type HH conductor the interlocking structure essential to prevent any "bird-caging" during handling should be noted. Some idea of its strength under crushing may be gained from an actual experience where one flange of a two-ton reel dropped on top of a 1.1 inch o.d. 500,000 c.m. type HH cable. The conductor was dented seriously but did not collapse. In fact, as it was an experimental length, it was pulled up on the line and the location is not detectable from the ground.

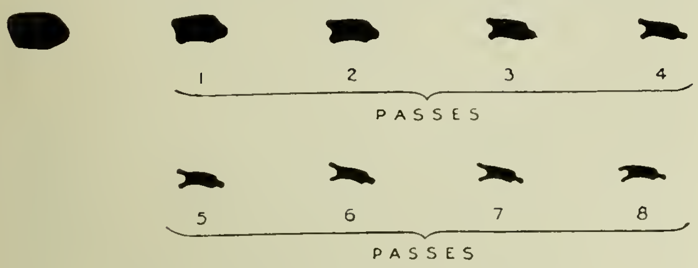

Fig. 5—Steps in Drawing Down Segments.

The Boulder dam-Los Angeles conductor is a 512,000 c.m. hard copper type HH hollow conductor of 1.4 inch o.d.

There are ten tongue and groove segments of 28-inch lay.

Ultimate strength	21,600 pounds.
Normal spans	1,000 feet.
Normal max. sag	46 feet.
Normal max. stress	40 per cent of ultimate.
Loading—Coastal	12-pound wind at 25 degrees F.
Loading—Desert	½-inch ice and 8-pound wind at 0 degrees F.
Weight	1,570 pounds per 1,000 feet.
Total length	1,640 miles.
Total weight	13,600,000 pounds.
Shipping lengths	1 mile (10 per cent—½ mile).

In the manufacture of the conductor the segments are drawn from flattened hot rolled copper rod through eight successive dies. (See Fig. 5.) The groove deepens and the tongue extends until section No. 8 is reached. Note the lower lip of the groove bent downward toward what will eventually be the inside of the cable. Also observe the neck of the tongue part.

In the closing machine ten of the final sections mentioned above are wound on bobbins in a little over one mile lengths. The bobbins are mounted in a rigid frame closing machine (by rigid is meant that the axis of the bobbin is fixed in, and in this case tangential to, the rim of the spider).

The segments, as the machine rotates, pay off through hardwood guides thence through a set of ball guides into the circular closing die which is the diameter of the finished cable. Here the segments are locked together by the action of a plug which rotates with the frame of the machine but which extends inside the converging segments as far as the die, with which it is concentric. This rotating plug closes the inside lip of the groove over the neck of the tongue and produces the completely interlocked conductor.

Joints and Dead-Ends

In conventionally stranded cables the inner elements are customarily gripped at the joint or dead-end by means of crushing or deformation of themselves and of the outer elements. The problem of jointing in type HH is particularly simple since all elements (segments) of this cable are readily accessible both externally and internally and over the greatest part of their peripheries.

Further the easiest shape to fit accurately with machined parts is a circular cross-section.

In the type HH joint a plug is inserted inside the conductor. Outside the conductor a conical split wedge is pulled down onto the conductor by an opposed wedge outside the inner wedge. Increasing tension in the conductor increases the grip in the joint. The dead-end is half a joint with an appropriate shank.

Vibration

The research work done in designing the Boulder dam-Los Angeles transmission line included some extensive work on the problem of conductor vibration which is the cause of so much worry to transmission line engineers all over the world.

If a uniform light breeze passes across a suspended conductor at approximately right angles to the line the conductor begins to vibrate vertically in wave lengths of from about ten to thirty feet depending on the wind velocity. The amplitude may be from infinitesimal to one or two inches, usually less than an inch. The wind velocities involved are from about 2 to 9 or 10 miles per hour. Above that value the characteristic wave length is so short that the energy necessary to maintain vibration becomes too great for the energy available from the wind, and vibration ceases. That at least is one of the theories of this vibration phenomenon.

The objection to the vibration is that its energy is dissipated mostly at suspension points which, being overworked, may fail under fatigue after a few months or few years service.

In line with their policy of caution the Los Angeles engineers have made a long research on vibration. Actual vibration in the field was studied by means of a double span erected on service towers at a location considered particularly liable to set up conductor vibration. An ingenious apparatus at the centre suspension point was developed by which a beam of light was projected through a pin point in a light metal diaphragm (the metal diaphragm being attached to the conductor or clamp, as the case might be, by piano wire) thence onto a travelling motion picture film. Simultaneously dots of light indicated time, wind velocity and wind direction.

Both conductor and suspension clamp motions were recorded simultaneously in order that relative motion between the two might be studied in the office. This relative motion represents the working on the cable tending to destroy it by fatigue.

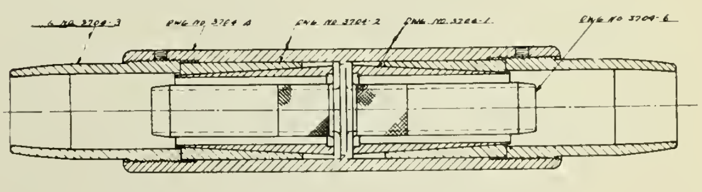

Fig. 6—Type of HH Joint.

This research indicated, up until about a year ago, that vibration occurred not over 3 per cent of the time during the worst season and during May, 1934, not over 1 per cent of the time. This is considered highly satisfactory.

Further, it was observed that no vibration occurred in winds above 6 miles per hour and the most at about 2 miles per hour. This means that the cable is such that it cannot follow the natural frequency due to the wind at the most dangerous velocities (i.e. when the energy content of the wind is high), and only vibrates when the wind energy available is so low as to greatly lower the possibility of damage.

At that time the maximum working angle between the cable and the clamps worked out to .0234 degree. In order to determine what this meant in reference to the ability of the cable to stand such working, the city engineer mechanically vibrated such a cable in a frame in their shops at over 15 times that value. The last report from this indicated that it had stood well over 500,000,000 cycles, without failure.

Additionally to these tests the city engineers studied the behaviour of clamps under vibrations mechanically imposed on the conductor.

At Leland Stanford, Dr. J. S. Carroll has been making extensive studies on vibration. In one study he electromagnetically vibrated various conductors at various wave lengths and various amplitudes, measuring the power input. Then in his unique wind tunnel he measured the frequency and amplitude at which various cables vibrated under various wind velocities. The wind tunnel is unique in that the wind blows across the long dimension instead of along that dimension. It was a big problem to get uniform wind velocities without pulsation or eddies perpendicularly to a fifty-foot sample.

Also at Leland Stanford, the P.G. & E. were studying vibration dampers, and at Los Angeles the Southern California Edison are erecting various types of cables on a tower line where particularly bad vibration trouble has been experienced in the past. The author understands that in Northern California the P.G. & E. are, or were, studying dampers on the line, an article having been published in "Electrical Engineering" during 1934 on their findings.

Altogether the State of California is very much alive to the vibration problem and there should be some valuable results available before long.

Present Status

The dam is complete, and the power house building practically complete. The first penstock will have been tested by the time this article is published.

The first two generators will be ready for operation June 1st, 1936, and two more by August 1st, 1936.

On November 1st, 1935, the water impounded was 4,013,000 acre feet, with a lake length of 80 miles. The inflow at that time was 5,270 second-feet with an outflow of 9,850 second-feet; i.e. the dam already is functioning to supply extra water during low stages of the river.

All the transmission line conductor has been shipped, the last shipment being made November 18th, 1935. All the desert single circuit tower transmission line has been completed and has passed, just recently, through a very severe wind storm. During this storm a number of transmission lines in the district, including an important 220-kv. line, were blown down. The Boulder dam-Los Angeles line described in this article was subjected, in the Cajon Pass section, to the highest recorded wind velocities in the district during the storm but a close and detailed examination showed no troubles.

The coastal district, 40 miles, has been held up until just recently due to right-of-way difficulties but these now are settled and the entire line will be finished by May 1st, 1936.

The author gratefully acknowledges information and illustrations received from Mr. W. O. Bolser, of the Department of Water and Power of Los Angeles, and Mr. D. M. Simmons, chief engineer of General Cable Corporation, manufacturers of the type HH transmission line conductor.

Geological Mapping With Aeroplane Assistance*

F. J. Alcock, Ph.D.,
Geological Survey of Canada, Ottawa, Ont.

Paper presented before the Ottawa Branch of The Engineering Institute of Canada, April 25th, 1935.

SUMMARY.—The author describes the advantages of employing aircraft in geological exploration in remote areas of the Precambrian shield. Accurate and complete topographic maps made from aerial photographic surveys are now available as a basis for geological work, many general features of which can also be obtained from the air. Aircraft facilitate ground exploration by transporting the bulk of a party's supplies, thus enabling the canoe parties to travel light and make their detail examinations with a minimum of physical effort.

During the field season of 1934 the author was engaged in mapping geologically a tract of country in northern Saskatchewan lying north of the Churchill river and drained by two of its tributary streams, the Mudjatik and the Haultain. The topographic mapping of the region by means of air photographs had brought out the possibility that the geology here might be worth investigating. Many of the lakes in the area are long and narrow and follow broad curves. Experience in other Precambrian fields suggested that this meant that the rocks in which the lake basins lie probably consisted of ancient sediments or volcanics intruded by oval-shaped masses of granite and that the drainage had adjusted itself to the softer formations surrounding the harder granite. Such an association of stocks of intrusive rock surrounded by older formations offers good prospecting territory. The region is also one of fairly easy access and it seemed desirable, therefore, to have it explored geologically since practically no information was as yet available concerning it. The provincial Department of Natural Resources offered, if the federal Geological Survey would undertake the investigation, to assist the party to and from the field, and to place at its disposal for the season a Vedette flying boat and a pilot.

When the author was asked to take charge of this exploration the proposal made a very strong appeal. Up to 1922 most of his work had been in northern Alberta, Saskatchewan and Manitoba in country very similar to this. Conditions of work, however, even as late as 1922, were entirely different from what this would be. In those days carrying out geological work in the western Precambrian meant not only studying the rock formations but it involved also making a topographic map to serve as a base to put the geology on for then the only maps available consisted of a few track surveys along the principal water routes. In more recent years our geologists in many areas have had the advantage of topographic surveys made from air photographs showing where the lakes and streams and muskegs lie thus enabling them not only to devote their main attention to their geology, but also to plan their work to much better advantage. Here in the Mudjatik region would be an opportunity not only to work with the new advantage of a good base map but to go one better and have in addition the use of a flying boat. It would be most interesting to see just how much help this would really be in saving time and labour and in doing more and better work.

The Mudjatik area may be reached by either of two routes both of which start from Prince Albert. The older is from end of steel at Big River and this still remains the one by which most of the freight is taken in. It follows along Cowan lake and Cowan river to Beaver river which empties into Ile-à-la-Crosse lake, an expansion of Churchill river. A new route has recently been opened up by way of Meadow Lake, about 125 miles northwest of Prince Albert where a clay belt has been developed into an important farming section. From Meadow Lake a truck road leads to Doré situated below what are known as the Grand Rapids of the Beaver and from there the Beaver offers a good water route to Ile-à-la-Crosse lake. Here is a trading post which has had a long interesting history for it lies on the old Methye portage route which for over one hundred years was the main highway to the Athabaska-MacKenzie region. Now in addition to the trading post there is a church, a hospital, a wireless station and district officer's quarters. At the north end of the lake where the Churchill makes a swing to the east is another post known as Wapache Wunak. The flying boat joined the party here and as the mouth of the Mudjatik is only about eight miles to the northeast, this post served as a convenient headquarters for provisions and gasoline.

The region to be investigated lies within the Canadian or Precambrian Shield and presents the features common over that vast region, the most striking of which is the multitude of lakes of all sizes and shapes which dot its surface. The relief varies from about 1,250 feet, the elevation of the Churchill river at the mouth of the Haultain, to around 1,850 feet the height of the higher ridge summits in the central part of the area. Rock ridges rise to heights of over 200 feet above the level of the adjacent lakes and most of the lakes have rocky shores. Being on a divide between three rivers, the streams of the area are all small, few of them large enough for travel even with light canoes. Hence in places to get from lake to lake long portages were

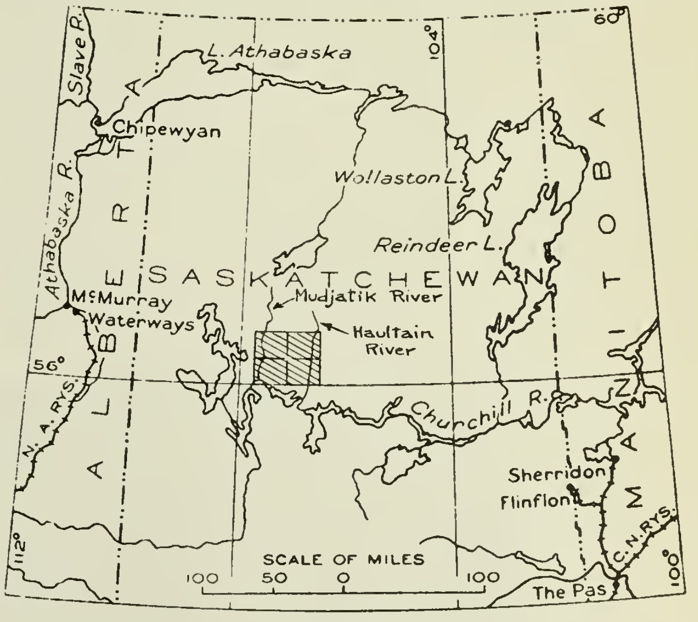

Fig. 1—Northern Saskatchewan. Hatched Section Indicates Area Surveyed.

necessary and the steep-sided character of many of the intervening ridges made the finding of feasible routes sometimes difficult. From the map a route of travel was planned through the area following the larger lakes so that from some places or other on it practically any point in the region could be reached. From camps conveniently spaced along this route the party proceeded by canoe in pairs to examine all the rock exposures along the lakes and to make

*Published with the permission of the Director of the Bureau of Economic Geology, Department of Mines.

inland traverses on foot at key places. Much of the country was covered by side trips lasting from two to four days away from the main camps made by members of the party travelling in pairs. With a light canoe and a silk tent it was often possible to travel without cutting trails and to make but one trip on the portages suffice.

With the assistance of the plane the amount of physical work necessary in travel of this kind was cut down to a minimum. Since regular trips were made by plane to Wapache Wunak for more gas and provisions it was never necessary to have more than ten days' supplies with us and when camp was to be moved loads were thus at a minimum. Before moving camp a preliminary flight was always made to choose the next camp site and to select the best route of travel for the canoes to follow along. In choosing a camp site first consideration had to be given the plane; there must be a sand beach or a muskeg shore where, when tied up, it would be safe no matter from what quarter a gale might blow. In moving, three flights of the Vedette usually took most of the load so that only one trip on the portage was all that was necessary for those travelling with the canoes. A most important feature which has already been referred to is that with the plane to do the portaging it was possible to travel with light canoes instead of with heavy freight ones, a vital consideration where portages are long and trails either poor or entirely lacking.

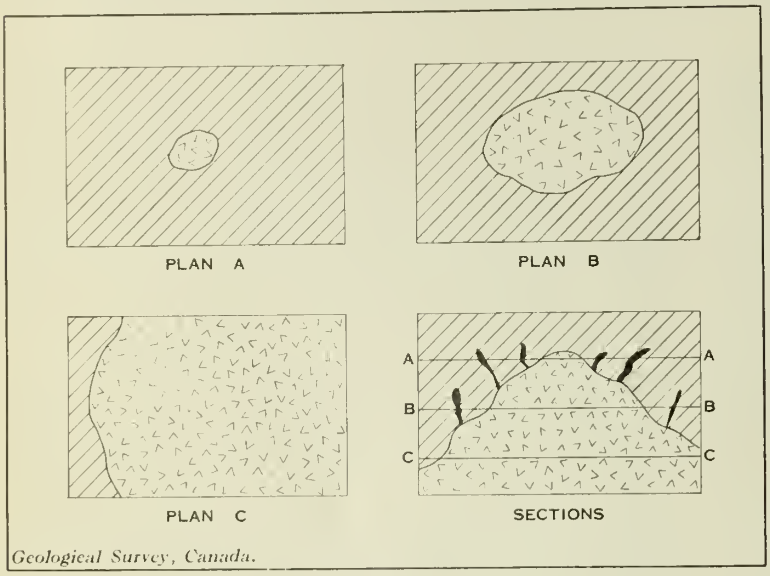

Fig. 2.

In addition to its labour-saving help the plane was of use in speeding up the actual geological mapping. Though the flying boat was unable to transport any of the ordinary canoes, the party was supplied with a collapsible canvas canoe which could be carried in the front cockpit. At times while members of the party were making traverses with the ordinary canoes, the pilot and the writer would fly to some lake, otherwise difficult of access, secure the plane fast in some bay, put the canoe together and spend the day examining the shore outcrops or in making traverses inland. In the evening a return would be made to camp. Some of the places which would have been the most difficult to reach by ground methods were thus reached and examined with a minimum of work and trouble.

Aside from these purely mechanical uses, it was interesting to see how much help could be obtained from the plane in connection with the more technical side of the work. It is the work of the geologist to study the various rock formations, to find out their relations, i.e., the sequence in which they were formed, and to indicate on a map their areal extent. If there are any known mineral occurrences it falls to his lot also to investigate these to try to find out why they are located where they are in order to direct intelligent search for more deposits. In the Mudjatik region there are a great many rock types but they all fall into three main groups. The first and oldest is a series of sediments originally laid down under water forming sandstones, shales, and locally limestone. Later a second group of dark rocks came up in a molten condition from deep within the earth's crust and injected themselves into the sediments for the most part along their bedding planes. All these rocks were later thrown into folds during mountain-building movements. Accompanying these movements great masses of granite arise from below in a molten state and intruded themselves into the overlying rocks. The granites carried mineralizing solutions which, during late stages of the cooling, were given off and resulted in the formation of ore deposits. A tremendously long period of erosion then followed during which the mountainous topography was reduced to one of low relief. This dissection brought to the surface the granites which had solidified at depths. in places denudation proceeded so far that only small remnants of the older formations were left. It is most important to have these areas of older rocks delimited for it is in the zones of contact between the older complex and the younger intrusive rocks that ore deposits may be expected to be found. The larger these areas of older rock the more hopeful are they as prospecting fields. Figure 1 is a diagrammatic representation of a region intruded by a large mass or batholith of granite. Plans A, B and C, represent geological maps of the region after it has been denuded to the respective levels shown in the section. It can readily be seen that at Stage A, the region is good prospecting country, that at Stage B, there is still hope of finding deposits, but that at Stage C, most of the ore deposits have been removed in the general dissection of the region. The geological mapping of the Mudjatik area brought out the fact that it is of the Stage C type, consisting of wide areas of granite or granite-gneiss with only narrow remnants of the older rocks remaining.

Much of the country had been swept by a series of forest fires and as a result there were large areas where from the air one could make a fairly good guess as to what

Fig. 3—Typical Topography of the Region.

rocks formed the ridges. For example, if we had paddled round a long narrow lake with continuous rocky shores and had seen nothing but granite-gneiss and, if on an adjacent lake nothing but that same rock type had been found, and further, if a flight over the intervening country showed bare hills of rock looking exactly like the exposures seen on the lake shores it was fairly safe to colour in the whole area without going to the trouble of making cross traverses on foot. In places where geological contacts on the ground had been located it was found possible to project these contacts by means of observation from the air. Even in burnt country, however, this had to be done with a great deal of caution while in country of green timber it was the author's experience that little reliance could be placed on guesses made from the air. Nevertheless air observation reduced to a minimum the amount of land traversing necessary and thus saved a great amount of time.

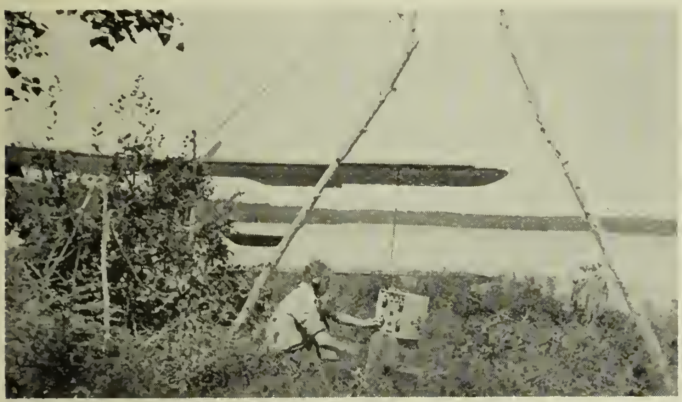

Fig. 4—Establishing Radio Communication with Ile-à-la-Crosse.

The only mineralization observed in the area were several large quartz veins and a few small sulphide showings none of which carried any appreciable gold content. Two of the quartz veins could readily be seen from the air. It is not the large veins of this type, however, which ordinarily prove of value and ground work must always be the method to locate the smaller gold-bearing veins. Sulphide deposits are commonly betrayed by their rusty gossan or iron-cap. In places these can be spotted from the air, but without careful ground work many more valuable ones might be readily passed up. Too much, therefore, must not be asked of the aeroplane.

It can be definitely stated, however, that aeroplane assistance has revolutionized geological mapping in the Precambrian fields of northern Canada. The difference between work with and without such assistance can only be fully appreciated by those who have worked under both sets of conditions. In a period of less than three months the author with aeroplane assistance mapped an area of some two thousand square miles. Modification of this work could be made to suit special undertakings. A plane capable of carrying canoes would be a still further improvement and help, and one such plane could service a number of geological parties working in the same general region. Geological supervision and co-ordination would also be possible by having an experienced geologist in charge of such a general undertaking. After the regional geological mapping was done in this way prospecting outfits could be placed in the likely areas delimited on the geological maps and these could similarly be serviced and supervised by aeroplane help. The possibilities of this new aid to geological investigation have only begun to be generally appreciated.

VOLUME XVIII DECEMBER 1935 No. 12

The Fiftieth Annual General Meeting

Notice is hereby given that in accordance with the By-laws, the Annual General Meeting of The Engineering Institute of Canada for 1936 will begin at Headquarters at eight o'clock p.m., on Thursday, January 23rd, 1936, for the transaction of the prescribed business, and will be adjourned to reconvene at the Royal Connaught Hotel, Hamilton, at ten o'clock a.m. on Thursday, February 6th, 1936.

The Quebec Electricity Commission

An important commission has been constituted under recent legislation in the province of Quebec, for the purpose of regulating public services in connection with the production, transmission and distribution of electricity in the province. Dr. Augustin Frigon, M.E.I.C., now Director of Technical Education of the province and Dean of the Ecole Polytechnique, Montreal, has been named chairman of the new Quebec Electricity Commission; Dr. O. O. Lefebvre, M.E.I.C., at present chief engineer of the Quebec Streams Commission, has been appointed vice-chairman, and J. W. McCammon, A.M.E.I.C., consulting engineer of Montreal, becomes a commissioner.

The powers of the new commission are very wide, and the future of the electrical power industry in the province of Quebec will be largely dependent upon its policies and activities. The provincial government is, therefore, to be congratulated on securing for the personnel of the commission three engineers of such standing and experience. The duties of the commissioners will involve technical knowledge and judgment of a high order, and it is refreshing to find that this fact has been realized by the government and that a departure has been made from the customary practice of selecting commissioners almost exclusively from men having a legal or business training. It is probable that the secretary of the commission, yet to be appointed, will be a lawyer, so that expert opinion will be available on the legal aspect of the commission's work.

The commission has power, generally, to hold enquiries into the electricity services in the province, particularly as regards quality of service, equipment, means of protection, extension of the systems, reports to be made, rules, regulations, conditions, and practices affecting the rates and charges connected therewith. It will be the judge in cases of dispute between a company and a municipality as to the right to use a street or water-course, and other similar questions. Its approval must be given to the construction or operation of any new line or plant, and the same control will apply to extensions or alterations to a plant. Whenever the public interest demands, the commission may order any public service to extend its line, network or system. No public service may wholly or partly suspend operations without its approval.

Schedules of all rates must be filed with the commission, and no increases or alterations in classification or rules will be permitted without showing justification to the commission, and getting its approval. All rates and charges claimed by a public service must be established in the interest of the consumer, and in that of the public service and of the investors therein, and must be fixed with due regard for the economic interests of the province and the particular conditions of the service concerned, so as to assure a just and reasonable revenue for such public service; taking into account, however, only expenses really and justly applicable to the operation of the public service in question.

The commission may set rates upon its own motion, as well as upon complaint. The commission may also disapprove or vary the terms of a contract hitherto existing, when it is a matter of distribution or sale of electricity for light, heat, energy or motive power.

Sales of one company to another or mergers of companies are subject to commission approval, and approval is required also for exchange of services. All capitalization of a public service is under the supervision of the commission, and uniform bookkeeping systems may be required. Contracts between a municipality and a public service also require ratification.

Guarantees of the impartiality and independence of the commission are provided, since no commissioner may hold any office or carry on any employment inconsistent with the performance of his duties, nor may he hold or be interested in any security of any public service corporation. The commissioners will give their attention exclusively to the work of the commission and must not follow any other occupation. They will be independent of the government and of political influence, since it is provided that they shall remain in office during good conduct, and may be dismissed only by the Lieutenant-Governor on a joint address of the Legislative Council and Legislative Assembly. Employees for the commission's service will be appointed by the Lieutenant-Governor-in-Council, and provision has been made for pensions for the commissioners on the same basis as for provincial judges.

The Nickel Industry

It is nearly fifty years since nickel was found to occur in the copper-bearing ores of the Sudbury mining district. In addition to copper, that area is now yielding gold, silver, selenium, tellurium, and metals of the platinum group, and, most important of all, is providing some eighty per cent of the world's requirements of nickel, the Canadian production of that metal in 1934 amounting to about 64,000 tons. An industry yielding over thirty million dollars a year is one in which Canadians certainly should be interested, particularly since its principal product has now become an essential in so many branches of engineering work.

The remarkable increase in nickel production which occurred in 1933 and 1934 was largely due to general improvement in industrial activity, but was greatly hastened by extensive researches carried out by the producing companies in order to discover and encourage new peace time uses for the metal. A useful resumé of the progress made in the metallurgy of nickel during the past ten years was given at the recent International Congress of Mines, Metallurgy and Applied Geology in Paris by Vice-President J. F. Thompson, of the International Nickel Company of Canada. Incidentally his statements will do much to correct the common idea that nickel is almost entirely used for military purposes. Striking figures were given by Dr. Thompson as to the great variety of commercial uses to which nickel is now applied.

Those who remember Sudbury in the days when the ore was roasted out of doors in great heaps, with wood as fuel, will learn with interest of the revolutionary changes that have been introduced in the treatment of the ore, particularly as regards the recovery of the platinum values from the ore of the Frood mine, and the production of metallic nickel of the extremely high purity now required, over 99.9 per cent. Much of the refined nickel used in Canada and the United States is now produced electrolytically at Port Colborne from the Sudbury matte, while metal of specially high purity is also made by the nickel-carbonyl process at Clydach in South Wales.

In his address Dr. Thompson drew attention to the

Fiftieth Annual Meeting

Members who recall the very successful meeting held in Hamilton seven years ago will be pleased to hear that the Annual Meeting Committee of that Branch, under the chairmanship of Mr. W. Hollingworth, M.E.I.C., are now completing their preparations for the welcome of members who will attend the Fiftieth Annual General and General Professional Meeting of The Institute to be held at the Royal Connaught Hotel, Hamilton, on Thursday and Friday, February 6th and 7th, 1936.

The city of Hamilton offers many advantages as a location for a gathering of this kind, not the least being easy access for the large Institute membership in the industrial area of Ontario in which it is so centrally situated. For those coming by train the railways will offer low rates for parties to be organized by our branch secretaries.

The following is an outline of the programme:

Thursday, February 6th:—

Morning:	Registration and Business Session.
	Induction of Incoming President and Council.
Noon:	Formal Luncheon.
Afternoon:	Technical Sessions.
	Reception and Tea for Ladies.
Evening:	Annual Dinner of The Institute.—Speaker, Sir E. W. Beatty.
	Dance.

Friday, February 7th:—

Morning:	Technical Sessions.
Noon:	Luncheon.
Afternoon:	Technical Sessions.
	Visits to Plants.
Evening:	Smoking Concert.

An attractive series of social events will be arranged, while as regards the technical features of the meeting, there will be a series of papers on transportation topics, featuring the effect of recent development of the various phases of that industry, especially with reference to the parts which different agencies of transportation can take in Canada's transport system. This timely presentation is expected to give rise to active discussion.

In addition, several papers will be presented on topics illustrative of some of Hamilton's manufacturing industries. These will be of particular interest in connection with electrical and ceramic work. Structural engineers will note an important paper on bridge construction.

The meeting will conclude with visits to a number of the varied engineering and industrial plants of which Hamilton possesses so many.

City of Hamilton from the Mountain

fact that over seventy per cent of the world consumption of nickel is used for alloys, and new uses for these alloys are being continually developed. For example, of the seventy-nine alloy steels in use in the automobile industry in North America, forty-one contain nickel, and that industry absorbs about twenty per cent of the world's production of the metal. There has been a corresponding increase in the use of alloy steels outside the automotive industry, due in large measure to advances in the technique of making these nickel-ferrous alloys. The old idea that alloy steels are useful only in the quenched and tempered condition is now quite discredited, as so many of them are giving excellent service in the "as rolled" condition, or after simple normalizing treatment. Certain nickel alloy steels have the remarkable property of retaining toughness at extremely low temperatures, and are finding employment for pressure vessels used at temperatures down to −75 degrees F., while others have been developed for use at high pressures and temperatures up to 1,500 degrees F., as in cracking stills and modern high pressure steam boilers.

Many troublesome technical problems have been solved by recent research in the metallurgy of nickel. Thus, the prevention of corrosion in condenser tubes by the use of a suitable copper-nickel alloy; the use of nickel-clad plates for tanks and containing vessels in the heavy chemical industries; the development of bright nickel plating requiring no buffing; the widening of the field of use of the stainless steels, are all achievements of which the industry may be proud. A multitude of new products have been placed at the disposal of the engineer, such as nickel-iron alloys which have special magnetic qualities, and age-hardening bronzes containing nickel and possessing remarkable properties as regards strength, hardness and ductility. All these are milestones on the road towards the era of alloys, and are results of the combined researches of the producers and the various consumer groups in the nickel industry.

Talking with Swiss Engineers

Canadian engineers in Montreal had an opportunity on the afternoon of November 22nd, 1935, of greeting their colleagues in Switzerland by speaking by trans-Atlantic telephone with a meeting of members of the Technical Society of Winterthur in Switzerland.

At the Winterthur meeting an evening lecture was being given by Professor Dr. Von Salis, on the subject of trans-oceanic telephone service, and by way of practical demonstration of his remarks, the brief addresses of the Montrealers were transmitted direct by wire and wireless telephony and received at the meeting over a loud speaker public address system installed in the lecture room.

The General Secretary of The Engineering Institute introduced the speakers to their Swiss audience, and with him in the board room of the Bell Telephone Company were Dr. F. A. Gaby, M.E.I.C., President of The Institute, Paul Ackerman, A.M.E.I.C., consulting engineer of the Shawinigan Power Company, and former student at the Federal Polytechnikum at Zurich, and Gaston Jaccard, Swiss consul-general, each of whom spoke in turn.

Dr. Gaby presented greetings from The Engineering Institute, and recalled incidents of two visits he had made to Switzerland some years ago, and M. Jaccard gave a brief resumé of conditions in Canada, both industrial and commercial. Mr. Ackerman gave a similar talk stressing recent engineering activities and achievements in Canada. The two latter gentlemen spoke in German.

Mr. M. Du Bois, Jr.E.I.C., assistant to the director of Sulzer Bros. Limited, Winterthur, and formerly a resident of Montreal, acknowledged and reciprocated the greetings of the Canadian engineers. The reception was excellent at both ends.

Mr. C. F. Sise, President of the Bell Telephone Company of Canada, a group of telephone officials and newspapermen listened to the two-way conversations through instruments installed for the occasion. The arrangements which made this telephone conversation possible in Canada were in the hands of the Bell Telephone Company of Canada, Limited. Facilities at the European end were given through the co-operation of the British Post Office and the Swiss Telephone Administration.

Committee on Consolidation

The Committee held its eighth meeting at The Engineering Institute Headquarters on Wednesday, November 6th, 1935, at 8 p.m. At this meeting the Chairman made a review of the activity which had taken place in the various Branches of The Institute and in the Professional Associations, with reference to the consideration of Consolidation, during the summer months.

This Report indicated that this important matter was being seriously considered throughout Canada, and that active discussions were being carried on among the general membership which had been productive of many constructive suggestions, and much general interest in the possibilities of the organization and development of the profession.

The returns on the "Questionnaire" issued by the Committee were received and analyzed, and indicated the following approximate figures:—

Possible Replies.	
Engineering Institute	2,630
Professional Associations	3,807
Total	6,437
Replies.	
Number of members represented by replies	4,262
Question No. 1—Yes, 4,234; No, 28.	
Question No. 2—Yes, 3,841; No, 353.	
Question No. 3—Yes, 3,900; No, 343.	
Question No. 4—Yes, 4,147; No, 33.	
Question No. 5—Yes, 3,953; No, 87.	

Membership of Branches of Institute and Provincial Associations not represented in the replies:

St. Maurice Valley Branch	27
Lethbridge Branch	24
Professional Association of Alberta	253
Vancouver Branch	127
Professional Association of British Columbia	808
	1,239

At its meeting of November 2nd, the Council of the Association of Professional Engineers of Alberta decided to continue its endeavours for co-ordination through the Dominion Council, and in this it is following the same policy as the Professional Association of British Columbia.

The Committee on Consolidation suggested to the Council of The Institute the advisability of issuing an invitation to all the Provincial Professional Associations through the Secretary of the Committee of Eight, to hold a meeting of that Committee in Hamilton, on the occasion of the Annual Meeting of The Institute in February, 1936. Council has issued this invitation.

All the suggestions relative to Consolidation which have been received by the Committee as a result of the "Questionnaire" or otherwise, are now being studied by the Committee, with a view to placing its report and recommendations before the Council of The Institute at its meeting of December 20th, 1935.

Gordon McL. Pitts, A.M.E.I.C.,
Chairman
Committee on Consolidation.

OBITUARY

John Simeon Armstrong, M.E.I.C.

John Simeon Armstrong, M.E.I.C., whose death occurred at Fredericton, N.B., on July 4th, 1935, was a member of many years standing, having joined the Canadian Society of Civil Engineers at its formation in January 1887.

A graduate of King's College, Windsor, N.S., of the year 1869, Mr. Armstrong was awarded the General Williams prize in engineering. His early work was in connection with railway construction on the Intercolonial Railway in 1870, and the following year he was engaged on the Bay Verte canal project. Subsequently Mr. Armstrong was assistant engineer with the Department of Public Works in charge of a party on the Saint John, N.B., harbour survey. His later appointments included the following: assistant engineer, locating and on construction of the Salisbury and Hillsboro Railway; leveler on Aulac and Cape Tormentine Railway survey; general survey and plan for Halifax sewerage; engineer for gold prospecting and mining in Nova Scotia; member of contracting firm engaged for five years in building construction in Saint John, N.B.; construction engineer and general manager, Lincoln Pulp and Paper Company at Lincoln, Maine; preliminary and location surveys for the Temiscouata Railway in Quebec and New Brunswick and charge of preliminary survey and construction of a section of the Edmundston and St. Francis branch of that railway; principal assistant engineer with the Chignecto Marine Transport Railway between the years 1888 and 1891; engineer and general manager, Chambersburg and Gettysburg Railway in Pennsylvania; manager of the Caledonia Mining and Manufacturing Company at Graffenburg, Pa.; chief engineer on preliminary and locating surveys for the Canso and Louisburg Railway in Cape Breton; bridge engineer and principal assistant on Midland Railway in Nova Scotia and later contractor's engineer for the Shubenacadie bridge.

In addition to the above, Mr. Armstrong was for a period engaged in private practice as patent attorney on the United States government register and was later engineer and secretary treasurer of the Coal Mining Company in the Grand Lake Coal district of New Brunswick. He was actively engaged in the Good Roads movement in New Brunswick particularly in connection with the formation of the Saint John City and County Goods Roads Association and the New Brunswick Good Roads Association. In 1926 Mr. Armstrong entered private practice as consulting engineer, specializing in harbours, canals, railways, transport, patents and special submarine works.

Mr. Armstrong joined the Canadian Society of Civil Engineers as a Member on January 20th, 1887.

PERSONALS

J. L. Balleny, A.M.E.I.C., has joined the staff of the Canadian General Electric Company Limited at Toronto, Ont. Following graduation from McGill University in 1925 with the degree of B.Sc., Mr. Balleny joined the staff of the company which he now rejoins, being engaged on general machine testing in the test department. In 1926 and 1927 he was in the industrial control engineering department on the design of miscellaneous equipment, and in 1927 he was appointed industrial electric heating engineer in charge of design, construction and the installation of all types of electric heating equipment, which position he held until 1929 when he became attached to the mechanical engineering department of the Dominion Bridge Company Ltd., Montreal. In 1932 Mr. Balleny was with the Beauharnois Light Heat and Power Company, at Beauharnois, Que.

THE QUEBEC ELECTRICITY COMMISSION

Dr. Augustin Frigon, M.E.I.C., who has been appointed the chairman of the new Quebec Electricity Commission, is a prominent French-Canadian electrical engineer, and a graduate of the Ecole Polytechnique, Montreal, of which he is now the Dean. Following graduation he studied at the Massachusetts Institute of Technology, Boston, and then travelled abroad. In Paris he took courses at the Ecole Supérieure d'Electricité and received the degree of Doctor

Dr. A. Frigon, M.E.I.C.

Dr. O. Lefebvre, M.E.I.C.

of Science from the University of Paris. Dr. Frigon is at present chairman of the Montreal Electrical Service Commission, and served on the Royal Commission appointed in 1928 to investigate radio broadcasting. He is a member of the National Research Council, Ottawa. His experience in the electric power industry in Quebec has been extensive and varied, largely in connection with the work of the Quebec Public Utilities Commission. He takes an active interest in Institute affairs and is a member of Council and a past-chairman of the Montreal Branch.

Dr. Olivier Lefebvre, M.E.I.C., a past-president of The Institute, vice-chairman of the new commission, graduated from the Ecole Polytechnique, with honours, in 1902. After some three years in the laboratories of the Department of Public Works in Ottawa, he became assistant to the Ottawa district engineer, and was engaged in river surveys and the construction of wharves, dams and other works carried out by the Department in that locality. In 1912 he was sent to Vancouver to make a complete survey of Burrard Inlet and False Creek. In 1913, leaving the Dominion Service, Dr. Lefebvre entered that of the province of Quebec as chief engineer of the Quebec Streams Commission, and since that time has been responsible for practically all of the important projects initiated by the Streams Commission to provide effective government regulation of the flow of the great rivers of the province whose power is being developed under private ownership. Dr. Lefebvre is a member of Council of The Institute, a Member of the American Society of Civil Engineers, and serves on the Administrative Board of the Ecole Polytechnique, Montreal. In 1929 he received the Honorary Degree of Doctor of Science from the University of Montreal.

J. W. McCammon, A.M.E.I.C., graduated from McGill University in 1912 with the degree of B.Sc., and later took an apprentice course with the Canadian Westinghouse Company at Hamilton, Ont. Following this he was for a time assistant to the mechanical and electrical engineer of Mackenzie Mann and Company on the Mount Royal Tunnel, Montreal, and was later for nine years manager of the pump and electrical departments of Canadian Fairbanks Morse Company, Montreal. He was connected with Charles Walmsley Company, Montreal. From 1929 to 1934 Mr. McCammon was assistant to the general manager of the Beauharnois Light, Heat and Power Company. Mr. McCammon served overseas during the War, having enlisted in 1915 with the 6th Siege Battery. He received

J. W. McCammon, A.M.E.I.C.

a commission in the Royal Garrison Artillery in 1917, was transferred to the Canadian Garrison Artillery with the rank of lieutenant in 1918, and demobilized in 1919. Mr. McCammon has been an Associate Member of The Institute since 1924.

A. T. Perrin, M.E.I.C., formerly chief engineer of the Whiting Corporation (Canada) Limited, Toronto, has been appointed general superintendent of Sawyer Massey Limited at Hamilton, Ont. Mr. Perrin was at one time with E. A. Turner and Company, Toronto, and prior to that was with the mechanical department of the Dominion Bridge Company at Lachine Que.

Lieut.-Colonel A. E. Dubuc, D.S.O. and Bar, Chevalier de la Légion d'Honneur, M.E.I.C., chief engineer of the Department of Railways and Canals, Ottawa, has been made a member of the board recently appointed to deal with the ports of the Dominion.

Colonel Dubuc graduated from Laval University in 1901 with the degree of B.A.Sc., and following graduation became an assistant engineer with the Department of Public Works, Canada, at Ottawa. In 1912 he was appointed district engineer for the Department at Montreal.

In October 1914 Colonel Dubuc enlisted for service overseas with the 22nd French-Canadian Regiment, being promoted to the rank of Captain in the same year. In 1915 he became a Major, and in 1916 acting Lieutenant-Colonel, commanding the Regiment in the actions of

Lieut.-Colonel A. E. Dubuc, M.E.I.C.

Regina Trench in 1916, at Vimy Ridge in 1917, and at Neuville-Vitosse, Mercatel, Amiens, Arras and Chérisy in 1918. Colonel Dubuc was wounded at Kemmel in 1915, at Yprès in 1916 and at Chérisy in 1918. In 1918 he became Lieutenant-Colonel. Colonel Dubuc received the Distinguished Service Order and was made a Chevalier de la Légion d'Honneur in 1917, and in 1918 received a Bar to his D.S.O. and was twice mentioned in despatches. In December 1920 he was promoted to the rank of Colonel and given command of the 11th Infantry Brigade.

Returning to Canada in 1919 Colonel Dubuc was appointed superintending engineer of the Department of Railways and Canals, and in 1924 became chief engineer of the Department.

ELECTIONS AND TRANSFERS

At the meeting of Council held on November 12th, 1935, the following elections and transfers were effected:

Member

ANDERSON, Hope Vere, (Glasgow and West of Scot. Tech. College), senior asst. engr., Dept. of Marine, Ottawa, Ont.

REID, Charles Roy, B.Sc., E.E., (Univ. of Oregon.), M.M.E., (Cornell Univ.), asst. gen. supt., Shawinigan Water and Power Co., Montreal, Que.

Associate Member

FRY, Edmund Botterell, B.Sc., (McGill Univ.), engr. and surveyor, Howey Gold Mines Ltd., Red Lake, Ont.

Juniors

FRASER, Innes Martell, B.Sc., (N.S. Tech. Coll.), potentiometer mtce. man., Imperoyal, Dartmouth, N.S.

KATZ, Leon, B.Sc., (Queen's Univ.), foreman, Monarch Battery Mfg. Co. Ltd., Kingston, Ont.

McGUIRE, James Francis, B.Eng., (McGill Univ.), apprentice, Montreal Armature Works Ltd., Montreal, Que.

Affiliate

WEBSTER, Frederick Henry Thomas, chief engr., Homoeopathic Hospital, Montreal, Que.

Transferred from the class of Associate Member to that of Member

GAUTHIER, Paul Gilles, B.Sc., (McGill Univ.), Civil Engineer and Quebec Land Surveyor, 660 de L'Epee Ave., Outremont, Que.

Transferred from the class of Junior to that of Associate Member

BENJAMIN, Abraham, B.Sc., (McGill Univ.), elect'l. designer, Montreal Light, Heat and Power Cons., Montreal, Que.
BOWN, Charles Roy, B.Sc., (McGill Univ.), asst. chief engr., Canada and Dominion Sugar Co. Ltd., Montreal, Que.
HARRIS, Arthur Clifford, B.Sc., (N.S. Tech. Coll.), asst. engr., City of Halifax, N.S.
HOLDEN, John Hastie, B.Sc., (McGill Univ.), sales mgr., Geo. W. Reed & Co. Ltd., Montreal, Que.
McBRIDE, Ernest Willard, B.A.Sc., (Univ. of Toronto), technical engr., Abitibi Power and Paper Co., Toronto, Ont.
WILSON, Archdale McDonald, B.Sc., (Queen's Univ.), asst. engr., Algoma Central and Hudson's Bay Rly., Sault Ste. Marie, Ont.

Transferred from the class of Student to that of Associate Member

BENNETT, Arthur J., B.Sc., (McGill Univ.), sales engr., English Electric Co. of Canada Ltd., Montreal, Que.
CUNNINGHAM, George Allin, B.A.Sc., (Univ. of Toronto), district representative, Imperial Oil Ltd., Peterborough, Ont.
DOBRIDGE, Ronald Wemyss, B.Sc., M.Sc., (McGill Univ.), transformer engr., Canadian Marconi Co., Montreal, Que.
HAMILTON, Robert William, B.Sc., (McGill Univ.), elect'l. engr., Dominion Electric Protection Company, Montreal, Que.

Transferred from the class of Student to that of Junior

BARBOUR, Clarence Allen, B.Sc., (Univ. of N.B.), prop., Maritime Radio and Electrical Supplies, Saint John, N.B.
HART, William O., B.Sc., (Queen's Univ.), sales and advertising mgr., Oshawa Dairy Ltd., Oshawa, Ont.
HUTTON, John R., B.Sc., (N.S. Tech. Coll.), engr., lamp dept., Canadian Westinghouse Co. Ltd., Hamilton, Ont.

Students Admitted

BEAULIEU, Gerard, (Ecole Polytech., Montreal), 3636 Henri Julien St., Montreal, Que.
ELMSLEY, Clarence Mathieu Remy, (Queen's Univ.), 30 Sydenham St., Kingston, Ont.
FIELD, George Lewis, instr'man., Beauharnois Light, Heat and Power Co., Montreal, Que.
GARDEN, Joseph MacKenzie, (McGill Univ.), 3420 Hutchison St., Montreal, Que.
LEY, Cecil John, junior dftsman., Dominion Bridge Co. Ltd., Lachine, Que.
McGREGOR, Leslie Stewart, (McGill Univ.), 5940 Clanranald Ave., Montreal, Que.
MOULE, Gerald William, (Univ. of Man.), 79 Balmoral Place, Winnipeg, Man.
RICE, Joseph Donald, B.Eng., (McGill Univ.), 2044 Victoria St., Montreal, Que.

BULLETINS

Belt Conveyors—The Jeffrey Manufacturing Company, Columbus, Ohio, have issued catalogue No. 610, containing 112 pages, and giving full particulars regarding belt conveyors and accessories manufactured by the company. Standard sizes range from 14 to 60 inches. The catalogue includes pertinent data and illustrations of typical installations.

Conveyors—A 16-page bulletin received from the Jeffrey Manufacturing Company contains particulars and illustrations of the methods used in excavation and handling of material in the building of the Grand Coulee dam.

Sheet Piling—A 12-page booklet issued by the Canadian Sheet Piling Company, Montreal, contains particulars of a number of installations of Larssen steel sheet piling.

Portable Air Compressors—Canadian Ingersoll-Rand Company Ltd., Montreal have issued a 24-page booklet containing data on the company's complete line of 2-stage air-cooled gasoline and oil engine driven portable air compressors.

Precision Lathe—A catalogue issued by the South Bend Lathe Works, South Bend, Indiana, describes the new 9-inch "workshop" precision lathe. The booklet contains a number of illustrations, describing the 8 different models of this lathe, and giving instructions for performing the many operations encountered in the machine shop, and displaying the complete set of attachments this lathe can be fitted with.

BOOK REVIEWS

Elements of Machine Design

By D. S. Kimball and John H. Barr. John Wiley and Sons (Renouf Publishing Company, Montreal), New York, 1935. Third and revised edition. 6 by 9¼ inches. Diagrams. 469 pages. Cloth, $4.00.

Reviewed by Professor N. M. Hall, m.e.i.c.*

The large number of mechanical engineers who are familiar with the 1909 and 1923 editions of this book will welcome the appearance of the new 1935 edition by the same authors, Dean Dexter S. Kimball of Cornell University and John H. Barr, formerly professor of machine design at the same institution.

It retains the same general form, adequately illustrated by diagrams of fundamental designs but unencumbered with photographs of machines, tables and catalogue matter which are subject to frequent change, and which are readily available from handbooks, catalogues and technical data issued from time to time by manufacturers.

While the book presupposes a knowledge of mechanics of machines, this subject is adequately reviewed in the opening chapters, and the remainder is devoted to the fundamentals which form the basis of machine design. At the end of each chapter will be found a useful list of references to books, transactions of national societies and manufacturers' data, from which further study of the subject matter of each chapter can be pursued.

Obsolete matter of the earlier editions has been eliminated, and considerable new material covering the advances in research and design have been inserted. This, for example, includes the recent work in lubrication and bearing design.

While written primarily for use as a college text book, it will prove useful to the designer who may wish from time to time to review the fundamentals of machine design and bring himself up to date on the recent advances in the subject.

The book has been enlarged to 469 pages and is adequately illustrated.

*Professor of Mechanical Engineering, University of Manitoba, Winnipeg, Man.

Industrial Electronics

By F. H. Gulliksen and E. H. Vedder. John Wiley and Sons, New York. (Renouf Publishing Company, Montreal). 6 by 9¼ inches. 245 pages. Cloth. $3.50.

Reviewed by G. A. Wallace, A.M.E.I.C.*

This book is a very business-like treatment of the application of electronic tubes in fields other than communication engineering and sound reproduction, and it will be greatly appreciated by those who are actively engaged in making such applications.

There is no excess verbiage in this book. From the first page to the last the authors have attended strictly to business and their working principle has apparently been to cram the maximum amount of information into the minimum amount of space. The result is a book which may seem a little dry to the casual reader, but which is full of interest to the practical worker.

The book is well arranged. The authors begin by devoting twenty-nine pages to a very concise classification and description of electronic tubes and their characteristics. This is followed by a thirty-page classification and description of the various methods of controlling these tubes. Then come the practical applications. These practical applications are very diverse, but the preliminary classification and treatment of the control methods serves to bring order and system into what might otherwise appear to be an uncorrelated jumble of miscellaneous devices.

The applications covered include photo-electric relays, elevator floor levelling, automatic control of lighting, sorting, grading, matching and counting by means of photo-electric cells, telemetering, smoke indicators, stroboscopes, rectifiers, inverters, welding, theatre dimming, oil-burner control, automatic train control, precipitation, X-ray equipment, automatic synchronizers, time delay relays, cycle splitters, protective relays for power systems, automatic regulators of voltage, speed, frequency, and temperature, register regulators for printing and cutting-off machines, tension regulators, colorimetric regulators, etc.

The numerous wiring diagrams are quite complete but the values of resistance, inductance and capacitance are not given; consequently the reader cannot duplicate these circuits, or apply them directly without doing a certain amount of design or experimental work. In other words the authors give the fundamental ideas and the circuit schemes that have proved effective, and leave the reader to work out the specific details to suit his own particular case. This is probably as far as any writer would care to go while the art is changing as rapidly as it is at present.

The bibliography at the end of each chapter is a valuable part of the book. A total of one hundred and twenty-nine references are given.

*Associate Professor of Electrical Engineering, McGill University, Montreal.

Well-known Toronto Engineer Dies

William Inglis, president and general manager of the John Inglis Company Ltd., Toronto, Ontario, who died recently was an affiliate of the Toronto Branch of The Institute.

Mr. Inglis was born at Guelph, Ontario, on October 20th, 1867, and in 1880 entered his father's business, Inglis and Hunt, as an apprentice. In 1881 the plant was moved from Guelph to Toronto, and in 1890 Mr. Inglis was admitted to the firm as a partner, the name being changed to John Inglis & Son. After the death of John Inglis in about 1895, Mr. William Inglis became the directing head of the company, and when the firm was incorporated in 1903 as the John Inglis Company, Limited, he became President. Mr. Inglis was also head of the S. Morgan-Smith-Inglis Co. Limited, Toronto, and of Webster-Inglis Limited, Toronto, and was a director of Dufferin Paving and Crushed Stone Limited, Toronto. In 1933 and 1934 Mr. Inglis was president of the Canadian National Exhibition, and had been a director for many years. He was known throughout Canada as a skilled expert in steel-plate construction, and was one of the original Canadian manufacturers of boilers, tanks, marine buoys and similar plate work.

Mr. Inglis had been chairman of the Ontario Branch of the Canadian Manufacturers' Association and always took a leading part in the affairs of that organization and of the Toronto Board of Trade of which he had long been an executive.

CORRESPONDENCE

Dominion Bridge Company Limited
Lachine, Que.
November 28th, 1935

To The Editor,
The Engineering Journal,

Dear Sir,

The interim report of the Consolidation Committee, which appears in the November Journal, must be disappointing to those who are anxious to solve the problem of organization of the Profession of Engineering in such a way as will serve the public and at the same time be of credit and advantage to the engineers themselves.

The Committee's report is merely a summary of the yeas and nays to the Questionnaire and it gives no further enlightenment as to the main principles and aims underlying Consolidation. Surely some of the remarks received from the members who replied to the Questionnaire bear on the question of objective and are worthy of consideration by the membership at large.

The correspondence by Mr. Wheatley in the same issue of the Journal and that of Mr. Pratley in the July number is more useful as it brings out clearly two divergent views on the general question of re-organization of the Engineering Profession. Mr. Wheatley bases his arguments on the recompense to which the individual engineer is entitled who has acquired a certain amount of conventional knowledge and believes in conferring upon him a mark of distinction which would carry a preference in obtaining employment. Mr. Pratley, on the other hand, bases his arguments on the profession's responsibility to the public by making the license a genuine mark of qualification and by making the Institute the path of advancement in the science of engineering.

It becomes apparent that the real controversy is over the extent to which the license permits its holder to practise engineering, and it is therefore the duty of the Committee on Consolidation to define clearly what it desires to accomplish by means of the license. It is imperative that it should be decided whether this is possible and if this licensing will benefit both the engineer and the public.

That there is need for licensing of engineers may be conceded, as very few will deny this desirability. Many of us go even farther and believe that most engineering work should be done under the legal responsible charge of a licensed engineer who is quite independent of the commercial side of the undertaking; but there are differences of opinion as to what the licensing is to accomplish. It must certainly be of some more tangible benefit than that of being merely a title or permit to employment. The various Provincial governments must have considered the license to be of benefit to the public when they passed laws granting the right to limit the practice of engineering to certain qualified persons, but is there any valid reason for licensing an employee whose employer is responsible for his doings?—especially when it must be acknowledged that an employer is a far better judge of the fitnessof the employee than a board of examiners none of whom may be experieneed in the particular line in which the applicant seeks to be employed. The university degree carries with it a far more useful indication of the potential value of the applicant than any license that can be issued by an examining body of the present organizations.

Commercial trading is not a profession nor does any learned profession recognize it as such; therefore, it should be clearly defined as to where the dividing line lies between engineering as a trade and engineering as a profession, as no lasting good would be accomplished by a policy which refuses to see that all engineering is not professional. Engineering is so closely allied to trade and so much of the most difficult and specialized designing is performed for competitive trading, that to debar commercially engaged engineers from our membership would prove fatal and exclude the greatest source of usefulness and progress. It is felt therefore that the Institute should include those engineers who are engaged for trading purposes, but that the license should be restricted to those who are uninfluenced and untrammeled by commercial considerations.

The definition of the exact meaning of "practice" and also of the term "rigid strictly professional body" applied to the various duties performed by engineers would help to clear up the differences of opinion far more effectively than bemoaning the fact that we are not as other professions are.

The whole question of Consolidation with all its ramifications, presents a very grave problem to those engineers who hold their vocation as something more serious than the mere means of gaining a livelihood. The members of the Institute are therefore looking hopefully to the Committee on Consolidation, trusting that it will have investigated all those controversial matters which concern their moral and intellectual standing, and which must affect the usefulness of the Institute. It is also hoped that this committee will present the result of such investigation clearly, explicitly and distinctly to the membership, before recommending any consolidation plan which might be binding for many years and which might prove, in the impossibility of its consistent application, to be an unsatisfactory disposition of the privileges which the Engineering Institute now enjoys.

Very truly yours,
F. P. Shearwood, M.E.I.C.

BRANCH NEWS

Border Cities Branch

C. F. Davison, A.M.E.I.C., Secretary-Treasurer.
F. J. Ryder, S.E.I.C., Branch News Editor.

Friday evening, October 18th, 1935, the Border Cities Branch held its first meeting after the summer adjournment, with twenty-two persons present.

J. Boyd Candlish, A.M.E.I.C., who is well known for his papers on the Diesel engine and his association with the "Power House" magazine, was the speaker for the evening, his subject being "Blended Fuels for Internal Combustion Engines."

BLENDED FUELS FOR INTERNAL COMBUSTION ENGINES

At the present rate of using crude oil for power engines, Mr. Candlish predicts that within fifteen to twenty years the supply will be diminished to the point where the price will be so high as to make it impractical as a fuel for internal combustion engines. At the present time a good deal of discussion and research is being carried on in the use of blended fuels to replace gasoline. This work is not new, as practically all there is to know with regard to the hydro-carbon group of alcohol-gasoline, hydrogen-gasoline and acetylene-gasoline was uncovered prior to the war.

The speaker believed that the subject of blended fuels will become one of a political nature in the near future. In the case of the domestic market, blended fuels will use up surplus grain supplies and thus aid the farmers. The foreign markets trend is towards blended fuel to save importing so much gasoline and to maintain a favourable trade balance.

A number of slides giving details and tables of actual experiments by Mr. Candlish were then shown. In all cases the mixtures used were gasoline and mixtures of gasoline with 5, 10, 15 and 20 per cent alcohol. First tables showed the theoretical values of the five mixtures. Other tables gave the results of using the mixtures in a standard automotive engine and then with various variations in the design of engine and carburetor adjustment. The general conclusions were that the use of blended mixtures in present-day engines would increase driving costs. However, with an ideal engine, designed to take full advantage of the highest useful compression-ratio, the cost of mileage to the motorists decreases enough to more than take care of increases in the cost of fuel.

With the use of alcoholic mixtures the cork parts, etc. would have to be replaced by metallic ones; the car would not be as easy to start as with gasoline owing to the high boiling point of alcohol, but smoother running would be obtained, for alcohol is a good doping agent against anti-knock; as for its effect on lubrication, the general opinion is that the blended mixture would not affect it.

A very interesting discussion followed, with suggested sources, starting qualities and substitutes for blended mixtures taking the main part. T. H. Jenkins, A.M.E.I.C., commended the paper highly and moved a vote of thanks to Mr. Candlish which was extended to the speaker by the Branch chairman, H. J. Coulter, A.M.E.I.C.

Edmonton Branch

R. M. Hardy, S.E.I.C., Secretary-Treasurer.

The winter activities of the Edmonton Branch of The Engineering Institute of Canada were commenced on October 31st, 1935, at the Macdonald hotel, when a banquet was held jointly with the Edmonton members of the Association of Professional Engineers of Alberta, and the northern Alberta Branch of the Canadian Institute of Mining and Metallurgy, in honour of the Right Honourable Sir Montague Barlow, Bart., P.C., K.B.E., etc., Chairman, Alberta Coal Commission; the Honourable Charles C. Ross, R.P.E., M.E.I.C., Minister of Lands and Mines of the Province of Alberta, and Mr. William Armour, M.I.Min.E., Technical Advisor to the Alberta Coal Commission.

F. K. Beach, M.E.I.C., chairman of the Branch, presided. A welcome to the guests was extended by Mr. F. J. Mitchell on behalf of the northern Alberta Branch of the C.I.M.M., and by A. W. Haddow, A.M.E.I.C., on behalf of the Association of Professional Engineers. Other speakers included J. D. Baker, M.E.I.C., W. J. Dick, M.E.I.C., Dr. J. A. Allan, and Mr. John Martland who brought greetings from the Alberta Association of Architects.

Mr. Armour, speaking as one of the guests and as a native of Scotland, gave a very entertaining talk during which he commented on the surprising number of his countrymen who held responsible positions in the coal industry of this province. He also expressed an appreciation of the high degree of skill evident in the mining operations of the province.

Sir Montague Barlow, as principal speaker of the evening, paid tribute to the great achievements of the engineering profession in the various parts of the Empire. He also expressed admiration for the accuracy of the engineer's figures, the elasticity of their estimates, and the bigness of their ideas. Speaking in more serious vein, he referred to the great problems confronting Canada due to the fact that it is a land economically geared-up for a population of 20,000,000 and at present has only one-half of this. At the same time, he said, these problems presented great opportunities for leadership and service to the engineering profession in this country.

During the summer months the activities of the Branch were as usual curtailed. However, a very pleasant social gathering was held on August 10th when the members and their families where the guests of the Branch chairman, F. K. Beach, M.E.I.C., and Mrs. Beach at their summer home at Kapasiwin Beach.

Hamilton Branch

A. Love, M.E.I.C., Secretary-Treasurer.
A. B. Dove, Jr.E.I.C., Branch News Editor.

"Diesel Engine Design, 1897 to 1935," was the subject of a talk given by E. F. Roberts, general manager of Jordan-Roberts Sales Ltd. of Brantford, to the Hamilton Branch on the evening of November 12th, 1935. Mr. Roberts gave a historical sketch of the Diesel engine and explained the development that had taken place since 1897 and the steps taken to approximate the Carnot heat cycle in this engine which is the most efficient that has been developed, giving up to 35 per cent efficiency.

First cost per horse power is greater in the large units than in the medium, hence the recommendation to use multiple medium size units in an installation rather than one large unit.

Mr. Roberts showed a series of slides illustrative of the points he dealt with such as PV curves, fuel injection, and combustion space. He touched on the semi-Diesel, described the methods of starting, and pointed out the improvement following the use of the Comet head which cuts down the exhaust fumes.

Aeroplane Diesel engines are now made of 1 pound per horse power deadweight and 2,200 r.p.m. The oil fuel required for this engine does not incur the fire hazard of the gasoline tank, a specially dangerous feature in aeroplanes with gas engines.

Many tugs on the Thames are now Diesel engined, showing many advantages over steam—one engine operator, and less engine and fuel space being noticeable. These engines are reversible and easily operated from one control point.

Moving pictures showed the work done in the plant at Stockport where the "Mirrlees" engine is made. It is interesting to note that the first Diesel engine made in Britain by Mirrlees Watson of Glasgow in 1897, is still operating satisfactorily.

In the automotive industry Diesel engines are widely used in trucks and busses, but in the passenger car certain problems have to be overcome. The car driver of to-day must have an engine that will start easily, that will run without vibration at all speeds, and that will operate over a wide range of temperatures without a falter, and this is asking a great deal of a high compression oil fuel engine.

After the lecture, questions were asked, some involving technical points, which Mr. Roberts kindly explained.

D. W. Callander, A.M.E.I.C., moved a vote of thanks, which was heartily accorded the speaker.

The meeting was held in the Science building, McMaster University. There were about sixty present. Mr. Hollingworth occupied the chair, and at the close announced that the following meeting on December 9th would take the form of a Students contest, five students or juniors having promised papers. Refreshments were enjoyed in an adjoining room.

Lethbridge Branch

E. A. Lawrence, S.E.I.C., Secretary-Treasurer.

Forty-three members and guests of the Lethbridge Branch visited the sugar factory at Picture Butte on Saturday, October 26th, 1935.

The inspection began with a trip to the large storage reservoir, north of the town, which has a capacity of 1,300 acre-feet of water. The dam is 7,000 feet long, 16½ feet high and rip-rapped with rock over a gravel bed on the inside slope. Underneath the dam is a clay core wall

View from Canadian Sugar Factories, Picture Butte, Alta.

16 feet deep for under drainage. The main water line from the reservoir to the factory is 3,300 feet long, constructed of 20-inch wood stave pipe.

The groups then inspected the various jobs going on about the factory site.

Dinner was served in the company's dining hall at 6 p.m., W. L. McKenzie, A.M.E.I.C., chairman of the Branch, gave a short address of welcome, following which Mr. I. B. Tucker made a short speech. Community singing was enjoyed, ably led by Wm. Meldrum, A.M.E.I.C.

Visit to Canadian Sugar Factories Plant.

C. S. Clendening, A.M.E.I.C., introduced the speaker of the evening, Mr. C. Bentall, president of the Dominion Construction Company.

In opening his remarks, Mr. Bentall stated that foundations are a primary consideration. First the financial foundation; and the B.C. Sugar Refining Company and the Canadian Sugar Factories are capable of carrying a fair load in this respect. Secondly the human factor; and the company has shown that it has the welfare of its employees at heart, in shortening hours, pensioning schemes, keeping up employment and wages, not at the expense of the public, but through increased efficiency.

In building a sugar factory choice of a site is important. The final choice in this case rested between Diamond City and Picture Butte, and on April 19th, it was decided to build at the latter location.

Some of the factors considered were: central to the beet growing area on the L.N.I.D., water storage facilities and length of pipeline from the reservoir, waste and waste water disposal, length of railway connection and availability of good sand and gravel.

On May 13th, pile driving commenced and 752 B.C. fir piles were driven under the bulk storage bins with a penetration of from 13 to 18 feet.

Following the taking of soil tests the footings were laid; these being designed for a load of 4,000 pounds per square foot. Thus the footings under the high sugar end which will carry a load of 350 tons, are 13 feet 2 inches square.

There are seven railway lines on the factory site, totalling 5,000 feet.

The beet storage occupies an area 300 feet by 400 feet and has seven concrete beet flumes leading into the factory.

The factory is a steel frame structure, with brick walls and concrete floors, and the roofs are made of a fireproof and weatherproof roofing called Transite, which is composed of concrete and asbestos.

The machine shop is well equipped and above this shop is the store-room. The office building is a three-storey structure and in the basement is the heating plant, showers, wash-room etc.; on the first floor the general office and on the top the laboratory.

There will be a power house, filtration plant and boiler house. Electrical power is used for most of the machines. Steam for the process work of the factory will be supplied by two boilers consuming some 10,000 tons of slack coal a year.

The packing room is a high building and the sugar will be taken to the top of this building and distributed to the various packing machines by gravity. In this building are also the beet seed and material warehouses.

The bulk storage is the second largest on the continent, and consists of six conical cylinders, 33 feet in diameter and 85 feet high, lined with two layers of 7/16 fir separated by wax paper and kept away from the concrete walls by 2 by 2 inch sticks.

The pulp silo is large, lined with timber and has car loading facilities.

About the whole project is an air of permanence and real efficiency and comfort.

J. B. DeHart, M.E.I.C., with a few well-chosen words thanked Mr. Bentall, his staff and the Sugar Company for an excellent afternoon's entertainment. The vote of thanks was tendered by Mr. McKenzie and heartily endorsed by all present.

Mr. W. T. Hill spoke on behalf of the Lethbridge Board of Trade and Mayor D. H. Elton on behalf of the city of Lethbridge.

London Branch

S. G. Johre, A.M.E.I.C., Secretary-Treasurer.
J. R. Rostron, A.M.E.I.C., Branch News Editor.

The Association of Professional Engineers of Ontario held their October meeting at the Hotel London in this city, on October 25th, 1935, and, as a cordial invitation was extended to all professional engineers in this district and to members of the London Branch of The Engineering Institute of Canada, no regular monthly meeting of the London Branch was held.

The Council of the Association held their business session in the morning, and the members of the Association and of The Institute assembled at the London Hunt and Country Club for luncheon, by the kind invitation of Colonel I. Leonard, M.E.I.C.

The luncheon was much enjoyed and thoroughly appreciated as it formed a good "get together" meeting.

It was a fine day and some of the members spent the afternoon in a game of golf while others were driven to various places of interest in and around the city.

A full dinner meeting was held at the hotel at 7 p.m., the president, J. Clark Keith, A.M.E.I.C., taking the chair. Proceedings were opened by the chairman who stated that the purpose of the meeting was to obtain the views and suggestions of the local engineers and members of the Association with regard to the matter of the proposed organization of the various Provincial Associations of Professional Engineers, with the ultimate view of combining them with The Engineering Institute of Canada. He called upon Col. I. Leonard, past-president, and upon A. Crealock, M.E.I.C., to say what had been accomplished in this direction, and also the present state of affairs.

This was done very clearly by these gentlemen and the meeting was then thrown open by the chairman for the expressions of opinions and suggestions of the members.

Amongst those who spoke were Professor Graham (Mining, Queens University), Mr. W. H. Riehl (City Engineer, Stratford), Mr. Brodsky (Brantford), Mr. E. T. Sterne, Professor R. W. Angus, M.E.I.C. (Mechanical Engineering, Toronto University), E. V. Buchanan, M.E.I.C. (Manager, Public Utilities Commission, London), and J. R. Rostron, A.M.E.I.C.

Approval of the continuance of the Committee of Eight was voiced and the suggestions ran along the lines of standardization of qualifications for admission to all the Provincial Associations together with uniform legislation for each province as a preliminary to combining the Association and The Institute.

A mention was also made of sub-dividing the Associations into separate bodies for each class of engineering such as civil, mechanical, electrical, mining, etc., while still being under the one head.

Many useful hints along these lines were given and no doubt the Committee of Eight will consider them.

The meeting concluded with votes of thanks to the chairman, Col. I. Leonard, and Mr. A. Crealock.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

THE EVOLUTION OF THE WAR SHIP

On October 10th, 1935, Engineer Commander A. D. M. Curry, R.C.N., M.E.I.C., Director of Naval Engineering, Department of National Defence, gave a most interesting talk on the evolution of the war ship, with particular reference to the developments following the early introduction of steam. The address was illustrated by a series of excellent slides, covering ships and equipment used since the earliest days of the British Navy.

F. S. B. Heward, A.M.E.I.C., acted as chairman.

VOICES ACROSS THE SEA

On October 15th, 1935, Dr. J. O. Perrine, Associate Editor of the Bell System Technical Journal, delivered an exceedingly interesting lecture before members of the Montreal Branch of The Institute and the Sigma Chi Society, at Moyse Hall, McGill University.

Speech was shown to be made up of a series of component waves which could be seen in action, and by the aid of slides and electrical equipment the sound of the human voice was analyzed from the time it left the mouth to the impulse on the auditory nerve leading to the brain of the listener. The entire audience listened-in on a conversation between two people in Moyse Hall and Dr. A. S. Eve, of McGill, and A. E. Barney of the American Telephone and Telegraph Company, both in London, England. The talk was illustrated with lantern slides and equipment.

The chairman was Dean Ernest Brown, M.E.I.C.

A NATIONAL SLUM CLEARANCE AND HOUSING PROGRAMME

On October 17th, 1935, Mr. James H. Craig, a Toronto architect spoke on the above subject, describing Canadian conditions and outlining a scheme whereby unemployment could be relieved by a national project of this nature. Suggestions were made for the financing of such a project.

Prior to the meeting a dinner was held at the Windsor hotel. G. McL. Pitts, A.M.E.I.C., was in the chair.

DIRECT CURRENT TRANSMISSION

On October 23rd, 1935, Mr. C. W. Stone, consulting engineer of the General Electric Company, Schenectady, N.Y. gave an interesting paper and demonstration on the development of direct current transmission. This system places full control in the hands of the operator who can at all times control not only the amount of power flow but its direction.

Previous to the lecture an informal dinner was held in the Windsor hotel. Dr. F. A. Gaby, M.E.I.C., President of The Institute, was chairman.

JUNIOR SECTION

On October 28th two papers were presented before the Junior Section, one by E. R. Smallhorn, A.M.E.I.C., on Junior Section Activities, and the other by T. R. Durley, JR.E.I.C., on "Kilns and Cement Burning."

Alex. Shearwood, S.E.I.C., was in the chair.

NICKEL AND ITS ALLOYS

T. H. Wickenden, assistant manager of the Development and Research Department of the International Nickel Company, Inc., New York, on October 31st gave a historical survey of the development, application and uses of nickel and its alloys. The talk was illustrated with motion pictures and consisted of a review of the nickel industry and interesting statistics of industrial applications. The chairman was R. S. Eadie, A.M.E.I.C

METHODS OF POWER FACTOR CORRECTION

British methods of power factor correction were explained by Mr. B. M. Burt, chief engineer of Bepco Canada Limited, on November 4th. The talk dealt not only with synchronous motors and condensers but with auto-synchronous motors, phase advancers and compensated induction motors. Walter J. Armstrong, M.E.I.C., was in the chair.

Niagara Peninsula Branch

P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

The Niagara Peninsula Branch held a dinner meeting at the King Edward hotel, Niagara Falls, on October 22nd, 1935, at which Mr. O. W. Titus, chief electrical engineer of the Canada Wire and Cable Company, was the speaker.

Although Mr. Titus dealt principally with the transmission line and electrical conductors, he prefaced his talk with some broad general details of the development along the Colorado river and showed several films illustrating the project, as well as the spinning of the new type HH conductor, the mechanical details of which were explained by Mr. H. B. Carnahan.

Paul E. Buss, A.M.E.I.C., was in the chair, and vice-chairman G. H. Wood, A.M.E.I.C., introduced the speaker as an old friend, who had served part of his apprenticeship in the Niagara district.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

FROM SAIL TO STEAM IN THE ROYAL NAVY

The course of British naval development from the crude ships of the early Britons to the fighting floating machines of the present day was graphically traced by Engineer-Commander A. D. M. Curry, M.E.I.C., of the Royal Canadian Navy, in an illustrated evening lecture held by the Ottawa Branch at the auditorium of the National Research Laboratories on October 29th, 1935. Dr. R. W. Boyle, M.E.I.C., chairman of the Branch, presided at the meeting which was the opening event of the fall and winter season. To this meeting the general public, including the ladies, were specially invited and there was a good attendance.

The remarkable advances, in particular during the past century, were elaborated upon by the speaker including the introduction of iron and then of steel in place of wood construction, the substitution of steam power for sails, using first the paddle wheel and then the screw propeller, and of various types of engines leading up to the efficient types of today. During the past half century, it was revealed, the size of the modern battleship has been quadrupled and its speed doubled.

Dr. Boyle, previous to introducing the speaker, referred to the great loss sustained by The Institute and by the engineering profession generally in the death on the previous day of Noulan Cauchon, A.M.E.I.C. Mr. Cauchon had been a chairman of the Branch, had held other offices in The Institute, and was one of its outstanding members.

Quebec Branch

Jules Joyal, A.M.E.I.C., Secretary-Treasurer.

Depuis son assemblée annuelle du 20 mai 1935, la Section de Québec a tenu trois réunions générales de ses membres comme suit:—

VISITE AU CAMP VALCARTIER

Cette visite eut lieu le 15 juin dernier; M. Alex Larivière, M.E.I.C., présidait à cette réunion des membres qui furent conduits sur les lieux par le Lt.-Col. J. B. Dunbar, A.M.E.I.C., et le Capt. A. J. Kerry, A.M.E.I.C., tous deux membres de notre section et attachés au service du district militaire No 5.

Au cours de cette visite nos membres ont rencontré tous les officiers du camp, entre autres deux de leurs confrères dont l'un, M. C. B. Bate, A.M.E.I.C., est ingénieur en charge du projet Valcartier et l'autre, M. G. D. O'Connor, A.M.E.I.C., est en charge de la fabrication des blocs de ciment servant à la confection des murs des diverses constructions.

A Valcartier l'on est à ériger un groupe de bâtisses destinées à remplacer la fabrique de cartouches qui est actuellement près du manège militaire de Québec; de plus on y construit des huttes qui serviront plus tard aux fins d'entraînement militaire et, entre temps, ces huttes sont occupées, dès leur complétion, par les chômeurs concentrés au camp Valcartier.

Ces constructions entraînent beaucoup d'autres travaux tels que chemins, lignes de transmission, aqueduc, égouts, etc.; en autant que possible ces travaux sont exécutés manuellement et avec des matériaux puisés dans les limites mêmes du camp.

Tous ceux qui ont pris part à cette excursion ont été vivement intéressés et Monsieur A. Larivière, M.E.I.C., président de notre section, se fit leur interprète pour remercier le Lt.-Col. Dunbar et tous les autres officiers du camp pour l'instructive visite qu'ils leur avaient fourni l'occasion de faire et pour leur cordial accueil aux visiteurs.

RÉUNION GÉNÉRALE

Deux jours plus tard, soit le 17 juin dernier, nos membres se réunissaient de nouveau, dans une salle du Château Frontenac, pour considérer le questionnaire soumis par le "Committee on Consolidation" et répondre aux questions qui y étaient posées; cette réunion était présidée par Monsieur Larivière et les réponses de notre section au questionnaire ont été transmises à qui de droit.

VISITE A LA ROCK CITY TOBACCO COMPANY LIMITED

Le 24 octobre dernier, nous avions la bonne fortune de visiter l'une des plus grandes industries de la cité de Québec, la Rock City Tobacco Co., Ltd.; aimablement reçus par M. A. C. Picard, vice-président de la compagnie, les visiteurs ont fait le tour de l'établissement en compagnie de quelques officiers de la Rock City et c'est ainsi qu'ils ont pu suivre, avec de nombreux renseignements, les différentes phases par lesquelles passe le tabac avant d'être mis sur le marché sous forme de tabac à fumer ou à chiquer, de cigarettes, cigars, etc.

Les machines qui servent aux différentes opérations sont fort intéressantes à voir fonctionner, particulièrement celles qui servent à la mise en paquets du tabac de même que celles qui servent à la fabrication des cigarettes et à leur empaquettage.

Cette visite fut des plus intéressantes et en l'absence du président de notre section, son vice-président, Monsieur T. J. F. King, A.M.E.I.C., adressa à Monsieur Picard et aux autres officiers de la compagnie des paroles de remerciements sincères tant pour l'aimable invitation de visiter leur usine que pour le chaleureux accueil fait aux visiteurs.

Avant de partir chacun fut cordialement prié de prendre, sur une table chargée à profusion des produits de la compagnie, un échantillon à son choix; tous se rendirent à cet appel généreux qui mettait fin à une réunion instructive organisée par M. Théo. M. Déchène, A.M.E.I.C., membre de notre Comité d'Excursions.

Sault Ste. Marie Branch

H. O. Brown, A.M.E.I.C., Secretary-Treasurer.

The Sault Ste. Marie Branch held the October monthly meeting at the Windsor hotel, Sault Ste. Marie, Ont., on Friday evening, October 25th, 1935.

As the evening meeting was to be an open one for members and guests from the various local industries, the business meeting was held at 6.15 with chairman Frank Smallwood, M.E.I.C., presiding. Following the business meeting dinner was served at 6.45 when fifty-four members and guests sat down.

ROLLER BEARINGS

At 8 p.m. the meeting was turned over to Mr. J. L. Young, assistant general manager of the Timken Roller Bearing Company of Canton, Ohio. Mr. Young gave a brief history of the development of the Timken roller bearing from the tapered waggon and buggy wheel bearing. Then a brief review was given of the introduction of these roller bearings into various industries which required the manufacture of larger and larger sizes until now bearings of 3 and 4 tons are in service.

Then followed a series of moving pictures illustrating the use of roller bearings in various industries. These pictures included:

Goss Printing Press of the Chicago Tribune.
Otis Steel Corporation—hot and cold strip mills.
Inland Steel Corporation—hot strip mill.
Timken equipped locomotives.
Carnegie Steel Company—52-inch beam mill.
Champion Coated Paper Co.—paper mills.

In addition to the above some scenic coloured moving pictures were shown to illustrate the wonderful colour effect that can be obtained with this recent development.

A very hearty vote of thanks was extended to Mr. Young for his talk and the moving pictures presented.

Toronto Branch

W. S. Wilson, M.E.I.C., Secretary-Treasurer.
N. MacNicol, M.E.I.C., Branch News Editor.

Some Problems of Transportation

On Thursday, October 17th, 1935, a luncheon meeting was held at the Royal York hotel. There were approximately ninety present to hear a paper given by Dr. F. A. Gaby, M.E.I.C., on "Some Problems of Transportation."

Dr. Gaby referred to the many complications in the transport problem outside the control of the industry itself. The advent and improvement of the internal combustion engine has been one of the greatest factors in the development of modern forms of transport. Economic causes have had a considerable influence, particularly important being the effects of the trade depression on the heavy industries. Motor-vehicle registrations in Canada have increased from 535 in 1904 to 1,129,532 in 1934. During the same period improved highways have been rapidly extended until in 1934 there was a total investment in provincial highways throughout Canada of 204 million dollars, representing 35 per cent of the entire provincial indebtedness.

He also referred to the increasing use of Diesel engines for economy in fuel consumption, both by railways and truck operators. Conditions in United States, Europe, England and Ireland were referred to. The rapid strides being made in air transport was also mentioned.

The speaker was of the opinion that in a properly co-ordinated transport system, the railway should assume the main burden of carriage of goods over distances exceeding 100 miles, and the trucks should operate as collectors and distributors of freight.

A hearty vote of thanks to Dr. Gaby was moved by Colonel C. S. L. Hertzberg, M.E.I.C. W. E. Bonn, M.E.I.C., chairman of the Branch, presided at the meeting.

Aircraft Development in Europe

On Thursday evening, November 7th, 1935, a meeting was held at Hart House, at which there were approximately one hundred and twenty-five present to hear an address by Professor T. R. Loudon, M.E.I.C., on "Aircraft Development in Europe."

The lecture was well illustrated by slides showing the many types of aeroplanes now in use in Europe and the number of regular air-routes extending many thousands of miles. Professor Loudon outlined the rapid growth taking place in air transport in many European countries, and stated that it was now possible to make the trip from Croydon field to Africa and return, a distance of 2,300 miles, in one day. During the last week of July 1935, 31,146 passengers were carried from Croydon field to Paris.

The speaker also referred to the splendid meteorological service in Europe giving accurate up-to-the-minute weather reports to all aerodromes. Pictures were shown of large wind tunnels built in United States and England for testing and research on full size aeroplanes.

After completion of his paper, Professor Loudon gave a brief talk on impressions received in England, Belgium and Germany during a trip made last summer. A hearty vote of thanks was moved by J. M. Oxley, M.E.I.C.

Winnipeg Branch

J. F. Cunningham, A.M.E.I.C., Secretary-Treasurer.
H. L. Briggs, A.M.E.I.C., Branch News Editor.

The Flow of International Rivers into Manitoba

A paper of considerable interest was presented on October 17th, 1935, by Professor Elwyn F. Chandler, Member A.S.C.E., hydraulic engineer, U.S. Geological Survey, Professor of Civil Engineering and Dean Emeritus of the College of Engineering, University of North Dakota, Grand Forks, on the above subject.

The runoff of a watershed is the remainder of the precipitation left after evaporation and transpiration have taken their share. In Manitoba, Saskatchewan and North Dakota it is the remainder, if any. For this area, the annual rainfall measured in inches, minus 20 inches for evaporation and transpiration, closely equals the runoff. Therefore the runoff varies widely, even though the total annual rainfall in this area almost never varies more than 50 per cent above or below the long term average.

For fifty-three years, the Red river at Grand Forks had a maximum total recorded flow for any one year (1882 and 1916) 2½ times the normal long period average, and a minimum total recorded flow (1934) as low as one-tenth the average. The similar variations in the Pembina at Neche, N.D., are maximum (1904) 4 times the average, and minimum (1915) one-seventh the average. For the Souris river at Minot, the maximum (1904) was 5 times the average, the minimum (1931) one-one hundredth of the average. The rates of flow show extremes for the Red at Grand Forks of 42,400 c.f.s. (1897) and 20 c.f.s. (1934); for the Pembina 3,850 c.f.s. (1904 and 1913) and 1 c.f.s. (1925); for the Souris 12,000 c.f.s. (1904) and zero c.f.s. (frequently).

Intensive drainage has increased both runoff and speed of runoff. On the other hand, the plowing up of the land, thereby breaking up the hard surfaced native buffalo prairie, has increased the receptivity of the land to the rainfall, thereby diminishing runoff.

An excellent opportunity for a combined storage and flood prevention reservoir exists at Red Lake, Minnesota. This lake has an area of 440 square miles. If the upper 6 feet of level were controlled by a dam, then 3 feet could be used for storage and 3 feet for flood prevention, which could be operated to reduce the largest floods on the Red river by about one foot at Grand Forks.

Those taking part in the discussion which followed included T. C. Main, A.M.E.I.C., D. L. McLean, A.M.E.I.C., C. H. Attwood, A.M.E.I.C., J. T. Rose, A.M.E.I.C., and C. P. Haltalin, A.M.E.I.C. A vote of thanks proposed by Dean E. P. Fetherstonhaugh, M.E.I.C., was heartily concurred in by the large audience.

Ontario Supreme Court Decision of Interest to Engineers

A Supreme Court decision affecting the engineering profession in Ontario has been rendered by Mr. Justice Kingstone, in dismissing a motion to compel the granting of a membership in the Ontario Association of Professional Engineers.

The case arose out of the predicament of an Ontario engineer, a non-member of the Provincial Association, who moved to the United States and sought registration in that country. This was denied him unless he could show membership in the Ontario association or unless he abandoned his Canadian citizenship. Accordingly he applied for registration in the Ontario association. Membership had been open to him during his years of residence in Ontario but he had postoned application. When he applied in Ontario while a resident of the United States, his application was refused by reason of the restriction of membership in the Ontario association to residents of the province.

The engineer took proceedings in the Supreme Court of Ontario to compel registration, contending that Section 12 of the Professional Engineers' Act did not require residence in Ontario. The court disagreed with him and dismissed his proceedings, holding that no engineer could acquire membership in the association unless he resided in Ontario at the time of his application.

Gasoline Losses from Storage Tanks

Two-thirds of the gasoline losses from unprotected storage tanks can be avoided by covering the tank with aluminum paint or whitewash and even greater savings can be effected by insulating the parts of the tank exposed to the sun, according to a report recently issued from the Division of Research Information, National Research Council, Ottawa, on evaporation from gasoline storage tanks under the influence of the sun's radiation. The subject is of considerable economic importance since it is probable that the combined oil storage capacity in Canada is not less than 500,000,000 gallons. The problem is to prevent the small percentage losses which arise from the heating of tank surfaces during bright sunny days and the cooling of the metal at night.

When a gasoline storage tank is nearly filled, the air above the liquid becomes saturated with gasoline. Then, when the sun shines on the tank, the vapour expands as it becomes warmer and escapes through the vent. Later, when the tank cools off as at night, the vapour contracts and draws in fresh air which in time becomes saturated with more gasoline. The process repeats itself daily. Losses from an 80,000-barrel tank may run above two barrels a day during the summer months.

Several methods may be employed to reduce the variations in temperature of the oil and vapour in storage tanks. Of these the simplest precaution is to reduce to a minimum the area exposed to the sun's rays and to coat the surface with paint or other material which has a high reflecting power such as aluminum or magnesia.

Insulation either as a special coating of plaster or as a second housing mounted on a steel frame can be used. It has been calculated that four inches of a good insulating material would reduce the temperature variation over the surface of a storage tank to about one-third of that observed on an unprotected tank. The effects obtained by insulation can be further improved by the use of highly reflecting surfaces, as for example aluminum foil.

In large installations cooling systems and means for trapping the vapours by connecting the storage tanks with gasometers similar to those used in cities for the storage of illuminating gas may be employed. Other plans provide for a pan-type floating roof, various types of breather roofs and pontoon roofs, all of which are described.

A copy of the report may be obtained on application to the National Research Council at Ottawa.

Preliminary Notice

of Applications for Admission and for Transfer

November 25th, 1935

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in January, 1936.

R. J. DURLEY, Secretary.

*The professional requirements are as follows.—

A Member shall be at least thirty-five years of age. and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility. in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professiona responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BARCLAY—JAMES BOW, of Vancouver, B.C., Born at Gourock, Scotland, Mar. 18th, 1903; Educ., Daniel Stewart's College, Edinburgh, 1917-21. R.P.E. of B.C. by Exam., 1929; 1921-24, ap'ticed struct'l. engr., and 1924-27, asst. engr., Palmer & Turner, Archts. and Engrs., Shanghai, China; 1928, asst. engr. ,Cons. Mining & Smelting Co.; 1928-30, asst. engr. and dftsman., Townley & Matheson, Stuart Cameron & Co., and B.C. Elec. Rly. Co.; 1930, chief concrete design on Burrard Bridge for J. R. Grant, M.E.I.C.; 1931, engr. and dftsman on design of govt. pier, for Sydney E. Junkins, M.E.I.C.; 1932-33-34 (not continuously), designer and dftsman. for John S. Metcalf Co.; 1930-35 (not continuously), engr., estimator and supt., on various projects, for Northern Construction Co.; 1934, steel detailer, Dominion Bridge Co.; 1935, chief concrete designer, Fraser River Bridge, for W. G. Swan, M.E.I.C.; 1935, consltg. struct'l. engr., associated with C. Elwood Walkins and Graham Johnson, Architects, in complete charge of struct'l, design of steel and concrete for Federal Bldg., Victoria, B.C.

References: J. R. Grant, W. G. Swan, A. S. Gentles, E. F. Carter, J. Robertson C. T. Hamilton.

BEANEY—SYDNEY WILLIAM, of 125 Erskine Ave., Toronto, Ont., Born at Liverpool, England, July 15th, 1905; Educ., 1919-24, Central Technical School, Toronto; 1927-31, dfting. and supervn. of constrn. for Baldwin & Greene, Watt & Blackwell, T. Eaton Co., H. L. Allward, Arch't.; 1931 to date, sales engr., Joseph Taylor & Son, Mfrs. Agents, Toronto. (Applying for admission as an Affiliate of the Institute.)

References: W. B. Redman, H. N. Gzowski, R. G. Saunders, H. E. Brandon, N. G. McDonald.

CASSIDY—STANLEY BERNARD, of 48 Fleet St., Moncton, N.B., Born Sussex, N.B., Mar. 7th, 1912; Educ., B.Sc. (E.E.), Univ. of N.B., 1933; 1932-33 (during senior year), asst. in elect'l. engrg., Univ. of N.B.; 1933 (6 mos.), head of geophysical party, N.B. Gas & Oilfields Ltd.; 1935 (1½ mos.), asst. on geological survey. (1 mo.), geogolical computations; at present, temp. employment with T. Eaton Co. Ltd., Moncton, N.B.

References: J. Stephens, A. F. Baird, E. O. Turner, G. L. Dickson, V. C. Blackett.

HOLDCROFT—JOHN BARBER, of 832 Cumberland Crescent, North Vancouver, B.C., Born at London, England, Aug. 24th, 1884; Educ., Private study. Passed Can. Soc. C.E. Exams. for Junior, 1912, for Assoc. Member 1913; 1904-08, rodman, asst. dftsman., computer and instr'man., Victoria, B.C.; 1909-10, surveyor and engr., Gore & McGregor, Land Surveyors and Engrs.; 1910-12, asst. engr., City of Victoria, B.C.; 1912-13, in own business, engrg. and constrn.; 1913, dftsman, Dept. of Lands, B.C., Forest Br., Dept. of Rlys., B.C.; 1914-18, overseas, Can. Engrs., Lieut. in charge of camp constrn. and mtce.; 1918, mine surveyor, Crow's Nest Pass Coal Co.; 1919-20, asst. engr., Dept. of Rlys., B.C.; 1920-22, private engrg. and constrn. work; 1922-23, designing dftsman., hydro-electric, Portland Elec. Rly., Light & Power Co., Portland, Oregon.; 1923 to date, hydraulic engr., and asst. mgr. from 1929, Pacific Coast Pipe Co. Ltd., Vancouver, B.C. In charge of design and supervision of constrn. of wood stave pipes, penstocks, tanks, etc., throughout Canada and Nfld. Also design and constrn. of paper mill equipment. Also engaged from time to time as private consultant on special questions involving hydraulic structures in timber constrn. and on hydro power development.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situation Vacant

SUPERINTENDENT, for radio manufacturing plant. Mechanical or radio engineer who has had several years successful experience in organization and operating factories on mass production principles. In replying give full information as to training and experience. Apply to Box No. 1233-V.

Situations Wanted

SALES ENGINEER, S.E.I.C.; B.Sc. C.E., 1930 (Univ. N.B.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ENGINEER AND ACCOUNTANT, Jr.E.I.C., (Capt. Can. Engrs., reserve). Age 35, Canadian. Experienced in mechanical and civil engineering, Diploma; general office, draughting and instrument work; assistant engineer erection Royal York hotel; assistant resident engineer T. & N.O. Ry. const. Desires position in Toronto where combination of technical and business experience will be of value, as have been director and accountant last three years. Apply to Box No. 377-W.

CIVIL ENGINEER, B.A.Sc. and C.E.; A.M.E.I.C., A.M. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

MECHANICAL ENGINEER, B.Sc. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

CONSTRUCTION ENGINEER, age 26, unmarried, graduate C.E. Experience includes hydro-electric, railroad, highway, and industrial plant construction, both field and office, including cost accounting, estimating, stores, layout, general engineering and supervision, as well as practical work in mechanical trades. Apply to Box No. 567-W.

MECHANICAL ENGINEER, experienced in mechanical and structural design, and plant maintenance. Apply to Box No. 571-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

ELECTRICAL ENGINEER, McGill '31, desires permanent position in engineering field. Experience includes draughting, designing and testing of induction motors, radio supervision and test, and some construction. Available immediately. Apply to Box No. 626-W.

ELECTRICAL AND RADIO ENGINEER, B.Sc. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

Situations Wanted

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc., Elec., '29, B.Sc., Civil '33. Age 27. Jr.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

Employment Service Bureau

This bureau is maintained by The Engineering Institute of Canada for the benefit of members and organizations employing technically trained men.

An enquiry addressed to 2050 Mansfield Street, Montreal, will bring full information concerning the services offered. Details can also be obtained from Branch secretaries who are located in the larger centres throughout Canada.

Brief announcements of men available and positions vacant will be published without charge in The Engineering Journal and the Bulletin. Replies addressed in care of the required box number will be forwarded to the advertiser without delay.

An additional service also offered those who are unemployed or wish to change their positions, is the opportunity of placing their names and records on file at 2050 Mansfield Street for consideration by employers wishing to employ engineers. This is of great assistance as many employers will not advertise or wish to locate a suitable man on short notice. If desired the information contained in these records can be kept confidential.

Forms for registration purposes may be obtained from The Institute Headquarters or Branch secretaries.

MECHANICAL ENGINEER, B.Sc., '27, Jr.E.I.C. Four years maintenance of high speed Diesel engine units, 200 to 1,300 h.p. Also maintenance of d.c. and a.c. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.Sc., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

Situations Wanted

CIVIL ENGINEER, M.Sc., A.M.E.I.C., R.P.E. (Ont.), ten years experience in municipal and highway engineering. Read, write and talk French. Married. Served in France. Will go anywhere at any time. Experienced journalist. Apply to Box No. 737-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.Sc. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

MANAFACTURERS' REPRESENTATIVE, at present doing business with leading industrial organizations in Canada, wishes to represent manufacturers of mechanical equipment. Such work as would involve technical data, and the preparation of plans where necessary, would be handled by an engineer whose experience with outstanding firms and projects, would be valuable to those seeking representation. Apply to Box No. 764-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E..Q, married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

SALES ENGINEER, A.M.E.I.C., graduate engineer, age 34, practical experience in the manufacture of power plant equipment, thoroughly conversant with Canadian power plant practice and equipment for the metal working industries. Available on short notice. Apply to Box No. 860-W.

Situations Wanted

CHEMICAL ENGINEER, B.sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, B.A.sc. in C.E., with business and sales experiences, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.SC., JR.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.sc. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ENGINEER, JR.E.I.C., E.E. '29, is very interested in applying electrical methods to cement testing and research work. Apply to Box No. 1062-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.sc., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.sc. (Univ. of B.C. '29); M.S. Age 27. Single. Four years experience in research work in applied mechanics and materials testing. Desires position involving analytical work in design, development or testing. Available on short notice. Apply to Box No. 1023-W.

PETROLEUM CHEMIST, B.sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER, B.sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.SC., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mach. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.sc. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.sc., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Writes and speaks both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211-W.

CIVIL ENGINEER, B.sc. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet tissues. Apply to Box No. 1246-W.

ELECTRICAL ENGINEER, B.sc. '34 (Univ. of N.B.), S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

CIVIL ENGINEER, Univ. Toronto '33, age 24, married. One year as instrumentman with provincial department of highways. Experience in concrete and retread construction grading, culverts, etc. Also draughting, estimating and general office practice. Apply to Box No. 1265-W.

ELECTRICAL GRADUATE, S.E.I.C., B.sc. '32, M.sc. '34. Experience includes four years as part time operator and announcer for a radio broadcast station. At present employed in radio repair dept. of a large wholesale firm. Apply to Box No. 1283-W.

ELECTRICAL ENGINEER, B.sc., E.E., A.M.E.I.C. University of Manitoba '28. Age 32. Married. Experience one year power line construction, five years resident and assistant district engineer on highway construction; two years highway traffic regulation in charge of district office. Good connections in Manitoba and Saskatchewan. Excellent references. Available at once and will go anywhere. Located in Winnipeg. Apply to Box No. 1316-W.

ENGINEER AND DRAUGHTSMAN, JR.E.I.C., age 33, married. Diplomas from Mtl Tech. Inst. in R.C. and Structural Design. 11½ years experience in civil engineering, draughting and instrument work. This includes 7 years with M.L.H. & P. Cons. as field engineer on construction and maintenance of gas mains. Present location Montreal. Available at once. Apply to Box No. 1326-W.

GRADUATE ENGINEER, (McGill), in responsible charge of design, construction and operation of hydro-electric plants. Also power design and mechanical maintenance of industrial plants. Apply to Box No. 1328-W.

MECHANICAL ENGINEER, recent grad. University of Toronto, B.A.sc. in mech. engrg, 24 years old, S.E.I.C., now managing a chain store, desires engineering work. Present location So. Ontario. Location immaterial. Best of references. Apply to Box No. 1348-W.

CIVIL ENGINEER, A.M.E.I.C. Married. Age 38. Twenty years experience in organization, design and estimating, and cost accounting. Active service in France. Apply to Box No. 1367-W.

Symposium on Welding

A symposium on the welding of iron and steel organised by the Iron and Steel Institute, London, England, in cooperation with fifteen other institutions and technical societies was held in London in May, 1935. One hundred and fifty papers were presented, and over one thousand persons were present at some of the sessions.

The bound volumes containing a full account of the proceedings were published in November, and take the form of two volumes containing respectively seven hundred and one thousand pages of print and a large number of illustrations, they include technical papers written for the symposium by leading experts and discussions of the papers and authors' replies.

The Organizing Committee has kindly offered to make the volumes available to members of The Engineering Institute at a specially reduced price of £1 12s. per set, carriage paid. To obtain this reduction from the standard rate of £2 4s. orders should be placed through The Engineering Institute.

Canada and U.S.A.

In connection with the negotiations which have been taking place for a commercial agreement between the United States and Canada, some interesting data have been made public regarding the balance of payments between the two countries in recent years.

According to a statement submitted to Washington by Ottawa, in no years since 1882 have Canadian exports to the United States exceeded in value the Dominion's imports from the United States. During the thirty years ending in 1933, Canada purchased in the United States almost 70 per cent of all her imports and sold in the United States only 37 per cent of all her exports. In the last ten years Canadians have spent over $1.60 in buying products of the United States for every dollar spent on Canadian products by purchasers in the United States, and Canada therefore has been obliged to meet the resulting debit balance by other means of payment. In the first nine months of 1934, again, Canadian imports from the United States increased more rapidly than Canadian exports to the United States, and the ratio between them is now stated at 10 to 7.
