Recent Bascule Bridges of Canadian Design and Construction

R. S. Eadie, A.M.E.I.C., Designing Engineer,
and
H. W. Buzzell, A.M.E.I.C., Structural Designer,
Dominion Bridge Company Limited, Montreal.

Paper to be presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

SUMMARY.—After mentioning the characteristics of the three principal kinds of bascule bridges, the paper describes three recent bridges of the simple trunnion type, giving the reasons leading to the particular arrangements adopted in each case, as regards the structure itself and the operating machinery. The paper indicates the manner in which the shop equipment, available transportation facilities, and local conditions at the site had to be considered in each case in deciding on the type of construction, general design, and methods to be employed in fabrication and erection.

Bascule bridges had their origin in the mediæval drawbridges which were used to span the moats surrounding military strongholds. As these, and the earliest types of bascule bridges, were not counterweighted they could only span narrow openings. With the advent of the timber truss it became for the first time possible to bridge navigable steams of some size.

The modern era of bascule bridge building may be said to have started with the construction of the London Tower Bridge, completed in 1894. Since then the bascule type has been developed rapidly and many sub-types have been invented which vary considerably in design. The vast majority, however, may be grouped into three classes:

1. The simple trunnion.
2. The rolling lift such as the Scherzer or Rall.
3. The multiple trunnion such as the Strauss or Brown.

A bascule bridge of any type may be built with either a single leaf or two leaves meeting at the centre of the opening. The single leaf bridge has the rigidity of a simple span and is, therefore, preferable, especially for railway traffic.

The simple trunnion type of bascule is one of the oldest, is the least complicated, and having a minimum of moving parts lends itself admirably to aesthetic treatment. It is essentially a see-saw rotating on fixed horizontal trunnions which turn in journal bearings supported on a pier. The fact that there are only two trunnions per leaf greatly reduces the difficulties of lining up the span during erection and also the amount of maintenance during its life. The London Tower Bridge was among the first notable bridges of this type and is still giving satisfactory service after forty years of operation. It is a double leaf structure providing a clear waterway of 200 feet and carries a 32-foot roadway and 8-foot 6-inch sidewalks.

The Scherzer type of rolling bascule has been used extensively for the past forty years and several bridges of this type span the new Welland canal. It is particularly adapted to locations where the counterweight must be kept above the roadway, but has no advantages over the simple trunnion type when the counterweight may be located under the floor.

The design of the supporting pier is complicated, particularly if rock or other good bearing strata is not found at a reasonable depth, due to the fact that the reaction from the span moves across the pier as the span opens and closes.

The design and fabrication of the track and segmental girders also present difficulties. The large load concentrations necessitate the use of very heavy metal and cumbersome details. The segmental girders particularly are costly and difficult to fabricate, taxing the facilities of the most modern fabricating plant.

The multiple trunnion type of bascule has also been extensively used. It can be built with the counterweight either above or below the roadway. It has no advantages over the simple trunnion type when the counterweight can be located below the roadway. The multiplicity of trunnions and their bearings in this type of bascule is its great disadvantage. They add greatly to the cost of fabrication and erection and also to the cost of maintenance and operation.

The three bridges dealt with in this paper are of the simple trunnion type and are located as follows:

1. Across the Red river at Norwood street, Winnipeg, Man.
2. Across the York river at Gaspé, P.Q.
3. Across the Richelieu river at Sorel, P.Q.

A general description will be given of the design, fabrication and erection of each bridge with special emphasis on those points which are peculiar to bascule bridges.

General Description

Norwood Street bridge consists of four 106-foot fixed deck plate girder spans and a single leaf deck plate girder bascule span across the navigable channel, providing an 80-foot clear waterway. The bridge carries a 50-foot roadway with two street car tracks in the centre and with an

8-foot sidewalk on each side. The bridge was built for the cities of Winnipeg and St. Boniface. Its design and construction were supervised by a board of engineers appointed by the provincial and civic governments, consisting of A. J. Meindl representing the city of St. Boniface; W. P. Brereton, M.E.I.C., representing the city of Winnipeg; and A. J. Taunton, A.M.E.I.C., representing the province of Manitoba. A plan and elevation of the bridge is shown in Fig. 1.

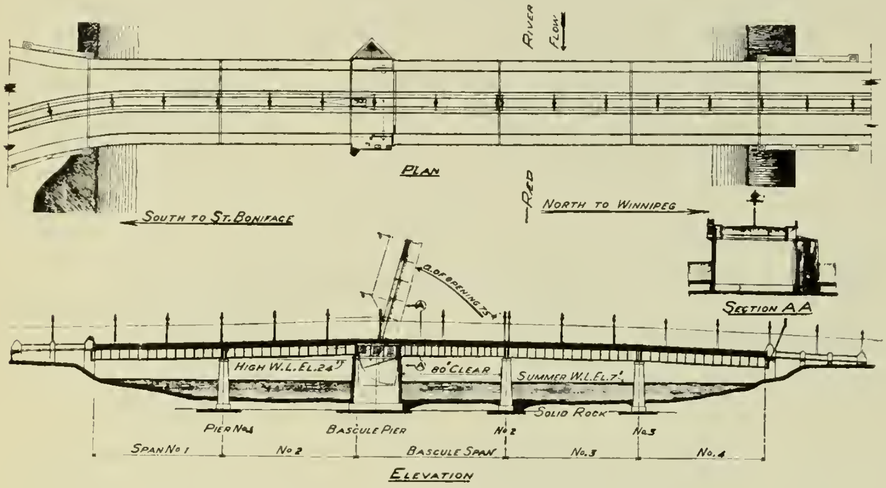

Fig. 1—Plan and Elevation of Norwood Street Bridge.

Gaspé bridge consists of five spans, four through-truss fixed spans and a double leaf deck plate girder bascule span across the navigable channel, giving a clear waterway of 90 feet. The bridge carries an 18-foot roadway with a sidewalk 4 feet 6 inches wide on one side. The owners of the bridge is La Compagnie du Pont de Gaspé Limitée, who hold a provincial franchise. The consulting engineers for the owners were Messrs. Baulne and Leonard, of Montreal. The design and details were also subject to the approval of Ivan Vallée, A.M.E.I.C., chief engineer of the Department of Public Works and Labour (Quebec). This bridge is now known as "Pont Monseigneur Ross." A plan and elevation of the bridge is shown in Fig. 2.

Sorel bridge consists of a double leaf bascule span of half-through truss construction, two steel deck truss flanking spans and reinforced concrete girder approaches. The bascule piers are 200 feet centre to centre, giving a clear channel of 165 feet. The bridge carries a 24-foot roadway with two 5-foot sidewalks. It was built for the Department of Public Works and Labour, province of Quebec, and Messrs. Monsarrat and Pratley of Montreal were appointed by the department as consulting engineers to approve the design and detail drawings. A plan and elevation of the bridge is shown in Fig. 3.

Specifications and Design

All three bridges were designed and built in accordance with the Canadian Engineering Standards Association Specifications A6-1929 and A20-1927 for Highway and Movable Bridges, respectively, as amplified by the owner's consulting engineers in each case. The design live loading varied for each bridge, the following concentrated loads being used: at Norwood street two 20-ton trucks abreast together with two 50-ton street cars on each track; at Gaspé two 15-ton trucks abreast; and at Sorel two 20-ton trucks abreast.

In addition to determining the stresses in the various members and proportioning the material to resist them, it is necessary, when designing a bridge, to carefully consider the shipping, transportation and field requirements to obtain a structure that can be fabricated, shipped and erected with the available equipment. It has also to be kept in mind that a movable bridge is a machine which must operate satisfactorily under widely varying weather conditions, and finally, but not least important, the outline must be such as to give the bridge the most pleasing appearance.

At Norwood a deck structure was adopted as it is the most pleasing type as viewed from the roadway and by using plate girders for all the spans a satisfactory outline was obtained. The approach to the bridge passes under the Canadian National Railway tracks. Due to this fact the distance between the crown of the roadway on the bascule span and high water was not sufficient to keep the counterweight clear of the water with the bridge open. To overcome this difficulty the bascule pier was built in the form of a watertight box into which the counterweight

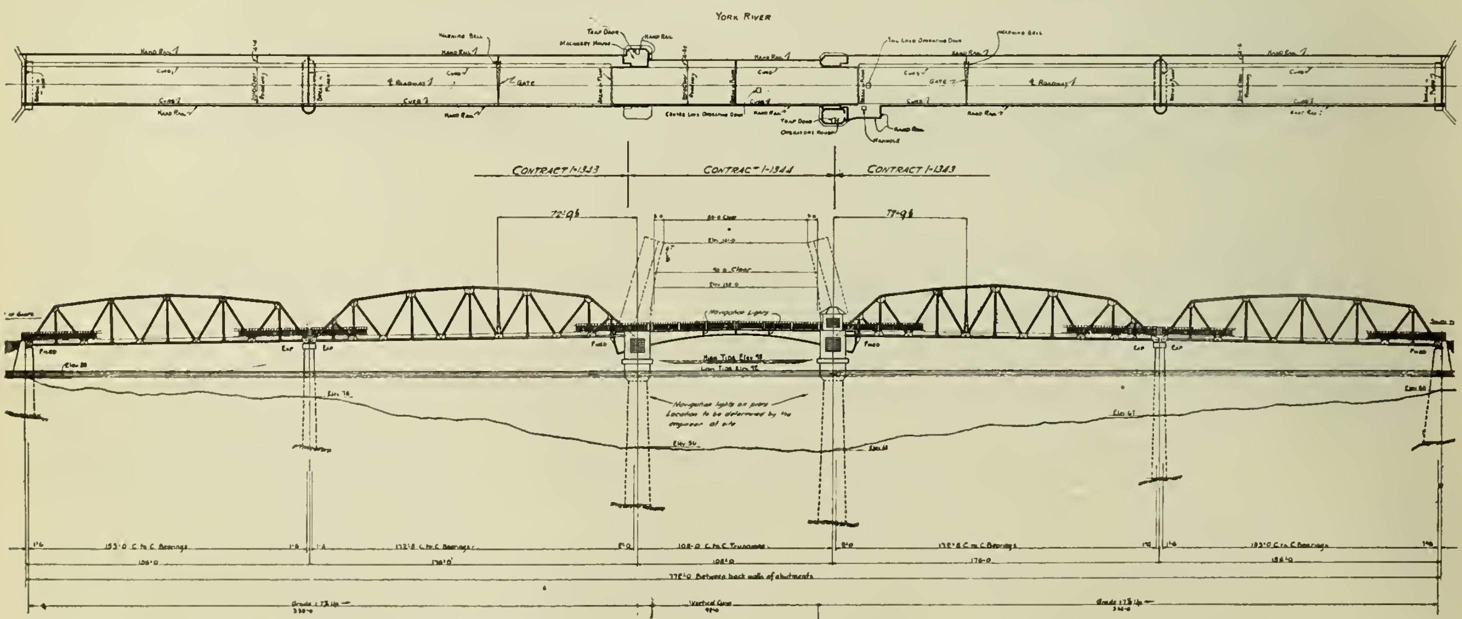

Fig. 2—Plan and Elevation of Gaspé Bridge.

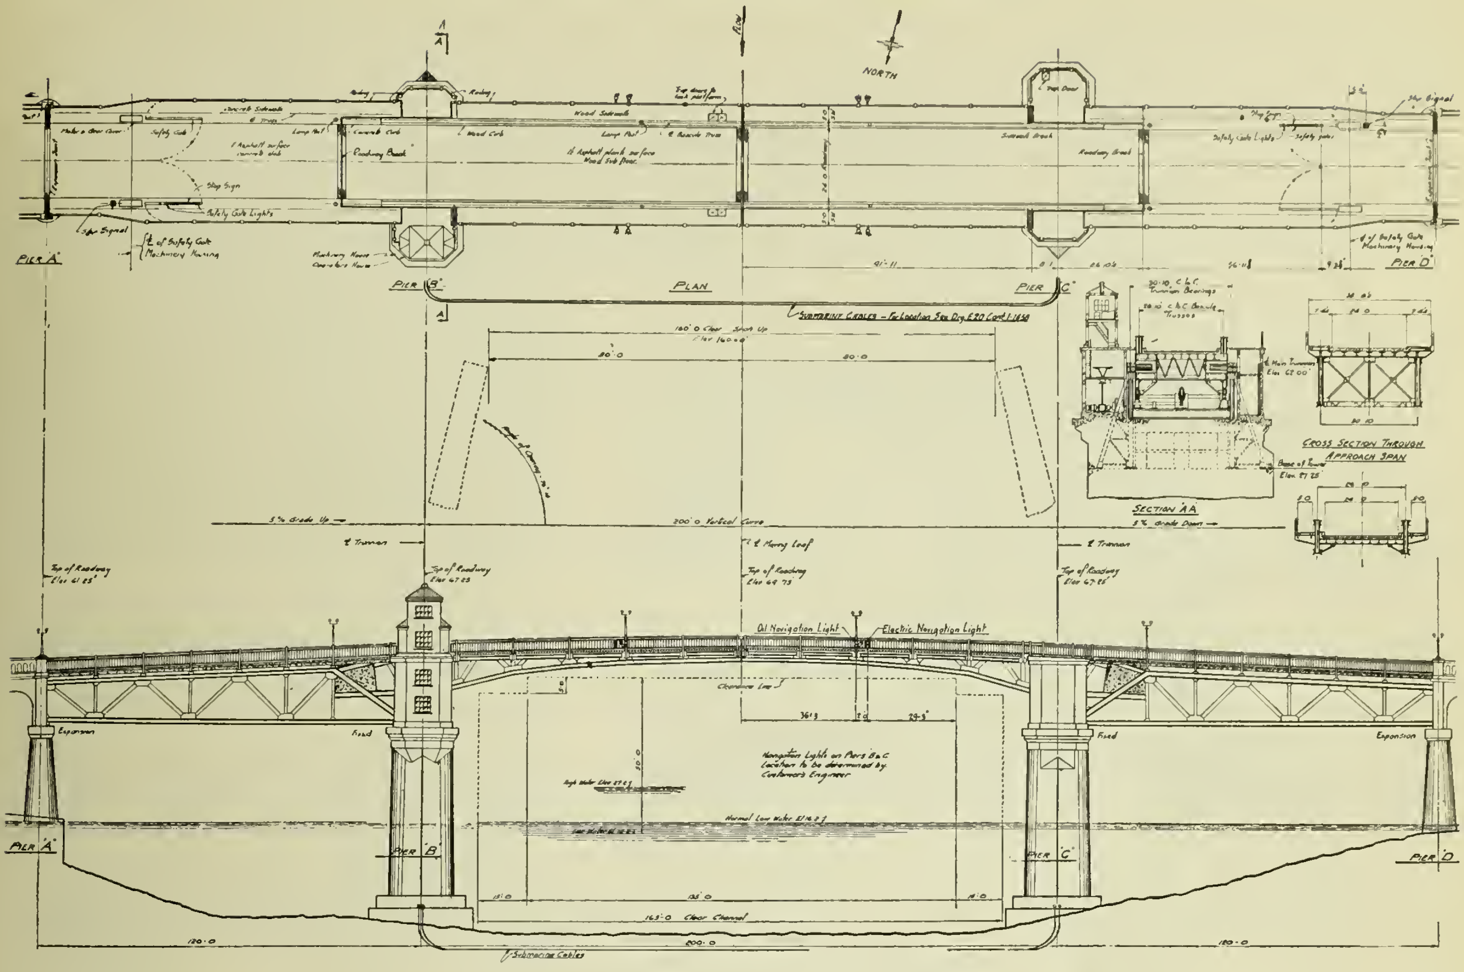

Fig. 3—Plan and Elevation of Sorel Bridge.

would sink and which would also house the operating machinery. This pier was given an architectural treatment which greatly enhanced the appearance of the bridge.

At Gaspé, due to foundation conditions, through trusses were most economical for the approach spans. Deck plate girders with a curved bottom chord were used for the bascule leaves. The counterweights are not enclosed in a pit as they normally swing clear of the water; however, they do not detract from the appearance of the bridge as they are largely hidden by the piers.

At Sorel, the approach spans are deck trusses, while the bascule leaves are half-through trusses with curved top and bottom chords. Deck trusses for the bascule leaves would have been more desirable from an æsthetic point of view, but could not be used due to the limited space between the navigation clearance line with the span down and the crown of roadway. The counterweights are in the open but are concealed for the most part by the piers and approach trusses.

The arrangement of the steel framing is shown in Figs. 4, 5 and 6 for Norwood, Gaspé and Sorel, respectively. The deck in all cases was creosoted wood protected by an asphalt plank wearing surface.

The design of the floor steel for a bascule span is identical with that of an ordinary highway span, except that provision must be made for transferring the weight of the floor to the trunnions when the bridge is in the open position. This is done by means of an auxiliary truss spanning between the main trusses in the plane of the laterals.

The stress calculations for the design of the main girders or trusses in this type of bascule are not involved. The dead weight of each bascule leaf must be balanced in all positions about the trunnions. This condition is attained by so locating the counterweight that the centres of gravity of the forward and rear arms of the leaf are on a straight line passing through the axis of rotation. The dead load stresses are, therefore, figured as for a simple cantilever, but the maximum stresses do not always occur with the leaf in the closed position. It is necessary to investigate the stresses for several positions of the leaf.

The live load stresses, in a single leaf bridge, are figured as for a simple span with a length equal to the distance from the trunnion to the rest pier. In a double leaf bridge the stresses in each leaf due to live loads symmetrically placed about the junction of the leaves are figured as for a simple cantilever supported at the trunnion, and with the uplift at the tail of the leaf resisted by the adjacent approach span. For live loads which are unsymmetrically placed about the junction of the leaves, the stresses are figured as for a cantilever with an elastic prop at its outer end. This is due to the fact that shear locks are provided between the ends of the two leaves to prevent unequal deflections.

Wind stresses with the bridge open are figured as for a cantilever span. The two cases of longitudinal and transverse wind must both be investigated. The wind stresses in a single-leaf span when closed are similar to those in a simple span, while in a double-leaf span each leaf is treated as a cantilever.

The maximum resultant stresses are obtained for different positions of the span by summing the co-existing stresses. The allowable unit stresses to be used in proportioning the truss members to resist the various combinations of stresses are laid down in the specification.

The design of the trunnion supports usually requires more ingenuity than the remainder of the bridge as it is difficult to place them so that they will clear the bascule leaf as it rotates. Two different methods of supporting the trunnions are used in these bridges.

At Norwood, each trunnion is carried by two bearings, one on each side of the girder web. At Gaspé and Sorel the trunnions project as cantilevers from the moving leaf, and each trunnion is supported by a single bearing.

At Norwood, the outer bearings are carried on columns which extend to the floor of the counterweight pit and which are braced laterally in two directions to its walls as shown in Fig. 7. The inner bearings are carried by trusses which span the counterweight pit and rest on its front and rear walls. The bottom flanges of the trusses are shaped to clear the counterweight when the span is closed, and the top flanges conform to the grade of the roadway because these trusses also carry the roadway framing over the counterweight pit. This allows the roadway break to be located ahead of the trunnion and obviates a gap in the floor when the bridge is open. Figure 8 shows one of these trusses in position. As can be seen, the trunnion is located about midway between the chords of the truss. To provide a seat for the trunnion bearing and to take care of the local bending stresses the end section of each truss is made into a double web plate girder. Openings are provided in these webs to clear the bearing and its cap. The bearing is seated on angle stiffeners riveted to these webs.

The load is transmitted directly to the trunnion from the main girder web, which is reinforced to take care of the heavy stress concentrations at that point. A cast steel sleeve is used to increase the bearing length on the trunnion. This sleeve is a press fit in the reinforced girder web and is securely riveted to it. The trunnion is in turn a press fit in the sleeve and keyed to it to prevent rotation.

At Gaspé and Sorel the supports for the trunnion bearings are braced towers located just outside the main girders. The framing of these towers is not the same for the two bridges because of differences in the size and shape of the bascule piers. Although the towers are finally embedded for about half their height in the mass concrete of the pier in both cases, the steel is designed to carry all the vertical and horizontal loads transmitted to them during the operation of the bridge. The arrangement of the trunnions, trunnion bearings and towers are shown in Figs. 5 and 6 for Gaspé and Sorel, respectively.

It is more difficult to connect the trunnions to the span with this arrangement than when two bearings support each trunnion. In the latter case, no bending strength is required in the connection, while in the former the connections must have sufficient bending strength to make the trunnions and trunnion strut act as a simple beam supported at its ends on the trunnion bearings and carrying the load from the leaf applied in the planes of the trusses.

At Gaspé, a box strut located symmetrically about the axis of the trunnions is framed between the main girders. Vertical diaphragms are provided in this strut, one about 3 feet from each girder. The main girder webs and these diaphragms provide the loading points for the trunnions, the webs being reinforced to give sufficient bearing area.

At Sorel a similar trunnion strut is used, but due to the greater loads to be carried and to the fact that the main trusses have two webs, certain complications arose not en-

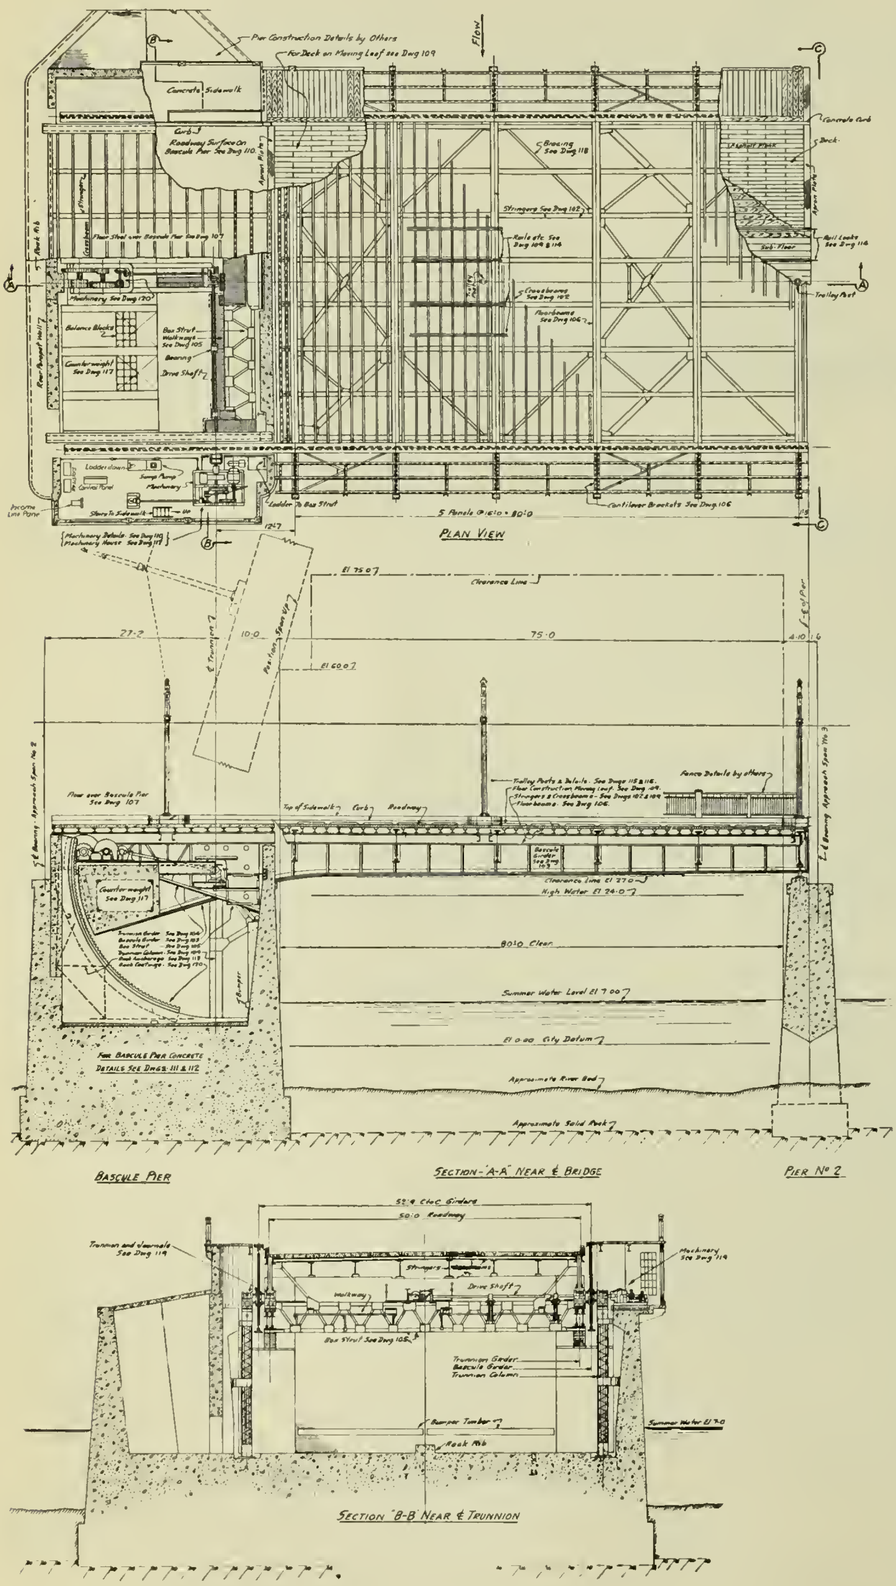

Fig. 4—Steel Framing Plan, Norwood.

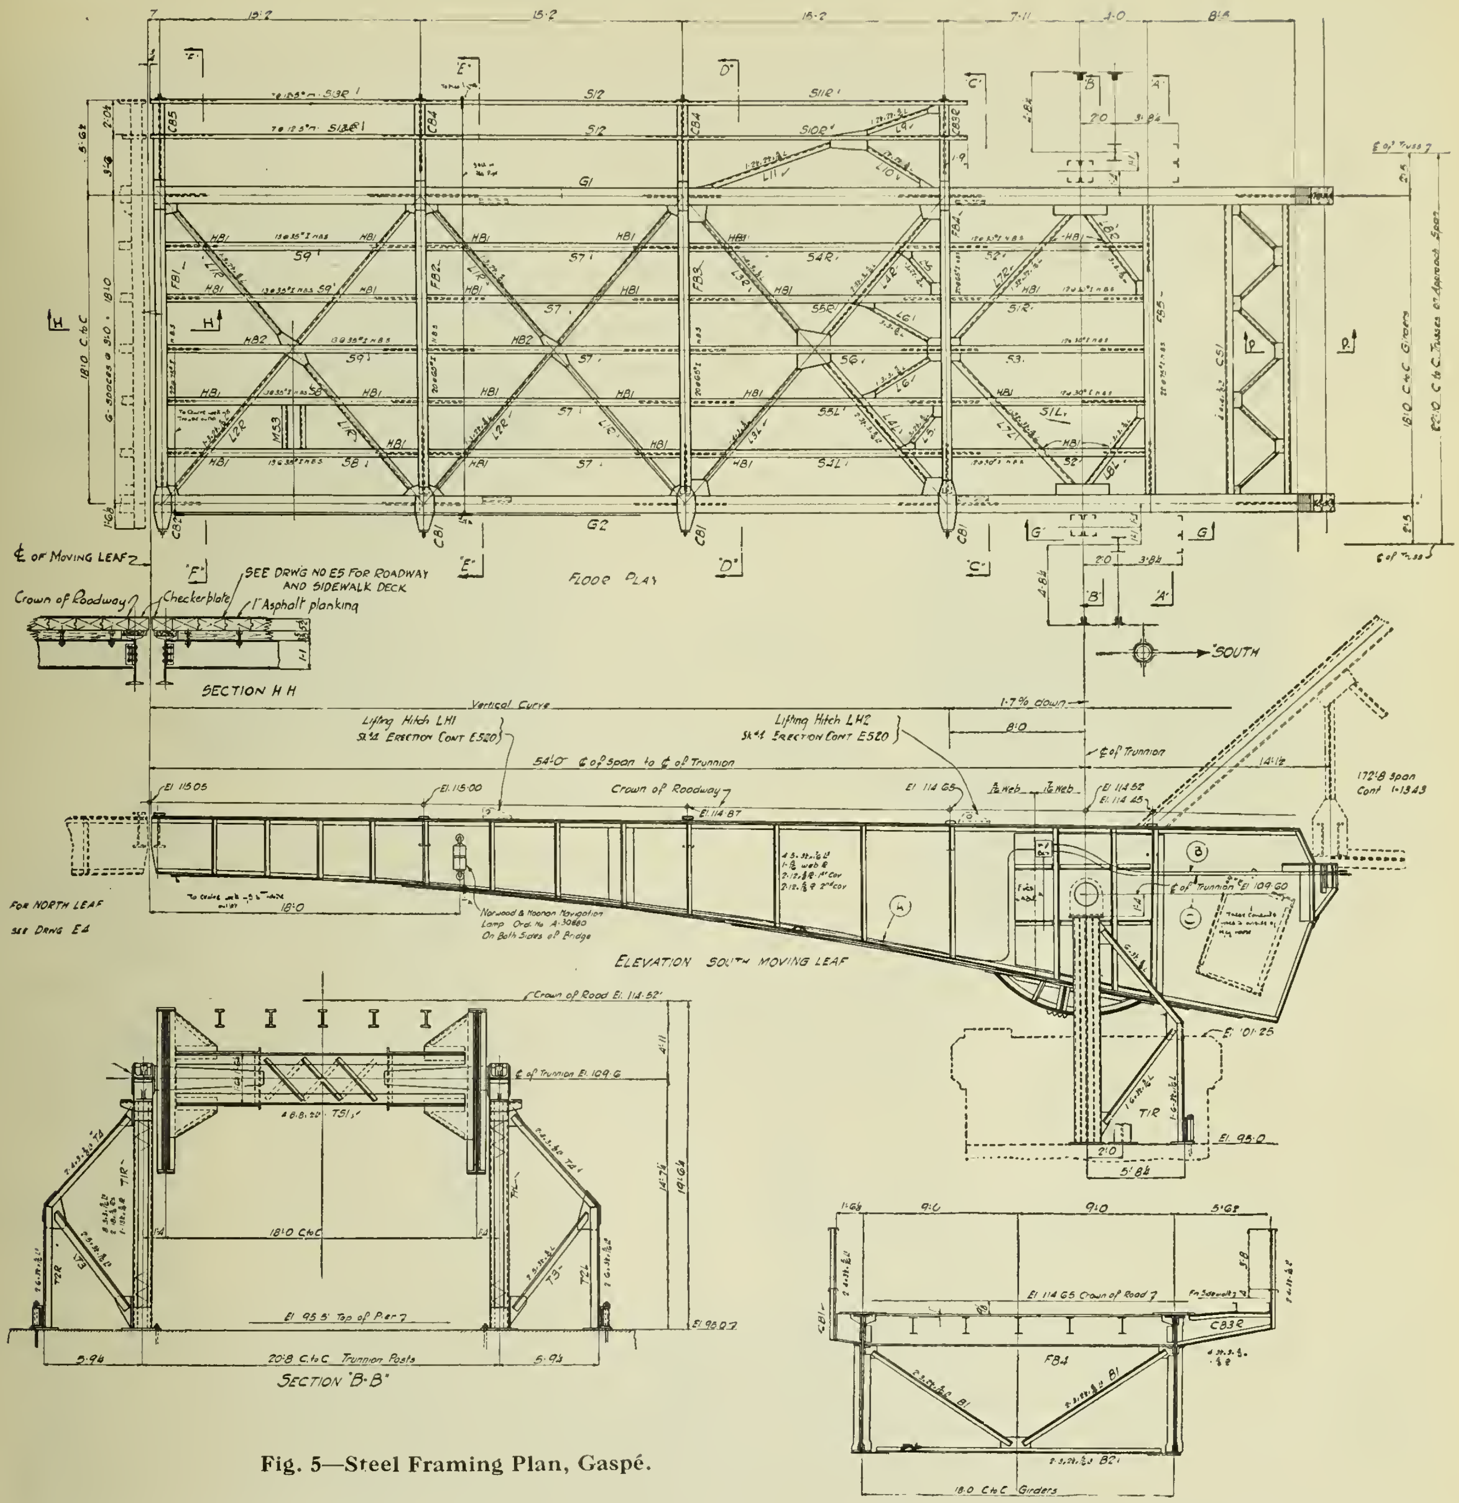

Fig. 5—Steel Framing Plan, Gaspé.

countered at Gaspé. To allow the trunnion strut to be connected to the trusses, web plates are used instead of web members for a distance of about 5 feet on either side of the trunnion.

In the first sketches made of the detail at this point, the trunnion strut was connected by angles to the inner web plates of each truss. Diaphragms were provided between the two webs of the truss in line with the end connections of the strut to distribute the load between the webs. Diaphragms were also provided in the strut about 5 feet from the centre line of each truss to carry the inner end of the trunnion. The trunnion was thus loaded by both webs of the truss. Investigation of the distribution of the load on the trunnion, considering only its deflection due to bending and shear, showed that the outer webs of the trusses delivered the greater part of the load. The distribution thus determined was not exact as it would be modified by the elastic deformation of the web plates themselves and it was impossible to evaluate this with any degree of accuracy.

Further investigation led to the development of another detail which was finally adopted. In this design the inner web plate of each truss is cut out to clear the trunnion strut which extends through and connects directly to the outer webs. Connection angles are provided on the four sides of the strut to connect to the inner webs of the trusses. The diaphragms are placed at about the same points in the struts as in the earlier design. With this

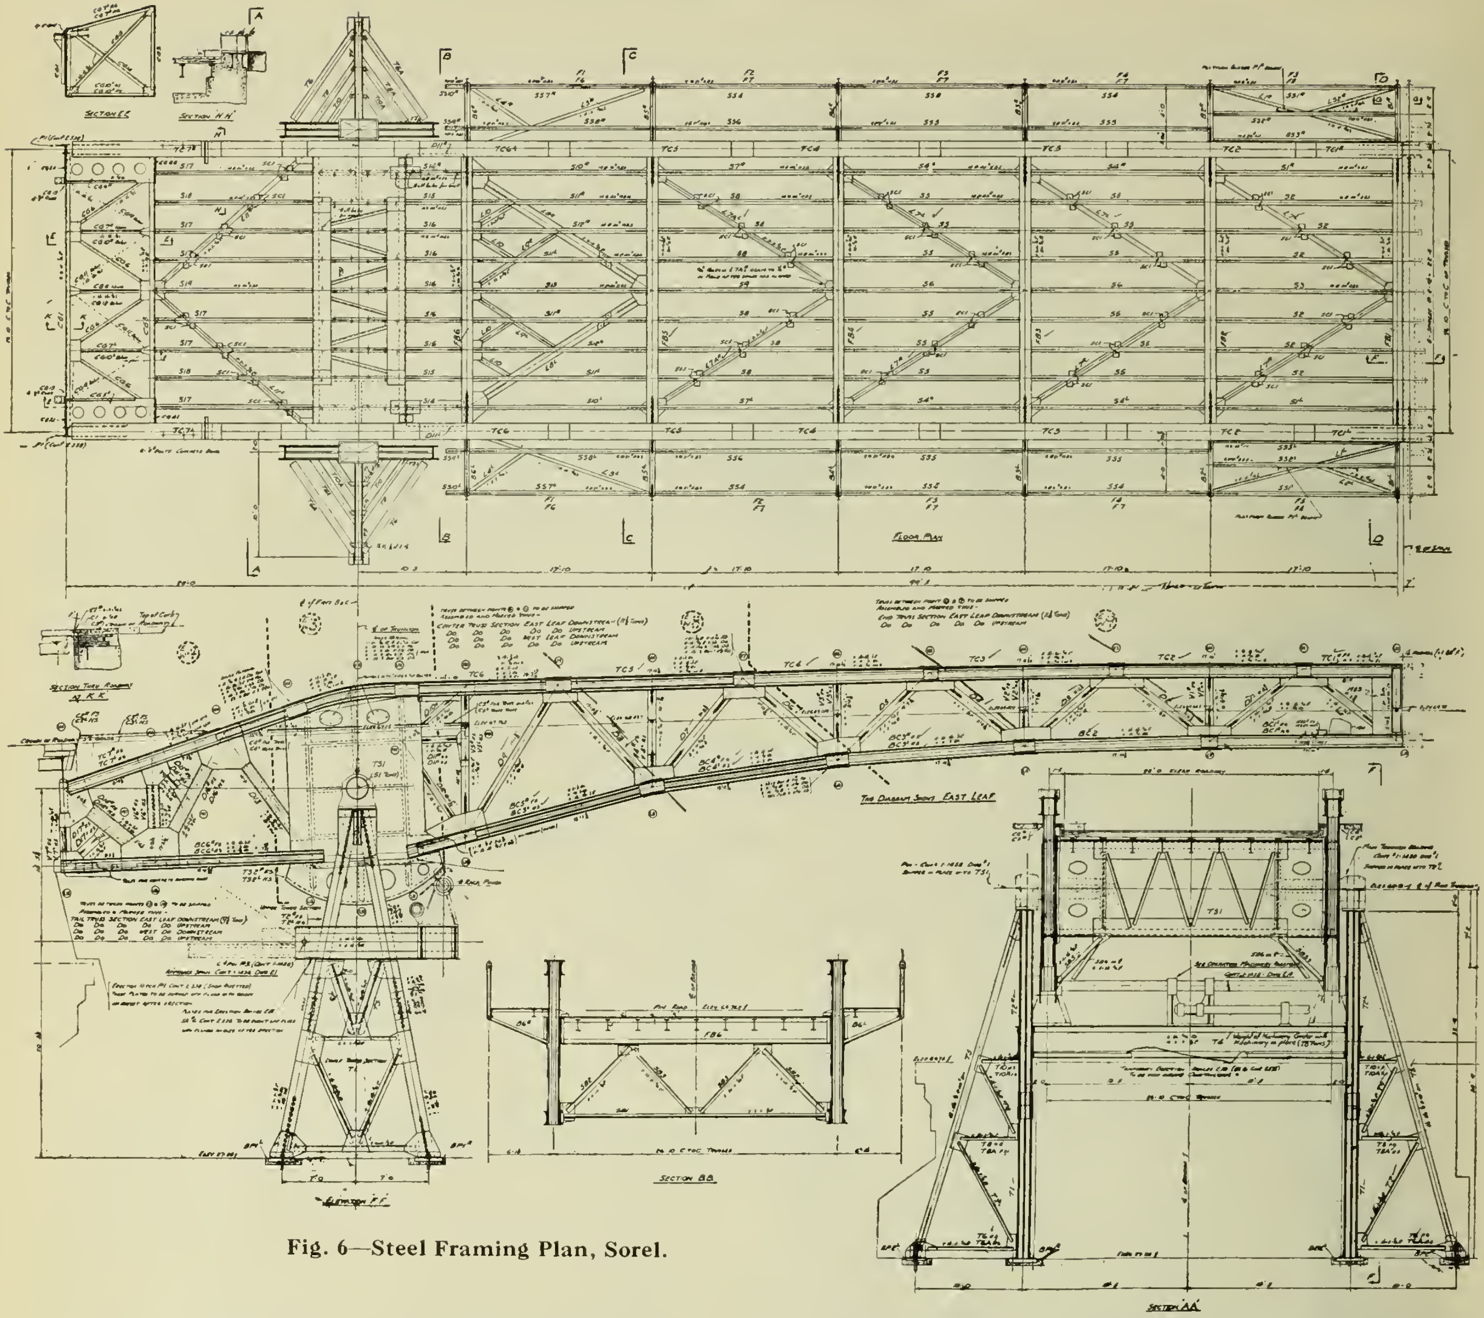

Fig. 6—Steel Framing Plan, Sorel.

detail each trunnion is only loaded at two points, i.e., at the outer truss web and at the diaphragm. This gives a satisfactory and determinate distribution of the load on the trunnion, which is a theoretical advantage.

The elimination of the inner web plate in the area of the trunnion strut was also a great advantage from the fabrication point of view. It made a much simpler and a much better detail to fabricate. In the original detail the necessary diaphragms between the two webs in this area left very cramped spaces in which to do the final assembly and riveting.

To avoid excessive wear on the trunnion bearing and to ensure easy operation of the bridge, it is essential that the trunnions have a uniform bearing on their journals. To ensure this, it was decided to limit the slope of the trunnions to .010 inches in the length of its bearing under maximum load conditions, neglecting the relief due to compressibility of the bearings themselves. This was done by increasing the size of the trunnion and trunnion strut over that required for the figured stresses. This increase in size of the strut is such that the figured stress in it is only about 4,000 pounds per square inch.

The necessity of maintaining a reasonable slope of the trunnion in its bearing is one of the limiting features of this arrangement of trunnion supports. As the weight of the leaf increases it is more and more difficult to design a stiff enough trunnion strut. There is an alternative, i.e., to tilt the trunnion bearing to the theoretical slope of the trunnion. This would require very accurate workmanship in shop and field, and as far as the authors know this method has never been used.

Mechanical Equipment

All three bridges are electrically operated with provision for handpower operation in case of electric power failure. In each case the torque is applied to the leaf through racks and pinions. At Norwood the pinion is on the leaf and rotates with it, while at Gaspé and Sorel the pinions are fixed and the racks are attached to the moving leaves. The machinery was designed so that it could be shop assembled in units on suitable structural frames. These were, where possible, directly connected to the bridge frame to facilitate the lining up of the mechanical equipment in the field.

All trunnions and large shafts were forged. All castings were steel and all gear teeth, including those on the racks, were cut. On similar structures in the future, due to the rapid strides that have been made in welding technique, castings would be largely replaced by welded units.

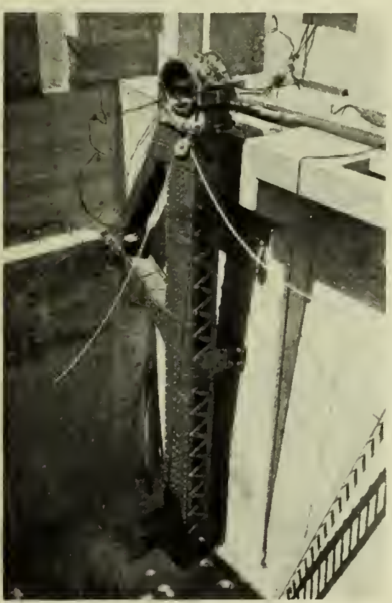

Fig. 7—Trunnion Bearing Post, Norwood.

Figure 4 shows the arrangement of the operating machinery at Norwood. A single pinion and rack on the centre line of the bridge operates the span. The motor, brake and gear reduction, located in the machinery house, were assembled in the shop on a structural base and were shipped as a unit. The operating pinion with its gear train was also assembled and shipped as a unit. This unit was connected in the field to the counterweight truss. The connecting shafts with their bevel gears were lined up in the field. The rack was assembled in the shop to a structural frame which was embedded in the back wall of the bascule pier. This frame was provided with levelling screws and anchors so that it could be brought to and held in its proper position in relation to the trunnion while concrete was poured around it.

Auxiliary mechanical equipment consists of: hand operated span locks of the sliding bar type; two air buffers attached to the toe of the bascule; and a centering device to centre the span when seating and to take the wind reaction with the span down. As it was not expected that the bridge would be frequently operated, interlocks between the span locks and the operating machinery, and highway gates, were omitted.

Fig. 8—Trunnion Truss at Norwood.

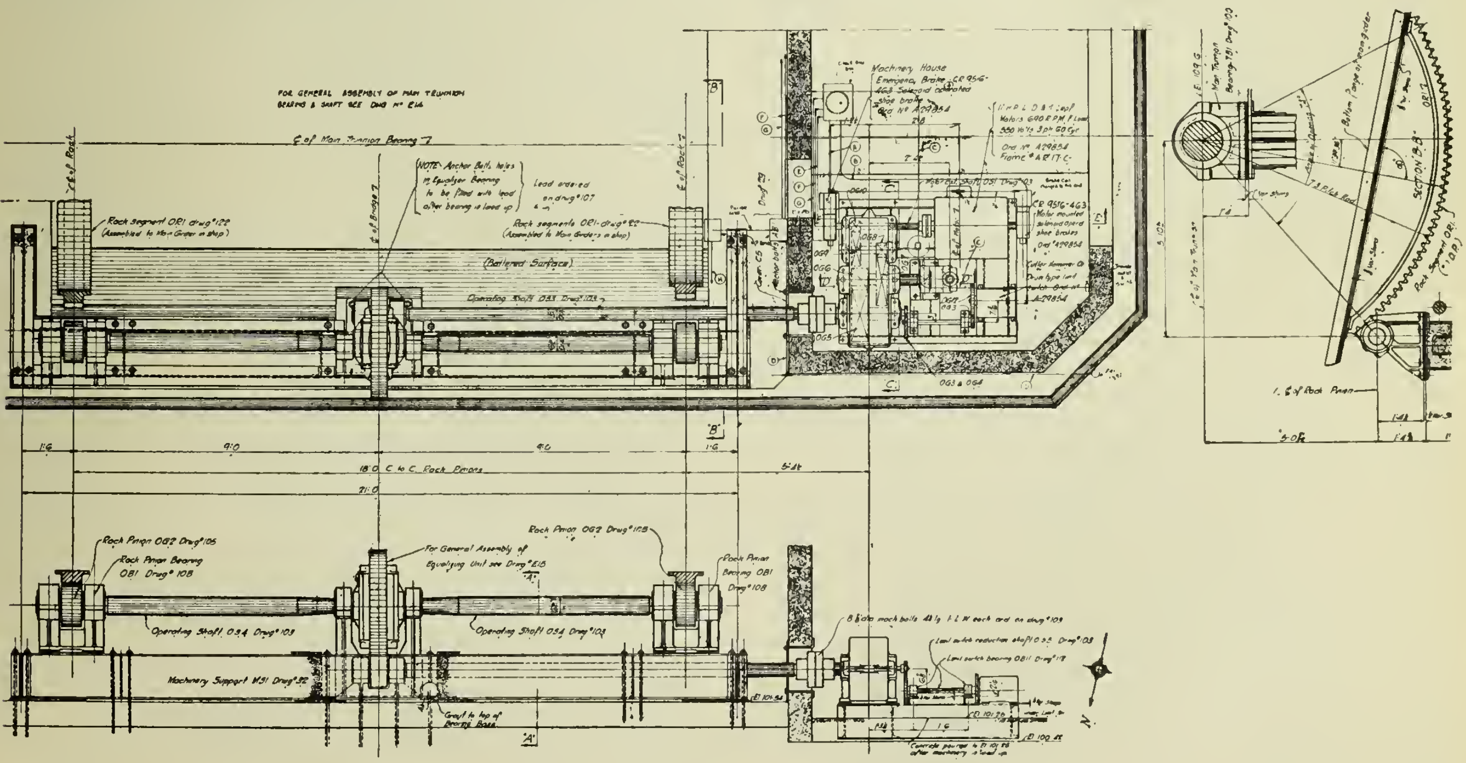

Fig. 9—Operating Machinery at Gaspé.

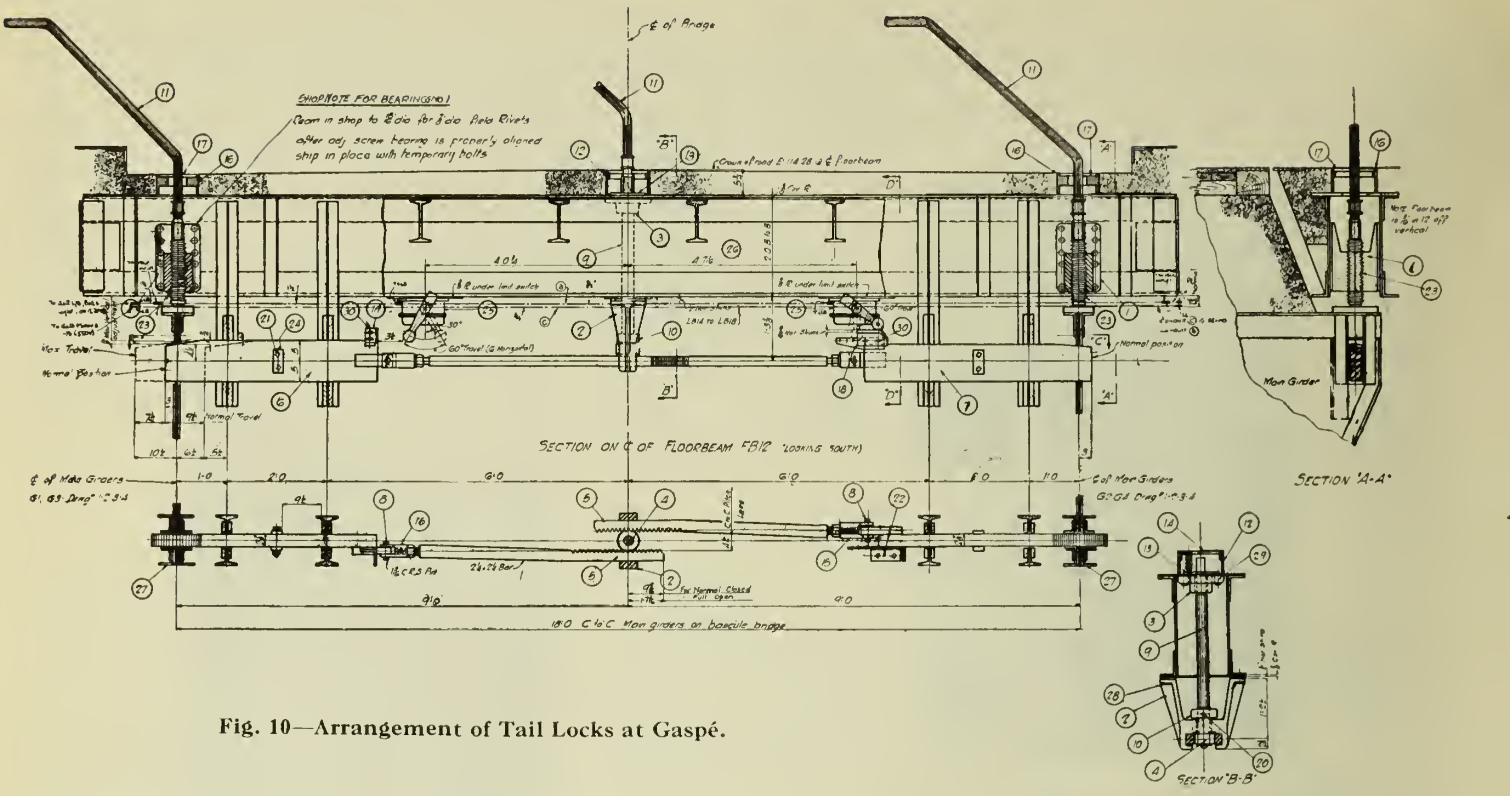

Fig. 10—Arrangement of Tail Locks at Gaspé.

Figure 9 shows the arrangement of the operating machinery at Gaspé. Each leaf is operated by two pinions and racks. The racks are attached to the bottom flanges of the girders over the piers. The operating machinery was assembled in the shop into two units: the first, consisting of the motor, brake and gear reduction unit; the second, of the equalizer unit, the main operating shafts with their bearings and the main pinions. The first unit is located in the machinery house and is connected to the second by an operating shaft which carries the pinion of the equalizing unit. The second unit was assembled on a box girder which was designed to be anchored to, and built into the pier after the main pinions were lined up.

The auxiliary mechanical equipment consists of manually operated shear-locks at the junction of the leaves, manually operated tail-locks at one end of one leaf to resist the reaction from live load on the portions of the bascule roadway behind the trunnions, and motor operated highway gates of the ordinary railroad crossing type. Figure 10 shows the arrangement of the tail-locks. Electrical interlocks are provided between the span locks, highway gates and operating machinery, to ensure that all operations are carried out in the proper sequence.

Figure 11 shows the arrangement of the operating machinery at Sorel. The arrangement of the operating pinions and racks is similar to that at Gaspé. The machinery was assembled in two units as at Gaspé, but the box girder carrying the equalizer, etc., was framed between the towers carrying the main trunnions. This allowed the main pinions to be lined up from the trunnion bearings in the shop and greatly reduced the time required for lining up in the field. This girder was also anchored to the pier and concreted in.

The auxiliary mechanical equipment consists of motor driven shear locks at the junction of the leaves; motor driven tail-locks; air buffers; and motor driven highway gates of the horizontal swinging type. Figure 12 shows the arrangement of the tail-locks and air buffers. Figure 13 shows the shear locks at the junction of the leaves. These are designed to line up the ends of the two leaves vertically if unequal deflections occur due to temperature differences. Air buffers were used as they were considered essential with a span of this weight to allow of closing it without imposing an excessive impact on the approach spans. They were not provided at Gaspé, as the mass of the moving leaf was relatively small.

Figure 14 shows the arrangement of the highway gates. This design is original and patents have been applied for. The gate, which is mounted on a vertical trunnion at the curb, is built of structural steel and is substantial enough to withstand, without damage, a moderate blow from a car. The trunnion, carried in a bearing attached to the floor steel, has a bullwheel rigidly attached to it underneath the floor slab. The gate is operated by means of a rope drive on this bullwheel. The operating mechanism, consisting of a motor, gear train and operating drum, is housed in a steel cabinet on the sidewalk. The operating rope between the drum and the bullwheel passes under a sheave mounted on a vertically guided counterweight which during normal operation of the gate rests on a bracket and has no function to perform. If, however, the gate is struck by a vehicle when in the closed position it swings open under the blow and the counterweight is lifted from its support, thus protecting the operating machinery from damage. As the vehicle backs away from the gate the counterweight brings it back to the closed position and the gate is immediately ready for normal operation.

Electrical interlocks are provided between the operating machinery, span locks and highway gates. A mechanical interlock is also provided between the tail-locks and highway gates.

Due to the modern practice of using cut teeth for all gears and the high degree of accuracy attained by modern shop methods, the question arises whether it is necessary to provide an equalizing unit between the main pinions as was done in these bridges. From an examination of the units at Sorel, it appears that no movement whatever has occurred in them. Their omission would result in considerable economy and the authors feel it is a question well worth the consideration of all those interested in movable bridge construction.

Electrical Equipment

At all three bridges the main power supply is 550 volts, 3-phase, 60-cycle; 110-volt power is used for the lighting and the control circuits in all cases.

At Norwood a 60-h.p. at 720 r.p.m. slip ring, wound rotor induction motor is used for operating the bascule span. It is capable of opening the bridge in three minutes under normal conditions, or six minutes with ice load. A service and an emergency brake, both thrustor operated, are provided. The service brake is mounted on the motor shaft, while the emergency brake is mounted on one of the operating shafts. The bridge is operated from a control desk at the sidewalk level. Control is through a semi-magnetic control panel located in the machinery room. A cam type rotating limit switch is mounted in the machinery house which cuts off the power and operates the various indicating lights. Two rotating cam type limit switches are also connected to the end locks. They are mounted in series and are closed only when the locks are fully withdrawn. A plunger type limit switch is attached to the end of the span and operates the "fully closed" indicating light on the operating desk.

At Gaspé, each leaf is operated by an 11-h.p. at 720 r.p.m. wound rotor motor, which can open it in one and a half minutes under normal conditions or three minutes with ice load. The highway gates are operated by four ¾-h.p. at 1,200 r.p.m. squirrel cage motors. Solenoid brakes are mounted on all motor shafts. The main power supply is obtained from a gasoline driven generator located on one floor of the machinery house. The gasoline engine is a 130-h.p. at 1,200 r.p.m. and is connected by a V-belt drive to a 93-kv.a., 550-volt, 60-cycle, 3-phase alternator. 550-volt power, in case of failure of the gasoline engine, and 110-volt power for the lights and control system at all times, are obtained from the local supply.

The generator, control panels, and operator's desk are located over the machinery house on the main pier on the Gaspé side. Power and control circuits are carried across the channel in submarine cables. These cables are buried five feet in the bottom of the river and are brought up the piers through pipes provided when they were built. The operator's desk, on which all switches and indicating lights together with a voltmeter and ammeter are mounted, is located in a house which is at deck level and from which the operator has a clear view of the whole bridge. The main incoming line switch is also mounted in this house. On the floor immediately below the operator's house the gasoline driven generator is located. The control panels and resistors are placed in the machinery house.

At Sorel, each leaf is operated by two 20-h.p. at 720-r.p.m. wound rotor motors, which open it in two and a half minutes under normal conditions, or five minutes with ice load. The end locks and centre locks are operated by four 3-h.p. at 720-r.p.m. squirrel cage motors. The roadway gates are operated by four 1-h.p. at 900 r.p.m., five minute rated, totally enclosed motors. Solenoid brakes are provided on all motors, and in addition an emergency thrustor operated brake is provided for each leaf. All motors are controlled by semi-magnetic control equipment installed on the Sorel side of the channel. The primary and secondary leads of the far side leaf motors, end lock motors, and gate motors, together with the leads for limit switches and lights, are brought across the channel in six submarine cables located downstream from the bridge. The cables are brought up to the machinery houses through pipes placed in the piers when they were built.

To house the control panels, resistors and operator's desk a two-storey brick house was built on the downstream end of the main bascule pier immediately over the machinery house on the Sorel side. The operator's desk and incoming line switch are located in the upper storey from which the operator has a clear view of all points on the bridge. The controls for all operations are mounted on the operator's desk. They consist of two drum controllers for the

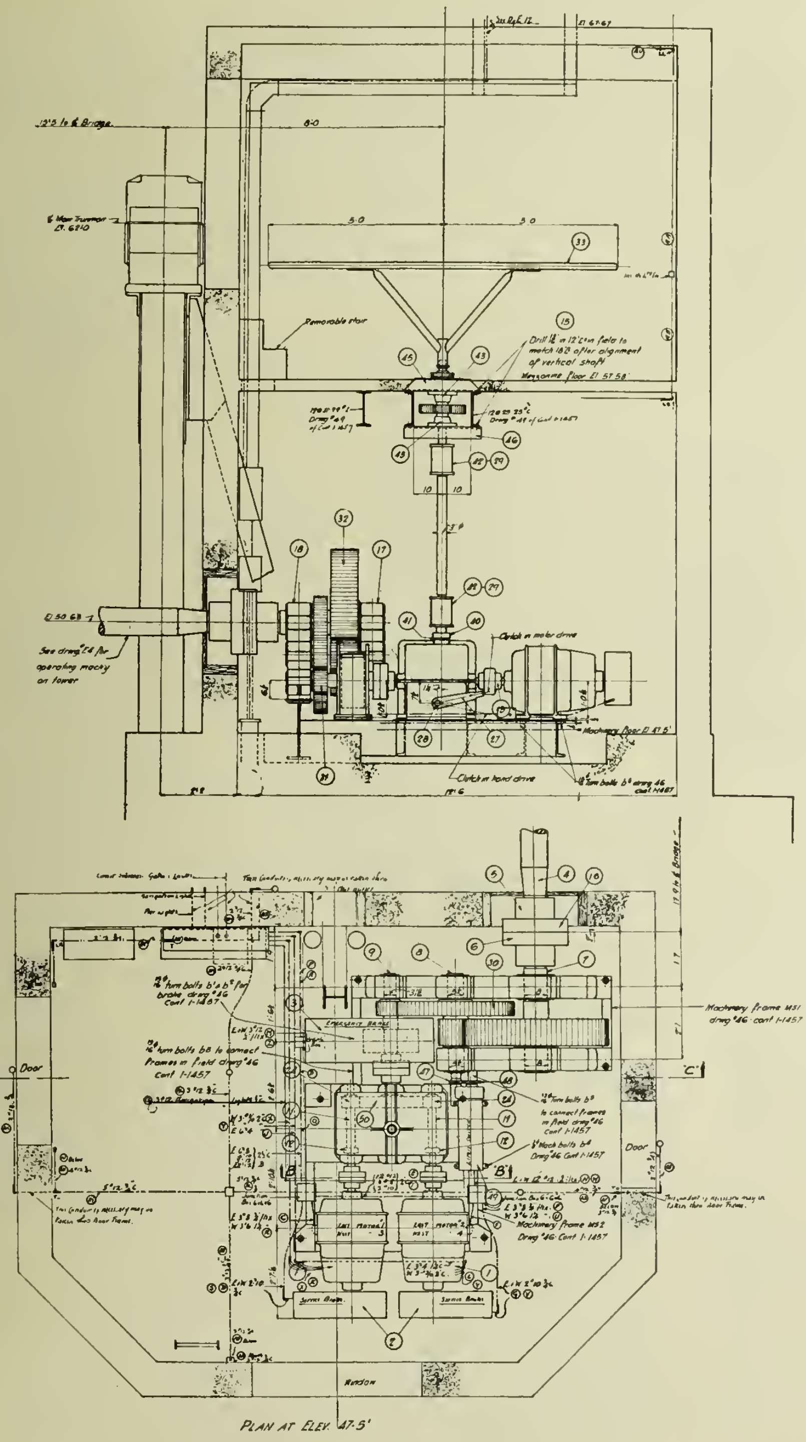

Fig. 11—Operating Machinery at Sorel.

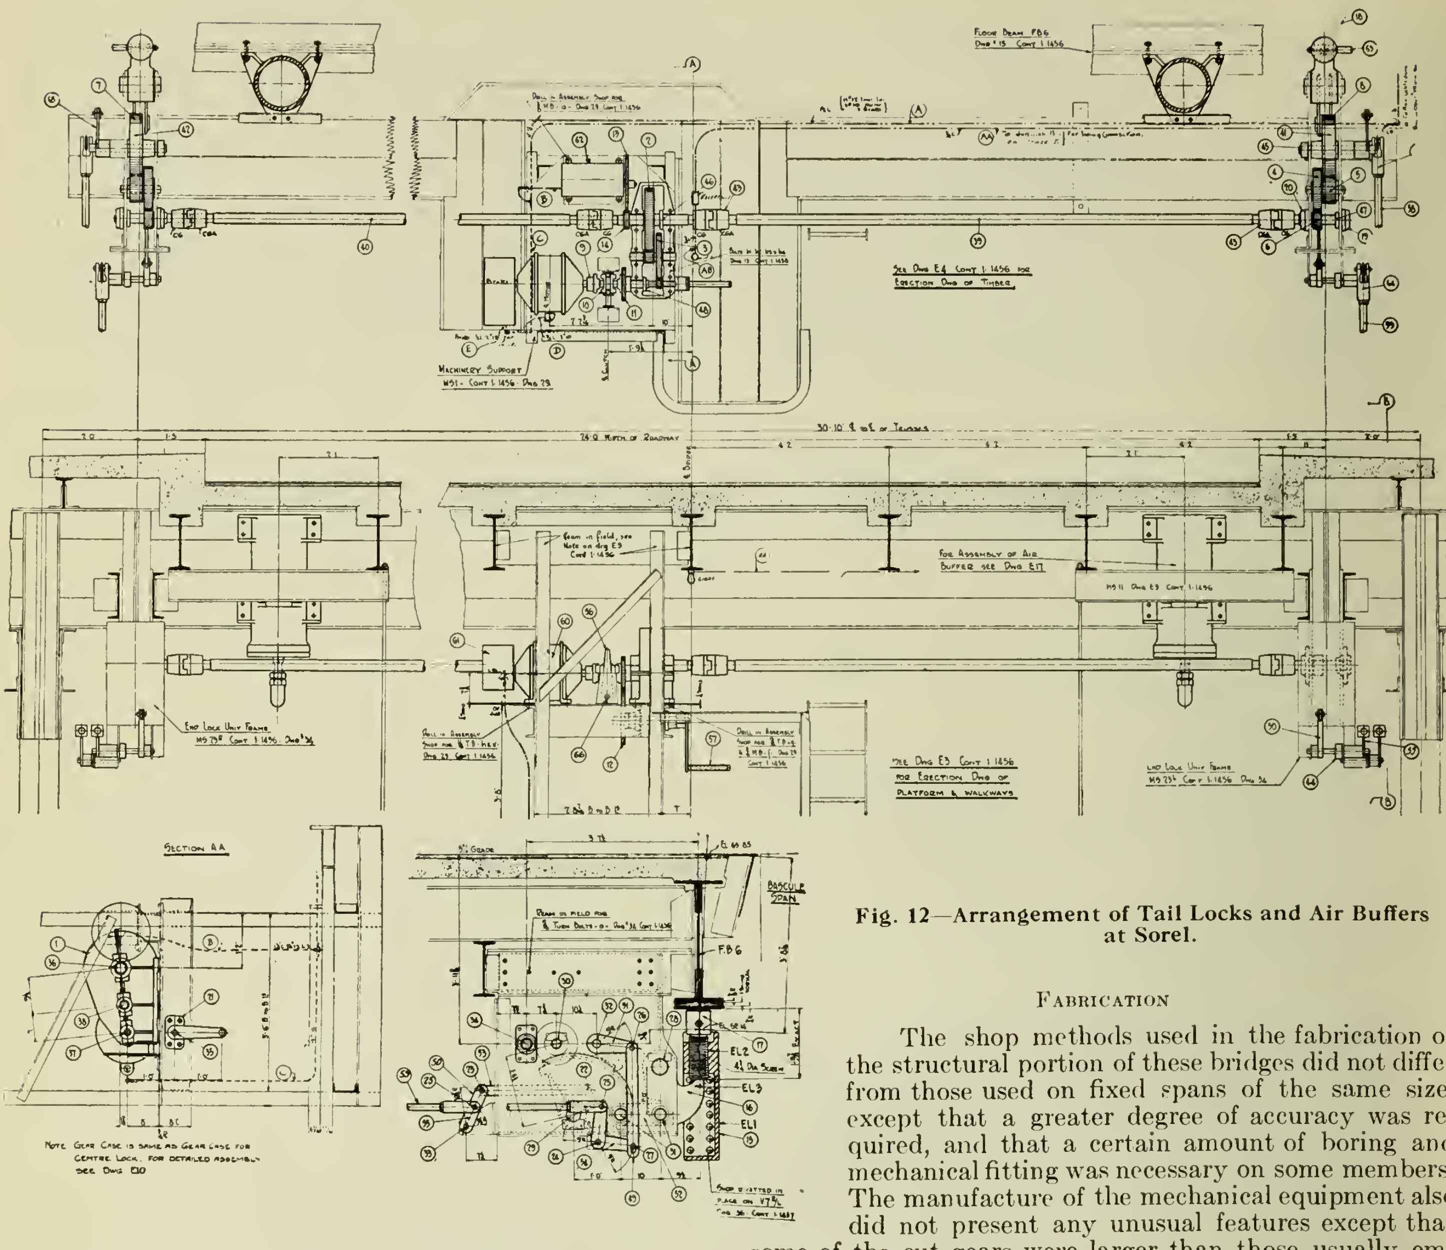

Fig. 12—Arrangement of Tail Locks and Air Buffers at Sorel.

main motors; four reversing drum switches for the end lock and centre lock motors; four reversing switches for the roadway gates; a switch for the bell circuit; eighteen indicating lights; seven tumbler switches for emergency brakes; a voltmeter; an ammeter; and two reduced torque push button stations.

The lower floor of the house contains the two control panels upon which are mounted the necessary switches, contactors, overload relays, undervoltage contactors necessary for all the motors, lighting and control circuits on the bridge. The necessary resistors are also located in this room.

Limit switches are provided on all motors, which operate lights on the operator's desk in such a way that he knows at all times the position of the bridge. Provision is also made to cut the power supply off from the main motors when the bridge is 7 degrees from both the fully closed and open positions. From that point the movement of the bridge must be completed by the operator by-passing the limit switch. When the switch is by-passed only a reduced torque is available at the motors which ensures easy closing of the bridge.

Fabrication

The shop methods used in the fabrication of the structural portion of these bridges did not differ from those used on fixed spans of the same size, except that a greater degree of accuracy was required, and that a certain amount of boring and mechanical fitting was necessary on some members. The manufacture of the mechanical equipment also did not present any unusual features except that some of the cut gears were larger than those usually employed. Shop assembly of the mechanical equipment to the structural portions of the spans was carried further than on any previous bridge. This was particularly the case at Sorel and the results obtained in the field fully justify the adoption of similar methods in the future. The erection of the mechanical equipment was expedited, and the operation of the bridge was improved.

At Norwood, the main girders were each 118 feet long, 13 feet deep at the tail end and weighed 56 tons. Ordinarily girders of this size cannot be shipped by rail in one piece, but in this case it was possible due to the short haul from the shop to the site. These girders were also heavier than the normal capacity of the shop cranes, but by careful planning both girders were fabricated and handled without undue difficulty.

The first operation in their construction was to assemble and rivet together the web and reinforcing plates forming the section of the girder around the trunnion. The 30-inch diameter hole for the trunnion sleeve was then bored in these plates after which the sleeve with the 24-inch diameter trunnion in place was assembled in position, the connecting holes reamed, and the rivets driven. The next operation was to assemble and bolt up the whole girder after which it was carefully lined up by transit and levelled so that the trunnion was at right angles to the girder web. All holes were then reamed and the rivets driven. The girders were turned into the vertical position and loaded for shipment.

At Gaspé, the main girders were assembled and riveted in the usual way without accurately locating the hole for the trunnion. The two girders of each leaf were then shop-assembled into a unit with the trunnion strut and counterweight strut in place, also sufficient floorbeams and bracing to give a rigid structure. The main connections were then reamed. The location of the holes for the trunnions in the webs of the girders, and in the trunnion strut diaphragms, was next carefully determined by means of transit and level. The leaf was dismantled and the holes bored for the trunnions on a horizontal boring mill. The two holes for each trunnion were bored in one setup on the machine as the trunnion strut was spliced at two points, with the portions containing the diaphragms shop riveted to the girders. The trunnions were next driven into position in the girders. The racks were then placed in position on the lower flange of each girder and after being centered about the trunnions were shop riveted in place. The equalizer unit and bearings for the main pinions were also shop assembled to the machinery girder and shipped in place on it. This girder was not connected to the trunnion bents so that it could not be lined up in the shop to the trunnion bearings.

The location of Sorel bridge was such that barge shipment direct from the shop to the site was most economical. This allowed the shipment of pieces of larger overall dimensions than could be sent by rail. As a result each leaf was shipped in sections, the largest of which consisted of a trunnion strut, two trunnion pins and the plated portion of two trusses adjacent to the trunnion. Each of these sections weighed 51 tons.

The various truss members were fabricated in the usual way after which each truss, except for the section at the trunnion, was assembled in the shop on the flat and carefully lined up by transit to its cambered shape. All joints were reamed and certain ones riveted before shipment. To take the place of the plated section at the trunnion during assembly, a skeleton section was built which had connection holes for adjacent members accurately located from the sections it replaced.

The plated sections at the trunnions after being completed were assembled to the ends of the trunnion struts, lined up and the connections reamed and riveted. The centres of the trunnion pin holes were then carefully located, by means of a level and a piano wire, on each of the four webs through which the trunnions passed. Each section was next placed in the boring mill and the holes bored. The bar of the boring mill was only long enough to bore the hole through the two webs at one end of the section, so that to complete the boring the piece was rotated about a vertical axis through 180 degrees. After boring was completed the holes were carefully checked for line and were found to be within a few thousandths of being in exact alignment. The trunnion pins were not finished turned until after the holes were bored so that any inaccuracies in the actual size of the holes could be compensated for in the diameter of the pins. After turning, the pins were driven into position with a heavy ram. They are held in place by keys and a nut on the inner end. The racks were next assembled in position and lined up from the trunnions.

As can be seen from Fig. 6, the trunnion towers are three-post triangular structures. They were completely assembled in the shop and shipped in one piece. A shop splice was provided in the two main legs of each tower, to permit of the shop assembly of the machinery girder on the towers, since the clearance under the available cranes was not sufficient to allow of erection of the complete towers. The two main posts with their bracing in the plane parallel to the centre line of the bridge were first assembled and riveted except for the shop splice which was reamed. The top sections of the two "A" frames for each pier were then set up with their connecting machinery girder. The trunnion bearings, equalizer unit, rack pinion bearings, operating shafts and rack pinions were next set in position and carefully lined up to their correct positions. The holes for the holding-down bolts for the units on the machinery girder were reamed and the bolts placed. It was originally intended also to ream the holes and place the holding-down bolts for the trunnion bearings, but it was later decided to leave them to be reamed in the field in case any twist should occur in the bents due to handling or riveting. The trunnion bearings were, therefore, held in place for shipment by tack welding. The machinery girder was removed from the tower with the machinery in place and was shipped in that condition. The towers were then assembled, riveted up, and shipped in one piece. Figure 15 shows the assembly of the trunnion bents with the machinery girders in the shop.

To facilitate the work in the field, it is essential that accurate centre lines be established in the shop on those

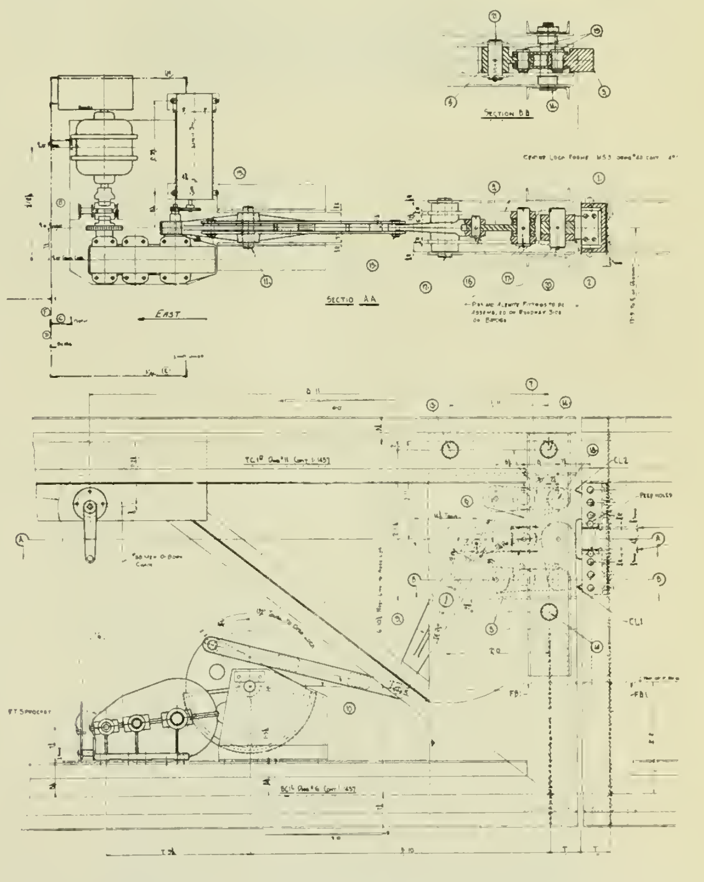

Fig. 13—Arrangement of Shear Locks at Junction of Leaves at Sorel.

portions of the structure which are first placed and on the accurate location of which depends the alignment of the whole structure. To do this, it is necessary to plan the erection procedure in advance so that the centre lines established in the shop are in suitable locations for use in the field. At Sorel, the erection procedure was established before the detail drawings were issued to the shop and the latter carried full instructions as to the points where centre lines were to be established on the trunnion bents and machinery girders. These lines were carefully laid out and clearly marked on the steel while the trunnion bents were assembled.

The remainder of the fabrication of the bridge did not present any unusual features.

Erection

The method of erection adopted for any bridge is not standard for all bridges of that type. It varies greatly due to differences in conditions at the site, the weight and size of pieces to be handled, and the equipment the contractor has available. Since no standard method can be laid down, it is essential for economical erection that each job be carefully planned in the office before erection commences and that sufficient drawings be prepared to show the arrangement of the equipment to be used and outline the sequence of, at least, the major operations.

The erection of these three bridges present examples of several of the methods, and of some of the different kinds of equipment that are used in bridge erection.

Norwood Street

At Norwood conditions at the site favoured the use of locomotive cranes, as a railroad line was situated close to the south end of the bridge. Also, the cranes were available at Winnipeg, and the bridge as designed was strong enough to carry them. As locomotive cranes can only handle heavy loads at a short radius, it was necessary to provide a track which would bring them close to their

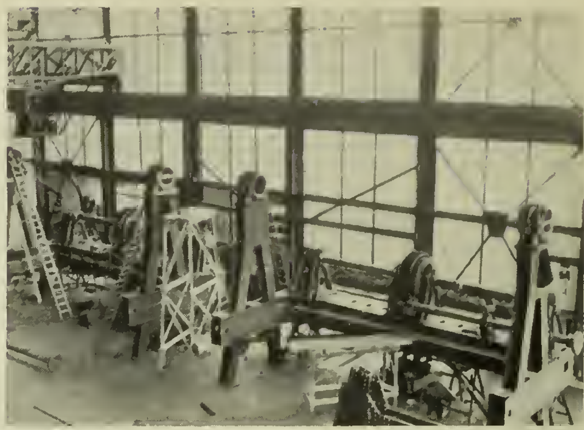

Fig. 15—Assembly of Machinery Girder and Bents.

loads. A pile trestle carrying a standard gauge track was, therefore, built across the gap on the centre line of the bridge. The bridge stringers were used to span between the pile bents and were placed at their correct elevation so that they could be connected to the floorbeams as the latter were placed, and thus release the piles for re-use. Sufficient piles were supplied for a trestle under three spans.

The first pieces erected on the bascule span were the

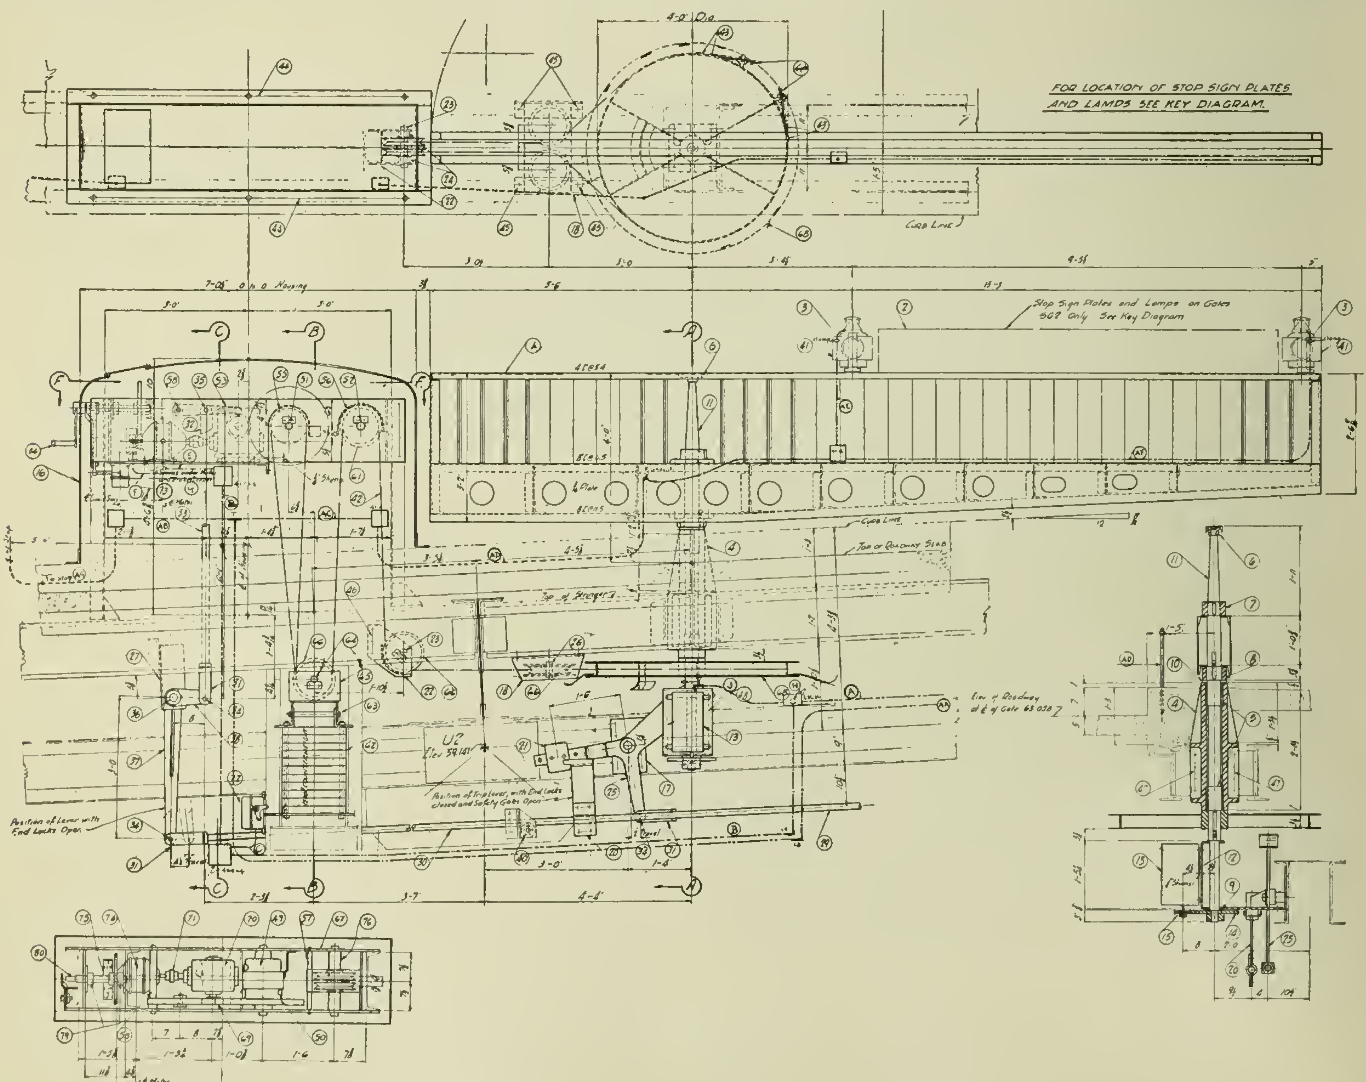

Fig. 14—Arrangement of Highway Gates at Sorel.

trunnion posts. They were set in position and shimmed so that the trunnion bearings were in perfect alignment. Figure 7 shows the downstream post in final position.

The main girders were next erected. Each girder was run out on two flat-cars between two locomotive cranes, as shown in Fig. 16. When the girder reached its proper position, it was lifted by the two cranes and landed on the piers about 8 feet 6 inches from the centre line of the bridge. The flat cars were then removed, and the track on the approach span next to the tail of the girder was swung out so that the crane could lift that end of the girder into its final position. The toe end was moved out on rollers. The tail end was lowered into the slot in the bascule pier wall until it rested on a temporary timber bent erected in the counterweight pit. This held the girder slightly above its final elevation. The trunnion trusses with the inside trunnion bearings were next placed.

The next operation was the lining up of the two main trunnions and the connecting up of the counterweight and bracing to the main girders. A piano wire was stretched through the holes provided in the trunnions and was used to line them up. The girders were jacked to their correct position longitudinally and laterally, and to an elevation such that the two trunnion pins were $\frac{1}{4}$ inch above their theoretical position. The counterweight strut was then erected and connected to the girders, care being taken to maintain the girders in position. The bearings on the trunnion posts were now shimmed up until there was $\frac{1}{8}$ inch clearance between the bearings and the trunnions, while the inside bearings were brought up to within $\frac{1}{4}$ inch of them. The outer bearings were left $\frac{1}{8}$ inch high to allow for the fact that the posts would deform more than the trusses under the load of the span. The strut connecting the trunnion trusses was next connected up and the main girders were jacked down until the full load came on the trunnion bearings. The alignment of the trunnions was again carefully checked, due allowance being made for the deformation of the columns which would occur when the full dead load of the span was in place.

The rack, shipped in one piece assembled on a structural frame, was next placed in position and centered with reference to the trunnions. Anchors and adjusting screws held

Fig. 16—Erection of Bascule Girder at Norwood.

it rigidly in position while the frame was concreted in. Dowels had been left projecting from the pier to provide a bond between this concrete and the pier.

The locomotive cranes completed the erection of the floor steel, machinery units and flooring, while at the same time the forms were built for the counterweight and the concrete poured. It was possible to do all this work with the span in the closed position, which greatly simplified all the erection problems.

The bridge was completed and formally opened on November 19th, 1931. Figure 17 shows the finished bridge.

Gaspé

At Gaspé, some of the factors governing the method of erection to be adopted were:—

(*a*) The river had a maximum depth of 50 feet and the bottom was covered with a thick soft layer of mud which gave little support for piles.

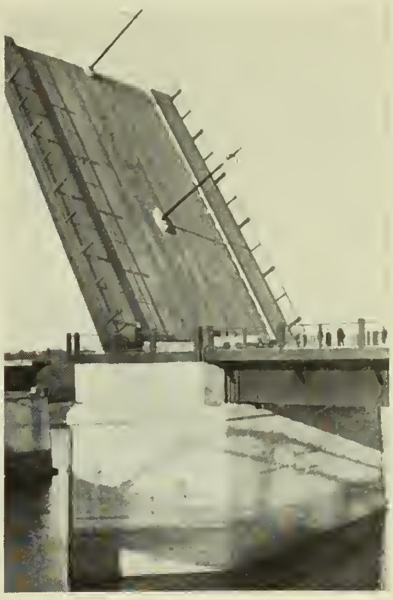

Fig. 17—Completed Norwood Street Bridge.

(*b*) The weight of the heaviest piece to be handled was only 14 tons.

(*c*) The span as designed could only carry relatively light erection equipment.

(*d*) Erection had to proceed from both ends as the bascule had to be erected in the open position.

(*e*) All material coming in by rail or boat arrived on the south shore of the river.

After considering all the factors involved, it was decided to erect the fixed spans one at a time on falsework at a suitable location and then float them into position on

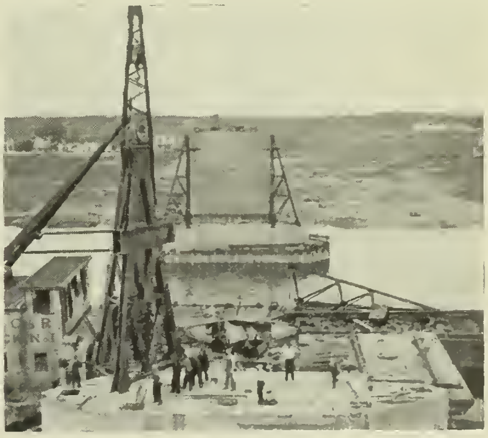

Fig. 18—Placing Trunnion Towers at Sorel.

scows, using the tide to lift the spans off the falsework onto the scows and again to lower them into position on the piers. The steel was erected on the falsework with a light traveller which consisted of a 5-ton stiffleg traveller mounted on a wooden base, together with the hoisting engine. The falsework was actually located between the abutment and pier No. 1, and the fixed spans were erected in order starting from the opposite end, so that the last span was erected in its proper location.

The trunnion towers were the first portion of the bascule span to be erected. As soon as the first bascule pier was completed to the elevation of their base, the towers were placed by a floating derrick. The piers had been bush hammered to exact elevation over the area required for the base plates. The towers were then lined up and anchored. The pier was next completed up to the elevation of the machinery house floor, after which the trunnion bearings were placed in position, lined up, and bolted to the trunnion towers. Shims were required to bring the bearings to correct elevation and the holes also had to be reamed for the connecting bolts. This gave a perfectly satisfactory job, but it was a slow and expensive operation to carry out in the field.

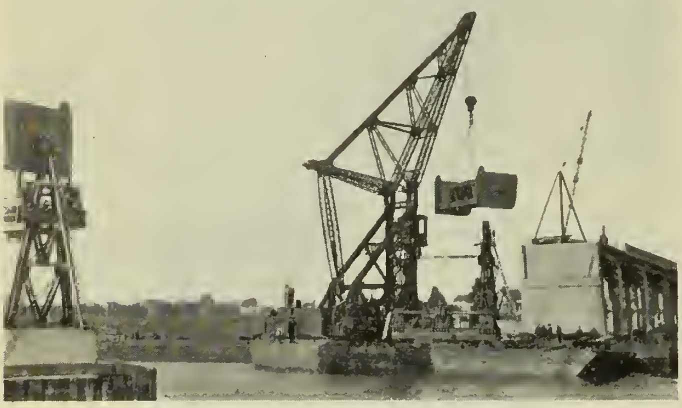

Fig. 19—Placing Trunnion Strut at Sorel.

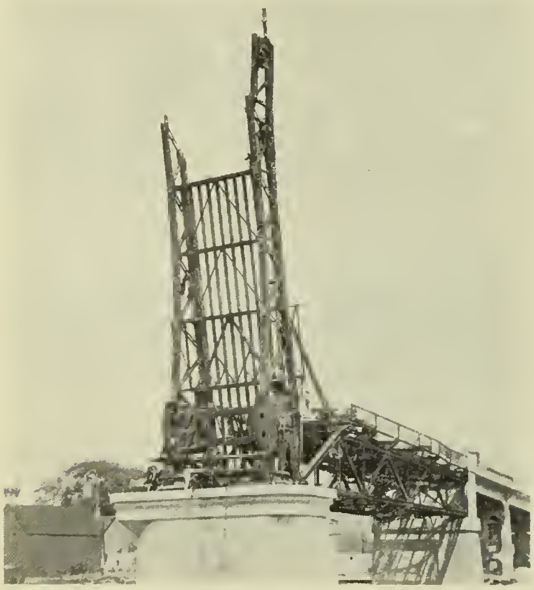

Fig. 20—Erecting Bascule Leaf at Sorel.

As soon as the trunnion bearings were located the machinery girder with the rack pinions, equalizer, etc., shop assembled to them, it was placed in position and the rack pinions lined up from the bearings. After this was done, the machinery girder was anchored in place and concrete was poured around it.

After one of the fixed spans adjacent to the bascule was floated in, a 12-ton stiffleg derrick was set up at its outer end and the steel was brought out to it on scows. The derrick then erected one leaf of the bascule. The girders, each of which had been shipped in one piece with the trunnions in place, were first erected. The girders were supported by the trunnions which rested in their bearings and also by blocking on the pier under their ends. To ensure the channel opening being maintained, the front ends of the girders were tied back temporarily to the fixed span. The trunnion and counterweight struts were then erected and connected up, after which the floor steel and bracing was placed. Before riveting was commenced the two girders were carefully lined up.

When the erection of the steel in the leaf was completed, the forms for the counterweight were built, the reinforcing steel placed and the concrete poured. While this was being done the machinery was placed in the machinery house and lined up. The derrick was then dismantled and transferred across the channel where it erected the other leaf in the same way.

As soon as the counterweight was poured, the roadway planking and the asphalt plank wearing surface were laid. The wooden floor was placed with the leaves in the open position, but the asphalt plank had to be placed with the bridge closed.

The contract called for the erection of the bridge to be completed by October 1st, 1931, but due to unavoidable delays in the completion of the piers it was only possible to place spans Nos. 4 and 3 in position during the summer of 1931. Span No. 2 was also completely erected but was not floated into position until the summer of 1932, upon completion of pier No. 2. The erection of the bascule span was also delayed until 1932. Unfortunately the first boat that passed through the opening after the first leaf was erected, but before the counterweight was poured, collided with the leaf and seriously damaged both girders, necessitating their removal and partial re-building. The bridge was opened on October 9th, 1932, and has operated successfully since.

Fig. 21—Completed Bridge, Sorel.

Sorel

At Sorel barge shipment direct from the shop to the site was adopted in preference to shipping by rail, as this permitted of lifting the steel direct from the barge to position in the bridge.

For the erection, no one piece of equipment was suitable for the whole job and it was found economical to combine the use of 15-ton derrick scows, a 75-ton floating crane, and a stiffleg derrick. By using the one most suitable for each operation an economical erection programme was developed.

In order to allow of easy and accurate setting of the trunnion bents, they were built with loose base plates which were accurately set in place on the piers before the bents arrived. Recesses were left in the piers in which the base plates were set to exact level. There were three base plates under each bent. These plates were brought to dead level and the same elevation with a straight edge and spirit level, after which the two sets on each pier were checked for elevation with a precise level. Each plate was brought to position and held there by means of levelling screws and anchor bolts. As soon as the plates were set and checked they were grouted in. Working lines were then established on the top of the pier and on the base plates parallel to and at right angles to the centre line of

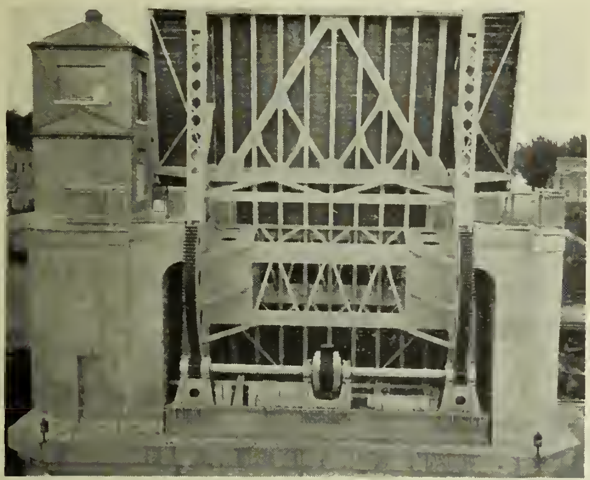

Fig. 22—End View of One Leaf, Sorel.

the bridge for use in locating the trunnion towers corresponding to the centre lines placed on the towers in the shop.

The trunnion towers, which were shipped in one piece, as previously noted, were placed by the derrick scow as shown in Fig. 18. The trunnion bearings were brought to correct line by shifting the towers on the piers, but without moving the bearings on the towers. The towers were then bolted down to the pier and the elevation and level of the bearings were checked. They were found to be correct without any shimming or adjusting, thus entirely justifying the shop assembly procedure.

The trunnion struts and machinery girders were the next pieces to be erected. Each of the former weighed 51 tons and the latter 28 tons. The method to be used in their erection was given a great deal of study, and the final decision was to use the Montreal Harbour Commissioners' 75-ton floating crane to place these four heavy pieces. The crane left Montreal at noon, on June 21st, 1932, and due to a favourable wind reached the bridge site about 6 o'clock. It immediately placed the trunnion strut on the Sorel side. Next morning it placed the machinery strut on that side and then crossed the channel and placed the other two units, completing its work by noon. Figure 19 shows one of these operations. To make the use of the floating crane economical it was essential that the operation be carefully planned and organized so that the crane on its arrival had only the four lifts to make. Without going to expensive overtime, there were about six working hours available, since the crane was only allowed away from Montreal harbour from Friday noon to Monday morning.

The following alternative method of erecting the trunnion struts and machinery girders was developed for use in case any unforeseen developments made it impossible to obtain the use of the 75-ton crane. The machinery shipped on the machinery girders was to be removed from them so that the 15-ton derrick scow could place the girders immediately after placing the trunnion towers. The machinery was then to be replaced on the girders by the scow. The approach spans were to be erected next by the same method as was actually used and which will be described later. On completion of one approach span a 50-ton steel ginpole was to be set up with its foot on the top of the pier and with its top guyed back to the approach span on which a hoisting engine to handle the hoisting lines was to be placed. The guys were so arranged that the pole would have sufficient fleet to pick the trunnion strut off a barge moored in front of the pier and lift it into position on its bearings. The ginpole and hoisting engine were then to be taken across the channel where the operation was to be repeated. This method would have been somewhat more expensive and a great deal slower than the one used.

When the machinery girders were fully riveted to the trunnion towers the alignment of the trunnions and trunnion bearings was again checked and found to be correct. The holes for the bolts connecting the trunnion bearings to the bents were then reamed and the bolts placed.

The approach span trusses on the Sorel side, each of which had been shipped from the shop in two pieces, were assembled on a scow and lifted into place by a derrick scow and a stiffleg derrick which had been erected on the end of the concrete approach spans. The stiffleg derrick then erected the remainder of the approach span steel and was moved out to the end of that span adjacent to the bascule. The derrick had a 100-foot boom and was used to erect the bascule leaf.

It first placed the tail end section of the bascule trusses and the counterweight strut. The lower ends of the trusses were tied to anchors previously placed in the pier which allowed the erection of the remainder of the span before the counterweight was poured. Figure 20 shows the placing of one of the last sections of the truss. As a clear navigation channel had to be maintained at all times, the leaves were necessarily erected in the open position. As soon as the steel in the leaf was all erected, the forms for the counterweight were built and the concrete poured. The stiffleg derrick also placed the machinery units in position on the piers after which the machinery houses were built around them.

On completion of the erection of the leaf on the Sorel side, the stiffleg derrick was moved across the channel and the other leaf was erected in the same way.

The bridge was completed in the late fall of 1932 and was opened to traffic at that time. Figure 21 shows a side elevation of the finished bridge and Fig. 22 is a view of the operator's house and operating racks and pinions on the Sorel leaf.

The superstructures of all three bridges were constructed by the Dominion Bridge Company Limited under the direction of Mr. F. P. Shearwood, M.E.I.C., chief engineer. The substructure of Norwood street was built by Foley Bros. of Winnipeg; of Gaspé by Dufresne Construction Company Limited, of Montreal; and of Sorel by Church Ross Company Limited, of Montreal.

The Montreal Neurological Institute and its Equipment

F. J. Friedman, M.E.I.C.,

McDougall and Friedman, Consulting Engineers, Montreal, Quebec.

Paper to be presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

SUMMARY—This building is for the treatment and study of diseases or injuries of the brain and nervous system. In addition to hospital wards, it contains extensive facilities for neurological research and investigation. The special features in its equipment are described particularly with reference to the service requirements in the wards, operating rooms and research laboratories.

The Montreal Neurological Institute is designed to take care of all cases in which there is a structural defect in the nervous system, whether the treatment is to be medical or surgical. All cases, whether public or private, are studied by the newer methods of investigation. These cases include immediate and late results of injury whether sustained during birth or later in life. They also include inflammation, degeneration and tumours of the nervous system. One half of the building is given over to scientific study of disease problems that are related to the nervous system. The remaining half of the building is devoted to actual care of patients.

The building is located on the east side of University street above Pine avenue, and is directly north of the McGill Pathological Institute to which it is connected by means of an underground tunnel. It also connects with the Royal Victoria Hospital on the west side of University street, by means of an overhead bridge.

The building is an eight storey and basement structure, built in modified Scottish baronial style to conform with the architecture of the adjacent buildings. Three of the floors are used for hospital purposes, two of which contain public wards, and one, private and semi-private rooms. One floor is given over to operating rooms and consulting offices. Two floors are devoted to research and animal experimentation. The balance of the building is given over to living quarters and general purposes. The building is jointly operated by McGill University and the Royal Victoria Hospital.

Prior to the design of the mechanical equipment, an extensive tour of hospitals and allied institutions was made, especially in connection with laboratory equipment and the housing and handling of various species of animals necessary for research.

Heating System

The building is heated by hot water with forced circulation and convertors for heating the water and the pumps are located in the basement of the Pathological Institute. Both a.c. and d.c. electric current are available, and in order to ensure against interruption of service, the circulating pumps are in duplicate, one with a.c. and one with d.c. motor. The temperature of water in the convertors is controlled by means of graduated action thermostats and pneumatically operated valves, etc., with a range of 100 to 190 degrees F. This was done in order to secure control over an unusually wide range of temperature. Steam is obtained from the boiler plant of the Royal Victoria Hospital, high pressure steam mains being brought through the tunnel under University street connecting the plant with the Pathological Institute. The mains are duplicated and provided with steam flow meters of the integrating and recording type. This steam is used both for the Pathological and Neurological Institutes; the condensation from each building is metered separately in order to charge each with its proper share of cost. All piping of two inches and larger throughout the building has welded joints. Reducing valves and other such equipment liable to require maintenance are duplicated or provided with by-pass connections to ensure against interruption of service. A steam separator is installed on the medium pressure steam line to ensure clean dry steam for sterilizers. All condensate flows through an economizer used for heating domestic hot water in connection with the hot water tanks. From here it flows through a condensate meter to an electric pump which returns it to the hospital boiler plant. All heating mains and other distribution piping are in tunnels under the basement. All radiators on the hot water heating system are cast iron and are tested for 100 pounds working pressure. There is a total of 13,000 square feet of radiation in the building.

Fig. 1—The Montreal Neurological Institute.

Ventilating System

The building is ventilated throughout by means of two supply and four exhaust systems. One of the supply systems takes care of the operating rooms and the other the balance of the building. One of the exhaust systems takes care of operating rooms alone, one is for general requirements, one for the animal section, and one for toilets and utility rooms. The squash court is provided with a separate disc fan and gravity inlet.

The two supply systems are provided with a common pre-heater, filter and air washer but with separate re-heater coils and fans, all located in the fan room in the basement. Each supply system is provided with an electrically controlled pneumatic damper which closes when the fan for

Fig. 2—Photographic Department.

that system is not in operation, thus preventing either fan from drawing back from the other system. The filter is of the automatic, self-cleaning "belt" type, and is installed because of the necessity of providing air as clean as possible for the building. The air washer is of a simple type and is intended principally for supplying and controlling humidity. No provision is made for recirculating any air exhausted from the building. The heating stacks have thermostatically controlled pneumatic by-pass and shut-off dampers, for controlling temperature of the air. The pre-heater stack is provided with a thermostatically operated pneumatic valve which allows steam to enter when the outside air temperature falls below 35 degrees F.

Manually operated pneumatic dampers are provided in the supply and exhaust to the lecture theatre, so that ventilation may be cut off from this room when it is not in use. Fan motors for the two supply systems are a.c., slip-ring, variable speed type.

Exhaust fans are located in the pent houses. The toilet exhaust fan, which runs continuously, is in the upper pent house. The other exhaust fans are in the pent house above the eighth floor. Electrically controlled pneumatic dampers in the outlets from each fan close when the motors are not running, preventing down-draughts into the rooms. The motors on the general and operating room exhaust fans are a.c., variable speed, slip-ring type, all others are constant speed. All exhaust fan motors are equipped with pilot lights and stop buttons located in the basement fan room. All the fans in pent houses are equipped with special sound deadening and absorbing bases. This is in order to guard against any possibility of transmitted sound or vibration likely to cause annoyance in the lower portion of the building. Special silent type electric motors are used throughout.

Plumbing System

Various items of the plumbing equipment will be described in the detailed accounts of the various rooms and departments.

Since the building has no typical floors, it was necessary that all interior groups of risers be very carefully studied in order to place them in positions where least space would be wasted and at the same time form an economical and practical arrangement. Piping in general is concealed throughout. In laboratories and other portions where future changes are likely to be made, certain services are exposed. Plugged outlets are provided on walls where no equipment is now installed. Heavy cast iron pipe is used for soil piping except where acids and chemicals are used, in which case, duriron pipe is installed with duriron traps on fixtures. All domestic hot water and cold water piping up to and including one inch is of brass pipe with screwed brass fittings.

Hot water for domestic purposes is heated in two storage type heaters located in the basement of the Pathological Institute. Each heater has 475 Imperial gallons storage capacity and a heating capacity of 500 Imperial gallons per hour. Steam for heating is supplied to the coils through self-contained, thermostatic temperature regulating valves. Cold water supply to tanks is admitted through the economizer previously mentioned under heating. Forced circulation is used in the domestic hot water system and a small electrically-driven centrifugal pump is used for this purpose.

Two separate vacuum services have been installed. One with moderate vacuum, is piped to outlets in all laboratories for use in various technical processes and to wards for wound drainage. The other is a high vacuum service for the operating rooms. The vacuum pumps are of the rotary type, direct connected to electric motors. The vacuum service for the operating rooms is maintained at 26 inches of mercury at the pump. The general vacuum system is under automatic control at 12 inches to 17 inches of mercury. Cocks for vacuum services are of the laboratory gas cock type with tip drilled and a screw plug provided

Fig. 3—Lecture Theatre.

for all cocks which are used only infrequently. All vacuum piping is brass with screwed brass fittings.

Compressed air is supplied by a small electrically driven compressor and piped to all operating rooms and to the principal laboratories. Cocks are similar to vacuum cocks and piping is of galvanized steel.

Electrical

Electric power for driving motors and lighting is supplied from the power house of McGill University to a substation feeding both the Pathological and Neurological Institutes. All circuits from the power house are duplicated. The services provided to the Neurological Institute are, alternating current, three-phase, 230 volts, alternating current, single-phase, 3-wire, 230-115 volts, and direct current, 3-wire, 230-115 volts.

The direct current service can be supplied either from the circuits of the Montreal Light, Heat & Power Consolidated through motor generator sets or from the steam-driven sets of the university. Provision is, therefore, made

Fig. 4—Typical Four-Bed Ward.

in the institute to allow for all important services to be transferred to direct current in emergency.

The main switchboard in the Institute is located in a special room in the basement and is of the NoFuze, dead front type, equipped with circuit breakers. The saving in space with this type of switchboard was considerable. From this board, light and power feeders are run in a vertical shaft to panel closets on each floor. All electrical services for each floor are controlled through panel boards installed in these closets.

Power equipment is mainly concentrated at two points, the exhaust fans and elevator controls being in the ninth floor pent house, and the air-conditioning equipment, supply fans and pumping equipment on the basement floor. Direct current power is supplied to the pent house for elevators, and also to panels on the second and sixth floors for distribution to d.c. service outlets in the photographic department and all laboratories.

Lighting panels on each floor are 3- to 2-wire, 115-230 volts, with plug fuse only in branch circuits. Each panel has a separate section with circuits controlling emergency lighting for the three operating rooms, stairways, corridors and exits. These emergency sections are on a separate riser, controlled by a 150-ampere, automatic a.c.-d.c. transfer switch in the switchboard room. Lighting of public spaces and stairways is controlled by group switching in the ground floor office. Lighting of ward corridors and public wards on each floor is controlled from the nurses' stations.

Due to the exceptionally close regulation required for the operation of large Coolidge tubes, the X-ray power supply is an entirely separate system, including transformer, 230-volt feeder, and distribution panel in the X-ray department. This power feeder also supplies outlets on the operating room service panels, for portable X-ray machines. A separate lighting panel controls all special lighting, X-ray viewing boxes, and dark room power.

A standard type nurses' calling system is provided for all private rooms and wards. On floors where there are two control stations, the annunciators are cross-connected with an indication to register any unattended call from the other section. At each control station there is an emergency button that will give an alarm and register on an annunciator in the first floor office, in case a patient may leave by way of the stairs. In the ward kitchens and utility rooms there are duty stations to indicate any room call and the section from which it came.

A paging system is installed, consisting of a master control station at the telephone switchboard in the Royal Victoria Hospital, from which code calls are automatically sent out to sounder units located at twenty-four points throughout the building. The sounding units consist of a magnetic plunger striking on a bakelite disc and are adjustable for volume of sound. The sounders operate from a low voltage relay controlled by the set-up at the master control station.

For the various groups of offices there are return call signal systems between the private offices and the office of the secretary for each section. There are also signal systems between the lecture theatre and the porter's office, lecture theatre and lantern, also from each operating room panel to nurses stations and laboratories. The operating room buttons consist of special elbow pushes.

The clock system consists of a self-winding master clock, controlling twenty-seven minute-impulse secondary clocks throughout the building. Batteries and charging equipment are located in the switchboard room in basement and the master clock in the enquiry office on the ground floor. Secondary clocks are minute-impulse, flush type, 10-inch or 12-inch dials with dull aluminum bezels.

A complete conduit system has been provided for future installation of a closed circuit coded fire alarm system. The equipment has not yet been installed, but provision has been made for tying in the new system with the existing system in the Royal Victoria Hospital.

Watchman's stations consist of twenty flush type key stations for operation of portable clock, located so that a

Fig. 5—Ward Kitchen, 2nd floor.

complete inspection of the building is covered on each round of the watchman.

Telephone service is controlled from the main switchboard in the Royal Victoria Hospital. Distribution is made from flush cabinets located in panel closets on the first, fourth, and seventh floors. Outlets in private rooms and wards consist of jacks installed in the room nurses' calling system plate. Telephone service is provided in all laboratories, offices, control stations and elevators.

A complete conduit system was installed with the required outlets for a future radio system. Provision was made for outlets in all private rooms and wards, also in each room of the staff quarters on the eighth floor. On the hospital floors there are outlets at each nurses' control station so that programmes may be received and distributed to the head sets in the wards, under the control of the floor nurse. In the major operating room, provision is made for the future installation of a microphone and a sound projector so that spectators in the glass-enclosed gallery may readily hear the remarks of the surgeon at the operating table.

Elevator

The building is provided with two elevator shafts to allow for one service and one passenger elevator. At the present time the service elevator only is installed and is used for service and passengers combined.

The hoisting machine is of the single wrap, geared-traction, auxiliary micro-levelling type, operating on 220 volts d.c., with full automatic push button control.

Special cork sound-proofing insulation is provided under the machine and controller to prevent transmission of noises and vibration to the building structure.

The car platform is 5 feet 6 inches wide by 7 feet 11½ inches back to front, outside measurements. The cab is of standard stock design, consisting of sheet steel panels with baked enamel finish and is equipped with top emergency exit, aluminum hand rail and manually operated Bostwick gate. The floor is covered with ¼-inch rubber tile flooring. A telephone is installed in the car. Hatchway doors are equipped with manually operated door closers and holding latches. Electrical interlocks are provided on all doors to prevent movement of car when any door is open.

The heating, ventilating, plumbing and electrical equipment has now been described in a general way in connection with the building as a whole. A description will next be given of certain special features, including the sterilizers, kitchen equipment and refrigeration, in connection with the various rooms in which they occur.

Basement

The basement is devoted largely to rooms required for the general purposes of the building. Most of the piping in connection with various services is in tunnels under the basement floor. On this floor are located janitor's quarters and living accommodation for certain of the female staff of the hospital. The fan room, lower part of the lecture theatre, a sterilizer room and storage room are on this floor. The transformer and main switchboard vault is also on this level but off the passageway to the Pathological Institute. A small switchboard room is also provided near the bottom of the elevator shaft.

The transformer vault is divided by partitions into two portions, the outer contains the low tension a.c. and d.c. switchboards and also the operating mechanism for the switches on the 4,000 volt incoming a.c. feeders. The inner portion contains the transformers for light, power and X-ray, also the oil circuit breakers in the 4,000-volt feeders, together with their disconnecting switches. Open bus-bars are used on 4,000-volt circuits while the low tension connections are run in conduit.

The sterilizer room contains a 20- by 48-inch four drum dressing sterilizer. Provision is also made for a future mattress sterilizer.

First Floor

The first floor contains the entrance hall, enquiry desk, head nurse's office and necessary cloak rooms. On this floor are also the photographic rooms and upper part of lecture theatre, and consulting rooms for the use of staff doctors.

The photographic department is equipped to take care of all classes of work necessary for the routine work of the hospital and for research. Special lighting is provided at one end of the room (see Fig. 2) for photographing specimens or subjects requiring intense illumination and is also used for making motion pictures of subjects where such a record may be of value. Micro-photographic apparatus is installed in a separate room, which has a special floor to avoid vibration being transmitted to the apparatus. This apparatus is extensively used in the work of the institute for making records of small specimens and microscopic slides.

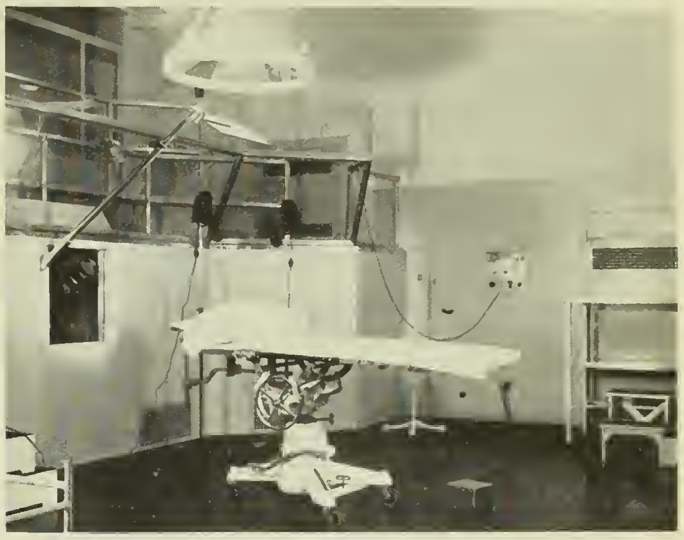

Fig. 6—Operating Room No. 1.

The dark room is equipped to take care of the developing of all classes of photographic work except motion picture film. The developing tank consists of a large alberene (soapstone) tank divided into three compartments with drainboards on either end. Each compartment is provided with a standing waste and a bell cold water supply inlet near bottom of tank. Each of the two outer compartments has a combination hot and cold water supply fixture. One drainboard has a shallow sink set in it and is used for hypo solution.

The lecture theatre (shown in Fig. 3) has a seating capacity of one hundred and twenty. It is two storeys high, running from the basement through the first floor. The seating is arranged in semi-circular rows in steep tiers. The room is used for general lecture and demonstration purposes, being so arranged that subjects may be brought in on the basement floor level. Due to the fact that there is no permanent table or desk for the lecturer, as all space available may be required at times for subjects under demonstration, the services, comprising water, gas, compressed air, drain and electrical outlets, are located in a recess in the wall beside the blackboard. The room is equipped with projection lanterns for handling all types of slides and opaque specimens. There is also provision for moving picture apparatus. Motor-operated blinds are controlled by a push button near the blackboard. There is both supply and exhaust ventilation in the room, supply outlets being located under the seating, and exhaust grilles in the ceiling. Radiators are thermostatically controlled.

Second, Third and Fourth Floors

The second, third and fourth floors, together with the operating suite on the fifth floor, form a hospital unit for the reception and treatment of patients. The second and third floors are used as public wards, the former for females, and the latter for males. The fourth floor is used for private and semi-private patients.

The second and third floors are similar in general arrangement and each contains a twelve- and a four-bed ward, two sound-proof observation rooms, diet kitchen, two utility rooms, dressings room, nurses' stations, small laboratory, continuous flow bath room, waiting, locker and storage rooms and lavatories.

The wards on the second and third floors are arranged so that the patients' beds are along blank walls with windows at the ends of the rooms only, as shown in Fig. 4. This aids in observing the condition of the eyes, an important feature of the diagnosis in the case of many patients. The one nerve of the brain that can be seen is the optic

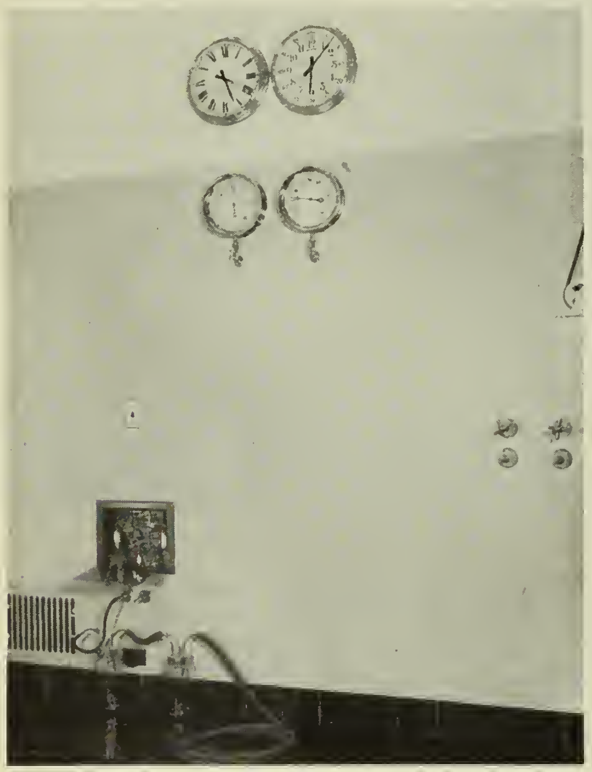

Fig. 7—Vacuum and Compressed Air Services and Electric Clocks in Operating Room.

nerve, which is visible through the lens of the eye. A study of this is a great help in the diagnosis of tumours of the brain. Due to the fact that there is a large expanse of blank outside wall where the beds are located, it was necessary to use concealed radiators. Permanent curtain rods are suspended from the ceiling to support curtains which may be drawn around beds for isolating patients. Vacuum cocks are located at various points in the wall for use in connection with wound drainage. A combination plate with nurses' call and electrical convenience plug receptacle is installed in connection with each bed, also an indicating dome light near the ceiling over each bed to show from which patient the call originated. Provision is also made so that each patient can be furnished with radio ear phones. Each ward has its own toilet room and bath room. Each ward has a nurses' station arranged so that the nurse may sit outside and have the ward under full observation through large windows.

Each of these wards has its own utility room equipped to provide for ward requirements. The utility room for the twelve-bed ward contains a utensil sterilizer, an instrument sterilizer, a bed-pan washer, bed-pan rack, utility sink, disposal sink and gas plate. There is also provision for a future bed-pan sterilizer. The utility room for the four-bed ward has the same equipment as the other, except that there is a bed-pan sterilizer instead of a utensil sterilizer.

Each hospital floor has one continuous-flow bath, used in the treatment of mental and nervous ailments. The important feature in connection with this bath is the constant temperature maintained by water continually flowing in through a number of inlets after passing through a thermostatically controlled mixing valve. These baths are 6 feet 6 inches long and are equipped with a canvas hammock so that a patient may lie comfortably when stretched out full length.

The second and third floors each have a dressings room, fully equipped for dressing wounds. Patients are wheeled into these rooms in their beds, thus avoiding dressings in wards which might disturb the other patients. There is an instrument sterilizer and an all-service sink in each of these rooms.

The fourth floor which is devoted to private and semi-private patients has two three-bed wards and nine private rooms. Four of the private rooms have private baths, the balance have basin and toilet only. There are two utility rooms on this floor, one for the three-bed wards, and one for the private rooms.

The three-bed ward utility room contains a disposal sink, bed-pan washer, bed-pan sterilizer, instrument sterilizer, gas plate and utility sink. The private patients' utility room contains a utensil sterilizer, combination bed-pan and utensil sterilizer, instrument sterilizer, gas plate and utility sink. Each private patient's toilet has a bed-pan washing jet built into the bowl. Each private room has a vacuum outlet for wound drainage. There is provision for telephone service in addition to nurses' call and radio. Concealed night lights are built into the walls near the floor. Each of the three floors has a built-in blanket warmer.

All food is cooked in the main kitchen of the Royal Victoria Hospital and brought across the bridge in electrically heated trucks. One ward kitchen (Fig. 5) is located on each floor, equipped for light cooking only and for serving meals from the electric trucks. The kitchen on the second floor has a dishwashing machine, all dishes in the building being brought to this floor for cleaning. Silver is washed in the sinks in each kitchen. All kitchen equipment is polished monel metal. Each kitchen has a hot water urn, a coffee tricolator, and a two-burner gas plate, all standing on a steam heated dish warmer which also acts as a serving stand for the electrically heated food trucks and is equipped with electric services to which the truck may be attached. The room also contains a monel metal sink, a combined serving table, storage cupboard and tray racks. Each of the kitchens on the second, third, and fourth floors is provided with individual refrigerators for general food storage, and in addition the kitchen on the latter floor has a refrigerator divided into six separate lock-up compartments in which patients may keep their own special supplies. All refrigerators are self-contained units and each is equipped with ice-making trays.

Each floor has medicine sinks located near each nurses' station, and one scrub-up sink located centrally in the corridor.

Each of the three floors has supply and exhaust ventilation for wards and utility rooms. All toilets and ward kitchens have exhaust only and corridors have supply only.

Fifth Floor

The fifth floor contains the operating suite, X-ray department, and consulting rooms for the neuro-surgical staff. The operating suite consists of two operating rooms, anæsthesia room, sterilizer room, instrument cleaning room, surgeons' rest room, linen room and visitors' room.

Operating room No. 1 which is shown in Fig. 6 is the larger of the two, and has a spectators' gallery with accommodation for twenty persons, which is divided from the operating section of the room by a plate glass screen. Access to the gallery is had from the visitors' room alongside. The operating room is finished in green tile and has a black soft rubber floor. This type of floor is necessary to reduce the fatigue resulting from the long operations common in brain surgery, some of which last from five to eight hours. They have to be done very slowly so that there will be as little bleeding as possible and because the tissues must be very carefully handled. The brain itself is insensitive to pain, and many of the operations are carried out under local anæsthesia with the patient fully conscious throughout the entire procedure. The principal lighting fixture is a Zeiss Pantaphos, arranged both for vertical adjustment and travel across the room on a rail attached to the ceiling. This type of fixture has been found particularly satisfactory for neuro-surgery, on account of its shadow-free field of operation, intense and uniform illumination both over the surface and in the depth of the incision. There is also a glass filter to absorb the heat rays and also to approximate daylight in colour. This light source takes 150 watts. In addition, portable spot lamps with floor stands are provided to supply high intensity local illumination when necessary. There is also general ceiling lighting for use when operations are not taking place.

Space is provided under the spectators' gallery for photographic apparatus. The camera is placed behind a window in the front of the gallery and pictures of operations can be taken by means of a mirror supported by an adjustable arm directly above the patient. Provision is also made for special high intensity illumination when moving pictures are being taken.

Fig. 8—X-ray Apparatus.

There are two electrically heated instrument sterilizers installed in a recess, one using water and the other oil as a sterilizing medium. The oil sterilizer is used principally for small steel instruments with sharp points or cutting edges. These sterilizers are placed in the operating room since it is often necessary to re-sterilize instruments during long operations without leaving the room.

One of the hot water heating radiators is under the gallery, the other in a metal enclosure in the side wall. There is also an additional steam radiator in an enclosure in the side wall, connected to the medium pressure steam system, which is used when heat is required in the operating room but not in the rest of the building, or to boost up the temperature quickly when necessary in an emergency. All the radiators are thermostatically controlled by means of two thermostats, one controlling the hot water radiators and one the steam radiator. Each thermostat is equipped with a lever, providing quick adjustment four degrees above and below the normal temperature setting. In addition the thermostat for the steam radiator has a lever by which the radiator may be turned on or off.

Fig. 9—Laboratory Service Shelf with Removable Work Table and Fixed Shelf and Services.

Vacuum and compressed air services are brought to the operating room and terminate in a monel metal box located in the wall (Fig. 7). This box contains sensitive adjustable vacuum and pressure regulators. Ten-inch diameter vacuum and pressure gauges are mounted on the wall facing the operator and are connected to the controlled vacuum and air services. Additional pressure and vacuum cocks are also provided which are connected directly to the lines ahead of the controls. The vacuum service in connection with brain surgery is very important as it is frequently used to remove tumour tissue from the brain by a suction instrument connected to this service which has to be carefully controlled. As mentioned earlier, there is a separate vacuum pump for the two operating rooms.

Four different electrical services are brought to a large plate on the wall provided with receptacles and switches for their use and control. In addition a cable is run from this plate carrying all services to a large portable metal spider box on the floor which has a number of plug receptacles to which attachments can be made. Electrical services provided are 230-volt a.c. for X-ray, 110-volt a.c. and d.c. for general purposes, and a 4-6-volt d.c. service operated from a storage battery located in the panel cupboard on the fifth floor. This latter service is brought to three-point polarized receptacles and is used for various small instruments and for emergency lighting. It also provides current for operating the small head lamp which the operator wears strapped to his forehead for certain operations. The storage battery is charged by a trickle charger. The wall plate previously mentioned also has switches controlling the room lighting and an elbow-operated push button for emergency use to summon aid to the room.

The operating room has one standard secondary clock with hours and minutes and one seconds-indicating clock on separate dial with a single stroke bell to indicate fifteen seconds periods. This seconds clock is started and stopped by a tumbler switch on the electric service plate.

A rim flushing floor drain with hot and cold water is provided for the operating room.

The operating room has its own supply and exhaust ventilating system as mentioned previously. This feature is included in the design to permit control of the air supplied to operating and anæsthetic rooms. This air is maintained at a temperature and relative humidity higher than that provided for the rest of the building. This is important as cases of explosion of anæsthetic fumes have been traced to sparks due to static electricity. The high humidity also reduces evaporation from the surface of exposed tissue at the high temperatures sometimes maintained as both the temperature and humidity are chosen for the benefit of the patient rather than for the comfort of the other occupants of the room. Supply air is brought in at both the floor and ceiling. The exhausted air is taken from the floor and ceiling at the opposite side of the room. Air is also supplied to the small photographic cubicle under the gallery. A certain amount of air is exhausted from the hood over the sterilizers in the sterilizer alcove.

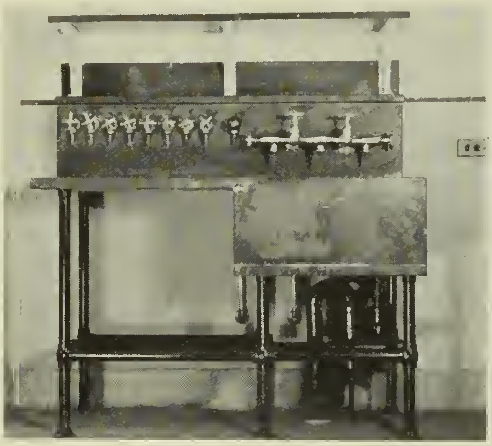

Fig. 10—Laboratory Sink, with Three-Outlet Supply Fixture, Steam and Cold Water Cocks.

A portable X-ray viewing cabinet in the operating room enables the surgeon to consult X-ray photographs at any time.

A door on the south side of the operating room leads into the instrument cleaning room, which is equipped for cleansing instruments and other apparatus. The sink is of monel metal with two compartments and two drainboards. Storage cupboards are provided for instruments and supplies.

Operating room No. 2 is generally similar to No. 1 but is smaller. No photographic cubicle is provided. A door communicates with the X-ray room permitting the patient to be moved to the X-ray apparatus so that necessary photographs may be taken conveniently and with little delay. The room is intended principally for encephalography and ventriculography which involve the injection of sterilized air into the cavities within the brain and over the surface of the brain, making certain conditions of inflammation or growths show up when X-ray pictures are taken.

The sterilizer room for the operating suite contains one 48- by 20-inch four-drum dressing sterilizer, a large utensil sterilizer, two instrument sterilizers, sink and drainboard and rim flushing disposal sink. The dressing sterilizer is equipped with recording and indicating thermometers in the condensate outlet from the chamber, thus ensuring that all air is vented and that the steam in the drum reaches the full temperature corresponding to its pressure necessary for proper sterilization. The usual indicating pressure gauges are also installed, both for safety and as a check against the thermometers. This room has both supply and exhaust ventilation.

The surgeons' scrub-up sink is installed in the passageway outside the operating rooms, and is large enough to accommodate four persons and has four combination hot and cold water supply fittings with blade handles.

The anæsthesia room, which is situated adjacent to the operating room, is equipped with sink and drainboard and a small refrigerator. Provision is also made for the future installation of an instrument sterilizer. Supply and exhaust ventilation is provided.

The X-ray room located alongside operating room No. 2 is equipped with all X-ray apparatus necessary for photography and fluoroscopic work (see Fig. 8). The main table is motor driven and has universal adjustments provided for making pictures with the patient in any position. Transformers for X-ray apparatus are located in a separate cubicle opening off the room, while the timer and control apparatus are located in the room.

The X-ray dark room is equipped to handle all the developing work for this department. The insulated developing tank is provided with a separate cooler for chilling wash water in hot weather. The cooler is cooled by a small individual refrigeration unit in the basement. The temperature of the water supplied to the tank is controlled by a thermostatic mixing valve. The use of this chilled water permits the technician to maintain uniform conditions of temperature for developing, fixing and washing films both in winter and summer, and has been found to improve the quality of the work produced. There is also an alberene sink and a motor driven film dryer. Exhaust ventilation only is provided for this room.

Rooms for X-ray viewing and film storage are located across the corridor from the X-ray room and are equipped with viewing boxes and stereoscopic viewing apparatus.

Sixth Floor

The sixth floor is devoted mainly to laboratories used for research work. It also contains a library, offices of the Director of the Institute, his secretary, an office for the neuro-pathologist and the chemist, a special room for cleaning glassware and rooms for general storage and the storage of specimens preserved in formalin. There are two chemical laboratories, large laboratories for the research fellows and routine technicians and several small private laboratories for special research work.

One of the chemical laboratories is used for the general chemical work of the institute. This laboratory contains an alberene stone fume cabinet with water bath and duriron sink, and services consisting of gas, hot and cold water, compressed air, vacuum and medium pressure steam. These services are arranged to be controlled from the apron on the outside of the cabinet when the cabinet is closed. The electrical plug receptacles and light and fan switches are also located on the front apron. The air from the cabinet is exhausted by means of a duriron exhaust fan. A chemical table in the centre of the room has a lead-lined trough running down the centre the entire length and emptying into an alberene sink at one end. Services are located along the centre of the table over the trough and include hot and cold water, gas, compressed air, vacuum and electrical plug receptacles both a.c. and d.c. In common with the other laboratories and certain special rooms, this laboratory is provided with a wooden service shelf which is about 10 inches wide and contains groups of services, each consisting of a copper funnel-type sink 6 inches in diameter inside fitted with duriron trap, a hot and cold water gooseneck supply fixture fitted with special removable hose connection tip, a double gas cock, and single compressed air and vacuum cocks, all as shown in Fig. 9. Duplex electrical plug receptacles for a.c. and d.c. are located in the wall above each service group. All piping for the service shelves is grouped under the shelves along the wall where it is of easy access for alterations and extensions. The front of the shelf has an apron 8 inches deep which partially hides the piping behind it. This arrangement for services was chosen to provide for flexibility in furnishings as it allows work benches of varying

Fig. 11—Alberene Stone Sink with Fume Hood in Research Laboratories.

heights or sizes to be placed in front of it. These work benches can thus be changed or removed at will without disturbing permanent piping or fixtures. Where radiators are under the shelves, grilles are countersunk into the top of the shelf and sheet metal enclosures lined with asbestos are placed around the front and sides of the radiators, thus shielding the legs of any one, working at the bench, from radiant heat.

All the alberene sinks and fixtures used in laboratories are of special design, as shown in Fig. 10. Each sink has an alberene shelf over the top of splash back, 6 inches wide. The supply fixture is of special design with four valves and three outlets so that hot, cold and mixed water can be drawn at the same time. Each of the three outlets has a special removable serrated nozzle to allow connection either to rubber tubing or to a standard hose fitting. Small ⅜-inch compression cold water cocks are located on the splash back over the drainboard and arranged with outlets to take rubber tubing. These outlets are used when it is necessary to allow a small quantity of water to flow continually over specimens in jars during the course of preparation. In certain rooms the sinks are also provided with a steam cock supplying medium pressure steam. The handles of steam cocks are coloured red to guard against mistakes.

This chemical laboratory also contains a water still, a single drainboard alberene sink, a refrigerator and a high temperature electric oven. A shower head with pull chain valve is installed for use in case of accidents.

The other chemical laboratory is smaller and is used principally for research. This room contains a small fume cabinet, alberene sink, centre chemical table without trough or sink, and service shelf with two groups of services. The principal chemist has a combined office and laboratory with alberene sink and service shelf. The office of the Director of the Institute has a work bench fitted with a group of services but with porcelain sink instead of copper funnel.

The routine technicians occupy the largest of the laboratories. This laboratory has a service shelf with six groups of services. Cabinets are placed at right angles to the wall and project out from the work bench in order to divide the room into a number of small cubicles for individual workers or types of apparatus. This room also contains a small refrigerator, a large electric oven, electric incubators, and an alberene sink and drainboard. This laboratory is used for hardening, embedding, cutting, staining and mounting material that is to be examined, such as tumour tissue that is removed during an operation. Frequently the only means of properly identifying this tissue is by microscopic examination and such identification is of importance in determining the future outlook and indications for treatment. This room is also used for preparation of material for the various researches that are carried on.

The research fellows' laboratory is similar in general arrangement to that of the routine technicians. It is provided with service shelf with six groups of services. alberene sink and drainboard, also centre tables arranged for microscopic work.

The two small research laboratories are each provided with a service shelf and alberene sink. These sinks (shown in Fig. 11) are different from the standard in that they have a ventilated alberene hood covering the whole of the sink and drainboard. This is provided to remove odours or fumes when working with specimens which are being impregnated with formalin solution.

The glassware cleaning room contains a large double alberene sink of special design with drainboards on both

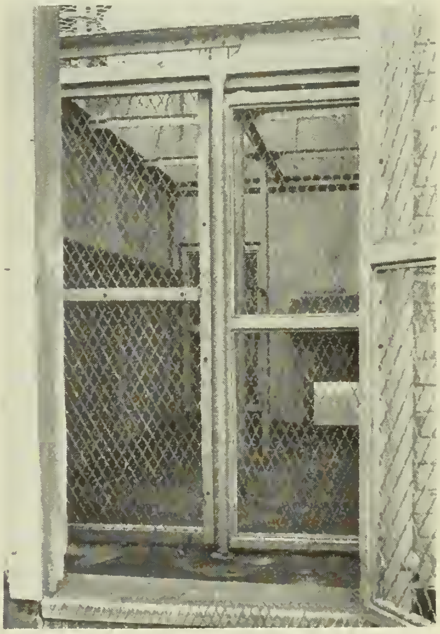

Fig. 12—Outdoor Animal Cage.

ends, extending through wickets opening into the routine technicians and research fellows' laboratories. Each sink compartment has a combination hot and cold water swivel supply fixture. One drainboard is cut to accommodate a special glass rinsing jet located in a monel metal cup. There is also a live steam cock located on the splash back of the sink to allow the operator to boil water in the sink.

Seventh Floor

The seventh floor is devoted to physiological researches into the action of the nervous system of animals and to the housing of animals.

The quarters in which the animals are housed consist of four rooms opening off a corridor and open air runways located on the roof adjacent to the rooms. The rooms are designed to house the larger animals, such as chimpanzees or large monkeys. They can also be used to contain cages for smaller animals. The wire enclosure around the runways and other equipment is made strong enough to take care of young chimpanzees only, which have approximately the strength of an ordinary man. An adult chimpanzee has the strength of about four men and is too difficult to handle in experimental work. Chimpanzees are used for observation of their behaviour under various conditions, their nervous system being the nearest to that of human beings. The entire animal quarters and corridor and its equipment is made "monkey proof" to prevent damage to the equipment, or animals, in the event of a monkey escaping from its cage. Each of the animal rooms contains a special drinking tap located in a flush monel metal box in the wall. The exposed part of the drinking tap consists of a spout and a lever handle. The spout is short and heavy and cannot be damaged very easily. The lever handles, however, are the only pieces of apparatus in the room that are not "monkey proof." These taps are installed for the use of chimpanzees who after they are once shown how to use them by putting their mouths to the tap and pressing down the lever do not try to damage or take them apart. Although they are very inquisitive and will try to dismantle everything, even using their nails as screw drivers to take out screws, after they are once shown that something is of real benefit to them, they will not try to damage it. This box also contains a hose connection with hot and cold water for cleaning purposes.

Fig. 13—Corridor to Animal Rooms.

The rooms are heated by enclosed hot water radiators controlled by individual thermostats in flush boxes behind heavy grilles. An enclosed steam coil is also provided in each room and connected to the medium pressure steam supply for use when the regular heating system is off and it may be necessary to provide heat for tropical or delicate animals. The lighting fixtures are flush with the ceiling with heavy reinforced glass plates on the front. The rooms opening into the corridor are provided with both solid wooden and sliding wire mesh doors. Each room has a swinging flap door and a wire mesh gate leading to wire mesh enclosed runways located on the roof as shown in Fig. 12. When the gate is open the animals can go back and forth through the flap door. If the attendant wants to keep the animal in or out, he shuts the gate. The gate is remotely operated from the front corridor or the passageway in rear of runways. The corridor serving the animal room contains a humidifier, a cage sterilizer, and a cage washing sink (see Fig. 13). The humidifier is placed behind a grille opening on the corridor and is of the fan circulating type, automatically controlled by a humidistat located in a flush box with grille in front. It is essential to have properly controlled humidity and temperature, as monkeys and chimpanzees are susceptible to pulmonary diseases. The cage sterilizer is of the built-in type and is large enough to take any of the cages used. The cages are sterilized by admitting steam directly into the closed chamber under atmospheric pressure. The sterilizer has a drain and large vent and an indicating dial thermometer located on the wall to show the temperature of sterilization. The cage washing is done in a deep alberene stone sink which also serves as an animal bath. The sink has hot and cold water, live steam for boiling the water, and a large quick opening gate valve in the waste. Each animal room and the corridor has exhaust ventilation only with a separate fan.

A special kitchen is provided for preparing food for the animals and contains a gas stove, monel metal sink and work table. A large refrigerated room for storing bulk food opens into the kitchen and is provided with a work table for certain operations in connection with the preparation of specimens requiring a cold atmosphere.

A gas fired incinerator is provided on this floor for the destruction of waste and rubbish originating in the animal department. A can washer is also located in the incinerator room.

The operating suite for animals consists of an operating room, a physiological room where various experimental tests are performed on animals under observation, and between these two rooms are located the sterilizer room and surgeons' scrub-up. The operating room contains a service shelf with one group of services, a general sink, compressed air and vacuum and a rim flushing floor drain. The electrical services are similar to those in the operating rooms on the fifth floor. A blanket warmer is located in a small work room adjacent to the operating room. The physiological room is supplied with the same mechanical and electrical services and equipment as the operating room.

The sterilizing room is equipped with a 36- by 20-inch, three-drum dressing sterilizer, instrument and utensil sterilizers, a disposal sink and one instrument cleaning sink and drainboard. It should be noted that this sterilizer room is completely equipped and provides for the possibility of as complete sterilization as is used anywhere for surgical work. A large scrub-up sink of sufficient size to accommodate three operators is provided in the scrub-up room. Supply air for ventilating is introduced into both the operating and physiological rooms and is exhausted from these rooms into the sterilizer and scrub-up rooms through grilles and swing doors.

There are also two laboratories on this floor which are used for special research. Each is equipped with a service shelf and an alberene stone sink and drainboard. Supply and exhaust ventilation is provided for both of these rooms.

Eighth Floor

The eighth floor is used as living quarters for the resident who is the chief interne, and five research fellows. There is also a squash court, the upper part of which is on this floor and the lower part on the floor below.

Two pent houses are located on the roof and contain all the exhaust fans and elevator machinery.

Wherever possible all material and equipment was of Canadian manufacture and a provision was made in all contracts which set a minimum wage per hour for workmen employed in the various trades.

Dr. Wilder G. Penfield, the Director of the Neurological Institute, together with his associates set the requirements for the building and those responsible for the design of the building and mechanical and electrical equipment were Ross and Macdonald, architects, McDougall and Friedman, consulting engineers, with Wilson and Kearns, associate consulting engineers, all of Montreal.

Modern Sewage Treatment Practice

Edmund B. Besselievre,
Sanitary Engineer, The Dorr Company Inc., New York.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, November 1st, 1934.

SUMMARY—The paper gives a survey of present practice in sewage treatment, outlining the development of the processes now in use for sludge digestion and secondary treatment of the effluent. Sludge disposal is briefly considered, and some figures are given as to capacity and cost of a few typical installations.

Sewage treatment is distinct from sewage disposal since it involves the provision of works to subject the sewage to some form of change which will render it safe to discharge into a nearby water course. Sewage disposal may mean only the discharge of the untreated sewage. It is with "sewage treatment" that this paper deals.

Sewage treatment in a definite form had its origin in England and the first recorded sewage plant was that at Merthyr Tydvil in Wales in 1857. Since that time many investigators have endeavoured to improve on the original methods and devise ways in which such plants could be built at less expense, occupy less ground area and cost less to operate.

The author's conception of sewage is that it is a relatively large volume of water representing the used water supply of a city containing materials which cause it to be a menace to health and comfort. In passing through the households of the city the water picks up solids of human origin, both fecal and from bath water; the kitchen contributes more in the way of finely divided solids washed down the sink, grease, etc. The streets contribute more through manholes and occasional downspout water containing grit, leaves, sand, etc. Then in unknown ways there is always a mass of solids which have no place in a sewer but seem to end up there. In the author's experience this has gone to the extreme of automobile seats, 5-gallon gasoline tins, mattresses and other objects.

Some of these ingredients are of large size, others are in a state of comminution barely visible to the eye. Sewage treatment is thus essentially a problem in classification, removing from the sewage solids of various types by the best means available for handling those solids and collecting them into separate masses for final disposition in a manner most effective for that particular mass.

Roughly sewage contains three classes of solids: first, garbage, consisting of fruit skins, wood, bottles, rags, paper, hair and other objects which have an appreciable size and which may be incinerated or disposed of without odour and which on the other hand take up useful room in tanks; second, inert solids such as grit, sand, coal and other material which is not a nuisance from an odour standpoint; third, organic solids, usually of human fecal origin, vegetable solids and other particles of small size which cannot be retained long in the neighbourhood of habitations without causing trouble and complaint.

The means provided for removing these various solids from the sewage vary materially but in modern plant practice have been so thoroughly developed that it is merely a matter of selecting the proper sequence of units to achieve any desired degree of treatment.

Selection of a Method of Treatment

The selection of a method of sewage treatment, and the degree of refinement to which such treatment must be carried, are matters of extreme importance. They must be determined after careful study and consideration of a number of factors such as the use of the stream into which the sewage is discharged, the effect of sewage upon the inhabitants of other towns, the changes in population, the effect and character of the industrial wastes in the sewage, the suitable site for the plant having regard to adjacent inhabitants and the use of by-products from the plant. The degree of treatment required is usually determined by the officials of the local health organization; in the case of Montreal by the Provincial Board of Health, whose duty it is to protect the potable streams and to determine the remedial measures that may be used. In most cases the health authorities do not attempt to pass on the relative merits of different methods unless a method of experimental type or doubtful value is submitted. The decision as to the method to be used is usually the function of the municipal engineer, or the expert consultant engaged to study the problem and design the proper plant.

At this point it is proper to discuss the advantages of having a recognized expert carry out this important work. It is true that there are numerous books which describe the sewage treatment processes in use. Naturally these works are always somewhat behind the times and the art of sewage treatment is developing so rapidly that it is difficult even for one who spends his entire life in contact with it to keep posted in all the new methods proposed. Therefore, to follow a textbook blindly and design a plant on the basis of data given therein, may, it is true, provide a city with a plant which will operate, but does not give the city the benefit of advanced knowledge in the reduction of costs and increased efficiencies. Many cities place the burden of design of sewage plants upon their city engineer. However, the average city engineer is so burdened with other duties that he has not the time to delve into the mysteries of sewage treatment, and when faced with the design of a plant which embodies biological, bacterial, chemical and mechanical factors he often relies to too great an extent upon the proponents of methods which are proprietary. To obtain the maximum benefits of economical cost and operation, minimum size of plant and maximum efficiency requires an intelligent weighing of all factors, methods and costs, and the balancing of the benefits of one method against another as well as the disadvantages. This the specialist in sanitary engineering is qualified to do. He has made a special study of sewage treatment, the basic principles of the art, the constituents of sewage, the reactions of that material to various bacterial, biological and chemical processes and is skilled in the art of selecting a combination of elements which will so treat the sewage as to achieve the desired degree of treatment with the end of handing over to the city a properly designed plant which has been built and can be operated at a moderate cost. The specialist is usually well worth his fee and in many cases can save many times that amount for his clients. While the placement of the responsibility for design in the hands of the expert is the best way, in many cases there are men employed in the engineering departments of the large cities who have had training in sewage treatment and can design plants embodying modern practices. But, even in such cases, it would be wise for the city to call in a qualified consultant and have him check the factors embodied in the design.

Sewage treatment in its earlier phases included provision for removing solids from sewage by hand operations, namely, screens were hand raked, tanks were cleaned by flushing or hand shovelling or squeegeeing, materials were carried in barrows or carts. The development of satisfactory electrical equipment has perhaps been the most important factor in the complete mechanization of sewage treatment works. This development has been so great and the mechanisms provided have been so generally successful and satisfactory that today engineers when designing a plant make it as completely mechanical and automatic as possible.

Development of Methods of Treatment

As previously stated sewage treatment is an intelligent utilization of the forces of nature, biological actions, bacteriological functions and chemical combinations. All of these factors may be combined in the design of a single plant, or one or more of them only may be required to carry out the desired end. Modern practice has not reversed this employment of nature's functions but has made an attempt to assist her in the performance of her work.

To be more specific, the larger solids in sewage will

Fig. 1—Separate Sludge Digestion Plant 4 m.g.d., Kitchener, Ontario.

settle, thus employing gravity, a natural function; others are of such size as to be intercepted by a barrier, say a screen, another natural function. Thus in the average plant old or new, a bar rack or screen with openings of from one-half inch to two inches is the first unit in the plant, put there for the sole purpose of intercepting such solids as will be caught by the bars. The solids thus retrieved may be incinerated or burned, and as these solids in many cases are of a light nature and float on the surfaces of streams it is usually considered necessary to remove them even when further treatment is not required.

The grit, sand and such inert solids in sewage may also be readily removed. They are usually of a higher specific gravity than water, therefore if the velocity of flow is reduced to a certain point these particles will settle out and may be removed. This material may in many cases be removed from the plant and used as fill, especially if one of the modern types of grit chamber is used, wherein the organic material in the grit is removed from it.

The organic solids in the sewage are the most difficult to remove due both to their inveterate tendency to decompose and cause odours and also to their size. They require a combination of natural forces and possibly some chemical means to remove them. The bulk of these solids are of a higher specific gravity than water and the usual way to trap them is to provide a tank, which in reality is simply an enlargement of the sewer, where the velocity of flow will be so reduced as to allow a downward tendency to the solids instead of being carried along in a vertical plane. However, the very fine solids and many which are in solution cannot be effectively removed by plain sedimentation and the practice of late has been to intensify this tendency to settle by the addition of chemical coagulants to the sewage, which tend to agglomerate the particles into flocs or larger particles, which then have a tendency to settle. There are several ways of doing this, but due to the cost of some it pays to make a careful study of all before any steps are taken. This addition of chemicals may also be carried too far from the standpoint of future handling of the solids so precipitated, but means are available whereby the maximum precipitation may be obtained without affecting the ability to handle the solids by biological means.

The solids which are caught in settling tanks are known as "sludge." They are in a condition amenable to rapid decomposition and thus cannot be held at the plant for long periods without the possibility of odour. This has always been a recognized fact and even in the earliest plants provision was made for allowing these solids to undergo the natural function of decomposition which is a bacterial breakdown of the solids into inert components but which in the process of breakdown may produce disagreeable odours. On the other hand intelligent control of this process of breakdown shows that better results can be obtained with no odours. This is simply an understanding of the basic principles and the employment of bacteria of one type instead of those of another.

The first unit for this purpose was known as the septic tank in which the collection of the solids and their decomposition was carried out in the same tank, no sludge being transferred; this, however, has practically passed out of use except for plants for individual houses and very small groups. It had many disadvantages, one of which was that the solids piled up in the tank and eventually the effluent from it became worse than the raw sewage going in, as the velocity of flow through the tank, due to the accumulation of solids, was greater after a period of operation than when the tank was first put into operation.

Study of the faults of this operation led to the invention of the Travis tank in England, and its later successor, the Imhoff tank of Germany, which recognized the basic difficulties of endeavouring to do two operations of a different nature in the same unit. Both of these tanks provided an upper compartment in which the solids were removed from the sewage by settling; these solids then passed into the lower or digestion compartment and were allowed to undergo their natural function of decomposition. These were decided improvements, but due to the superimposition of the settling tank upon the digestion compartment and the fact that the flow line of the average sewer at the plant was several feet below the ground these tanks had to be very deep, and in cases where wet or rocky ground was encountered they were expensive to build. Many thousands have been built, but they still had faults. Frequently they "foamed," that is, upheaved digesting solids over the top. The gas, which is a by-product of the digestion process, was discharged into the air and frequently resulted in odours in the vicinity of the plant. Finally, perhaps first at Birmingham, England, there was developed the "separate sludge digestion" process, which simply meant that instead of trying to carry out the two functions of settling and digestion in the same tank, a separate tank was provided for each step. This was a material improvement, as it eliminated from the settling tank the disturbance of quiescent settling due to uprising gas bubbles and it allowed manipulation of the digestion tank's contents to produce more definitely satisfactory results. This type of tank was also less costly to build as it could be made relatively shallow and placed above ground if necessary.

The Digestion Process

Studies on this type of tank and the basic reactions that went on showed that they had the same tendency to foam and create odour that the earlier types had. A study of the bacterial reactions indicated that this was caused only when acid conditions existed in the decomposing mass in the tanks. Experiments with reagents changing the mass to an alkaline condition gave an immediate improvement in the operation, no foaming, no odours and the production of a large volume of gas. In the acid stage of decomposition gas is produced but it is highly charged with hydrogen sulphide which has an offensive odour. The gas produced by the alkaline digestion contains a large quantity of methane and does not have a disagreeable odour. In fact it has so little odour that in Germany, when sewage gas is utilized, the law requires the addition of mercaptans to add odour to facilitate the detection of an escape of gas.

A small scale plant using this separate system was built at Rochester, N.Y., in 1921 and there the advantages of the alkaline digestion were developed. It was noticed, as had been the experience elsewhere, that in the cold months the sludge digestion tanks acted as storage tanks and very little bacterial action went on until the tank contents warmed up in the spring. This led to the belief that if the tank contents could be heated the destructive action of the bacteria could be maintained throughout the year, and therefore if the digestion process could be made continuous tank sizes could be reduced and plant cost cut down. However, the expense of heating large tanks, sometimes reaching 100 feet in diameter and 30 feet deep, seemed an insurmountable obstacle until it was found that the natural process of digestion produced a very appreciable amount of combustible gas. Observation of the amount of this gas showed that it was sufficient to provide all the heat needed to heat the tanks under all climatic conditions. Further observation showed that this gas runs normally about 74 per cent methane and consequently has a heat value of over 600 B.t.u. per cubic foot, and operating conditions have since shown that the production of this gas, when the tanks are kept heated, is sufficient not only to maintain the heat required in the tanks but also to provide a source of power. Checks on operating plants have shown an average of gas production of one cubic foot per capita per day when heated digesters are used.

The best temperature at which to maintain a rapid digestion cycle is between 80 and 90 degrees F. Experiments have been made at 120 degrees F. and higher ("thermophilic" digestion), but due to the difficulties of maintaining this temperature, the caking qualities of the sludge on heating coils and the fact that if the temperature fails the bacteria which work best at the thermophilic range do not live in the lower ranges, it is difficult to assure continuous action. The result of this work on heated, closed and entirely separate digestion tanks has been so successful that few plants now are built without them and the boards of health of various states have allowed material reductions in the sizes of digestion tanks required.

Fig. 2—Activated Sludge Plant, Guelph, Ontario.

Another development of the digestion cycle was the feeling that there must be some means of causing contact between the digesting masses of organic solids in the digestion tank and the mass of fresh solids being added daily. This was first done by means of a rotating mechanism which stirred the bottom sludge and broke down the scum which collected at the surface, and numerous tanks are in operation using this type of digester mechanism. Later types consisted of a rapidly moving propeller at the top of the tank to keep the tank contents in motion; other means have been the provision of a pump outside the tank to pump the sludge from the bottom of the digester to the top. It is now recognized that some means of maintaining this intimate contact between the actively digesting mass and the fresh mass is essential.

A recent development embodies the two-stage principle of digestion, that is, a series of two tanks, the first equipped for high speed agitation for the purpose of breaking down the solids rapidly, with the result that 90 per cent of the total possible gas is produced in from ten to twelve days instead of the normal twenty to thirty days by the single tank method. After this initial high speed phase the sludge automatically passes to the second or finishing stage in a tank in which there is no agitation, but which is provided with a gas holder which collects the gas produced in both the first and second or completion stage. The effect of this system is to reduce the size of the tanks, thus cutting the cost of the plant, and to provide a larger volume of gas which may be used for power generation.

Utilization of Gas

Reference has been made to the use of the gas derived from sewage sludge as a means of providing heat for the digesters. Early work on this showed that there was always an excess of gas over and above that needed for heat and that a considerable quantity was being wasted. Consequently studies were made of the feasibility of its use for power production. The first attempts along this line were to use the ordinary type of gasoline engine but this was not found satisfactory. Sewage gas is a high temperature gas and contains some hydrogen sulphide so that the valves of an engine of the automobile type will not stand up. The most satisfactory type of engine is that built for use with natural gas, the nearest to sewage gas in its general constituents, and a number of these have been operating with success in this country. The gas from the digester, or from the gasometer, is conducted to the intake of the gas engine, with or without scrubbing. The cooling water from the engine after passing through an exhaust heater is used as circulating water in the heating coils of the digester and contains sufficient heat for the maintenance of satisfactory digestion. It has been found that from 15 to 20 cubic feet of sewage gas, depending upon the B.t.u. value and the type of engine, will produce one horse power hour, and when it is considered that the production of gas is averaging one cubic foot per capita per day it can readily be computed that for every twenty of the population connected to a sewage plant, an output of one horse power hour of electrical current is possible.

Where electric current is costly the development of power from gas reduces the cost of plant operation and many of the modern plants are employing the gas in this way. In Germany and England the author saw a number of plants which had been employing gas for power for long periods, and although the types of engines used varied the average results were very much the same.

In several cases, where electrical energy is cheap, it has been found expedient to purchase current and to sell the gas to the local gas company for mixing with their supply. In this way a revenue is provided which will offset some of the operating costs of the plant. As sewage gas averages 650 B.t.u. per cubic foot and the illuminating gas generally supplied by a utility company averages 525 B.t.u. per cubic foot, it is evident that the sale of gas should be on a basis of B.t.u. value rather than so much per cubic foot. The city of Baltimore, for example, is arranging to sell its gas to the local gas company and several other large cities are also considering similar propositions. In Germany it is often sold to gas companies while in one plant the gas is bottled in cylinders under pressure and sold to small users.

Secondary Treatment of Effluent

The final treatment of the liquid effluent is the factor which affects public health to the greatest extent. The handling of the sludge has always been the most troublesome end of the work but in general this does not affect the health of adjoining communities; it is more apt to be a source of nuisance to the plant operators and the citizens of the locality in which the plant is located. The reduction of the constituents of the residual effluent to a condition where they will not cause sludge banks in the stream, or reduce the oxygen content to a point where the stream is rendered useless for recreational or domestic use, is an entirely different phase, and is known as secondary treatment.

Methods of secondary treatment have, like the general elements, run the gamut of wide change and experimentation. The desire has always been to achieve the required results with the minimum of time and space requirements. The increasing knowledge of bacteriology and biological processes and the use of chemicals has changed this picture materially from the old basis. In the early days it was found that the oxidation, which is the step required to stabilize the organic solids in solution to a point where they will not further decompose or deplete the oxygen in the stream, could be obtained in several ways which normally combined keeping the sewage in contact with the air and at the same time providing a medium for the culture of aerobic bacterial growths which broke down the organic organisms. Other forms of anaerobic treatment were found effective. The first form employed a bed of sand over which the sewage was allowed to flow and through which it percolated to the underdrain system. The objection to this system, except for very small places, was that the large areas required made it an expensive process. The average allowance for sand filter beds on sewage is 150,000 gallons per acre per day. As that was out of the question for large cities, investigations made on other means of oxidation developed the contact bed, which consists of a concrete tank, perhaps 5 to 6 feet deep, filled with broken stone. The sewage is allowed to fill up to within six inches of the surface of the stone, and lie dormant for two hours, during which period the anaerobic bacteria operate on the organic matter, after which the sewage is released. The average rate of application to this type of filter is around 400,000 gallons per acre per day. This was better but still not good enough for large installations.

Fig. 3—240 m.g.d. Addition to Calumet Activated Sludge Plant, Chicago.

Further experiment led to the development of the aerobic type of filter consisting of a heap of stone 6 to 8 feet deep. The sewage is sprayed over this by fixed sprinkler nozzles or revolving distributors, and allowed to trickle through to the bottom, the aerobic bacteria, clustered in a form of jelly on the stones of the bed, destroying the organic matter as the sewage passes. This form of bed is very effective, and the rates of application are much higher than the other types, the usual maximum allowed by boards of health being 300,000 gallons per day per acre per foot of depth; in other words a bed one acre in extent with an average depth of 6 feet is capable of treating 1,800,000 gallons of sewage per day. This development assisted materially in the building of plants for large cities.

However, when it came to the plants for the largest cities, there was still a need for some method of treatment that would require a still smaller area, in order to be able to locate these plants within a moderate distance of the

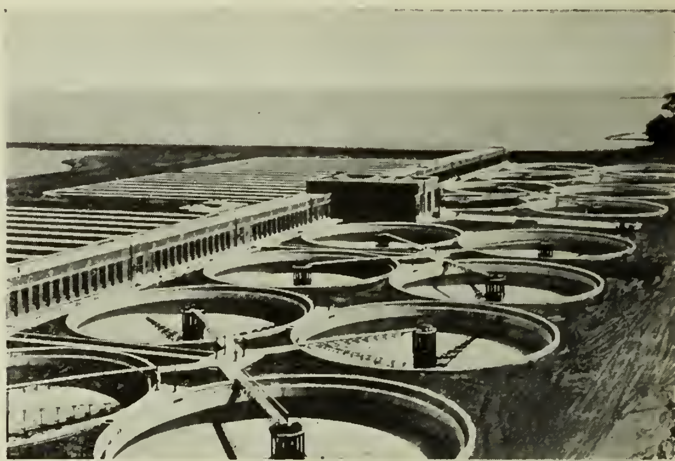

Fig. 4—Activated Sludge Plant for 123 m.g.d., Cleveland, Ohio.

city at a reasonable cost. Developments begun at the Lawrence Experiment Station in Massachusetts and also carried on in England, demonstrated the possibility of oxidizing by the direct application of oxygen, air being blown through the sewage mass as it passed slowly through the tanks. It was found that if this operation could be carried on in the presence of active bacteria that still more successful results were obtained. This became known as the "activated sludge" method and until recently has been the method generally used for the largest cities, enabling them to construct plants of large capacity, in many cases within the city boundaries, as for example in Milwaukee, Chicago, New York.

For some years it has been known that there was a need for some flexible method of treatment between the mere removal of coarse solids followed by sedimentation, and complete treatment by one of the accepted methods of oxidation. The oxidation processes are not flexible and when operated to their highest degree of efficiency produce an effluent which in many cases is of a better quality than needed, and when these processes are not operated as they should be, the results are poor. As every degree of refinement in treatment costs money, the system which will allow an adjustment of the degree of treatment to meet the needs of the case, will provide sufficient relief in many cases; and if this treatment may be increased in efficiency at will it is so much the better. In order to obtain this, much work has been done, especially in the past five years, on the addition of chemicals, in combination with some of the other methods, to achieve a greater removal of solids, both suspended and dissolved, and produce an effluent which would be suitable in a great majority of the cases for discharge into a stream. This has led to the development of several methods, some of them proprietary and some a combination of accepted known methods. Several of these methods have shown the possibility of building a plant in which the efficiency may be regulated to suit seasonal conditions, and which will be adjustable to varying loads or sudden influxes of solids. Most of them embody the use of several chemicals to precipitate the solids and additional chemicals to facilitate the dewatering and rapid handling of the sludge. There is not space to discuss all of these methods, but at the present time several plants of one type are in operation at Dearborn, Michigan, a large scale demonstration has been made at Chicago on another, and a still larger experiment at Atlanta on a third. A full scale plant at Birmingham, Alabama, has been in operation since early this year employing a combination of chemical precipitation with biological processes with an extremely satisfactory result. This plant employs only one chemical and has been able to show very high removals of suspended solids, total bacteria and reduction of biochemical oxygen demand at an expense averaging less than $6.00 per million gallons, omitting interest on investment and amortization of principal. This plant is so flexible that it may be operated in any one of six different ways to obtain varying results as the seasonal demands require. New York city is about ready to take bids on the first units of a chemical precipitation plant which will have an ultimate capacity of 140 million gallons per day which will utilize chemical precipitation in the summer and primary treatment in the winter months. The main objective in these studies is to reduce the initial plant cost and the operating costs. Practically every one of these chemical processes will reduce the first cost, but in some the cost of operation, due to the complexity of chemical dosage, runs higher than in some of the older oxidation processes.

Disposal of the Sludge

Sludge, which is the solid residue from any type of plant, is the greatest problem of all. This material, running in volume from approximately 1,800 gallons per day for primary treatment, with a moisture content of 94 per cent, to 15,000 gallons per day for activated sludge plants with a moisture of 98 per cent, presents a problem because of its tendency to decompose and cause odours. Digestion of these sludges, with control of the *pH* value and temperature can be effected satisfactorily, but as the ultimate residue of the digestion is a mass of relatively inert but wet material averaging 50 per cent of the original mass, there is still the problem of final disposal. Much thought has been given

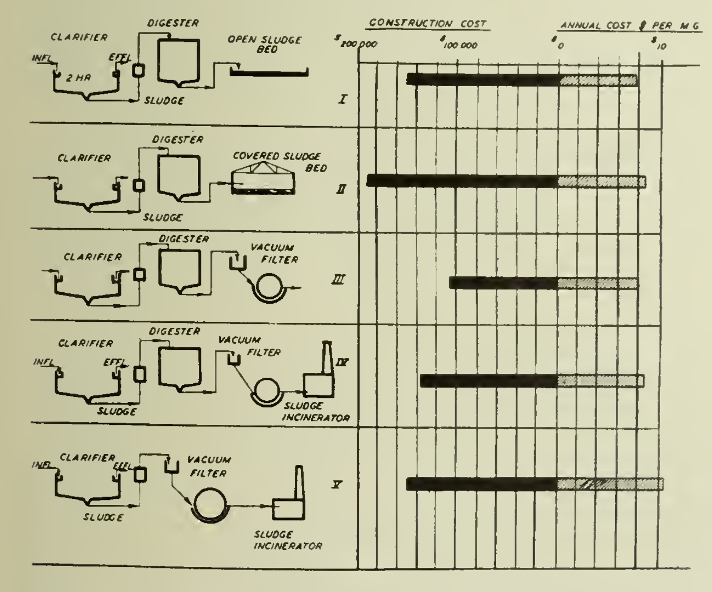

Fig. 5—Relative Cost of Primary Treatments of Sludge Disposal for Plant of 10 m.g.d. Capacity.

to a further reduction in the moisture content of the digested sludge and this has led to the employment of the vacuum type of filter. This filter, which has been used in the metallurgical and other fields, provides a rapid means of withdrawing the moisture from mixtures of solids and liquids by a high vacuum and delivering the material in the form of a cake. For digested sludge these units have proved their ability to handle the material in a small area and at a low cost, delivering a sludge of around 75 per cent moisture which is in a suitable condition to be hauled away and used as a fertilizer. In some of the activated sludge plants the wet sludge has been applied to the vacuum filters direct but subsequent drying by heat has been found necessary to put the sludge in a condition for final disposal. The digestion of the activated sludge excess combined with the raw sludge from the primary settling tanks has proved to be an economical step, reducing the amount of material to be filtered and consequently reducing the amount of conditioning chemical to be added to the sludge. A further step has been recently developed

Fig. 6—Fine Screening Plant, Los Angeles, Calif.

at Baltimore, in experiments with "elutriation" or washing of the sludge to remove from it some of the fine particles. This has resulted in increased capacities of filters, with a higher rate of application, a reduced chemical dosage and consequently a lowered cost all around, all leading in the end to complete plants in a small space at less cost.

The earliest method of disposing of sewage sludge was to discharge it into lagoons where it dried as it could. This was a noisome operation and soon reached its limit. The next step was the discharge of the sludge on to sand drying-beds, but here the sludge was subject to the weather and dried irregularly. These beds ordinarily occupied a space of one square foot per capita served, which in a large plant meant a large area. To overcome this difficulty and provide a bed that would not be delayed by wet weather, glass covers of the greenhouse type have been adopted in recent years. This allowed these beds to be built on the basis of one-half square foot per capita, but this halving of the size did not halve the cost, as the extra cost of the covered bed more than made up the difference. However, by retaining the sludge under cover it was found that the beds could be located closer to built-up districts, and the people did not seem to object to them, perhaps for the reason that a greenhouse being associated with flowers and pleasant smells made them forget that sewage had any odour.

The relative costs for construction and operation of five methods of sludge disposal are shown in Fig. 5.

The extent to which sewage treatment should be carried is, as previously stated, a matter for serious study with a knowledge of all conditions, and consideration will now be given to the various accepted methods and the results that may be anticipated.

The removal of coarse solids by bar screens is not considered a method in itself, but is usually the primary element in all plants. With bars spaced one inch apart a bar screen may be expected to remove between 2 and 4 cubic feet of material per million gallons of sewage. If equipped with mechanical means for removing the solids caught on the bars and with provision for operating the cleaning mechanism when accumulations have been built up on the bars, screen operation is simple and fool proof.

Where the removal of visible solids is the main consideration, fine screens should be used. A fine screen is a revolving drum or a rotating disc covered with plates which have openings or slots in them ranging in width from $\frac{1}{16}$ to

¾ of an inch depending on the amount of material to be removed. Figure 6 shows a fine-screening plant at Los Angeles, California, having a capacity of 150 million gallons per day and using five screens 14 feet in diameter by 12 feet long, with $\frac{1}{16}$ inch by 2 inch slots. The fine screen recognizes size alone and will not remove very fine solids or solids in solution. It cannot be considered a complete treatment and removes normally between 10 and 15 per cent of the total suspended solids in the sewage. These solids may be incinerated and disposed of with little effort.

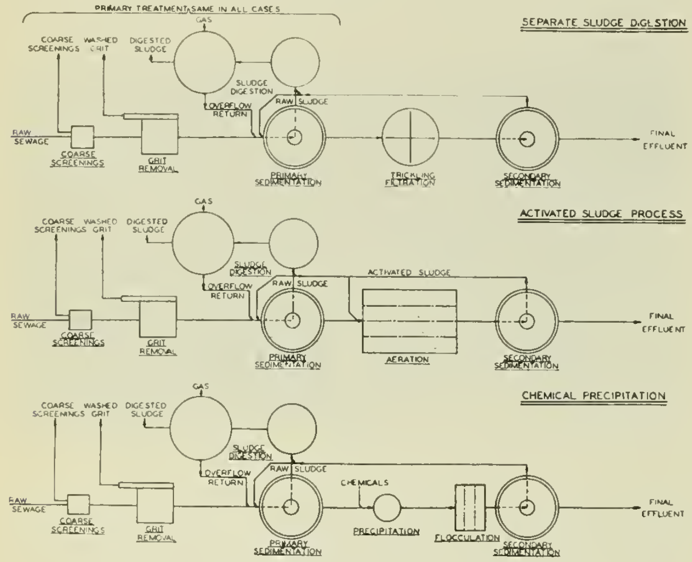

Fig. 7—Typical Sewage Treatment Flow Sheets.

Where a higher removal of the finer solids is required it is common practice to utilize sedimentation tanks, with from one hour minimum time of detention to four hours maximum, an average of two hours being accepted by most engineers as satisfactory. An efficient modern sedimentation tank will remove from 60 to 70 per cent of the total suspended solids in two hours when equipped with modern methods for collecting and removing the sludge so that the volume of the tank is always maintained at its maximum.

Treatment Varies With Requirements

In many places a bar screen and a sedimentation unit will accomplish the desired result at a moderate cost. Chemical precipitation may be applied to the sedimentation unit and this will increase the percentage of removal to 90 per cent or more, thus making this method applicable to a great majority of cases.

Where a high degree of purity is required for effluents to be discharged into streams used as the source of potable supplies for other cities, one of the accepted methods of oxidation may be employed, such as trickling filters, either of the fixed nozzle or revolving distributor type, or activated sludge.

The various combinations that may be made are shown diagrammatically in Fig. 7, while Fig. 8 shows the comparative results to be obtained, from the standpoint of removal of suspended solids, together with the relative initial cost per million gallons of treatment for plants averaging 10 million gallons per day (the sewage of about 100,000 people), also the amount of land required.

In the author's opinion the work done by sewage plants should be the criterion of cost of treatment. For instance, a fine screening plant, which will remove 15 per cent of the suspended solids and costs approximately $10,000 per million gallons for installation shows a cost per part per million removed of $666 whereas a plant comprising sedimentation and sludge digestion for the same volume, which will cost $30,000 per million gallons and will remove say 60 per cent of the suspended solids shows a cost per part per million removed of $500. As the percentage of removal of solids is the index of completeness of any given method it would seem logical that the method which removed the highest percentage of these solids at the lowest cost per part per million removed is the most economical system to adopt. In any given case these questions must be decided on their individual merits and with due regard to all local conditions.

Today the modern sewage treatment plant consists of a series of mechanical units so related to each other that the functions are performed continuously and with the least manual attention. The adoption of mechanical units has made efficiency of plant operation an essential. To instill in the minds of the plant operator the importance of his job the various sewage works associations in the United States, England and Canada all have as their basic object the encouragement of the operator to have pride in his plant, and make it operate as it was designed to do.

In the older plants the idea was that as sewage was an outcast product, the only place to put the plant was as far away from the residents of the town producing it as possible, and there was a concurrent idea that "sewage must smell" so why worry about it if the plant was odorous. It is now realized that this idea was wrong, as with the advancement of modern methods sewage is as much a matter of municipal concern as water supply, garbage collection or other municipal activity and must be handled in a manner to give the least offence. The improvement in the architectural design of the sewage plant, and the development of methods of treatment to the point where plants may be odourless, have made it possible to place the plants in the most suitable location, namely where the sewage drains best by gravity, whether that be in the centre of the city or on the outskirts. That this has been done successfully is evidenced by the illustrations of some of the modern plants reproduced in this paper.

Sewage treatment must be looked on as a science. When a city is faced with a problem involving so much in the way of municipal economy, continuity of efficiency and the maintenance of public health, the best interests of its own citizens and its neighbours justify thorough investigation and the employment of the best advice. The object is to provide the most suitable plant for the conditions, at the least cost consistent with modern construction and complete usefulness to the end of the period of expected life of the structures.

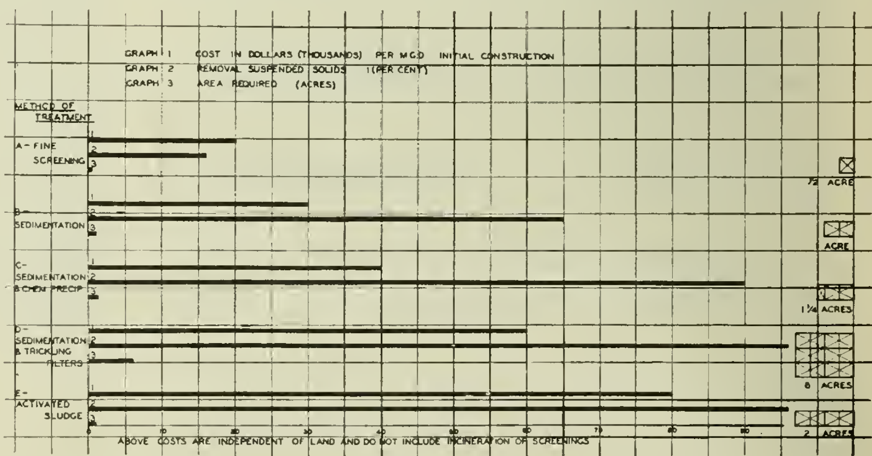

Fig. 8—Degrees of Sewage Treatment with Cost and Area Required.

Testing of Aircraft Fuels

M. S. Kuhring,
Engine Test Laboratory, Division of Physics and Engineering, National Research Council, Ottawa, Ont.

Paper presented before the Ottawa Branch of The Engineering Institute of Canada.

SUMMARY—The quality of gasoline for aircraft use is determined by tests for colour, gum, sulphur, vapour lock and freezing point, as well as by fractional distillation, which gives its characteristics as regards starting, acceleration, distribution and crank-case dilution. These tests are described and the paper concludes with a discussion of knock-testing and the determination of the octane number of a given fuel.

It is the intention of this paper to describe the various tests which are imposed on fuels to prove them satisfactory for use in aircraft engines. Perhaps the most important question is not how the test is conducted, but rather why it is done. If this is not kept in view, the test then becomes purely routine.

The tests which are carried out are of two general classifications: (*a*) laboratory tests; (*b*) road or service tests. The laboratory tests include development and routine work, while the service tests give what might be termed "full scale" results, showing the effect on the actual operation of the engine for which the fuel is intended.

Fuel specifications are as numerous as the wide range of uses for which gasoline is employed. Some operators insist on writing their own specification; others are content to use an existing specification, while others will use almost any fuel which will run through a feed line and burn.

Unless all factors are taken into consideration, a specification for fuel does not serve its purpose. For example, suppose the operator of low compression engines insists on the same quality of anti-knock fuel as that which is intended for high compression or supercharged engines, the cost will be considerably higher than that of a fuel which will successfully suppress detonation in his engine, and no particular gain is made, but detonation must be suppressed or else serious damage to the engine will result.

To be satisfactory, specifications must suit the purpose for which they are written, and anything more than a safe tolerance is imposing a restriction on the refiner who must charge for it. Specifications must vary to suit the wide range of uses for fuel, but the less variation there is, the more economical they will be.

Fuel specifications usually start off with a general clause which is self-evident, stating that the fuel shall be free from impurities and may insist that it consist of a straight run gasoline. This is because the fuel is not intended for immediate use, and cracked gasolines do not stand storage as well as do straight run gasolines.

Colour

Colour for identification is generally specified to be of a certain depth. This depth is usually determined by a chromometer.

The Saybolt chromometer consists of two glass tubes about 20 inches in length and 14-16 mm. inside diameter, held in a vertical position. The lefthand tube is of plain glass and is open at both ends. At the bottom of this tube is a collar for holding one or more glass slides. The other tube is calibrated and is closed at the bottom with a colourless plate. Below the tubes is a mirror to reflect the light through them into the optical prism eye piece at the top. The field appears as two halves of a circle, one half having the colour of the glass discs and the other the colour of the fuel or oil in the calibrated tube.

It should be stipulated that the colouring material used be such that no ill effects may be experienced by clogging the carburettor jets, etc.

Apart from tinting the fuel for identification, colour indicates very little to the average operator. Of the clear gasolines, some remain clear for long periods, while others turn quite yellow in a short time. Most of the cracked gasolines fall into this latter group. A negligible sulphur content will help to give a yellowish tinge to the fuel, or the colour change may indicate the presence of gum.

A change in colour does not necessarily mean that the fuel is not good, but there is a certain hesitancy on the part of consumers to buy a fuel that is neither crystal clear nor highly coloured. Taking advantage of the present demand for coloured gasolines helps to solve this problem.

To test the fuel's resistance to colour change, it is placed in a bottle containing oxygen and kept at a moderately elevated temperature. Change in colour is thus greatly accelerated, and the length of time that it retains its clarity gives an indication as to its resistance to colour change.

Gum

Gum is a resin-like substance which can easily cause serious trouble in an engine. As fuel containing gum is sprayed on a heated metal surface, the gum comes out of suspension and is deposited on this surface. As it is deposited, it is still soluble in gasoline, but when baked to a hard varnish-like residue, it is no longer soluble in gasoline and must be dissolved with either acetone or chloroform.

It may easily be imagined what the effect of this gum would be on the operation of an engine. Cracked gasolines are the worst offenders. This is mainly due to the unsaturated hydrocarbons which are present. Gum formation from these unstable hydrocarbons is essentially an oxidation process. Gum will not be formed in the entire absence of oxygen. Natural gasolines seldom, if ever, produce gum.

There are two main types of tests for gum: (*a*) a test to determine the suitability of the fuel for use at the time of testing; (*b*) an accelerated ageing test to ensure that the fuel will not form excessive gum in storage.

Several variations of the first group are in common use. Essentially, they consist of evaporating a small amount of fuel (about 100 cc.) in a copper, iron, glass or porcelain dish, and weighing the residue. The container is generally placed in a steam bath and some methods call for an air jet to play on the surface of the fuel. A good deal of confusion results when an attempt is made to interpret results of tests conducted under one set of conditions in terms of tests under different methods. A tentative standard method has been adopted(1) for a gum test in which fuel is placed in a glass beaker and evaporated in a constant temperature bath at 320 to 330 degrees F. Heated air is blown over the surface of the fuel during evaporation.

For automobile requirements, less than 10 to 15 mg. of gum would indicate that the fuel is satisfactory for use. For aircraft this figure should be reduced considerably; three mg. often being used as the limit.

Accelerated Ageing Test

The apparatus (shown in Fig. 1) consists of a bomb into which an uncorked bottle of gasoline is placed. The bomb is then closed and oxygen forced into it at a pressure of 100 pounds per square inch. The bomb is then placed in boiling water and the pressure increases to a constant value. Unless the bomb is leaking, this pressure will remain constant for a certain period. This period, which is called the induction period, will vary, depending on the fuel.

(1) American Society for Testing Materials (D 381-34T).

It is generally agreed that a fuel which will stand the four-hour induction period without dropping pressure will stand long periods of storage; but whether or not the test is too severe for those fuels which do not pass this test is still an open question.

A third phase in the gum problem is the correlation between the various laboratory tests and the results of engine tests. Most of this work has been done on single cylinder engines and more information on tests made on multi-cylinder engines would be of material help.

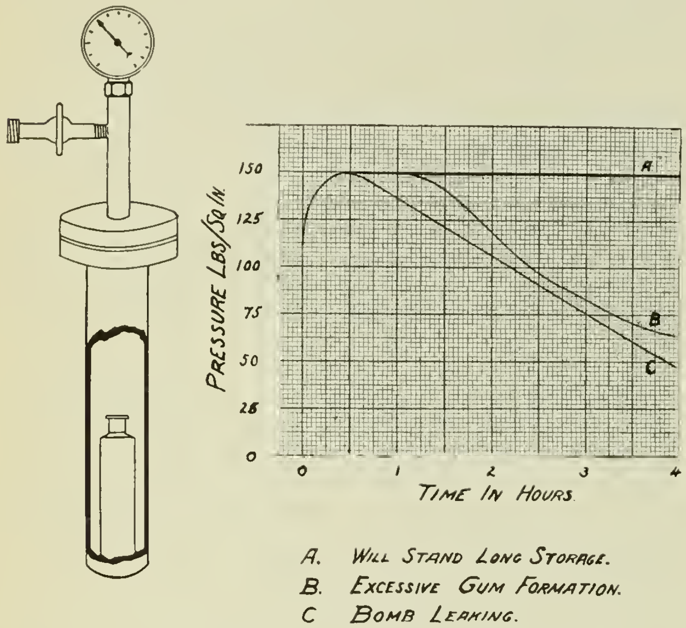

Fig. 1—Oxygen Bomb for Accelerated Ageing Test.

Gum inhibitors are sometimes used, which considerably delay the formation of gum, but this is a subject about which information is still incomplete.

Sulphur

There are two forms of corrosion due to sulphur, one in the fuel system and the other in the crankcase. The former is due to sulphur in the fuel before combustion and the latter due to the products of combustion.

A sulphur content of above 0.1 per cent in a fuel has been known to cause rapid and serious corrosion, especially at wristpins, bearings, and even on cylinder walls. Therefore it is obvious that the sulphur content must be limited, and this is generally set at 0.1 per cent.

To test a fuel for sulphur content, the A.S.T.M. lamp method is generally employed (see Fig. 2). The test consists of burning a known amount of fuel and the absorption and titration of the SO_3 formed.

Vapour Pressure

The property of a fuel which determines its tendency to boil and cause vapour lock, is called vapour pressure. If this occurs in the fuel line of an aircraft or automobile, the engine, because it is receiving insufficient fuel, sputters and stops.

The three fundamental variables in connection with vapour lock are: (*a*) temperature, (*b*) pressure, (*c*) vapour pressure.

With the exception of propane, gases are not usually present in commercial fuels in sufficient quantities to cause vapour lock. Removing this propane robs the fuel of a certain amount of its anti-knock value. A propane content of 1 per cent, which is not uncommon in some fuels, will raise the vapour pressure approximately 2 pounds per square inch.

From tests made at the United States Bureau of Standards(2) the following formula has been developed to give approximately the temperature at which vapour lock may be expected.

$$t = 560\frac{5.167 - \log p_r}{5.167 - \log p} - 460$$

where

t is temperature in degrees F.
p_r is Reid vapour pressure in pounds per square inch
p is atmospheric pressure at the given altitude in pounds per square inch.

In the case of a fuel having a Reid vapour pressure of 8 pounds, vapour lock on the ground might be expected at 130 degrees F. This temperature would be lower as the plane rises. Proper design of the fuel system will materially aid in avoiding vapour lock.

The Reid vapour pressure is determined by means of a Reid vapour pressure bomb (Fig. 3), which consists of two chambers, one above the other, with a pressure gauge at the top. The upper and larger chamber is for air, and the lower for gasoline, all three sections being connected internally.

The fuel chamber is purified and then filled by immersion in gasoline. The temperature of the air chamber having been taken and noted, the fuel chamber is then screwed on and the whole bomb immersed in a constant temperature bath and kept at 100 degrees F. Occasionally, it is taken out and shaken vigorously to permit the fuel to pass into the larger chamber where it comes in contact with the heated air. It is then put back in the bath. This is repeated until the pressure stops rising. The maximum pressure is noted and correction made for the original temperature of the air chamber; the net result being the Reid vapour pressure in pounds per square inch.

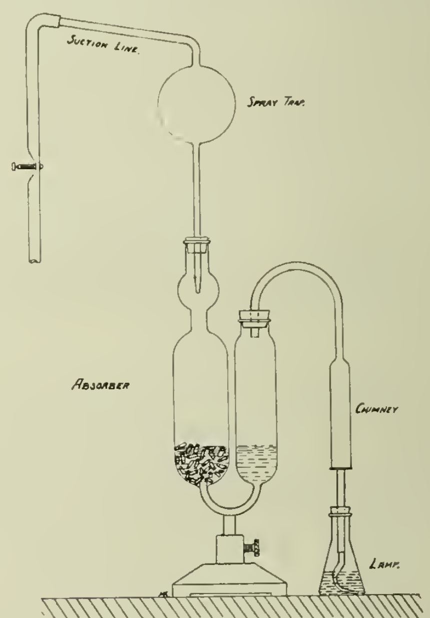

Fig. 2—A.S.T.M. Sulphur Lamp Apparatus.

Distillation Range

The distillation curve of a fuel gives a very good indication as to how that fuel will act in an engine as regards starting, acceleration, distribution and crankcase dilution. These points may be more fully understood from a description of the test procedure.

Figure 4 shows the A.S.T.M. distillation apparatus. 100 cc. of fuel are measured into the graduate and trans-

(2) See Properties of Gasolines with reference to Vapour Lock, Bridgeman and Aldrich, S.A.E. Journal, July 1930, page 93.

ferred directly to the Engler flask which is mounted on a stand immediately above a Bunsen burner. Around the flask and burner is a metal shield. The vapour outlet tube from the flask is connected to a condenser which in turn is set in a bath of ice and water or other cooling medium. The outlet of the condenser is placed in the mouth of the same graduate which was used to fill the flask, and a cover slipped over the top. Heat is applied to the flask at a specified rate. The temperature at which the first drop falls from the condenser tube is taken as the initial boiling point. Temperatures are also taken as the level of the distillate reaches each 10 cc. mark in the graduated receiver. The end point or maximum temperature is the highest temperature observed on the thermometer. This point is usually reached after the bottom of the flask has become dry.

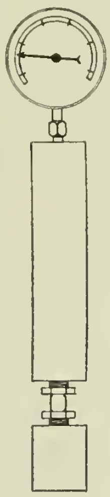

Fig. 3

The recovery is taken as the total volume of distillate as collected in the graduate. The residue is the volume of condensed vapour left in the Engler flask. The distillation loss is the difference between 100 cc. and the sum of the residue and the recovery.

When these 10 cc. points are plotted on a temperature-volume basis, the result is the distillation curve for that fuel (Fig. 5). The ideal fuel is one whose boiling point is sufficiently high to avoid vapour lock and fire hazard, but which will have a more complete removal of the hump in the distillation curve.

Starting characteristics are dependent upon the temperature at which the first 5 to 10 cc. are distilled. If this temperature is too high, starting will be impossible. If this temperature is too low, vapour lock may be expected. Heavier fuels are slightly more economical, but these cause hard starting and tend to crankcase dilution. Starting should not become impossible unless the initial boiling point is more than 140 degrees F. below the 10 per cent point. Ease of acceleration generally depends upon the slope of the curve between the 30 to 70 per cent points.

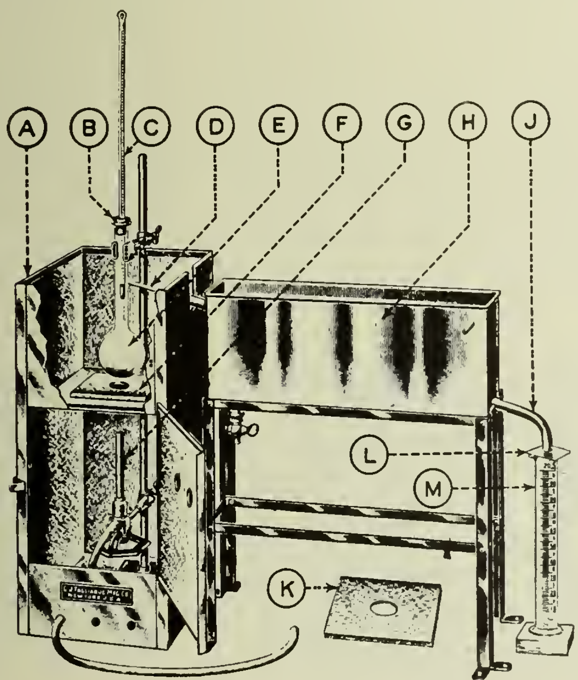

Fig. 4—A.S.T.M. Distillation Apparatus.

Distribution in an engine relates to the percentage of fuel which is evaporated in the manifold. Since the temperature of the engine from "all cold" until it warms up varies considerably the significant part of the curve varies from the 10 to 90 per cent points.

Various tests show that crankcase dilution is determined by the temperature of the 90 per cent point. The higher the temperature at this point, the greater the dilution that may be expected. The 90 per cent point is also an indication of the maximum temperature to which fuel should be heated in the manifold.

The initial boiling point has no bearing on the volatility of the fuel as a whole.

Freezing Point, Acid Heat and Specific Gravity

The main reason for the freezing point test is, of course, to ensure that the fuel will not freeze at the low temperatures that may be encountered in service, but it also shows whether or not there is much benzene in the fuel. The temperature of the fuel is gradually lowered and the point of initial formation of solid matter is taken as the freezing point.

Acid Heat

The acid heat test is conducted to determine whether or not there are present in the fuel unsaturated hydrocarbons in sufficient quantities to cause trouble, as these unsaturateds are apt to form gum in storage.

About 150 cc. of the fuel are placed in a thermos flask with 30 cc. of sulphuric acid, and shaken. This mixes the two thoroughly.

If there are unsaturated hydrocarbons present, the temperature will rise. Other impurities will also tend to raise the temperature.

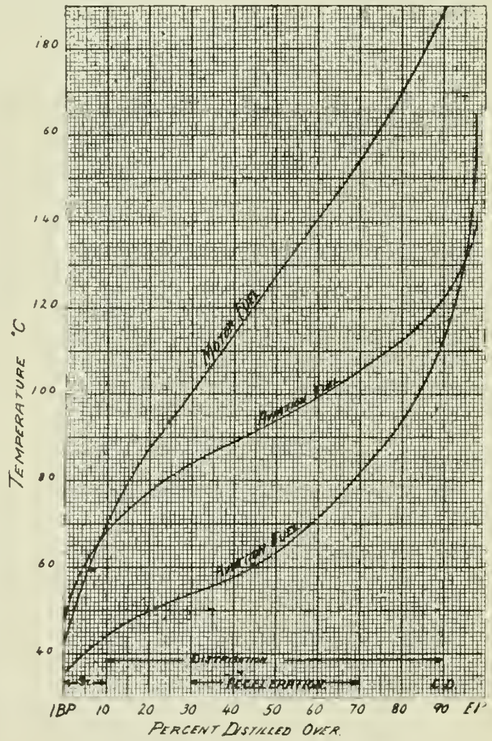

Fig. 5—Distillation Curves.

For aircraft fuels this temperature rise is limited to 20 degrees F.

Specific gravity used to be taken as one of the main considerations in selecting a fuel, but little importance is attached to it at the present. Most specifications disregard it completely. The test is made with a hydrometer or with a weighing bottle.

Acidity

The acidity test is made to ensure that no acids are present in sufficient quantities to cause damage in an engine. The fuel is well shaken with water, and the presence of acid determined with an indicator. Methyl orange is often used as the indicator, the methyl orange changing colour in the presence of acids.

Corrosion may be caused by acidity or excess sulphur in the fuel. If the fuel corrodes engine parts it may be very serious and for this reason a corrosion test is made.

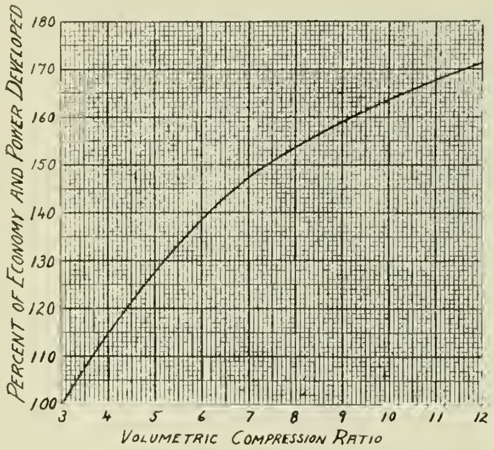

Fig. 6—Effect of Compression Ratio on Operation.

If the copper dish method is used for the actual gum determination, as described earlier in the paper, the dish may be examined after evaporation is completed and the two tests thus combined. The test consists of evaporating a small quantity of fuel in a polished copper dish. There should be no grey or black corrosion of the dish. An alternative test is to place a freshly polished strip of copper in a test tube with gasoline. The test tube is placed in a bath and kept at 122 degrees F. for three hours. Discolouration of the copper strip indicates corrosion.

Anti-Knock Value or Octane Number

When a combustible mixture is ignited, the flame, under normal conditions, tends to travel from the point of ignition at a definite velocity. Should the pressure in an engine show instantaneous instead of gradual rise before ignition is complete, accompanied by a metallic "pinking" and temperature rise, detonation is said to occur. This knocking or pinking is due to high period vibration and is not at all regular. If detonation is permitted to continue, it is apt to increase in intensity and in severe cases, pass over into pre-ignition.

The chief difference between pre-ignition and detonation is that pre-ignition involves a large part, or the whole of the charge, and is caused by faulty ignition timing or spontaneous combustion. With detonation there are present only vibration, roughness and higher temperatures. While there is a good deal of difference, in theory, between detonation and pre-ignition, in practice it is sometimes impossible to tell whether an engine is pre-igniting or detonating.

A poor air-fuel ratio will reduce detonation, but this of course is not a solution. Heat accentuates the tendency of a fuel towards detonation. Change in the design of the combustion chamber and location of the spark plugs may also reduce detonation.

The chief fuel factors which influence detonation are:

(*a*) Composition of the fuel. Some of the hydrocarbons are very apt to knock at low compression ratios, while others resist detonation. The paraffin group show the greatest tendency towards detonation while the aromatics show the least, though there are exceptions. The highest useful compression ratio (H.U.C.R.) or compression ratio determined on a variable compression engine at which power increase stops, has been found for many of these hydrocarbons, a few of which are given below.

N heptane	2.75 to 1
N pentane	3.8 to 1
Iso-octane	6.9 to 1
Benzene (above)	15.0 to 1
Toluene	13.6 to 1
Cyclo hexane	4.5 to 1
Absolute ethyl alcohol	11.6 to 1

(*b*) The stability of the mixture at the induction pipe temperature.

(*c*) The mixture or air fuel ratio.

A compression ratio low enough to resist detonation in all fuels in use would give very poor engine performance as regards power and economy, as is shown in the curves in Figs. 6 to 9 which have been plotted from tests made at various compression ratios and show the marked improvement resulting from an increase in compression ratio from 5.2:1 up to 7.0:1. Increasing the compression ratio definitely increases the power of an engine providing detonation is suppressed; and the inertia loads are actually decreased.

Figures 10 and 11 show the effect of an increase in the compression ratio upon wheel torque and gasoline consumption in an automobile.

Carbon deposits cause a big problem for high compression engines by seizing the piston rings in their grooves and by filling the combustion space, thus increasing the compression ratio, but this can be partly overcome with a carbon solvent.

The reason for this detonation phenomenon has been the subject of close study and the cause of a great deal of controversy ever since the end of the great war, when the octane number of commercial gasoline in England was about 35 in some cases. It is not intended to convey the impression that all combustion study started at that time. A lot of work had been done previous to this, but perhaps without the same object in view.

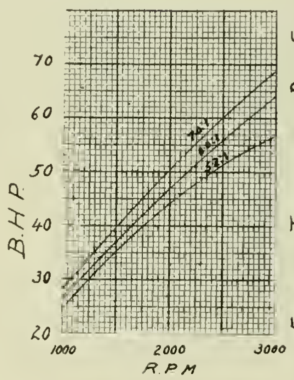

Fig. 7

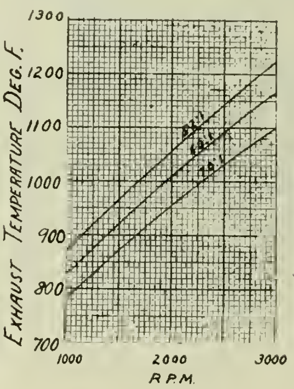

Fig. 8

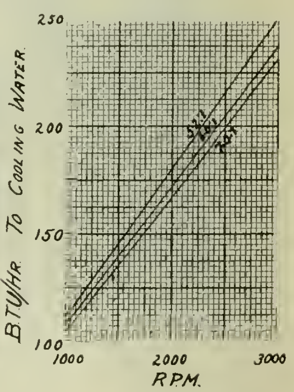

Fig. 9

Effect of Compression Ratio on Operation.

An article by Whatmough appeared in the Automobile Engineer for November 1927, covering fifteen theories which had been advanced to explain detonation. Even at the present time, it is generally conceded that a complete explanation of this phenomenon has not yet been found, and although some very reasonable assumptions are made, they do not satisfy all cases.

What is probably the clearest account, is that put forward by the late Professor Callendar of the Royal College of Science, London.[3] His explanation of the phenomenon is that organic peroxides are formed and these are known to explode violently. In some cases these peroxides have been found, though not in all. He also stated that microscopic drops consisting of the less volatile hydrocarbons, act as foci of ignition as their ignition point is lower than that of the vapour. The process seems to be a chain reaction in which the energy that starts the initial reaction releases other energy sufficient to start other reactions, and so on.

To bear out the peroxide theory, tests were made to find a relation between the substances which formed these peroxides, and those which did not. The results are as follows:

(*a*) Substances which showed peroxide formations.
- Amyl and ethyl ether
- Paraffin hydrocarbons (pentane to undecane)
- Turpentine
- Paraffin oil
- Paraldehyde
- Propyl aldehyde

(*b*) Substances showing no peroxide formation, or traces only.
- Ethyl alcohol
- Methyl alcohol
- Amyl alcohol
- Butyl alcohol
- Benzene
- Aniline

(*a*), it will be noted, are pro-knocks, while (*b*) are anti-knocks.

A third group consisting of detonating substances was tested, but no peroxides were found. If the combustion process can be controlled until the combustion of the whole mixture is more advanced, then this reaction will not be so violent. This would seem to show why such a small amount of knock-inhibitor affects the combustion. The knock inhibitor appears to absorb the oxygen that would otherwise form peroxides. Engine speed also affects detonation, by altering the time of the explosion stroke. This is shown in tests carried out in England giving the following results:—

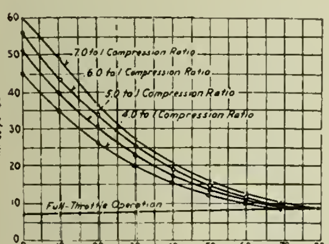

Fig. 10

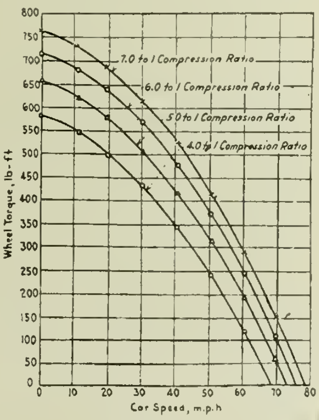

Fig. 11

Effect of Compression Ratio on Operation.

r.p.m.	H.U.C.R.[4]
1,200	4.45:1
1,300	4.65:1
1,400	4.90:1
1,500	4.95:1
1,600	5.00:1

Increase in compression ratio with its attending increase in compression pressure and temperature is the greatest cause of detonation.

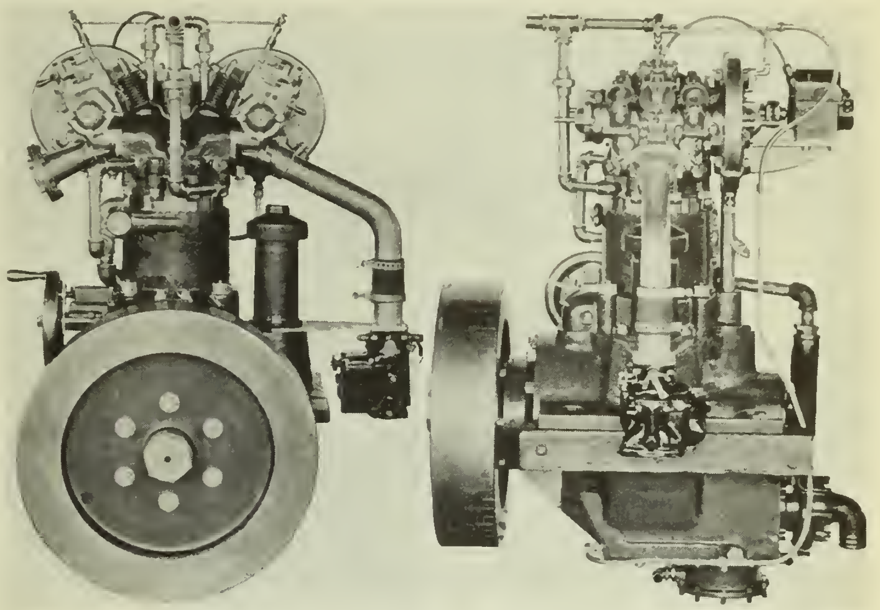

Fig. 12—N.A.C.A. Universal Engine for Testing Fuels.

When this phenomenon was recognized, it became necessary to find some means to control it if engines were to be as efficient as possible. It was found that several substances when added to fuel tended to decrease or to prevent the knock. It was also found that some of these substances were much more effective than others. To date, lead tetraethyl is the most effective knock inhibitor that has been found, and the number of substances tried runs literally into the thousands. Numerous other substances suggest themselves as knock inhibitors, but the main difficulty is to find some form of that substance which is soluble in gasoline and which will not attack the engine parts.

The effect of lead tetraethyl may be better understood when it is known that the engines which are used to test the fuels can detect as little as 1/10 cc. of lead per gallon. The amount present in a combustion chamber is estimated as 4/10,000 of a gramme. Lead has its disadvantages, however, as upon exposure to light or heat, it tends to lose its effectiveness, though this does not usually affect the ordinary consumer. As to its toxic effects, it is undoubtedly an unpleasant substance to handle in its concentrated state, but tests made by the United States Bureau of Mines[5] show that there is no danger to the engine operator in using a fuel containing it.

The response of different fuels to anti-knock substances varies considerably. Cracked gasolines do not respond as readily as do straight run fuels. Because of the wide variation in response to knock inhibitors, it is necessary to have a basic standard to which fuels may be compared.

(3) Report of Aeronautical Research Committee, 1927, page 669.

(4) H.U.C.R. The Highest Useful Compression Ratio. This is the highest ratio at which a given fuel may be used without detonation.

(5) Experimental Studies on the Effect of Ethyl Gasoline and its Combustion Products. Report of U.S. Bureau of Mines, 1927.

The selection of such a standard is not at all an easy matter. Up to a few years ago, practically every laboratory had their own method of reporting knock ratings. Some of these could be duplicated on other scales, but with others there was no connection at all, so that a serious attempt was made to establish standards. To be satisfactory a standard must:

(*a*) Cover the entire range of fuels to be tested.
(*b*) Be chemically pure and stable.
(*c*) Be cheap and easily obtainable.

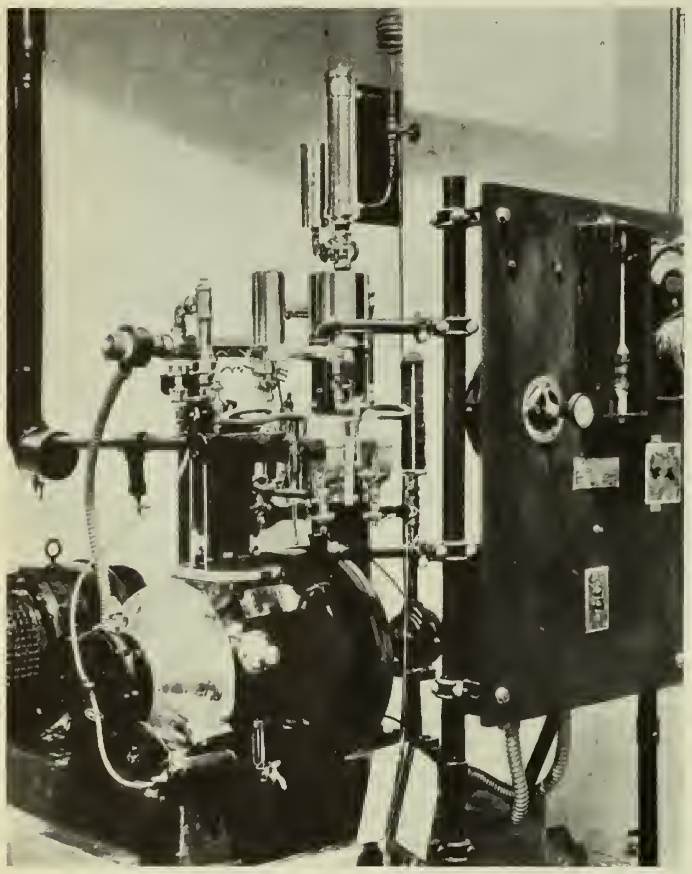

Fig. 13—Ethyl Gasolene Corporation Engine 30B for Testing Fuels.

Obviously, gasoline, which is a complex structure, is not suited for use as a standard.

The choice of hydrocarbons is wide. The result of this movement for standardization was the adoption of a mixture of iso-octane (or 2-2-4 trimethyl pentane), and normal heptane. Unfortunately, the cost of these standards is very high at present, ranging from $20 to $25 per gallon (U.S.).

The term octane number is defined as the percentage by volume of iso-octane (the anti-knock), in a blend of iso-octane and normal heptane (the pro-knock). The higher the octane number, the higher the anti-knock quality. The statement that a fuel has an octane number of 76 means that when tested under certain definite conditions in a specified test engine, the knock intensity of the fuel will be identical with the knock intensity of a mixture of 76 per cent iso-octane and 24 per cent normal heptane when tested on the same engine under the same conditions. In some cases it is admitted that the H.U.C.R. of iso-octane will not be high enough, and benzene may have to be added, but benzene is not satisfactory as a reference fuel, mainly because of its high freezing point.

This term octane number as applied to a fuel means little or nothing unless it is qualified by the engine speed, compression pressure and temperature of the air–fuel charge of the engine on which it was tested. It is an easy matter for a test to be arranged so that a fuel will appear to have an octane number of seven or eight above that which would be allotted to it should it be tested according to more severe test conditions. An endeavour is therefore being made to standardize knock-rating tests. Tests now in general use for various fuels include cooling liquid temperatures of 120, 212, 300, 345, and up to 394 degrees F. while speeds include 600, 750 and 900 r.p.m.

These different knock-testing conditions are however rapidly giving way to the Cooperative Fuel Research Motor Method in the case of automobile fuels, while tests are being conducted with a view towards standardization of test conditions for aero engine fuels.

Knock rating tests do not always agree if they are made on different types of engines, although those made on two engines of the same type agree with surprising regularity; therefore, standardization of engines was the next step. Certain engines, because of satisfactory service, have been standardized in certain localities, but there are still several types of engines in use. Some of these are described to give an idea of the type of engine used for this purpose.

The Ricardo E35 poppet valve, variable compression engine was especially designed for research problems on fuels. The compression ratio varies from 3.7:1 to 7.5:1. The original of this type of engine was built in 1919 and is still in use. The engine has two inlet and three exhaust valves, operated by an overhead cam-shaft. Mixture is controlled by means of a needle valve and a swinging field electric dynamometer is supplied. Fuel consumption is measured by checking the time to use a known amount of fuel. Two fuel systems are used and a three-way cock permits a quick change-over.

The Ricardo E5 engine is of the sleeve valve type produced by the same manufacturer as the above engine. Variable compression is accomplished by lowering or raising the crown of the combustion chamber. Two inlet and two exhaust ports are provided in the valve sleeve, any of which may be blocked to vary the port area.

The Armstrong Whitworth engine was developed by Messrs. Armstrong Whitworth and the Anglo-Persian Oil Company. A variable compression head is fitted, and the variation is accomplished by raising or lowering a plug in the combustion chamber. Tests would seem to show that no excessive collection of exhaust gases remains in this pocket. The cylinder head and cylinder walls have individual cooling. A swinging field dynamometer is provided and intake air may be heated. Flow meters are supplied and air fuel ratios are governed by a needle valve in the jet. The above engines are produced in England, and more used on that side of the Atlantic.

In the United States, other engines have been produced, among which the following are being largely used:

The compression ratio of the N.A.C.A.[(6)] Universal Test Engine Model A shown in Fig. 12 may be altered while the engine is running. This is accomplished in the same manner as used in the Ricardo E35 engine. The cylinder base has a heavy thread cut on it, and a ring with an internal thread is turned by a crank. The compression ratio ranges from 5:1 to 13:1. The valve timing and lift may be altered while the engine is running. The valve lift is varied by changing the position of the fulcrum of the rocker. A single carburettor with two fuel systems is provided. This engine is rated at 35 h.p. with a speed of 1,800 r.p.m. A second type, the model B engine, is supplied without the valve adjustment mechanism, though variable compression is retained.

---

(6) National Advisory Committee for Aeronautics.

The Ethyl Gasolene Corporation "Delco" model engine was developed from the Delco lighting plant. The compression ratio is set at 7.5:1 and the density of the charge is governed by the throttle. Speed is controlled by means of a rheostat which applies loading to the generator which is coupled directly to the engine. The carburettor has a fixed jet in which the fuel level is raised or lowered by moving the float chambers. In this way the air fuel ratio may be varied at will.

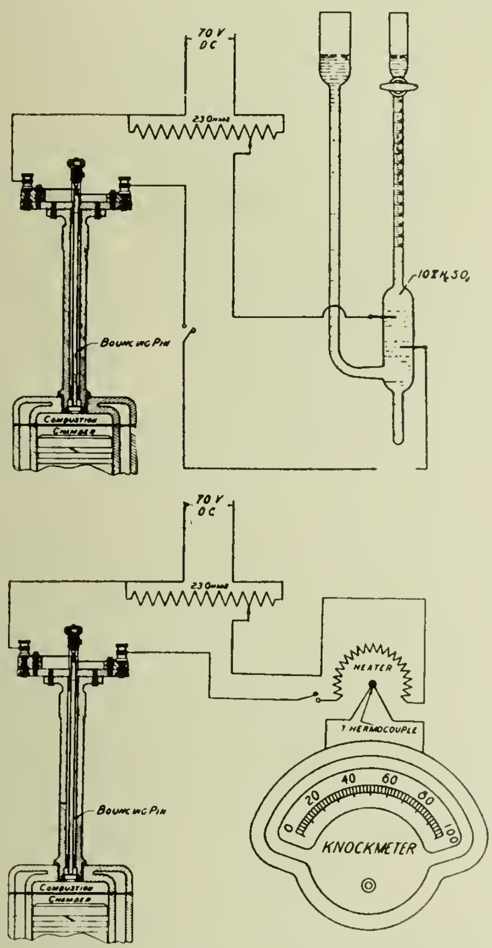

Fig. 14—Apparatus for Measurement of Detonation.

Figure 13 shows the Ethyl Gasolene Corporation Series 30B engine. From experience in the operation of the Delco model, this apparatus was developed. Speed is controlled by a synchronous motor and provision is made for running at higher jacket temperatures. Compression pressure may be adjusted by slipping shims under the cylinder flange. A neon tube ignition indicator is provided. It was for this engine that the "knock meter" was developed.

The Cooperative Fuel Research engine has been developed by the Society of Automotive Engineers and the American Petroleum Institute and has been adopted for use in the United States as a standard engine, and it is considered extremely likely that it will be standardized generally as conditions may warrant.

The usual method for testing the fuel on most of these engines is to compare it to a standard, though knock-testing may be done in several ways. These include the determination of highest useful compression ratio and power loss, and the use of indicator card, aural detection, ballistic device, bouncing pin and thermocouples.

The highest useful compression ratio of a fuel is found in a variable compression engine. This result, unless a standard engine is used, can not always be reproduced on another type of engine, owing to difference in the combustion chamber characteristics. Measuring the power loss is accomplished by measuring the power of a standard fuel and comparing it to the power output of the sample being tested. Indicator cards would be ideal, if there was a satisfactory engine indicator for this purpose, but at present there is no indicator sufficiently accurate and flexible to serve this purpose, especially for routine tests. Aural detection depends too much on the human element, and while good results have been obtained, it is not to be recommended. The ballistic device is much like the Midgely bouncing pin. A plunger rises according to the pressure in the cylinder, and actuates a lever arm. The reading of this instrument, however, depends too much upon the eye of the operator.

The Midgely bouncing pin (Fig. 14) consists of a thin steel diaphragm which forms part of the wall of the combustion chamber. On this diaphragm rests a slender pin which is loosely held in guides. When detonation occurs, the sudden pressure rise causes the diaphragm to deflect and the pin is projected upwards, with a force depending on the intensity of the detonation. As the pin rises, it closes an electrical contact. The greater the force of the pin, the longer the time the contacts will remain closed. The current that passes through these contacts goes either to an electrolytic cell or else to a meter. In the case of an electrolytic cell, it breaks up water in the cell into hydrogen and oxygen. This gas is collected in a calibrated

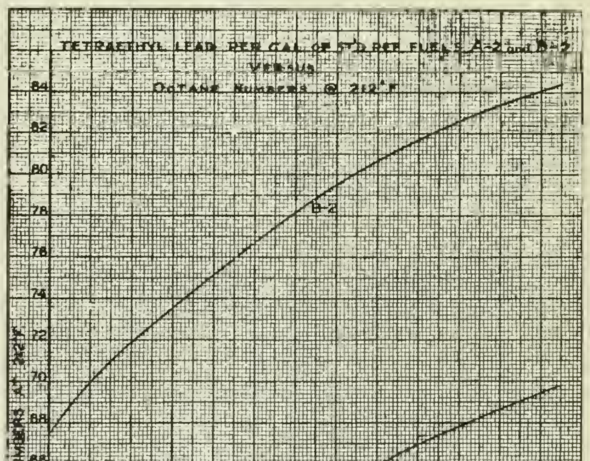

Fig. 15—Reference Fuel Calibration Curves.

tube and the greater the detonation, the more gas formed. Readings are generally taken for a period of one minute. If a meter is used, the readings may be taken directly. Instead of a bouncing pin, a thermocouple is sometimes used and the temperature used in place of pressure.

When work is started on the testing of fuels, the operator needs some practice work to become familiar with all the various details in connection with the operation of the engine and the procedure of the test. These test engines, considering the treatment they necessarily receive, give remarkably good service, but sometimes, in spite of the care that is taken, errors do creep in. These errors are often due to such small causes that it is hard to find them. For example, the engine may be operating with all the variables kept as constant as possible, when suddenly the indicated intensity of the knock will increase or decrease considerably. This is of course taken as a sign that attention is needed in some part of the engine, or in the instruments. Parts which suggest themselves from the character of the trouble are first examined, and if this does not correct it, the whole installation must be gone over.

Perhaps nothing will be found wrong, and the engine is tried again. The faults are quite apt to correct themselves before they are found. Of course, there is a reason for all these variations, but long periods are often spent in trying to locate them. The newer engines are not so liable to such difficulties.

In the knock-testing of fuels, the following is an outline of the method of test as carried out on some types of engines.

There is, in the laboratory, a reference fuel, whose anti-knock value, in terms of octane number, is known. Also, the reaction of this fuel has been tested as lead tetraethyl is added. (Incidentally, this secondary reference fuel is checked periodically against the more costly basic standards.) This fuel, it is remembered, is to be the measure against which the unknown fuel is checked.

To find the octane number of the unknown sample of fuel, it is placed in one fuel system, and the known reference fuel is placed in the other. The engine is first run on one of these fuels, and the air-fuel ratio gradually changed from lean to rich. During this operation, the knock intensity will increase until a maximum is reached, and will then decrease. This air-fuel ratio which produces the maximum knock is the point for which we are looking, and all the others are ignored.

The same procedure is carried out on the other fuel and the maximum knock found for it.

The engine is then run first on one fuel and then on the other alternately, at the air-fuel ratio of maximum knock, until it is determined beyond doubt that the readings obtained are correct, and comparison is made.

Suppose that the reference fuel indicates a knock intensity of 68 on the meter, while the sample only shows an average of 62, it is obvious that the reference fuel requires more lead to reduce its knock. Lead is added, and the procedure again carried out until the two fuels match exactly. Reference is then made to the calibration curves which accompany the secondary reference fuels (see Fig. 15), and the octane number found for that fuel plus the necessary addition of lead. This octane number will also be given to the unknown sample.

For the refiner's purpose, the test is reversed. He has his reference fuel made up and wants to know how much lead per gallon he must add to his product to bring it up to standard. Therefore by trial and error, he finds this out by working on the point of maximum knock.

Lead Analyses

It is sometimes stated that only a certain amount of lead is to be added to a fuel. To ensure that this amount has not been exceeded, a lead analysis is made.

The fuel is placed in a separatory funnel and shaken with nitric acid. The acid layer is drawn off and partly evaporated. Sulphuric acid is then poured into the beaker and the rest of the nitric acid evaporated. Water is then added to the sulphuric acid and the lead precipitated as lead sulphate. This is filtered off in a Gooch crucible and weighed. It is then an easy matter to calculate the amount of lead tetraethyl per gallon that was in the fuel. This method was developed by the Standard Oil Company of New York, and gives very satisfactory results.

From the above it will be evident that there is no single fuel which is best for every type of engine.

As far as octane number is concerned, and that commands the largest interest at present, if a high compression engine is used, a high octane number fuel is essential. If a lower compression engine is used, it may be operated on a fuel of lower octane number. However, a whole series of tests would have to be made with consideration given to the engine conditions under which the fuel would be used before a definite selection can be made. The real solution is to use a fuel which it is found by experience will give most miles per dollar with the least trouble.

The Forty-Ninth Annual General and General Professional Meeting

The Annual General Meeting for 1935 will be convened at Headquarters, 2050 Mansfield Street, Montreal, on Thursday, January 24th, 1935, at eight o'clock p.m.

After the transaction of formal business, the meeting will be adjourned to reconvene at the Royal York Hotel, Toronto, at ten o'clock a.m. on Thursday, February 7th, 1935, continuing with the professional sessions on the following day.

Programme of Meeting at Toronto

(Subject to Minor Changes)

THURSDAY, FEBRUARY 7th

9.00 a.m. REGISTRATION (Main Mezzanine Floor).

10.00 a.m. ANNUAL GENERAL MEETING (Tudor Room).
Reception and discussion of reports from Council, Committees and Branches.
Scrutineers' report and election of Officers.
Retiring President's address.
Induction of New President.

12.45 p.m. FORMAL LUNCHEON (Roof Garden).
Members $1.00. (Complimentary to visiting Ladies.)
Welcome by the Chairman of the Toronto Branch, R. E. Smythe, A.M.E.I.C., and by His Worship the Mayor of Toronto.
Address by J. B. Carswell, M.E.I.C., of Hamilton, introducing the subject of the afternoon's discussion.

2.15 p.m. PROFESSIONAL SESSION (Tudor Room).
The afternoon will be devoted to a discussion on the **Status of the Engineer.**
C. S. L. Hertzberg, M.E.I.C., will be in the chair.
The discussion will be based on three papers:—
The Engineer in Industry, by R. E. Smythe, A.M.E.I.C.
The Engineer in Private Practice, by J. M. Oxley, M.E.I.C.
The Engineer in The Public Service, by G. J. Desbarats, M.E.I.C.

4.30 p.m. RECEPTION AND TEA for Ladies (Roof Garden).

7.30 p.m. ANNUAL DINNER of The Institute (Ball Room).
The President in the chair.
Dr. A. S. Eve, C.B.E., F.R.S., Dean of the Faculty of Graduate Studies, McGill University, Montreal, will address the members and ladies present.
The Prizes and Medals of The Institute will be presented.

9.30 p.m. RECEPTION AND DANCE (Banquet Hall).
Tickets for Dinner, $2.00 per person.
Tickets for Dance, $2.00 per person.
Tickets for Dinner and Dance, $7.00 per Couple.

FRIDAY, FEBRUARY 8th

9.30 a.m. PROFESSIONAL SESSIONS for the Presentation and Discussion of Papers will be held in three rooms concurrently.

(Hall C)

(*a*) **Research and Testing work for the Hydro-Electric Power Commission of Ontario**, by W. P. Dobson, M.E.I.C., Chief Testing Engineer, H.E.P.C. of Ontario, Toronto.

(*b*) **Gaseous Conductor Lamps and their Applications**, by J. W. Bateman, Manager of Lighting Service, Canadian General Electric Co., Toronto.

(Library)

(*a*) **Simple Graphical Solution for Pressure Rise in Pipes and Pump Discharge Lines**, by R. W. Angus, M.E.I.C., Professor and Head of Mechanical Engineering, University of Toronto, Toronto.

(*b*) **The Montreal Neurological Institute and its Service Equipment**, by F. J. Friedman, M.E.I.C., and C. P. Creighton, A.M.E.I.C., of McDougall and Friedman, Consulting Engineers, Montreal.

(Tudor Room)

(*a*) **The Toronto Waterworks Extensions, a General Description of the Scheme with Details of some outstanding Features**, by William Storrie, M.E.I.C., of Gore Nasmith and Storrie, Consulting Engineers, Toronto.

(*b*) **Three Bascule Bridges of the Simple Trunnion Type**, by H. W. Buzzell, A.M.E.I.C., and R. S. Eadie, A.M.E.I.C., Designing Engineers, Dominion Bridge Co., Montreal.

FRIDAY, FEBRUARY 8th (Continued)

12.45 to 1.45 p.m. BUFFET LUNCHEON (Ball Room). Tickets $1.00.

2.15 p.m. PROFESSIONAL SESSION (Tudor Room).
The afternoon will be devoted to a discussion of **The Water Supply of the Prairie Provinces and its Bearing on their Economic Development.**
Chairman—S. G. Porter, M.E.I.C.
The following communications will be considered:—

(*a*) **Precipitation in the Prairie Provinces**, by John Patterson, Director, Meteorological Service of Canada, Toronto.

(*b*) **Run-off and Stream Discharge in the Prairie Provinces**, by J. T. Johnston, M.E.I.C., Director, Dominion Water Power and Hydrometric Bureau, Ottawa.

(*c*) **Water Conservation in the Prairie Provinces**, by T. C. Main, M.E.I.C., Assistant Engineer—Water Supply, Canadian National Railways, Winnipeg.

(*d*) **The Surface Waters of the Canadian Prairies**, by P. C. Perry, A.M.E.I.C., Division Engineer, Canadian National Railways, Regina.

(*e*) **Domestic Waters in the West**, by W. Calder, Director, Petroleum and Natural Gas Division, Department of Lands, Edmonton.

(*f*) **Relationship of Geology to Soil Drifting in Southern Manitoba and Southern Saskatchewan**, by W. A. Johnston, Chief, Division of Water Supply, and R. T. D. Wickenden, Assistant Geologist, Geological Survey, Ottawa.

(*g*) **Some Possible Sources of Ground Water in Southern Saskatchewan**, by R. T. D. Wickenden, Assistant Geologist, Geological Survey, Ottawa.

(*h*) **Mineral Character of the Underground Waters in Southern Saskatchewan**, by D. C. Maddox, Associate Geologist, Division of Water Supply, Geological Survey, Ottawa.

8.00 p.m. SMOKING CONCERT (Concert Hall). Tickets $2.00.
A variety show with refreshments.
Ladies' THEATRE PARTY (complimentary to visiting Ladies).
For details of Ladies' entertainment, see Ladies' Programme.

SATURDAY, FEBRUARY 9th (Morning)

9.30 a.m. Arrangements will be made for visits to engineering works of interest, such as the following:—
Laboratories of the Hydro-Electric Power Commission, Strachan Avenue.
Laboratories of the Ontario Research Foundation.
Bell Telephone Company's Toronto Toll Equipment.
Victoria Park Filtration Plant.
Factory of the Goodyear Tire and Rubber Co. of Canada.
Details will be announced later.

Hotel Arrangements

Members are recommended to make their reservations as early as possible.

The leading Toronto Hotels quote the following rates:—

	Royal York	King Edward
Single room with bath................	$4.00	$3.00
Double room with bath...............	$7.00	$5.00

Railway Rates

Both railways offer special return rates for groups of ten or more as follows:—

(*a*) Organized parties having a minimum of ten up to fourteen persons: single fare and one half. Time limit sixteen days.
(*b*) Organized parties of fifteen or over: single fare and one quarter. Time limit sixteen days.
(*c*) Rate good on coaches only, a minimum of fifteen persons: single fare and one tenth. Time limit seven days.

All these fares require travelling together on the same train and date, with individual return on any train within the time limit.

VOLUME XVIII JANUARY 1935 No. 1

The New Year

The President and Council extend to all members of The Institute a cordial greeting for 1935.

The Old Year closes with many definite indications of improved conditions in Canada which will lead to growing activity in engineering work.

Our difficulties are not yet over, but we are encouraged to await with confidence the events of the coming year.

Construction Contracts and Contract Forms

The engineering side of the construction industry has undergone marked changes during the past twenty years, both in its technical and commercial aspects. Much of the work is now on a larger scale and is carried out by the aid of much more elaborate equipment, which, together with new facilities for inspection and testing, and improved accounting methods, makes it possible for the engineer and the contractor to control more closely the quality and cost of the work. The sub-contractors, each undertaking the work of some particular trade, now play a far more important part than in the past. These and other developments increase the responsibilities devolving upon the parties concerned, and make it more than ever necessary to define clearly the duties and mutual relations of the owner, the engineer and the contractor.

The documents defining these relations, and forming the conditions of contract for the execution of engineering work are, however, of importance not only to consulting engineers and contractors, but to everyone interested in the construction of public works or large buildings, the fabrication of structural work, or the supply and erection of heavy mechanical and electrical equipment. This is particularly the case since the engineering staffs of large corporations are now called upon to undertake some of the design and planning work which used to be entrusted to consulting engineers.

Documents governing engineering contracts have, first, to define the legal relations existing between the owner or purchaser of a projected work, the engineer acting on his behalf, and the contractor and the people working for him. It is then necessary to set forth the general conditions under which the work is to be performed, taking account of the various contingencies which may occur. The parties interested should evidently have some knowledge of the law of contracts, the essentials of which were so ably dealt with in an address given by a Toronto barrister before the Toronto Branch of The Institute in December 1933.[1] Their attention should also be called to the Standard Forms of Construction Contract which have been prepared for, and recently issued by, the Canadian Construction Association, and are now available for public use. These forms[2] have been submitted to and approved by the Council of The Institute as applying to contracts for work to be supervised by an engineer, and (with the word "architect" replacing the word "engineer") also have the approval of the Royal Architectural Institute of Canada in the case of construction coming under an architect's direction.

There are two forms, dealing respectively with work to be done for a stipulated sum, and work to be done when the contractor's remuneration is a percentage of cost or a fixed fee. Each form consists of two parts, the Agreement between the Owner and the Contractor, and the General Conditions of the Contract.

The principal clauses of the Agreement relate to the contractor's undertaking for the proper and complete performance of the work by him and his sub-contractors, the owner's undertaking to pay the contractor, and, in the case of a cost-plus contract, the exact way in which the cost shall be computed.

As regards the General Conditions, these first define the contract documents, including the drawings and specifications, and set forth the respective responsibilities of the engineer and the contractor as regards these. The engineer's powers and duties are next stated as to the interpretation of the contract and the supervision and inspection and approval of the work. The clauses which follow deal with the correction of faulty work, the protection of the owner's property and the work while in progress, insurance, and the powers of the engineer to stop the work in an emergency. The difficult subject of changes or additions is next taken up, followed by various provisions regarding the engineer's certificates, payments, liens, and the contractor's responsibilities in connection with permits and patent fees. The circumstances are stated under which the owner can take over the work or terminate the contract, or under which the contractor can cease work in certain eventualities; the conditions applying to sub-contractors in relation to the owner, contractor and engineer are given, and the final clauses deal with the settlement by arbitration of disputes between the owner, or the engineer on his behalf, and the contractor.

The contract form relating to work done on a basis of cost-plus percentage or fixed sum necessarily differs somewhat in detail from the stipulated sum contract, and omits certain clauses which are found in the latter, but which are not applicable on a cost-plus basis. It contains also certain clauses regarding the engineer's powers, the purchase of materials by the contractor, and methods of accounting and

[1] H. D. Anger, The Law of Contracts and Bonds of Particular Application to Engineers and Architects, Engineering Journal, May 1934.

[2] Canadian Standard Forms of Construction Contract.—Copies can be had from The Manager, Canadian Construction Association, 717 Ottawa Electric Building, Ottawa, Ont.

audit which are not required in the other form, since the ways of remunerating the contractor, and therefore his responsibilities, are different in the two cases.

Both these forms of contract embody the results of years of experience in construction under Canadian conditions on the part of representative engineers, architects and contractors. Their provisions have thus been tried and found to work satisfactorily. Some requirements commonly found in documents of this kind have been omitted or modified as being causes of possible difficulty or dispute. For example, in the stipulated sum contract, the time-honoured statement that "in case of dispute the engineer's decision shall be final" does not appear. Instead it is provided that the engineer is to "decide on questions arising under the contract documents" and if the contractor considers that such decision has been given in error, he notifies the engineer before proceeding to carry it out. Should the engineer maintain his decision, the work is to proceed and any question of cost is to be decided by arbitration.

With contract forms available which have been so carefully prepared, and which are based on such wide experience, good reasons would have to be given by an owner or contractor for departing materially from their provisions, at least in any case of work to which either form is really applicable. Those who are opposed to any kind of standardization, and look upon uniformity as a thing to be abhorred, will perhaps object to these forms as an attempt to impose still more hidebound regulations upon a suffering community. This is not the case, for while the standard forms are now available for the convenience and use of the public, there is no legal compulsion to use them. Their employment offers many obvious advantages. For example, when such forms come into general use, an owner contemplating construction, or a contractor proposing to tender for work, will be under no uncertainty as to the effect of the various clauses of a document with which he is already familiar. The disputes which occasionally arise as to the precise meaning of some clause specially written for an individual contract will no longer occur. Contractors will be able to prepare their tenders in the knowledge that the work will be carried out under legal conditions and restrictions to which they are already accustomed. Engineers will be able to advise owners with the assurance that the relations between the owner and the contractor will be clearly defined, so that each party knows beforehand exactly what are his rights and obligations.

There will no doubt be a few cases in which these forms are not applicable as they stand. Such instances, however, will be relatively few, and the Canadian Construction Association and the two organizations which have given approval to the forms in question are to be congratulated on making available to the Canadian public such clear-cut and well tried documents.

Entrance and Transfer Fees

At its meeting on October 6th, 1933, Council thought it desirable to waive the existing provisions of Section 32 of the By-laws, and as a temporary measure reduced the entrance fee for all classes of membership to $5.00. On the recommendation of the Finance Committee, Council has decided to continue this policy for the present. Thus, until further notice, the entrance fee, which should accompany applications for admission as Member, Associate Member, Junior or Affiliate, will be $5.00. There is no entrance fee for admission as Student.

While this reduced entrance fee is in force, there will be no transfer fee, except for transfers from the class of Student, in which case the sum of $5.00 is payable. This follows from the provisions of Section 38 of the By-laws.

The Bank of Canada Directorate

As soon as the method of electing directors for the Bank of Canada was announced, the Council of The Institute, naturally desirous that the engineering profession should have adequate representation on the board, appointed a committee to look into the matter. That committee secured the names of four members of The Institute who were eligible and had been duly nominated, and recommended that their candidature should be endorsed by The Institute.

At its meeting on December 14th the committee report was approved and Council unanimously decided to support the candidature of those members, directing that this should be announced in The Journal with the suggestion that members who are shareholders in the Bank would be well advised to vote for the candidates in question, namely:

W. D. Black, M.E.I.C., Vice-President and General Manager, Otis-Fensom Elevator Company, Hamilton.

J. W. Hughson, A.M.E.I.C., W. C. Hughson and Sons Limited, Ottawa.

W. L. R. Stewart, A.M.E.I.C., Managing Director, The Stewart Construction Company Limited, Sherbrooke, Que.

Arthur Surveyer, M.E.I.C., Consulting Engineer, Montreal.

A brief account of the career of each of these gentlemen follows.

W. D. Black, M.E.I.C., graduated from the University of Toronto with the degree of B.A.Sc. in 1910, and was subsequently resident engineer on the Kentucky River high bridge for Gustav Lindenthal. In 1911 he joined the staff of the Otis-Fensom Elevator Company Limited as manager for Quebec and the Maritime Provinces. In 1918 he was engineer in charge of munitions production for the company, and later, until 1921, he was manager of construction. In 1921-1925 Mr. Black was works manager for the same company, and in 1926 became vice-president and managing director, which office he has held until the present time.

Mr. Black is president of the Industrial Relations Committee of the Canadian Manufacturers' Association, and was this year appointed employers' delegate to the International Labour Conference at Geneva. He has been actively associated with the efforts of the Canadian Construction Association to promote revival in the construction industry.

J. W. Hughson, A.M.E.I.C., graduated from McGill University with the degree of B.Sc. in 1912. From February 1916 until November 1918 he served in the Canadian Expeditionary Force, and in 1917-1918 was with the Canadian Forestry Corps in France, having the rank of Captain. After the war he was for a year in Brooklyn, N.Y., as engineer in charge of Tidewater Paper Mills, and returning to Canada in 1920 he was for some time with the Montreal Engineering Company Limited. In 1923 he became associated with the financial firm of W. C. Hughson and Sons Limited, Ottawa, and has remained with that organization until the present time.

W. L. R. Stewart, A.M.E.I.C., graduated from the Royal Military College, Kingston, Ont., in June 1920. Following graduation he was for a time with Lockwood Greene and Company as assistant on construction work. In 1921-1922 he was with the Abitibi Power and Paper Company and Morrow and Beatty Limited, as assistant resident engineer on the Twin Falls power development, and on townsite development work at Iroquois Falls and Kapuskasing, Ont. He was later engineer on building construction work for the Robert Reford Company, Montreal, and in 1924 was field engineer with the Newton Dakin Construction Company Limited, remaining with that firm until 1927, first as office engineer and estimator at the Montreal office, and then as manager of the Sherbrooke office and district. In March

1927 he founded and became managing director of the Stewart Construction Company Limited, at Sherbrooke, Que. and has held that office up to the present time. He has served as vice-president of the Canadian Construction Association.

Dr. Surveyer graduated from Laval University with the degree of B.A. in 1898, and from the Ecole Polytechnique with the degree of B.A.Sc. and C.E. in 1902. In 1924 the degree of Doctor of Engineering was conferred upon him by the Rensselaer Polytechnic Institute. He commenced his professional career with the Public Works Department of Canada in 1904, and remained with that Department until 1911 when he entered private practice in Montreal. In 1912 he reported to the Federal government on the effect of the Chicago Drainage Canal diversion on the harbours of the St. Lawrence river and the Great Lakes. He was later associated in making a joint report on the advisability of the government guaranteeing the bonds of the Montreal Tunnel Company and the Montreal Central Terminal Company. During his career Dr. Surveyer has been employed in a consulting capacity by many important cities in the province of Quebec as well as the Department of Public Works, Canada, the Department of Lands and Forests, Quebec, and the Quebec Streams Commission.

Dr. Surveyer has rendered voluntary service for a number of years on the Research Council of Canada. He became President of The Institute in 1924 on the death of W. J. Francis, and served until the end of 1925.

A Proposed Structural Welding Bureau for Canada

The structural fabricating firms of Canada, realizing the great progress that has been made during the past few years in the important art of electric welding and that this art is a very useful tool in the processing of structural units when in the hands of competent operators and under the guidance of technically trained supervisors, have foreseen the necessity of some controlling body for the certification of operators, supervisors and shops.

The rapid growth in the application of welding to structural work is the result of a demand by purchasers, architects and engineers throughout the country, also by the general public for quiet erection, particularly in the large cities.

Specifications covering welded structural building frames, together with a code covering the qualification and testing of operators, are at the present time being formulated by the Canadian Engineering Standards Association. For the protection of the public, it is very necessary that there should be some controlling body for the operation of such a code, through which purchasers and engineers can be assured of good workmanship, combined with open competition. Further, there is the necessity of control to safeguard first class fabricating firms against unfair competition and to prevent an undue distrust in welded fabrication. The public, purchaser, engineer and fabricator can only be adequately protected by the operation of some competent controlling body.

At a meeting of fabricators, representatives from the steel mills, and the engineering profession, held in Toronto on December 13th, 1934, it was decided:—

(1) To form a Structural Welding Bureau.
(2) That the Bureau should control the operation of the Code.
(3) That the membership of the Bureau should be open to all first class fabricators and have the active support of public engineering opinion.
(4) That the Bureau should be put into effective operation without undue delay and as soon as the Code is formulated and accepted by the C.E.S.A.

Such a code and governing authority are not new in this country or the United States and have for instance been in operation for some years in Canada in connection with the fabrication of pressure vessels under the control of the Provincial Departments of Labour. This could also be done with regard to structural welding fabrication, but it was felt that a great deal of time would be lost while provincial laws were being enacted, and there would also be the possibility of having to work under a different code for each province; whereas, if the matter were made nationwide by the formation of a Dominion-wide Structural Welding Bureau, the provinces would adopt the code and operate it if at any time they should see fit.

Efforts have also been made in the United States by some members of the American Welding Society to establish a code and governing authority for structural welding. In Australia, where through lack of adequate riveting facilities, the art of welding has been developed intensively, they have a well-drawn specification and rigid requirements for the training and certification of both operators and supervisors.

At the meeting held in Toronto a provisional committee was formed consisting of Mr. R. K. Palmer, M.E.I.C., of the Hamilton Bridge Company; Mr. R. A. Spencer, A.M.E.I.C., of the Canadian Bridge Company; Mr. C. E. Disher of the Disher Construction Company, and Mr. F. Newell, M.E.I.C., of the Dominion Bridge Company Limited, as Chairman and Secretary, for the purpose of organizing the Bureau and placing it in operation as soon as the code has been formulated and passed by the Canadian Engineering Standards Association.

Meeting of Council

A meeting of the Council of The Institute was held at Headquarters on Friday, December 14th, 1934, at eight o'clock p.m., with President F. P. Shearwood, M.E.I.C., in the chair, and four other members of Council present.

After consideration it was unanimously resolved that The Institute recommend to the Kelvin Medal Award Committee that the 1935 award of the medal be made to Sir James Alfred Ewing.

Council considered and approved the report of The Institute's committee appointed by Council to make recommendations on questions dealing with the letting of contracts for public works, which had been referred to The Institute by the National Committee on Sound Public Finance, a body sponsored by the Canadian Chamber of Commerce, and it was decided to forward it to the Canadian Chamber of Commerce as a report from the Council of The Institute.

A letter from the chairman of the Winnipeg Branch was submitted stating that the proposals for joint executive control of the Winnipeg Branch of The Institute and the Association of Professional Engineers of Manitoba, had not been approved by the Council of that Association. Accordingly it would not be possible to carry out the proposals, and it had been necessary for the executive committee of the branch to drop the amendments to the branch by-laws which had been approved by Council at its meeting on November 16th. This announcement was noted and received by Council with great regret.

Three resignations were accepted, four requests for reinstatement were approved, a number of members were replaced on the active list, three Life Memberships were granted, and a number of special cases were considered.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Assoc. Members	2	Assoc. Member to Member	3
Affiliate	1	Junior to Assoc. Member	1
Students admitted	5	Student to Junior	1

The Council rose at eleven twenty-five p.m.

OBITUARIES

Edward Arthur Hoare, M.E.I.C.

With the death at Quebec, Que., on November 23rd, 1934, of Edward Arthur Hoare, M.E.I.C., The Institute loses one of its oldest members, who joined the Canadian Society of Civil Engineers at its formation nearly fifty years ago.

Mr. Hoare was born in Hampshire, England, on December 8th, 1846, receiving his education at a preparatory school in London and the King's School in Rochester, and his engineering training at the Royal Engineers' Depot, Chatham, and in the office of T. W. Wilson, civil and mechanical engineers, in London.

Coming to Canada in 1868, his first appointment was as assistant engineer with the Toronto, Grey and Bruce Railway, which position be held until 1870 when he became resident engineer for the Great Western Railway, the Wellington Grey and Bruce Railway, and assistant engineer for the London, Huron and Bruce Railway. In 1873-1884 Mr. Hoare was resident engineer for the North Shore Railway, and chief assistant to the chief engineer of the same line when it was transferred to the Quebec Government Railways. From 1884 until 1898 he was superintendent engineer for H. J. Beemer, contractor, on railway and waterworks construction, and chief engineer of the Quebec and Lake St. John Railway, and of the Great Northern Railway (from the main line of the Quebec and Lake St. John Railway to Hawkesbury, Ontario). In 1898 Mr. Hoare was appointed chief engineer of the Quebec Bridge and Railway Company, and in 1909 became district engineer of the Quebec Terminals for the National Transcontinental Railway. In 1913 he was appointed superintending engineer for the Federal Department of Public Works, in charge of the St. Charles river harbour improvement works, and held that post until his retirement in 1921.

Mr. Hoare was a Member of the Institution of Civil Engineers (Great Britain). He joined The Institute (then the Canadian Society of Civil Engineers) as a Member on January 20th, 1887, and was made a Life Member on October 17th, 1930.

Lewis Wynne Wynne-Roberts, M.E.I.C.

It is with great regret that we place on record the death at Toronto, Ontario, on December 8th, 1934, of Lewis Wynne Wynne-Roberts, M.E.I.C.

Mr. Wynne-Roberts was born at Caernarvon, North Wales, on November 14th, 1891, and was educated at the South African College School, Capetown, the county school Towyn, Wales, 1907-1909, and the University of London, London, graduating from the latter institution in 1912 with the degree of B.Sc.

Coming to this country in that year, Mr. Wynne-Roberts went to Regina, and until November 1915 was assistant engineer with the Board of Highway Commissioners of the government of Saskatchewan, engaged on bridge construction. At the beginning of 1916 he was with the Ministry of Munitions in England, and from April of that year until November 1919 served with the Royal Engineers as follows: in India as instructor in military engineering; in Mesopotamia with a Sapper Field Company, and in Persia as field engineer on roads and bridges. Returning to Canada, Mr. Wynne-Roberts was engineer in charge of erection of the Barrett plant at Ashbridge's Bay, Toronto, until May 1920, and later, until May 1922, was resident engineer, with the Department of Public Highways, Ontario, on bridge and highway construction. He then became assistant engineer with Frank Barber and Associates, Toronto, and in April 1923 joined the firm of Wynne-Roberts, Son and McLean, consulting engineers, designing and supervising the construction of water supply systems, sewerage systems, sewage disposal plants, pavements, etc., and being engaged on numerous investigations and appraisals of an engineering nature.

Mr. Wynne-Roberts was elected a Junior of The Institute on February 10th, 1914, an Associate Member on July 22nd, 1919, and a Member on April 28th, 1933. He took an active interest in Institute affairs, and in those of the Toronto Branch of which he was chairman in 1928-29. He represented the Toronto Branch on the Council during the years 1930, 1931 and 1932.

L. W. WYNNE-ROBERTS, M.E.I.C.

His untimely death removes one of the most promising of our younger engineers and leaves a gap in their ranks which will be difficult to fill.

Abram Silas Code, A.M.E.I.C.

Regret is expressed in placing on record the death of Abram Silas Code, A.M.E.I.C., at Alvinston, Ontario, on November 23rd, 1934.

Mr. Code was born at Alvinston on September 18th, 1873, and after serving three years with Messrs. Coad and Robertson, Glencoe, Ont., was admitted to the Association of Ontario Land Surveyors in 1896. In the same year he was assistant surveyor for the townships of Archibald and Tupper, and in 1897 he became township engineer for Brooke Township. In 1899 Mr. Code was assistant engineer for the Tilsonburg, Lake Erie and Pacific Railroad, and in 1901 he was engaged on the erection of a steel bridge for Lambton county over the Sydenham river. In 1902 he built two steel bridges for Brooke township, devised a steel bridge for Petrolia, Ont., and made a survey for the Ontario government of Lundy township. He was later town engineer for Watford, Alvinston, Thedford and Oil Springs. Mr. Code was subsequently in private practice in Alvinston, and was a recognized expert in drainage work, having laid out and supervised many drainage projects in south-western and eastern Ontario.

Mr. Code became an Associate Member of The Institute (then the Canadian Society of Civil Engineers) on April 23rd, 1903.

XIVth International Housing and Town Planning Congress

The XIVth International Housing and Town Planning Congress is to be held in London, England, in July 1935. The exact date will be announced shortly, with a preliminary programme. The principal subjects for discussion will be: Rehousing the People; Positive Planning, and Planned Rural Development.

The President of the Congress will be the Right Hon. Sir Edward Hilton Young, M.P., British Minister of Health.

The new developments in housing and town planning in England are of the greatest interest and importance and facilities have been promised that will make the Congress one of the most valuable that the Federation has held.

PERSONALS

A. S. Holder, S.E.I.C., has recently joined the staff of Canadian Industries Limited at Shawinigan Falls, Que. Mr. Holder graduated from the Nova Scotia Technical College this year with the degree of B.Sc.

G. H. Duggan, M.E.I.C., president of the Dominion Bridge Company Limited, and the Dominion Engineering Works, Ltd., has been appointed a vice-president of the Royal Bank of Canada. Mr. Duggan has been a director of that institution since 1916.

Mr. Duggan is a director of the Steel Company of Canada, the Dominion Steel and Coal Corporation, the Montreal Trust Company, the Wayagamack Pulp and Paper Company, and a number of other industrial concerns. He was a director and chief engineer of the St. Lawrence Bridge Company when that company designed and constructed the superstructure of the Quebec bridge.

In 1930 Mr. Duggan was the recipient of the Sir John Kennedy Medal, which is awarded by The Institute not for the presentation of a paper, but as a recognition of outstanding merit in the profession, or of noteworthy contribution to the science of engineering.

James A. Knight, M.E.I.C., has recently been appointed to the staff of Brunner, Mond (Canada) Limited at Toronto, Ont., and will be engaged in research work and the sales development of calcium chloride.

Mr. Knight graduated from the University of Toronto in 1914 with the degree of B.A.Sc., and shortly afterwards went overseas with the Canadian Engineers. Returning to Canada in 1919 he was with the Hydro-Electric Power Commission of Ontario as designing draughtsman until 1926 when he was appointed assistant testing engineer. In 1928 Mr. Knight joined the staff of the Alcoa Power Company as hydraulic engineer on the Chute-a-Caron development, remaining with that company until 1930 when he became designing engineer with the Beauharnois Construction Company at Beauharnois, Que.

Mr. Knight has taken an active interest in the affairs of The Institute, having served on the Executive committee of the Toronto Branch for several years, and as vice-chairman of the Branch in 1928.

M. V. Sauer, M.E.I.C., has been appointed hydraulic engineer and general superintendent of generating stations for the Montreal Light, Heat and Power Consolidated, Montreal.

Mr. Sauer is a graduate of the School of Practical Science, University of Toronto, of the class of 1901, and took a post graduate course in 1902, receiving a fellowship in 1903. Following graduation, Mr. Sauer was with the Ontario Power Company at Niagara Falls, first as draughtsman and later as assistant to the mechanical engineer. He was appointed chief designer of the Niagara Falls Power Company, Niagara Falls, N.Y., in 1905, and the following year was construction engineer for the Iroquois Construction Company, Buffalo, N.Y. In 1907 Mr. Sauer again became associated with the Ontario Power Company, as chief designer, then as mechanical assistant to the engineer-in-charge, and subsequently, in 1912, as mechanical engineer in full charge of design, field and inspection department. He was later connected with the Hydro-Electric Power Commission of Ontario, and occupied a prominent position on the design and construction of the Queenston-Chippawa power development. In 1923 Mr. Sauer became hydraulic engineer for Canadian Vickers Limited, with headquarters at Montreal, and in 1925 he was transferred to Toronto, and was chief engineer of the hydraulic department of the then recently incorporated Vickers and Combustion Engineering Limited. In 1926 he was appointed vice-president of William Hamilton, Limited, at Peterborough, Ont., holding that office until 1928 when he went to Winnipeg, Man., as designing engineer for the Winnipeg Electric Company. In December 1929 Mr. Sauer returned to the east as hydraulic engineer for the Beauharnois Construction Company at Beauharnois, Que., and in March 1934 he was appointed assistant chief engineer for the Beauharnois Light, Heat and Power Company, from which position he has now resigned.

GROTE STIRLING, M.E.I.C.

Grote Stirling, M.E.I.C., Appointed to Cabinet

The Hon. Grote Stirling, M.E.I.C., has been appointed Minister of National Defence and acting Minister of Fisheries in the Bennett Cabinet.

Mr. Stirling was born at Tunbridge Wells, England, on July 31st, 1875, and was educated at University College School, London, and the Crystal Palace School of Engineering, graduating from the latter institution in 1895. Following graduation he was for several years occupied in railway work as assistant resident engineer and resident engineer with the Midland and Great Northern Joint Railways, and in 1907-1911 he was in private practice in Norfolk, England. Coming to this country in 1911, Mr. Stirling was resident engineer during 1912-1913 on the construction of the Black Mountain Water Company's main irrigation system at Kelowna, B.C., and has since been engaged in private practice in that part of the country.

In 1901 Mr. Stirling was elected an Associate Member of the Institution of Civil Engineers, and joined The Institute as a Member in 1927.

He was first elected to Parliament in November 1924, when the seat at Yale, B.C., was vacated by the death of J. A. McKelvie, and he was re-elected in the three succeeding general elections of 1925, 1926 and 1930.

Sir Herbert S. Holt, M.E.I.C., has relinquished the presidency of the Royal Bank of Canada and now becomes chairman of the board and chairman of the executive committee. In assuming the newly created position of chairman of the board, Sir Herbert will continue a connection with the Royal Bank which began nearly thirty years ago with his election as a director in February 1905. He was appointed vice-president of the bank two years later, and became its president on November 16th, 1908.

Born in Ireland in 1855, Sir Herbert Holt was educated in that country, and on coming to Canada in 1873, he became an assistant engineer on the Toronto Water Works. From December of that year until May 1874 he was assistant engineer and transitman on a topographical survey for the Credit Valley Railway, and following this became transitman and assistant engineer on the Victoria Railway. In the next year Sir Herbert was division engineer on the

Lake Simcoe Junction Railway, and he later returned to the Credit Valley Railway as engineer in charge of track, buildings and bridges on 93 miles. From May 1880 to March 1883 he was engineer of the railway, and in addition from February 1882 he was engineer in charge of the draughting office of the Ontario and Quebec Railway. From March 1883 to July 1884 Sir Herbert was assistant superintendent of construction and engineer in charge of construction of track, buildings and bridges on 500 miles of the Canadian Pacific Railway, and in 1885-1886 he was contractor for heavy tunnel and rock work on the Rocky Mountain division of the Canadian Pacific Railway. In 1886 he was contractor on the Ontario and Quebec Railway, and in 1887 contractor and engineer for 40 miles of the Winnipeg and Hudsons Bay Railway. Later Sir Herbert came east, and acquiring control of the Montreal Gas Company and the Royal Electric Company, proceeded to build up around these two companies the organization that is now known as Montreal Light, Heat and Power Consolidated. Sir Herbert Holt's career as a banker dates from 1902 when he became president of the Sovereign Bank, from which he resigned to become a director of the Royal Bank of Canada. He received the honour of knighthood in 1915.

He is one of our senior members, having joined The Institute (then the Canadian Society of Civil Engineers) as an Associate Member in 1889, transferring to Member in December of the same year.

ELECTIONS AND TRANSFERS

At the meeting of Council held on December 14th, 1934, the following elections and transfers were effected:

Associate Members

BERRY, Theodore Victor, B.A.Sc., (Univ. of B.C.), Secretary-Treasurer, Vancouver and District Joint Sewerage and Drainage Board, Vancouver, B.C.

TREMBLAY, Solyme Nérée, (Member by exam., Corpn. Prof. Engrs. Que.), engr., Quebec Streams Commission, Montreal, Que.

Affiliate

WINDER, John, chief electrn. and elect'l. engr., Molsons Brewery Limited, Montreal, Que.

Transferred from the class of Associate Member to that of Member

BERRY, Albert Edward, B.A.Sc., M.A.Sc., C.E., Ph.D., (Univ. of Toronto), director, Sanitary Engrg. Divn., Ontario Dept. of Health, Toronto, Ont.

COLHOUN, George A., Grad. S.P.S., (Univ. of Toronto), designing engr., Hamilton Bridge Company, Hamilton, Ont.

MOUNT, Wilfred Rowland, (Camborne Sch. of Metalliferous Mining), res. engr., City of Edmonton, Alta.

Transferred from the class of Junior to that of Associate Member

HALL, Stewart William Sheridan, B.A.Sc., (Univ. of Toronto), plan examiner, City Bldg. Dept., Toronto, Ont.

Transferred from the class of Student to that of Junior

WISHART, William Donald, B.Sc. (E.E.), (Univ. of Man.), Lieut., R.C.C.S., Camp Borden, Ont.

Students Admitted

BURRI, Henry William, (McGill Univ.), 1581 St. Andre St., Montreal, Que.

COUSINEAU, Louis Philippe, (Ecole Polytechnique), 4603 St. Catherine St. East, Montreal, Que.

DEMBITZKY, Thomas, (Univ. of Toronto), 206 Royce Ave., Toronto, Ont.

LONDON, Woodrow Parker, B.Sc. (E.E.), (Univ. of N.B.), 174 Waterloo St., Saint John, N.B.

TRUDEL, Louis, (Ecole Polytechnique), 3450 Berri St., Montreal, Que.

CORRESPONDENCE

The Secretary,
Engineering Institute of Canada,
2050 Mansfield St.,
Montreal, Que.

Vancouver, B.C.
December 20th, 1934

Sir:—

The writer has been much interested in the article by J. B. Macphail, A.M.E.I.C., in the December issue of The Journal, in which he treats of The Hydrostatic Cord.

In the Brooks aqueduct, designed twenty years ago by the writer, the trough is built to this curve-variety as shown in the author's Fig. 2g. In the Brooks aqueduct, the tangents at points of suspension slope at 60 degrees to the horizontal.

Prior to undertaking the design, the writer attempted a mathematical analysis of the curve and arrived at a differential equation similar to that of the author. He realized that integration would involve elliptic functions but his mathematical equipment failed him at that point. However, knowing that the curve was one form of The Elastica, he worked out a method of determining the *X-Y* co-ordinates by a mechanical process. Preliminary work to determine the best form—i.e., the best tangent angle—was done with a piece of clock spring and a planimeter. The final determination of the co-ordinates was made full size with a spline of clear fir ¾ by 3 inches supported on bicycle balls to eliminate friction. After the spline was bent to approximate shape, the platform was jarred until apparent movement ceased. The co-ordinates were then measured and recorded. This was repeated several times with different splines. Each spline was used four times—turned end for end and inside for outside—and, while differences in the co-ordinates were observed, none were of great magnitude. The average of all was finally adopted. Later, the writer worked out an approximate method of calculating the co-ordinates from the property that the radius of curvature varies inversely with the depth of the point below the surface. This calculation checked, but did not alter the values from the splines.

The shell of the aqueduct is concrete with tension reinforcement in two layers. The question of stresses under a partial load—partially filled—came up. These could be calculated approximately and appeared to be moderate but, to make sure, a full-size model was tested. Deflections were found very small, and the apparent stresses much less than were calculated.

H. B. Muckleston, M.E.I.C.

BOOK REVIEWS

Die Castings

By Herbert Chase, John Wiley and Sons, New York, 1934. 6 by 9¼ inches, 264 pages, $3.50. Cloth.

Reviewed by H. P. Ray*

For anyone wishing to keep abreast of the times, as to the progress made of recent years in the art of die casting, a perusal of this book would be well worth while.

To one who had trouble with some of the die castings produced a decade or two ago, it is very interesting to learn that die casters have now discovered the cause of such defects as dimensional instability, and intergranular corrosion, and take such precautions with their alloys that the faults too often prevalent in the early die castings have been practically eliminated.

The first third of the book contains many halftone illustrations of die castings made for various applications: automotive, household, office and store, machine, electrical, instrument, hardware, liquid and gas, toy and sporting and ornamental. The footnotes under the illustrations are very complete in giving information as to the basic alloy used for the part illustrated, and, if relevant, the reason for the choice is also stated.

The next chapter deals with alloys: zinc, aluminum, copper, tin, lead and magnesium. Several tables give both the composition and physical properties of alloys codified by the A.S.T.M. or the S.A.E. and the same information on alloys commonly used but not yet codified by a national society.

A chapter on the design of die castings is well illustrated with line drawings of typical castings. The main dimensions and tolerances on particular dimensions give one a good idea of the size of castings, and the degree of accuracy at present attainable. The author wisely stresses the desirability of complete co-operation between the customer and die caster. Co-operation usually reacts to the benefit of both parties, particularly the customer, for the die caster has many stunts in his bag of tricks.

A chapter on specifications, inspection and tests fully covers these details.

The last chapter gives a comprehensive outline of the various types of finishes available for die castings. It covers the preparation of the surface to receive the subsequent finish; the technique of plating with nickel, chromium, copper, silver and gold; and the application of the organic finishes: paints, varnishes, enamels, lacquers and japans.

Industrial Standardization

By John Gaillard, the H. W. Wilson Company, New York, 1934. 6¼ by 9 inches. 123 pages. $2.00. Cloth.

Reviewed by B. Stuart McKenzie, m.e.i.c.*

This book is an engineering thesis written by the author in preparation for a higher engineering degree in a European university. He has, for some years, occupied the position of mechanical engineer on the staff of the American Standards Association, and as such has been responsible for the mechanical features of A.S.A. specifications and has been the representative of that organization at conferences of the International Standards Association held at various European centres. He is therefore well equipped to speak with authority on standards from both the American and the European point of view.

Starting with the evolution of types of standards in the early stages, he traces the development through different types of industry, outlining the essential functions of standardization and discussing technical and managerial standards. He discusses also the benefits of standardization in company organization, with special reference to design, manufacture, inspection and testing, giving information on the technique of standardization and simplification. The author deserves special mention for the summary which appears at the conclusion of each chapter.

Chapter I, on the evolution of standardization, notably the discussion of the human factor, can be commended to the thoughtful consideration of those who have an honest desire to inform themselves on the underlying principles of standardization; principles which are all too seldom appreciated by those in whose interests the work is prosecuted.

In Chapter II, the author cites the case of the automobile industry, one of the most outstanding examples of what intelligent standardization can accomplish in the mechanical field, and he makes special reference to the work of the Society of Automotive Engineers.

In Chapter III, the author enunciates a comprehensive definition of a standard and proceeds to discuss it in detail under two main headings, technical and managerial, the first dealing with mechanical or scientific matters and the second with an even more important feature, the human element.

Chapter IV, is somewhat technical, dealing with interchangeability, limits and fits and tolerances, and the standpoint of the mechanical engineer is here somewhat emphasized.

In Chapter V, the author traces the development of standardization mainly in the United States, giving some data on expenditures on this work. Reference is made to the work of Mr. F. W. Taylor, who as far back as 1895 set forth his principles of shop management, which were at that time received with little enthusiasm by engineers and industrialists. Now, however, these principles have proved to be essentially sound as evinced by the increasing interest which trade associations are taking in the work of industrial standardization.

Chapter VI deals with standards in a manufacturing concern, indicating the relation between a standards department and the other departments involved and stressing the benefits accruing to each department. This matter is considered under three main heads, design, manufacturing practice, inspection and testing.

In the concluding chapter the author presents a working plan for a standards department. In elaborating on this plan he deals with company standardization, the position of a standards department, and the technique of standardization work, including redesign and simplification. The summary at the end of this chapter is specially recommended for careful reading.

This book can be heartily recommended to anyone who has a sincere desire for information on an industrial movement which was never more valuable to industry than at the present time.

*Secretary, Canadian Engineering Standards Association, Ottawa, Ont.

Lighting Calculations

By H. H. Higbie, John Wiley and Sons Inc., New York, 1934. 6 by 9¼ inches, 503 pages. Diagrams, tables. $5.00. Cloth.

Reviewed by H. J. MacLeod, m.e.i.c.*

The author of this book is professor of electrical engineering in the University of Michigan and a past-president of the Illuminating Engineering Society. The book has grown from material compiled to supplement text-books in the teaching of this subject over a period of twenty-five years. It is a comprehensive source-book of lighting data which, the author states, is introduced not as an end in itself, but as a basis for questions and problems and as a means to stimulate interest in the subject and to indicate its significance and importance. The author believes in the problem method of teaching and other teachers of illumination will undoubtedly welcome the large number of practical problems which form a considerable portion of the book. Altogether there are about a thousand problems which are designed for the most part so that they cannot be solved by merely imitating an example.

The book is divided into ten chapters with the following titles: Why Bother about Lighting Calculations? Illumination and Light Flux. Candlepower and Point Source of Light. Brightness. Surface Sources of Light. Linear Sources. Multiplying Light by Reflections in an Enclosure. Utilization Coefficient: Efficiency of the Lighting System. Lamps: Light Generators. Visual Effectiveness of Lighting. These titles indicate the general scope of the book which also contains a large number of references for the convenience of readers who may wish to study particular topics in greater detail. While its main purpose is educational, it contains a large amount of information which should be of value to engineers who are interested in the problems of lighting.

The book is stimulating and imparts something of the author's evident enthusiasm for the subject which has not received the general attention that it unquestionably deserves.

*Professor of Electrical Engineering, University of Alberta, Edmonton, Alta.

BULLETINS

Pumps.—A 32-page booklet received from the Decatur Pump Company, Decatur, Ill., gives particulars of the Burks super-turbine pumps. These pumps are manufactured in a number of sizes and can be utilized for various purposes.

Rock Drills.—A 4-page folder issued by the Worthington Pump and Machinery Corporation, Harrison, N.J. gives details regarding the "Rock Master" rock drilling equipment.

Blowers.—The Roots-Connersville Blower Corporation, Connersville, Ind., have issued an 8-page bulletin which gives the characteristics of standard and heavy duty blowers. Examples of the various kinds of installations are given.

Automatic Switches.—A 48-page folder received from S.A. des Interrupteurs Automatiques, Berne, Switzerland, contains information regarding the installation and maintenance of time and cutout switches, group, staircase, temperature, and remote control switches and thermoregulators.

Blowers.—The Autovent Fan and Blower Company, Chicago, Ill., have issued bulletin No. 88, containing 16 pages, which gives particulars of Type D. Uniblade universal discharge blowers together with performance tables of the various sizes.

Unit Heaters.—Catalogue No. 33, issued by the Autovent Fan and Blower Company, Chicago, Ill., gives tables of capacities for various sizes and steam pressures.

Fans.—A 15-page booklet issued by the Autovent Fan and Blower Company, Chicago, Ill., contains particulars of a number of types of fans for various uses with performance tables.

Concrete.—The Portland Cement Association have issued a 32-page booklet entitled "Cement and Concrete Reference Book—1934" which shows the growth of the cement industry in the United States during the past 60 years, together with graphs and tables illustrating the various phases of this growth such as employment provided, roads and streets paved, road, street and airport maintenance costs, etc.

BRANCH NEWS

Calgary Branch

J. Dow, M.E.I.C., Secretary-Treasurer.
H. W. Tooker, A.M.E.I.C., Branch News Editor.

The first of a series of "Thirty-Minute Addresses" to be given by various members with organized discussion constituted the programme for the meeting held on Thursday evening, November 15th, 1934, at which over thirty members of the Calgary Branch and their friends were present. The addresses presented were:

1. "Farming Problems on Irrigation Projects," by R. S. Stockton, M.E.I.C., superintendent of operation and maintenance, Western Section, Department of Natural Resources, Canadian Pacific Railway.
2. "Air Conditioning and Central Heating," by W. B. Trotter, A.M.E.I.C., president and manager of Trotter and Morton Ltd., contractors.

Farming Problems on Irrigation Projects

The use of land in the dry belt of Alberta and Saskatchewan is of outstanding importance and is an engineering as well as a farm problem. In this great area, nearly 400 miles, east and west, and 200 miles wide, there are millions of acres of prairie soil that have been broken by the plough and continuously farmed for grain production. This has resulted in reduced fertility and drifting soil.

Problems of drifting soils extend into the area of greater rainfall and the remedies that have been proposed are as follows:

(*a*) Strip farming for grain, cover crops, and proper cultural practices that will keep the soil furrowed or rough.
(*b*) Building up humus by seeding large areas to native and tame grasses as a permanent method of utilizing the land and also a crop rotation with grains.
(*c*) Carrying a reasonable number of live stock on the farms and using the manure to build up the soil.
(*d*) Conservation of the available run-off water from all streams, rivers and all drainage areas and using it as far as practicable to promote plant growth.
(*e*) The planting of trees and shrubs to break winds.
(*f*) The scientific and careful classification of the land for its best use.
(*g*) The introduction, selection, breeding and propagation of plants most suitable to our climate conditions.
(*h*) Reducing and adjusting land taxes to encourage proper land use and making up any deficiency in necessary tax revenue by increasing the tax on expenditures and dividing the increase as required.

Irrigation and water conservation deserve study and analysis, also the working out of practical reforms should be considered, as well as the further development and safeguarding of our great natural resources. A planned development based on technical surveys and information of the most scientific and complete order would be of the greatest benefit to this vast region.

Those taking part in the discussion were P. J. Jennings, M.E.I.C., O. H. Hoover, A.M.E.I.C., and M. W. Marshall, M.E.I.C.

Air Conditioning and Central Heating

Air conditioning has been defined as the simultaneous control of the temperature, moisture content, cleanliness and motion of the air in an enclosure. It is the interplay of temperature and humidity that complicates the problem of conditioning and both must be considered if comfortable living conditions are to be obtained.

Actually 45 to 50 per cent humidity is considered a reasonable figure, so that for given temperatures and humidity, the amount of water to be evaporated can be calculated for any space. In round numbers the ordinary home will require from 12 to 20 gallons a day in cold weather. In summer the condition is reversed, high temperatures occur with high humidity, and both heat and moisture have to be abstracted. If the temperature only is dropped the relative humidity may be raised and the room is more uncomfortable than before.

Experiments have defined the comfort zone as being the limits of temperature and humidity between which 60 per cent or more of the occupants will feel comfortable.

The problem is further complicated in public buildings by the variable number of occupants; as for instance theatres, necessitating a complicated system of controls and a measure of hand control in addition.

Filters are necessary to clean air, and are usually mechanical. Either dry or viscous ground glass, steel wool, cheese cloth oiled and many other products are used, some require cleaning others are of the throw-away type.

To fully condition the air in any building it will be necessary to have equipment to move heat, cool, filter and moisten the air, and to do all this under strict control which may be done by central installation or by individual units.

Mr. Trotter's lecture was illustrated by a number of interesting slides.

Those taking part in the discussion were Messrs. W. S. J. Miller, A.M.E.I.C., J. Haddin, M.E.I.C., H. J. McEwen, A.M.E.I.C., and W. Adams, following which Mr. J. H. Bird proposed a very hearty vote of thanks to both speakers. The meeting adjourned at 10.15 p.m.

Hamilton Branch

A. Love, A.M.E.I.C., Secretary-Treasurer.
V. S. Thompson, A.M.E.I.C., Branch News Editor.

The Hamilton Branch held a meeting in the Science Hall of McMaster University on November 21st, 1934, when H. B. Stuart, A.M.E.I.C., chairman of the Branch, presided. Owing to several other counter-attractions, the attendance was not up to the usual number, about sixty being present.

W. J. W. Reid, A.M.E.I.C., chairman of the Meetings and Papers Committee, introduced the speaker of the evening, T. Stanley Glover, A.M.E.I.C., a member of the Branch Executive. The Meetings and Papers Committee has presented a variety of subjects at the Branch meetings, and at this meeting the speaker related his experiences in Nigeria, where he served under the British Colonial Office in the Administrative Department and later in the Department of Public Works.

An Engineer in Nigeria

Nigeria was pictured as one unit of a vast Empire, a Crown Colony, of about the same area as Ontario, peopled by twenty million negroes and possibly four thousand transient whites—government officials, missionaries and merchants.

The geography and economics of the Colony were briefly described, also the available transportation facilities. It was interesting to note the expansion of both rail and road communication, also the development of harbours and docks at the various coastal towns.

Mr. Glover explained the duties that devolved upon a political officer, and how he had been trained for such duties in an intensive course in England prior to leaving for Africa. In the case of certain

crimes such as murder and slave trading, the British were adamant and demanded the full penalty, but with others justice was freely tempered with mercy, and the Administrator was required to possess and use a large amount of common sense as well as a working knowledge of the law.

Speaking of his work as a Public Works Engineer, Mr. Glover told of the difficulty of obtaining proper material and equipment for certain works and how it was necessary very often to apply what could be obtained locally to complete the work. Even with material and equipment available, there was still the labour problem—not the lack of men but the difficulty of keeping them at work. The payroll was also a source of worry and annoyance; as the native worker is paid in specie the Public Works Engineer has to transport heavy loads of shillings and pennies to pay his large army of workers.

The lecture was fully illustrated by slides, and gave the audience a wonderful picture of the nature of the country, the life of the natives and also the life of the Colonial whites.

After a number of questions had been asked, and answered by the speaker, W. Hollingworth, M.E.I.C., expressed his appreciation of the lecture. He remarked on the wide experience which Mr. Glover had, including military service in France, service with Dr. Grenfell in Labrador, in Tropical Africa, and now in Canada. Adjournment was then made to an adjoining room where coffee and sandwiches were served.

Lethbridge Branch

E. A. Lawrence, S.E.I.C., Secretary-Treasurer.
J. E. Hawkins, S.E.I.C., Branch News Editor.

The regular meeting of the Lethbridge Branch, The Engineering Institute of Canada, was held in the Marquis hotel, Saturday, November 10th, 1934.

The meeting was preceded by a dinner with chairman C. S. Donaldson, A.M.E.I.C., presiding and twenty-nine members and guests present.

During the dinner many delightful selections were played by Mr. and Mrs. Geo. Brown and their orchestra. Interspersed with the community singing ably led by G. S. Brown, A.M.E.I.C., vocal solos by Mr. A. Jarvis and Mr. W. Stott were enjoyed.

After thanking the artists for their enjoyable programme the chairman introduced the speaker of the evening, J. M. Campbell, A.M.E.I.C., divisional engineer, Canadian Pacific Railway, Lethbridge Division.

Economics Old and New

Mr. Campbell, in introducing his subject, said that engineers were continuously dealing with the question of economics in the course of their work and have quite properly graduated from a consideration of economics in their own field to that in a broader field.

Economics may be described as a science, and, while it can be founded on laws that will stand the keenest scientific scrutiny, the present economic system is not so founded.

There are those who say that we have always had booms and depressions and let it go at that, but the more intelligent are applying their skill and thought to the prevention of such recurrences.

The speaker then gave a resume of the changes in economic and social systems that had taken place in recent years. Russia broke away from orthodox capitalism. Italy was under the rule of a powerful dictator and industrial activity had been sorely regimented. In Germany another dictator is doing his utmost to dominate the people of a highly industrialized country smarting under the sense of military disaster with what results we do not yet know. Great Britain, with its vast accumulated wealth and experience, would seem to be endeavouring to stabilize currency as far as may be possible, for the purpose of assisting in export and import trade. In the United States there is the New Deal, a scheme that is being enforced by strong arm methods and which can be blocked by the selfishness or desire for freedom of action of a small minority.

Now, continued Mr. Campbell, consider the economic laws laid down by one of the world's wisest men, Moses, and see if they are applicable to our complicated civilization of to-day.

The first law was that there should be no interest on money, and Mr. Campbell here pointed out the distinction between interest and dividends.

The next law was that of inflation. Here the speaker exhibited charts and graphs illustrating his interpretation of the Mosaic law, the effects of the Sabbatical year, the year of the cancellation of money as well as the Jubilee or fiftieth year, when virtually a new start was again made. The ever-widening gap between the buying and selling or the cost and selling price was shown and in this respect the Mosaic law endorsed the Douglas theory. By inflation and periodical cancellation the circulation of money was insured.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

On December 10th, 1934, a supper meeting was held in honour of F. P. Shearwood, M.E.I.C., President of The Engineering Institute of Canada. J. G. Mackinnon, A.M.E.I.C., chairman of the Branch, presided. Mr. Shearwood was introduced to the meeting by C. S. G. Rogers, A.M.E.I.C., who formerly served under him in the Dominion Bridge Company.

In addressing the Branch on Institute affairs, the President stated that he wished to learn the views of members rather than express opinions of his own. Various matters affecting the present and future of The Institute were discussed, including the possibility of amalgamation with the provincial associations. Following the President's remarks, members took part in a discussion. G. C. Torrens, A.M.E.I.C., ex-president of the New Brunswick Association of Provincial Engineers, was of the opinion that the provincial associations would first have to agree among themselves before amalgamation was possible. Such agreement was bound to come although it might take time. When it did come, The Institute could step in and take its place as the national engineering body.

The chairman then called on Mr. J. F. Sexton, who entertained the gathering with "Some Engineering Reminiscences."

The President later addressed the meeting on "Problems of Bridge Erection." With the aid of slides Mr. Shearwood explained the care, ingenuity and skill called for in the erection of structures that mark Canada's development from the Atlantic to the Pacific. Of particular interest, also, were illustrations showing advances being made in the science of welding.

A vote of thanks was tendered the speaker on motion of F. O. Condon, M.E.I.C., seconded by H. J. Crudge, A.M.E.I.C.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

Economics Study Group

The first meeting of this group was held on November 21st, 1934, and it is hoped to arrange weekly meetings throughout the winter season.

Some twenty-five members are attending and the lectures will be handled largely by Dr. D. M. Marvin, economist of the Royal Bank of Canada. The course is self supporting and limited to approximately twenty-five. However, all members of the Branch were given an opportunity of enrolling.

The talks are not elementary and are built up around a discussion of current problems including various aspects of "money," the real effect of international credits, etc., with particular reference to the work of those attending.

Application Engineering on Motors and Control

On November 22nd, 1934, Mr. W. C. Raube, industrial engineer with the General Electric Company, Schenectady, N.Y., gave an address on the choice of electric motors and controls to suit different applications. This was accompanied by a series of interesting charts and graphs.

Previous to the meeting a dinner was given for Mr. Raube in the Oak Room of the Windsor hotel.

E. C. Kirkpatrick, M.E.I.C., acted as chairman.

Electrical Section

On the evening of November 23rd, Mr. Raube continued his talk as given on Thursday evening, making his presentation more technical and using the following points as a basis for informal discussion:

The Characteristics I Want — by the industrial user.
The Motor you Should Use — by the manufacturer.
The Motor you Can Use — by the power company.

X-Ray in Medical Science

Dr. W. Lloyd Ritchie, director of the department of radiology at the Montreal General Hospital, delivered a lecture on November 29th, dealing with the X-ray in Medical Science, indicating the value of the penetrative ray in diagnosis, treatment of fracture and disease, and its importance to the doctor, dentist, surgeon and neurologist. A series of slides of X-ray studies illustrated the talk.

B. R. Perry, A.M.E.I.C., presided.

Junior Section Meeting

The manufacture and use of Safety Glass was the subject covered by a talk and sound film given before members of the Junior Section in the Engineering Building at McGill University on December 3rd. This was arranged through the courtesy of Pilkington Brothers (Canada) Limited.

H. W. Lea, Jr.E.I.C., presided.

Design and Application of Gears

On December 6th, Mr. W. P. Muir, chief engineer of the Mining Metals and Plastics Machinery Department of the Dominion Engineering Works Limited, delivered a paper on the design and manufacture of gear applications covering a very wide field. His talk was fully illustrated with slides and proved to be most interesting. Copies of the paper were available to those present.

R. C. Flitton, A.M.E.I.C., acted as chairman.

Mechanical Section

Messrs. M. J. Berlyn, A.M.E.I.C., and C. D. Bailey on December 10th gave short talks further developing Mr. Muir's paper, this with particular reference to certain phases of modern design of gear teeth and manufacturing methods. A movie film illustrated modern methods of gear cutting and was followed by an interesting informal discussion.

The Relationship Between Architecture and Engineering

On December 13th, J. M. Oxley, m.e.i.c., partner of the firm of Chapman and Oxley, architects, Toronto, delivered an address on the above subject treating the similarity, dissimilarity and the points of contact between the two professions.

The architect tends to visulize form and proportion, the engineer tends to think in quantities. The aptitudes of the one perfected by training supplement the other. If the two collaborate from the outset, the advantage is mutual and the client is protected as well by the lowering of cost and superior result. Cases of collaboration, hypothetical and actual were treated and illustrated by slides. Considerable discussion followed.

A. J. C. Paine, a.m.e.i.c., was in the chair.

Previous to the meeting a dinner was held in the Oak Room of the Windsor hotel.

Electrical Section

"Electron Tubes in Industry" was the subject of a paper presented on December 12th by Mr. D. L. West, formerly with the Baird Television Company of London, England, and the Canadian Television Company Limited of Montreal. This covered the application of electron tubes in industrial work, one of the most popular, of course, being the electric eye.

I. S. Paterson presided.

Junior Section

On December 17th two papers were given before this section, "Electrical Control at Rapide Blanc," by Mr. W. Spriggs, and "The Engineer and the Present Economic Conditions," by Mr. Raymond Reed. Both authors are with the Power Engineering Company and though the papers were on widely diversified subjects both proved exceptionally interesting.

W. W. Graham, Jr.e.i.c., acted as chairman.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Transmission Gearing

An address on the subject of "Transmission Gearing" was given at the noon luncheon of the Ottawa Branch at the Chateau Laurier on November 8th, 1934, by Martin J. Berlyn, m.a., a.m.e.i.c., of Dominion Engineering Works, Montreal. Alan K. Hay, a.m.e.i.c., chairman, presided and in addition head table guests included: Dr. Charles Camsell, m.e.i.c., R. S. Smart, m.e.i.c., Group Captain E. W. Stedman, m.e.i.c., Captain M. Windsor, Dr. R. W. Boyle, m.e.i.c., A. V. Gale, a.m.e.i.c., J. T. Johnston, m.e.i.c., Major W. E. Blue, a.m.e.i.c., Squadron Leader A. Ferrier, a.m.e.i.c., and John Murphy, m.e.i.c.

The address was of a technical nature and was illustrated by lantern slides. Beginning with the premise that the incorrect design of teeth in gearing induces excessively destructive wear upon machinery due to a non-uniform transmission of motion, the speaker traced the successive steps in the generation of tooth profiles with which the transmitted motion would be uniform. These latter were based upon the involute, which is the figure traced by a curve of progressively larger radius.

A large range of tooth forms based upon the involute is possible, all of which will transmit motion uniformly. The shape of the involute is entirely dependent on the diameter of its "base circle" from which the curve is generated. The larger the base circle, the more nearly straight will the sides of the teeth become.

With small pressure angles, the non-effective inner portion of the teeth is undercut to allow a proper meshing. This has a tendency to weaken the strength of the teeth at a point where they should be strongest. The speaker explained how much of this could be obviated by attention to certain features of the design.

The great flexibility of the involute system in permitting the design of gears to fit in existing gear boxes, in varying the ratio slightly for the same centre distance; in varying the length of contact and in securing varying proportions of sliding to rolling contact to suit lubrication conditions.

The address dealt to a considerable extent with commercial considerations influencing the cutting or re-cutting of gearing, and the choice of gearing for various purposes. Thus a type suitable for use while completely immersed in oil might not be quite so effective where the lubrication is by some other method.

Placing Concrete by Pipe Line and Vibration

On Thursday evening, November 22nd, 1934, H. E. McKeen of Montreal, president of H. E. McKeen & Company Limited, and Managing Director of the Electric Tamper and Equipment Company of Canada, Limited, gave an address on the subject "Placing Concrete by Pipe Line and Vibration." The meeting was held in the projection room of the Photographic Section of the R.C.A.F., Jackson Building, and A. K. Hay, a.m.e.i.c., chairman of the Ottawa Branch of The Institute, presided.

Mr. McKeen stated that his interest was first aroused to the possibilities of pumping concrete to place in the fall of 1929. A pump for this purpose had been invented in Germany by a man named Giese, who secured very strong method patents all over the world and licensed individual firms in different countries. Improvements dealing largely with cylinder and valve design were invented by one of the licensees in Holland, named Kooyman, and from a merger of the Giese and Kooyman patents the pump now in use was developed. With this new pump it was quite possible to adopt the standard practice in concreting in this country. Last year, for instance, about one and a half million yards of concrete were so handled, a great deal being on Mississippi lock and dam work where a three-quarter inch slump was used, with aggregate up to two and one-half inches.

The pump is simply a plunger pump with specially designed cylinders, pistons and valves with the concrete entering the pump chamber by gravity instead of by suction. The concrete moves through the pipe line at a comparatively low speed; wear is not excessive, and as the mix has to be lubricated to be pumpable, a badly designed concrete is practically impossible. Although the pump line itself is not very flexible, so far little difficulty has been experienced in devising simple methods of distribution at its outlet.

The pumping of concrete into place may not be possible of universal application but in the speaker's opinion it had very definite advantages in some fields, such as filtration plants, sewage disposal plants or similar jobs where comparatively small quantities of concrete are scattered over large areas. The method, he was inclined to believe, would have a pronounced effect on present day practice in submarine work.

Mr. McKeen devoted the latter portion of his address to methods of concrete placement by vibration. Vibrators—essentially tools devised to increase the workability of the concrete—are of two types: external and internal. The former transmits its vibration through the form, the latter directly within the concrete itself.

The address was followed by several reels of motion pictures illustrating the operation of both single and double action pumps and the use of the vibrators; after which the meeting was given over to discussion.

Peterborough Branch

H. R. Sills, Jr.E.I.C., Secretary.
E. J. Davies, Jr.E.I.C., Branch News Editor.

Annual Dinner

The annual dinner of the Peterborough Branch was held on November 20th, 1934, at the Empress hotel, under the chairmanship of J. W. Pierce, m.e.i.c. President F. P. Shearwood, m.e.i.c., was among the guests and responded to a toast to The Institute proposed by A. L. Killaly, a.m.e.i.c. The president brought messages of felicitation from headquarters and other branches, and spoke of the western convention of The Institute in Vancouver and dealt with a number of other Institute affairs. The guest speaker of the evening was Professor C. W. Woodside of the University of Toronto, who spoke on the subject, "Germany After Two Years of Hitler." Professor Woodside, who spent the recent summer in Germany, withheld the colour of his own opinion and presented in a straightforward manner the evidence observed by himself on this tour. He asserted that he did not wish to be taken as a scaremonger, but declared that the time has come when the world must face the facts about Germany.

Germany After Two Years of Hitler

Devoting first a few words to the good in the Nazi movement, Mr. Woodside said Hitler had brought back to Germans a belief in Germany. The young of the nation have been infused with this belief to a degree of fanaticism. Yet two and three years ago, before Hitler, hardly was there a single German to be found with a trace of faith in the future of the country, he said.

The Nazis have restored order to Germany, he continued. Germany is in an iron hand. Canadians would find it hard to like that type of control, but the Germans are an order-loving people. They find the present ordered regime much more to their liking than the chaos which existed before Hitler.

Between three and four millions of Germans who idled in the streets before the Nazis took control are now occupied, he added. True, three-fourths of them are engaged in war business and many others are in labour camps, yet the situation, from the German viewpoint, has been greatly relieved, he asserted.

Turning to the evil of the Nazi era, he declared that the worst feature is the brutalizing tendency of the movement. Possibly the entire movement is the calculated effort of the leaders to revive the Germany ego, yet it is having a deep and lasting effect on the peoples, he said.

The prejudicing of the entire German future by a campaign of militarism and re-armament is one of the greatest of Nazi evils. From his own observations in Germany he knew the worst rumours of Germany's re-armament to be true.

Mr. Woodside said that the evidence points to no other conclusion than that Hitler is preparing for war. The nation has thrown everything to the winds—economic stability, world respect, treaty agreements and the contentment and prosperity of its people. The manufacturing industries are organized to a degree unsurpassed in wartime itself for war production.

These men who are leading Germany to-day are dangerous, twisted men—the worst product of the Great War. They are not to be trusted.

What can Canadians do about it? Mr. Woodside, asking the question, said it is doubtful if anything can be done. He suggested, however, that the tension could be somewhat eased if the world would tender a friendly hand to Germany, if the world would attempt in some way to show the German people that they are not actually the victims of a world-wide hatred and persecution. Canadians might aid in this by leading the way, he suggested.

Professor Woodside's address was received with great enthusiasm by those present and evoked a lengthy discussion.

R. L. Dobbin, M.E.I.C., drew attention to the absence, due to illness, of two members of the Branch who have long been faithful workers in Branch activities. It was moved and seconded that a message of good cheer and a floral token of appreciation be sent to these members.

Among the guests present were W. E. Bonn, A.M.E.I.C., vice-president of the Toronto Branch; Col. C. S. L. Hertzberg, M.E.I.C., of Toronto, who introduced Professor Woodside; Professor H. E. T. Haultain, M.E.I.C., of Toronto University, and W. E. Ross, A.M.E.I.C., of Toronto, a former chairman of the Peterborough Branch.

Stresses in Wire Rope and Fittings Used With Same

On Thursday, December 13th, 1934, the regular monthly meeting of this Branch was held, at which Mr. C. D. Meals, of the B. Greening Wire Co. Ltd., Hamilton, Ontario, was the speaker and some of the mysteries in the manufacture and multitude uses of wire rope were capably outlined.

Mr. Meals pointed out that wire rope is relatively a modern product, having first been made in Germany in 1834. The first machine-made rope was made in England in 1840. However, the first big stride in wire rope making occurred in 1854 when the first tempered or "patented" steel wire was made in England. This was a revolutionary event and opened up the field of development of the high strength steel wire as it is used to-day. Prior to this, the tensile strength of drawn wire was only 90,000 per square inch.

In the year 1919 one of the largest wire rope makers in the United States started designing their wire ropes in the draughting room, making proper allowance for the angle of lay of the wires in the strand and the strand in the rope. Previously, the making of the rope had been left entirely to the judgment of the rope shop superintendent. Now the practice is to co-ordinate the engineer's field experience with designing and shop practices and, in many cases, the wire rope engineer makes up the complete specifications for a wire for a given service.

Mr. Meals then dealt in a highly technical manner with the complexity of stresses and abuses to which wire ropes are put in their use in the modern mining, contracting, industrial and marine fields.

Wire rope, he pointed out, is sold largely on its tensile strength property, yet it was not until 1918 that a rational formula was developed to determine the breaking strength of a wire. But even after this the formula was overlooked by the engineering world.

The interest evoked by this paper was indicated by the lengthy and animated discussion, and a vote of thanks by A. B. Gates, A.M.E.I.C., and Mr. E. Bruce Fowler, a guest who is also in the wire rope field, was tendered to the speaker through the chairman, V. S. Foster, A.M.E.I.C.

Saint John Branch

H. P. Lingley, S.E.I.C., Branch News Editor.

The Automotive Diesel Engine

On September 25th, 1934, a meeting of the Saint John Branch was held in the Admiral Beatty hotel at 8.15 p.m. The chairman, E. J. Owens, A.M.E.I.C., presided, and about thirty members and visitors were present.

The speaker of the evening, J. L. Busfield, M.E.I.C., delivered an address on "The Automotive Diesel Engine." Several slides of graphs, engines and various diesel driven vehicles were shown. The address followed the lines of the article written by Mr. Busfield and published in the July 1934 issue of The Journal. A short discussion followed the address.

Vickers Armstrong Films

On October 18th, 1934, the members of the Branch viewed the Vickers-Armstrongs Ltd. films which dealt with the various branches of industry engaged in by this company, namely steel making, aviation and shipbuilding. About 45 members were present.

Broadcasting Equipment and Methods

On November 20th, 1934, Mr. J. G. Bishop, chief engineer of CHSJ, addressed the Branch on "Broadcasting Equipment and Methods." The speaker spoke of sound and the effect the walls of the studio had on sound waves, and the reason why a studio had to be specially treated for broadcasting purposes. He mentioned the range of frequency that should be transmitted for natural reproduction, the different types of microphones and described the operation of the dynamic type.

He commented on the factors which affect the fidelity or faithfulness of reproduction in its journey through the equipment. The principle of the operation of the radio transmitter was described as well as some of the causes of distortion and the causes and effects of fading.

The speaker explained the synchronization of stations and outlined some of the problems which have to be dealt with in simultaneous operation of two stations on the same frequency and carrying the same programme.

A short discussion followed, and then the meeting adjourned to inspect the broadcasting station CHSJ.

Address by the President

On December 4th, 1934, thirty-six members of the Branch assembled at a dinner meeting at the Admiral Beatty hotel at 6.30 p.m. to meet F. P. Shearwood, M.E.I.C., President of The Engineering Institute of Canada and chief engineer of the Dominion Bridge Co. Ltd., Montreal.

The president spoke of his visits to the Western branches during the past summer and the joint annual meeting of The Institute and the American Society of Civil Engineers at Vancouver recently.

He also spoke on "The Work and Aims of The Institute," and the meeting came to a close after a very interesting illustrated lecture on "Some Problems in Bridge Erection" by Mr. Shearwood.

Saskatchewan Branch

S. Young, A.M.E.I.C., Secretary-Treasurer.

The City Manager Form of Local Government

The regular monthly meeting of the Branch was held in the Dining room, Parliament Buildings, Regina, at 7.45 p.m. Friday, November 16th, 1934, being preceded by a dinner at which twenty-one were in attendance. A. P. Linton, A.M.E.I.C., presided.

After a short business session, the chairman introduced the speaker of the evening, Mr. A. W. Ellson Fawkes, consulting engineer, Moose Jaw, his subject being "The City Manager Form of Local Government."

In introducing his subject, Mr. Fawkes stated that, due to his versatile training, the civil engineer was peculiarly fitted for the job, 75 per cent of city managers in America being engineers.

About four hundred cities on this continent, containing approximately 10,000,000 people, use the city manager form of government; and of these but four have reverted to the former system.

This form of government bases its origin on the introduction of approved business methods into city government. Under this system the council in effect becomes a board of directors. It deals only with questions of policy and in so doing performs two functions, the enacting of required local legislation and the adoption of a budget of expenditures. The manager then makes the departmental allotments thus making an equitable distribution of funds.

The growth of the movement has been retarded by—

(*a*) lack of public interest,
(*b*) local (petty) politics.

The effectives of the system is difficult to estimate but the facts, (1) that it is growing and (2) that but four cities in Canada and the United States have reverted, are significant. Where the plan has broken down, the failure may be attributed very largely to interference by local politicians.

There are three essential requirements to the plan—

(1) Budget,
(2) Budget control,
(3) Centralized purchasing.

The budget should be binding except in cases of genuine emergency. Under our present system of municipal government it is not an uncommon occurrence to have the budget considerably altered at the end of two or three council meetings, the ultimate being a budget completely disorganized.

The value of a budget lies principally in its economy of preventing foolish and unwarranted expenditures. It ties an administration down to a definite policy of expenditure of public funds.

Mr. Fawkes gave as an example of the working of the system the city of Brandon where, through the application of the principles of scientific business methods, over a period of six years as opposed to the previous haphazard methods the cost of administration had been progressively reduced, taxation lowered, and general efficiency increased, the total effect being increased financial credit and a more satisfied electorate. In concluding his address Mr. Fawkes stated that in effect the city manager is the technical head of a municipal corporation acting under a board of directors (the council) but having vested in him powers which ordinarily are exercised by the council.

A hearty vote of thanks was tendered the speaker.

Sault Ste. Marie Branch

H. O. Brown, A.M.E.I.C., Secretary-Treasurer.

The monthly meeting of the Sault Ste. Marie Branch was held in the main dining room of the Windsor hotel on Wednesday, December 5th, 1934, preceded by a dinner with an attendance of about forty-five members and visitors. After the dinner the usual general meeting business was dispensed with and the speaker of the evening, Mr. Jas. S. Dobie, was introduced by the chairman, E. M. MacQuarrie, A.M.E.I.C.

Mr. Dobie's address was on "Reminiscences of Northern Ontario," and was well illustrated with lantern slides. As the speaker has spent a number of years of his professional life on surveys throughout northern Ontario he was able to tell of a great many interesting incidents.

Historical sketches were given of some of the Indian Missions along the Albany river and the work that is being carried on there to-day.

Means of transportation of survey camp equipment and the methods of portaging were illustrated very clearly. Various survey camp sites were shown and the equipment used for office work in the field was described.

The survey problems, of course, were many and varied. Along the low lying lands to the north many flooded areas could only be crossed by wading. Around the rocky shores of the islands and the north shore of Lake Superior suitable station points for the transit were often obtained with great difficulty.

Mr. Dobie's remarks on the country through which the proposed highway along the north shore of Lake Superior would pass was of particular interest at this time. The geological formations and minerals to be found were discussed. The scenery as described and illustrated certainly seemed to be all that could be desired.

At the close of Mr. Dobie's address a very hearty vote of thanks was tendered to the speaker on the motion of Judge F. Stone, seconded by Dr. A. D. Roberts, M.L.A.

Victoria Branch

Kenneth Reid, Jr.E.I.C., Secretary-Treasurer.

The annual meeting of the Victoria Branch of The Institute was held at the Dominion Hotel on December 4th, 1934. The meeting was preceded by a dinner in the hotel at which twenty-seven members and guests of the Branch attended. The specially invited guests included G. M. Irwin, Victoria city engineer, and Arthur Dixon, Deputy Minister of Public Works in the British Columbia provincial government. The most important business of the meeting following the dinner was the election of officers for the ensuing year.

In assuming the chairmanship of the Branch, D. MacBride, A.M.E.I.C., paid glowing tribute to the work of the retiring executive during the past years, particularly to the chairman, H. L. Swan, M.E.I.C., and the Secretary-Treasurer, I. C. Barltrop, A.M.E.I.C., whose untiring efforts resulted in the present good standing of the Branch.

Following the meeting, Norman Yarrow, A.M.E.I.C., manager of the firm of Yarrows Ltd., Esquimalt, B.C., and member of the Branch, gave an illustrated address on the methods and procedure of the launching of large ships with particular references to the launching of the Cunard-White-Star liner *Queen Mary*, and the French liner *Normandie*. Mr. Yarrow dealt with the technical problems and difficulties connected with such engineering feats, and his paper was illustrated with numerous slides.

In collaboration with Mr. Yarrow's paper six reels of motion pictures were shown on three connected subjects, the titles of which are practically self-explanatory, as follows:

> Steel making at the works of the English Steel Corporation, Sheffield,—including operation of Siemens furnaces and heavy forging press.
>
> Aviation—showing the launching and trial flights of the Vickers supermarine *Seagull V*. Trials of the *Scapa* twin engine flying boat, and the erection and tests of the *Vildebeest* aeroplane fitted for carrying torpedoes.
>
> Construction and trials of the P. & O. steamers *Strathaird* and *Strathnavar* at the Naval Construction Works of Vickers-Armstrongs, Limited, at Barrow-in-Furness.

The excellent quality of these films and the universal interest of the subjects made them very favourable indeed, particularly when shown in conjunction with Mr. Yarrow's paper.

The evening concluded by the showing by Mr. Yarrow of a number of excellent slides depicting man's early attempts to soar above the earth in both heavier and lighter-than-air machines.

Winnipeg Branch

E. W. M. James, A.M.E.I.C., Secretary-Treasurer.
E. V. Caton, M.E.I.C., Branch News Editor.

Geology of the Great Plains

The meeting of October 18th, 1934, with F. V. Seibert, M.E.I.C., in the chair, was addressed by Dr. L. S. Russel, Ph.D., Geological Survey of Canada, who gave a lecture on "Geology of the Great Plains."

Dr. Russel, who has for several years been carrying on investigations of the geology of the Great Plains, gave a most interesting address. He dealt chiefly with the southwestern portion of Alberta and discussed geological history, life in the geological time, and the economic resources of that area.

During the business of the meeting G. E. Cole, A.M.E.I.C., chairman of the Papers committee, addressed the Branch on the programmes for the coming season, mentioning that it was proposed to alternate the meetings between one of general interest and one of technical interest.

The chairman also gave notice of a special meeting to be called on October 25th to consider the question of closer co-operation between the Association of Professional Engineers of Manitoba and the Manitoba Branch of The Engineering Institute of Canada, which members of both associations are invited to attend.

At the meeting of the local Branch of The Engineering Institute on the evening of November 1st, 1934, Professor H. N. Fieldhouse, Professor of History at the University of Manitoba, gave an address on "Germany of Today."

Professor Fieldhouse, who is recognized as an authority on European politics, spent the past summer in a tour of Europe making observations and getting information.

The lecture was extremely interesting and appreciated by all.

A novel feature of the meeting was that an invitation was extended to the ladies to attend.

At the local Branch meeting of The Engineering Institute of Canada, held on Thursday evening, November 15th, 1934, two very interesting papers were presented by Mr. J. L. Greenlaw, B.Sc., and Mr. W. Peterkin, B.Sc., both members of the local branch of the Junior Engineers' Association.

The Science of Lighting

Mr. Greenlaw, who is with the lamp sales division of the Canadian General Electric Company, opened the programme of the evening with a paper on "The Science of Lighting." He first pointed out how the design of proper lighting had evolved from the old trial and error method to the scientific method as used today where design is based on experimentally determined facts. He also touched on the physiological and psychological effects of lighting and brought out some interesting facts, such as—

> In order to effect a general improvement in seeing from a lower intensity of illumination to a higher it is necessary to double the intensity of illumination, and in connection with this he showed that the wattages of present day lamps increased approximately in this geometrical ratio.
>
> Glare, due to high intensity of illumination, produces a nervous muscular tension and is just as fatiguing as a very low level of illumination.
>
> In a test performed on one hundred people with normal vision it was found that the majority of them picked 100 foot candles as the intensity for comfortable seeing.

At the conclusion of Mr. Greenlaw's paper an interesting discussion followed and a vote of thanks was tendered by Dean Fetherstonhaugh, M.E.I.C.

A New Process of Metallization

Mr. Peterkin then commenced his paper, the subject of which was "A New Process of Metallization." He first of all explained this process as consisting of spraying finely divided hot metal on the surface of the material to be metalized. The spray gun used is fitted with air oxygen and acetylene intakes. In the operation of the gun the correct mixtures of oxygen and acetylene are ignited and the material to be atomized is drawn through this flame in the form of a wire and after melting is broken up into fine spray by a stream of compressed air. Part of this air is used to drive a small turbine in the gun which is adjusted to feed the wire into the flame at the correct rate of speed.

This process was investigated back in 1882 but it was not until 1911 that a patent was taken out by Dr. Schoop, a German scientist. It is just recently, however, that the process has been introduced in this country.

Mr. Peterkin pointed out a very large number of applications of this process, such as the building up of worn shafting, the spraying of dairy kettles, the coating of steel parts of seaplanes with cadmium for protection against salt water corrosion, and the spraying of a bridge in Toronto with a coating of zinc.

He also stated that the coating of metal can be built up to any thickness but that one of its properties is that it has no appreciable tensile strength and is very brittle. It has, however, a high compressive strength which of course is an advantage in the case of built up shafting or crank pins.

During Mr. Peterkin's talk a number of questions were asked and at the conclusion a hearty vote of thanks was tendered both these men by T. C. Main, A.M.E.I.C.

The recent consolidation whereby the *Brown Instrument Company* of Philadelphia became a subsidiary of *Minneapolis-Honeywell Regulator Company* of Minneapolis unites two of the largest and oldest firms in the control field. The Minneapolis-Honey well Regulator Company Limited thus rounds out and complements its line of heating, ventilating, cooling, humidifying and air conditioning control equipment for domestic and large building applications as well as its line of automatic process controls.

The Brown Instrument Company's business has been exclusively in the industrial field and consists of a complete line of instruments for indicating, recording and controlling of high temperatures, pressures, flows, liquid levels, CO_2, speeds, etc., serving such varied industries as oil, power, steel, chemical, glass and automotive industries.

Plans are being made for manufacturing and servicing the Brown Instrument line at the Toronto plant of the Minneapolis-Honeywell Regulator Company.

J. T. Donald and Company Limited, Montreal, have been appointed official assayers to the Canadian Commodity Exchange Incorporated, which is the official title of the new silver exchange in Montreal.

Couplings—Parker Appliance Company, Cleveland, Ohio, have issued Bulletin No. 37, containing 64 pages, and giving particulars and price list of the Parker tube couplings and associated equipment.

Leadership, Profits and Recovery

In many countries it is difficult for business to take the lead in efforts to restore prosperity because of public distrust of business leaders. Unusual prosperity seems to break down the homely virtues and in many instances, although by no means generally, to undermine business morality.

While all authorities are in agreement that increased purchasing power is a necessity as a means toward recovery, authorities disagree as to the means by which this end may be best attained. There is a very considerable body of opinion which has advocated an advance in wages as the most direct means of securing increasing national purchasing power. The arguments in favour of this viewpoint have been widely broadcast in recent months and there is no need to do more than mention it in general.

On the other side of this argument is the experience of the individual company executive who is using every means within his power to lower costs and restore his company to a position where it will show profits. Many such executives are in sympathy with the viewpoint previously expressed, but they cannot see how such an argument applies to their own situation, since they have the knowledge that without drastic retrenchment they will be forced to restrict operations or, in extreme cases, to close down and thus accentuate deflation.

During the worst of the depression the maintenance of employment even at low wages may mean less suffering than that which will follow upon a mounting volume of unemployment. The total real income of the country is the total volume of production. As the total volume of production is diminished there must be a corresponding decline in consumption and a proportionate decline in the standard of living. The maintenance of a wage scale which reduces the total volume of production necessarily accentuates depression. If this is a fair statement of the wage policy during depression, let us examine the comparative effects of relatively low wages and of advancing real wages in the early stages of recovery.

The company which has been operating for three or four years without profits is not likely to be willing to pay out in wages the full additional amount which it receives as a result of the first advance in prices which occurs during recovery. Quite aside from the point that the owners have been receiving little or no return on their investments, it is doubtful whether such immediate wage payments constitute the most effective method of cutting down unemployment and increasing the aggregate buying power of the community. In the first place, if wages are increased, the resulting expenditure will add a direct increment to the purchasing power of the community, but it also follows that management will make special efforts to keep down the number of new employees, both by the use of new labour-saving machinery and by other methods of increasing per-man output. If the new increment in revenue goes to capital instead of to wages, the corporation which has been showing no profits for several years, may show reasonable earnings. In terms of values in the security markets the securities of the corporation are likely to advance by at least ten times the increment in earnings. They may advance much more than this, since the psychological situation will have changed from one in which security holders fear the worst to one in which they hope for the best. In the second place, the corporation itself will be in a far better position to undertake and to finance expansion of its own activities, including under this heading, alterations, repairs and improvements as well as direct increases in production. Each of these activities will tend to swell the total volume of wages within the country. In the third place, as the holders of the securities of the corporation begin to see their holdings advance in value, their own reactions to the situation change, and they are willing to realize upon or borrow against the additional values of the securities mentioned to finance expansion of both a corporate and private character. The amazing building programme in Great Britain which has been the feature of their recent recovery, can be clearly identified with the great improvement in values of government and corporation securities beginning with the government's scheme of debt conversion.

Certainly, the question as to whether increased profits should precede or follow upon increase in wages is a subject upon which there has been insufficient research. Which plan will bring about the quickest restoration of employment? Which plan will lead most quickly to an increase in the total volume of wages and a rise in the buying power of the country as a whole?

The government which desires to secure business co-operation in restoring employment must create conditions where profits are possible. Such theories may not sound idealistic, but it is important that in this matter governments should be pragmatic; that they shall do that which brings real recovery by the shortest route. To create that stability which will permit well-managed companies to make profits is an objective well worthy of pursuit. Business is adaptable and can acclimate itself to widely varying conditions, provided those conditions remain stable. Uncertainty as to future legislative action is most disturbing. The business world seeks stability and prosperity can be best attained where basic laws are unchanging and where peace is assured.

—From The Royal Bank of Canada Monthly Letter for November, 1934.

Once Again, Relief or Recovery?

In a recent issue of the *New York Herald Tribune*, Walter Lippman considers a matter that has often been discussed. He tries to reconcile and if possible combine governmental efforts in behalf of relief and recovery.

Much of his analysis is sound, especially when he points out the danger of doling out relief merely to keep body and soul together; he sees that the relief that is cheapest from a pecuniary aspect is also the most demoralizing to its recipient. He sees also the need for administering relief and recovery measures with due regard for their effect upon each other.

* * *

To accomplish Mr. Lippman's original purpose of reconciling relief and recovery there is but one practical course. That is to have a relief programme for relief and a public construction programme for recovery. Experience has taught us that the relief programme must not be permitted to invade and complicate that field of public works construction which now is available to the normal functioning of the construction industry. The purpose of a public works programme is to foster recovery by using the public credit to sustain the process of capital investment until such time as increasing confidence leads private capital into the construction market. This calls for a sound public works programme operated with no taint of relief psychology.

Mr. Lippman's programme would scuttle the recovery of the construction industry in the interest of direct relief, turn back the recovery clock and gamble on the speed with which private enterprise will be ready and able to go in for substantial construction.

—Willard Chevalier in the December 20th, 1934, issue of the Engineering News-Record.

Engineering in Fascist Italy

The engineering operations carried out by the Fascist government during the first ten years of its existence are described in a volume entitled "Opere Pubbliche, 1922-1932" published by the Italian Minister of Public Works.

During that time some 400,000,000 lire have actually been spent, and when the programme has been completed the total outlay will amount to about 1,000,000,000 lire compared with the 347,000 lire during the fifty-two years preceding 1922. This money has, it is claimed, not been expended as a temporary measure to reduce unemployment, but has been directed solely to the development of the trade and industry of the country, the backbone of which is agriculture. Thus hydro-electric plant has been installed to replace foreign coal, watercourses and irrigation works have been constructed, and harbours, railways and roads have been built to assist in the distribution of the produce of the fields. In this way it is hoped that the 300,000 persons, who formerly emigrated each year, will be settled on the large areas of land that have been reclaimed and that the prosperity of the country will be greatly increased.

The network of main highways directly controlled by the state is 12,758 miles long and is administered by a Board. 5,350 miles of these roads have been improved and a further 684 miles are under construction.

In the field of railways, the activities of the state are exerted directly and through the medium of assistance to private enterprise. In all, 1,784 miles of new line have been completed and a further 812 miles are in course of construction.

Under the heading of "Ports and Harbours" it is learned that work has been undertaken at eighty-two places, comprising the construction of basins with an area of 68,000,000 square feet, of 22.4 miles of jetties, and of 29,500,000 square feet of new quayage. These are fully equipped with cargo-handling appliances.

The construction of 4,850 miles of drainage canals and 706 miles of irrigation canals, with their correlated villages and roads, have enabled 1,710,000 acres to be put under cultivation, while when the work is completed the acreage reclaimed will amount to 6,000,000. The most nteresting of these schemes is that on the Pontine Marshes, where 56,000 acres will be reclaimed.

Italy possesses abundant water resources, and in the ten years under review 4,093,518 kw. of plant has been installed in 805 stations, thus nearly trebling the amount available in 1922. Over one hundred reservoirs with a total capacity of 304,090 million gallons have been constructed, and eighteen more with a capacity of 58,750 million gallons are under construction.

—Engineering.

Make your Arrangements NOW to Attend

THE ANNUAL MEETING

The Engineering Institute of Canada

TORONTO, Ont., ***February 7th, 8th and 9th, 1935***

Preliminary Notice

of Applications for Admission and for Transfer

December 27th, 1934

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in February, 1935.

R. J. Durley, Secretary.

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BALDRY—GEORGE EPHRIAM, of 810 Wolseley Ave., Winnipeg, Man., Born at Osgoode, Ottawa Valley, Ont., Oct. 29th, 1883; Educ., Wesley College, Winnipeg, and private tuition; 1901, Carlton Drainage; 1902-03, C.P.R.; 1904-05, general engrg.; 1906, with L. A. Smart organized the Baldry Engineering Company, specializing in concrete foundation work, concrete piles, designing as well as building the Cornwall, Wolseley, Lincoln and Gloucester Apts., and many others, until interrupted by overseas service. On return, resumed old work, and out of such experience has developed a cast-in-place concrete pile. Has put in many hundreds of these piles, possibly 75% of all the foundation work under existing bldgs. that has been done in Winnipeg. At present chief engr., Baldry Engrg. and Construction Co. Ltd., Winnipeg, Man.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situations Vacant

YOUNG ENGINEER WITH CAPITAL

Contracting engineer will sell part holdings in active company to young engineering graduate desirous of learning contracting business. Salary $65 to $75 per month. Capital needed $7,000 minimum to $10,000 maximum. Location eastern Canada. Apply to Box No. 1090-V.

DRAUGHTSMAN, with pulp or paper mill experience for work in Northern Quebec. Give full information regarding age, education, experience, etc. in first letter to Box No. 1092-V.

AEROPLANE DESIGNER. Candidates must be British or Canadian citizens. Location Canada. Apply giving full details of experience to Box No. 1096-V.

ENGINEER, for aeroplane stress analysis. Man without experience will be considered. Candidates must be British or Canadian citizens. Location Canada. Apply giving full details of experience to Box No. 1097-V.

SALES REPRESENTATIVE FOR WESTERN CANADA

Internationally known firm selling steam heating systems desires one or two sales engineers to represent them in the western provinces. Men already handling other mechanical lines preferred. Apply to Box No. 1098-V.

Situations Wanted

ESTABLISHED SALES ENGINEER. Univ. of Toronto '24, with plant and manufacturing experience, wishes to represent manufacturers of technical equipment. Connections with automobile and electrical equipment dealers, throughout Canada. Will make small investment if necessary. Apply to Box No. 1-W.

MECHANICAL ENGINEER, Canadian, with technical training and executive experience in both Canadian and American industries, particularly plant layout, equipment, planning and production control methods, is open for employment with company desirous of improving manufacturing methods, lowering costs and preparing for business expansion. Apply to Box No. 35-W.

MECHANICAL ENGINEER, graduate McGill Univ. Experience on hydro-electric power construction and design and installation of equipment of pulp and paper mills. Desires position as mechanical engineer in an industrial plant or pulp and paper mill, or as representative on the sale of heavy machinery. Apply to Box No. 142-W.

PURCHASING AGENT. Graduate mechanical engineer, Canadian, married, age 36, with fourteen years experience in industrial field, including design, construction and operation, eight years of which had to do with the development of specifications and ordering of equipment and materials for plant extensions and maintenance; one year engaged on sale of surplus construction equipment. Full details on request. At present employed. Apply to Box No. 161-W.

SALES ENGINEER, S.E.I.C.; B.Sc. C.E., 1930 (Univ. New Bruns.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ELECTRICAL ENGINEER, B.Sc., A.M.E.I.C., Am.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

CIVIL ENGINEER, B.A.Sc. and C.E.; A.M.E.I.C., Jun. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.Sc. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

Situations Wanted

MECHANICAL ENGINEER, B.Sc. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.Sc., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment. Four summers as instrumentman on surveying and highway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern where the combination of technical and business experience will be of value. Apply to Box No. 564-W.

Employment Questionnaire

In December an employment questionnaire was sent to some two hundred members of The Institute registered with the Employment Service Bureau as unemployed and from whom we had not been in communication for some months.

On December 31st replies had been received from just over 50 per cent of those written to with the following result:

40 per cent are still unemployed.

40 per cent are temporarily employed but wish to be retained on our list of those available.

20 per cent advise that they have secured permanent positions.

This is in addition to the number already placed through the Employment Service Bureau and, we believe, makes the outlook for 1935 distinctly encouraging.

It would be appreciated if those who have not yet returned this questionnaire would do so at their earliest convenience in order that complete information may be available for the Annual Meeting of The Institute.

MECHANICAL ENGINEER, A.M.E.I.C. Experienced on plant maintenance, steel plant, cement plant and mining plants. Available on short notice. Apply to Box No. 571-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

CHEMICAL ENGINEER, S.E.I.C., B.Sc., University of Alberta, '30. Age 31. Single. Six seasons practical laboratory experience, three as chief chemist and three as assistant chemist in cement plant; one year's p.g. work in physical chemistry; three years experience teaching. Desires position in any industry with chemical control. Available immediately. Apply to Box. No. 609-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

Situations Wanted

ELECTRICAL ENGINEER, B.Sc. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box. No. 651-W.

ELECTRICAL ENGINEER, Univ. Grad. 1928. Two years Students' apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660 W.

ELECTRICAL AND RADIO ENGINEER, B.Sc. '30 Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc., Elec., '29, B.Sc., Civil '33. Age 27. Jr.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.Sc., '27, Jr.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.Sc., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.Sc. (McGill Univ.), O.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box. No. 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

Situations Wanted

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.Sc. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten years diversified electrical and mechanical experience in the industrial field. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, college graduate, age 27, single. Experience includes surveying, draughting, concrete construction and design, street paving both asphalt and concrete. Available at once; will consider anything and go anywhere. Apply to Box No. 816-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with fifteen years experience mostly in pulp and paper millwork, reinforced concrete and structural steel design, field surveys, layout of mechanical equipment, piping. Available at once. Apply to Box No. 825-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C., age 24. Experience, three summers on railroad maintenance, and seven months on highway location as instrumentman. Willing to do anything, anywhere, but would prefer connection with designing or construction firm on structural works. Available immediately. Apply to Box No. 846-W.

BRIDGE AND STRUCTURAL ENGINEER, A.M.E.I.C., McGill. Twenty-five years experience on bridge and structural staffs. Until recently employed. Familiar with all late designs, construction, and practices in all Canadian fabricating plants. Desirous of employment in any responsible position, sales, fabrication or construction. Apply to Box No. 851-W.

Situations Wanted

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box. No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, B.A.Sc. in C.E., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.Sc. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

Situations Wanted

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.Sc., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box. No. 1127-W.

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.Sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.Sc., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.Sc., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Write and speak both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211 W.

COMBUSTION ENGINEER, A.M.E.I.C., with extensive experience in all phases of combustion engineering, including plant layout, piping, etc. Lately connected with prominent firm of automatic oil burner manufacturers. Apply to Box No. 1224-W.

MECHANICAL ENGINEER, B.Sc. McGill. Experienced as supt. of plant manufacturing home appliances—purchasing of supplies and equipment of technical nature. Plant engineer of works for manufacture of railway equipment and of copper and brass rolling mill and seamless brass and copper tube mill and brass cartridge cases. Designing engineer on special machinery, maintenance engineer, plant layouts. Apply to Box No. 1241-W.

TREASURER
J. B. CHALLIES, Montreal, Que.

SECRETARY
R. J. DURLEY, Montreal, Que.

OFFICERS OF BRANCHES

HALIFAX
Chairman, C. S. BENNETT
Sec.-Treas., R. R. MURRAY, 87 Cambridge St., Halifax, N.S.
Executive, R. M. McKINNON, W. H. NOONAN, J. R. KAYE, F. C. WIGHTMAN, E. L. MILES, G. MEDFORTH, J. D. FRASER, J. M. M. JONES
(Ex-Officio) R. L. DUNSMORE, A. F. DYER

CAPE BRETON
Chairman, C. M. SMYTH
Vice-Chair., W. E. BOWN
Sec.-Treas., S. C. MIFFLEN, 60 Whitney Ave., Sydney, N.S.
Executive, K. H. MARSH, C. M. ANSON, W. E. BOWN, W. E. CLARKE

SAINT JOHN
Chairman, E. J. OWENS
Vice-Chair., V. S. CHESNUT
Sec.-Treas., F. A. PATRIQUEN, 19 Horsfield St., Saint John, N.B.
Executive, F. M. BARNES, W. H. BLAKE, G. H. THURBER
(Ex-Officio) G. A. VANDERVOORT, W. J. JOHNSTON, S. HOGG, A. GRAY

MONCTON
Chairman, J. G. MacKINNON
Vice-Chair., H. B. TITUS
Sec.-Treas., V. C. BLACKETT, Eng. Dept., C.N.R., Moncton, N.B.
Executive, F. O. CONDON, R. K. DeLONG, T. H. DICKSON, JAS. PULLAR, C. S. G. ROGERS, G. E. SMITH
(Ex-Officio) H. J. CRUDGE, H. W. McKIEL

SAGUENAY
Chairman, G. E. LAMOTHE
Vice-Chair., J. SHANLY
Sec.-Treas., J. W. WARD, Arvida, Que.
Executive, D. A. EVANS, F. L. LAWTON, E. LAVOIE, M. G. SAUNDERS
(Ex-Officio) N. F. McCAGHEY, G. F. LAYNE

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, HECTOR CIMON
Vice-Chair., ALEX LARIVIERE
Sec.-Treas., J. JOYAL, Quebec Public Service Comm., Court House, Quebec, Que.
Executive, T. J. F. KING, R. B. McDUNNOUGH, J. G. O'DONNELL, A. G. SABOURIN, P. METHE, L. BEAUDRY
(Ex-Officio) A. B. NORMANDIN

ST. MAURICE VALLEY
Chairman, B. GRANDMONT
Vice-Chair., E. B. WARDLE
Sec.-Treas., J. A. HAMEL, 642 Notre Dame St., Three Rivers, Que.
Executive, J. E. FLEURY, R. MORRISSETTE, J. H. FREGEAU, H. J. WARD

MONTREAL
Chairman, F. S. B. HEWARD
Vice-Chair., J. B. D'AETH
Sec.-Treas., C. K. McLEOD, 1440 St. Catherine St. W., Montreal, Que.
Executive, F. E. V. DOWD, J. H. LALONDE, J. G. HALL, B. R. PERRY, J. H. LANDRY, R. H. FINDLAY
(Ex-Officio) C. B. BROWN, A. COUSINEAU, O. O. LEFEBVRE, F. NEWELL, J. A. McCRORY, P. L. PRATLEY, J. L. BUSFIELD, E. BROWN, A. FRIGON, F. P. SHEARWOOD

OTTAWA
Chairman, R. W. BOYLE
Sec.-Treas., F. C. C. LYNCH, Dept. of Mines, Motor Bldg., Ottawa, Ont.
Executive, B. F. HAANEL, A. V. GALE, T. A. McELHANNEY, J. H. PARKIN, G. R TURNER
(Ex-Officio) A. K. HAY, C. M. PITTS, G. J. DESBARATS, C. CAMSELL

PETERBOROUGH
Chairman, J. W. PIERCE
Secretary, H. R. SILLS, Canadian General Electric Co. Ltd. Peterborough, Ont.
Treasurer, W. T. FANJOY
Executive, J. BARNES, V. R. CURRIE, E. J. DAVIES, A. L. DICKIESON
(Ex-Officio) V. S. FOSTER, E. R. SHIRLEY, R. L. DOBBIN

KINGSTON
Chairman, W. CASEY
Vice-Chair., R. A. LOW
Sec.-Treas., L. F. GRANT, Royal Military College, Kingston, Ont.
Executive, N. C. SHERMAN, M. E. CROUCH, G. G. M. CARR-HARRIS
(Ex-Officio) J. E. GOODMAN, L. F. GOODWIN

TORONTO
Chairman, R. E. SMYTHE
Vice-Chair., W. E. BONN
Sec.-Treas. W. S. WILSON, Mining Bldg., University of Toronto Toronto, Ont.
Executive, J. M. OXLEY, W. MACLACHLAN, W. G. CHACE, O. HOLDEN, A. U. SANDERSON, W. W. GUNN
(Ex-Officio) A. B. CREALOCK, J. J. TRAILL, J. ROY COCKBURN, C. S. L. HERTZBERG

HAMILTON
Chairman, W. HOLLINGWORTH
Vice-Chair., J. STODART
Sec.-Treas., A. LOVE, 40 Paisley Ave. S., Hamilton, Ont.
Asst. Sec., A. B. DOVE
Executive, W. J. W. REID, V. S. THOMPSON, E. G. MacKAY, D. W. CALLANDER
(Ex-Officio) F. W. PAULIN, H. B. STUART

LONDON
Chairman, F. C. BALL
Vice-Chair., S. W. ARCHIBALD
Sec.-Treas., H. A. McKAY, 1500 Dundas St., London, Ont.
Executive, D. M. BRIGHT, E. V. BUCHANAN, J. FERGUSON, W. C. MILLER, W. M. VEITCH
(Ex-Officio) W. R. SMITH, V. A. McKILLOP, J. R. ROSTRON, J. A. VANCE

NIAGARA PENINSULA
Chairman, W. R. MANOCK
Vice-Chair., P. E. BUSS
Sec.-Treas., P. A. DEWEY, 1224 Ontario Ave., Niagara Falls, Ont.
Executive, L. P. RUNDLE, E. L. HAVILAND, G. C. MOUNTFORD, C. W. WEST, L. C. McMURTRY, C. N. GEALE, G. H. WOOD, C. S. BOYD, J. C. STREET
(Ex-Officio) E. G. CAMERON, W. JACKSON, A. J. GRANT

BORDER CITIES
Chairman, H. J. COULTER
Vice-Chair., T. H. JENKINS
Sec.-Treas., C. F. DAVISON, 32 Indian Road, Sandwich, Ont.
Executive, E. M. KREBSER, D. T. ALEXANDER, B. CANDLISH
(Ex-Officio) O. ROLFSON, H. J. A. CHAMBERS

SAULT STE. MARIE
Chairman, F. SMALLWOOD
Vice-Chair., J. L. LANG
Sec.-Treas., H. O. BROWN, Abitibi Power & Paper Co., Sault Ste. Marie, Ont.
Executive, C. W. HOLMAN, H. W. SUTCLIFFE, C. J. RUSSELL, A. A. ROSE

The Toronto Waterworks Extensions

A General Description of the Scheme with Details of Some Outstanding Features

William Storrie, M.E.I.C.,
Gore, Nasmith and Storrie, Toronto, Ontario.

Paper to be presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

SUMMARY.—In 1926 the city of Toronto commenced extensions to its water system which were estimated to cost $14,500,000. These are described in the paper and include a new intake in Lake Ontario, 7,500 feet of intake tunnel, a water purification plant to deal with 100,000,000 gallons per day, and capable of extension, one low lift and two high lift pumping stations, 49,000 feet of filtered water tunnel, a 50,000,000-gallon covered reinforced concrete reservoir, together with the necessary additional mains, elevated storage tanks etc., to connect the supply to the five water districts of the city which have an area of about 46 square miles.

The purpose of this paper is to describe in a general way the main features of the extensions to the Toronto waterworks system now under construction and to give a more detailed description of a few of the somewhat unusual features embodied therein. The scope of the work covers too wide a field to attempt to adequately describe in detail all the varied phases of the scheme.

The extensions were decided upon after reports had been submitted by a Board of Engineers in 1912, by Commissioner of Works R. C. Harris in 1913 and by the late William Gore, M.E.I.C., and Mr. H. G. Acres, M.E.I.C., in 1926. This latter report confirmed the recommendation made by Mr. Harris that the site for the main works known as Victoria Park should be adopted. This scheme was ultimately passed by a vote of the ratepayers and the work ordered to be proceeded with at an estimated cost of $14,317,000.

In coming to a decision as to the necessity for increasing the water supply facilities the following conclusions were arrived at as a result of an extensive study of the then existing conditions:—

(1) That the demand rate had reached a point which taxed the capacity of the system beyond the limit of safe operation.

(2) That an extension to the existing system had become absolutely necessary in the public interest.

(3) That Lake Ontario constituted the best available water supply for the extension scheme.

(4) That the intake works for this extension must not be constructed in the neighbourhood of the existing intakes south of Centre Island.

(5) That of all possible intake locations that at Victoria Park was the most suitable under all conditions.

Having fixed on Victoria Park as the proper location for a raw water intake the other main features of the scheme were developed so that the system now under construction consists essentially of the following:—

(*a*) At Victoria Park an intake tunnel ten feet in diameter, constructed in shale, and extending from the shore out underneath the lake bottom a distance of 3,300 feet, into thirty feet depth of water, and terminating in a submerged tunnel shaft. This tunnel has a maximum capacity of 300,000,000 gallons[1] per day.

(*b*) From the end of the tunnel shaft provision has been made for the laying of three concrete lined steel intake pipes, only one of which has been laid, this being eight feet in diameter, 4,172 feet in length, and terminating in fifty feet depth of water. The eight foot pipe installed has a capacity of 125,000,000 gallons per day. The other two pipes will be laid as and when the demand arises.

(*c*) At Victoria Park a low lift pumping station, coagulating basins, filters, reservoir, general offices and laboratory, with provision for treating initially 100,000,000 gallons of water per day, and so laid out as to permit of this capacity being at least doubled in the future.

(*d*) At Victoria Park a high lift pumping station for supplying all that area lying east of the Don river.

(*e*) From Victoria Park the distribution mains for connecting to the existing mains, and also additional feeder mains for supplying the area lying east of the Don river.

(*f*) From Victoria Park a concrete lined filtered water supply tunnel seven feet in diameter, and 31,087

[1] Wherever the word "gallon" is used in this paper the Imperial gallon is referred to.

feet in length, constructed through shale to the existing main pumping station at John street.

(*g*) From John street station a concrete lined filtered water tunnel six feet in diameter, and approximately 18,575 feet in length, constructed through shale to a point on the lake shore road north of the Canadian National Railway tracks, and immediately east of Parkside drive.

Fig. 1—General Layout of System.

(*h*) At the above mentioned point a high lift pumping station for supplying the western and northwestern area of the city, and to further serve as a connecting link to the contiguous northern areas now served or to be served.

(*j*) From the above mentioned Parkdale high lift pumping station a 42-inch diameter distribution main running northwards to connect to the existing system in District No. 2, and a 30-inch diameter distribution main to District No. 1.

(*k*) At the south-east corner of St. Clair avenue west and Spadina road a covered reinforced concrete reservoir with a storage capacity of 50,000,000 gallons for supplying Districts Nos. 2 and 5.

(*l*) At the above site an ornamental elevated storage tank with a capacity of 500,000 gallons for supplying District No. 3.

(*m*) The necessary connecting mains to and from the St. Clair avenue-Spadina road reservoir and elevated tank.

Existing Supply

The existing water supply system of the city of Toronto and district covers an area of about 46 square miles. The area of supply stretches along the northern shore of Lake Ontario, a distance of about 10 miles, and to the north a distance of about 8 miles, measured from the existing water purification plants on Toronto Island. The ground surfaces within the area of supply rise more or less gradually to the north to a height of nearly 400 feet above the lake level. The difficulty of maintaining the proper pressures in the service pipes therefore lies both in the loss of head by friction in the pipes over the long distances traversed by the water and in the rising elevations of the ground surfaces, the more distant areas being at greater elevations. To meet this situation the water supply area hitherto has been divided into seven districts with fairly uniform pressures in each. The new works now under construction are so laid out as to reduce the number of districts to five, one of which is on Toronto Island and supplied directly from the existing water purification plants there. Figure 1 shows a general layout of the completed system.

Districts Nos. 1 and 2 will be supplied from the existing John street pumping station and from the new pumping stations at Victoria Park and Parkdale. Districts Nos. 3 and 4 will be supplied by boosting the pressures from Districts Nos. 1 or 2. The supply in District No. 1 will be balanced as at present by the existing Rosehill service reservoir and similarly the supply in the enlarged District No. 2 will be balanced by the St. Clair service reservoir. A new overhead ornamental tank will balance the supply in District No. 3 and the existing standpipe in District No. 4 has been enlarged to balance the supply within this district. Thus the new works will supply water directly or indirectly at both ends and towards the middle of both Districts Nos. 1 and 2. The balancing reservoirs are situated almost in the centre of the districts to be supplied in an easterly and westerly direction but outside of these districts and to the north in order to secure higher elevations than exist within those districts. A diagrammatic layout of the complete system showing the elevations of the various water districts will be found in Fig. 2.

The present city waterworks system consists essentially of two 6 feet diameter submerged intakes, with the inlets located—one in about 43 feet and the other in about 79 feet depth of water off Centre Island and about 2,190 feet and 2,383 feet respectively from the shore. The water is pumped from the intakes to either the slow sand or drifting sand water purification plants at Centre Island having a total nominal capacity of 100,000,000 gallons per day. A 7,000,000-gallon clear water reservoir adjacent to the filters holds the filter effluent from which the water passes through into two steel pipes, 7 feet and 6 feet in diameter respectively, laid across the island to a tunnel shaft and from thence into a tunnel having a section equivalent to 8 feet 4 inches

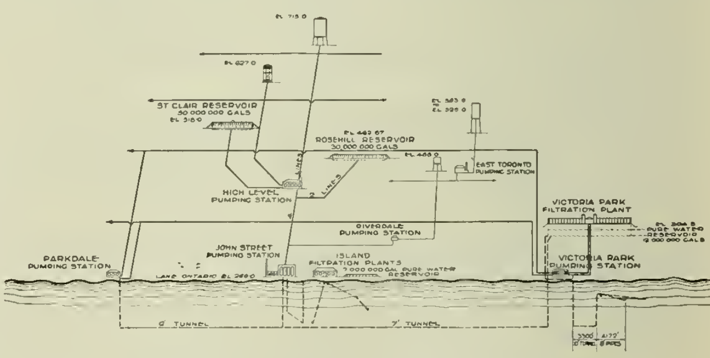

Fig. 2—Elevation of Water Districts

in diameter, which leads underneath Toronto bay to the suction wells at the foot of John street where the main pumping station is located and the water is there pumped into the distribution system throughout the city. The pumping station at John street has a total installed pumping capacity of 212,000,000 gallons per day, of which 102,000,000 gallons capacity is steam driven, and 110,000,000 gallons is electrically operated.

From the John street pumping station the distribution system radiates throughout the city through eight mains, seven of 36 inches diameter and one of 30 inches diameter. The operating pressure on the pumps is 102 pounds per square inch. Filtered water storage reservoirs are provided at Rosehill with a capacity of 38,000,000 gallons and at St. Clair with a capacity of 50,000,000 gallons. The St. Clair reservoir was built as part of the programme of extensions now under way.

The water supply is chlorinated at the island only. Dechlorination with sulphur dioxide for the removal of taste is carried out at the John street pumping station.

Enlargement of Present System

Fortunately the information and records of the conditions existing in Lake Ontario both as to foundation possibilities and the condition of the raw lake water over a long period were available in greater detail than is usually obtainable under similar circumstances. From the standpoint of comparative freedom from physical and bacterial pollution the Victoria Park location was easily the most favourable for a raw water intake. It is the nearest available source of supply of suitable and presumably sustained quality and from a topographical and structural viewpoint equally satisfactory conditions were obtainable. Contour lines of the lake bottom were obtained and a series of borings were made. These borings were taken as far out as 9,600 feet from the shore in 54 feet of water. The borings penetrated the overburden and 25 to 60 feet into the underlying shale formation. A profile of the lake bottom at Victoria Park (Fig. 3) indicates the typical relationship which exists at that point between the surface of the water, the earth overburden and the surface of the rock. This overburden consists for the most part of a 30-foot stratum of stiff clay with a minor admixture of gravel and firm sand, the whole constituting an entirely safe bearing medium for any heavy structure which has its footing depressed sufficiently to prevent any possibility of scour.

Intake

The underlying foundation material in the lake at Victoria Park was such that at any distance up to 6,500 feet from the shore line the construction of an intake tunnel with a reasonable depth of shore shaft offered no unusual working difficulties. The placing of the shore portion of the intake in tunnel avoids the hazards commonly encountered from ice accumulation on the foreshore, where such intakes are laid on or immediately under the lake bottom.

The intake was constructed under two contracts. A shaft was sunk at the shore line to a depth of 110 feet below lake level and 60 feet below the top of the shale. From this shaft a tunnel was excavated through the shale of circular section and 10 feet in diameter of a total length of 3,300 feet. As soon as the shale was excavated the rock surface had a coat of gunite placed thereon thus forming an effective seal which prevented further spalling of the shale and reduced to a minimum the seepage of water through the fissures in the shale. At the outer end of the intake tunnel a junction shaft was constructed forming a connection between the tunnel at elevation 143.27 and a series of three pipes, each 8 feet in diameter, placed at elevation 202.00.

The construction of the junction shaft was carried out by sinking a steel caisson through sand and clay into the rock by means of the pneumatic method. After the caisson had been sealed with concrete at the cutting edge the air pressure was released and the balance of the shaft and the lower elbow were excavated through the rock in the open and the connection driven through into the existing tunnel.

The steel caisson was fabricated and then assembled at a wharf in Toronto bay and when completed was placed in the water, after which the upper section of the caisson was placed on top of the lower part of the caisson. The elbow for the junction shaft was also formed in steel and built into the caisson, the entire structure then being in a floating condition. This steel caisson is 35 feet in diameter and 34 feet high. The working chamber, which was completely encased in steel, had 7 feet 6 inches of head room above the cutting edge. Two access working shafts, each 45 inches in diameter, were constructed from the working chamber roof through the elbow to the top of the caisson. One shaft was used for workmen and the other for handling

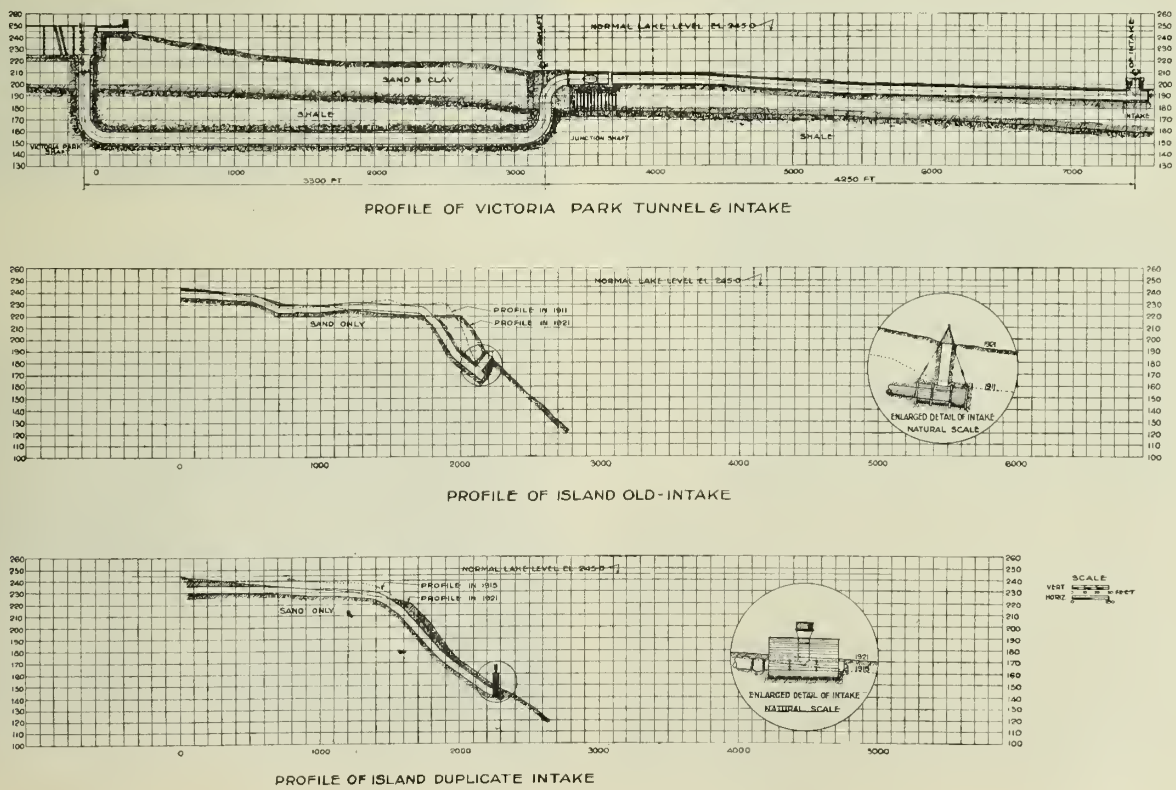

Fig. 3—Profile of Intake Pipes and Tunnel.

the excavated material and concrete. Before the caisson was towed out to its final location in the lake 115 cubic yards of concrete were placed in the caisson, which filled the working chamber walls and about one foot thick over the roof. With this concrete in place the caisson was drawing approximately 17 feet of water which just provided the necessary stability for towing. The caisson was towed out into the lake without any difficulty and placed in position. Some 873 cubic yards of concrete were placed in the caisson in the period of two days after which the two working shafts were extended 40 feet and air locks fitted to the top of each shaft. Under compressed air the excavation was carried on night and day until the cutting edge reached its final elevation of 178.00. Sand, gravel, clay and gravel with some boulders and shale were encountered in the excavation. The air pressure at the start was 15 and at the end 28 pounds per square inch. After the caisson was sealed and the air pressure released the balance of the junction shaft was carried down in the open. All rock was broken up with pneumatic paving breakers, no explosives being used at any time. The steel bulkhead was left in place until the butterfly valve was placed in position and closed, which permitted unwatering of the three-way distributor.

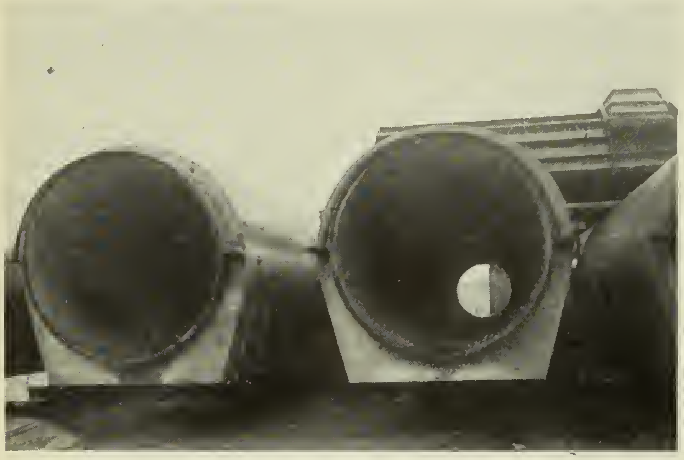

Fig. 4—Intake Pipes 96 inches in diameter ready for Laying.

The three-way distributor connects to the side of the caisson at the upper elbow having a finished inside diameter of 11 feet at this point. The other end of the distributor branches out into three openings, each 8 feet in diameter. Two of these openings have been fitted with watertight bulkheads made of oak timber reinforced with steel. These bulkheads will be removed when additional capacity is required by laying further 8 feet diameter pipes out into the lake.

In the construction of the intake pipe proper the southerly branch of the three-way distributor was used. The distributor weighing 235 tons was constructed on the mainland and placed in position on top of a concrete mat, 3 feet thick, resting on timber piles.

To permit of the tunnel being unwatered at any time an 8-foot diameter butterfly valve is located between the three-way distributor and the first length of intake pipe. The valve is constructed so as to operate by means of a hydraulic cylinder mounted on a cast iron bracket attached to the top of the valve.

From the distributor is laid the intake pipe running in a south-easterly direction, consisting of forty-one sections of pipe, each 100 feet long. These pipes are constructed of steel plate lap welded in courses approximately 7 feet wide. The end courses are ½-inch plate, the middle courses ⅜-inch plate and the balance $\frac{3}{16}$-inch plate. The two ends of each pipe are provided with a half band of 12-inch by ¾-inch plate bent out at right angles at the centre of each side and connected to lug angles. These horizontal extensions have holes 3 inches in diameter. The bands are attached to the upper half on one end and the lower half on the other end of the same pipe thus forming matching connections for succeeding lengths of pipe, held together by 3-inch diameter taper steel pins in the 3-inch holes in the connection lugs. The steel fabricated pipes were conveyed to the contractor's yard in two 50-foot sections and there electrically welded into 100-foot lengths. After being placed on saddles resting on wood bottom forms the outside steel reinforcing was placed. The outside forms were then set and concrete poured forming a horse-shoe shaped outside encasement. Each 100 feet length of pipe required 97 cubic yards of concrete. The inside reinforcing bars were then placed in position and the 2-inch gunite lining completed on the interior. Each section of pipe (Fig. 4) when completed weighed 250 tons. After being thoroughly cured the pipes were placed on a specially constructed derrick boat, taken out into the lake and lowered into position in the trench previously prepared for them.

The pipes had to be transported a distance of almost seven miles and the time of placing these pipes was governed entirely by weather conditions. The derrick boat (see Fig. 5) had to be placed in exact position for lowering the pipe after which divers were stationed at the end of the pipe on the lake bottom and by the use of submarine telephones gave instructions as to shifting of the pipe in

Fig. 5—Placing Intake Pipe, Diameter 96 inches.

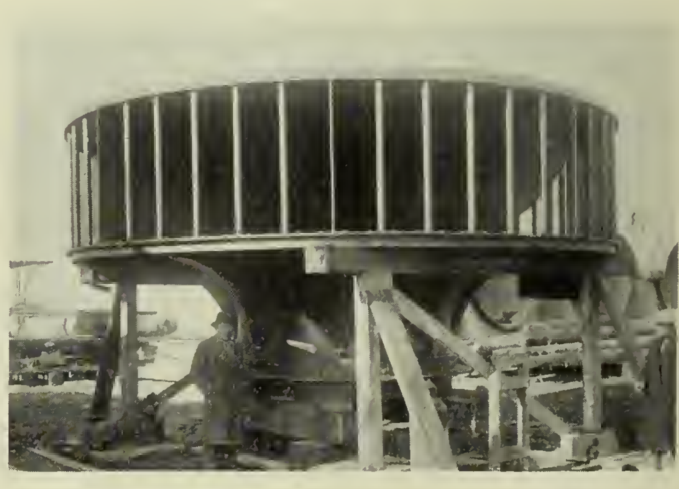

Fig. 6—Inlet to Intake Pipe, Diameter 20 feet.

order to make the connection. Ahead of the laying of the pipe a clamshell dredge carried out the dredging work and after this had been done and before the pipe was laid a gravel bed was prepared on which the pipe was laid.

Precautions were taken to prevent concrete and other material getting into the joints between the pipes and after a sufficient time had expired the concrete joints were poured. The 24-inch length of exposed steel plate was completely encased in concrete, all concrete being placed by the tremie method from a floating concrete plant.

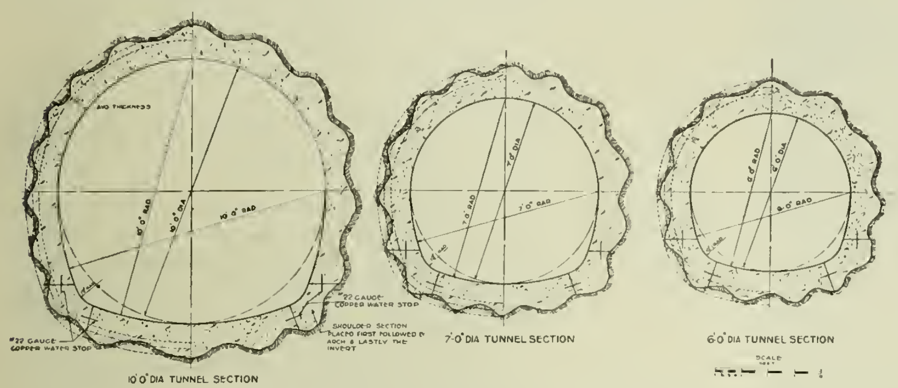

Fig. 7—Sections of Various Sized Tunnels.

At the end of the intake pipe the intake tee is located. This tee is 20 feet long with a 2-inch gunite lining. The outer end of the tee is sealed with a steel plate bulkhead. The 8-foot diameter outlet on top is provided with a flange to which the circular intake is bolted. This intake structure (see Fig. 6) is 20 feet in diameter and divided into eight sections by vertical baffle plates. This furnishes eight rectangular openings arranged in a circle each opening being 7 feet 10 inches wide and 4 feet high. These openings are protected by vertical steel bars 2½ inches in diameter at 15½-inch centres extending from the top to the bottom of the openings. The plates are ⅝ inch in thickness and riveted construction is used throughout.

Tunnels

The raw water intake tunnel under Lake Ontario and the filtered water supply tunnel along the water front were carried out in one contract. From Victoria Park a concrete lined filtered water supply tunnel has been constructed to the existing John street pumping station and continues westward to a pumping station to be erected at Parkdale. The raw water tunnel is 10 feet in diameter, the tunnel from Victoria Park to John street is 7 feet in diameter and from there to Parkdale 6 feet in diameter. At the John street and Parkdale pumping stations surge tanks are provided.

In all, eight shafts were sunk over the entire length of 49,662 feet of filtered water tunnel. A detailed section of each size of tunnel is shown on Fig. 7. After the contract was awarded the section of the tunnel was changed from a true circle to a horse-shoe shape so as to permit of easier transportation facilities. This increased the area of cross section by approximately 5 per cent without any change being made in the contract sum.

The shafts were lined down to the shale level with steel sheet piling and in the shale portion of each shaft the surface was treated with gunite soon after being exposed in order to reduce to a minimum the spalling of the rock. Headings were driven from each shaft and all excavation was taken out in one yard dump cars on a 24-inch gauge track using 25-pound rail, all the hauling being done by ponies. The track was of the one-way type with passing switches. The excavated material was hauled to the surface at each shaft by means of a cage, dumped into a 50-cubic yard hopper and taken away by trucks to a series of disposal areas provided by the city, in most cases in close proximity to the shafts. The line of tunnel being along the waterfront, suitable disposal areas in close proximity to the shafts were secured in connection with the reclaiming of land for harbour development. Generally the shafts were 18 feet in diameter in the overburden where they were lined with steel sheet piling and 13 feet in diameter in the rock. The steel sheet piling was driven by a steam hammer and braced internally with angle rings. The headings were driven 2 feet larger than the finished diameter of the tunnel. The tunnel lining throughout consisted of concrete with a minimum compressive strength of 2,500 pounds per square inch over a twenty-eight-day period. All of the concrete was mixed in transit, then deposited into a 4-cubic-yard hopper at the top of the shaft and placed just below ground level. One-cubic-yard cars were placed on the cage and filled from the hopper, lowered in the cage and hauled along the tunnel to the Ransome pneumatic placing machine which had a capacity of 14 cubic feet for each shot. The concrete was dumped into a box and then placed on the belt conveyor which carried it to the hopper of the pneumatic placer. The concrete was then shot by air into the forms. Steel forms were used throughout and a maximum length of 100 feet was poured at one operation.

The rock shale through which the tunnel was driven disintegrated quickly when exposed to the air. This difficulty was overcome by guniting the walls of the tunnel before the concreting was commenced. The gunite was generally ¾ inch thick and the operation was commenced as soon as possible after the excavated material had been taken out. The gunite successfully prevented further disintegration of the rock and held the surface intact over a period of several months until the final concrete was placed. At each shaft there was erected a pump having a capacity of 130 gallons per minute to take care of the leakage into the tunnel through fissures in the rock and also an electrically driven air compressor for operating

Fig. 8—Steps Forming Ramp in 7-Foot Tunnel.

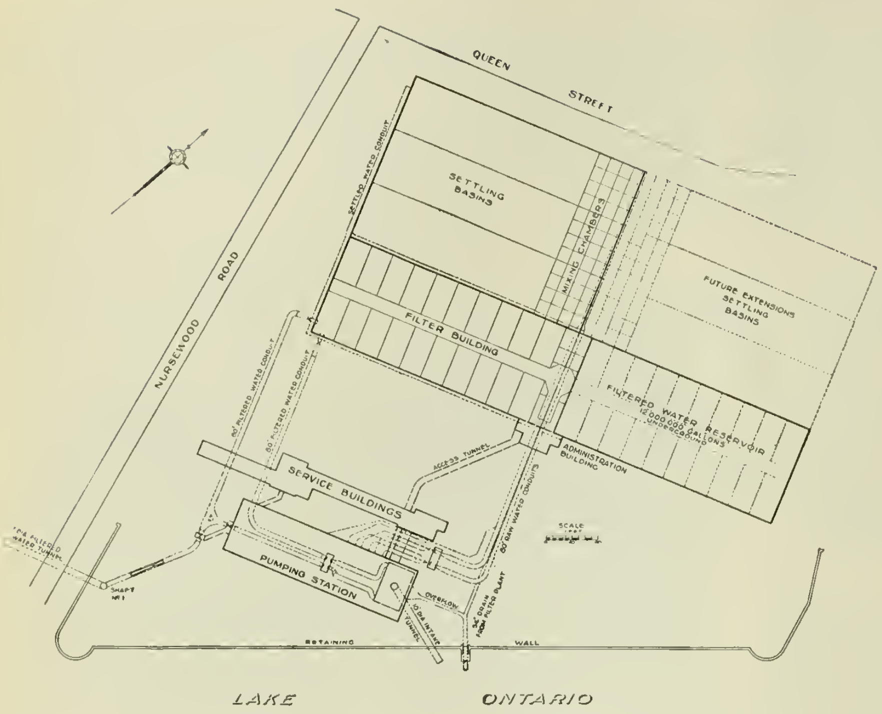

Fig. 9—Layout, Victoria Park Water Purification Plant.

the rock drilling equipment, a double drum mine hoist electrically operated for hoisting the equipment and an electrically driven reversible blower of 2,000 cubic feet capacity for ventilating purposes. These fans developed a maximum pressure of 3½ pounds per square inch. As soon as the blasting had taken place in the heading, the fans, which were supplying fresh air to the heading, were reversed and used to suck the powder smoke from the heading. After running in this way for thirty to sixty minutes the fans were again reversed for pumping fresh air to the underground workings. The air line for the drilling equipment was 4 inches in diameter and for the ventilating air a 10-inch galvanized pipe was used throughout. Figure 8 shows a view of a ramp in the 7-foot diameter tunnel.

Water Purification Plant

The water purification plant and pumping station now in the course of erection at Victoria Park are the major units in the waterworks extension scheme. The general layout of the works at Victoria Park is shown in Fig. 9. The general design of the purification plant was influenced to a large extent by the shape and topography of the site.

The water purification plant consists of a filtered water reservoir, having a capacity of 12,000,000 gallons, over which are constructed the filters, pipe galleries, concourse and chemical room. For the present, twenty filters comprising the western half of the ultimate plant have been completed, together with the administration building, the central concourse and chemical section. Above the concourse and chemical section the wash water tanks are placed.

The portion of the reservoir extending to the east of the main concourse forms the foundation for an additional twenty filters which will give the plant an ultimate capacity of 200,000,000 gallons daily at the standard rate of filtration of 105,000,000 gallons per acre per day. As the roof of the reservoir forms the floor of the filters and pipe gallery all wall and floor castings, filter effluent conduit, concrete Venturi meter, etc., required for the future filters have been constructed where these are located within the reservoir.

The mixing chambers and settling basins are located to the north of the reservoir and filters.

The filters are arranged on either side of a single filter-operating gallery, underneath which is the pipe gallery. The pipe gallery contains only the main wash water and the filter effluent piping, the settled water influent and the wash water waste conduits being at the back of the filters.

Each filter (Fig. 10) is 68 feet long and 35 feet 7 inches wide and has a net filter area of 2,103 square feet which at the standard rating of 105,000,000 gallons per acre per day gives each unit a capacity of 5,000,000 gallons per day.

These filter units are unusually large and particular attention has been given to the design of the wash water system in order to secure an even distribution of wash water and therefore a uniform rate of back wash throughout the whole filter area.

The underdrain system of one filter unit consists of a concrete conduit, 3 feet square in cross section, constructed integral with and underneath the filter floor and along its centre line. The wash water enters this conduit from the 36-inch cast iron pipe in the filter pipe gallery through a 30-inch hydraulically controlled gate valve and then passes upwards through fourteen rectangular ports into a rectangular distribution manifold constructed in concrete. These ports are of sizes and spacing designed to compensate for the varying conditions of flow such as the friction loss, reduction in velocity and increase in pressure along the length of the conduit.

From the manifold the wash water will be distributed through the underdrain lateral pipes which were designed to secure, as far as practical, equal flow through each orifice. The lateral pipes are of cast iron 4 inches in diameter at the inlet end and tapering to 2½ inches and are spaced 12 inches apart. The orifices are on the underside and consist of brass nozzles of ¾-inch bore, also spaced 12 inches apart resulting in one orifice per square foot of filter area. The outer ends of the underdrain laterals are interconnected by a cast iron manifold pipe extending along the side walls of the filter, the purpose of which is to offer a further equalizing effect should the pressure in one area be greater or less than in another.

The filter bed consists of graded gravel to a depth of 18 inches over which is a blinding layer of coarse sand 2 inches thick. Over this, filter sand to a depth of 26 inches will be placed. The filter sand will have an effective size of 0.55 millimeters and a uniformity coefficient of 1.4.

The wash water troughs are of reinforced concrete (Figs. 10 and 11) leading to a central main drain in each filter. The piping in the main gallery is of cast iron throughout and all of the control valves are hydraulically operated. The complete control of the operation of each filter together with the recording apparatus is governed from an operating table situated on the operating floor, one table to each filter. The operating gallery has a terrazzo and marble floor with skylights running throughout the entire length of the building. In order to keep down the cost of heating the building each side of the operating gallery has been enclosed with windows. The outside walls of the building are of gray stock brick with stone trimmings. The flat roof over the filters is of reinforced concrete and covered with cork insulation, felt and gravel roofing.

A feature worth special mention is the provision for chlorinating and dechlorinating the filtered water. The effluent pipes from each filter discharge into a concrete filtered water conduit in the reservoir in which a meter of rectangular section is constructed. After passing through this meter the filtered water is dispersed within a walled area at the centre of the reservoir into which the chlorine solution is diffused. To reach the reservoir outlet the chlorinated water must travel a definite path by reason of the concrete baffle walls, the purpose of which is to ensure a minimum contact period of chlorine and water when superchlorination is practised. Also the path of the water is arranged to permit of dechlorination prior to the water leaving the reservoir.

The purpose of the Venturi meter in the filtered water conduit is to afford a continuous indication of the rate of filtration for the guidance of the chemical operators.

Chlorine and sulphur dioxide will be stored in one-ton cylinders in the chemical storage room. The solution feed machines and evaporators will be located in the chemical machine room directly over the reservoir and within a few feet of the point of application of the chemical. The chemical storage room is equipped with an overhead water fine spray system which can be controlled from outside the room in the event of a major gas leak.

The filter-rate controllers are of the double butterfly valve type and are connected to a central master control which is actuated either by a float on the water level in the reservoir or manually. Under normal working conditions the maximum rate will be set on the manual control but when the water level in the reservoir is within one foot of the overflow the float control will regulate the rate according to the distance the water level is below the overflow.

The whole operation of the filter plant will conform closely to the standard practice used in mechanical filtration. The water will be treated with filter alum or other coagulants which will be supplied from dry feed machines placed in a separate building. Provision has also been made for treating the water with activated carbon should this be found necessary.

One of the main features connected with the plant is the mixing and coagulating tanks. This type of mixing tank was developed by the late William Gore and is usually referred to as the "Gore mixing tank." Previous to the construction of the Ottawa water purification plant two trial filters were erected there, chiefly with the object of

Fig. 11—Concrete Wash Water Troughs in Filter Unit.

developing better methods of coagulation previous to settling out and filtration. The results obtained from the operation of this plant are fully described in a paper entitled "The Trial Filtration Plant, Ottawa, Canada" by George G. Nasmith.[2] The method as now worked out

[2] Volume 22, No. 8 of the Journal of the American Water Works Association.

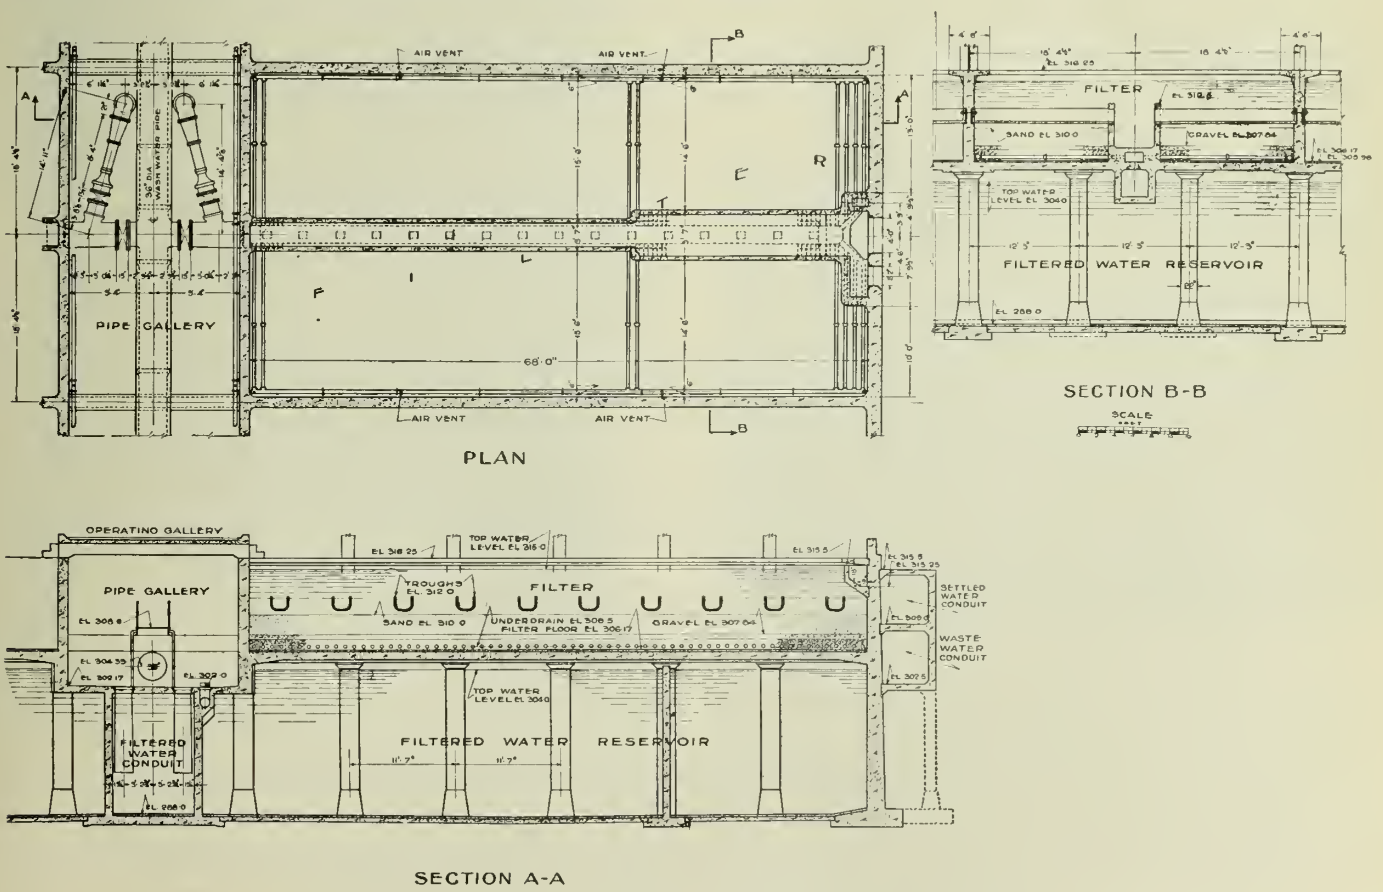

Fig. 10—Typical Filter, Victoria Park Water Purification Plant.

has proved exceptionally efficient and for several years has been in operation at Ottawa, Calgary, Belleville and St. Thomas. For the maximum rate of flow the mixing tanks have a capacity for forty minutes' treatment and the settling tanks for two hours and fifty minutes. The combined mixing and settling tanks are three in number, each 389 feet 3 inches in length, 90 feet in width and a depth of 23 feet 8½ inches. Each mixing chamber is 90 feet

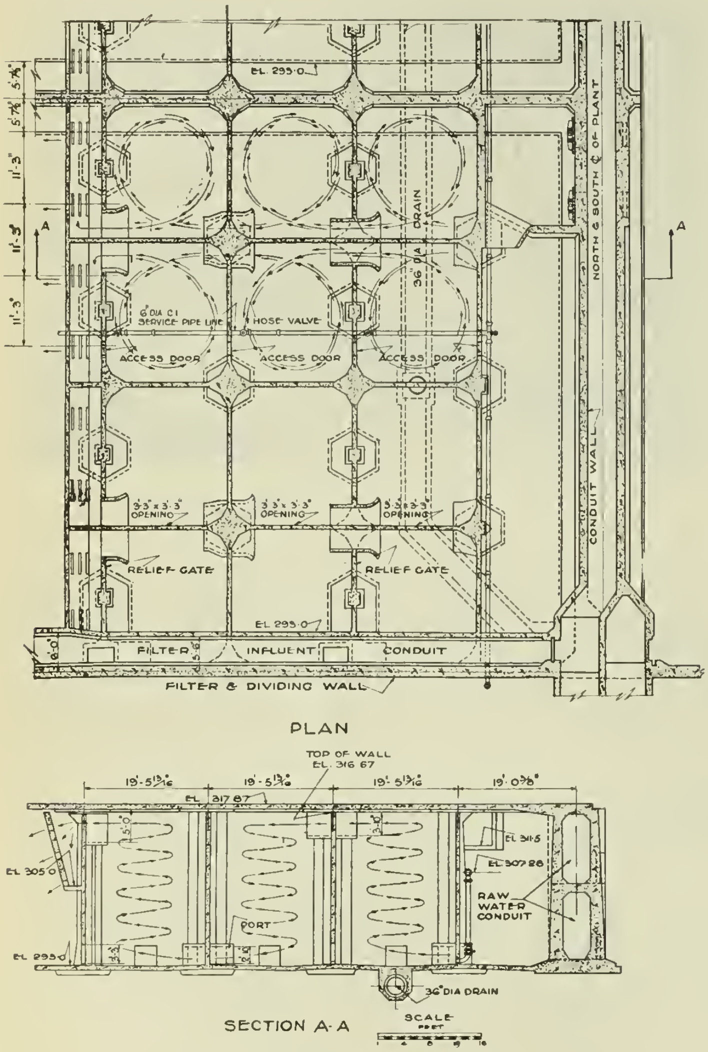

Fig. 12—Mixing Chambers.

in width and 73 feet in length, divided into twelve separate compartments. This part of the plant was designed to produce a very gentle stirring action and distribute the flocculated water into the settling tanks without breaking up the floc which is extremely fragile. Short circuiting was reduced to a minimum by dividing the process into several stages and by the special design of the passages. The raw water after treatment with the necessary chemicals is brought to the settling tanks by a concrete conduit running along the easterly wall. From this conduit the water enters the mixing chambers and the direction of flow from one compartment to another changes until the water finally reaches the settling tank as shown in Fig. 12. The coagulation obtained in these chambers is most effective and the total loss of head in passing through the various compartments will be about four inches at normal capacity. Figures 13 and 14 show inside views of the mixing chambers and settling tanks.

The administration building, situated in the centre of the final development, contains, besides the administrative offices, a fully equipped laboratory with all the necessary apparatus for controlling and directing the water purification operations.

Reservoir Leakage Test

On top of the concrete floor of the reservoir a waterproof membrane was placed consisting of a layer of asphalt-saturated asbestos mopped with a coating of asphalt waterproofing cement using 30 pounds of such cement for each 100 square feet, and while still hot a layer of asphalt-saturated fabric was embedded in it. The surface of this saturated fabric was again mopped with a coating of waterproofing cement and while still hot a layer of asbestos felt laid at right angles to the fabric with joints lapped 3 inches was embedded in it. Over the surface of this felt a coating of waterproofing cement was placed. Once this had been completed and allowed to set thoroughly, a two-inch layer of concrete was placed throughout the entire reservoir floor.

Under the contract a leakage test was carried out extending over a period of five days. The permissible invisible leakage during the test was not to exceed 60 Imperial gallons per minute. The total floor and wall area of the reservoir subject to leakage is about 174,000 square feet and the test showed that the total leakage during one hundred and twenty hours was 6,160 gallons or somewhat less than one Imperial gallon per minute.

Pumping Stations

The pumping station to be constructed at Victoria Park will be an all-electric station without auxiliary power of any kind other than a relatively small supply obtained

Fig. 13—Outlet Section of Mixing Chambers.

from storage batteries which will be available at all times for the automatic operation of switching equipment and for certain emergency lights, selsyn motor and synchronous clock circuits. The pumping station will contain the low lift pumps which will pump raw water to the filter plant and the high lift pumps which will pump filtered water into the distribution system. Also included in the station will be the wash water pumps.

The pumping station structure is to be 295 feet in length by 84 feet in width and is divided into four parts, the intake and screen section, low lift pump section, high lift pump section and administrative and control section. In addition to the pumping station proper there are several valve and meter chambers with interconnecting galleries and a very substantial group of service buildings comprising the chemical plant, heating plant, transformer station, workshops and stores, the location and extent of which are evident from a study of Fig. 9.

Fig. 14—Settling Basin Looking Towards Mixing Chambers.

The intake and screen section of the pumping station is built directly over the intake shore shaft and will contain four and ultimately eight mechanically operated travelling screens through which the incoming water will pass to two 84-inch suction headers. Each of the screens is contained in a separate compartment which can be isolated by electrically operated sluice gates. In the construction of the screen section provision is made for a surge overflow duct which will adequately handle any surge that may be caused by sudden stoppage of the raw water pumps due to failure of the power supply.

The low lift pump section will in the beginning contain four synchronous-motor-driven, single-stage, centrifugal pumps having capacities of 50, 40, 25 and 20 million Imperial gallons per day, respectively, against a total head of 82 feet. In addition to the provision of space for two future pumping units the piping for all pumps is designed on the basis of 50,000,000 gallons capacity to provide for ultimate requirements.

The high lift pump section will contain two synchronous-motor-driven, two-stage, centrifugal pumps each having a capacity of 12,000,000 gallons daily against a net head of 191 feet, and two units of similar type each having a capacity of 18,000,000 gallons per day against a net head of 260 feet. The former units are for pumping filtered water into No. 1 District of the distribution system and the latter units will serve No. 5 District of the distribution system (see Fig. 1). In addition the high lift section will contain three induction-motor-driven, single-stage, centrifugal pumps for pumping filtered water to the wash water tanks in the filter plant to be used for back-washing the filters. These pumps will have capacities of 10, 7½ and 5 million gallons daily, respectively, against a total head of 54 feet.

The discharge pipe line from each of the raw water pumps will contain a Venturi meter and all such meters are placed in a meter gallery which lies between the pumping station proper and the chemical plant. Beyond these meters the raw water discharge pipes are merged in two groups into two 84-inch conduits leading to the filter plant. Each of these conduits is equipped with a controller valve, the purpose of which is to automatically maintain the level of water in the settling basins within predetermined limits.

The discharge pipe lines from each of the high lift pumps will contain combined automatic stop, check and throttle valves, Venturi meters and surge suppressors.

In the equipment of the pumping station a very extensive and modern system of remote indication and control is provided for. For instance the rate of flow as measured by the individual Venturi meters on the raw water pumps will be electrically totalized to control automatically the application of chemicals to the raw water. Also the rate of flow indicated by each individual Venturi meter, the degree of valve opening, suction and discharge gauge pressures, will be remotely indicated on dials in the pump control cabinets set on the pump room floor and also, in some cases, on similar instruments mounted on the main switchboard in the control room. In addition to the valves meters and gauges directly connected with each pumping unit, other main valves used in connection with the operation of the plant, various water level gauges, and the 84-inch Venturi meter which will measure the filtered water being drawn by the combined John street and Parkdale pumping stations will be equipped with remote indicating devices mounted in the main control room.

As previously stated the Victoria Park pumping station is designed solely as an all-electric station without standby power of any other kind. In consequence of this the whole electrical installation from "incoming" lines to distribution busses, inclusive, is to be completed in duplicate with the most modern equipment and protective devices obtainable to ensure the minimum interruption to service. Power will be furnished by the Toronto Hydro-Electric System at 13,200 volts from the Carlaw avenue and the Danforth avenue substations and will be brought to the transformer station at Victoria Park over two underground cables. Provision is also made at this substation for a third "incoming" line. At Victoria Park power will be transformed from 13,200 to 2,300 volts.

Fig. 15—Filtered Water Conduit in Reservoir.

The main switchboard in the control room is of the bench board type with dummy bus and push button control. The electric installation includes auto transformers for reduced voltage starting and motor generator exciter sets for field current. The switching equipment is so arranged that the synchronous motors will start on reduced voltage and when up to approximately synchronous speed will automatically be thrown on full voltage and the field applied. The rheostats in connection with the exciter sets will be motor operated from the bench board.

The discharge valves from the eleven pumps and the two regulating valves may be opened or closed or otherwise controlled from the bench board in the control room. Also the position of each valve so controlled, the rate of flow, gauge pressures and water levels are all transmitted to, and indicated on, this board. In addition to the main bench board the control room contains a relay board and service board. A further transformation from 2,300 to 550 volts is made in the pumping station to provide 550-volt power for drainage pumps, cranes, travelling screens and various other equipment, the distribution of which is controlled from the service board.

It is intended to provide metal clad switch gear for all 13,200- and 2,300-volt switches and oil disconnects.

The Parkdale pumping station in general follows the requirements laid down for the Victoria Park pumping station except that there will be no pumps of the low lift type.

Chemical Treatment

The chemical plant is designed to contain a reasonable storage of alum having in mind an ultimate capacity of 200,000,000 gallons daily. Alum will be delivered to the plant in bags by trucks and will be handled by pneumatic conveying equipment into the storage bins. From the storage bins it will be drawn by gravity into weight hoppers furnished in connection with the dry feed chemical machines. Two such machines are to be installed at present for alum and a third machine which may be used for activated carbon or such other chemicals as may be required in the future. From the solution chambers of the chemical machines the solution will flow by gravity and be applied to the incoming raw water at the intake well.

Each of the two storage bins has capacity for 140 tons of alum. It is estimated that the dosage of alum applied to the raw water will average 0.5 grains per gallon and will not exceed 1.5 grains per gallon.

St. Clair Reservoir

The first actual work to be placed under construction and put in service was the St. Clair reservoir to take care of District No. 2. This reservoir has a capacity of 50,000,000 gallons, is built of reinforced concrete throughout, the roof being supported on columns. The flat slab roof has the 3-way system of reinforcing and is 10 inches in thickness. The earth fill to a depth of 2 feet has been sodded over and a most serviceable park for the use of the citizens is available at all times. Tennis courts and other outdoor recreations are in full swing particularly in the summer months. The reservoir is divided into two compartments of equal capacity. Figure 17 gives typical cross sections through the outer wall, dividing wall and columns. There are 830 columns supporting the roof. The columns are spaced at 21 feet 6 inches centres and the reservoir has a water depth of 23 feet. The volume of concrete placed amounted to 42,452 cubic yards. The total cost of the reservoir, excluding land and engineering, was $884,395, which works out at approximately $17,688 per million gallons capacity.

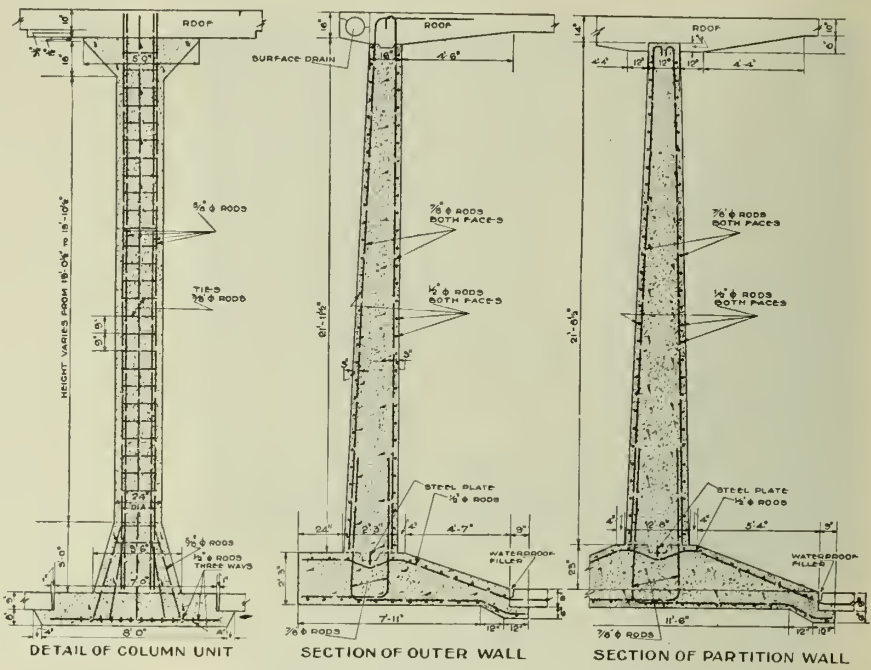

Fig. 17—St. Clair Reservoir, Concrete Details.

St. Clair Overhead Tank

Plans have been prepared for the erection on the same site of an enclosed steel overhead storage tank having a capacity of 536,000 gallons to serve District No. 3. In keeping with the surroundings this tank is of an ornamental type as shown on Fig. 18. The concrete piers for supporting the tank were built on a ring footing which was constructed a few feet below the original ground surface. The earth fill at this part of the reservoir embankment

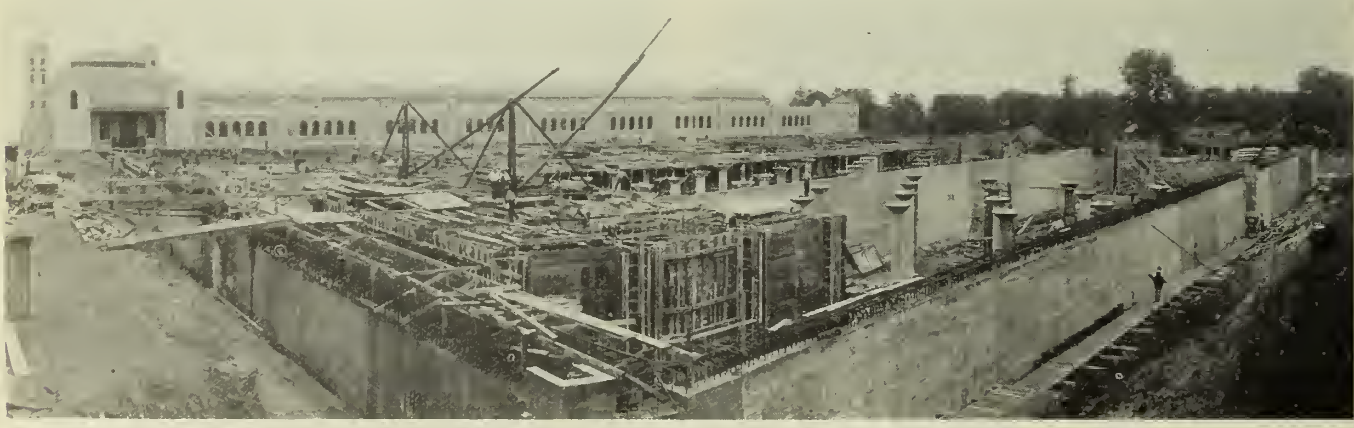

Fig. 16—Northerly Elevation of Victoria Park Filter House, Mixing and Settling Tanks in Foreground.

is about 29 feet in depth and to curtail the total load on the hill the piers were connected by a circular wall and the enclosure was left unfilled. The tank is 45 feet inside diameter with a maximum depth of 65 feet supported on 12 steel columns and having a riser pipe 8 feet in diameter. The overflow pipe is 14 inches in diameter and access openings are provided on the roof and at the base of the riser pipe. The structure is designed to withstand safely the weight of the steel tank, the weight of the buildings surrounding the structure, the weight of the water in the tank, wind stresses caused by a hurricane blowing at the rate of 100 miles per hour from any direction and the snow load on the roof of the tank. Stresses caused by emptying and subsequent filling of the tank in a space of thirty minutes were taken into account in designing the structure. The tank bottom is of the elliptical type with a depth of the elliptical section of 15 feet. All structural steel columns, beams, brackets and the overhead tank including roof and riser pipe (inside and outside) are to be coated with gunite 1½ to 2 inches thick.

In general the building is to be faced with brick of first quality grey stock with stone base, pilasters and trim cut from the best quality Queenston limestone. The total cost of the overhead tank excluding land is estimated to be $120,000.

Conclusions

On the completion of the waterworks extensions Toronto will have available a water supply capable of taking care of a population of 1,000,000 persons and so laid out as to permit of extensions being made whenever required to supply 1,500,000 persons. The extensions everywhere contain the most up-to-date equipment and every known precaution has been taken to ensure the safety and continuity of the supply. To adequately safeguard the raw water supply the city council has under consideration extensive additions to the sewage disposal works, the effluent from which at the present time discharges into Lake Ontario about midway between the existing Centre Island intakes and the new intake at Victoria Park.

Engineering

The whole project is being carried out under the direction of R. C. Harris, Commissioner of Works, with George G. Powell as deputy city engineer, and the late James Milne, M.E.I.C., and latterly A. U. Sanderson, A.M.E.I.C., as chief engineer of the Water Supply Section.

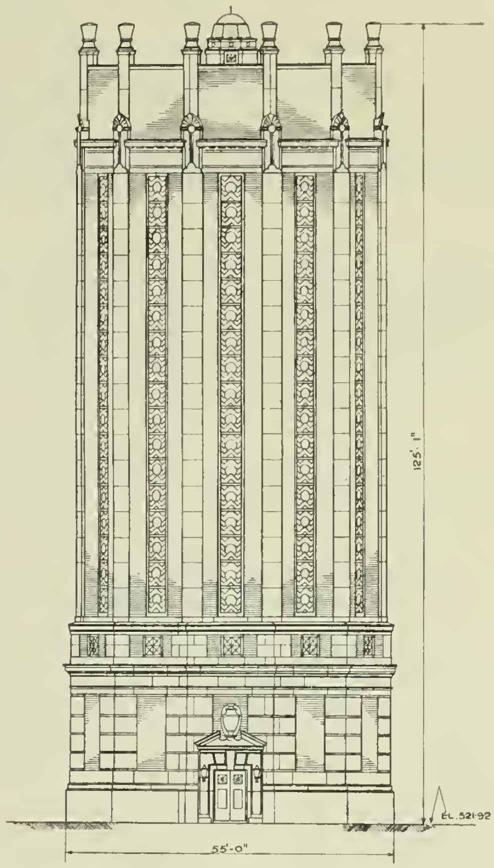

Fig. 18—Water Tower for District No. 3.

The design of the works, the supervision of construction and the operation for a period of one year after placing the works in service is being carried out by H. G. Acres and Company, Limited, and Gore, Nasmith and Storrie, joint consulting engineers on the work

Simple Graphical Solution for Pressure Rise in Pipes and Pump Discharge Lines

Robert W. Angus, M.E.I.C.,
Professor and Head of Mechanical Engineering, University of Toronto, Toronto.

Paper to be presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

SUMMARY.—Dealing with the problem of finding the pressure changes in a pipe line, caused by changes in the flow of water, the author explains a graphical method of calculation based largely on the work of Allievi. A number of numerical examples are worked out, involving the effect of rate of gate-closure, resonance, surge-tank action, and supply by a motor driven centrifugal pump.

The problem of finding the pressure change in a pipe line where there is variable flow produced, for example, by altering the opening in a discharge valve, has always been an important one and frequently very baffling. Where the pipe is uniform in size, the solution is much simpler than in the case of tapering pipes, and the addition of branches from the main line greatly complicates the problem.

The names of Joukovsky and Allievi will always be associated with this problem, the former engineer having done a lot of fundamental experimental work and established the general theory and certain fundamental equations. Lorenzo Allievi,(1) still living in Rome, greatly simplified the work previously done and prepared many very important diagrams and charts for the solution of certain types of problem. Allievi's book was written in Italian, later translated into German and into French, but did not exist in English till 1925 when Mr. Eugene Halmos(2) of New York translated the work under the title "Theory of Water Hammer, Notes I to V"; this edition was printed in Rome and contains a number of errors in spelling and grammar (but few in mathematics) and many curious and unusual phrases; yet the author of this paper never read anything of any kind that so thrilled and pleased him, as he saw the elegance and completeness with which Professor Allievi had mastered his subject. The book is a masterpiece, extremely simple and logical and must be regarded as the basis of modern work on this subject.

Notwithstanding all the merit Allievi's book possesses, it is not much read by engineers, most of whom lay it aside because they think it contains too much mathematics. The entire mathematical difficulty in the work is due to two equations established by Allievi from hydrodynamics, which may be readily verified and which are actually unwittingly used by all persons solving problems on water hammer. Before proceeding further, these equations must be explained. In Fig. 1 the simplest case is shown, where a pipe of uniform diameter discharges through a nozzle, or valve or turbine gate, or other similar device. Friction will first be neglected, as is usual, and because it produces very small effects in most of the cases discussed herein.

The symbols used throughout the paper are tabulated below for convenient reference.

The words "gate," valve," "nozzle" have the same meaning and refer to the device at the discharge end of the pipe, by which velocity changes are made.

A_P = Area of pipe, square feet, assumed uniform.
A_1 = Area through gate or nozzle or valve, square feet.
A_E = Effective area in square feet through gate = $A_1 \times$ coefficient of discharge c_d.
$G = \frac{A_E}{A_P}\sqrt{2g}$ and varies only with A_E.
c_d = Coefficient of discharge.
Q = Discharge through pipe at any instant, cubic feet per second.
v = Velocity in pipe at any instant, feet per second.
u = Demand velocity in problem on surge tank, feet per second.
v_{Bt}, etc. The notation is similar to that for H.
a = Velocity of the pressure wave in the pipe, feet per second.
H = Head in feet (not including velocity head) in pipe close to gate, or at the point and time indicated by the subscript used with it.
H_{Bt}, etc. = Pressure in feet at the point B at t seconds after gate movement begins. Thus, $H_{A3.2}$ is the pressure in feet at the gate end of the pipe 3.2 seconds after the gate is first moved.
h = Instantaneous pressure rise (or fall) in feet due to a small gate movement.
F = Sum in feet of all the instantaneous direct pressures up to any instant.
f = Sum in feet of all the instantaneous reflected pressures. It has been written with a plus sign but is numerically negative.
l = Length of pipe, in feet.
x = Distance from the gate to the section under consideration, feet.
t = Time in seconds after gate movement begins, at which the events occur.
$X = v/v_0$ and $Y = H/H_0$ at the point and time designated by the subscript used.
$A\,3.2$ on the diagram is a point showing the pressure and velocity at the gate end of the pipe 3.2 seconds after the gate begins to move, and so on for other points.
A, B, C are points on the pipe line at the valve end, at an intermediate point and at the reservoir end, respectively, unless otherwise stated.

The subscript zero placed after any of the above symbols denotes the value at steady pipe flow, and before gate motion begins.

$\rho = \frac{av_0}{2gH_0}$ the pipe line characteristic of Allievi.

At any instant after gate movement begins, let the discharge be Q cubic feet per second, which corresponds to a head H feet at the nozzle; and if at this instant the pipe and gate areas are A_P square feet (assumed uniform from end to end of the pipe) and A_1 square feet, respectively, then the corresponding velocities will be v feet per second and u feet per second, respectively, in the pipe and from the nozzle.

Now let $A_E = A_1 c_d$ be the effective nozzle area, by which is meant the actual discharge area multiplied by a suitable coefficient of discharge. Let the quantities corresponding to the above, for steady motion (that is, before gate movement begins) be Q_0, H_0, A_P, A_{E0}, v_0 and u_0, respectively.

For the exact explanation of what happens in the pipe during gate movement, the reader is referred to standard textbooks and papers, such as the author's "Hydraulics for Engineers"(3) and numerous papers, amongst which may be specially mentioned those by N. R. Gibson(4) and Miss

(1)Numbers refer to bibliography at end of paper.

O. Simin.[5] The author sees no justification for repeating here the explanation given in those publications.

Briefly, it may be stated that when any slight closing movement of the gate occurs it extinguishes a part δv of the velocity, and causes a momentary rise in pressure h feet to travel from the gate up to the reservoir and back again at a velocity of a feet per second, the time interval required for the complete travel of this wave being $2l/a$ seconds, where l is the pipe length in feet. When this wave of positive pressure returns to the gate it is reflected as a

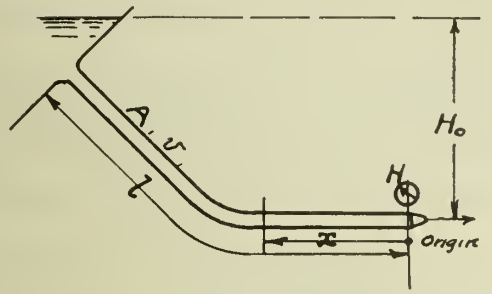

Fig. 1

negative wave of equal magnitude, and this process continues till it finally dies out through friction. It is easy to show (see articles already referred to) that the relation between the quantities is

$$h = \frac{a}{g} \cdot \delta v \qquad (1)$$

This is Joukovsky's relation.

Referring now to Fig. 1, the following relations are evident, for any given interval:

$$Q = A_P v = A_E \sqrt{2gH}$$

or, at any instant

$$v = \frac{A_E}{A_P}\sqrt{2gH} = G\sqrt{H} \qquad (2)$$

also, before movement begins

$$v_0 = \frac{A_{E0}}{A_P}\sqrt{2gH_0} = G_0\sqrt{H_0} \qquad (3)$$

Hence $$\frac{v}{v_0} = \frac{G}{G_0}\sqrt{\frac{H}{H_0}} = E\sqrt{\frac{H}{H_0}} \text{ where } E = \frac{G}{G_0} \qquad (4)$$

To determine the change of velocity and the corresponding pressure rise due to any gate movement, the two equations (1) and (2) are available and are most easily solved by a trial and error process. For the first pressure wave it is evident that

$$v = G\sqrt{H} = G\sqrt{H_0 + h}$$

and G is known from the method of moving the gate. For any later period after several movements of the gate, the equations are the same, G being known as already explained, but the h to be used is the algebraic sum Σh of all the pressure changes, positive and negative, up to the time considered, or

$$v = G\sqrt{H_0 + \Sigma h} \qquad (5)$$

An example taken from the author's textbook is given here for illustration. The water in a pipe 643 feet long has a steady velocity, with open gate, of 14.44 feet per second, under a head $H_0 = 400$ feet, and the valve at the discharge end of it is assumed to close in such a way that its effective area decreases uniformly with time; that is, there is a straight line relation between A_E and the time reckoned after gate motion begins. The velocity of wave travel $a = 3{,}800$ feet per second has been used. It is desired to find the pressure changes in the pipe.

The two equations give corresponding values of H and v at the gate, which satisfy them; and the method is assumed to be well enough known to require no detailed explanation. For the case mentioned, the results are shown in Fig. 2, the actual pressures being taken directly from the author's textbook. In the illustration, the pressure waves are shown by single lines instead of by the typical diagram for the first gate movement at (a) Fig. 2; in the single line pressure-wave diagram at (b) Fig. 2, the heavy lines indicate the direct or positive waves, while the light lines indicate the negative or reflected waves.

Below the pressure-wave diagram (b) there are shown at (c) the sums of all the positive or direct pressures up to each time given, these being designated by F on the diagram; at (d) are shown the sums of all the negative or reflected pressures, designated by f, up to the time given; at (e) are plotted the algebraic sums of the positive and negative pressures, which are simply the sums $F + f$, and as f is always negative these are really numerical differences; at (g) are the algebraic differences of the positive and negative pressures, and for the reason just stated these are numerical sums.

The above diagrams give pressures at the gate, but if similar information is desired at another point on the pipe, then corresponding pressure diagrams may be drawn for that point; e.g. the one for the centre of the pipe cor-

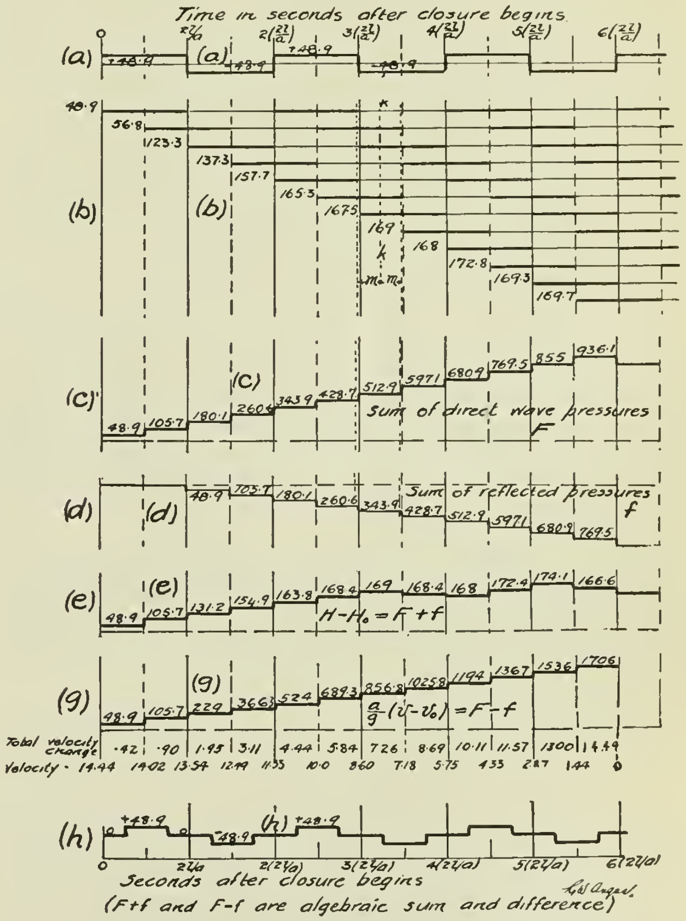

Fig. 2—Pressure Wave Curves for Pipe 643 Feet Long.

$a = 3{,}800$ ft. sec. $v_0 = 14.44$ ft. sec. $H_0 = 400$ ft.

Closure Time $T = 6\left(\frac{2l}{a}\right)$ sec.

responding to the first movement of the gate is shown at (h) on Fig. 2. This is the diagram for the centre of the pipe at a time $l/2a$ seconds later than the corresponding diagram at the gate, since the pressure rise produced at the gate takes $l/2a$ seconds to reach the centre of the pipe. By drawing the series of pressure diagrams for the centre of the pipe for each gate movement, as has been done for the gate end at (b) Fig. 2, the pressure at any instant is easily found by the method already described, and well known as arithmetic integration.

With these preliminary statements, Allievi's equations, as given by Halmos,(2) may now be stated, and should be easily understood from the illustrations which follow.

ALLIEVI'S EQUATIONS

$$H - H_0 = F\left(t - \frac{x}{a}\right) + f\left(t + \frac{x}{a}\right) \ldots\ldots\ldots\ldots (6)$$

$$v_0 - v = \frac{g}{a}\left[F\left(t - \frac{x}{a}\right) - f\left(t + \frac{x}{a}\right)\right] \ldots\ldots\ldots (7)$$

$$H_n + H_{n-1} - 2\,H_0 = \frac{a}{g}(v_{n-1} - v_n) \ldots\ldots\ldots (8)$$

The origin for distance is taken at the gate and x is the distance (measured towards the reservoir) at which the pressure is H feet at t seconds after closure begins, the velocity corresponding to H being v feet per second.

The quantity $F\left(t - \frac{x}{a}\right)$ is the sum of all the direct or positive pressures at time t and at a point x feet from the gate. The sums of these pressures at the gate, where $x = 0$, are given at (c) Fig. 2; in this case $F\left(t - \frac{x}{a}\right) = F(t)$, which in that figure is denoted by F. Similarly, $f\left(t + \frac{x}{a}\right) = f(t)$ at the gate, which is denoted by f in Fig. 2 at (d).

In the case shown, these summations are made for each half interval, and this is desirable in any case, and is absolutely essential if the pressure at the centre of the pipe is to be found; it would be necessary to make the calculation for each quarter interval if the pressure at $\frac{1}{4}\,l$ or $\frac{3}{4}\,l$ from the gate was desired.

For the centre of the pipe $x = l/2$ and

$$F\left(t - \frac{x}{a}\right) = F\left(t - \frac{l}{2\,a}\right) \text{ also } f\left(t + \frac{x}{a}\right) = f\left(t + \frac{l}{2\,a}\right),$$

so that at any instant t after closure begins, one would take the algebraic sum (numerical difference) of the direct pressures $l/2\,a$ seconds earlier, and of the reflected pressures $l/2\,a$ seconds later, which is easily done by means of diagrams (c) and (d) Fig. 2. The dotted line kk corresponds to $t = 6.5\,l/a$ and the additions and subtractions are taken at the lines distant m from kk.

A little reflection will show that these formulæ of Allievi only express in algebraic manner the process actually carried out arithmetically in the example given above, as is shown by the following illustrations:

(a) *A point at the gate end of the pipe where* $x = 0$.

(1) At $t = 3\left(\frac{2\,l}{a}\right)$ seconds after closure begins, the pressure rise is clearly $F(t) + f(t)$, or the sum of the two curves (c) and (d) in Fig. 2 at time $t = \frac{6\,l}{a}$; i.e. $H_3 - H_0 = 428.7 + (-\,260.6) = 168.1$ feet (curve e) and so on for all times desired.

Then $H_3 = H_0 + 168.1 = 568.1$ feet.

(2) At the same time $t = 3\left(\frac{2\,l}{a}\right)$ seconds the velocity change is

$$\frac{g}{a}[F(t) - f(t)] = \frac{32.16}{3800}[428.7 - (-\,260.6)]$$
$$= 5.84 \text{ feet per second}$$
$$= v_0 - v_3 \text{ (curve } g\text{)}$$

or $v_3 = 14.44 - 5.84 = 8.60$ feet per second.

(3) $H_3 + H_2 - 2H_0 = 568.1 + 554.9 - 2 \times 400 = 323$ feet for the third interval, and $(g/a)\ 323 = 2.73$ feet per second; it may be shown that this is the same as is found by the arithmetic method already referred to. H_2 and H_3 are the pressures at the ends of the second and third phases, respectively.

(b) *A point at centre of pipe for the same pressure wave.*

Here $x = l/2$ and the time $t + \frac{l}{2\,a}$ seconds after closure begins, corresponds to t at the gate.

(1) At $t = 3\left(\frac{2\,l}{a}\right) + \frac{l}{2\,a}$ seconds after closure begins, it is readily seen, by drawing the pressure diagrams like (h) Fig. 2, for this point, that the pressure rise is 84.8 feet. Equation (6) would give $H - H_0 = 428.7 - 343.9 = 84.8$ feet, the dotted line k corresponding to the time $3\left(\frac{2\,l}{a}\right) + \frac{l}{2\,a}$ and the distances m being equal to $\frac{l}{2\,a}$ seconds, so that F and f are easily read off.

(2) At the same time the velocity change is, by equation (7), $v_0 - v = \frac{g}{a}\,[428.7 + 343.9] = 6.54$ feet per second or $v = 7.90$ feet per second.

If the reader will take the trouble to actually draw the complete set of pressure diagrams and carry out the calculation by arithmetic integration, he will very soon be convinced of the accuracy of the equations (6), (7) and (8). While equation (8) applies only to pressure rise at the ends of two successive intervals, equations (5) and (6) apply to any point on the pipe, and at the reservoir end where $x = l$ the pressure rise is zero because the values on curve (d) at any instant are the same as those on curve (c) at a period $\frac{2\,l}{a}$ seconds earlier. Familiarity with the meaning of these three equations makes the rest of this paper relatively simple, and indeed, makes it easy to read almost any article on water hammer.

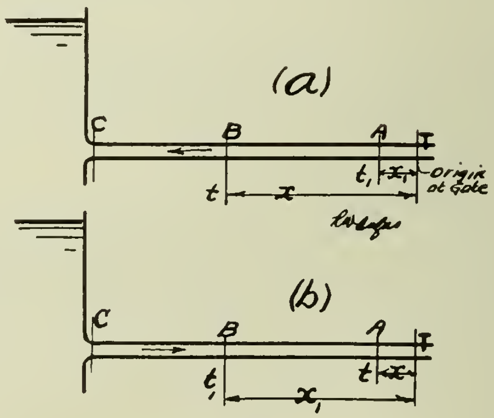

Fig. 3

Taking now Allievi's equations (6) and (7), just discussed, and adding them, gives:

$$H - H_0 = -\,\frac{a}{g}\,(v_0 - v) + 2\,F\left(t - \frac{x}{a}\right) \ldots\ldots\ldots (9)$$

and by substracting them

$$H - H_0 = +\,\frac{a}{g}\,(v_0 - v) + 2\,f\left(t + \frac{x}{a}\right) \ldots\ldots\ldots (10)$$

where H and v are corresponding values for any point x feet from the gate, t seconds after closure begins. Selecting two sections A and B on the pipe, as shown on Fig. 3 (a), equation (9) gives

$$H_{Bt} - H_{B0} = -\frac{a}{g}(v_{B0} - v_{Bt}) + 2F\left(t - \frac{x}{a}\right) \ldots\ldots\ldots (11)$$

$$H_{At1} - H_{A0} = -\frac{a}{g}(v_{A0} - v_{At1}) + 2F\left(t_1 - \frac{x_1}{a}\right) \ldots (12)$$

Where the pipe is of uniform size throughout, $v_{A0} = v_{B0}$ and if, as is most usual, the velocity heads are small relative to the pressure heads, then $H_{A0} = H_{B0}$.

Again, a pressure wave takes $\frac{x - x_1}{a}$ seconds to travel from A to B, so that if events for B are reckoned at a time $\frac{x - x_1}{a}$ seconds later than those for A the very same pressure wave will be under consideration in both cases. But this condition evidently means $t - t_1 = \frac{x - x_1}{a}$ or $t - \frac{x}{a} = t_1 - \frac{x_1}{a}$ or $F\left(t - \frac{x}{a}\right) = F\left(t_1 - \frac{x_1}{a}\right)$.

Therefore with the assumption made as to the times, the subtraction of equation (12) from (11) results in

$$H_{Bt} - H_{At1} = +\frac{a}{g}(v_{Bt} - v_{At1}) \ldots\ldots\ldots\ldots\ldots (13)$$

For the reflected wave, equation (10) when treated in a similar manner gives (see Fig. 3 (b)):

$$H_{Bt1} - H_{B0} = +\frac{a}{g}(v_{B0} - v_{Bt1}) + 2f\left(t_1 + \frac{x_1}{a}\right) \ldots\ldots (14)$$

$$H_{At} - H_{A0} = +\frac{a}{g}(v_{A0} - v_{At}) + 2f\left(t + \frac{x}{a}\right) \ldots\ldots\ldots (15)$$

For the reasons already stated, times are reckoned so that $t - t_1 = \frac{x_1 - x}{a}$ or $t + \frac{x}{a} = t_1 + \frac{x_1}{a}$ from which (14) and (15) give

$$H_{At} - H_{Bt1} = -\frac{a}{g}(v_{At} - v_{Bt1}) \ldots\ldots\ldots\ldots\ldots (16)$$

If three points on the pipe are being studied, then calling them A, B and C and assuming them located as in

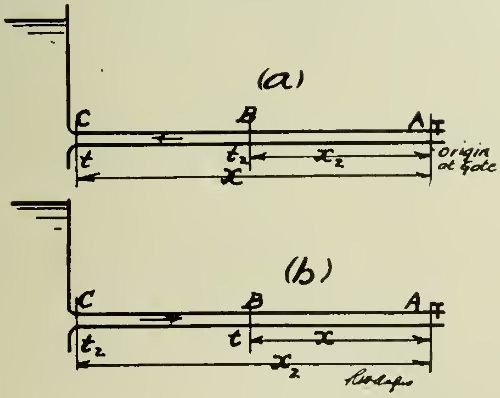

Fig. 4

Fig. 4, the following equations may be written, by the use of (13) and (16):

$$H_{Bt} - H_{Ct2} = -\frac{a}{g}(v_{Bt} - v_{Ct2}) \ldots\ldots\ldots\ldots\ldots (17)$$

$$H_{Ct} - H_{Bt2} = +\frac{a}{g}(v_{Ct} - v_{Bt2}) \ldots\ldots\ldots\ldots\ldots (18)$$

These equations may also be applied, if the pipes AB and BC are of different sizes, with the single change in the value of a, which is different for the two sections. It is assumed that the difference in velocity heads in the two sections is very small compared with H_0.

The four equations (13), (16), (17) and (18), together with a relation similar to (5) which establishes a connection between the law of gate motion, the head H, and the velocity v, are sufficient to solve all problems. To make the case clear, let a pipe 7,000 feet long be attached to a reservoir at C, discharging through a gate near A, and let it have a value of a = 3,000 feet per second. If now A, B and C are, respectively, 100, 2,000 and 7,000 feet from the origin at the gate, then the pressure wave travels from A to B in $\frac{2000 - 100}{3000} = 0.63$ second, and from B to C in $\frac{7000 - 2000}{3000} = 1.67$ second. Hence the four equations already derived, when applied to this case, would be

$$H_{B(t+.63)} - H_{At} = +\frac{a}{g}(v_{B(t+.63)} - v_{At}) \ldots\ldots\ldots (13)$$

$$H_{A(t+.63)} - H_{Bt} = -\frac{a}{g}(v_{A(t+.63)} - v_{Bt}) \ldots\ldots\ldots (16)$$

$$H_{B(t+1.67)} - H_{Ct} = -\frac{a}{g}(v_{B(t+1.67)} - v_{Ct}) \ldots\ldots (17)$$

$$H_{C(t+1.67)} - H_{Bt} = +\frac{a}{g}(v_{C(t+1.67)} - v_{Bt}) \ldots\ldots (18)$$

It is frequently convenient in work of this kind to get the values of H/H_0 and v/v_0 instead of H and v. To save letters, the former will be denoted by Y and the latter by X, as these are the axes on which the quantities are plotted later on.

From equation (13) by dividing by H_0 there results

$$\frac{H_{Bt}}{H_0} - \frac{H_{At1}}{H_0} = \frac{av_0}{gH_0}\left(\frac{v_{Bt}}{v_0} - \frac{v_{At1}}{v_0}\right)$$

Now the quantity $\frac{av_0}{2gH_0}$ has been designated by ρ by Allievi, who called this quantity the pipe line characteristic. For each pipe and condition of flow it has a fixed value which will appear later on as a most important factor in water hammer.

Using the above symbols with this equation gives

$$Y_{Bt} - Y_{At1} = +2\rho(X_{Bt} - X_{At1}) \ldots\ldots\ldots\ldots (19)$$

and by going through a similar transformation with the other equations (16), (17), (18), there results

$$Y_{At} - Y_{Bt1} = -2\rho(X_{At} - X_{Bt1}) \ldots\ldots\ldots\ldots (20)$$

$$Y_{Bt} - Y_{Ct2} = -2\rho(X_{Bt} - X_{Ct2}) \ldots\ldots\ldots\ldots (21)$$

$$Y_{Ct} - Y_{Bt2} = +2\rho(X_{Ct} - X_{Bt2}) \ldots\ldots\ldots\ldots (22)$$

These equations now enable any problem to be readily solved and will be made use of in the following illustrations. The value of a depends on the material of the pipe and its relative thickness, and for steel pipe the book[3] already referred to gives a formula $a = \frac{4660}{\sqrt{1 + 0.01\, d/b}}$ where d is pipe diameter and b is its wall thickness.

Graphical Construction

The graphical construction for solving these problems may now very easily be understood. For example, a uniform steel pipe 2,400 feet long, with a = 3,000 feet per second, is discharging freely through a gate under a head of 332 feet. Let the gate be closed so that its effective discharge area decreases uniformly with time, the total closure taking T = 4 seconds; the pressure rise at the gate is to be plotted on a time base.

For this pipe the time of travel of the pressure wave from the gate to the reservoir and back is

$$\frac{2 \times 2400}{3000} = 1.6 \text{ seconds,}$$

so that closure is in $T/1.6 = 2.5$ intervals.

Now the relation between the gate setting and the pipe velocity has already been established as $\frac{v}{v_0} = E\sqrt{\frac{H}{H_0}}$, equation (4), where E varies only with the gate setting, and is therefore dependent solely on the time elapsed after gate closure begins. With full gate $E = 1$, and one second after closure begins the value of $E = 0.75$, since the gate is one-quarter closed. These relations were explained earlier in the paper.

The diagram to be constructed has the axes shown in Fig. 5, and equation (4) will be represented on this diagram

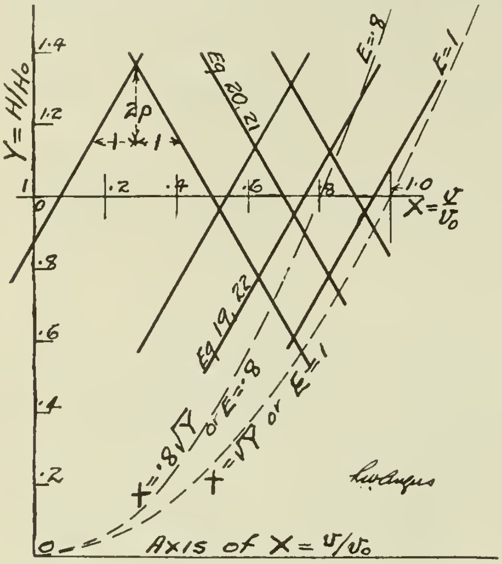

Fig. 5—Representation of Equations Used.

by a series of parabolas with vertices at 0. For full gate $E = 1$ and $\frac{v}{v_0} = \sqrt{\frac{H}{H_0}}$ and after the lapse of 0.8 second, or one-fifth of the total closing time, $E = .80$, or $\frac{v}{v_0} = 0.8\sqrt{\frac{H}{H_0}}$ and so on. These parabolas are very easily drawn by aid of a slide rule, and parts of two of them spaced 0.8 second apart are shown and marked $E = 1$ and $E = 0.8$.

Clearly on this diagram, equations (19), (22), (20) and (21) are represented by two series of parallel lines; the former two give lines with a slope whose tangent is $+ 2\rho$ and the latter two have tangents $- 2\rho$. Conditions at the reservoir are always represented by some point on the horizontal $Y = 1$ because there $H/H_0 = 1$, at least with a large reservoir, and if there is no friction in the line. Evidently the conditions at the gate are always shown on a parabola of the kind described and drawn with a suitable value of E.

Gate Closure

Proceeding now with the problem, the location of all points A, showing conditions at the gate end of the pipe, and of all points C showing those at the reservoir end, may be effected by using equations (19) and (20). Each point on Fig. 6 and all following diagrams is marked with a letter and a figure, the first corresponding to the point being considered, and the latter to the time after gate movement begins, at which the events at that point occur. Evidently points A_0 and $C\,.8$ are at $v = v_0$, $H = H_0$, because conditions at the reservoir end are not changed until 0.8 second later than at the gate end. The equations may then be written

$$Y_{A1.6} - Y_{C.8} = -2\rho\,(X_{A1.6} - X_{C.8}) \quad \ldots\ldots (20)$$
$$Y_{C2.4} - Y_{A1.6} = +2\rho\,(X_{C2.4} - X_{A1.6}) \quad \ldots\ldots (19)$$
$$Y_{A3.2} - Y_{C2.4} = -2\rho\,(X_{A3.2} - X_{C2.4}) \quad \ldots\ldots (20)$$
$$Y_{C4.0} - Y_{A3.2} = +2\rho\,(X_{C4.0} - X_{A3.2}) \quad \ldots\ldots (19)$$

In this way the points A and C at the beginning and end of each interval are determined and are shown on the upper diagram in Fig. 6. The drawing corresponds to the initial velocity $v_0 = 8$ feet per second, which gives $\rho = 1.125$. All points C are on the line $Y = 1$, since friction is being neglected.

Suppose now that it is desired to find the pressure at a point B located 0.25 l feet from A, then the time required for the pressure wave to travel from A to B is 0.2 second, and from B to C is 0.6 second, so that A_0, B 0.2 and C 0.8 are all located at one point. The line A 1.6 C 0.8 has already been located, and it is readily observed that A 0.4, A 0.8, A 1.2 are at the intersection of the parabolas E = .9, .8, .7 with this line. Further, the point B 1.4 coincides with A 1.2 because

$$Y_{A1.6} - Y_{B1.4} = -2\rho\,(X_{A1.6} - X_{B1.4}) \quad \ldots\ldots (20)$$
$$Y_{B1.4} - Y_{A1.2} = +2\rho\,(X_{B1.4} - X_{A1.2}) \quad \ldots\ldots (19)$$

The first of these lines coincides with A 1.6, A 1.2 and the second is a line through A 1.2 at slope $+ 2\rho$, so that B 1.4 coincides with A 1.2 and B .6 and B 1.0 are located as shown.

Again

$$Y_{C1.2} - Y_{B.6} = +2\rho\,(X_{C1.2} - X_{B.6}) \quad \ldots\ldots (22)$$

(this gives C 1.2)

and

$$Y_{B1.8} - Y_{C1.2} = -2\rho\,(X_{B1.8} - X_{C1.2}) \quad \ldots\ldots (21)$$
$$Y_{B1.8} - Y_{A1.6} = +2\rho\,(X_{B1.8} - X_{A1.6}) \quad \ldots\ldots (19)$$

(this gives B 1.8)

This process may be continued for all points.

The pressure diagram on a time base is also given in Fig. 6.

Gate Opening From Closed Gate

If the problem is to determine the drop in pressure due to quick opening of the gate, the method is exactly similar

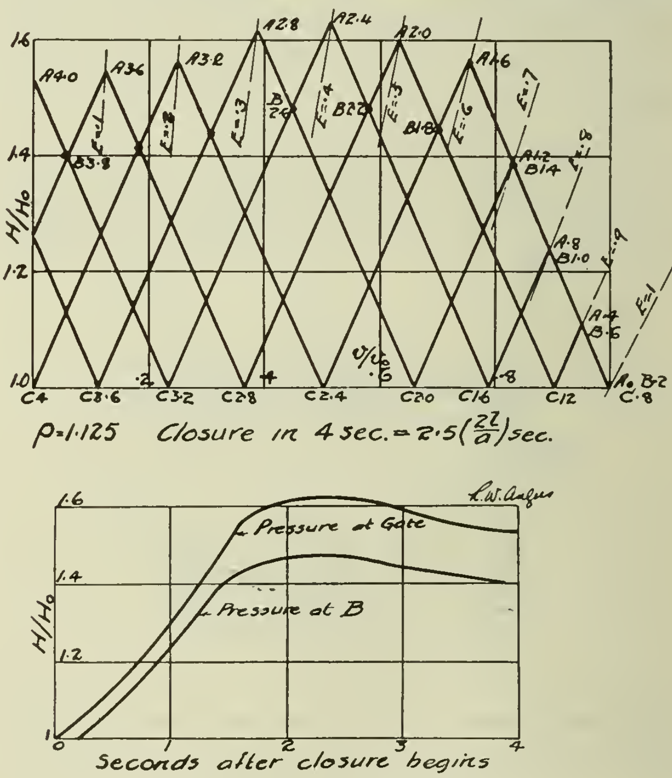

Fig. 6—Gate Closure in 4 sec.
$2\,l/a = 1.6$ sec. $\rho = 1.125$.

to the foregoing. Suppose, for example, that a pipe with a = 3,400 feet per second has a gate on the end of it that is quickly opened. The initial head H_0 = 317 feet, the final steady velocity for full gate is 6 feet per second, and the pipe is 3,400 feet long; it is assumed that the gate is fully opened in T = 4 seconds in such a way that the effective valve area increases uniformly with time. Evidently $2\,l/a = 2$ seconds and $\frac{aT}{2l} = 2$ intervals,

also $\rho = \frac{3400 \times 6}{2 \times 32.2 \times 317} = 1$ Friction is neglected.

Evidently this diagram (Fig. 7) starts at the top left corner, since $v = 0$ when $H = H_0$ just before gate movement begins. This problem will be worked out with ten equal gate movements, so that there are ten parabolas with $E = .1, .2, .3 \ldots 1.0$ drawn as shown on Fig. 7. Through the point A_0 the line A_0A_2 is drawn to represent equation (20), the tangent to its slope being $-\,2\,\rho$, then the points A .4, A .8, A 1.2, A 1.6 and A 2 give the pressure and velocity at A at 1/10, 2/10, 3/10, etc. of T, i.e. at 0.4, 0.8, 1.2 . . . seconds after opening begins. The line A 2-C 3 representing equation (19) gives the velocity at the reservoir end at 1.5 intervals after opening begins, and finally equation (20) represented by the line C 3-A 4 gives the point A 4 corresponding to the pressure and velocity at the instant the gate is fully open.

At the four-tenths of the intervals the conditions at the gate are represented by A .8, A 2.8, and so on for other points. The pressure diagram on a time base is also plotted at the right of Fig. 7. It is to be noted that the pressure oscillations do not cease the instant the gate is fully open, but their actual values may be found by continuing the construction already described, only that now all points corresponding to the pressure at the gate end must be on the parabola $E = 1$, since the gate is fixed. The pressures quickly die out as would be found from the diagram.

Gate Opening From Part Gate

If the gate is partly open under steady flow and is then quickly moved to the wide open position, the pressure and velocity changes are found in a similar way to the preceding case. For example, a pipe (a = 3,470 feet per second) working at normal static head of 90 feet, is discharging with a velocity of 2 feet per second with partly open gate, it is required to find the velocity and pressure changes at the gate when the latter is opened at uniform rate so as to produce a final steady pipe velocity of 5 feet per

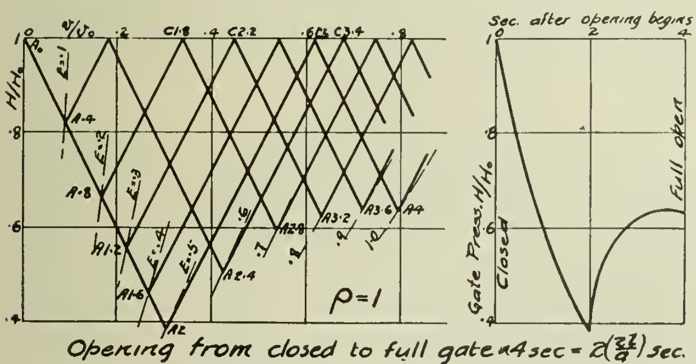

Fig. 7—Gate Opening.
$\rho = 1 \qquad 2\,l/a = 2$ sec.

second. (Effective gate area is 2.5 times the original). Let the movement of the gate take place in three intervals of 3 seconds each, so that $3\left(\frac{2l}{a}\right) = 9$ seconds. The data give $\rho = 3$.

The diagram for this case is shown in Fig. 8. The initial parabola is drawn for $E = .4$ and a series of parabolas are drawn for E = .5, .6, .7, .8, .9, 1.0, from which pressures and velocities at both the middle and the ends of the intervals are easily found. The slopes of all the lines have tangents + 6 or − 6 and the construction needs but brief explanation. For the first interval the pressure and velocity may be scaled off, at the middle and end of it, from points A 1.5 and A 3, whereas A 4.5 and A 6 give the corresponding values for the second interval, and A 7.5 and A 9 for the third, the pressure falling to $A\,9 = .55\,H_0$ at the instant gate movement stops, and the velocity at this instant is $0.75 \times 5 = 3.75$ feet per second. If the gate

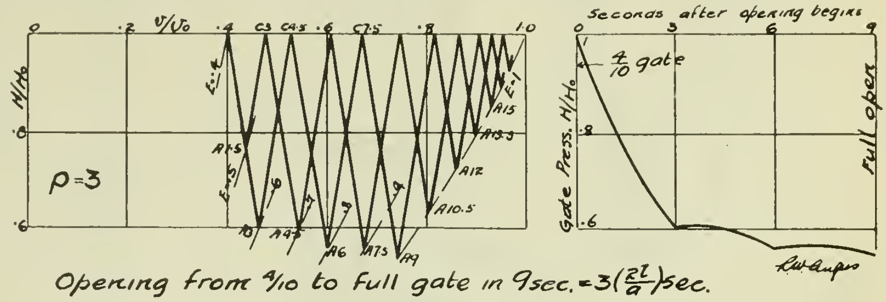

Fig. 8—Gate Opening from Part to Full Gate.
$\rho = 3 \qquad 2\,l/a = 3$ sec.

remains in this fixed position then the lines following A 9 give the pressure and velocity changes until the final steady position $v/v_0 = 1$ and $H/H_0 = 1$ is reached. The pressure diagram for 9 seconds only, is given at the right of Fig. 8.

A rather interesting example is shown in Fig. 9, which corresponds to the case where a valve, originally closed, is opened in one interval of $2\,l/a = 3$ seconds, and then closed again in the same time. In this case, one starts at the point $v = 0$ and $H = H_0$ and the first opening movement is represented by a line A_0A_3 with slope of tangent $-\,2\,\rho$, this line terminating on the parabola $E = 1$. This line is followed by another sloping at $+\,2\,\rho$ and terminating on the line $H = H_0$ at $C = 4.5$, representing equation (19), which gives the condition at the reservoir at the end of 4.5 seconds. By drawing the line C 4.5 A 6, the pressure at final closure is obtained on the line $v = 0$. If it is desired to get the oscillation of pressure following closure, the construction is continued about the vertical through $v = 0$.

The figure shows two cases, each with $2\,l/a = 3$, the left hand diagram employing a large value of $\rho = 1.9$ and the right hand one a much smaller value of $\rho = 0.25$. The parabola $E = .5$ enables the pressures and velocities at the middle of each interval to be drawn. For the large value of ρ (low head) the peculiar case results of the pressure after closure exceeding that at the time of closure.

Resonance

It may happen that if a governor lacks stability it will swing the gates to and fro, "hunting" for a position where the gate should finally remain. If the governor causes each inward swing and each outward swing to take place in $2\,l/a$ seconds, then a condition of resonance is set up, and in an unfavourable case very high pressures may result. This problem is very easily examined by the graphical construction already described.

Suppose that a plant has a riveted steel penstock 1,765 feet long, with a velocity of 4 feet per second, at full gate under a head of 73 feet. Let a = 3,530 feet per second.

then $\rho = \frac{3530 \times 4}{64.32 \times 73} = 3$ and $2\,l/a = \frac{1765 \times 2}{3530} = 1$ second.

Now suppose the governor is so adjusted as to completely close the gates in 3 seconds, or three intervals for the pipe, and let this plant be running at full load, followed by a sudden rejection of part load which is sufficient to start the

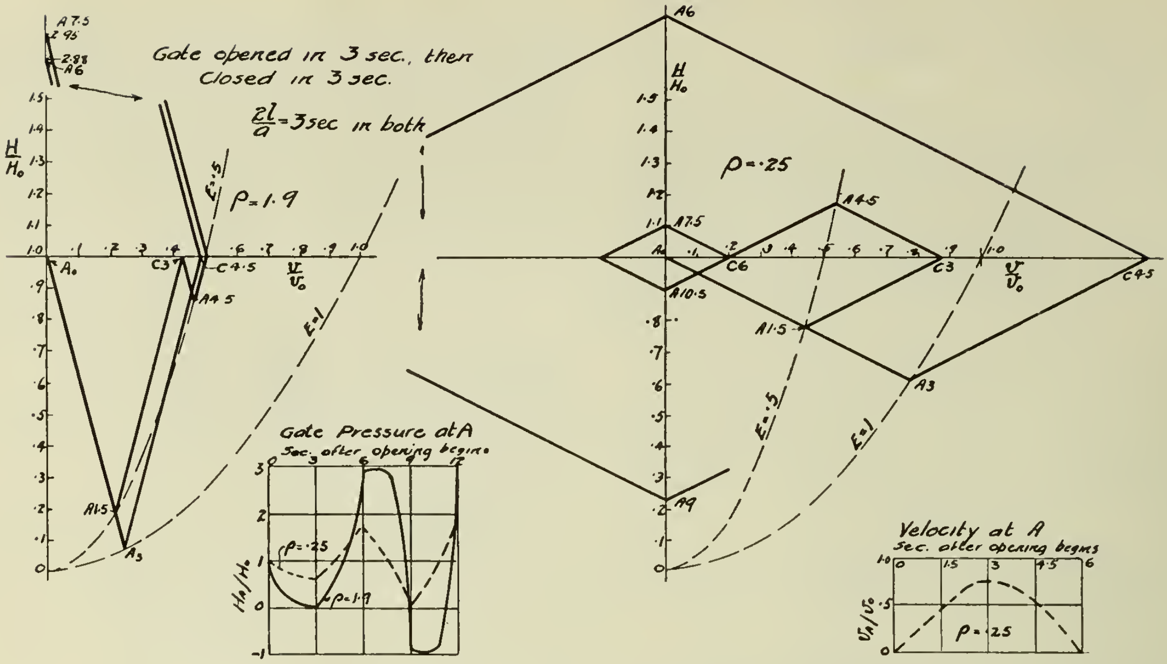

Fig. 9—Gate Opening Followed by Closure, each requiring $2\,l/a$ sec.

governor, and with it the gates, to swing repeatedly between full gate and 2/3 gate, the time of movement in each case being one interval of one second. The diagram for this case is shown on the upper part of Fig. 10, and evidently the

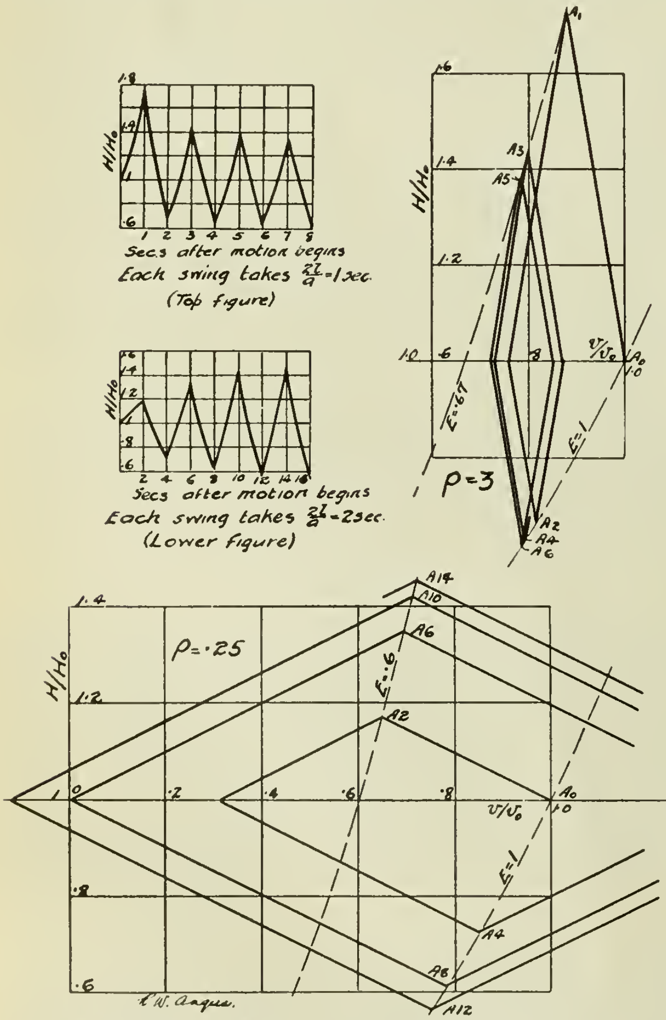

Fig. 10—Resonance Effect due to Continual Swinging of Gate between part and full opening, each Swing taking $2\,l/a$ sec.

two parabolas $E = 1$ and $E = 0.67$ will give the limiting positions of the pressure lines.

Since the first movement is from full open gate, the first pressure line starts at A_0 (upper diagram in Fig. 10) and slopes upward so that its tangent is $-2\rho = -6$ and the pressure at the end of the first closing movement is $H/H_0 = 1.734$, the velocity being $0.88\,v_0 = 3.52$ feet per second. The construction shows that at the first opening movement following, the pressure falls to $0.66\,H_0$ and at the ends of the successive movements the pressures are 1.44, 0.62, 1.39, 0.616 times H_0, or the pressure surge is gradually dying out, as is clearly indicated on the pressure diagram shown (top figure).

If, however, this same governor is used on a pipe of exactly similar dimensions but with an initial head of $12 \times 73 = 876$ feet, then $\rho = 0.25$ and the result is shown on the lower diagram of Fig. 10, which indicates that the pressure surge is continually increasing and must in time become very dangerous, although for the swings illustrated it has not reached the value shown in the upper case in the first movement. Whether the resonance effect is dangerous or not, clearly depends largely on the value of ρ, all other conditions remaining unchanged.

Simple Surge Tank

A further illustration of the use of this method is given in the simple surge tank. The case solved in Fig. 11 is that of a plant with 3,400 feet of 48-inch pipe with a surge tank 12 feet diameter, and a full-load pipe velocity of 9 feet per second. The static head on the plant is 200 feet, and it is desired to plot the surge tank levels resulting from a sudden reduction of load to 1,000 h.p. These levels are determined if the pressures at A, the surge tank end of the conduit are known; C is at the reservoir end. The value of a will be taken as 3,400 feet per second, so that $2\,l/a = 2$ seconds, and friction will be considered in this case.

Equation (8) is suitable for this problem and is best written

$$\frac{H_n + H_{n-1}}{2} - H_0 = +\frac{a}{g}\left(\frac{v_{n-1} - v_n}{2}\right) \ldots\ldots (8)$$

where H_n and H_{n-1} are the heads at the nth and the $(n-1)$th intervals, respectively. The axes for plotting are the velocity v in the conduit and the rise in tank level, which also gives, on the same axis, the head H. By any of the ordinary methods the hydraulic gradient may be drawn, which shows the level in the tank corresponding to each steady velocity in the 48-inch pipe, and it is quite easy also to plot a curve of demand velocity u in this pipe for 1,000 h.p. at each head, suitable assumptions being made as to the turbine efficiency. These two curves are shown in the figure.

In this case the pressure lines are evidently to be drawn so that their tangents are $\pm \frac{a}{g} = \pm 105.7$. The construction throughout is the same, but that at the 19th interval has been selected for illustration.

Equation (8) for this interval is

$$\frac{H_{A38} + H_{A36}}{2} - H_{0.38} = + \frac{a}{g}\left(\frac{v_{36} - v_{38}}{2}\right)$$

The point A 36 represents v_{36} and scales 7.223 feet per second, also the surge tank level at the end of 36 seconds, or of the 18th interval, is at A 36, and by scale from the drawing $H_{A36} = 194.88$ feet. The H_0 for this interval corresponds to the value of C 37 and is 187.09 feet.

But in addition to equation (8) there is another equation which may be written

$$A_P\,(v - u)\ \delta t = A_T \times \text{rise in tank in time } \delta t \text{ second}$$

where A_P and A_T are, respectively, the areas of the pipe and tank. Since $\delta t = 2\ l/a = 2$ seconds, the rise in the tank level in one interval is evidently $H_n - H_{n-1}$ so that

$$A_P\,(v - u)\ \delta t = A_T\,(H_n - H_{n-1})$$

or, since the surge tank area is 9 times that of the pipe

$$v - u = \frac{9}{2}\,(H_n - H_{n-1})$$

The drawing shows how $H_n - H_{n-1}$ may be read off directly on a specially made cardboard scale, where 9 inches on the special scale corresponds to 2 inches on the velocity scale. Scaling from the diagram

$$(v_{36} - u_{36}) \times \frac{2}{9} = 0.60 \text{ feet}$$

so that

$$H_{38} - H_{36} = 0.60 \text{ feet}$$

and by drawing the line C 37-A 38 at a slope with a tangent $- a/g = -105.7$ and locating A 38 at 0.60 foot above A 36 gives the level at A 38 at the 19th interval, or $19\left(\frac{2l}{a}\right) = 38$ seconds after the load rejection. Drawing the line A 38-C 39 with slope $+ 105.7$ locates point C 39 at the end of the 19th interval, and the velocities at the end of

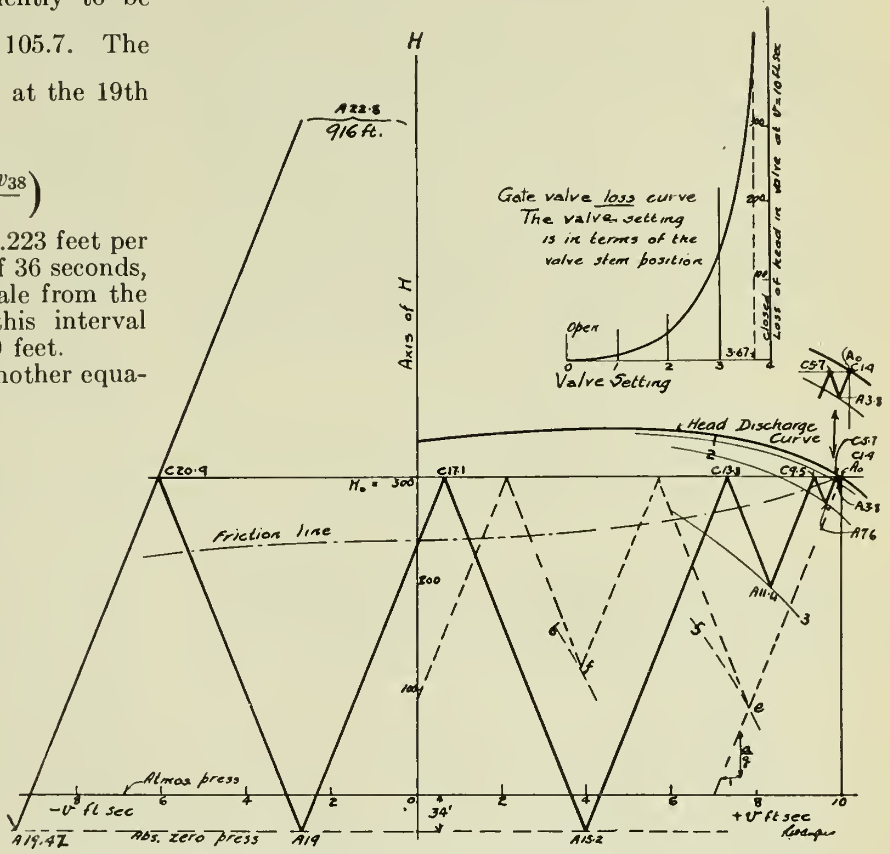

Fig. 12—Discharge Valve Closed with Pump Running up to Speed.
$a = 3{,}220$ ft. sec. $\quad 2\,l/a = 3.8$ sec.

the 18th and 19th intervals are found by scaling the positions of A 36 and A 38, respectively, from which $v_{36} = 7.223$ feet per second and $v_{38} = 7.07$ feet per second. These

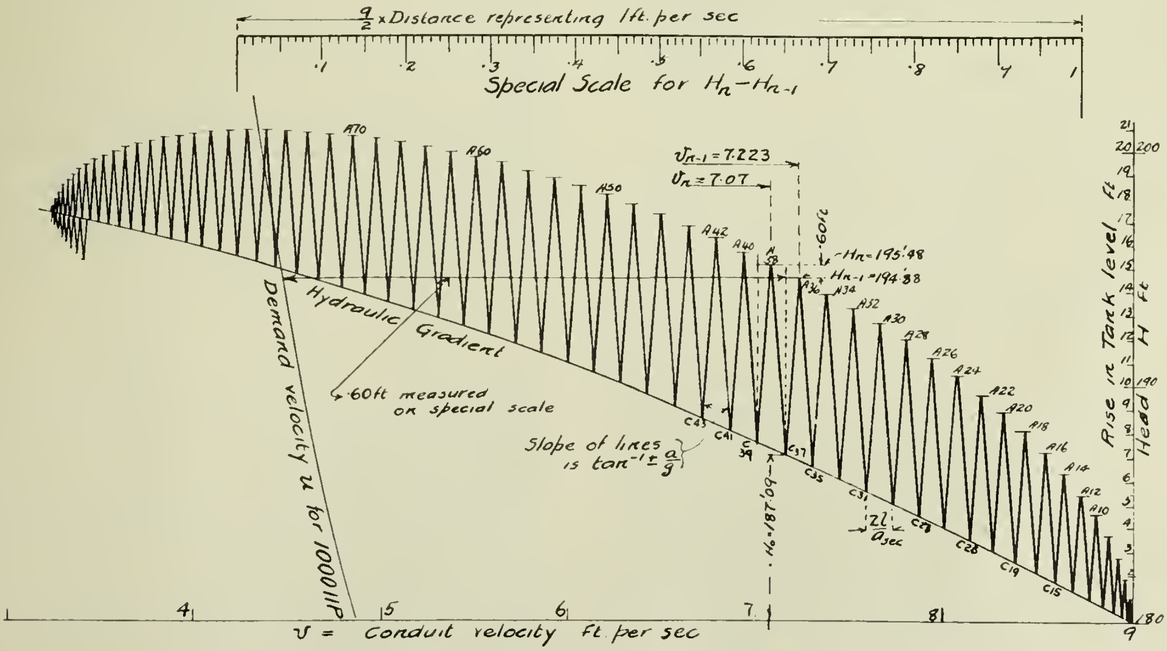

Fig. 11—Simple Surge Tank 12 ft. dia. at the end of 3,400 ft. of 48 in. pipe.
$H_0 = 200$ feet. $\quad v_0 = 9$ ft. sec. $\quad a = 3{,}400$ ft. sec.

results are easily checked by the use of equation (8) which gives

$$\frac{195.48 + 194.88}{2} - 187.09 = 8.09 \text{ feet}$$

and also

$$-\frac{a}{g}(v_{38} - v_{36}) = -105.7\left(\frac{7.07 - 7.223}{2}\right) = 8.09 \text{ feet},$$

as before.

By carrying on this process throughout it is easy to find the change of level and the change of velocity in each interval of $2\,l/a = 2$ seconds, and from these to plot a curve of the tank level and the pipe velocity variation. The whole process is executed very simply by the graphical process exclusively. The process could be used with the differential tank and probably with much less chance of error than by the arithmetic integration method.

This solution is the same as that already used although slightly different in appearance. Equations (13) and (16), when applied to this case in which $2\,l/a = 2$ seconds give:—

$$H_{A\,36} - H_{C\,35} = -\frac{a}{g}(v_{A\,36} - v_{C\,35}) \quad \text{(16)}$$

$$H_{C\,37} - H_{A\,36} = +\frac{a}{g}(v_{C\,37} - v_{A\,36}) \quad \text{(13)}$$

$$H_{A\,38} - H_{C\,37} = -\frac{a}{g}(v_{A\,38} - v_{C\,37}) \quad \text{(16)}$$

The difference in the heights of $H_{A\,36}$ and $H_{A\,38}$ is found as in the other case. The diagram is too cramped to show all the points, but a few of them have been marked according to the notation of the above equations.

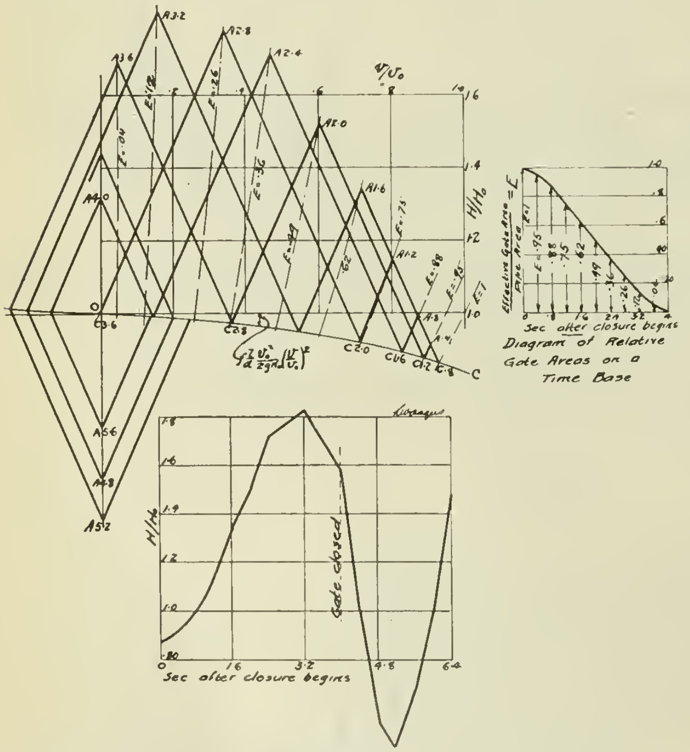

Fig. 13—Gate Closure according to Curve Shown in 4 sec.
$2\,l/a = 1.6$ sec. $\rho = 1.125$ Pipe Friction allowed for (see Fig. 6).

Pump Discharge Lines

Of recent years the very common practice of driving centrifugal pumps with electric motors has produced a water hammer problem of no small importance, because, through failure of power supply or other cause, the current to the motor may be suddenly cut off, and unless special precautions are taken, the stopping of the return flow of the water may produce disastrous results. Pump discharge lines are always provided with a gate or check valve near the pump, and unless it is properly adjusted and operated the pressure rise may be very great; for example, if the check valve is mechanically closed and held in that position immediately after the power fails, then the outward flow of the water will continue for a brief interval, causing a vacuum on the pipe side of the valve, and when the return column again reaches the closed valve the pressure may rise to about four times the normal value.

The magnitude of this water hammer depends not only on the type of check valve used but also on the construction of the pump itself; if the rotating elements in the motor and pump have a small moment of inertia the pump may stop almost instantly and, indeed, it may actually reverse, running as a turbine, before the check valve stops the return flow. In this paper it is not possible to do more than suggest the method of solution of some problems that arise in this connection.

The first case examined will be the determination of the pressure changes produced in a pipe line by closing the pump discharge valve, while the pump is still running up to speed. To take a definite case, let a pump with a known characteristic curve be discharging into a pipe line 6,120 feet long with a value of $a = 3{,}220$ feet per second, and let the gate valve on the discharge side of the pump be closed in 15.2 seconds in such a way as to lower the disc in the valve at a uniform rate. Evidently for the pipe, $2\,l/a = 3.8$ seconds, so that complete closure is effected in four intervals. Experiments on the loss of head in the valve in terms of the pipe velocity give the loss curve shown at the right of Fig. 12, the base line of which represents the position of the valve disc, and, from the assumption as to closing, represents also times in seconds, or in intervals of $2\,l/a$. On Fig. 12 the characteristic head discharge curve of the pump is drawn, and beneath this is a series of curves showing the pressures on the pipe side of the valve corresponding to each gate position, or more conveniently to each interval of 3.8 seconds during closing. The numbers on these curves correspond to those on the resistance diagram on the right, and data for them are taken from the resistance curve.

For this case equations (13) and (16) may be written in the form

$$H_{Ct} - H_{At\,1} = +\frac{a}{g}(v_{Ct} - v_{At\,1})$$

$$H_{At} - H_{Ct\,1} = -\frac{a}{g}(v_{At} - v_{Ct\,1})$$

Friction in the pipe line will be neglected, so that the pressure at the pump end corresponding to the reservoir level is 300 feet, and further, since $2\,l/a = 3.8$ seconds the value of $t - t_1 = 1.9$ seconds. For the first few points

$$H_{A\,3.8} - H_{C\,1.9} = -\frac{a}{g}(v_{A\,3.8} - v_{C\,1.9})$$

$$H_{C\,5.7} - H_{A\,3.8} = +\frac{a}{g}(v_{C\,5.7} - v_{A\,3.8})$$

$$H_{A\,7.6} - H_{C\,5.7} = -\frac{a}{g}(v_{A\,7.6} - v_{C\,5.7})$$

The points A 3.8, A 7.6, A 11.4, C 1.9, C 5.7, C 9.5, are shown on the figure, and the explanation given for former cases suffices for this one.

The diagram shows quite clearly that this method of operating the valve is very bad, because the line C 13.3-A 15.2 should end on the line $v = 0$ for the closed valve. It is, however, unable to do so, because a perfect vacuum exists at A 15.2, and yet there is a velocity of 3.86 feet per second toward the reservoir, so that an empty space will form on the reservoir side of the valve and the pressure will remain at absolute zero during the whole of this 3.8-second interval, since the changes of pressure are assumed instantaneous at the beginning of each interval. At the end of the interval the flow of water will reverse in direction, and when the whole column strikes the valve the flow will be suddenly stopped because the valve is closed.

At the next (fifth) interval the pressure and velocity are represented at A 19 where the velocity toward the pump is 2.82 feet per second, but at this point the empty space behind the valve has not been filled because its original volume was

$$3.86\left(\frac{2\,l}{a}\right) A_P = 3.86 \times 3.8\, A_P = 14.7\, A_P \text{ cubic feet,}$$

where A_P is the pipe area in square feet, and the volume put back into it in this interval is only

$$2.82 \times 3.8\, A_P = 10.7\, A_P \text{ cubic feet.}$$

In the next interval the pressure and velocity correspond to A 19.42 which shows a negative velocity (toward the gate) of 9.50 feet per second. The space will then be completely filled in $\frac{(14.7 - 10.7)\, A_P}{9.5\, A_P} = 0.42$ second after point A 19 is reached.

Since at the instant the water is stopped it has a velocity of 9.50 feet per second, the pressure rise will be $9.50\left(\frac{a}{g}\right) = 950$ feet above absolute zero, or a gauge pressure rise to $950 - 34 = 916$ feet, as shown in Fig. 12. The pressure due to water hammer in this case is thus 3.05 times the normal operating pressure, and in the next interval the pressure reaches its maximum of 1.584 feet.

In this case friction has been neglected, but may easily be taken into account. Suppose the loss in the line at full draught is 60 feet then the friction line corresponding to this loss is drawn, with a dot and dash curve, below the horizontal line through the normal operating point A_0 where $H_0 = 300$ feet. This friction line may then be used as the locus of all points C, since the effect of friction is practically to lower the reservoir, as the velocity decreases. The construction for this case is easily drawn, but has been omitted to avoid confusion of the figure, but it will, of course, show a lower pressure rise.

A much better method of operation would be to close the valve in the first interval of 3.8 seconds, to correspond to the curve 5, this being the resistance curve corresponding to $3.67/4 = 92$ per cent of complete closure. The pressure will then fall to e and if in the next interval the gate reaches the position where the loss through it corresponds to curve 6 the pressure will fall to f, and closure may be completed in the next interval with a final fall in pressure to g of 92 feet, or a drop of 208 feet below normal pressure. In this case the pressure will oscillate 208 feet above and below normal pressure till the wave dies out through friction. This case is also shown in dotted lines in Fig. 12, no allowance being made for friction in the pipe line.

Effect of Friction

While it is not difficult to include friction, it has been neglected in this paper in most cases except that of the surge tank; the example there, however, shows how it may be allowed for. Care must be taken to make a proper distinction between flows to and from the reservoir, because friction acts in opposite ways in the two cases. Only one further illustration will be given on this point.

If it were desired to solve the same problem as in Fig. 6, but considering friction in the pipe line, the solution would be modified. Friction in the line produces, in this case, an effect similar to the gradual raising of the reservoir level as the flow decreases, and hence the former construction may be used, if instead of using a horizontal line to represent reservoir levels, a curved line is used, such that its distance below the horizontal, at any velocity, represents the loss of head at that velocity.

The case shown in Fig. 13 uses the same data as on Fig. 6, but friction has been considered and also the rate of gate closure, instead of being uniform, is variable, as shown on the right hand diagram of Fig. 13. The friction line OC represents the substituted changing reservoir level, the vertical distance to the horizontal line at any point representing, for the corresponding velocity, the loss of head divided by H_0. This distance may be calculated by the formula

$$f \cdot \frac{l}{d} \cdot \frac{v^2}{2g} \cdot \frac{1}{H_0} = f \cdot \frac{l}{d} \cdot \frac{v_0^2}{2\,gH_0} \cdot \left(\frac{v}{v_0}\right)^2$$

where f is the friction factor and d the pipe diameter. If this curved base is used instead of the horizontal one, the resulting pressures will be those that would result if friction is considered. The complete solution is shown and should need no explanation.

Conclusion

While the problems solved here as illustrations have not, so far as the author knows, appeared elsewhere, at least not in English, yet the theory used has been developed in Europe and has been briefly mentioned in the recent Water Hammer Symposium of the American Society of Mechanical Engineers.

It is a pleasure to acknowledge the help received from the excellent papers of Dr. O. Schnyder(6) of Switzerland, particularly that entitled "Uber Druckstösse in Rohrleitungen," appearing in Wasserkraft und Wasserwirtschaft in March 1932. Dr. Schnyder has devised some elegant solutions to such problems as those under consideration. A valuable paper by Professor L. Bergeron(7) on "Variations de régime dans les conduites d'eau" appeared in the Proceedings of the Société Hydrotechnique de France 1932. The author is also greatly indebted to the paper by A. W. K. Billings(8) and others on "High Head Penstock Design," presented to American Society of Mechanical Engineers last year; the application of the method explained here to a pipe of varying diameter is given in that paper. Reference may also be made to the work of Dr. L. Loewy.(9)

Report of Council for the Year 1934

Last year the report of Council drew attention to the improvement in business activity which had become manifest towards the end of the year. During the twelve months which have elapsed since then the anticipated progress has continued, although not so vigorously as could be wished. Industrial statistics now available continue to show an upward trend, and it is encouraging to note that the number of members of The Institute known to be unemployed has been reduced since this time last year.

During the year a considerable number of members have found it necessary to ask to be carried on the non-active list, and the decrease in the number of members on the roll of The Institute is largely due to this cause. There is, however, encouragement in the fact that the number of applications for admission shows a substantial increase over 1933, and that applications are beginning to come in from members who are on the non-active list, and who desire to resume their active connection with The Institute.

From the Finance Committee's report it will be noted that the income and expenditure for 1934 have agreed closely with the budget. The Council realizes that this desirable result is largely due to the careful control of expenditure exercised by the Finance Committee and to the painstaking and thorough study of our financial condition made at the beginning of the year.

The Council also desires to express appreciation of the way in which the members of The Institute have responded to requests to reduce the arrears of outstanding dues. It must be realized that as long as any considerable number of members remain on the non-active list, services to members may have to be curtailed, while any increase in such service will be impossible.

In order to lighten the initial cost of joining The Institute during these difficult times, your Council has deemed it advisable to keep in force, for the coming year, the reduction of the entrance fee to $5.00 for all classes of membership. This was put into effect last year and the Annual Meeting will be asked to approve Council's action.

The number of our members engaged in the work of the Relief Camps of the Department of National Defence is now decreasing, and as there have been many cases in which our members were aided and relieved by the Department's action in making employment in these camps available to them, it is fitting that the Council should here record the indebtedness of The Institute to the Department and to Major-General A. G. L. McNaughton, C.B., M.E.I.C., for all that has been accomplished in furnishing relief by acceptable employment to so many members in their time of need.

During the past year the officers of The Institute have spoken and corresponded with Ministers of the Crown regarding the difficulties which are now being experienced by young engineering graduates in finding work of a kind that will give them professional experience. Although the Ministers gave no promises their replies were sympathetic.

In this connection Council has noted with regret the many cases in which recent graduates have not been able to secure employment which will allow them to apply instead of lose their university training. Council would draw attention to the increasing number of positions in connection with the works of our manufacturing or fabricating industries in which technically trained graduates, who have acquired the necessary practical experience in construction or workshop methods, can now find openings. These give opportunities different, perhaps, from those arising in the older paths of engineering employment, but which nevertheless enable the young engineers to utilize their professional training to great advantage.

An encouraging feature of recent Institute activities has been the effective work done by the Junior Sections of several of our branches. These have organized and held many well attended section meetings, at which worth-while papers have been presented and discussed by Juniors and Students of The Institute. The Peterborough and Montreal Branches have been particularly successful in this respect, and the Council feels that their efforts may with advantage be emulated by an increasing number of other branches.

The proposed new by-laws drafted last year, and adopted at the Sixth Plenary Meeting of Council in October 1933, were duly discussed at the Annual Meeting of 1934 before being sent out to ballot. The proposals failed to carry, for although the affirmative votes numbered 505 and the adverse votes 289, 24 affirmative votes were lacking to reach the necessary two-thirds majority. The suggestion has been made that, without re-opening the whole question, it may be advisable to put forward again those of the proposals whose adoption would tend to improve the routine and administrative conduct of affairs of The Institute, leaving controversial matters until more unanimity is evidenced.

Your Council has not been advised that any further progress has been made by the Associations' Committee of Eight in regard to the co-ordination of the activities of the eight Associations of Professional Engineers. In the meantime an effort has been made in Manitoba towards co-operation between the Winnipeg Branch of The Institute (whose territory includes the whole of Manitoba) and the Association of Professional Engineers of Manitoba. As a result the Winnipeg Branch requested the Council to approve certain changes in the branch by-laws and organization, which would be required to enable that branch of The Engineering Institute and the local Professional Association to function under a common executive and staff. This project, which was frankly experimental, received the Council's hearty approval as a trial measure, and was endorsed by the membership of the Winnipeg Branch of The Institute, but since a ballot of the Professional Association membership showed only a small majority in favour of this action, the Council of the Association felt it would be unwise to recommend its adoption at present.

Your Council has supported as far as possible the activities of the National Construction Council of Canada in its efforts to promote the revival of the construction industry.

At the request of a special Committee on National Sound Finance appointed by the Canadian Chamber of Commerce, a committee appointed by Council under the chairmanship of Mr. R. E. C. Chadwick, M.E.I.C., has submitted a report recommending the procedure desirable in calling for tenders and letting contracts for public works. This has been forwarded to the National Committee.

Your Council has given its support to the nomination of engineers on the Directorate of the Bank of Canada with the object of having the profession represented on the Board.

The second issue of the E-I-C Engineering Catalogue has been commented on favourably. Letters received indicate that the volume has been found of use by an increasing number of members and non-members. The third issue, for 1935, now in the press, embodies a number of improvements and the corrections necessary to bring its index up to date. The financial results for the first two years have been disappointing, but it is expected that this next issue will not entail any loss.

From time to time members who have given papers at their branch meetings have been good enough to visit other branches and repeat their addresses or demonstrations, often at considerable personal sacrifice of time and energy. Your Council desires to acknowledge with many thanks public-spirited effort of this kind, which does so much to bring together the widespread membership of The Institute, and is particularly appreciated by the smaller branches.

Your Council has noted with appreciation the active interest shown in the affairs of The Institute, on the occasion of the President's visits to the various branches throughout Canada. On these occasions many important matters concerning the future of The Institute were brought to the attention of the branch members, in the hope that they will give serious thought to such topics, and that The Institute will thus have the benefit of their deliberations when future opportunities for progress arise.

The Forty-Eighth Annual General and General Professional Meeting was held in Montreal on February 8th and 9th, 1934, the formal Annual General Meeting of January 25th having been adjourned to those dates. Although the meeting was limited to two days for reasons of economy, its unqualified success showed the result of the excellent preliminary work of the committee of the Montreal Branch who sponsored it.

The greater part of the business session was taken up by a discussion of Council's proposals for amendments to the by-laws, prior to their submission to the membership for ballot. The debate was active, and a large number of members took the opportunity of offering suggestions and criticisms, particularly with regard to the possible effect of the proposed amendments upon the future relations of The Institute with the Provincial Associations.

The social functions were well attended, and at the Annual Dinner of The Institute, the Prime Minister, The Rt. Hon. R. B. Bennett, was kind enough to present the prizes and medals, and delivered an inspiring address with a message of hope particularly addressed to the younger members of the profession. At the technical sessions nine papers were presented and discussed, and the meeting concluded with an enjoyable smoker at which a novel feature was a boxing tournament.

The Western Professional Meeting, which took place in Vancouver on July 11th to 13th, was memorable as it was held in conjunction with the Annual Convention of the American Society of Civil Engineers. Arrangements for this joint event were in the hands of an active local committee composed of members of both societies, under the chairmanship of Mr. E. A. Cleveland, M.E.I.C., to whom the thanks of Council and The Institute are due for the able way in which the meetings were organized and the success which attended their work. The social features of the meeting were held jointly by the two societies; the technical sessions were held separately. Both organizations were well represented and at the meetings of the American Society of Civil Engineers no less than twelve papers were presented and discussed. Our own list, while less numerous, included a series of papers dealing with western engineering work. In arranging for the social features and excursions, the committee, as was to be expected, took full advantage of the amenities of the City and its beautiful surroundings. These favourable conditions, combined with the traditional western hospitality, made the gathering one which will be long remembered. It was the first occasion on which an Institute meeting has been held jointly with a convention of a sister society, and the result was all that could be desired. All our members were happy to take part in welcoming their fellow engineers from the United States.

Roll of The Institute

During the year 1934, one hundred and seventy candidates were elected to various grades in The Institute. These were classified as follows:—Ten Members, forty-one Associate Members, twelve Juniors, one hundred and one Students, and six Affiliates. The elections during the year 1933 totalled one hundred and twenty-eight candidates.

Transfers from one grade to another were as follows:—Associate Member to Member, seven; Junior to Associate Member, thirty-eight; Student to Associate Member, nineteen; Student to Junior, twenty-nine; Junior to Affiliate, three; Affiliate to Associate Member, one; a total of ninety-seven.

The names of those elected or transferred are published in The Journal each month immediately following the election.

Removals from the Roll

There have been removed from the roll during the year 1934, for non-payment of dues and by resignation, ten Members, thirty-one Associate Members, eight Juniors, one hundred and fifty Students, and eleven Affiliates, a total of two hundred and ten.

Two hundred and three reinstatements were effected and eleven Life Memberships were granted.

During 1934 four hundred and thirty-nine names were placed on the Non-active List which now numbers six hundred and nine.

Deceased Members

During the year 1934 the deaths of thirty-eight members of The Institute have been reported as follows:—

Honorary Member

Aberdeen, The Right Hon. The Earl of, P.C., K.T., G.C.M.G., G.C.V.O.

Members

Armstrong, Major-General Charles Johnstone, C.B., C.M.G., V.D.
Aylmer, John Athalmer
Bowman, Archibald Abercromby
Chadwick, Kenneth Murray
Cruttwell, George Edward Wilson
Donkin, Hiram Fergusson
Fuller, George Warren
Gauvreau, Narcisse Belleau
Gore, William
Green, Samuel Martin
Helbronner, Pierce Michel
Hoare, Edward Arthur
Johnson, George Arthur
Lee, William States
Milne, James
Seurot, Paul Albert Nicolas
Svenningson, Sven
Wardwell, William Henry
Wynne-Roberts, Lewis Wynne

Associate Members

Archibald, Cyrus Witter
Ashley, Bertram Scott
Aylmer, Harry Brooke
Bernier, Jos. Adelard
Code, Abram Silas
Cunningham, William John
Fox, Charles James
Milne, Alexander
Munro, John Herbert
Murphy, Michael Joseph
Panneton, Frank
Philipps, James Benjamin
Pope, Harry Bonfield
Rounthwaite, Cyril Henry Ernest
Shector, Sidney Samuel
Treanor, Walter Charles
Vanier, J. Emile

Student

McBeath, Ernest Harrison

The membership of The Institute as at January 1st, 1934, totals three thousand, seven hundred and sixty-four, The corresponding number for 1933 was, four thousand. and seventy. These figures do not include those members who have been placed on the Non-Active List.

Total Membership

	1933		1934
Honorary Members	9	Honorary Members	8
Members	965	Members	914
Associate Members	1,894	Associate Members	1,782
Juniors	346	Juniors	299
Students	820	Students	727
Affiliates	36	Affiliates	34
	4,070		3,764
Members on Non-Active list	337	Members on Non-Active list	609
	4,407		4,373

Respectfully submitted on behalf of the Council,

F. P. Shearwood, M.E.I.C., *President.*
R. J. Durley, M.E.I.C., *Secretary.*

Finance Committee

The President and Council:—

The Finance committee, in submitting the auditors' and their own report, do so with a definite feeling of encouragement in view of the fact that, in spite of continued and seemingly unabated depression in active construction and general engineering work, the figures show a tendency toward recovery.

With the experience of 1933 to guide them, your committee balanced the budget in January on a basis of about $56,500.00 revenue and expenditure, including the third catalogue, which it was then hoped would yield a profit of about $1,250.00. On a strictly cash basis this meant that apart from the catalogue an operating deficit of $1,250.00 was considered permissible. Actually, apart from the catalogue, the year's balance sheet shows a surplus of $621.77 which has permitted the reinsertion of depreciation on the furniture and books, in the auditors' statement, as a charge against operations. This item was deliberately omitted last year in view of the abnormal deficit encountered. The depreciation is set up as $670.68 with the result that a small deficit of $48.91 is indicated in the auditors' report.

The income from all sources exceeded the budget by over $2,500.00 and, as the revenue from Journal advertising was guessed within 1/20th of 1 per cent, the improvement is due almost entirely to the enjoyment of a better response from the paying membership than your committee, in their 1933-born pessimistic mood, dared to anticipate, and this applies to current fees, entrance fees, and arrears of fees. As a matter of fact, at the end of 1931 the latter item is lower in amount than ever before and the actual number of members in arrears is also the smallest on record. The expenditure on services was allowed to exceed the budgeted amount by $1,329.46 in accord with the policy of doing the best possible for the membership under present circumstances, but the authorized list of office salaries furnished by your committee to the General Secretary early in February was strictly adhered to. The actual increases were largely consumed in the two items of rebates to Branches, and Professional Meetings, the former of course automatically, and the latter by resolution.

The basis of operations is shown in the Auditors' statement to be about $45,500.00 income and expenditure (exclusive of the catalogue) which compares with an expenditure of $47,129.76 in 1933 and with figures running considerably over $80,000.00 in years like 1924, 1929, and 1930.

By agreement, the catalogue finances are omitted from the general statement of revenue and expenditure this year, so that the possibility of fogging the result by the inclusion of "estimated" items of considerable magnitude, is removed. It is even yet, at the date of writing, too early to make estimates for the third catalogue, just now going to press, with much precision, so that the pertinent figures are all deferred until the 1935 report when they will be known exactly.

Meanwhile, the net result of the first two editions can now be definitely appraised. The assets of The Institute have been drawn upon to finance the publication of these catalogues, against which can be listed the building up of a valuable good-will and a prospect of future revenue.

STATEMENT OF ASSETS AND LIABILITIES AS AT 31st DECEMBER, 1934

Assets

CURRENT:

MONTREAL, 10TH JANUARY, 1935.

Audited and verified, subject to our report of this date.

RITCHIE, BROWN & CO.,
Chartered Accountants.

While it can be foreseen that the cost of production on the third edition will be comparatively less than on previous editions, and while the chances of making a definite profit are still considered good by those best able to judge, it is hardly to be expected that the whole loss up-to-date can be recovered during 1935.

The advertising in The Journal has been remarkably steady month by month during the past year and this fact encourages the management and your committee to feel that the low point has not only been reached but passed, as the total income from this source is about $1,000.00 better than last year, although still only about 45 per cent of the average during the period 1925 to 1931.

In the statement of assets and liabilities it will be noticed that the surplus is again reduced, due to the loss on the second issue of the catalogue having been greater than estimated in the 1933 report. The value of the land and buildings at Headquarters is noted as an "at cost" figure which is undoubtedly seriously in excess of present day valuation. No capital increase to the library or furniture has been made during the year and the Branches have returned some $225.00 of advances. Investments remain unaltered but the temporary bank overdraft is slightly higher than previously. Members will doubtless realize that while the expenditures are reasonably uniform month by month, the majority of the income of The Institute both from fees and from the catalogue, reaches Headquarters in the first three months of the year and is sufficient to wipe out the above overdraft entirely by March or April, but that toward the end of the year the overdraft will inevitably build up again until such time as a greater cash surplus has been established.

Your committee has been constantly faced with the difficult problem of recommending to Council some reasonable method of accommodating an increasingly large num-

Finance Committee

(*Continued from page 85*)

ber of members who find themselves compelled to ask for extension of time in respect to the payment of dues, and a further large number who merely delay payment without advising The Institute at all as to their situation, prospects, hopes, or intentions.

The non-active list has been widely extended, but it is sincerely urged upon members that they regard this classification merely as a means of providing them some temporary relief from financial responsibility, but not as something to be endured or enjoyed longer than necessary. They are, therefore, respectfully asked to resume active membership at the earliest practicable moment and thus lend their co-operation to The Institute in its endeavour to serve the profession. There are many useful services to be resumed or extended when revenue permits; there are numerous lines along which The Institute can advantageously direct its energy and exert its influence when the funds available rise above the present level of barely meeting essentials. Gratified as your Finance committee feels with the degree of support advanced by the membership during 1934, particularly with the efforts made by certain Branches to encourage resumption of active membership and the early payment of fees, it is nevertheless felt that much more can and should be done toward increasing The Institute's potentiality for service.

Respectfully submitted,

P. L. Pratley, m.e.i.c., *Chairman.*

Nominating Committee—1935

Appointments to the Nominating Committee for the year 1935 have been made by the various Branches, and the Chairman has been appointed by Council, as shown on the following list, which is now presented for announcement at the Annual Meeting in accordance with the By-laws:—

Chairman: L. F. Grant, m.e.i.c.

Branch	*Representative*
Halifax Branch	A. F. Dyer, a.m.e.i.c.
Cape Breton Branch	R. R. Moffatt, a.m.e.i.c.
Saint John Branch	J. N. Flood, a.m.e.i.c.
Moncton Branch	C. S. G. Rogers, a.m.e.i.c.
Saguenay Branch	A. W. Whitaker, a.m.e.i.c.
Quebec Branch	P. Methe, a.m.e.i.c.
St. Maurice Valley Branch	J. H. Fregeau, a.m.e.i.c.
Montreal Branch	H. G. Thompson, a.m.e.i.c.
Ottawa Branch	J. McLeish, m.e.i.c.
Peterborough Branch	A. L. Killaly, a.m.e.i.c.
Kingston Branch	R. A. Low, a.m.e.i.c.
Toronto Branch	E. L. Cousins, m.e.i.c.
Hamilton Branch	J. R. Dunbar, a.m.e.i.c.
London Branch	H. A. McKay, a.m.e.i.c.
Niagara Peninsula Branch	C. G. Moon, a.m.e.i.c.
Border Cities Branch	S. E. McGorman, m.e.i.c.
Sault Ste. Marie Branch	A. H. Russell, a.m.e.i.c.
Lakehead Branch	
Winnipeg Branch	A. J. Taunton, a.m.e.i.c.
Saskatchewan Branch	P. C. Perry, a.m.e.i.c.
Lethbridge Branch	R. Livingstone, m.e.i.c.
Edmonton Branch	H. J. MacLeod, m.e.i.c.
Calgary Branch	H. W. Tooker, a.m.e.i.c.
Vancouver Branch	W. H. Powell, m.e.i.c.
Victoria Branch	J. N. Anderson, a.m.e.i.c.

Past-Presidents' Prize Committee

The subject announced for the year 1933-1934 was "The Engineering Features of City Management." No essays having been submitted, the committee is unable to make a report.

The hope is expressed that this condition will not be repeated in 1934-1935 since the subject prescribed, "The Co-ordination of the Activities of the Various Organizations in Canada," is of such importance and general interest.

SPECIAL FUNDS AS AT 31st DECEMBER, 1934

			Represented by:		
Leonard Medal Fund:					
Balance as at 1st January, 1934	$ 613.25		$500 Title Guarantee and Trust 6% 1933 Certificate	$ 500.00	
Add: Bond interest	30.00		Cash in Savings Bank	128.79	
Bank interest	2.79

Gzowski Medal Committee

The President and Council:—

The committee would recommend that the Gzowski Medal for the prize year 1933-1934 be awarded to W. H. Powell, M.E.I.C., for his paper entitled "First Narrows Pressure Tunnel, Vancouver, B.C." published in The Engineering Journal for June 1934.

Respectfully submitted,
Robert W. Angus, M.E.I.C., *Chairman.*

Plummer Medal Committee

The President and Council:—

In the opinion of your committee, the Plummer Medal for 1933-1934 should be awarded to F. E. Lathe for his paper on "The Utilization of Magnesian Carbonates" as published in The Engineering Journal for December 1933.

Respectfully submitted,
L. F. Goodwin, M.E.I.C., *Chairman.*

Leonard Medal Committee

The President and Council:—

I beg to advise that the Leonard Medal Committee, 1934, of The Engineering Institute of Canada, has decided that the Leonard Medal should be awarded to D. E. Keeley, M.C.I.M.M., for his paper "Guniting at the McIntyre Mine" (June 1934 Bulletin of the Canadian Institute of Mining and Metallurgy).

Respectfully submitted,
J. G. Dickenson, M.E.I.C., *Chairman.*

Students' and Juniors' Prizes

The reports of the examiners appointed in the various zones to judge the papers submitted for the prizes for Students and Juniors of The Institute were submitted to Council at its meeting on January 18th, 1935, and the following awards were made:—

H. N. Ruttan Prize (Western Provinces)—No award.

John Galbraith Prize (Province of Ontario)—To F. A. Masse, Jr.E.I.C., for his paper "A History of Paper Making."

Phelps Johnson Prize (Province of Quebec, English)—To C. B. Charlewood, S.E.I.C., for his paper on "Steam Distribution in the Newsprint Mill."

Ernest Marceau Prize (Province of Quebec, French)—No papers received.

Martin Murphy Prize (Maritime Provinces)—No papers received.

Membership Committee

The President and Council:—

Your committee, which was appointed by Council in February 1933, has again continued its activities during the past year, presenting a mid-year report to Council on June 15th, 1934.[1]

It will be remembered that a membership campaign was instituted in the spring of 1933 and as a result a number of branches appointed special membership committees, while in other cases the branch executive committees undertook to act. The results of this campaign were presented to the Plenary Meeting of Council in October 1933.[2]

In April 1934, in accordance with the suggestions outlined in the above report the General Secretary communicated with all branches in university centres reminding them of your committee's suggestions which urged the desirability of The Institute members entering into closer relationship, if possible, with the undergraduates in the engineering schools, to whom the advantages of joining The Institute should be definitely presented during their college courses. Several other suggestions were made which it was hoped would prove helpful.

During the early part of the summer, in view of the intention of the President of The Institute and the General Secretary to visit the branches of The Institute, a communication was sent to all branches outlining the work of your committee to date, and forwarding a list of the names of those prospective members previously submitted in reply to the June 1933 circular, from whom applications had not yet been received. It was hoped that these names would again be canvassed and that the President and the Secretary during their visits to the branches would be asked for any information required.

Some very encouraging replies were received in reply to these letters and the chairmen and members of the various committees reporting are to be congratulated on their efforts.

A number of branch committees have also been active in canvassing members on the non-active list, in an endeavour to have them resume active membership, and in interviewing those intending to resign. Branch membership committees are reminded that during the sixty days that will elapse from the time their branch secretary receives a notification of a resignation and the time action is taken by Council to accept it, there is a good opportunity to ask the member concerned to reconsider his decision. Any suggestion of this kind, to be successful, must have the help of members of the branch executive or membership committees.

Elections and transfers during the past year show a marked improvement over the previous year and may be subdivided as follows:—

Elections—	Members	10
	Associate Members	41
	Juniors	12
	Affiliates	6
	Students	101
	Total	170
Transfers total		97

These totals of 170 elections and 97 transfers compare with 128 elections and 33 transfers during 1933.

Your committee believes that the reduced entrance and transfer fees have been of assistance in securing these improved results, along with the help offered to unemployed members, the increased activities of the student sections, and the personal visits to the branches of the President of The Institute and the General Secretary, this summer.

In the opinion of your committee continued activity by branch membership committees is essential, as while the increase in new members obtained during the past year is encouraging it is far short of the required three hundred estimated in the last report of your committee, as being the minimum necessary to make up for normal losses.

By far the best way to foster membership is for each member to contribute what he can in the way of technical papers or discussions, service on Institute or branch committees, and publicity in the press or elsewhere or among his friends and acquaintances regarding the essential and beneficial work that The Institute is doing. As a well-known advertising slogan has it "There is no substitute for quality." Furthermore it is the opinion of your committee that the success of The Institute will be enhanced by the co-operation of its branches and members with other societies that directly or indirectly promote interest in engineering matters, particularly the Associations of Professional Engineers, and also by a broader interest in national, provincial and municipal affairs and welfare generally.

Respectfully submitted,
D. C. Tennant, M.E.I.C., *Chairman.*

Papers Committee

The President and Council:—

Your Papers committee has not held a meeting during the past year and as a committee has done nothing. It is

[1] Engineering Journal, July 1934, p. 335.
[2] Engineering Journal, Feb. 1934, p. 79.

hoped, however, that each member has been of some assistance to the branches in his zone in obtaining papers for their branch meetings.

The difficulty encountered by some of the smaller and more isolated branches in obtaining interesting papers for their meetings, is accentuated in these times as funds cannot be found for the purpose of having speakers travel from larger centres. The chairman approached Mr. W. Storrie, M.E.I.C., of Gore, Nasmith & Storrie, with a view to having him stop off wherever possible on his proposed trip to the west in January. Mr. Storrie has some very interesting material and Mr. Durley is at present arranging with him to give a talk to as many of the branches as he can conveniently visit.

It is my opinion, which I believe is shared by the other members of the committee, that the main duty of this committee is for each member to try, in this way, to get papers from competent members passing through their zone on other business. This will eliminate a large part of the cost of obtaining papers of value.

It is suggested that the members of the committee should be kept informed by Headquarters whenever outstanding members of The Institute intend passing through their zone. The committee man of that zone could then communicate with such members with a view to having them visit the Branch and, if desired, present a paper. The individual members of the committee should also inform Headquarters when engineers of their zone are travelling to other zones.

In this way it is considered that not only would valuable papers be obtained but that the branches would receive much benefit from meeting men from Headquarters or from other zones.

Mr. Durley was able to obtain this year some very interesting moving picture films from England and it is thought that such films might be circulated with great benefit to the branches.

Respectfully submitted,
C. S. L. Hertzberg, M.E.I.C., *Chairman.*

Publication Committee

The President and Council:—

In view of the fact that the transactions of The Institute have not been published this year, your committee has to report that neither papers nor other matters have been submitted to it and that, therefore, it has been unnecessary to hold meetings.

Respectfully submitted,
Hector Cimon, M.E.I.C., *Chairman.*

Library and House Committee

The President and Council:—

The work of the library and information service has been carried on as extensively as the funds and staff available would permit. Your committee would draw attention to the increasing value for purposes of professional information of our files of back numbers of engineering periodicals and proceedings. The very small appropriation available is spent almost entirely on subscriptions to these periodicals, practically no books being purchased. For its accessions the library is dependent on donations so far as technical books are concerned.

The following are the statistics for library activities during 1934; the figures do not differ materially from those for 1933:—

Requests for information	617
Requests for text books, periodicals, reprints, etc.	487
Technical books borrowed	102
Bibliographies compiled for members	32
Accessions to library (largely reports, etc.)	597
Requests for photoprints	30
Total pages of photoprints furnished to members	169
Books presented for review by publishers	22

The headquarters premises have been maintained in good condition. After over twenty years' service it has been found necessary to make changes in some of the heating mains, renew a considerable portion of the electric wiring in the basement, and continue the renewal of portions of the exterior wood work, all at a cost of approximately $600.00.

Respectfully submitted,
A. Cousineau, A.M.E.I.C., *Chairman.*

Report of the E.I.C. Members of the Main Committee of the Canadian Engineering Standards Association

The President and Council:—

The Institute nominees on the Main Committee of the Canadian Engineering Standards Association are now as follows:—

Dean C. J. Mackenzie, M.E.I.C., retires March, 1935.
Mr. J. Morrow Oxley, M.E.I.C., retires March, 1936.
Mr. P. L. Pratley, M.E.I.C., retires March, 1937.

During the year a new Sectional Committee on Steel Construction has been organized, under which a Subcommittee on Procedure, Specifications and Standards, and Panels on Unit Stresses for Bridges, Unit Stresses for Buildings, and Structural Welding are now operating. The Subcommittee above referred to replaces the Joint Panel on Structural Steel for Bridges and Buildings which was reported last year.

Industrial conditions are still having their effect on the income of the Association. There have been five resignations from sustaining membership, and two sustaining members have felt compelled to reduce their subscriptions. To offset this, however, there have been added eight new sustaining members, one member has increased the subscription, and three former members have resumed membership. The total number of sustaining members and subscribers is now sixty-eight, and the total amount received for the year was $5,160, which is a reduction of only $40 from the amount received in 1933.

The Association continues to occupy quarters in Room 3064 of the National Research Building, through the courtesy of the National Research Council, and with other economies which have been effected the Association has thus been able to carry on for the year.

The Secretary attended the annual meetings of the Canadian Electrical Association and The Engineering Institute of Canada, and in May a joint meeting with the Standardization Committee of the American Railway Engineering Association was held, at which several of the officers and members of the Association were given an opportunity to give information on the work of the C.E.S.A.

At the Annual Meeting of the Association and at a meeting of the Main Committee, a proposed reorganization of the Main Committee was under discussion and it was decided to take this in hand actively. It is expected that a report from the Executive Committee will be sent out shortly for approval. The financial situation of the Association was also discussed, and it is hoped to put this on a more stable basis.

The publication of the C.E.S.A. Bulletin has been continued and is serving a very useful purpose. It has not been found possible to resume the publication of the Year Book, owing to lack of funds, but it is hoped that this can be resumed before long as it has been exceedingly valuable in promoting publicity for the work.

Work in Progress

A — Civil Engineering and Construction

Building Materials.—The Panel on Brick Sizes, after very carefully studying the situation, completed its report, and this has been generally approved by the Committee on Building Materials and is now before this Committee by letter ballot. The report recommends one size of brick for all purposes and includes suggestions for wall construction using the recommended size.

Close contact has been maintained with the committees dealing with the Toronto Building By-laws, and C.E.S.A. specifications will be recognized wherever possible.

Wood Poles and Piling.—As decided upon at the meeting of the Main Committee, arrangements will be made to merge the different committees on Wood Poles, and it is hoped to take up more actively during the coming year the question of standards for both eastern and western timber, also the proposed specification for piling.

B — Mechanical Engineering

Screw Products.—The standard for Non-heat-treated Machine, Carriage and Plough Bolts was issued in August, and it is believed that this standard now represents up-to-date practice in Canada. Information is given on the heavier type of Machine Bolts which are used in railroad practice, but this does not include track bolts. The latest information on wrench openings and nuts for the different types of bolts is also included, and the standard is strongly recommended for adoption by those interested.

No further action has been taken with reference to standards for Wood Screws and Small Rivets. It has been found difficult to get agreement on the proposed standard for Small Rivets and a final decision has not yet been reached.

Safety Code for Passenger and Freight Elevators.—The first draft and the comments thereon are still before the Committee, but a special panel has been organized to review these comments and prepare a revised draft and a report is not yet available.

Safety Code for Mechanical Refrigeration.—A committee has been organized to study this question, but it is possible that this work may be taken over by the National Research Council, who are studying the question of safety codes in general.

Oil Burners.—The Association has been advised that this work will probably be taken over by the National Research Council, but final arrangements have not yet been made.

C — Electrical Work

Canadian Electrical Code, Part I.—As a result of a meeting of the Special Committee on Code Revisions, held in March, the final revisions for the third edition have been approved by the Code Committee and also by the Sectional and Main Committee of the Association, and the third edition of the Code is now off the press and is being issued as the Canadian standard for 1935.

In connection with Part II of the Code, covering Approval Specifications, the specifications for Service Entrance and Branch Circuit-breakers, Capacitors (Electrical Condensers), Fractional Horsepower Motors, Electric Portable Lighting Devices and Outlet Boxes have been published and specifications for Motor-operated Blowers and Stokers and Electrical Equipment for Gasoline Measuring and Discharge Devices are now on the press. The specification for Electric Heating Pads is to continue in draft form until November 1st, 1935. Specifications for Insulated Conductors for Power-operated Radio Devices, Cable for Luminous-tube Signs and Oil-burner Ignition Equipment, and Soldering Lugs are now before the Code Committee for letter ballot. Revised drafts of the specifications for Enclosed Switches, Transformers for Luminous-tube Signs and Oil-burner Ignition Equipment, Industrial Control Equipment, Cord Sets and Oil Circuit Breakers are now before the Panel on Specifications for final approval. Specifications for Automatic Controllers of Small Capacity, Dust Tight Enclosures, Auxiliary Gutters, Junction Boxes and Pull Boxes, Wireways and Busways and Asbestos-insulated Stove Wire, have been out for comment and a summary of comments received is now before the Panel in preparation for meetings early in the year. First drafts of specifications for Panelboards, Enclosed Branch-circuit Cutouts, Switchboards and Switching Equipment, Electrically-operated Refrigerating Machines, Electric Cranes and Hoists and Electrode Receptacles for Luminous-tube Signs have been sent out for comment.

The publication of bulletins to electrical manufacturers has been continued, and five of these bulletins have been issued during the year, making a total of ten issued to date.

In connection with Part III of the Code, covering Outside Wiring Rules, some progress has been made, particularly in connection with the work of Sub-panel No. 3 on Inductive Co-ordination and Sub-panel 4 on Conductive Co-ordination. Under Inductive Co-ordination, the draft covering Definitions and Principles has been generally approved by the Panel on Outside Wiring Rules, and if approval can be obtained it is proposed to issue this in mimeograph form in the meantime. This also applies to the report on Principles and Practices Governing Radio Interference. A report on Conductive Co-ordination has been approved by the Panel on Outside Wiring Rules, and also by the Canadian Transit Association. No report is available on Underground Systems, but in connection with Sub-panel No. 1 on Overhead Systems, a report from the railway group on wire crossings was sent out for comment, also a preliminary draft on Overhead Systems, and comments on these documents are still being received.

Enamelled Magnet Wire.—It is hoped to have a second meeting of the Committee to discuss the second draft of this specification early in the year.

Insulated Power Cable.—A meeting of the Committee was held during the year and a complete revised draft has been sent out to the Committee for their comment. It is hoped to have a further meeting early in the year, at which it may be possible to secure approval of this draft.

Dielectric Strength and Insulation Resistance.—In the discussion of rules in Part I of the Canadian Electrical Code, and in the preparation of approval specifications under Part II of the Code, it has been found that there has been difficulty in securing uniform standards for dielectric strength and insulation resistance, and it has now been decided to organize a committee to deal with this subject and it is hoped to take this matter up actively early next year.

G — Ferrous Metallurgy

Heavy Steel Shaft Forgings.—At a meeting of the Committee held during the year, the revised specification was prepared and is still before the members of the Committee for comment.

Commercial Bar Steel.—It is believed that the existing C.E.S.A. specifications might be revised with advantage, and a circular has been issued to the Committee giving information on the situation and asking for suggestions as to future revisions.

Reinforcing Materials for Concrete.—Revisions to the three C.E.S.A. specifications are also being considered, and information has been sent out to the Committee asking for their comments.

S — Steel Construction

The Sub-committee on Procedure, Specifications and Standards has now reported, and four new specifications covering Medium Steel, Mild Steel, Silicon Steel and Rivet Steel have been prepared. The Sub-committee has also approved a report on proposed Unit Stresses for Bridges and Buildings. The specifications and the report will be presented to the Sectional Committee for approval and also to the Chairmen of existing C.E.S.A. Committees on Steel Railway Bridges, Steel Highway Bridges, and Steel

Structures for Buildings, for consideration, with the object of revising the C.E.S.A. specifications on bridges and buildings if necessary. A report on the Welding standards is not yet available.

CO-OPERATION AND PUBLICITY

Contact with the British Standards Institution, particularly with the work on approval specifications, has been continued and many helpful suggestions have been received.

As a matter of interest, the B.S.I. has issued a specification for Electric Signs, which has been largely inspired by the specification issued by the C.E.S.A.

The drafts of approval specifications are sent to the Underwriters' Laboratories at Chicago, and the Standardization Committee of the National Electrical Manufacturers Association at New York, and this contact has proved of great benefit.

The Association is again indebted to the technical press and newspapers for their generous co-operation in giving publicity to the work of the Association and the announcement of new publications.

The sale of publications has kept up well and there is every indication that they are being freely used throughout Canada.

The regular exchange of publications with the different standardizing bodies has been continued, particularly with the standardizing bodies of Great Britain and the other Dominions. A standardizing organization has now been established in Greece, and a set of C.E.S.A. publications has been sent to them for their information.

Respectfully submitted,
C. J. MACKENZIE, M.E.I.C.

Committee on Relations with National Societies

The President and Council:—

The Committee on Relations with National Societies has had a restful year.

We note that the International Electrotechnical Commission held a very good meeting at Prague, Czechoslovakia, in October, 1934. The attendance, as might be expected, was much smaller than usual; that condition, however, was not the fault of Great Britain—twenty-seven technical experts from the British Isles having been in attendance. All-America, which usually had from twenty to thirty representatives at these international gatherings—one or two, being the usual number of delegates from Canada—had one lone representative, Mr. R. E. Hellmund, from the United States National Committee.

An effort is being made to hold a large Plenary Meeting with Belgium and Holland combining as host-countries, next year.

The success of the *international* Prague meeting, coming as it did at "an exceptionally difficult period of world depression and extreme economic 'nationalism'," seems to be worth recording.

Respectfully submitted,
JOHN MURPHY, M.E.I.C., *Chairman.*

Board of Examiners and Education

The President and Council:—

The results of the examinations held during 1934 for admission to The Institute are as follows:—

Description	*No. of Candidates*	*No. of Papers Written*	*No. of Passed*	*Papers Failed*	*No. of Candidates Completely Passed*
Examined under Schedule "B" (Junior)...........	1	1	..	1	..
Examined under Schedule "C" (Associate Member)—					
Structural Engineering......	1	3	1	2	..
Electrical Engineering......	1	2	2	..	1
Metallurgical Engineering......	1	2	1	1	..

Your Board also reported favourably on the standing of the examinations set by the Institution of Electrical Engineers of Great Britain, and also on the standing of the engineering undergraduates attending the Memorial University College, St. John's, Newfoundland.

Respectfully submitted,
A. F. DYER, A.M.E.I.C., *Chairman.*

Unemployment Committee

The President and Council:—

Your committee wishes to report regarding its work during the year 1934. Before doing so, however, a short summary of activities to date may be of interest.

The apointment of this committee was first made by Council on April 15th, 1932, when, due to unsatisfactory conditions throughout Canada, it was felt that Council should have reliable data as to the extent of unemployment among the members of The Institute. Your committee's first step was to make a general survey of the membership and as a result of its findings[1] The Institute branches were requested to form local committees to assist unemployed members in their districts.

Since that time these committees have been of great assistance to those unemployed in locating positions. They have supervised relief payments where necessary, and have enabled your committee to keep in touch with conditions in the various branches.

In September 1933 further enquiries were made of all branches as to the number then known to be unemployed and in need of relief. The information received was presented to the Plenary Meeting of Council in October 1933.[2] The report also included particulars of 133 placements on the supervisory staffs of the Department of National Defence Relief Camps. These openings were at that time, and have since, proved to be of great assistance to many of our members in need of relief.

In April 1934, believing that possibly there was more unemployment among our members than the registration at headquarters indicated, your committee again communicated with all branches requesting a check on the members known to be unemployed or in need of relief, and data regarding expenditures for relief and any other pertinent information available.

As a result of the replies received it was possible to report to a meeting of Council on June 15th,[3] that it was estimated there had been a reduction in unemployment among members of approximately 25 per cent. This reduction was apparently greater among our own members than among engineers generally, also some localities were better than others. At that time, however, the number registered with The Institute Employment Service Bureau had not diminished, as the 1934 engineering graduates had just been added to our lists. A considerable improvement was shown on January 1st, 1935, however, with 334 registered, as compared with January 1st, 1934, when the number was 384, of whom some 35 per cent are actually employed in temporary or part time work.

In order that up-to-date information might be available for your committee's annual report, a further communication was sent to all branches in November 1934, enclosing a list of those in each branch then registered as unemployed at headquarters and requesting particulars of the activities of their unemployment committees during the year. At the same time headquarters communicated with all those registered with the Employment Service Bureau who had not been heard from for some time; as a result of this check and other placements, it has been possible to reduce the number registered to that mentioned above.

[1] Engineering Journal, July 1934, p. 335.
[2] Engineering Journal, December 1933, p. 528.
[3] Engineering Journal, July 1934, p. 335.

Sixteen branches returned a report of their activities and from an examination of these it would appear that no branches other than Toronto, Kingston and Montreal had members in immediate need of relief, or had found it necessary to make an expenditure for relief purposes. Montreal had the largest expenditure, amounting to $1,208.60, members of the branch subscribing $710 during the year to a special fund for relief purposes. Other branches found it unnecessary to add to previous contributions, or utilized surplus branch funds. A synopsis of the comments received from the branch committees appear as follows:—

Cape Breton—Steady improvement. Prospects better than they have been for some time.

Halifax—Prospects for employment during winter and spring not very good. Recent mining activity has helped situation but construction at low ebb.

Saint John—Prospects for employment during winter are not very bright particularly for students. For the spring, highway construction would appear to be the only work in view.

Quebec—Number of unemployed have decreased and conditions seem to be improving.

Montreal—Considerable decrease in the number of unemployed, but little demand for more experienced men at present.

Ottawa—Slightly improved conditions but prospects for 1935 not definite. Fourteen engineers in district have left positions on the supervisory staffs of the Department of National Defence Relief Camps to take more remunerative positions.

Kingston—Employment meagre during winter. The last eighteen months would have been disastrous except for the Department of National Defence Unemployment Relief Camps.

Peterborough—Conditions are brighter than for some years.

Toronto—Employment situation has improved, very few requests for assistance from Loan Fund.

Niagara Peninsula—Considerable number of engineers unemployed, or employed in other lines. Poor prospects for further employment on either public works or industrially during winter. Spring prospects will vary with amount of local public works allocation.

Border Cities—Employment prospects for winter and spring much better than a year ago.

Saskatchewan—Possibly some improvement, but very slight.

Lethbridge—Expect sufficient employment for all members without relief assistance.

Edmonton—At present rather quiet but expect considerable temporary employment will be available in the spring.

Vancouver—Present engineering employment in British Columbia rated at not higher than 50 to 60 per cent of normal.

Victoria—Situation slightly better than last winter. No immediate prospects for employment other than Department of National Defence Unemployment Relief Camps.

From the above reports it would appear that nearly all branches find conditions somewhat improved. Several, however, expressed the hope that both Federal and provincial governments would endeavour to carry out as large construction programmes as possible in the near future with a view to relieving unemployment.

It has been hoped that the programme of work being undertaken by the Federal Public Works Department would provide employment on their staffs for a number of engineers. However, the department was able to carry out their programme with very few additions to their staff.

A satisfactory indication of improved conditions is the heavy outflow of engineers from the Relief Camps of the Department of National Defence, many of whom are known to have gone to better positions. Throughout Canada over one hundred engineers, or over one-half of the number employed on the supervisory staffs, have left the camps during the past year.

Council's Committee on Unemployment desires to thank all Branch Executives and Branch Unemployment committees for the good work already accomplished. They wish to record also their appreciation of the co-operation shown in a number of centres by the Associations of Professional Engineers in assisting in relieving unemployment. The work of Colonel R. E. Smythe, A.M.E.I.C., chairman of the Toronto Branch Unemployment committee, should be particularly mentioned. Finally, they wish to express their thanks to all who contributed towards the actual relief of needy cases.

Your committee has understood its purpose to be the finding of work and the helping of needy unemployed engineers by supporting and co-ordinating the efforts of the various branch committees and feel that this work may have to continue for some time yet owing to the uncertainty still prevalent in business generally.

Respectfully submitted,

D. C. Tennant, M.E.I.C., *Chairman.*

Employment Service Bureau

The President and Council:—

The Employment Service Bureau of The Institute is able to report an improvement in employment conditions, as will be seen by the following figures for placements effected during the last four years:—

1931	*1932*	*1933*	*1934*
33	58	50	70

The following figures show the extent of the Bureau's work for 1934 as compared with 1933:—

	1934	*1933*
Number of registrations during the year—members	102	138
Number of registrations during year—non-members	39	46
Number of members advertising for positions	115	102
Replies received from employers	56	21
Vacant positions registered	124	92
Vacancies advertised	16	4
Replies received to advertised vacancies	59	16
Men notified of vacancies	139	147
Men's records forwarded to prospective employers	446	210
Placements — temporary and permanent — definitely known	70	50

The above placements do not include eleven members and four non-members placed on the Supervisory Staffs of the Department of National Defence Unemployment Relief Projects, in which the Employment Service Bureau worked in conjunction with the Branch Unemployment Committees.

At the present time 334 members are registered with the Employment Service Bureau, 95 of whom are temporarily employed and 29 employed with the Department of National Defence Unemployment Relief Camps.

The principal demand has been for mechanical engineers with pulp and paper mill experience, draughtsmen in the same line, plant engineers, and chemical, metallurgical and mining engineers. There have been a number of enquiries for sales engineers, but in several cases on a commission basis only, which accounts for a number of the unfilled vacancies.

The bureau has been instrumental in placing a number of 1933 and 1934 graduates in mechanical, electrical and chemical engineering, mainly in the Montreal district, and at the present time comparatively few recent graduates in mechanical and chemical engineering are registered with the bureau. At this point may we point out to members the advantages of being registered with the bureau. When we are notified of a vacant position prompt action is necessary so that only the records of experience of members already on file can be forwarded to the prospective employer. Usually there is not time even to notify the members of the vacancy before sending out their records for consideration.

In some cases a registrant's engineering record has been sent out in this way as many as ten times without his knowledge; thus as a rule members are not aware of the extent of service received through having their names and records on file with the bureau.

In December 1934 a questionnaire was sent to all members registered with the Employment Service Bureau, with whom we had not been in communication for some time, in order to ascertain if they had secured employment.

One hundred and ninety-three letters were sent out and replies have been received as follows:—

22 have secured employment and wish their names removed.

48 have secured temporary employment in engineering and otherwise but wish their names retained on the list of men available.

45 are still unemployed.

The above information is felt to be distinctly encouraging and should employment conditions continue to improve as now seems likely, it will be possible to place many more of our unemployed members.

Respectfully submitted,

R. J. Durley, M.E.I.C., *General Secretary.*

Branch Reports

Border Cities Branch

The President and Council:—

The Executive committee of the Border Cities Branch, Engineering Institute of Canada, submits the following report for the calendar year 1934.

The Executive committee has held seven meetings for the transaction of business during the past year.

Eight regular dinner meetings and one special meeting were held as follows:—

1934

Jan. 12.—**The Diesel and High Speed Engines** by Boyd Candlish, A.M.E.I.C., of the Palmer Bee Co., Detroit. Attendance, 36.

Feb. 16.—**A Trip Through the Past** by Mr. Ernest Wilby, A.A.I.A., Professor of Architecture at the University of Michigan, Ann Arbor. Attendance, 22.

Mar. 9.—**The Development of Cementing Materials and Architectural Concrete from Earliest Times** by J. M. Breen, A.M.E.I.C., technical engineer of the Canada Cement Co., Montreal. Attendance, 20.

April 20.—**An Adventure in Politics** by S. E. McGorman, M.E.I.C., of the Canadian Bridge Co., Walkerville, and Mayor of Ojibway. Attendance, 26.

May 18.—**The Design and Construction of the Dominion Public Building in Windsor** by Mr. H. P. Sheppard, of Sheppard and Masson, architects. Attendance, 17.

May 25.—Visit to the Dominion Public Building conducted by Mr. H. P. Sheppard. Attendance, 27.

Oct. 19.—**The Electronic Valve** by Mr. George Chute, of the General Electric Co. Attendance, 28.

Nov. 16.—**Gasoline** by Mr. J. M. Miller, of the Standard Oil Co. of Indiana. Attendance, 30.

Dec. 14.—**Construction of a Steel Plant in Russia** by Mr. M. J. Wohlgemuth, of the Westinghouse Electric Co. Attendance, 50.

The average attendance at regular meetings was 29.

The papers submitted throughout the year have been of a high standard. We are glad to announce that our papers committee has secured speakers for each meeting up to the close of the winter season.

Membership

The membership of the Branch is made up as follows:—

	Resident	*Non-Resident*	*Total*	*Non-Active*
Members	12	2	14	3
Associates	25	7	32	9
Juniors	1	2	3	..
Students	9	4	13	..
Affiliates	1	..	1	..
	48	15	63	12

A comparison of our present membership with that of other years is shown in the following table:—

	1930	*1931*	*1932*	*1933*	*1934*
Members	23	24	21	17	14
Associates	50	53	42	34	32
Juniors	12	12	8	5	3
Students	16	15	11	11	13
Affiliates	1	1	1	1	1
	102	105	83	68	63

Financial Statement

(For the year ending December 31st, 1934)

Respectfully submitted,

H. J. A. Chambers, A.M.E.I.C., *Chairman.*

C. F. Davison, A.M.E.I.C., *Secretary-Treasurer.*

Calgary Branch

The President and Council:—

On behalf of the Executive committee of the Calgary Branch, we are happy to anounce considerable progress during the past year.

The following report covers the activities of our Branch from January 1st to December 31st, 1934.

Membership

	December 31st, 1934		
	Resident	*Non-Resident*	*Total*
Members	16	8	24
Associate Members	46	13	59
Juniors	3	1	4
Students	13	4	17
Branch Affiliates	10	..	10
	88	26	114

It is with deep regret that we have to report the passing of B. S. Smith, Affil.E.I.C., on May 16th, 1934.

During the year we have added seven associate members, one of which was a transfer from junior grade, and one transferred from another branch, while three students were added.

Several applications are pending for membership in various grades.

The Executive committee met nine times during the year to deal with and dispose of the various items which arose. An Unemployment committee dealt with all questions pertaining to that activity.

General Meetings

Fifteen general meetings were held, and the interest and attendance at each were a marked success. The papers and discussions were particularly interesting and timely. Among the many subjects, one innovation proved a decided success, i.e., Students and Juniors competition for a handsome cash prize, and so successful was this feature from every standpoint, that one of our members donated a prize for a similar competition this season, of which two papers have already been delivered, and several others will be given at intervals during the winter.

1934

Jan. 11.—**Construction of the Big Bend Highway in British Columbia by the National Parks of Canada** by J. M. Wardle, M.E.I.C., Banff. Attendance, 100.

Jan. 25.—**Engine 8000** by Mr. T. F. Donald, C.P.R., Montreal. Attendance, 110.

Feb. 15.—Joint dinner with Professional Engineers of Alberta and the Canadian Institute of Mining and Metallurgy. Attendance, 64.

Mar. 1.—Students Competition:

1st. **Construction and Principals of Operation of the New Sewage Disposal Plant at Bonnybrook.**

2nd. **The Application of Heavisides Operational Calculus to Engineering Problems.**

Mar. 2.—Continuation of Students Competition:

3rd. **Railway Construction in the Peace River Block.**

4th. **Recent Developments in Radio Receiver Design.** Attendance, 85.

May 3.—**Construction and Operation of the British Grid System** (3 reels) and introductory address by G. H. Thomson, A.M.E.I.C., general manager, Calgary Power Co. Attendance, 60.

May 25.—**Construction of Power Lead Across the Desert from the Boulder Dam** and **Construction of Cable** (6 reels), courtesy of Canada Wire and Cable Co. Attendance, 35.

May 26.—Inspection of Engine 8000 at Ogden Shops, courtesy of C.P.R. and Mr. T. F. Donald. Attendance, 20.

July 23.—Complimentary dinner to our President, F. P. Shearwood, M.E.I.C., and address on **Bridge Erection** by F. P. Shearwood, M.E.I.C., Montreal, chief engineer, Dominion Bridge Co. Attendance, 35.

Sept. 15.—Golf Tournament. Attendance, 35.

Oct. 18.—**From the Ground Up** (5 reels). Attendance, 76.

Nov. 1.—Contest open to Corporate, Junior and Student members—two papers.
1st. **Photo Electric Cells and Some of their Applications.**
2nd. **Pressure Vessels for Cracking Oil.**
Also address **Timber Design, Working Stresses and Preservative Treatment** by W. H. Greene, M.E.I.C., chief engineer, Canada Creosoting Co. Ltd.
Attendance, 45.

Nov. 15.—**Land Utilization and Farming Problems on Irrigated Projects** by R. S. Stockton, M.E.I.C., C.P.R., D.N.R., Experimental Farm, Strathmore.
Air Conditioning by W. B. Trotter, A.M.E.I.C.
Attendance, 50.

Nov. 29.—Supper Dance. Attendance, 85.

Dec. 13.—**Commercial Air Transport** by A. Griffin, M.E.I.C., chief engineer, C.P.R., D.N.R., Brooks.
Activity at Vickers Armstrong Ltd., Barrow-in-Furnace (6 reels).
Attendance, 110.

Average attendance at meetings, 62.5.

Cape Breton Branch

The President and Council:—

The annual report of the Cape Breton Branch is as under.

During the year the Branch held four meetings as follows:—

1933

Dec. 19.—Annual Meeting and Banquet at which H. M. Roscoe, of Canadian Industries Limited, read a paper on **The Manufacture and Use of Explosives.** This paper was illustrated and gave rise to much discussion. Attendance, 33.

1934

Jan. 16.—General meeting held, by invitation, at the Royal Cape Breton Yacht Club, and addressed by Major J. W. Maddin on **Some Engineering Problems of Nova Scotia.** Attendance, 53.

Feb. 20.—General meeting at which H. C. Carlton, of Reyrolle Co., gave an illustrated paper on **The Development of Metal-clad Switch Gear.** Attendance, 28.

April 3.—General meeting at which G. B. Mitchell, M.E.I.C., of the Atlas Construction Co., gave some reminiscences of his work in Central and South America. Attendance, 19.

Due to the difficulty of getting speakers we have not been able to hold meetings during the fall months but it is expected that monthly meetings will be resumed throughout the winter. We much regretted that on his Maritime visit the President could not afford the time to visit us.

Edmonton Branch

The President and Council:—

On behalf of the Executive committee of the Edmonton Branch we beg to submit the following report for the year 1934.

Membership

	Dec. 31st, 1933 Resident	Non-Resident
Members	11	2
Associate Members	23	6
Junior Members	3	..
Student Members	33	..
	70	8

	Dec. 31st, 1934 Resident	Non-Resident
Members	10	3
Associate Members	18	6
Junior Members	5	..
Student Members	26	..
	59	9

It is with deep regret that we record the loss of W. J. Cunningham, A.M.E.I.C., an esteemed member of this Branch, and Mr. G. Law, who until recently was an active member of the Branch. Both these gentlemen passed away during the course of the year.

Meetings

The following meetings of the Branch were held during the year:—

1934

Jan. 9.—**Television and the Sending of Pictures by Wire** by Mr. A. M. Mitchell, Comptroller of the Alberta Government Telephones. Attendance, 35.

Feb. 6.—**The Century of Progress** by C. E. Garnett, A.M.E.I.C., of Gormans Ltd., Edmonton. Attendance, 18.

Mar. 14.—**Domestic Waters** by Mr. W. Calder, Director of the Petroleum and Natural Gas Division, Department of Lands and Mines, of the Alberta Provincial Government. Attendance, 24.

May 2.—A film showing the **Development of the New Super-Power Transmission System in Great Britain.** Attendance, 30.

Oct. 24.—**Development of Flying in the North Country** by Mr. C. H. Dickins, Superintendent of Canadian Airways, Ltd., Western Lines. Attendance, 40.

Nov. 20.—Films loaned to the E.I.C. by Vickers-Armstrong, Ltd., and dealing with **Steelmaking, Aviation and Shipbuilding.** Attendance, 21.

Three meetings of the Executive committee were held to deal with special questions which arose.

Halifax Branch

The President and Council:—

On behalf of the Chairman and Executive of the Halifax Branch the following report is submitted for the year 1934.

Including the Annual Meeting there have been eight regular meetings and eight meetings of the Executive. The following meetings were held:—

January.— Annual banquet held in conjunction with the Nova Scotia Professional Society of Engineers.

February.— Meeting at Halifax hotel addressed by E. H. James, M.E.I.C., consulting engineer, of Montreal, on **Marine Substructures.**

March.— Meeting at Halifax hotel addressed by Mr. W. B. Burchall of Canadian Airways on **The Development of Canadian Airways.** Attendance, 40.

July.— Summer meeting at Green Acres, Waverley, N.S. Attendance, 75.

October.— Students meeting. Showing of films loaned by Vickers-Armstrong Ltd. Attendance, 250.

December.— Meeting at Halifax hotel addressed by President F. P. Shearwood, M.E.I.C., on matters of interest to members of The Institute. Attendance, 45.

December.— Meeting at the Nova Scotia Technical College addressed by President F. P. Shearwood, M.E.I.C., on **Some Problems of Bridge Design and Construction.** Attendance, 125.

The Executive arranged for a series of broadcasts over the local radio station during the year. These broadcasts were on subjects of engineering interest intended to enlighten the public regarding the engineering profession.

1.—E. L. Miles, M.E.I.C., Standard Paving Company (N.S.), gave a general discussion on **Roads and Road Construction and Dustless Highways.**

2.—H. S. Johnston, M.E.I.C., chief engineer, Nova Scotia Power Commission, gave a general talk on **Hydro-Electric Stations in Nova Scotia.**

3.—I. P. MacNab, M.E.I.C., Public Utilities Commission, gave a general outline of the Public Utilities Act and a discussion as to how it applies to the various utilities in Nova Scotia.

4.—W. A. Winfield, M.E.I.C., general superintendent of plant, Maritime Telegraph and Telephone Company, gave a general talk on the dial telephone and its application in Nova Scotia.

5.—G. V. Douglas, A.M.E.I.C., professor of Geology at Dalhousie University, gave a general talk on **The Geology of Nova Scotia.**

6.—W. P. Copp, M.E.I.C., professor of Civil Engineering at Dalhousie University, gave a general talk on **Surveying and the Method of Determining Boundaries of Lands.**

7.—J. B. Hayes, A.M.E.I.C., general manager of the Nova Scotia Light and Power Company, gave a talk on the service given by his company to the people of Nova Scotia.

8.—J. Morris, sales engineer of Wm. Stairs, Son and Morrow, Limited, gave a general talk on **Diesel Engines.**

9.—W. B. MacKay, A.M.E.I.C., managing director of Farquhar Bros. Ltd., gave a talk on **Modern Heating Systems.**

Arrangements were made for a joint meeting of representatives of the Halifax Branch and of the Nova Scotia Society of Professional Engineers at which the general subject of amalgamation was discussed and a general policy for further action was recommended to both Societies.

Suggestions to other Maritime Branches regarding interchange of speakers have been made to other Branches of The Institute and it is hoped satisfactory arrangements can be made during the coming year.

The average attendance at meetings was greater than during the past few years and it is interesting to note that a number of the younger members are taking a more active interest in the affairs of the Branch.

The finances of the Branch are in good shape and the audited statement shows an operating balance for the year of $26.98, making the total cash on hand at the close of the year 1934—$455.95.

Respectfully submitted,
R. L. Dunsmore, A.M.E.I.C., *Chairman.*
R. R. Murray, A.M.E.I.C., *Secretary-Treasurer.*

Hamilton Branch

The President and Council:—

The Executive committee of the Hamilton Branch submits the following report for the calendar year 1934:—

The Executive committee held 11 meetings throughout the year. The following is the list of professional meetings and visits:—

1934

Jan. 9.—Branch Annual Business Meeting.
Operation and Application of the Teletypewriter by R. A. Cline, equipment engineer, Bell Telephone Co. Attendance, 50.

Feb. 13.—**Activities of the Ontario Research Foundation** by O. W. Ellis, Director of Metallurgical Research, Ontario Research Foundation. Attendance, 45.

Mar. 1.—Joint Meeting with the Toronto Branch E.I.C. in Toronto.
The Status of the Engineer in Industry by a Committee of the Hamilton Branch, J. B. Carswell, M.E.I.C. (chairman), E. P. Muntz, M.E.I.C., H. B. Stuart, A.M.E.I.C. Attendance, 100.

Mar. 17.—Visit to the Plant of the Sovereign Potteries Ltd., Sherman Ave. N., Hamilton. Members and ladies. Each lady was the recipient of a cup and saucer, specially made for the occasion, and bearing The Institute crest. Attendance, 125.

April 6.—Joint Meeting with the Toronto Section A.I.E.E. in the Canadian Westinghouse auditorium.
Circuit Interruptions by Dr. Joseph Slepian, consulting engineer, Research Laboratories, Westinghouse Electric and Manufacturing Co., Pittsburgh. Attendance, 195.

May 8.—**Corrosion and Wire Galvanizing** by A. B. Dove, Jr.E.I.C.
Manufacture and Application of Wire Rope by C. D. Meals, wire rope engineer, B. Greening Wire Co., Hamilton.
Attendance, 70.

June 9.—Visit to new Soaking Pit Building, Dominion Foundries and Steel Ltd., Hamilton. A 100 per cent made-in-Canada building. Attendance, 30.

Sept. 18.—Joint Meeting with the Hamilton Chemical Association.
The X-ray in Industry by Dr. L. R. Hess. Attendance, 150.

Oct. 9.—**The Geology of the Gold Fields of Ontario** by Dr. E. M. Burwash, geologist, Provincial Department of Mines, Toronto. Attendance, 75.

Oct. 26.—Joint Meeting with the Babcock-Wilcox and Goldie-McCulloch Engineering Society, Galt.
Moving pictures showing the Boulder Dam Construction on the Colorado River. Attendance, 250.

Nov. 1.—Joint Meeting with the Toronto Branch E.I.C. at Toronto.
Moving Pictures descriptive of work done at the plants of the Vickers-Armstrong Co., England. Attendance, 150.

Nov. 20.—**An Engineer in Nigeria** by T. Stanley Glover, A.M.E.I.C. Attendance, 60.

The professional meetings of the Branch have introduced a wide variety of subjects, which proved very attractive. The second committee paper sponsored by the Branch was read at a joint meeting in Toronto and aroused a great deal of interest and favourable comment. Two of our own members—A. B. Dove, Jr.E.I.C., and T. Stanley Glover, A.M.E.I.C.—gave papers before the Branch and proved themselves most attractive speakers.

The Branch has again enjoyed the privilege of holding its meetings in the Science Hall, McMaster University, where accommodation for lecture and demonstration is of the best. We appreciate the kindness of the University authorities in granting this privilege and in doing everything possible to make us comfortable.

The Executive committee acknowledges its indebtedness to the local press for the many courtesies extended to the Branch throughout the year.

The books of the Branch have been placed in the Hamilton Public Library. After being catalogued they will be placed in the reference room, but may be taken out on a borrower's card by any member on presentation of a card, signed and stamped by the Secretary.

E. H. Darling, M.E.I.C., represents the Branch on the committee revising the City of Hamilton Building By-laws.

H. B. Stuart, A.M.E.I.C., represents the Branch on the Regional Committee of the National Construction Council.

Kingston Branch

The President and Council:—

During the year 1933-34 the Kingston Branch met four times as follows:—

1933

Oct. 24.—Annual Dinner and Meeting for the election of officers and for receiving reports.

1934

Jan. 17.—The Branch was honoured by a visit from the President of The Institute, Dr. O. Lefebvre, M.E.I.C., who was tendered a dinner at the Badminton Club, following which he gave a very interesting talk on **The Activities of The Institute.**

Feb. 15.—A film of the Abitibi Power Development was lent to the Branch by the Dominion Construction Co.

Mar. 1.—A paper on **The History and Development of the Military Tank** was presented by Lt.-Col. N. C. Sherman, M.E.I.C., R.C.O.C.

EMPLOYMENT

The situation as regards employment continues to be very discouraging for a few members of our Branch, and it is hoped that any having work to offer will give the first opportunity to members of The Institute.

MUNICIPAL AFFAIRS

No meetings of the International Bridge Committee were held during the year. The committee appointed to confer with the city authorities on the subject of sewage held one meeting with the Mayor, with inconclusive results.

MEMBERSHIP

	Hon. Members	Members	Assoc.	Juniors	Students
1931-32	1	12	17	6	7
1932-33	1	13	16	6	16
1933-34	1	11	19	7	14

FINANCIAL STATEMENT

The financial statement is appended below. It should be noted that as no payment is now made by The Institute for Branch News, the only source of revenue for the Branch is the rebate from dues. The failure of even three or four members to pay their annual fees becomes a serious matter to so small a branch.

During the year, the attention of your secretary was called to the fact that about fifteen years ago $50 was advanced to the Branch by The Institute. Inquiries to previous secretaries confirmed this, and the amount is now shown in the statement of assets and liabilities.

Lakehead Branch

No report received.

Lethbridge Branch

The President and Council:—

The following is a report of the operations of the Lethbridge Branch during the year 1934.

Since January 1st, 1934, 8 regular and 8 executive meetings have been held, attendance at the former averaging 40 and at the latter 7.

The usual procedure was followed in connection with our regular meetings, i.e. dinner meetings with short musical programmes interspersed with community singing, followed by an address or films.

It is becoming more difficult every year to secure material for programmes. Speakers are hard to secure and usually if an outside speaker is available the Branch is liable for some of his expenses, which under the present conditions they find hard to meet. We have had some very good films this year and The Institute are to be commended for securing the "British Grid System" and the "Vickers-Armstrong." The Programme committee have worked hard, and are to be congratulated on securing a well balanced programme.

Through the efforts of an active Entertainment committee the musical and social end of our meetings have been well up to average.

During the first six months of this year, due to low finances, no set schedule of meetings was followed and interest in Branch and Institute affairs seemed to lag; as a result it was decided to operate as before, with a set programme and admitting Branch Affiliates at a reduced rate of $2 providing they paid their fees before March 1st.

The list of speakers and subjects chosen follows:—

1934

Feb. 17.—Motion pictures on **Manufacture of Cotton** loaned by Dominion Textile Ltd. Open to ladies. Attendance, 65.

Mar. 15.—Annual Meeting. Attendance, 10. Very bad weather, unexpectedly.

June 4.—Motion pictures on **British Electrical Grid System** loaned by British Electrical Board. Attendance, 60.

July 20.—F. P. Shearwood, M.E.I.C., President Engineering Institute of Canada, **Bridge Erection** and **Institute Affairs.** Attendance, 19.

Oct. 13.—J. M. Wardle, M.E.I.C., **The Big Bend Highway.** Open to ladies. Attendance, 55.

Nov. 10.—J. M. Campbell, A.M.E.I.C., **Economics Old and New.** Attendance, 29.

Nov. 24.—Motion picture of the various works and jobs accomplished by Vickers-Armstrong Ltd., England. Attendance, 45.

Dec. 15.—D. H. Elton, K.C., **Democracy at the Cross Roads.** Ladies night. Attendance, 40.

At December 31st, 1934, the membership of the Branch was as follows:—

	Resident	Non-Resident	Total
Members	4	..	4
Associate Members	17	4	21
Juniors	1	1	2
Students	4	7	11
Affiliates	18	..	18
	44	12	56

Financial Statement
(As at December 31st, 1934)

London Branch

The President and Council:—

During the year 1934, the following meetings were held:—

1934

Jan. 17.—Annual meeting with General Armstrong, Commanding Officer M.D. No. 1, as guest speaker. Attendance, 40.

Feb. 21.—Illustrated lecture by Mr. G. A. Woonton of the University of Western Ontario on the **Oscillograph and its Uses.** Held at U. of W.O. Attendance, 60.

Mar. 21.—Address by Mr. Chas. Hunter on **Ionization and its Relation to the Modern Subject of Air Conditioning.** Attendance, 36.

April 25.—A social evening by members at the home of E. V. Buchanan, M.E.I.C. The guests were entertained at bridge. Refreshments served by the host.

Oct. 31.—Address by Mr. Wm. Duffield, president of the City Gas Co. of London, on **The Dawn Gas Fields.** Attendance, 29.

1935

Jan. 4.—Considered as regular December meeting, in which the Vickers-Armstrong films were shown at the London Technical School. Estimated attendance, 800.

Average attendance of all meetings, 160.

In addition to the above, six Executive meetings were held throughout the year with an average attendance of eight.

Moncton Branch

The President and Council:—

On behalf of the Executive committee we beg to submit the fifteenth annual report of Moncton Branch.

The Executive committee held four meetings. Ten meetings of the Branch were held, at which addresses were given and business transacted as follows:—

1934

Jan. 29.—A meeting was held in the City Hall for the purpose of discussing proposed amendments to Institute By-laws and making recommendations to the forthcoming annual meeting.

Feb. 26.—A meeting was held in the City Hall. Herbert Tucker, M.A., Ed.M., M.R.E., Ph.D., Professor of Economics, Mount Allison University, Sackville, delivered an address on **The Proposed Central Bank for Canada.**

Mar. 14.—A meeting was held in the City Hall. W. B. Burchall, advertising manager, Canadian Airways, Ltd., Montreal, delivered an illustrated address on **The Contribution of the Aeroplane to Canadian Industrial Development.**

Mar. 20.—A combined meeting of Moncton Branch and the Engineering Society of Mount Allison was held in the Eurhetorian Hall of the University of Sackville. H. J. Crudge, A.M.E.I.C., building engineer, Canadian National Railways, Moncton, read a paper on **Engineering Estimates.**

April 10.—A combined meeting of Moncton Branch and the Engineering Society of Mount Allison was held in the Centennial Hall of the University at Sackville. T. H. Dickson, B.Sc., A.M.E.I.C., delivered an illustrated address on **Streamlined Vehicles.**

April 17.—A meeting was held in the City Hall. H. E. Bigelow, Ph.D., F.R.S.C., Professor of Chemistry, Mount Allison University, Sackville, delivered an address on **Chemistry in Industry.**

At this meeting nominations were made for branch officers for the year 1934-35.

May 31.—The annual meeting was held, at which the annual report and financial statement was presented, the report of the scrutineers received and the branch officers for 1934-35 announced.

Oct. 5.—A meeting was held in the City Hall for the purpose of discussing with the branch Councillor, H. J. Crudge, A.M.E.I.C., certain matters to be dealt with at the next meeting of Council.

Oct. 16.—A meeting was held in the City Hall. Six reels of motion pictures were shown, descriptive of ship building operations and aeroplane trials at the works of the Vickers-Armstrong Company, England.

Dec. 10.—A supper meeting was held in the Y.M.C.A. in honour of President F. P. Shearwood, M.E.I.C. Mr. Shearwood addressed the meeting on Institute affairs and also gave an illustrated address on **Some Problems of Bridge Erection.**

Membership

Our membership at present consists of forty-seven members as follows:—

	Resident	Non-Resident
Members	5	1
Associate Members	19	6
Juniors	2	2
Students	4	6
Affiliates	2	..
	32	15

It is with deep regret that we record the passing of Michael Joseph Murphy, A.M.E.I.C., a former chairman of the Branch, whose death occurred on December 30th.

Montreal Branch

The President and Council:—

We have the privilege of submitting the following report of the activities of the Montreal Branch during the past year.

There are a certain number of activities which from year to year come under the responsibility of the Executive committee. These are usually considered by the membership as a matter of course, though they represent the bulk of the business of the Branch. This routine work includes various items such as looking after our weekly meetings and meetings of the Executive committee; the organization of many sub-committees; keeping contact with the Council of The Institute; and helping Headquarters as much as possible in collecting the dues from the members of the Montreal Branch, and generally keeping the Branch alive.

In regard to this general work we feel that we can report that results this year have been up to the high standard established by past Executive committees.

Our financial statement given below shows that notwithstanding increased service to our membership and the expense of holding the Annual General Meeting in Montreal, our finances are in good shape. We have managed to keep our surplus at practically the same level it has been in recent years. A greater number of technical meetings have involved higher expenses in the sending out of notices and in the courtesies extended to our speakers. If it were not for the loss sustained by the Annual Meeting we would have been able to show a substantial surplus on the year's operation. In view of these facts we feel satisfied with the results shown.

Financial Statement
Revenue

Ordinary:			
Rebates from Headquarters	$1,593.60		
Affiliate dues	43.00		
Interest	7.53		
		$1,644.13	
Surplus from 1933		1,220.48	
Revenue from A.G. and P.M.		1,859.59	
Dinners to speakers		50.80	
			$4,775.00

Disbursements

Post cards notices	$ 669.11		
Stationery and stamps	25.35		
Secretary's honorarium	300.00		
Stenographic service	120.00		
Telephone and telegraph	60.95		
Lantern operator and slides	103.00

Thursday refreshments	76.80		
Speakers' travelling and dinners	109.24		
Economics course	21.19		
Miscellaneous	27.25		
		$1,530.89	
Annual General and Professional Meeting		2,106.11	
Cash on hand		1,138.00	
			$4,775.00

We have also carried out the excellent work promoted by our predecessors in regard to the help extended to our unemployed. During December and January 1933 and 1934 we raised by subscriptions from the members $872.50. During November and December 1934 we were forced to make an additional appeal when an amount of $710.00 was subscribed. While this latter amount was a little lower nevertheless it is very encouraging to receive such a generous response under present financial conditions. Our successors will have a difficult task concerning unemployment, but we trust that with the help of the membership they will be able to carry on for the benefit of those of us who are in dire straits. The financial statement for the year ending December 31st, 1934, for the Unemployment Relief Fund is as follows:

Subscriptions	$1,582.50	
Bank interest	11.20	
Repaid to fund	43.83	
		$1,637.53
Disbursements	$1,208.60	
Deficit—1933	54.97	
Balance on hand	373.96	
		$1,637.53

We have on two occasions this year interested ourselves in the affairs of our city. A special general meeting was held on March 15th at which it was decided to join the "Montreal Board of Trade" and the "Chambre de Commerce" in requesting the Prime Minister of this province to take steps towards the appointment of a commission which would for a certain period be entrusted with the government of the city of Montreal. Later on during the year, a committee was appointed to collaborate with the sanitary engineer of the city of Montreal in the preparation of by-laws to regulate certain phases of building construction.

The Branch had the privilege of being host to the Annual General Meeting of The Institute in February. The Annual Report of The Institute will show that the attendance at that meeting was more than satisfactory. We hope that we have succeeded in upholding the reputation of this city, by our hospitality and attention to out-of-town members.

On two occasions we had the honour of officially receiving the Presidents of The Institute. In January Dr. O. O. Lefebvre, M.E.I.C., addressed the Branch, while in October we had an address by Mr. F. P. Shearwood, M.E.I.C.

Besides taking care of the normal business of the Branch, we believe that it is the duty of each successive Executive committee to promote some new activity or at least to improve very definitely on some part of the general routine work. This has been achieved this year to a great extent through the excellent work of our Papers and Meetings committee under the most able chairmanship of J. G. Hall, M.E.I.C., as shown by many innovations which undoubtedly you have already noticed. We are therefore pleased to incorporate in our report the following remarks which were presented by Mr. Hall in his report to the Executive committee:—

Senior Section

Meetings held during spring session were as follows. These meetings had been arranged for by the previous committee.

Meetings held Spring Session 1934:—

Jan. 4.—Branch Annual Meeting. Official visit of Dr. O. O. Lefebvre, M.E.I.C.

Jan. 11.—**Historical Aspects of Radio Development** by J. H. Thompson, A.M.E.I.C.

Jan. 18.—**Geology and Civil Engineering** by R. F. Legget, A.M.E.I.C.

Jan. 25.—**Increasing Continuity of Service** by Mr. F. A. Hamilton, Jr.
Feb. 1.—**European Construction** by Mr. Jacques Rabut.
Feb. 8.—Annual Meeting of E.I.C. held in Montreal.
Feb. 15.—**Central Heating** by W. G. Chace, M.E.I.C.
Feb. 22.—**Development in "Long Distance"** by Mr. A. B. Clark.
Mar. 1.—**The Contribution of the Aeroplane to Canadian Industrial Development** by Mr. W. B. Burchall.
Mar. 8.—**Common Frequency Radio: Broadcasting** by Messrs. J. L. Clarke, M.E.I.C., and C. B. Fisher.
Mar. 15.—Student Night.
Mar. 22.—**The Operation of an Hydro-Electric System** by Messrs. C. R. Reid, W. R. Way, A.M.E.I.C., and E. W. Knapp, A.M.E.I.C.
Mar. 29.—**The Automotive Diesel Engine** by J. L. Busfield, M.E.I.C.
April 5.—**Main Cables and Suspenders for Suspension Bridges** by Mr. C. D. Meals.
April 12.—**Some Aspects of Railway Maintenance** by Mr. W. O. Cardworth.
April 26.—**Co-operation of the Engineer and Architect in Town Planning** by Mr. Jacques Gréber.
May 3.—**Empire of Steel.** Movie.

Meetings held from July to December 1934:—

July 26.—**The British Grid System.** Movie.
Sept. 6.—**Prestressing Suspension Bridge Cable Strands.** Actual operation by courtesy of Dominion Bridge Co.
Oct. 4.—**Construction of S.S. Strathnaver and Steel Making at Sheffield.** Movie.
Oct. 11.—**Some Problems Facing the Institute** by F. P. Shearwood, M.E.I.C.
Oct. 18.—**Construction Equipment of the Hoist Operated Type** by C. C. Langstroth, A.M.E.I.C.
Oct. 24.—**Grounds and Grounding** by S. H. Cunha, A.M.E.I.C.
Oct. 25.—**City Noises and the Need for Their Control** by Prof. H. E. Reilley.
Nov. 1.—**Modern Sewage Treatment Practice** by Mr. E. B. Besselievre.
Nov. 8.—**Un Nouveau Gazogène pour l'Industrie Canadienne** by Paul Vincent, S.E.I.C.
A Small Power Plant for a Game Lodge by Mr. E. S. Cooper.
Nov. 15.—**Economics of the Durable Goods Industry** by Dr. D. M. Marvin.
Nov. 22.—**Application Engineering on Motors and Control** by Mr. W. C. Raube.
Nov. 23.—Discussion of Mr. Raube's Paper.
Nov. 29.—**X-Ray in Medical Science** by Dr. W. L. Ritchie.
Dec. 6.—**Design and Application of Gears** by Mr. W. P. Muir.
Dec. 10.—Further development of above subject by Mr. W. P. Muir.
Dec. 12.—**Electron Tubes in Industry** by Mr. D. L. West.
Dec. 13.—**Relationship Between Architecture and Engineering** by J. M. Oxley, M.E.I.C.

The programme for the Spring Session of 1935 has already been published and additions may be made later.

During the term from July to December, excluding student night, the total attendance was 1,747 with 16 meetings, being an average per meeting of 109 or 134 per week. This corresponds to a total attendance of 1,155 with 11 meetings during the similar period of 1933.

It will be noted that four meetings were held on evenings other than Thursday. These were to give an opportunity for a more complete and informal discussion of the subjects in question by members of the sections more particularly interested.

A series of special lectures by Dr. D. M. Marvin on "Current Economic Topics" is being held. These are for members of The Institute only, and are being attended by twenty-one members. These lectures are self-supporting, a fee being charged to cover expenses.

An interesting feature in connection with the activities of the Junior Section was the number of papers presented in French.

Based on experience this past year your committee begs to submit the following suggestions for the consideration of the incoming Papers and Meetings committee:—

1. That the chairman and vice-chairman of each section add to their numbers and meet to discuss their programme for the year, apart from the general committee meetings.
   This should—
   (*a*) Increase the scope of subjects obtained.
   (*b*) Save considerable time at the general committee meetings.
   (*c*) Increase the number of members actively interested in Branch activities.
2. That the policy of having Section Meetings on evenings other than Thursdays be developed to include possibly all sections. It is believed that in this way the members of the Branch will be encouraged to make greater use of the facilities available and take a greater interest in the work of The Institute.
3. That consideration be given to a more standardized form both for invitations to present, and tendering thanks, for papers presented.

Our members will agree that a decided step forward has been taken this year in our technical meetings which represent, after all, the most important part of the service which we can render to our members.

Junior Section

The Junior Section of the Branch have just completed their second complete year of activities and have held fourteen meetings in all. On each evening two papers were usually given, a number of them being in French. The majority of the papers were given by the Junior members and we feel that this is a very excellent part of the Branch work, as it is serving to develop public speaking in the Branch and overcoming the engineer's usual hesitation at standing on his feet in public.

Membership

Fortunately, notwithstanding adverse conditions, our membership was maintained, so that at present it includes a total of 1,127 as against 1,125 last year. This includes 130 who are on the non-active list, but there were approximately the same number last year.

During the past year we lost a large number of members through death, several of them being well known in public life as well as being active in The Institute. You will note that two of them were Charter Members. It is with deep regret that we record their names as follows:—

Members:

Major General Charles Johnstone Armstrong, C.B., C.M.G., V.D.
Archibald Abercromby Bowman.
Pierre Michel Helbronner.
Paul Albert Nicholas Seurot.
Sven Svenningson.
William Henry Wardwell.

Associate Members:

Harry Brooke Aylmer (1887).
Harry B. Pope.
S. S. Shector.
J. Emile Vanier (1887).

Judging by the interest that has been shown at the meetings and in the affairs of the Branch in general, we feel sure that 1935 will be a successful year.

Respectfully submitted,

A. Frigon, M.E.I.C., *Chairman.*
C. K. McLeod, A.M.E.I.C., *Secretary-Treasurer.*

Niagara Peninsula Branch

The President and Council:—

The Executive committee of the Niagara Peninsula Branch presents herein the report for the year 1934.

The Executive held four regular meetings and one electoral meeting with an average attendance of ten.

The meetings are listed as follows:—

1934

Jan. 19.—Dinner meeting, Fox Head Inn, Niagara Falls; speaker, A. W. McQueen, A.M.E.I.C., of H. G. Acres Co.; topic, **Engineering Investigation in India.**
Feb. 15.—Joint dinner meeting with A.I.E.E. at Niagara Falls, N.Y.; speakers, W. H. Rodgers of Westinghouse Co. and R. H. Rodgers of General Electric Co.; topic, **Recent Developments in Electrical Research.**
April 11.—Dinner meeting, Lincoln Hotel, St. Catharines; speaker, Mr. F. Nagler, Canadian Allis Chalmers Co., Toronto; topic, **What Mechanical Tests are Worth While.**
May 17.—Annual meeting, Fox Head Inn, Niagara Falls; Mr. F. P. Shearwood, M.E.I.C., President of the E.I.C., was present and gave a short talk on Institute affairs; Col. Morrow, Fort Niagara, Youngstown, N.Y., gave a talk on his experiences in Siberia.
Sept. 28.—Inspection trip at Old Fort Niagara, Youngstown, N.Y., followed by a dinner at the Old Fort Inn and talk by Mr. Claude Hultzen describing the restoration work.
Oct. 19.—Inspection trip Yale & Towne Manufacturing Co., St. Catharines; Dinner at Lincoln Hotel followed by talk by Mr. Ellis Jones, manager of Yale & Towne Co., on the **History of Locks.**

Ottawa Branch

The President and Council:—

On behalf of the Managing committee of the Ottawa Branch we beg to submit the following report for the calendar year 1934.

During the year the Managing committee held eight meetings for the transaction of general business. In addition the Branch held eighteen meetings. These meetings were well attended and excellent addresses were enjoyed at the Branch meetings.

It is with deep regret that we report the loss through death of two members—S. Bray, M.E.I.C., and W. C. Treanor, A.M.E.I.C.

As in previous years the Branch donated two sets of draughting instruments to the Ottawa Technical School for presentation as prizes for proficiency in draughting, and a copy of "Standard Handbook for Electrical Engineers" to the Hull Technical School for presentation as a prize to a student in the Department of Electricity.

Proceedings and Publicity

During the year twelve luncheon meetings and five evening meetings were held, and a visit made to the studio and transmitting station of the Canadian Radio Broadcasting Commission at Ottawa. The dates of the meetings and speakers are as follows:—

1934

Jan. 11.—Luncheon address, Major D. L. McKeand, **Eastern Arctic Patrol 1933.** Attendance, 88.

Jan. 11.—Annual Meeting of Branch, Standish Hall. Attendance, 80.

Jan. 25.—Luncheon address, Professor Theo. J. Lafreniere, M.E.I.C., **Public Health in Quebec.** Attendance, 60.

Feb. 8.—Annual Meeting of Institute, Montreal.

Feb. 22.—Luncheon address, Dr. D. F. Kidd, **The Great Bear Lake District.** Attendance, 93.

Mar. 8.—Luncheon address, Col. E. J. C. Schmidlin, M.E.I.C., **North-west State Railways of India.** Attendance, 85.

Mar. 22.—Luncheon address, W. P. Dobson, M.E.I.C., **The Hydro-Electric Power Commission Laboratories.** Attendance, 75.

April 4.—Evening meeting, Jackson Building, discussion on proposed amendments to By-laws. Attendance, 20.

April 20.—Luncheon address, C. W. Wright, **Canada at the World's Fair.** Attendance, 45.

May 3.—Luncheon address, J. Clark Reilly, **What the Construction Industry Means to Canada.** Attendance, 55.

May 26.—Visit, Studios and Transmitting Station, Ottawa, of the Canadian Radio Broadcasting Commission. Attendance, 60.

June 15.—Evening meeting, National Research Laboratories, Mr. Messter and Mr. Heinz Grüner, demonstration lecture on **Photogrammetic Apparatus.** Attendance, 50.

Oct. 4.—Luncheon address, J. Grove Smith, **Re-housing a Nation.** Attendance, 71.

Oct. 18.—Luncheon address, Dr. J. J. Green, **Streamlining.** Attendance, 65.

Oct. 25.—Evening meeting, Vickers Armstrong films. Attendance, 120.

Nov. 8.—Luncheon address, Martin J. Berlyn, A.M.E.I.C., **Transmission Gearing.** Attendance, 62.

Nov. 22.—Evening meeting, H. E. McKeen, **Placing Concrete by Pipe Line and Vibration.** Attendance, 40.

Dec. 6.—Luncheon address, F. E. Lathe, **Refractories in Industry.** Attendance, 70.

Dec. 20.—Luncheon address, T. A. McElhanney, A.M.E.I.C., **Engineering and Economic Aspects of Forest Products Industries.** Attendance, 61.

Membership

Owing to deaths, resignations, and members removed from the roll, the membership shows a decrease of 21 during the year.

The following table shows in detail the comparative figures for the years 1933 and 1934:—

	1933	*1934*
Honorary Members	1	1
Members	80	76
Associate Members	173	166
Affiliates of Institute	3	3
Juniors	16	15
Students	33	34
Branch Affiliates	36	31
Resident Members	342	326
District Members	63	59
	405	385

Finances

The attached financial statements show that the Branch had a surplus of $83.70 in revenue over expenditure at the end of the year. The year closed with a balance of $652.49 in the bank, $17.05 cash on hand, and $1,000 in Government Bonds; a total of $1,669.54. In addition the Branch has assets of $42.90 in rebates due from the Main Institute; and $21 in equipment, etc., making a total of $1733.44.

Committee on Unemployment

No new relief projects were started in the Ottawa district and therefore no new appointments were available on the supervisory staff. Two vacancies however were filled by engineers recommended by The Institute.

At the present time the Committee has no report of any members in urgent need of relief or employment though many members are out of employment.

The Committee has kept in touch with the administration of the Relief Projects of the Department of National Defence and has to thank the departmental officers for their co-operation.

Aeronautical Section

This section of the Ottawa Branch has a membership of 95. Eight evening meetings were held, when technical papers dealing with aeronautical or related subjects were read and discussions held.

Peterborough Branch

The President and Council:—

On behalf of the Executive committee of the Peterborough Branch of The Engineering Institute of Canada, we have the honour to submit the following report covering the activities of the Branch during the year 1934:—

1934

Jan. 11.—**What Mechanical Tests are Worth While** by Mr. F. A. Nagler, M.A.S.M.E., chief engineer, Canadian Allis Chalmers Co., Ltd., Toronto.

Feb. 8.—**Industrial Applications of Photo Electric Relays** by Mr. A. G. Turnbull, Canadian General Electric Co. Ltd., Toronto.
Mar. 8.—**The Mining Industry of Northern Ontario** by Mr. G. Klein, Canadian General Electric Co. Ltd., New Liskeard, Ont.
April 12.—**The Contribution of the Aeroplane to Canadian Industrial Development** by Mr. W. B. Burchall, advertising publicity manager, Canadian Airways Ltd.
May 10.—Annual Meeting, Reports and Election of Officers.
June 2.—Visit to Plant of General Motors of Canada, Ltd., Oshawa, Ont.
Sept. 8.—Annual Outing, Rotary Camp, Clear Lake.
Oct. 11.—**Experiences of an Engineer in Soviet Russia** by Mr. T. G. Fechnay, The Pratt & Whitney Co. of Canada, Ltd.
Nov. 8.—Showing of Vickers Armstrong films at Capitol Theatre, Peterborough.
Nov. 20.—Annual Dinner, Empress Hotel, Peterborough. Speakers: Mr. F. P. Shearwood, M.E.I.C., President E.I.C., Mr. C. W. Woodside, University of Toronto.
Dec. 13.—**The Stresses in Wire Rope and in Fittings for Same** by Mr. C. D. Meals, The B. Greening Wire Co. Ltd., Hamilton, Ont.

The average attendance at the ordinary Branch meetings was 40.

The visit to the Oshawa Plant of the General Motors was enjoyed by approximately 80 of the members and their friends, and the showing of the Vickers-Armstrong films was witnessed by over 300 people.

Number of Executive meetings held during the year was six.

Special sub-committees were as follows:—

Meetings and Papers Committee	B. Ottewell, A.M.E.I.C.
	A. B. Gates, A.M.E.I.C.
	E. J. Davies, Jr.E.I.C.

Quebec Branch

The President and Council:—

On behalf of the Executive committee of the Quebec Branch, we have the honour to submit the following report covering the activities of the Branch during the year 1934.

MEMBERSHIP

January 1st, 1935	*Resident*	*Non-Resident*	*Total*
Honorary Member (Branch)	1	..	1
Members	14	..	14
Associate Members	63	9	72
Juniors	2	..	2
Students	9	2	11
Affiliates	1	..	1
	90	11	101

It is with the deepest regret that we report the death of E. A. Hoare, M.E.I.C., who died in Quebec on November 23rd, 1934; Mr. Hoare was one of the founders of our Branch and had been a member of The Institute since 1887, the year it was incorporated as The Canadian Society of Civil Engineers.

MEETINGS

During the year 1934, the Branch Executive committee held six regular meetings with an average attendance of seven.

In addition the Branch held ten general meetings as follows:—

1934

Jan. 15.—Luncheon meeting at Chateau Frontenac. Speaker: Lt.-Col. J. B. Dunbar, A.M.E.I.C., District Engineer Officer, Military District No. 5, Quebec. Subject: **Road Making by Hand Methods, Using an Asphaltic Emulsion.**
Feb. 12.—Evening meeting at Palais Montcalm. Speakers and subjects: Marc Boyer, A.M.E.I.C., Bureau of Mines, Quebec: **Valuation of Non-Metallic Mineral Deposits;** Maurice Royer, C.E. of Ricard & Royer, Quebec: **Météorologie Moderne;** E. D. Gray-Donald, A.M.E.I.C., Quebec Power Company, Quebec: **Operation of a Hydro-Electric Power System.**
Feb. 23.—Evening meeting at Palais Montcalm. By courtesy of the Otis-Fensom Elevator Company, two films were shown to our members: one on **The Construction of the Empire State Building,** the other on **The Construction of the George Washington Bridge.**
Mar. 12.—Evening meeting at Palais Montcalm. Speaker: H. P. Burrell, Vice-President and General Manager of Franki Compressed Pile Co. of Canada Ltd., Montreal. Subject: **The Evolution of the Cast-in-Place Concrete Pile.**
April 6.—Luncheon meeting at Chateau Frontenac. F. P. Shearwood, M.E.I.C., President of The Engineering Institute of Canada, visiting our Branch addressed the members on Institute matters.
April 17.—Evening meeting at Palais Montcalm. Speaker: J. Antonio Lalonde, A.M.E.I.C., chief engineer, A. Janin & Company Ltd., Montreal. Subject: **La sous-structure et les approches du pont du lac St-Louis.**
May 14.—Annual Meeting and election of officers.
Aug. 15.—First visit to the Isle d'Orleans Bridge.
Oct. 20.—Second visit to the Isle d'Orleans Bridge.
Oct. 22.—Evening meeting at Palais Montcalm to see the display of three films loaned to The Institute by the Vickers-Armstrong Limited, London, England.

The average attendance at the above meetings was 42.

Saguenay Branch

The President and Council:—

On behalf of the Executive committee of the Saguenay Branch of The Engineering Institute of Canada, we beg to submit the following report for the calendar year 1934.

MEMBERSHIP

Our membership this year shows a gain of two. This does not include four applications which are now in, two of which are for admission as Associates and two for transfer from the grade of Student to that of Associate.

The following table gives a comparison of our membership as of December 31st for the past five years.

	1930	*1931*	*1932*	*1933*	*1934*
Members	6	5	4	3	3
Associate Members	25	19	16	18	19
Junior Members	7	4	4	3	3
Student Members	11	7	5	5	6
Affiliates	..	..	1	..	..
	49	35	30	29	31

Branch Meetings

During the year Branch meetings were held as follows:—

1934

Jan. 31.—The meeting was addressed by Mr. N. F. Russell on **Applications of Aluminum with special reference to the Mining and Transportation Fields.** On this date we experienced one of the worst storms of the winter, which closed all the roads, so that only twenty-five members and guests were present—all from Arvida.

May 9.—P. L. Pratley, M.E.I.C., addressed a meeting, his subject being **Recent Bridge Construction in the Province of Quebec.** Fifty members and guests were present.

Aug. 2.—F. L. Lawton, A.M.E.I.C., read a paper before an attendance of thirty-five on the subject of **Heat Economy and Comfort in the Home as Influenced by Heating Methods and Building Construction.** This paper appeared in the November issue of the E.I.C. Journal.

Aug. 30.—The Annual Meeting preceded by a dinner was held at The Staff Club at Arvida, seventeen members being present. The results of the annual election of officers were announced and the latter part of this meeting was spent in listening to a paper given by M. G. Saunders, A.M.E.I.C., on the subject of **The Production and Explosibility of Gases Generated in Electric Boilers.**

Oct. 22.—A. Lariviere, M.E.I.C., presented a paper before a meeting of forty-five members and guests on **The Fundamental Principles of Radio Electricity.**

Meetings

Seven meetings of the Branch Executive committee were held during the year, also nine Branch meetings as follows:—

1934

Jan. 25.—Joint dinner of The Institute and the Association of Professional Engineers of New Brunswick. Following the dinner Professor B. S. Kierstead of the University of New Brunswick addressed the Branch on **The Task of Economics.**

Mar. 13.—Mr. W. B. Burchall of the Canadian Airways gave an illustrated lecture on **The Contribution of the Aeroplane to Canadian Industrial Development.**

Mar. 27.—C. S. MacLean, A.M.E.I.C., spoke on **The Operation of the Lobnitz Rock Breaking Apparatus.**

April 12.—This meeting was called to give the members a chance to discuss the question of Re-organization.

May 8.—Annual dinner and meeting held at the Riverside Golf and Country Club. The present officers of the Branch were elected at this meeting.

Sept. 25.—**The Automotive Diesel Engine** by J. L. Busfield, M.E.I.C.

Oct. 18.—The Vickers-Armstrong films.

Nov. 20.—**Broadcasting Equipment and Methods** by J. G. Bishop, chief engineer of CHSJ. After the address the Branch visited the studio and broadcasting room of the above station.

Dec. 4.—Dinner tendered F. P. Shearwood, M.E.I.C., President of The Institute.

St. Maurice Valley Branch

The President and Council:—

The St. Maurice Valley Branch submits its annual report for the year 1934.

The membership at the end of this year was as follows:—

Members	5
Associate Members	24
Juniors	8
Students	10
	47

During the present year, the activities of the Branch have not been very considerable, owing to the fact that the city of Trois-Rivières has celebrated the tercentenary of its foundation. Most of the engineers were on different committees in connection with this organization, and have devoted their time to contribute to the success of this celebration. However, the Branch was able to hold three meetings during the year.

Nevertheless, all the questions submitted by the Council of The Institute and by different branches have been studied, discussed and transacted.

As during the past, our Branch has followed with interest The Institute's deliberations and has devoted its full energy to all the matters tending to the protection and promotion of the interests of The Institute and its members.

The St. Maurice Valley Branch deeply regrets the death of two of its members: Messrs. J. A. Bernier, Manager of the City of Grand' Mère, and Frank Panneton, engineer for the City of Trois-Rivières, who were always devoted to The Engineering Institute and also to their engineering profession.

The financial standing of the Branch is very satisfactory, the cash on hand on December 31st being $89.61.

At its last general meeting held on December 22nd, 1934, the officers of the Branch for the year 1935 were elected.

Financial Statement

Bruno Grandmont, A.M.E.I.C., *Chairman.*
J. Albert Hamel, A.M.E.I.C., *Secretary-Treasurer.*

Saskatchewan Branch

The President and Council:—

On behalf of the Executive we submit the following report of the activities of the Saskatchewan Branch for the year 1934.

Membership

The membership of the Branch is as follows, being a decrease of eight from last year:—

	Resident	Non-Resident	Total
Members	4	7	11
Associate Members	27	23	50
Juniors	2	4	6
Students	6	10	16
Branch Affiliates	4	..	4
	43	44	87

Committees

The Executive committee was elected on March 16th, 1934, and held six meetings during the year.

The standing committees are:—

Papers and Library........S. R. Muirhead, A.M.E.I.C. (Convenor)
Nominating..............D. A. R. McCannel, M.E.I.C. (Convenor)
Unemployment...........H. R. MacKenzie, A.M.E.I.C. (Convenor)
Membership..............P. C. Perry, A.M.E.I.C. (Convenor)

Meetings

There were six regular meetings of the Branch, each being preceded by a dinner at which the average attendance was twenty-eight, a decrease of seven from last year. The general interest in the meetings has been fair. In addition a general meeting was held during the month of February with a programme suitable for "Ladies Night." The attendance at this meeting was good.

The programme for the year was as follows:—

1934

Jan. 19.—Address by F. C. Curtis, B.C.L., on **Disarmament.**

Mar. 16.—Seventeenth Annual Meeting. Address by S. E. Slipper on **Gas and Oil Possibilities of Saskatchewan.**

July 25.—Special meeting. Address by F. P. Shearwood, M.E.I.C., on **The Present Status of The Engineering Institute of Canada,** following which Mr. Shearwood gave a lantern slide lecture on **Bridge Construction.**

Oct. 19.—Moving pictures showing the construction of **The Big Bend Highway** in British Columbia.

Nov. 16.—Address by A. W. Ellson Fawkes, consulting engineer, on **The City Manager Form of Government.**

Dec. 21.—Address by M. J. Coldwell, Provincial Leader C.C.F., on **The World Outlook for 1935.**

Saskatoon Section

Immediately following the annual meeting a Saskatoon section was formed under the direction of a committee composed of:—

R. A. Spencer, A.M.E.I.C. (Convenor)
A. R. Greig, M.E.I.C.
C. C. Hay, A.M.E.I.C.
A. M. MacGillivray, A.M.E.I.C.

Prior to the midsummer season three meetings were held, the respective programmes being:—

The Douglas Theory by B. P. Scull and W. L. Foss.

Recent Advances in Science by Dr. T. Thorvaldson, Dr. T. A. Alty, Professor W. G. Worcester, C. B. Jackson, E. J. Durnin, Jr.E.I.C., and A. B. Olsen—(Half-hour talks).

The Wheat Situation by Mr. Wesson of the Saskatchewan Wheat Pool.

Two meetings were also held during the latter part of 1934:—

Oct. 22.—Moving pictures showing construction of **The Big Bend Highway in British Columbia.**

Nov. 16.—Vickers-Armstrong films depicting **Steel Making, Aviation and Ship Building.**

In addition to sponsoring the above meetings, the Committee has spent considerable time on a study of Institute affairs.

Finances

The present financial standing of the Branch is as follows:—

Receipts		
Bank balance, December 31st, 1933	$100.12

Sault Ste. Marie Branch

The President and Council:—

Ten dinner meetings were held during 1934, eight at the Windsor hotel and two at the Sault Country Club.

We were honoured with two visits of officers from Headquarters. The General Secretary, R. J. Durley, M.E.I.C., addressed a special meeting at the Sault Country Club on July 27th. On August 3rd President F. P. Shearwood, M.E.I.C., also visited us and gave an illustrated talk on "Bridge Erection" followed by a talk on Institute affairs.

The average attendance at dinners was 26 with an average meeting attendance of about 32.

The meetings and speakers were as follows:—

1934

Jan. 26.—**Theory and Application of Industrial Methods for the Measurement of Flow in Pipes** by O. Brauns, A.M.E.I.C.

Feb. 23.—**The History of Great Lakes Shipping from 1812** by Captain James McCannel, Master of the *Assiniboia.*

Mar. 28.—**The History of Paper Making** by F. A. Masse, Jr.E.I.C.

April 27.—**The Tidal Phenomenon** by H. F. Bennett, A.M.E.I.C.

May 25.—**The Value of Engineering and Superintending of Oxy-Acetylene Welding and Cutting** by D. S. Lloyd, A.M.E.I.C.

July 27.—Visit of the General Secretary, R. J. Durley, M.E.I.C.

Aug. 3.—Visit of the President, F. P. Shearwood, M.E.I.C.

Sept. 28.—Discussion of the President's address.

Dec. 5 (Postponed from Nov. 30).—**Reminiscences of Northern Ontario** by James S. Dobie, O.L.S., D.L.S., of Thessalon, Ont.

Dec. 19.—Films from Vickers-Armstrong. Annual Meeting.

We regret to report the loss of two of our members by death during the past year.

The membership at the close of the year stands as follows:—

	Resident	Non-Resident	Total
Regular:			
Members	9	11	20
Associate Members	12	26	38
Juniors	5	9	14
Students	..	17	17
Branch Affiliates	7	..	7
	33	63	96
Non-Active:			
Associate Members	1	3	4
Students	..	2	2
	1	5	6

This represents an increase in membership of one regular and one non-active during the past year.

Toronto Branch

The President and Council:—

On behalf of the Executive committee, we submit the report of the Toronto Branch for the calendar year 1934.

The Annual Meeting of the Branch was held on March 29th, 1934, and the officers for 1934-35 were elected. During the autumn J. M. Breen, A.M.E.I.C., was transferred to Montreal, and Wills Maclachlan, M.E.I.C., was appointed to the vacancy thus created on the Executive, to complete the unexpired portion of Mr. Breen's term of office.

Following the Annual Meeting, the undermentioned were named chairmen of the Standing Committees:—

Papers........................R. E. Smythe, A.M.E.I.C.
Finance........................W. E. Bonn, A.M.E.I.C.
Publicity........................A. U. Sanderson, A.M.E.I.C.
Meetings and Reception........W. G. Chace, M.E.I.C.
W. W. Gunn, A.M.E.I.C., *Vice-Chairman*
Membership........................J. M. Breen, A.M.E.I.C.
Student Relations..............O. Holden, A.M.E.I.C.
Branch Editor..................J. M. Oxley, M.E.I.C.

The Executive committee of the Branch held seventeen meetings for the transaction of Branch business.

Twelve regular meetings of the Branch were held, as follows:—

1934

Jan. 18.—**Planning Toward Economic Recovery** by Professor Gilbert E. Jackson, Professor of Political Economy, University of Toronto. This meeting was arranged with the co-operation of the Canadian Political Science Association. Attendance, 60.

Feb. 1.—**Valuation and Depreciation** by W. J. Moulton-Redwood. Attendance, 40.

Mar. 1.—**The Status of the Engineer in Industry**, a paper prepared by J. B. Carswell, M.E.I.C., H. B. Stuart, A.M.E.I.C., and E. P. Muntz, M.E.I.C., of the Hamilton Branch, and presented by Mr. Carswell before a joint meeting of the Hamilton and Toronto Branches. Attendance, 100.

Mar. 19.—**Discussion of the Proposed Amendments to the By-laws of The Institute.** Attendance, 20.

Mar. 29.—Annual Meeting. Attendance, 25.

April 13.—**The Contribution of the Aeroplane to Canadian Industrial Development** by Mr. W. B. Burchall, advertising publicity manager of Canadian Airways, Limited. Attendance, 50.

April 19 and April 20.—**Can the Canadian Construction Industry be Stabilized?** A two-night joint meeting of the Toronto Branch of the Canadian Political Science Association, the Ontario Association of Architects; Hamilton Branch E.I.C.; Ontario Section A.S.M.E.; Toronto Branch A.I.E.E.; Toronto Branch Am. Soc. H. and V. Eng.; Ontario Chapter A.S.M.; Toronto Branch Ill. Eng. Soc.; Toronto Branch I.R.E.; Toronto Branch S.A.E.; Toronto Branch E.I.C. Attendance, 150 at each meeting.

Oct. 12.—**The Boulder Dam** by Dr. W. M. White, D.Sc., manager and chief engineer of the Hydraulic Department of Allis-Chalmers Manufacturing Company. A joint dinner meeting of the Toronto Branch E.I.C.; Ontario Section A.S.M.E.; Toronto Section A.I.E.E.; Canadian Section S.A.E.; Ontario Chapter A.S.M. Attendance, 400.

Nov. 1.—Vickers-Armstrong films. Attendance, 150.

Nov. 22.—**The Relations between the Structural Engineer, Engineers Concerned with Mechanical and Electrical Installations, the Architect, the Fabricator, and the Contractor.** A general discussion by the Members. Attendance, 60.

Dec. 13.—**Welding** by Mr. David Boyd, Dominion Bridge Company, Limited. The American Society of Metals and the Ontario Section of the A.S.M.E. also joined in this meeting. Attendance, 150.

It will be noted that quite a number of the meetings have been held jointly with other engineering societies, and these have proved most enjoyable. Joint meetings with the Hamilton Branch have also been held. Dinner is frequently arranged for previous to the meetings, and while the numbers attending have been encouraging, it is regretted that more members do not avail themselves of these pleasant gatherings.

In spite of reduced receipts, the Branch has been able to keep its expenditures well within its income.

The Toronto Branch E.I.C. Loan Fund, established two years ago for the assistance of members, is in a satisfactory condition. Requests for assistance from this fund for the past year have been very few, and from present indications it would seem that it would not be necessary to ask for further contributions. The employment situation has improved considerably, so far as the members of the Branch are concerned, during the present year and it is confidently hoped that this improvement will continue during the coming year.

The membership of the Branch as at December 31st, 1934, is made up as follows:—

	Resident	*Non-Resident*	*Total*
Members	96	4	100
Associate Members	196	15	211
Juniors	46	1	47
Students	74	16	90
Affiliates	4	1	5
Branch Affiliates	1	..	1
Total—1934	417	37	454
Total—1933	461	40	501
	−44	−3	−47

It is with regret that we record the death of the following members of the Branch during the past year: William Gore, M.E.I.C., James Milne, M.E.I.C., L. W. Wynne-Roberts, M.E.I.C., and C. R. Scott, A.M.E.I.C. Our heartfelt sympathy is extended to their families in their loss.

Vancouver Branch

The President and Council:—

We beg to submit the following report of the activities of the Vancouver Branch during 1934.

MEETINGS

Six general meetings of the Branch were held, as follows:—

1934

Jan. 8.—Joint Meeting with A.I.E.E., Vancouver Branch. A. G. Dickenson, electrical engineer of Consolidated Mining and Smelting Co., on **Utilization of Electrical Energy at the Trail Smelter and Refinery.**

Feb. 12.—Brig.-Gen. Sir Charles Delme-Radcliffe on **The Nistri Three Dimensional Method of Photogrammetrical Surveying.**

Mar. 12.—H. N. MacPherson, A.M.E.I.C., on **The Preservation of Timber.** Illustrated with motion pictures.

April 12.—R. Rolleston West on **The Scientific Side of Flight.**

May 10.—Dominion Government 5-reel motion picture, **From the Ground Up**, dealing with the manufacture of automobiles.

Nov. 19.—Annual Meeting.

The average attendance was 49.

Seven Executive meetings have also been held since the last Annual Meeting.

INSTITUTE DEVELOPMENT

The past year has witnessed the decision of the corporate membership of The Institute to reject the By-law Amendments sponsored by the 1932-33 Committee on Development, which proposed a radical change in Institute grades and qualifications, aimed to broaden the basis of its membership by lowering its standards of admission. Our interpretation of this occurrence is that Institute members as a whole have declined to forsake their conception of The Institute as being a body of engineers, strictly professional in character. Although the 1933 Executive committee withdrew its objections in the interests of harmony, after gaining some modifications of the Committee on Development's original proposals, the 1934 Executive committee cannot but admit considerable satisfaction in the final outcome.

In July, 1934, during the Western Professional Meeting at Vancouver, the President, F. P. Shearwood, M.E.I.C., addressed the Executive committee on matters of special interest to Western Branches, most of which were definitely concerned with the problem of Institute Development and Institute relations with the provincial professional associations. The sincerity and earnestness of purpose that marked the President's effort, together with his frank invitation to submit our views on the matters in question, has opened a new channel for exchange of opinions that is very opportune under the circumstances of the moment.

Acting in the spirit of this invitation, a carefully prepared statement of views was approved by the Executive committee at a meeting in October, copies of which were forwarded to the President and all members of Council prior to the meeting of Council held in Toronto on October 19th.

JOINT CONVENTION OF THE E.I.C. AND A.S.C.E.

The principal event of the year was the very successful Joint Engineering Convention held by The Institute and the American Society of Civil Engineers at Hotel Vancouver, Wednesday, July 11th to Saturday, July 14th. Arrangements were in the hands of a local

Joint Committee with E. A. Cleveland, M.E.I.C., as Chairman, and J. C. Oliver as Secretary-Treasurer. The technical sessions held during the first two days were of exceptional interest, and the entertainment features which followed were no less successful. The convention provided a unique opportunity for local engineers to come in contact with distinguished men in their own special branch.

ASSOCIATION OF PROFESSIONAL ENGINEERS

The President and Registrar were again honorary members of the Executive.

WALTER MOBERLY MEMORIAL PRIZE

The 1934 winner is D. Lawrence McMullan of Salmon Arm, B.C.

Victoria Branch

The President and Council:—

The undersigned have the honour to submit the following report on the activities of the Victoria Branch of The Engineering Institute of Canada during the calendar year 1934.

MEETINGS

The Branch met on seven occasions, the average attendance, including visitors, being 32. Only one technical paper was presented to the Branch, a most interesting paper by Norman Yarrow, A.M.E.I.C., on the launching of ships, which was followed by a showing of the six reels of Vickers-Armstrong films, obtained through arrangements made by Headquarters.

Earlier in the year the Branch, on its own initiative, obtained a film entitled **From the Ground Up** dealing with the Automobile Industry in Canada. A small hall was hired for this meeting and printed tickets issued to persons interested or engaged in the industry locally, and some 70 persons attended. In organizing this meeting, the Executive committee had in mind the desirability of occasionally arranging meetings which are of general technical interest. The cost of this meeting was rather heavy.

Other meetings included three luncheon meetings, one visit to H.M.S. *Norfolk*, and one social meeting, namely, the Annual Bridge Party which has proved to be a most popular and inexpensive function, largely due to the courtesy of Mr. and Mrs. F. C. Green, who again kindly placed their home at the disposal of the Branch.

There were five meetings of the Executive committee with an average attendance of 90 per cent. It is the custom in this Branch to hold the Executive committee meetings in the evening at the homes of various members, an arrangement which has been very successful in securing a good attendance, and it ensures that every item of business is thoroughly discussed, which would not always be the case if meetings were held down town in less comfortable surroundings.

MEMBERSHIP

Our total membership shows a net loss of three. We gained one new member and one new associate member from the efforts of the membership committee. In addition, one member, one associate member, one junior, and one student, were transferred to Victoria.

One member and one associate member left Victoria; one associate member and one affiliate resigned. Four students were removed from the list for non-payment of dues, and we lost one member through the untimely death of K. M. Chadwick, M.E.I.C., past Secretary, Vice-Chairman, and Councillor of the Branch.

Membership now stands as follows:—

Members	20
Associate Members	33
Junior Members	4
Student Members	6
Branch Affiliate	1
	64

The average total membership, since 1918, is 68: maximum is 89; minimum, 55.

WESTERN PROFESSIONAL MEETING

This meeting, held in July, 1934, at Vancouver, was well attended by members of the Victoria Branch. Two papers by members of the Victoria Branch were presented at this meeting and subsequently published in The Journal, these being **Highways and Highway Transportation in British Columbia** by Patrick Philip, M.E.I.C., and **The Columbia River Basin** by J. C. MacDonald, M.E.I.C.

VISIT OF PRESIDENT AND SECRETARY

The Victoria Branch was honoured by a visit from Mr. F. P. Shearwood, M.E.I.C., and Mr. R. J. Durley, M.E.I.C., who remained two days in the city. At a well attended luncheon meeting, Mr. Shearwood addressed the members outlining his views on matters concerning the future of The Institute. Through the courtesy of the Vancouver Branch, a copy of Mr. Shearwood's address was mimeographed and sent to all members of the Branch.

Mr. Durley also addressed the members and explained several matters which were brought up by members.

FINANCES

Attached is a copy of the financial statement; expenditures exceeded receipts by $6.56; revenue was $120.15, being considerably less than the previous year. The Branch continued to function without any dues, other than the rebates from Headquarters—this has been made possible by giving up the room formerly rented in town and by sundry other economies. It is considered, however, that the total revenue of $120.15, which is less than $2.00 per member, is the minimum under which the Branch can continue to function.

UNEMPLOYMENT

During the year it was reported that six of the Branch members previously unemployed had obtained employment, either temporary or permanent, and at the time of writing it may be said that as far as is known, there are no cases of need as far as the Victoria Branch members are concerned.

The Annual General Meeting of the Branch was held on December 4th, 1934, when the officers were elected for the year 1935.

In concluding this report, we wish to express our thanks and appreciation of the unfailing courtesy and assistance we have received from the Secretary and Assistant Secretary at Headquarters in all matters.

Winnipeg Branch

The President and Council:—

The following annual report of the Winnipeg Branch for the year ending December 31st, 1934, is respectfully submitted.

The membership of the Branch is tabulated below.

	Resident	*Non-Resident*	*Total*
Members	28	4	32
Associate Members	61	16	77
Juniors	6	2	8
Students	27	3	30
Affiliates	2	..	2
Branch Affiliates	2	..	2
	126	25	151

There were held during the year 12 meetings of the Branch, particulars of which are given below.

1934

Jan. 4.—**Iron Debts and Rubber Dollars** by R. D. Colquette, Editor The Country Guide. Attendance, 46.

Feb. 1.—**Outline and Operation of Public Works Administration of N.R.A.** by Wm. Nelson Carey, Federal Engineer P.W.A., Minnesota. Attendance, 100.

Feb. 15.—Electrical film exhibited. Attendance, 46.

Mar. 1.—**Electric Soil Heating** by J. W. Tomlinson, Jr., engineer, Winnipeg Electric Company. Attendance, 46.

April 5.—**The Beauharnois Project** by A. E. Grassby; **Aerial Navigation** by Walter Murray, S.E.I.C.; **Public Works Projects** by Wallace Walkey. Attendance, 66.

Note.—These young speakers, members of the Junior Engineers Association, co-operated with the Branch for the delivery of the above mentioned addresses and succeeded in making a very interesting event of this meeting.

June 25.—Visit of General Secretary R. J. Durley, M.E.I.C., and the Junior Engineers Association. Attendance, 51.

July 27.—Visit of President F. P. Shearwood, M.E.I.C., who addressed the meeting on **Unusual Problems in Steel Bridge Erection.** Attendance, 57.

Oct. 4.—**Science in Naval Warfare** by Prof. J. F. T. Young, Department of Physics, University of Manitoba. Attendance, 53.

Oct. 18.—**The Geology of the Great Plains** by Dr. L. S. Russell, Geological Survey of Canada. Attendance, 79.

Oct. 25.—Special joint meeting with Association of Professional Engineers of the Province of Manitoba for the discussion of a report by J. W. Sanger, A.M.E.I.C., and E. V. Caton, M.E.I.C., on the subject of Joint Control of the Branch and Association. Attendance, 72.

Nov. 1.—**Germany of Today** by Prof. Fieldhouse, Professor of History, University of Manitoba. Attendance, 84.

Nov. 15.—**Science of Lighting** by J. Greenlaw, B.Sc.; **A New Process of Metallization** by W. Peterkin, B.Sc. Attendance, 66.

Dec. 6.—On this date, the usual meeting was replaced by a Smoker held jointly with the Association of Professional Engineers, the Canadian Institute of Mining and Metallurgy and the Association of Manitoba Land Surveyors. This function was largely attended and was voted a great success.

The average attendance at Branch meetings is 64, which, considering that two of the principal meetings took place in the summer months, when many of the members were absent from the city, is very gratifying.

The Branch was especially fortunate this year in having as visitors the General Secretary in June and the President in July.

Many matters of importance in Institute affairs were discussed with the President and Secretary by which a better understanding was arrived at. The events of a more social nature, the luncheon at which Mr. Durley met the members, and the dinner at Lower Fort Garry at which Mr. and Mrs. Shearwood were the guests of honour, were of a very enjoyable nature, and the members of the Branch feel that it would be a very fine thing if visits from the President and General Secretary could become annual events.

Very lively interest was taken in the proposal to try for a year to have joint executive control of the Branch and the Association of Professional Engineers of the Province of Manitoba, as a first step to complete co-ordination of the functions of these two bodies with the ultimate object of Federal amalgamation of The Institute and the several Provincial Associations or Corporations of Professional Engineers. A report on this subject was prepared by Messrs. J. W. Sanger and E. V. Caton, and the report was considered and discussed by the Executive committee of the Branch and the Council of the Association. So favourably were these bodies impressed with the possibilities of the suggestions outlined in the report, that it was decided to assemble a joint general meeting of the members of both bodies. This was done and the reaction of the meeting was such that questionnaires and ballots were circulated so that all who were not present at the meeting might record their views.

However, upon return of the ballots and questionnaires it was found that of the Association members, 74 were in favour of joint executive control, and 52 against. Of The Institute members, 58 were in favour of joint executive control, and only 1 against. It therefore seemed advisable to the Executive committee and Council to postpone any further efforts for the present but to make it a point to request the incoming Committee and Council to give this matter further special study with the hope that it may be again presented to the members of both bodies in an improved form.

VOLUME XVIII FEBRUARY 1935 No. 2

Engineering Progress in the State of Victoria and The Melbourne Centenary

A recent issue of the Journal of the Institution of Engineers, Australia, contains a series of articles giving the historical record of one hundred years of engineering enterprise in the State of Victoria. The story is a striking one, and some of its features are of particular interest to Canadians as involving problems of a kind familiar to the Canadian west, particularly as regards irrigation and rural water supply in areas of low rainfall, and the utilization of large deposits of lignite. The natural resources and the transportation facilities of the State appear to have been developed in most cases under public control or ownership rather than as a result of private enterprise.

The eastern part of the State is mainly a plateau from 1,000 to 2,000 feet high with some peaks over 5,000 feet; the mountain slopes are forest-clad, and much of the timber is of large size.

The northwest portion of the State is more level, and sections of it have lower rainfall (from ten to twenty inches), particularly on the northern plains extending to the Murray river, which flows to the northwest, divides Victoria from New South Wales and is the principal source of water supply for the arid districts. As in the Canadian west, large areas of land where precipitation is small, only require a moderate additional supply of moisture to become extremely productive.

Irrigation projects in Victoria were contemplated as early as 1860, but it was not until 1886 that extensive development took place under the provisions of the State Irrigation Act, which was passed in that year. This act was somewhat revolutionary, because it vested in the Crown the right to use the water in any stream, lake or swamp, provided for the extinction of any riparian rights that might prevent the use of water for irrigation, authorized the construction of national works by the State, and enabled local authorities to carry out their water conservation schemes with money advanced from the public treasury.

Later, in 1904, another Water Act dealt more particularly with rural water supply and effected complete centralization of all water resources under a State Rivers and Water Supply Commission. Under this legislation the beds and banks of all streams became the property of the Crown, so that in the State of Victoria streams and other natural sources of water supply are now completely nationalized.

The first important irrigation project involving high-lift pumping on a large scale was at Mildura on the Murray river. A large part of the drainage area of that river lies in the State of New South Wales, so that both States are concerned in the utilization of its waters, accordingly the large irrigation storage at Hume on the Murray is a joint undertaking. The Hume dam is over a mile long, 106 feet high and stores 1,250,000 acre-feet of water.

As regards irrigation in general, the area commanded by the 5,200 miles of irrigation channels is nearly two million acres, to which a very large addition will be made when the contemplated Yarrawonga dam across the Murray is constructed.

The domestic water supply of rural areas is also regulated by the Commission, which has paid close attention to the needs of rural municipalities and individual farmers. For this purpose local divisions known as domestic and stock supply districts are organized, and these cover some fifteen million acres of the agricultural lands.

Over one million acres of farming land are supplied by sub-artesian bores, and in other districts water for domestic and stock purposes is supplied by over 8,000 miles of channels filled by pumping or gravitation.

Farmers are required to provide excavated earthen storages on their farms which must be of sufficient capacity to meet all their water requirements for twelve months, and the Commission channels are run once only each year to fill them.

The magnitude of the task of supplying rural Victoria with water (quite apart from irrigation requirements) will be appreciated when it is noted that by channels, bores and other methods, about one quarter of the whole area of the State is artificially supplied with potable water for domestic and stock purposes, and that in this way areas, otherwise non-productive, have been added to its farming lands.

The State government has been no less active in the field of power supply and fuel utilization. The State Electricity Commission, formed in 1918 after a study of the fuel and water power resources of the State, embarked on a policy of power development, of which perhaps the most interesting feature is the electric generating station and briquetting factory at Yallourn, some 90 miles east of Melbourne, where an immense deposit of brown-coal (lignite) 180 feet thick, with 35-foot overburden, is mined on an open cut system and electrical energy is developed on the site for transmission at 132,000 volts.

Electric power is used for the removal of the overburden and the excavation and handling of the fuel, the amount produced being approximately 10,000 tons per day. The fuel as mined contains 65 per cent of moisture, and has a calorific value of 3,000 B.t.u. per pound. Some 1,200 tons per day are briquetted for transport, the briquetted fuel having a calorific value of 8,750 B.t.u., the remainder being used in the generating station and briquetting plant.

In addition to the brown-coal deposits, the State produces some half a million tons per annum of bituminous coal which is principally shipped to Melbourne.

In the early days, however, gold mining was the outstanding feature of the State's mineral industry. In 1851 remarkable discoveries of alluvial gold deposits were made at Ballarat and Bendigo. There was a phenomenal inrush of gold-seekers, and in 1852 there were 65,000 people in the mining camps of the district.

The alluvial workings later gave place to lode mining and in 1898 sluicing and dredging methods began to be applied to the alluvial deposits, much of the equipment being manufactured within the State. Within the past five years there has been a marked revival of the gold industry with an increased application of modern methods.

The city of Melbourne had its beginning in 1835 in a small settlement on the shores of Port Phillip, the large bay which gives access from the sea to the mouth of the Yarra river. The city had a population of 77,000 in 1851, the year when the State of Victoria was separated from New South Wales.

The sensational development of the gold fields during the next few years led to rapid growth which has since continued almost uninterruptedly, and Melbourne is now a city of over one million inhabitants.

Its site, like that of many Australian cities and towns, was originally determined by the existence of an adequate water supply, so that the city itself lies some distance from the mouth of the river. Round the shores of Hobson's Bay, the northern portion of Port Phillip, the suburbs extend for more than ten miles, while at the mouth of the river are the piers and wharves of Williamstown and Port Melbourne.

The city has fine public buildings, wide, well-kept streets, and extensive public gardens and parks. Melbourne is one of the great ports of the world, and its harbour can now accommodate vessels drawing 37 feet of water, as compared with a depth of 12 feet 6 inches in 1876. Over three thousand vessels used the port in 1933.

The provision of an adequate water supply for Melbourne has been made easy by the availability of well-forested catchment areas within a reasonable distance and these have been vested in the Metropolitan Board of Works. The four main reservoirs give a gravity supply and store twenty-three billion gallons.

The main drainage system of the city was planned in 1890, the sewage flowing to a main pumping station whence it is discharged to a sewage farm 16 miles distant. Rainfall and storm flow is sewered separately and discharged into the Yarra river and Port Phillip bay.

As regards transportation, the metropolitan area is provided with a modern system of electric tramways, although some portions of the original cable system established in 1885 are still in operation.

There are now more than 4,700 miles of railway (5-foot 3-inch gauge) in the 90,000 square miles of the State of Victoria.

Road development, particularly in the rural districts, is of more recent growth, but has been favoured by a temperate climate and the availability of excellent material. Highway construction in Victoria is based on contributions from municipalities and the State, aided in some cases by a Federal grant, the funds being administered under the Country Roads Board.

Over £14,000,000 have been expended on the system of main roads, developmental roads and State highways.

The development of mechanical and electrical engineering establishments in Victoria received its first impetus in connection with the early activity in gold mining. The construction of mining machinery was followed by that of agricultural implements, and in Victoria more recently the manufacture of pumping plants, locomotives, steel pipes and general machinery has become well established. Progress can also be noted in the electrical industry, particularly as regards transformers and switchgear, and there is at Geelong a large modern cement mill.

The centenary of the city of Melbourne is being celebrated this year and in connection with the celebrations, the Institution of Engineers, Australia, are holding an engineering conference which will take place from the 11th to the 16th of March, 1935. One of the principal features of this conference will be an historical review of the engineering developments of the State for the past one hundred years.

The Institution has invited The Engineering Institute of Canada, among other national engineering societies, to take part in the conference and to nominate an official representative.

In response to this invitation, Council expressed The Institute's thanks and has appointed as our delegate one of our members long resident in Australia. Accordingly The Engineering Institute of Canada will be represented at the conference by Mr. T. P. Strickland, M.Sc., (McGill), M.E.I.C., the chief engineer of the Melbourne and Metropolitan Tramways Board, who will convey to the conference and to the Institution the best wishes of The Institute, together with our congratulations on the remarkable engineering developments which have taken place in the State of Victoria and the city of Melbourne.

Meeting of Council

A meeting of Council was held at Headquarters on Friday, January 18th, 1935, at eight o'clock p.m., with President F. P. Shearwood, M.E.I.C., in the chair, and ten other members of Council present.

Dr. Lefebvre reported that good progress had been made in collecting data for the committee under his chairmanship which is preparing a communication on the Montreal and Ship Channel Water Levels for the Board which is investigating that problem. His committee would be able to report shortly.

The Annual Report of the Finance Committee and the auditors' statement were received and approved for presentation to the Annual Meeting.

Consideration was given to the question of those members in arrears for 1934, who would consequently be removed from The Institute list if the provisions of the by-laws were enforced. After discussion, on the recommendation of the Finance Committee, it was decided to continue these members on the roll of The Institute for the present, in order to give them an opportunity to liquidate their indebtedness or furnish explanations which will justify Council in waiving the provisions of the by-laws.

The Report of Council and the committee and branch reports for the year 1934 were received and approved for presentation to the Annual Meeting.

The membership of the Nominating Committee for the year 1935 was noted, and it was unanimously resolved that Major L. F. Grant, M.E.I.C., be appointed chairman of that committee.

The reports of the various medal and prize committees were received and approved for presentation to the Annual Meeting.

A resolution was presented from the Ottawa Branch, for transmittal to the Annual Meeting, suggesting that renewed steps should be taken to effect as early as possible closer unity with the Association of Professional Engineers.

The thanks of Council were voted to Mr. William Storrie, M.E.I.C., for his kindness in visiting and addressing The Institute members at Port Arthur, Winnipeg, Saskatoon, Edmonton and Regina.

Three resignations were accepted, a number of members were placed on the Non-Active List, one Life Membership was granted, and several special cases were dealt with.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:—

Elections		*Transfers*	
Member	1	Member to Assoc. Member	1
Associate Members	6	Junior to Assoc. Member	2
Juniors	2	Student to Assoc. Member	1
Students admitted	10	Student to Junior	1

The Council rose at eleven thirty p.m.

J. J. Traill, M.E.I.C.,
Chairman,
Annual Meeting Committee.

The Annual General and General Professional Meeting

FEBRUARY 7th, 8th and 9th, 1935

J. W. Falkner, A. M.E.I.C.,
Chairman,
Registration Committee.

C. S. L. Hertzberg, M.E.I.C.,
Chairman,
Papers and Meetings Committee.

A. U. Sanderson, A.M.E.I.C.,
Chairman,
Publicity General Committee.

Blank & Stoller Ltd.

C. J. Ingles, A.M.E.I.C.,
Chairman,
Finance Committee.

W. B. Dunbar, A.M.E.I.C.,
Secretary,
Annual Meeting Committee.

Committee of Toronto Branch in Charge of Arrangements

A. B. Crealock, A.M.E.I.C.,
Acting Chairman,
Annual Meeting Committee.

ROYAL YORK HOTEL, Toronto, Ont.

R. B. Young, M.E.I.C.,
Chairman,
Publicity re Attendance Committee.

W. E. Bonn, A.M.E.I.C.,
Chairman,
Entertainment and Hotel Committee.

W. S. Wilson, A.M.E.I.C.,
Secretary-Treasurer,
Toronto Branch.

G. H. Davis, M.E.I.C.,
Chairman,
Hotel Committee.

A. M. Reid, A.M.E.I.C., Chairman,
Entertainment and Excursions
Committee.

OBITUARIES

William Charles Adams, M.E.I.C.

It is with very deep regret that we record the death at Montreal on January 7th, 1935, of William Charles Adams, M.E.I.C.

Mr. Adams was born in Martin county, Minnesota, on September 10th, 1880, and graduated from the University of Minnesota in 1904 with the degree of E.E.

Following graduation Mr. Adams became connected with a number of electrical companies where he gained

W. C. Adams, M.E.I.C.

a wide and varied experience in the science of electrical communication, and in 1906 he joined the staff of the Western Electric Company, being engaged until 1908 on telephone equipment engineering. From that time until November 1909 he was inspector of apparatus manufactured in the company's New York shops, and was subsequently until 1913 engineering inspector of completed telephone control office equipment, being in charge of this inspection work for the last year and a half. From March 1913 until June 1914 he was in charge of all engineering inspection work at the company's Hawthorne plant at Chicago, and from that time until 1919 he was responsible for the detail inspection of material, tools and apparatus purchased by the company for its customers from other suppliers. In April 1919 Mr. Adams was transferred to the Montreal plant of the Northern Electric Company Limited as head of the Engineering Department and held that position until 1934 when he was appointed consulting engineer, reporting to the president.

Mr. Adams was a member of the Main Committee of the Canadian Engineering Standards Association, representing the Canadian Manufacturers' Association, and was the Northern Electric Company's representative in the American Society for Testing Materials. He was also a member of the Corporation of Professional Engineers of Quebec, the Telephone Pioneers of America, and the American Institute of Electrical Engineers.

Mr. Adams joined The Institute as a Member on May 17th, 1921, and took a keen and active interest in its affairs, having represented the Montreal Branch on Council in 1927, 1928 and 1929, and acted as Treasurer of The Institute in 1931 and 1932.

Charles James Fox, A.M.E.I.C.

It is with regret that we announce the death of Charles James Fox, A.M.E.I.C., at Vancouver, B.C., on November 20th, 1934.

Mr. Fox was born at Dublin, Ireland, on February 23rd, 1880, and received his early education in that city.

From April 1896 until February 1900 he was engaged on draughting surveying and general engineering work with the civil branch of the Royal Engineers, Dublin, and in the following year was designing and superintending the erection of steel frame buildings, etc., with Kennan and Sons, Dublin. In January 1901 he went to London and was on the staff of David Rowell and Company, and was later, until July 1905 with Dr. G. F. Deacon, consulting engineer, as his pupil and assistant on the design and construction of large water supply and hydraulic works. Coming to this country, Mr. Fox was for over four years with the Atlantic Quebec and Western Railway, in charge of design work in connection with steel bridge foundations, timber bridges, culverts, etc., and as resident engineer on three sections of construction and in complete charge of the carrying out of various bridge foundations, timber trestle bridges, and concrete retaining walls. Following this Mr. Fox was for six months resident engineer with the Alberta and Great Waterways Railway in Alberta, and was subsequently with the Canadian Northern Pacific Railway for three years, and with the Pacific Great Eastern Railway, in British Columbia, for two years. Mr. Fox served overseas for four years, enlisting at North Vancouver, and going to France as a sapper with the 1st Divisional Engineers. He received his commission in the field, and returned as a Captain, having been awarded the M.C. For the past fourteen years Mr. Fox has been in the engineering department of the Vancouver Harbour Commissioners being respectively chief draughtsman and later assistant engineer, which position he held at the time of his death.

Mr. Fox joined The Institute as an Associate Member on December 21st, 1915. He was active in Institute affairs and in those of the Vancouver Branch, on whose Executive Committee he served in 1931, 1932 and 1933.

Michael Joseph Murphy, A.M.E.I.C.

Deep regret is expressed in placing on record the death of Michael Joseph Murphy, A.M.E.I.C., which occurred at Moncton, N.B., on December 30th, 1934.

Mr. Murphy was born at Halifax, N.S., on June 4th, 1881, and received his early education in that city. He was

M. J. Murphy, A.M.E.I.C.

the son of the late Dr. Martin Murphy, M.E.I.C., a former President of The Institute.

He commenced his engineering career as a member of the survey staff on the Nova Scotia Eastern Railway in 1903-1903, and the following year was spent in the provincial engineer's office at Halifax. From April 1905 to March 1906 Mr. Murphy was engaged with the Halifax and South Western Railway, and from that time until April 1907 he was topographer and leveller on the Canadian Northern Railway in the provinces of Quebec and Ontario. Later in 1907 he was instrumentman on the construction of a spur line from the Algoma Central Railway to the Superior Copper Company's mine in Ontario, and in 1908 he was assistant engineer for a time on the Georgian Bay canal. From 1909 to 1914 Mr. Murphy was with a location party through the Rocky Mountains, and was then engaged on the construction of the Grand Trunk Pacific Railway through the mountain section in Alberta and British Columbia. In 1914-1915 he was assistant to the consulting engineer with the Canadian Government Railways, and in 1915 was appointed assistant engineer at Moncton, which position he held up to the time of his death.

Mr. Murphy became an Associate Member of The Institute on May 26th, 1920, and has always been keenly interested in Institute activities, having been vice-chairman of the Moncton Branch in 1929, and chairman in 1930.

John Herbert Larmonth, M.E.I.C.

Members of The Institute will learn with regret of the death at Montreal on January 3rd, 1935, of John Herbert Larmonth, M.E.I.C.

Mr. Larmonth was born at Montreal on May 19th, 1872, and was educated at the High School and McGill University, graduating from the latter institution in 1894.

After leaving college Mr. Larmonth was for a time in the locomotive shops and draughting office of the Grand Trunk Railway, Montreal, and was afterwards with the Laurie Engine Company. Moving to Ottawa, Mr. Larmonth worked in the office of C. H. Keefer, and subsequently was with the E. B. Eddy Company, Hull, as construction engineer. He was later for six months resident engineer under C. H. Keefer on hydraulic power house and dam construction at Peterborough, Ontario, and following this was for two years engaged on mechanical engineering work for the Quaker Oats Company at Peterborough, later becoming works manager of that company. Mr. Larmonth was also for five and a half years chief engineer and general manager for the Peterborough Hydraulic Power Company, the Peterborough Radial Railway Company and the Peterborough Light and Power Company, being for a short time general manager of the Electric Power Company. During the war Mr. Larmonth was connected with the Imperial Munitions Board as superintendent of the Steel Department, and in 1918 began practice as a consulting engineer in Montreal. Becoming interested in the railway supply business in 1922, he took over the representation of a number of companies, later becoming president of Engineering Materials Limited, the position which he held at the time of his death.

Mr. Larmonth joined The Institute (then the Canadian Society of Civil Engineers) as a Student on March 29th, 1894; on April 14th, 1904, he became an Associate Member, and on March 9th, 1912, a full Member.

PERSONALS

Gordon J. Jue, S.E.I.C., who graduated from McGill University with the degree of B.Eng. in 1932, is now located at Canton, China, where he is teaching at the Pui Ching Middle School.

Brigadier A. C. Caldwell, M.E.I.C., has retired from the position of Quartermaster-General, Department of National Defence, Ottawa, Ontario.

Brigadier Caldwell, who graduated from the Royal Military College in June, 1898, has had a long and distinguished career.

From December 1899 to February 1900 he was on the staff of the officer commanding Royal Engineers, western lines of communication in South Africa, and from April to November 1900 he was on the staff of the field intelligence department. In May 1901 he was appointed to the 14th Regiment as lieutenant, and in August, 1902, was transferred to the Canadian Engineers. In April 1903 he became Captain in the Corps of Guides, and in July 1903 he was appointed Intelligence Staff Officer, being promoted to the rank of Major in February 1904. In March 1905 he was transferred to the Royal Canadian Engineers as a Captain, and in July of the same year he was appointed assistant director of intelligence, becoming a Major with the Royal Canadian Engineers in October 1907. In May 1911 Major Caldwell was appointed chief engineer, 2nd Divisional area, and in May 1915 he was promoted to the rank of Lieutenant-Colonel, becoming Brevet Colonel in October 1917. In March 1918 he was appointed General Staff Officer Grade I, Militia Headquarters, and in June 1922 he became substantive Colonel, Royal Canadian Engineers, and was appointed Director of Engineer Services, Department of National Defence, Ottawa, Ont. On January 1st, 1930, he was promoted to the rank of Brigadier, and received the appointment from which he has recently retired.

Brigadier Caldwell became a Member of The Institute in 1927.

Brigadier W. H. P. Elkins, Affiliate E.I.C., formerly commandant of the Royal Military College, Kingston, Ontario, has been appointed officer commanding Military District No. 2, Toronto, Ontario. Brigadier Elkins graduated from the Royal Military College in 1905, and was subsequently a lieutenant in the Royal Canadian Horse Artillery. From May 1908 until February 1910 he served in India with the Royal Horse Artillery, and in November 1910 he was promoted to the rank of captain in the Royal Canadian Horse Artillery. From 1914 until 1919 he served overseas, commanding A. Battery R.C.H.A. in France from February until December 1916, and commanding the R.C.H.A. Brigade in France from the last mentioned date until the end of the war, when he returned to Canada in command of the Brigade, which he held until 1922. From 1920 until 1922 he was commandant of the Royal School of Artillery (Mobile), on post war reorganization from 1922 to 1925 he commanded the Royal Canadian Artillery, Halifax and was commandant of the Royal School of Artillery (Coast Defence and Anti-aircraft), from 1925 to 1926 he resumed the appointment which he had held in 1920-1922. In 1927 he was appointed staff officer, Artillery, Department of National Defence, Ottawa, and also chairman of the Standing Arms Committee, and in 1930 he received the appointment from which he now resigns.

Thomas W. Harvie, M.E.I.C., has retired from the position of general manager of the Montreal Harbour Commission, which he has held for some years.

Born in Scotland in 1877, Mr. Harvie was educated at the Glasgow and West of Scotland Technical College, later, from 1894-1899 serving his apprenticeship with Messrs. Kyle, Dennison and Frew, civil engineers, of Glasgow. In 1899-1900 he was assistant engineer with the same company, and in 1900 he joined the staff of the Caledonian Railway Company as assistant resident engineer. In 1902 Mr. Harvie entered the service of the Clyde Navigation Trust as assistant engineer, which position he held until 1904 when he became resident engineer for the Trust. From 1907 until 1910 he was agent and chief engineer on the construction of Yorkhill basins and quays for the Clyde Navigation Trust. Coming to Canada in 1910 Mr. Harvie was resident engineer on the construction of the new Victoria pier, shore wharves, etc., for the Montreal Harbour Commissioners, and in 1913 he was appointed assistant chief engineer, holding that position until 1922 when he became chief engineer, an appointment which he retained until his promotion to the office from which he now retires.

J. L. Busfield, M.E.I.C., has been appointed managing director of Gardner Engines (Eastern Canada) Limited, the Canadian subsidiary of Norris, Henty and Gardners Limited, of Patricroft, Lancs., England (manufacturers of the Gardner Diesel engine) operating in the territory from the Maritime Provinces to Saskatchewan.

Mr. Busfield was born in London, England, in 1888, and was educated at the City of London School and Dulwich College, and in 1907 graduated from the Central Technical College (City and Guilds Institute) and London University, receiving from the latter institution the degree of B.Sc., with honours in engineering.

J. L. Busfield, M.E.I.C.

Following graduation he came to Canada, and during the years 1907-1912 was with the eastern division of the Grand Trunk Railway, first on the resident engineer's staff and later as principal assistant to the resident engineer. In 1912 Mr. Busfield was appointed chief of party in charge of surveys with the Mount Royal Tunnel and Terminal Company in connection with the construction of the double-track tunnel through Mount Royal at Montreal. Subsequently he became assistant engineer in charge of surveys and alignment on the eastern division of the work and later office engineer in charge of the preparation of the terminal designs. In 1915 Mr. Busfield became engineer with the chairman of the Georgian Bay Canal Commission and was engaged in investigating the economic feasibility of that project. In 1916 he joined the staff of Walter J. Francis and Company as principal assistant, and during the following six years was engaged principally on hydro-electric work. In 1922 Mr. Busfield was a partner with de Gaspe Beaubien, M.E.I.C., in the firm of Beaubien, Busfield and Company, Montreal, and in this capacity was in charge of the construction of hydro-electric plants, reporting on numerous similar projects and other related work. In 1927 he entered the commercial sphere and became president of the firm of Busfield, McLeod Limited, successors to Chemical Engineering Equipment Company Limited, changed early in 1934 to J. L. Busfield and Company Limited, and in these later capacities acted as Eastern Canadian representative of Norris, Henty and Gardners Limited.

Mr. Busfield has been prominent in the affairs of The Institute for many years, having been secretary-treasurer of the Montreal Branch in 1919-1922; vice-chairman of the Branch in 1924, and chairman in 1925. He has served almost continuously on the Council of The Institute since 1926, and has been chairman at one time or another of such committees as Finance, Publication, Papers, Library and House, Remuneration of Engineers, Prizes, Development and others.

G. Gordon Gale, M.E.I.C., former vice-president and general manager of the Gatineau Power Company, has been made president of that company and also of the Canadian Hydro-Electric Corporation. Mr. Gale was educated at McGill University, obtaining the degree of B.Sc. in mining engineering in 1903, the B.Sc. in electrical engineering in 1904, and the M.Sc. in 1905. Following this Mr. Gale was for a time assistant engineer with the Canadian Rubber Company, becoming resident for Messrs. Ross and Holgate at Deschenes, Que., in 1907. Later in the same year he was appointed superintendent of power with the Hull Electric Company, holding that position until 1909 when he became acting general superintendent. In 1914 he was made general manager of the company and remained in that position until he was appointed general manager of the Gatineau Power Company.

ELECTIONS AND TRANSFERS

At the meeting of Council held on January 18th, 1935, the following elections and transfers were effected:—

Member

RIGGS, Henry Earle, B.A., (Kansas Univ.), C.E., (Univ. of Mich.), consltg. engr., 527 East Liberty St., Ann Arbor, Mich.

Associate Members

BAILEY, Charles David, engr., Dominion Bridge Co. Ltd., Montreal, Que.

BEATON, Neville, res. engr., Powell River Co. Ltd., Powell River, B.C.

BELANGER, René, B.A.Sc., C.E., (Laval Univ., Montreal), engr. and supt. of plants of Quebec Pulp & Paper Corpn., Société d'Eclairage et d'Energie Electrique du Saguenay, and Chicoutimi Mills, Ltd., Chicoutimi, Que.

JOHNSTON, Alexander Charles, elect'l. supt., Aluminum Company of Canada, Ltd., Arvida, Que.

PERRY, Aubrey Huffman, B.A.Sc., (Univ. of Toronto), asst. engr., Dept. of Pensions and National Health, St. Catharines, Ont.

STOBBART, William Morley, asst. engr., Dominion Bridge Co. Ltd., Montreal, Que.

Juniors

BECKER, Donald Fay, B.A., B.Sc., (Univ. of Alta.), secretary-treasurer, Richfield Distributors Ltd., Calgary, Alta.

BECKER, Howard Warren, B.A., B.Sc., (Univ. of Alta.), vice-president, Richfield Distributors Ltd., Calgary, Alta.

Transferred from the class of Associate Member to that of Member

ADDIE, George Kyle, B.Sc., (McGill Univ.), consltg. engr., Quebec, Que.

Transferred from the class of Junior to that of Associate Member

KILLAM, Donald Alexander, B.Sc., (McGill Univ.), designing engr., Canadian Industries Ltd., Montreal, Que.

STEPHENS, Donald McGregor, B.Sc., (Univ. of Man.), technical dftsman., Surveys Br., Dept. Mines and Natural Resources, Winnipeg, Man.

Transferred from the class of Student to that of Associate Member

CARVER, Stanley Cox, B.A.Sc., (Univ. of B.C.), asst. designing engr., Fleming Bros., Struct'l. Engrs., London, England.

Transferred from the class of Student to that of Junior

ADDISON, John Hillock, B.A.Sc., (Univ. of Toronto), engr. in charge of surveying, Minefinders Ltd., Noranda, Que.

Students Admitted

BOOK REVIEWS

Suspension Bridges of Short Span

By F. H. Frankland, American Institute of Steel Construction Inc., New York, 1934. 6 by 9¼ inches, 128 pages, diagrams, photos. $3.50. Cloth.

This book is an endeavour to furnish in easily usable form, basic information on the design and construction of modern suspension bridges smaller in size than monumental structures such as the George Washington bridge.

Bridge engineers will find in this book the data necessary to make a complete design for suspension bridges of all types, with loaded or unloaded backstays, self-anchored or gravity-anchored, ordinary or multiple-span arrangements. The author notes the recent important advance in suspension bridge design brought about by the introduction of the generalized deflection theory.

Aesthetics and their relation to economics of design are discussed, a subject frequently omitted from books on the design of bridges.

The author deals with impact and explains his method of designing the entire cross section of the floor system and stiffening members as a unit to resist shear, bending moment, transverse wind and compression when a self-anchored design is used.

The chapter on multiple span bridges is timely in view of present tendencies in the United States practice.

A complete chronological table of suspension bridges with main spans of 800 feet and less, built since 1900, is included as is also a bibliography of seventy books and papers, in English and foreign languages, dealing with matters discussed in the book.

The book is well illustrated and adequately indexed.

An Introduction to Practical Organic Chemistry

By W. A. Waters, Longmans Green and Company, Toronto, 1934. 5 by 7½ inches, diagrams, etc. $1.10. Cloth.

Reviewed by Dr. E. E. Massey*

Dr. Water's purpose is to provide a laboratory manual for those students having a limited number of hours at their disposal for the study of practical organic chemistry. The aim is at a wide range of important reactions rather than depth of treatment.

The book consists of three sections, dealing respectively with technique, preparation and identification of organic compounds. The section on technique is more thorough than in many manuals of wide scope. This is to be commended, since it is common for students who have presumably completed a course of elementary preparations to be at a complete loss when required to carry out some simple fundamental process, mainly because the necessity has not occurred in the preparations which have been made. The section contains, in addition, useful paragraphs on such topics as "cleaning vessels," "decolorization of solutions," and "avoidance of bumping." In addition to details of technique, attention is paid to difficulties which are likely to occur in carrying out the processes. The preparations described are sufficient for a short course, though it might have been advisable to include a Grignard reaction or acetoacetic ester synthesis. Considerable emphasis is placed on the value of test tube reactions, a point frequently ignored in laboratory manuals in organic chemistry. The arrangement differs from that of many books on the subject. The author does not omit all compounds containing a benzene ring from sections dealing with reactions of aliphatic compounds. Hence, there is less likelihood of a student reaching the erroneous conclusion that the side chain of an aromatic compound behaves differently from an aliphatic compound. This often occurs where a rigid division is made between aliphatic and aromatic substances. The section dealing with identification is, in effect, an extension and summary of the reactions of the most important organic groups.

The type is good, and the book is comparatively free from misprints, these being limited to an occasional missing letter. Illustrations are, in general good, but on page 20 both tubules of a condenser are represented as exits, and in the sketches of separatory funnels the stop cock vent is at right angles to the correct position.

The author succeeds in accomplishing his purpose, and the manual should be especially valuable to those who are compelled to acquire their knowledge of organic chemistry while engaged in plant practice. It should be used in conjunction with an adequate theoretical treatment of the subject.

**Research Chemist, Donald-Hunt, Limited, Montreal.*

Mechanical Vibrations

By J. P. Den Hartog, McGraw Hill Book Company, New York, 1934. 6 by 9¼ inches. Figs., tables. $5.00. Cloth.

Reviewed by Professor A. R. Roberts, A.M.E.I.C.*

This book by Professor Den Hartog is intended to provide an introduction to the subject of mechanical vibrations to meet the needs of students and practising engineers. It is assumed that the reader is familiar with the mechanics and calculus of the usual engineering curriculum but a previous knowledge of differential equations is not essential. Equations of this type, when they occur, are discussed at length and the significance of the terms fully explained.

The first chapter deals with the kinematics of vibration and includes representation by vectors and complex numbers. The succeeding chapters are devoted to vibrating systems having one, two or more degrees of freedom, multicylinder engines, rotating machinery, self-excited vibration and to systems having non-linear characteristics. The concluding section contains a short appendix on the gyroscope, a fairly complete bibliography and answers to problems.

Numerous examples are worked out and these, together with the problems set at the end of each chapter, will be found to be of material assistance to the student.

Not the least important feature of the book is the introduction by the author of frequent references to illustrative examples which, to quote but a few, include hydraulic penstocks, ship stabilizers, turbine discs, wing flutter, floating power, galloping transmission lines, gear noises, oil whip in bearings.

As an authoritative treatment particularly well adapted for an introduction this volume can be highly recommended.

**Professor of Mechanical Engineering, McGill University, Montreal.*

Handbook of Chemistry

Compiled and edited by N. A. Lange, Ph.D., Handbook Publishers, Inc., Sandusky, Ohio, 1934. 5¼ by 8 inches, 1,545 pages, tables, etc. $6.00. Fabrikoid.

Reviewed by Dr. S. G. Lipsett*

Professor Lange has produced a comprehensive and commendable handbook for chemists. It contains 1,513 pages of tables and data without being cumbersome. In a book of this nature of course the value lies in the choice of the contents. It would be impossible to please everyone but on the whole this should be a handy reference book, both to the works chemist and to the research worker.

The tables on the properties of inorganic and organic compounds are quite complete. There are tables describing the properties of natural and synthetic resins, alloys, alkaloids, oils, fats, waxes and minerals. Many tables are devoted to the solubility of compounds at different temperatures and the specific gravity of solutions of different concentrations.

A number of tables include information of particular interest to physical chemists, such as vapour pressure, surface tension, viscosity, thermochemical data, spectra, etc.

A considerable amount of miscellaneous material is included in this handbook which will be found useful at the right occasion. For instance, there will be found information on analytical procedures, equivalents of volumetric solutions, materials of construction, corrosion-resistant materials, composition of foods, water treatment, ceramics, pipes and valves, freezing mixtures.

There is a considerable section devoted to mathematics and mathematical tables.

The basic formulæ and theorems in algebra, geometry, trigonometry and calculus are listed and described. Then follow tables of logarithms, trigonometric functions, powers, roots, reciprocals and many other tables of purely mathematic interest.

This handbook has fulfilled its function of presenting a vast amount of information in a small volume and should prove a valuable book to anyone engaged in chemistry or allied sciences.

Research Chemist, Donald-Hunt, Limited, Montreal.

Undertakings Without Precedent

Extracted from an editorial foreword in the *Engineering News Record* for November 29th, 1934, referring to a series of articles on a group of federal public works projects now under construction.

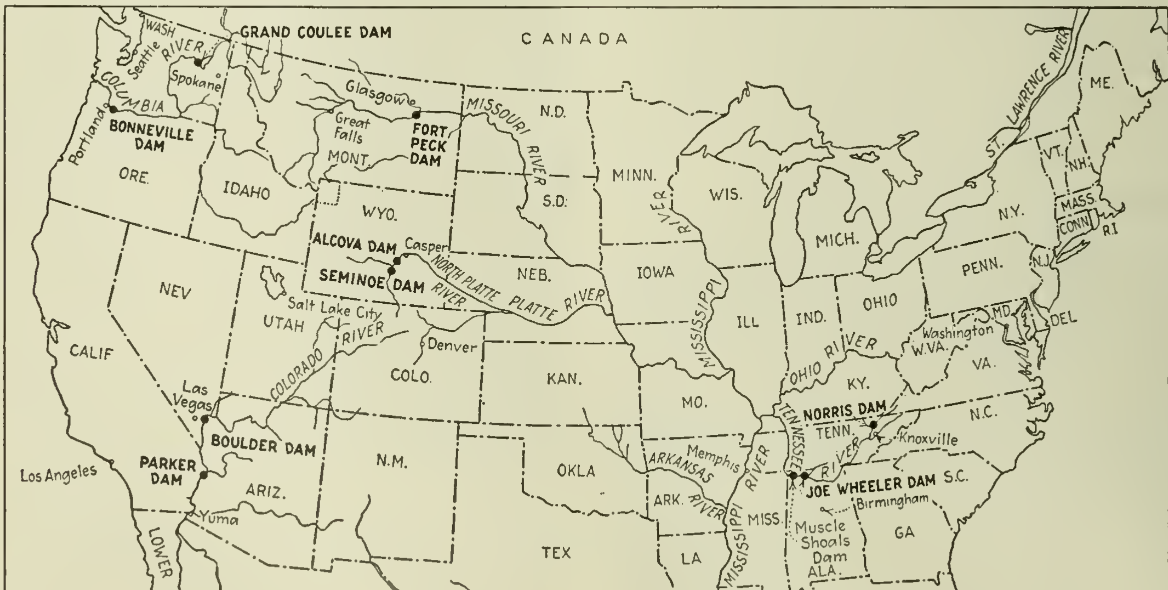
The federal government at the present time is engaged in the construction of a group of great projects for power development, flood control, navigation or water conservation, projects that will cost in the neighbourhood of $400,000,000 and will increase the nation's power-producing capacity by one million horse power. In the northwest the government is building a $63,000,000 dam for power development on the Columbia river near the mouth of the Grand Coulee, and at Bonneville on the same river it is building a combined power and navigation dam costing $32,000,000. In Black Canyon on the Colorado the government is building Boulder Dam, the greatest concrete dam ever attempted by man. At Fort Peck on the upper Missouri river the world's largest earth dam, estimated to cost $84,000,000, is under construction to regulate the flow of the Missouri as an aid to navigation, and, incidentally to produce power and provide water for a limited amount of irrigation. On the North Platte river in Wyoming a power and storage dam is to be built at Seminoe, and below it near Casper, work has begun on a diversion dam and irrigation project, the whole to cost $22,000,000. And, finally in the southeast there is under construction Norris dam on the Clinch river, costing $34,000,000; on the Tennessee river there is Joe Wheeler dam, costing $23,000,000; and as recently announced, Pickwick Landing dam at a cost of $22,000,000, all three being built by the Tennessee Valley Authority with federal funds. Except for Norris dam and the work on the Colorado river, this work is all being carried forward without specific Congressional approval, being authorized under the broad powers granted the President under the Recovery Act. Further, these projects are outside the normal programme of river control and land-reclamation work carried on by the Corps of Engineers and the Bureau of Reclamation, work planned far in advance of execution and undertaken only as authorized by Congress.

This is an unprecedented situation. For those who would look beyond the present spectacular construction operations to enquire into the purpose of the undertakings, it raises questions whose answers either never have been given or have been obscured by other matters. Why were the projects undertaken? How do they fit into plans for the orderly development of the river system on which they are located? How are they related to the economic development of their respective regions? Are they economically justified, either in part or as a whole? Is there a market for the power to be developed? Are the power plants logical additions to the power systems of the region in which they are located, or must the government enter into direct competition with existing electric utilities in order to develop a market? Will the land to be irrigated ever produce a return on the investment?

These and similar other questions are being asked by engineers on all sides. In this issue an attempt is made to answer as many of them as possible by setting forth the known facts upon which answers must be based.

Aside from their function in the employment-for-recovery campaign, these projects, other than those on the Colorado river, are outstanding physical expressions of a leading New Deal characteristic —the willingness to try out a promising or attractive idea even at stupendous cost, regardless of whether it meets the test of sound business procedure. It is what the President has often described as the experimental approach to the solution of national problems. Only the dire national emergency justified the method, of course.

With the exception of the great works on the lower Colorado and part of the construction work undertaken by the Tennessee Valley Authority, the projects are outgrowths not of planning and economic determination of service value, but of the dictatorship vested in the President by the emergency laws enacted by Congress in early summer of 1933. Social objectives and the desire to set up regulatory public power systems evidently were the motives in part. Political reasoning appears to have entered, at least to some extent. For example, Grand Coulee had never been planned as a government power enterprise, but instead had been conceived as part of a huge regional development based on irrigation, with power in large part a service feature for irrigation pumping. In this scheme, the dam and power plant were to cost nearly $200,000,000; and the whole project, because of its vast size in both money and other elements, was regarded as being far in the future. But local political demand for it was strong. The Administration, unwilling to allocate to the state of Washington so large a sum, fixed the amount at $63,000,000 to be spent for a power enterprise alone, and it then became necessary for the engineers of the



Map showing location of nine dams now under construction by the Federal Government.

Bureau of Reclamation to design a dam and power plant to fit this sum. In effect, the present Grand Coulee represents not a project that was worked out on its own merits, but merely $63,000,000 worth of dam.

And while even this minor Grand Coulee dam alone could supply all of the unsatisfied power needs of the northwest states for many years, Oregon too sought something for itself. Authorization of Bonneville resulted.

* * * * *

The favourable attitude of the administration toward public power development also had an important bearing on the financing of these projects. President Roosevelt went into the White House in 1933 fresh from a long contest with the electric utility interests in New York State, which resulted in the establishment of the New York State Power Authority, created expressly to undertake development of the great power resources of the international section of the St. Lawrence river as a means of checking the further exploitation of the state's power resources for private profit. In Washington he found the federal government already committed to a large power-generation programme in the southwest at Boulder dam, and with a white elephant on its hands in the southeast in the shape of the power plant at Muscle Shoals. Through the establishment of the Tennessee Valley Authority to take over the latter plant and supplement it with other plants, the President saw that it would be possible to dominate the power market in the southeast. Thus there was soon to be at hand what he termed a "power yardstick" both in the southwest and southeast. To round out control of the country, similar domination was needed in the northwest and the northeast. The St. Lawrence ultimately, the President believes, will provide a yardstick in the latter region; there remained still the northwest to be provided for. Bonneville and Grand Coulee provide that yardstick. The Bonneville project in theory is a navigation aid but it will produce a large amount of power. The Grand Coulee dam as now being built has power generation as its only objective.

This is the background against which the several projects discussed must be viewed. From a survey of the factors affecting the projects it will be seen that no one of them is so sound financially as to make it an attractive undertaking. But in an emergency like the present one the government is justified in looking beyond the immediate direct return to see whether an undertaking is sufficiently desirable as a national asset to warrant its construction.

Thus it is difficult to formulate a binding rule as to whether or not the federal government is justified in putting up the money to pay the cost of the projects reviewed in this issue. It should, however, be possible to state a general rule that no great power development should be undertaken without first having reasonable assurance that the power can be marketed in reasonable time without entering into destructive competition with existing plants. Were this rule applied, it is evident that some of the projects considered in this issue would not be undertaken.

Hydro-Electric Progress in Canada during 1934

The Dominion Water Power and Hydrometric Bureau of the Department of the Interior of Canada has issued Bulletin No. 1784, the annual review of hydro-electric and water power development throughout the Dominion during the year 1934, which gives a brief description of those undertakings which were begun or which reached the developed stage during that period and of extensions and replacements in existing plants.

This review discloses that during 1934 no new large water power undertakings were begun. Work was continued, however, on several developments already under construction and as a result net new installations aggregating 214,965 horse power were brought into operation during the year. This brings the total installation for the Dominion at the end of 1934 to 7,547,035 horse power. The recovery in power demand which was evident in 1933 gained momentum in 1934, and it is now evident from the monthly figures published by the Dominion Bureau of Statistics that the total output for 1934 will not only greatly exceed that of the previous year, but will establish a new high record. It is of special interest to note that this expansion of output is principally due to increased domestic, commercial and industrial demand, and not to increased export or secondary uses. The gain in output has been general but is most pronounced in the province of Quebec.

Copies of this bulletin may be obtained free of charge on application to the Director of the Dominion Water Power and Hydrometric Bureau, Ottawa, Ont.

Canadian Electrical Code

The Canadian Electrical Code, Part I, 3rd edition, has just been issued by the Canadian Engineering Standards Association. This succeeds the edition published in January 1930, and it is believed that it is now in accordance with up-to-date Canadian practice.

This Code has now been adopted by the nine provinces of Canada and in some provinces special provincial editions have been issued which consist of a special cover or an insert referring to legal regulations.

Copies of this publication may be obtained on application to the Secretary, Canadian Engineering Standards Association, National Research Building, Ottawa, the price being 25 cents per copy.

BRANCH NEWS

Calgary Branch

J. Dow, M.E.I.C., Secretary-Treasurer.
H. W. Tooker, A.M.E.I.C., Branch News Editor.

Commercial Aviation

A short address on Commercial Aviation presented by A. Griffin, M.E.I.C., chief engineer, Department of Natural Resources, C.P.R., and six most interesting reels of motion pictures dealing with Aviation, Steel Making and Ship-building, made up a programme given at a meeting of the Calgary Branch held on Thursday evening, December 13th, 1934, at which over sixty members of the Branch and their friends were present.

Scheduled commercial transport, or more particularly, the United Air Lines, operate ships (as they are now termed) from New York to San Francisco, Vancouver to San Diego and branch lines from Chicago to Kansas City and from Salt City to Spokane, Portland and Seattle, and also have inter-connections with various other air transport companies and with various railways.

It is of significance, the speaker said, that the early experimental stages were passed some years ago, since which scheduled service has been maintained with astonishing regularity in all but the worst weather and with a remarkable record of safety.

In describing the type of plane (Model 247) in use by the United Air Lines, the speaker pointed out that they had fifty in service carrying a crew of three, pilot, co-pilot and stewardess, and powered with two Pratt and Whitney engines, air cooled and mounted in the wings, and supercharged to develop 550 h.p. at 5,000 feet elevation. The plane is complete in all necessary facilities and when fully loaded carries ten passengers at 170 pounds each, plus 30 pounds of baggage per passenger, plus 747 pounds of cargo (mail and express). It has a cruising speed of 165 miles per hour and maintains an average speed of 150 miles per hour from San Francisco to New York. Gasoline consumption is at an average rate of one U.S. gallon per minute and costs about 60 cents per mile to operate. Engines are overhauled twice in sixteen hundred hours and at twenty-five hundred hours they are turned in for new ones, which may appear to be a short period but if put into miles it is more imposing at 130,000 miles between overhauls and a life of nearly 500,000 miles.

United Air Line planes, the speaker said, are equipped with a bewildering number and variety of instruments and controls, such as radio and a 50-watt crystal controlled telephone transmitter, and all useful aids to navigation.

When weather conditions require it, the pilot can follow the radio beam to the airport in almost any weather. This beam, the speaker understood, spreads about one mile in twenty each side of the course, and from it the pilot knows whether he is on his course or to one side.

While every effort is made to maintain fixed flying schedules, and this with a large measure of success, safety is a primary consideration. Passengers and sometimes mail and express are forwarded by train as required over those portions of the route where flying conditions are not safe.

Following Mr. Griffin's address the six reels of motion pictures were shown as follows: Steel Making, Aviation and Construction and Trials of the P. and O. steamers *Strathaird* and *Strathnaver*.

A very hearty vote of thanks was given the speaker and to those responsible for procuring the motion pictures, by J. Hadden, M.E.I.C.

The meeting adjourned at 10.15 p.m.

Tuesday, January 8th, 1935, was the occasion of a joint luncheon meeting of the Canadian and Rotary Clubs and the Calgary Branch of The Institute, held at the Palliser hotel. The subject of the address was "The Drought Situation in the Prairie Provinces" and the speaker was Mr. W. L. McTavish, editor of the Winnipeg Tribune.

The speaker said that large sections of fertile western farm lands had in the course of years been reduced to actual desert, and twenty million acres of the world's finest hard wheat land had been left to the depredation of sow thistle, and as a playground for gophers. Drought, recurring more frequently and with greater severity, teaming up with wind and soil drift, had caused irreparable damage.

The speaker was introduced by Dr. J. M. McCaffery, president of the Canadian Club, and a vote of thanks was tendered by G. P. F. Boese, A.M.E.I.C., chairman of the local Branch of The Engineering Institute of Canada.

Halifax Branch

R. R. Murray, A.M.E.I.C., Secretary-Treasurer.
C. Scrymgeour, A.M.E.I.C., Branch News Editor.

President's Address

During the month of December the Halifax Branch of The Engineering Institute of Canada held three meetings, the first on December 6th, this being the regular supper meeting held at the Halifax hotel with forty-five members present and under the chairmanship of R. L. Dunsmore, A.M.E.I.C., the guest for the evening being F. P. Shearwood, M.E.I.C., President of The Engineering Institute of Canada, who delivered a splendid address on Institute affairs, after which the meeting was thrown open to discussion and a large number of the members took part in a free expression of opinion on the affairs of The Institute relative to the present, past and future.

Bridge Construction

On December 7th a meeting was also held at the Nova Scotia Technical College at which the engineering students of the College and members of The Engineering Institute of Canada, totalling some two hundred or more, heard a particularly fine address by President Shearwood on "Bridge Construction." This meeting was under the direction of Professor Faulkner who, on behalf of the local Branch, expressed to Mr. Shearwood the great pleasure the Halifax members had had by his visit and by the addresses he had given during the two evenings he was their guest in the city of Halifax.

Annual Meeting

The annual meeting of the Halifax Branch was held in the Halifax hotel on December 20th at which the guest speaker was Squadron Leader Edwards, R.C.A.F., who spoke on the development of airways, aircraft and the Air Force in general since its inception in Canada, and also spoke on the development of Unemployment Relief Camps outlining their objects and achievements, the address being followed by a series of lantern slides. Following this address the annual business was enacted which included the reading of the reports of the various 1934 committees including the financial statement which showed a very creditable balance on hand.

In congratulating the new Council and introducing the new chairman, Howard Fellows, A.M.E.I.C., to the members, the retiring chairman, R. L. Dunsmore, A.M.E.I.C., expressed his appreciation of the fine support that the members of the Halifax Branch had given him during his year of office.

Hamilton Branch

A. Love, M.E.I.C., Secretary-Treasurer.
V. S. Thompson, A.M.E.I.C., Branch News Editor.

The Annual Meeting of the Branch took the form of a dinner and smoker, and was held in the Wentworth Arms hotel on Tuesday, January 8th, 1935.

At the head table were H. B. Stuart, A.M.E.I.C., chairman of the Branch, W. Hollingworth, M.E.I.C., chairman elect, E. G. Cameron, A.M.E.I.C., vice-president of The Institute, F. W. Paulin, M.E.I.C., Councillor, E. E. Kent, representing the Hamilton Construction Association and several past chairmen of the Branch.

After the loyal toast had been honoured, Mr. Stuart expressed his pleasure at seeing such a representative gathering and welcomed specially the out of town guests. The Branch Secretary read the annual report which showed that the meetings of the year had been well attended, they presented subjects of wide variety and general appeal, and the place of meetings—McMaster University—was a home from home. There was a matter of a slight operating deficit for the year, the amount being $4.80, but nobody took it very seriously, and figured the money had been well spent.

Vice-President Cameron gave a short talk on Institute affairs. He spoke of the virility of the Branches, which really became the virility of The Institute. He told of the experiment which the Winnipeg Branch hoped to make by having the same personnel on the Executives of the Branch and the Professional Association. He touched briefly on the finances of The Institute, told of increasing revenue from fees which reflected improved condition of the engineer and his loyalty to The Institute in immediately making up arrears.

Councillor Paulin, who followed, told of the splendid work done by the President, Mr. Shearwood, and of the pleasure it had been to serve on the Council under him. Mr. Paulin thanked the retiring Executive for their loyalty and co-operation at all times.

E. H. Darling, M.E.I.C., past chairman of the Branch, who is the representative on the committee revising the city of Hamilton building by-laws, then gave a short talk. He explained the immensity of the task in getting up a set of by-laws, even when a model by-law drafted by the fire underwriters had been used to start with. Starting with this they had chopped and changed, so as to suit this department or that board, or some government edict as the case might be. It was not surprising therefore to learn that they were now at the third draft and it would probably all be rewritten before finally accepted by the city council.

On the motion of J. B. Carswell, M.E.I.C., the thanks of the Branch were tendered to Mr. Darling who, with H. S. Phillips, M.E.I.C., has worked assiduously on the revision of these by-laws.

The names of the new executive were then announced and Mr. Stuart asked Mr. Hollingworth, the new chairman, to take charge of the meeting, wishing him every success in his year of office.

After a few words of thanks and an appeal for the same support as his predecessor had been shown by the members of the Branch, Mr. Hollingworth introduced Mr. E. E. Kent, who brought felicitations from the Hamilton Construction Association and wished the Branch every success.

C. G. Moon, A.M.E.I.C., of the Niagara Peninsula Branch, spoke briefly and mentioned the possibility of a joint meeting and later on a trip along the Welland Canal, with the Niagara Peninsula Branch.

A number of the past chairmen of the Branch were then heard from: R. K. Palmer, M.E.I.C., E. P. Muntz, M.E.I.C., and H. A. Lumsden, M.E.I.C.

W. J. W. Reid, A.M.E.I.C., chairman of the Meetings and Papers committee, gave a brief outline of the papers he had lined up for the ensuing five months, the subjects including illumination, gold mining, Diesel engines, material handling and possibly welding.

Kingston Branch

L. F. Grant, M.E.I.C., Secretary-Treasurer.

The members of the Kingston Branch had the pleasure, on January 16th, 1935, of entertaining at dinner Mr. F. P. Shearwood, M.E.I.C., President of The Institute.

The attendance was the largest for some time, the members being most anxious to do honour to the distinguished guest, and also to hear the two discussions which he later gave, one on Institute affairs and one on Bridge Erection.

Mr. Shearwood gave a very complete, though brief, resume of the affairs of The Institute from coast to coast, of its relations with the various Provincial Associations, and outlined several suggestions for the future policy of the profession. At the conclusion he was called upon to answer a number of questions, and several members took part in the discussion. Those present were very glad to have the opportunity of hearing something of their engineering brethren throughout Canada, of whom they would like to see much more than they do.

In Mr. Shearwood's talk on "Bridge Erection" he showed a large number of interesting slides of outstanding bridge work, and explained some of the difficulties encountered, and the ingenious and frequently daring means by which they were overcome. He left his audience with a very high impression of the skill of the engineers and their subordinates who are engaged in this branch of the profession.

In thanking Mr. Shearwood for his address, the Branch chairman, William Casey, M.E.I.C., expressed the pleasure which the Kingston Branch took in meeting the President, and in hearing an address which he was so well qualified to give.

Two new members of the Branch, H. V. Ellegett, S.E.I.C., and J. M. Silliman, A.M.E.I.C., were introduced to the members at the meeting.

London Branch

H. A. McKay, A.M.E.I.C., Secretary-Treasurer.
Jno. R. Rostron, A.M.E.I.C., Branch News Editor.

No Branch meeting was held in December in view of the fact that it was proposed to hold a meeting on January 4th, 1935, for the purpose of showing the Vickers-Armstrong films which have been going the round of all the Branches of the E.I.C. This date being the earliest available for this purpose.

As these films are of interest to the general public as well as engineers, it was decided to advertise the exhibition in the press and to engage the auditorium of the Technical School. This was done with very gratifying success, about nine hundred persons being present.

Frank Ball, A.M.E.I.C., took the chair and described the various films to be exhibited. The writer does not propose to give a description of them for, presumably, the whole of the members of The Engineering Institute of Canada will have had the opportunity of seeing them.

Mr. Ball called for a vote of thanks to the Vickers-Armstrong firm for their generosity in supplying the films, to Mr. Simpson, head teacher of the electrical department of the Technical School, who operated the lantern, and to Col. Murray Dillon and his Vimy Orchestra who supplied the music during the interludes. These were received and passed with much applause.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Refractories in Industry

The Ottawa Branch at its luncheon meeting on Thursday, December 6th, 1934, was addressed by F. E. Lathe, of the National Research Council, who spoke on "Refractories in Industry."

Alan K. Hay, A.M.E.I.C., chairman of the Ottawa Branch, presided, and in addition head table guests included: Dr. Charles Camsell, M.E.I.C., J. McLeish, M.E.I.C., Group Captain E. W. Stedman, M.E.I.C., Gordon Gale, M.E.I.C., Dr. G. S. Whitby, H. Frechette, G. D. Mallory, Dr. C. W. Drury, S. F. Kirkpatrick, S. P. Eagleson, and C. McL. Pitts, A.M.E.I.C.

In introducing the subject, Mr. Lathe emphasized the fundamental role played by metals in the history of civilization, particularly in the last one hundred years, and pointed out that metallurgy is wholly dependent upon refractories. Dividing the history of the race into three periods, he showed that during the first or pre-industrial period, extending from the earliest production of brick and pottery to the 15th century, it had been impossible to obtain temperatures above 1,100 degrees C. and demands upon refractories had therefore not been great.

The second period began with the production of cast iron in blast furnaces in Germany and extended to the middle of the 19th century. While cast iron gave an enormous impetus to industry and armament manufacture, fireclay and silica refractories were still ample for the demands made upon them.

The third period was ushered in by Bessemer's remarkable discovery of a cheap method of producing wrought iron and steel. This discovery was followed within twenty-five years by the development of the open-hearth steel furnace and the adoption of basic refractory linings in order to permit the elimination of phosphorous. This led to the use of several new refractories, including dolomite, Austrian magnesite, and the neutral refractory, chromite. Recently Canada has been coming to the front with the production of special basic refractories which are finding a wide market in this field.

The adoption of basic linings for copper converters was cited as an example of a change in refractories bringing about a radical reduction in the cost of a metallurgical operation. A still more recent development is the use of suspended arches for copper reverberatory furnaces, permitting the use of basic brick roofs and wider furnaces and resulting in a greatly increased tonnage per furnace. Basic bottoms for copper anode furnaces also represent an important improvement.

Mr. Lathe outlined the major applications of each of the chief refractories and expressed the opinion that new refractories must soon be developed to meet the demand for higher operating temperatures in metallurgy, and referred to the successful research being carried out by the National Research Council in co-operation with Canadian Refractories, Limited, and the Department of Mines.

At the noon luncheon on December 20th, 1934, T. A. McElhanney, M.E.I.C., Director of the Forest Products Laboratories of Canada, Department of the Interior, spoke upon "Engineering and Economic Aspects of Forest Products Industries." Alan K. Hay, A.M.E.I.C., chairman, presided and head table guests in addition included: Hon. T. G. Murphy, Minister of the Interior; J. B. Hunter, Deputy Minister of Public Works; Dr. Charles Camsell, M.E.I.C., Deputy Minister of Mines; Dr. H. M. Tory, President of the National Research Council; C. P. Mahoney, President of Ontario Retail Lumbermen's Association; R. A. Gibson, Assistant Deputy Minister of the Interior; R. L. Sargent, Secretary of Canadian Lumbermen's Association; Group-Captain E. W. Stedman, M.E.I.C., past chairman of the Ottawa Branch; C. Jackson Booth, of the Booth Lumber Company; B. Stuart McKenzie, M.E.I.C., Secretary of the Canadian Engineering Standards Association; and E. H. Finlayson, M.E.I.C., Director of the Dominion Forest Service.

Engineering and Economic Aspects of Forest Products Industries

Pulp and paper manufacture is Canada's largest industry, stated Mr. McElhanney, with the lumber industry, when lumber conversion plants are included, ranking second. Total capital invested in the wood and paper group of industries is nearly one and one-half million dollars.

The forest products industries roughly may be divided into logging operations, sawmill operations, wood conversion plants, and pulp and paper mills.

As a structural material the speaker stated that wood is encountering increasing competition from other materials. This competition has introduced many technical problems into the industries, which have been further accentuated by the development of foreign markets and competition with foreign timbers. For this reason, about twenty years ago the Forest Products Laboratories were established in Canada. Three of these now operate: the main laboratories in Ottawa, a branch laboratory in Vancouver, and the pulp and paper laboratory in Montreal.

Considerable difficulty has been encountered by engineers and architects in specifying timber for structural purposes on account of the lack of standard structural grades for all Canadian species. The Toronto Building Code Committee, who are getting out a new building code, have been paying particular attention to this in co-operation with lumber associations and the Forest Products Laboratories.

About $40,000,000 worth of wood is used for fuel each year in Canada. On the Pacific Coast a special type of burner has been developed for the utilization, for this purpose, of sawdust from sawmill operations. A market has thereby been developed in that area for sawdust which has yielded a return to the mills of about a quarter million dollars per year.

Losses through seasoning of lumber in Canada amount to about 7 per cent of the value of all the lumber produced, which in the total is upwards of $10,000,000 per year. In order to curtail this loss and at the same time provide to the various lumber markets served by Canadian timber, a product suitable for their immediate purpose, it has been necessary for Canada to pay increasing attention to the methods of seasoning lumber.

With particular reference to the pulp and paper field, competition is increasing and the industry is dependent on research to keep its costs down and its quality up and the pulp and paper industry co-operates in the work of the Forest Products Laboratories.

Luncheon to the Hon. Grote Stirling, M.E.I.C.

At the most largely attended luncheon so far of the season, honour was done at a noon luncheon, Thursday, January 10th, 1935, by The Engineering Institute of Canada to the Honourable Grote Stirling, M.E.I.C., in recognition of his elevation to the portfolios of National Defence and of Fisheries. Alan K. Hay, A.M.E.I.C., chairman of the local Branch, who presided at the luncheon, in introducing the Honourable Mr. Stirling, stated that it was the first time that a member of The Institute had become a member of the federal cabinet in Canada.

The Right Honourable R. B. Bennett, prime minister of Canada; the Hon. H. A. Stewart, minister of Public Works; the Hon. R. J. Manion, minister of Railways; the Hon. Alfred Duranleau, minister of Marine; and the Hon. T. G. Murphy, minister of the Interior, fellow members of the Cabinet, were head table guests. In addition, F. P. Shearwood, M.E.I.C., of Montreal, president of The Engineering Institute of Canada, and Fred Newell, M.E.I.C., councillor for Montreal, attended to represent The Institute at large and the Montreal Branch; and other head table guests included: Dr. Charles Camsell, M.E.I.C., Deputy Minister of Mines and past president of The Institute; G. J. Desbarats, M.E.I.C., and C. M. Pitts, A.M.E.I.C., councillors for Ottawa of The Institute; Group Captain E. W. Stedman, M.E.I.C., past chairman, Col. L. R. LaFleche, deputy minister of National Defence; and Commander C. P. Edwards, A.M.E.I.C., past councillor for Ottawa for The Institute.

The Honourable Mr. Stirling, after his introduction by the chairman, gave a short address in which he traced down to the present the trend of engineering practice from the days when civil engineering as distinct from military engineering began to receive public recognition in Great Britain. He stated that the engineer had been characterized as a man who ought to be able to tackle anything and was of the opinion that his services were equally important to those of the man who caused two blades of grass to grow where only one had grown before.

In his own two departments there was plenty of scope for the engineers' attainments. He briefly sketched some of the work which they were called upon to do. He paid tribute to The Engineering Institute of Canada as an organization through which the engineer could keep abreast of the times in his own profession, and reminded his hearers that they might quite well exert a greater influence in the community than they do.

G. J. Desbarats, M.E.I.C., expressed the pleasure of the Branch in welcoming a fellow-engineer and congratulated him on his high honour. He briefly sketched the career of the Hon. Mr. Stirling, indicating the very important engineering work for which he was chiefly responsible a few years ago in connection with the irrigation of the Okanagan valley of British Columbia.

F. P. Shearwood, M.E.I.C., president of The Institute, also extended congratulations on behalf of The Institute as a whole. He stated that he felt that the training of the engineer should be of inestimable value in helping to solve some of the problems affecting the social and economic life of the world today. The engineer was able to accomplish much in the way of labour saving devices; he should be able to help in solving some of the problems created by them.

Quebec Branch

Jules Joyal, Secretary-Treasurer.

La Section de Québec a tenu son premier déjeuner-causerie de l'année 1935 au Château Frontenac le 14 janvier; l'invité d'honneur était M. E. D. Gray-Donald, M.S., A.M.E.I.C., surintendant de la Division du Pouvoir pour la Quebec Power Company, qui nous fit une très instructive conférence intitulée "Some Considerations Governing the Undertaking of Hydro-Electric Power Developments."

M. Hector Cimon, M.E.I.C., président de la Section, présenta le conférencier à l'auditoire et M. A. A. MacDiarmid, M.E.I.C., lui proposa un vote de remerciements que l'assistance seconda par de longs et vigoureux applaudissements.

Nous publierons plus tard un extrait de cette conférence.

Saskatchewan Branch

S. Young, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Saskatchewan Branch, Engineering Institute of Canada, was held in the dining room, Parliament Buildings, Regina, on Friday evening, December 21st, 1934, at 7.45 p.m., being preceded by a dinner. A. P. Linton, A.M.E.I.C., occupied the chair.

P. C. Perry, A.M.E.I.C., was duly nominated and elected as Branch representative on The Institute Nominating Committee.

The chairman then introduced the speaker of the evening, M. J. Coldwell, leader of the C.C.F. in Saskatchewan, the subject of his address being "The World Outlook for 1935."

The World Outlook for 1935

Mr. Coldwell stated that travellers returning from abroad, particularly Europe, bring with them a feeling that in the near future we will have either military warfare or social revolution. Consequently he looked forward to the year 1935 with doubt and misgiving.

Two years ago the Ball report emanating from a conference held in Switzerland forecast economic doubt. Immediately following this report there was the economic conference in Great Britain followed by the disarmament conference and more recently the naval conference in Washington. All these conferences have been failures.

Mr. Coldwell remarked that the difficulty faced today is a problem of machine production. Machinery has been made so efficient that the masses are in grave danger of wholesale unemployment. At the present time there are in operation industrial plants using eight men, the whole being equivalent to the former labour of four million men. The speaker stated that not until this problem is solved, namely the proper control of machine production, will we overcome the present depression.

Present production has approximately doubled that of twenty years ago and there being no market for this production we have unemployment with its consequent unrest. In all probability this situation will become more aggravated during the coming year.

In Europe we have recently seen the breakdown of the existing social structures, with the exception of Great Britain, Norway, Sweden and Denmark, where there is comparative tranquillity. Most of the countries of Europe are under one form or other of dictatorship. The danger in particular is that in all those countries where there is economic strife it may develop into military warfare.

The problem then becomes one of control. So far the League of Nations is the most forward step taken internationally. Mr. Coldwell, however, ventured the opinion that the problem must be settled nationally. In the last four years in the city of Regina the collegiate population has increased by eighty per cent with in all probability an actual reduction in the total population of the city. This condition is a direct result of the machine age, the additional students being in the collegiate not entirely from a desire for knowledge but as a direct result of unemployment. Canada is the most highly industrialized nation per capita in the world. These are problems for solution in Canada alone. They cannot be solved by the League of Nations. In general it is in the interests of Canadian social and economic life that the general standard of living be raised.

The problem, being a world problem, is at the root national in character. Consequently any solution, national in character, will be a step forward. To do this use must be made of our democratic institutions to control the cause, namely, the peculiar economic and social condition now existing.

The address was provocative of considerable discussion touching various phases of the subject including the "Douglas Theory." A hearty vote of thanks was tendered the speaker on motion of P. C. Perry and H. S. Carpenter, M.E.I.C.

Vancouver Branch

A. I. E. Gordon, Jr.E.I.C., Secretary-Treasurer.

Annual Meeting

Business and pleasure were combined when the annual meeting of the Vancouver Branch was held on Monday, November 19th, 1934, in the Aztec room of the Hotel Georgia. The meeting was called to order at 8.15 p.m. by P. H. Buchan, A.M.E.I.C., the retiring chairman. Following the reading of the minutes H. B. Muckleston, M.E.I.C., conveyed the thanks of the President and Secretary of the American Society of Civil Engineers and the local Branch to the Executive committee of the Vancouver Branch of The Engineering Institute of Canada for their co-operation and assistance in connection with the Joint Engineering Convention in Vancouver last July.

Elections held at the meeting resulted in the unanimous selection of Jas. Robertson, A.M.E.I.C., and H. N. MacPherson, A.M.E.I.C., as chairman and vice-chairman respectively and G. M. Gilbert, A.M.E.I.C., as secretary-treasurer. New committeemen elected are J. P. MacKenzie, A.M.E.I.C., and P. Sandwell, A.M.E.I.C.

Following presentation of the annual report and financial statement, Mr. Buchan turned over the chair to the new chairman, Mr. Robertson. A vote of thanks to Mr. Buchan was moved by Mr. Muckleston and seconded by Mr. Wheatley. They paid tribute to the energy and ability displayed by Mr. Buchan during his three years as chairman and especially to his ability as a writer and his monumental work in the cause of Institute Development. W. H. Powell, M.E.I.C., rose to express the hope that Mr. Buchan's latest study on the subject of development, which is considered a most able review of the whole situation, would be published in an early issue of The Journal.

At the close of the business session which lasted an hour and an half, refreshments both liquid and solid were enjoyed and the next two hours were devoted to the very excellent programme of songs and entertainment arranged by A. S. Wootton, M.E.I.C., and largely contributed to by local members.

Winnipeg Branch

E. W. M. James, A.M.E.I.C., Secretary-Treasurer.
E. V. Caton, M.E.I.C., Branch News Editor.

On Friday evening, December 7th, 1934, a joint smoker of the Winnipeg Branch of The Institute, the Manitoba Branch of the Canadian Institute of Mining and Metallurgy, the Association of Professional Engineers of the Province of Manitoba, and junior engineers, was held at the Marlborough hotel.

A station was cut in Shaft No. 13 at the first level, Jorge Koal superintending, chairs and tables were brought along, and the entire shift downed jackhammers and drifters and set about to make the best of the occasion.

Liquid refreshments with exactly the right reactions were served in miniature glass flotation cells, and the solids on concentrating tables, both being transported by white-jacketed conveyors under the supervision of Shift Boss Marcel Bocquin, who later led the singing of "Alouette," after the sand pumps were primed. The solids were quickly reduced by automatic jaw crushers, and after grinding and classifying, were clarified and precipitated in the usual way.

S. E. McColl, A.M.E.I.C., took the part of mine captain and directed an extra shift of entertainers who included Ferris Healey and Trevor Rees in interludes of harmony; Dr. R. M. Cornelius, Lenny Morris and George Seibert, of Blades Fencing Club, in bouts with the foils; Bill Kicenko and Bill Syrnk in bouts of boxing; Jack Trott and Joe Myers in bouts of wrestling; the four O'Tooles in more interludes of harmony; and J. H. Whyard in a burlesque dancing novelty.

The organizer of the party and master of ceremonies was S. E. McColl, A.M.E.I.C.

Employment of Engineers in the United States

An intensive study of the United States census for 1930, made by the American Engineering Council, reveals that in that year there were 225,800 who called themselves engineers, forming 0.46 per cent of the total of 48,830,000 gainfully employed. One engineer was listed for every 500 of population, and one for every 210 persons gainfully employed. The distribution of the engineers by professional classes was as shown in Table I. The fact that the total membership in technical societies was but 115,000 in 1929 indicates that minor technicians were probably included in the census total.

Table I.—*Distribution of Engineers in the United States. By professional classes according to U.S. Census of 1930.*

Class	Number	Per cent
Civil	101,946	45.1
Electrical	57,735	25.6
Mechanical	54,264	24.0
Chemical and Metallurgical	3,434	1.5
Mining	8,408	3.8
	225,787	100.0

Table II.—*Distribution of Engineers by Employment Groups.*

Group	Number	Per cent
Agriculture	625	0.3
Forestry	768	0.3
Extraction Industry	7,730	3.4
Communication	13,211	5.9
Public Utilities	13,700	6.1
Building Industry	16,490	7.3
Transportation	29,349	13.0
Industry and Trade	65,383	28.9
Total of industrial groups	147,256	65.2
Government Service	24,890	11.0
Professional and consulting engineers	53,641	23.8
	225,787	100.0

Although 65 per cent of the engineers were listed as employed by industry and commerce, it should be noted that some industries employed practically no engineering talent. From a study of Table II it appears that the future of the engineering profession is still in the field of private industry, and that a real opportunity lies in the development of backward industries.

A profession-wide survey is now under way by the Bureau of Labour Statistics to determine how the status of engineers has changed since the last Federal Census was taken. This census and survey is being undertaken by Dr. Isador Lubin, Commissioner of Labour Statistics, co-operating with national, state and local engineering societies, through the American Engineering Council.

—*Civil Engineering.*

Analysis of Rigid Frame Concrete Bridges

A third edition of "Analysis of Rigid Frame Concrete Bridges" has been published by the Portland Cement Association, and includes the results of recent studies.

In addition to analysis by moment distribution, a new chart and a new formula are given as basis of a procedure by which moments may be determined quickly without use of frame analysis.

A simple method of correcting moments in frames by allowing for deck curvature is presented, and important structural details used in rigid frame concrete bridges are added. There is also a new convenient method of determining stresses in double-reinforced concrete sections subject to combined bending and axial thrust.

The presentation is brief but clear and complete enough to enable engineers of bridges to analyze rigid frame buildings quickly.

Copies of this 40-page booklet are available by writing to the Portland Cement Association, 33 West Grand Avenue, Chicago, Ill.

Ransomes and Marles Bearing Company of Canada Limited announce a change in name to *R. & M. Bearings Canada Limited.* The Company will be located at the same addresses in Montreal and Toronto.

Preliminary Notice

of Applications for Admission and for Transfer

January 25th, 1935

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in March, 1935.

R. J. Durley, Secretary.

*The professional requirements are as follows.—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

COXWORTH—THOMAS WALKER, of 8045 Chappel Ave., Chicago, Ill., Born at Deloraine, Man., Sept. 2nd, 1903; Educ., B.Sc., Univ. of Man., 1926; 1924-26, chief of party on land and subdivn. surveys, W. & A. Smadbeck Inc., New York, N.Y.; 1926-27, field engr. in charge of land, topographic and subdivn. surveys, for same company; 1927 to date, with McClintock-Marshall Corpn., Chicago, 1927-29, in various capacities in fabricating shop and erecting dept., and 1929 to date, asst. engr. in engrg. and estimating depts., in charge of preparation of estimates and designs, and engaged in a variety of problems of an engrg. nature involving the use of struct'l. steel.

FOR TRANSFER FROM THE CLASS OF JUNIOR

CARRUTHERS—CLARENCE D., of 253 Castlefield Ave., Toronto, Ont., Born at Millbrook, Ont., Oct. 10th, 1901; Educ., B.A.Sc., Univ. of Toronto, 1927; 1920-21, jr. dftsman., B. N. Brack, Arch'ts.; 1921-22, jr. clerk of work, Sunnyside Development, Toronto Harbour Commn.; 1923, dftsman., Truscon Steel Co.; Summers 1925-26-27, in charge of small party, Geodetic Survey of Canada, mapping of City of London; 1927 to date, designer, dftsman., with Gordon L. Wallace, M.E.I.C., Consltg. Engr., Toronto, Ont. (*St. 1927, Jr. 1929.*)

References: G. L. Wallace, C. R. Young, F. P. Steers, L. A. Lee, J. Hole.

DAVIDSON—JOHN KNOX, of Buckingham, Que., Born at Stranraer, Scotland, Feb. 1st, 1905; Educ., B.Sc., Univ. of St. Andrews, Scotland, 1926; Passed exams. for A.M. Inst. C.E., London, England, 1928. Elected A.M.I.C.E., 1931; 1926-27, asst. engr. and 1927-28, asst. chief engr., Corpn. Waterworks, Dundee, Scotland; 1928 (May-Nov.), asst. field engr., Sir Robert McAlpine and Sons, Contractors, London, England; 1929 (Jan.-Apr.), asst. to Robert Gibson, consltg. engr., Dundee; 1929-30, detailer, designer and field engr., Dominion Bridge Co. Ltd., Montreal; 1930-31, res. engr. in charge of constrn. of rapid sand filtration plant for City of Brantford, Ont.; May 1932 to date, chief engr., Electric Reduction Co. Ltd., Buckingham, Que., in charge of gen. plant operation and design and constrn. of plant developments. (*Jr. 1930.*)

References: L. H. Burket, W. S. Lea, F. P. Adams, C. A. Waterous.

GRAHAM—WALTER WHITE, of 5746 Charlemagne Ave., Montreal, Que., Born at Glasgow, Scotland, Aug. 29th, 1901; Educ., B.Sc., McGill Univ., 1925; Summers: 1922, rodman on rly. constrn.; 1923, concrete inspr., Steel Co. of Canada, Montreal; on installn. work, La Gabelle development, Shaw. Water and Power Co.; 1925-28, elect'l. and hydro-electric design, Power Engrg. Co.; 1928 to date, elect'l. designer, Shawinigan Engineering Co., Montreal, Que., on design and installn. of equipment, etc., particularly in connection with Rapide Blanc development. (*St. 1923, Jr. 1928.*)

References: S. C. Hill, A. B. Rogers, R. E. Heartz, A. S. Poe, J. A. McCrory.

LAIDLAW—DOUGLAS STAUNTON, of Toronto, Ont., Born at Toronto, Sept. 23rd, 1905; Educ., B.A.Sc., Univ. of Toronto, 1928; 1928-29, inspr., testing lab. and dftsman., hydraulic dept., H.E.P.C. of Ont.; 1930-32, designing dftsman., DeHueck and Mattice, United Engrs. and Constructors and Beauharnois Constrn. Co., Montreal; 1932-34, asst. to John B. Laidlaw, then chief agent for Canada of the Norwich Union Life Assurance Society, supplemented by private practice as a struct'l. engr.; at present, private practice as struct'l. engr. in partnership with Catto and Catto, Architects, Toronto, Ont. (*Jr. 1930.*)

LOVETT—PERCY ARTHUR, of 107 Morris St., Halifax, N.S., Born at Liverpool, N.S., April 17th, 1903; Educ., B.Sc. (E.E.), N.S. Tech. Coll., 1928; 1927 (summer), C.G.E., Peterborough, Ont.; 1928, asst. on N.S. Advisory Board of Fuel Investigation; 1928-30, graduate ap'tice, Canadian Westinghouse Co. Ltd., Hamilton, Ont.; 1930-33, asst. engr., Maritime Tel. and Tel. Co.; 1933, associated with J. R. Kaye, A.M.E.I.C., on consltg., supervision and design work; 1933 to date, consltg. engr. with Engineering Service Co. Ltd., consltg., supervn. and design work. (*St. 1928, Jr. 1931.*)

References: I. P. MacNab, J. R. Kaye, W. A. Winfield, F. R. Faulkner, F. A. Bowman.

FOR TRANSFER FROM THE CLASS OF STUDENT

ARMSTRONG—OWEN FRED CALDER, of 4594 Decarie Blvd., Montreal, Que., Born at Round Hill, N.S., Jan. 26th, 1901; Educ., B.Sc. (Mech.), N.S. Tech. Coll., 1928; 1925 (summer), highway constrn.; 1927 (summer), bldg. constrn.; With Bell Telephone Co. of Canada as follows: 1928-29, student engr.; 1929-31, asst. to divn. traffic engr.; 1931-33, asst. to district traffic supt.; 1933 to date, asst. to gen. employment supervisor, Gen. Traffic Dept. (*St. 1926.*)

References: C. L. Brooks, E. Baty, A. M. Robertson, H. E. McCrudden, F. W. Angus.

COSTIGAN—JAMES PERCIVAL McDOUGALL, of 494 Grosvenor Ave., Westmount, Que., Born at Westmount, Oct. 15th, 1904; Educ., B.Sc., McGill Univ., 1926; With Shawinigan Water and Power Company as follows: Summer 1924, La Gabelle development; 1926-28, power ap'ticeship course; 1928-33, design and supervn. of constrn. of distribution lines, transmission lines, and substations; 1933 to date, design and supervn. of mech'l. and elect'l. equipment of industrial bldgs., T. Pringle & Son Ltd., Industrial Designing and Supervising Engrs., Montreal, Que. (*St. 1925.*)

References: C. V. Christie, R. H. Mather, G. M. Wynn, J. H. Fregeau, G. R. Hale, A. C. Abbott.

GREENWOOD—FREDERICK DWYER, of Timmins, Ont., Born at New Liskeard, Ont., July 14th, 1907; Educ., B.Sc., Queen's Univ., 1931; 1298 (summer), township survey, Nor. Ont.; With Ford Company of Canada as follows: 1929-30 (summers), tool room; 1931 (summer), millwright dept.; 1931-32, designer, tool design dept.; 1932-33, engrg., engrg. dept.; 1933-34, stationary engr., Vipond Mines; Oct. 1934 to date, designer, Hollinger Cons. Gold Mines, Timmins, Ont. (*St. 1928.*)

References: J. E. Porter, W. A. Dawson, L. T. Rutledge, L. M. Arkley, V. W. MacIsaac.

STRIOWSKI—JOHN BENJAMIN, of 230 Arlington St., Winnipeg, Man., Born at Winnipeg, April 11th, 1907; Educ., B.Sc., Univ. of Man., 1929. (Thesis still to be completed for M.Sc.); 1926-27-28 (summers), surveys and constrn. of branch lines, rodman and instr'man., C.N.R.; 1929 (summer), and 1930-31, Northwestern Power Co. Ltd., Winnipeg, dftng., design and detailing of reinforced concrete structures, Seven Sisters hydro-electric power development; 1929-30, demonstrator in civil engrg., Univ. of Man.; 1931-33 (intermittently), with Dept. of Northern Development, Kenora, Ont., topog'r., levelman, transitman on location surveys, also res. engr. on constrn. Trans-Canada Highway. (*St. 1927.*)

References: J. N. Finlayson, A. E. MacDonald, G. H. Herriot, N. M. Hall.

WICKWIRE—LAWRENCE DAVID, of Liverpool, N.S., Born at Milford, N.S., Aug. 24th, 1907; Educ., B.Sc., N.S. Tech. Coll., 1933; 1925-26, lumber checker, elect'ns. helper; 1933 to date, engrg. dftsman., Mersey Paper Co., Liverpool, N.S. (*St. 1933.*)

References: J. H. M. Jones, C. H. L. Jones, F. R. Faulkner, R. L. Seaborne, W. P. Copp.

Worker Unrest in Construction

For three years construction employment has been low. It is still low, and especially in heavy construction a good job ought to be welcome. But it does not seem to be welcome if the strike of a group of workers on the Midtown tunnel in New York is any criterion. The tunnel workers have good hours and wages—PWA hours and wages, in fact,—yet they strike. Wages and working conditions evidently are not the issue.

The contractor says that the strike began without notice or demand and pickets who walk before the shaft carrying "Unfair" signs say that they do not know what union is striking or why. A union representative says that the strike is a protest against the employment of non-union labourers on the job. So the issue seems to be compulsory unionization, with the usual symptoms of regimentation by organizers and threats of a sympathetic general strike.

It is strange that workers strike when they have just found a good job and have no complaint against hours, wages or treatment.

Out of this confusing situation two facts emerge prominently. One is that the extensive new rights granted to labour by the Recovery Act do not include the right to compulsory unionization or the right to deprive non-union men of work. The second is that the course of the NRA officials in dealing with labour relations has been such as to mislead labour into believing that it was given this right and is entitled to fight for it. A third fact ought to be noted with these—namely, that in many of the recent strikes the majority of workers desired to stay at work but were either tricked or intimidated by the minority.

To bring this strike fever to an end is as important to the workers as to industry and consumer. It is at present the most critical essential to continuation of the recovery process. Construction in particular ought to guard itself against the strike habit so that it may continue to perform its essential service of stimulating general recovery of business and industry.

If the present labour difficulties are to be ended, it will come about through steady and sensible firmness on the part of the sound majority of labour, working in harmony with the employers who also in the large majority are seeking for stable and mutually advantageous relations with their employees.—*Engineering News-Record.*

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situations Vacant

DRAUGHTSMAN, with pulp or paper mill experience for work in Northern Quebec. Give full information regarding age, education, experience, etc. in first letter to Box No. 1092-V.

RADIO ENGINEER, under 35 years of age wanted for responsible position in production department of large manufacturing concern. Must be experienced in transformer winding, design of test apparatus, supervision of test procedure and quality control. Apply giving references, education, experience, age and salary expected to Box No. 1100-V.

PURCHASING ENGINEER, man with broad commercial and business experience for purchasing department of large manufacturing concern. Technical experience required. In reply please outline in detail complete experience. Apply to Box No. 1102-V.

Situations Wanted

ESTABLISHED SALES ENGINEER. Univ. of Toronto '24, with plant and manufacturing experience, wishes to represent manufacturers of technical equipment. Connections with automobile and electrical equipment dealers, throughout Canada. Will make small investment if necessary. Apply to Box No. 1-W.

MECHANICAL ENGINEER, Canadian, with technical training and executive experience in both Canadian and American industries, particularly plant layout, equipment, planning and production control methods, is open for employment with company desirous of improving manufacturing methods, lowering costs and preparing for business expansion. Apply to Box No. 35-W.

MECHANICAL ENGINEER, graduate McGill Univ. Experience on hydro-electric power construction and design and installation of equipment of pulp and paper mills. Desires position as mechanical engineer in an industrial plant or pulp and paper mill, or as representative on the sale of heavy machinery. Apply to Box No. 142-W.

PURCHASING AGENT. Graduate mechanical engineer, Canadian, married, age 36, with fourteen years experience in industrial field, including design, construction and operation, eight years of which had to do with the development of specifications and ordering of equipment and materials for plant extensions and maintenance; one year engaged on sale of surplus construction equipment. Full details on request. At present employed. Apply to Box No. 161-W.

SALES ENGINEER, S.E.I.C.; B.Sc. C.E., 1930 (Univ. New Bruns.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ELECTRICAL ENGINEER, B.Sc., A.M.E.I.C., Am.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

CIVIL ENGINEER, B.A.Sc. and C.E.; A.M.E.I.C., Jun. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.Sc. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

Situations Wanted

MECHANICAL ENGINEER, B.Sc. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.Sc., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment. Four summers as instrumentman on surveying and highway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern where the combination of technical and business experience will be of value. Apply to Box No. 564-W.

Employment Activities

The attention of members is called to the reports of The Institute Committee on Unemployment and of the Employment Service Bureau which appear on pages 90 and 91 of the February, 1935, issue of The Journal.

These reports show considerably improved conditions over those reported during the past few years.

MECHANICAL ENGINEER, A.M.E.I.C. Experienced on plant maintenance, steel plant, cement plant and mining plants. Available on short notice. Apply to Box No. 571-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

CHEMICAL ENGINEER, S.E.I.C., B.Sc., University of Alberta, '30. Age 31. Single. Six seasons practical laboratory experience, three as chief chemist and three as assistant chemist in cement plant; one year's p.g. work in physical chemistry; three years experience teaching. Desires position in any industry with chemical control. Available immediately. Apply to Box. No. 609-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL ENGINEER, B.Sc. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box. No. 651-W.

Situations Wanted

ELECTRICAL ENGINEER, Univ. Grad. 1928. Two years Students' apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660 W.

ELECTRICAL AND RADIO ENGINEER, B.Sc. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc., Elec., '29, B.Sc., Civil '33. Age 27. Jr.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.Sc., '27, Jr.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.Sc., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.Sc. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box. No. 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

Situations Wanted

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.Sc. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten years diversified electrical and mechanical experience in the industrial field. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, college graduate, age 27, single. Experience includes surveying, draughting, concrete construction and design, street paving both asphalt and concrete. Available at once; will consider anything and go anywhere. Apply to Box No. 816-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with fifteen years experience mostly in pulp and paper millwork, reinforced concrete and structural steel design, field surveys, layout of mechanical equipment, piping. Available at once. Apply to Box No. 825-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C., age 24. Experience, three summers on railroad maintenance, and seven months on highway location as instrumentman. Willing to do anything, anywhere, but would prefer connection with designing or construction firm on structural works. Available immediately. Apply to Box No. 846-W.

BRIDGE AND STRUCTURAL ENGINEER, A.M.E.I.C., McGill. Twenty-five years experience on bridge and structural staffs. Until recently employed. Familiar with all late designs, construction, and practices in all Canadian fabricating plants. Desirous of employment in any responsible position, sales, fabrication or construction. Apply to Box No. 851-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

Situations Wanted

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box. No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, B.A.Sc. in C.E., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.Sc. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

Situations Wanted

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.Sc., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, N.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box. No. 1127-W.

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.Sc., Queen's '33 Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.Sc., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.Sc., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Write and speak both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211 W.

CIVIL ENGINEER, B.Sc. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

COMBUSTION ENGINEER, A.M.E.I.C., with extensive experience in all phases of combustion engineering, including plant layout, piping, etc. Lately connected with prominent firm of automatic oil burner manufacturers. Apply to Box No. 1224-W.

MECHANICAL ENGINEER, B.Sc. McGill. Experienced as supt. of plant manufacturing home appliances—purchasing of supplies and equipment of technical nature. Plant engineer of works for manufacture of railway equipment and of copper and brass rolling mill and seamless brass and copper tube mill and brass cartridge cases. Designing engineer on special machinery, maintenance engineer, plant layouts. Apply to Box No. 1241-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet and tissues. Apply to Box No. 1246-W.

Testing and Research for the Hydro-Electric Power Commission of Ontario

W. P. Dobson, M.E.I.C.,
Chief Testing Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ontario, February 8th, 1935.

SUMMARY.—The work of the Commission's department of testing inspection and research is described, including the inspection and testing of materials and equipment for the use of the Commission, the investigation of technical problems arising in the Commission's work and the approval of electrical equipment for use under the Canadian Electrical Code.

Practically all large electrical power companies have laboratories which carry on testing and research in varying degrees depending upon the size of the organization. These departments have been established to supply a variety of services, among which are the following:

(*a*) The determination of quality of material and equipment submitted for purchase, and its compliance with guarantees.

(*b*) The application of special knowledge in physics, mathematics and chemistry to practical problems encountered in construction and operation.

(*c*) The control of quality of material and equipment in service by periodic tests and inspections which will detect signs of failure.

(*d*) The furnishing of technical information based on special studies within the capabilities of the equipment and staff.

These demands imply the existence of testing equipment and of a staff trained in test methods and the handling of instruments, and permitted to devote their energies to more specialized and scientific studies than those engineers wholly engaged in the problems of design, construction and operation of power systems. The logical and economical method of providing these services is to centralize staff and equipment in a single department. Hence the existence of testing and research laboratories in power companies. These departments have almost without exception dated from the beginning of the organizations they serve, and their evolution has kept pace with the growth of the parent organizations.

The Testing and Research Laboratories of the Commission developed in a manner somewhat similar to that just outlined. Shortly after the Commission completed its original construction programme and began supplying power, equipment for testing lamps was installed in the Strachan avenue terminal station. This was in 1911. The intention of the Commission was to assist the municipalities in the purchasing of lamps, and this activity has continued to be an important function of the department. From this beginning the department has grown and now occupies about 29,000 square feet in the service building on Strachan avenue. A wide range of equipment is available for making electrical, physical, chemical, metallurgical and photometric tests. Many parts of this have been developed and constructed in the laboratory. The work of the department is not confined to the laboratory, but the duties of the staff take them on occasions to all parts of the systems.

The first duty of the department is to furnish a testing and inspection service to the other departments of the Commission and to the municipalities. The Commission has always followed the general policy of making important purchases in accordance with strict specifications, and it is the task of the laboratory to determine whether or not material and equipment submitted for purchase conforms with the requirements of the specifications. The services of the laboratory are also demanded in connection with the maintenance of equipment and the operation of the systems, and a large portion of the routine testing is at present concerned with operating problems.

During periods of active construction, the work naturally increases in volume. This portion of it, however, varies from year to year depending upon the amount of construction work under way. The portion arising in operating problems, however, is of a more permanent character and shows a steady growth from year to year. This is fortunate since it enables the department to retain a minimum permanent staff thoroughly conversant with the organization and its methods of operation. The value of this is self-evident.

The research work carried on has a distinctly practical aspect, since it is concerned of necessity with problems which arise in the construction and operation of the Commission's systems. Problems of a purely scientific nature are left to universities and scientific institutions. Even with these limitations, however, its scope is sufficient to embrace a wide field in engineering theory and practice and in the properties of materials.

Demands are continually being made upon the department to furnish information of a scientific nature, and it thus serves as a clearing house for the different departments in the interchange of technical information beyond the scope of ordinary requirements.

The functions of the department may thus be briefly stated by saying that it is required to assist the Commission in securing material and equipment of good quality, in maintaining this equipment in good condition after it has been installed, and in furnishing a variety of services of a specialized character. At the same time, it has an executive standing based upon the policy of the Commission in co-ordinating activities connected with testing and research within one department. Thus the testing and inspection of materials is carried on only by the Laboratories, and the research work carried on in the Commission is under the direction of the department.

Fig. 1—Service Building, Strachan Avenue, Toronto.

The Approvals Laboratory

The department carries on another important function not directly connected with the construction and operating problems of the Commission. This is the approval testing of electrical equipment which is complementary to the inspection of electric wiring and installations carried on by the Commission under Section 80 of the Power Commission Act. No attempt will be made here to describe this work in detail. It involves laboratory testing, inspection in factories, and a great deal of field work in checking the quality of electrical appliances sold to the public. It was undertaken by the Commission as a matter of necessity about sixteen years ago. The regulations of the Commission required that such materials and equipment should conform to a minimum safety standard and this involved the testing of the equipment. The only organization then furnishing a testing service of this kind was Underwriters' Laboratories of Chicago, and since its approval was not obligatory in the United States much equipment of American origin offered for sale in Ontario did not bear its approval. The Commission accordingly decided to make use of its existing laboratory for the purpose of controlling the quality of this equipment. The work was carried on essentially in the same manner as by Underwriters' Laboratories, and its effects were soon apparent in the improvement in safety characteristics of equipment offered to the public of Ontario. The commencement of the Commission's activity in this connection synchronized with another movement which was destined to prove of great importance to the electrical industry of Canada. The demand for a uniform set of rules governing electrical wiring and installations which would be acceptable all over Canada resulted in the organization of a committee under the auspices of the Canadian Engineering Standards Association—then recently formed—to prepare such a set of rules. This resulted in 1927 in the appearance of the first edition of the Canadian Electrical Code. Following this legislation was passed in all provinces of Canada providing for provincial control of the inspection of electrical installations and in many cases also the control of the sale of appliances to the public. The last province to enact such legislation was Prince Edward Island in 1932. These regulations involved the approval of appliances and the Code accordingly defined "approval" and recognized Underwriters' Laboratories, the Laboratories of the Hydro-Electric Power Commission, and a Dominion government laboratory when such should be established. The adoption of the Canadian Electrical Code produced an increased demand upon the services of the Commission's Approvals Laboratory, and following the withdrawal in 1932 by Underwriters' Laboratories of its electrical testing service from Canada all Canadian manufacturers of electrical equipment since have made use of the Commission's service. The National Research Council has established research laboratories in Ottawa and has been requested by various provincial departments to set up safety standards and to approve apparatus. The question of the future of the electrical approval testing work is now under discussion between the Council and the Commission.

The procedure followed by a manufacturer in obtaining approval involves the submission of representative samples of his product to the laboratory, where they are examined to determine compliance with specifications in which minimum safety requirements are set forth. When the laboratory is satisfied that the equipment conforms with the specifications, a report describing the equipment and the tests, and recommending approval, is prepared and circulated to a committee of about thirty members located in all parts of the country and including electrical inspectors, underwriters, contractors, fire marshals, engineers and others interested in the enforcement of safety regulations and competent to pass upon the reports. Upon the acceptance of the recommendations of the laboratory by the committee, the equipment is listed as approved. The manufacturer then signs an agreement with the laboratory whereby he undertakes to manufacture the product approved in duplicate of the sample submitted, and to permit the laboratory to make periodic inspections in his factory in order to determine whether or not this is being done. The laboratory publishes a list of approved equipment and circulates it to all inspection offices in the country and to officials connected with the enforcement of sales control regulations. The specifications governing the tests were formerly prepared by the laboratory in co-operation with the manufacturers, but this work is now being done under the auspices of the Canadian Engineering Standards Association by committees composed of laboratory representatives, manufacturers and others. The Canadian Engineering Standards Association issues the specifications, which are then adopted by the laboratory and enforced in the same way as the provisions of the installation rules of the Canadian Electrical Code. The cost of the approval service is borne by the manufacturers in the payment of fees both for approval testing and for periodic re-examination. Approved equipment may be identified either by labels supplied by the laboratory or by reference to the approved list of equipment.

This brief summary describes only the principal features of this work, which entails a vast amount of detail both in testing and inspection, and in the keeping of records. The last edition of the list of approved equipment contains the names of fourteen hundred and forty-three manufacturers located in Canada, the United States, Europe and Japan.

Testing and Inspection

The nature of the testing and inspection work has been indicated above, and a large portion of it is connected with routine operations and special problems encountered in maintenance and operation. During the fiscal year ending October 31st, 1934, over forty-six thousand tests were made in the laboratories including electrical, chemical, physical, mechanical and photometric. During the same period the factory inspection included steel for all purposes, transmission line conductors, turbines, generators, transformers, circuit breakers, and other equipment. The examples given below have been chosen as typical of

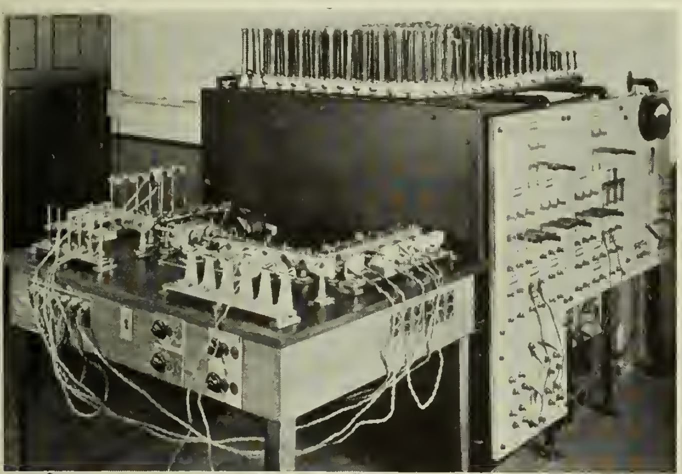

Fig. 2—Machine for Making Endurance Tests on Sockets, Switches, etc.

the method of carrying on the work of testing and inspection and will indicate its extent. It should be pointed out that an effort is continually being made in this work to maintain a proper economic balance, and that the completeness of the inspection depends upon the size of the equipment or of the development, and the decision to inspect a particular item is reached after consultation with the Engineering Department having due regard to the cost of the equipment, its importance in the scheme of operation, and the consequence of its failure in service. Accordingly, it is often necessary to inspect a very small and apparently insignificant item of equipment, because its failure in service might involve the shutting down of a huge generator for a considerable period of time, and the consequent loss of revenue to the Commission or the interruption of service to a large section of the community. This, of course, must be avoided as far as humanly possible. On the other hand, relatively large items are sometimes accepted without complete inspection. This acceptance is based on the department's knowledge of conditions in the shops as well as upon other factors, such as the exigencies of the construction programme.

In the construction of power developments both mechanical and electrical equipment is required in large quantities.

The department first assists the Engineering Department in the preparation of specifications, particularly in matters involving the properties of materials or characteristics of equipment. The fabrication of the equipment is followed as closely as possible in the shop and when the development is large enough to warrant it, inspectors are stationed in the shops.

Turbines and generators require close and detailed inspection covering all phases of manufacture and erection from the time the castings and forgings are made until the machines are finally assembled and ready for service. This work calls for the services of experts thoroughly trained in the actual inspection and intimately acquainted with the conditions under which the machines will be used.

An inspector is present to witness the behaviour of the metal during the pouring of castings and the forging of ingots for runners, frames, bearing brackets, shafts and other large sections used in powerhouse units. Later, these are examined in the "green" condition and also after annealing and heat treating to detect cracks, slag holes and similar defects. Physical tests are made in the manufacturers' shops and samples of the metal are given microscopic examinations at the laboratory to determine the character of the crystal structure. Important machining and welding operations are carefully scrutinized and rigid checks on shaft dimensions and alignment are required before release is granted for shipment to the field.

Circuit breakers and transformers are similarly inspected in the shop to ensure that they are electrically and mechanically perfect. This involves inspection of tank welds, checking of dimensions, dielectric tests and frequently the determination of speed of operation.

The final acceptance of a generating unit is based upon tests made after erection. A field acceptance test on a large unit is an engineering project of some difficulty and of great importance, requiring a staff of engineers and assistants and often consuming several weeks. It includes the determination of turbine and generator efficiency and of temperature rise under load; the application of specified dielectric tests to the generator insulation; the observation of performance under overspeed and sudden short circuit conditions; and the application of many other tests designed to reveal any defects still existing in the equipment.

The procedure of the Commission in inspecting concrete has been described in a number of papers by members of the laboratory staff. It is in outline as follows: When a power development is projected the laboratory is instructed to recommend a suitable source of building materials. This involves a search in the neighbourhood of the development and a survey of available deposits of sand and gravel. Test pits are sunk, samples secured and tested at the laboratory. When a suitable source has been acquired, preliminary proportions for the concrete are set by laboratory tests and an inspector trained in laboratory methods is stationed in the field and provided with a field laboratory and the necessary testing equipment if the job

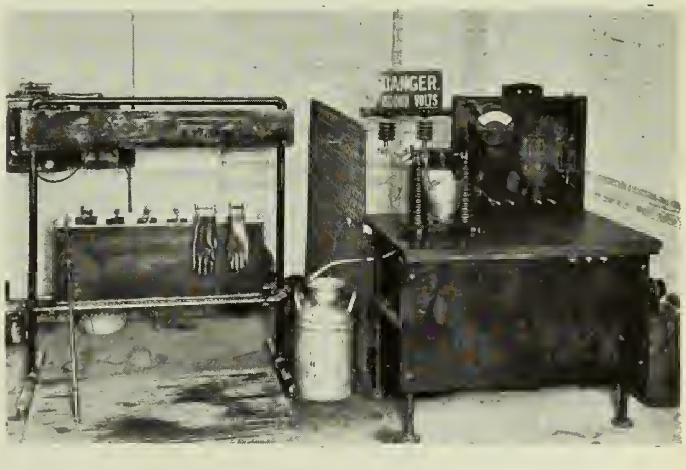

Fig. 3—Equipment for Testing Rubber Gloves and Transformer Oils.

is large enough to warrant this expense. The inspector follows all the operations of mixing and placing the concrete and of testing its quality from time to time in order to obtain compliance with the strength requirements set by the design department.

Inspection of concrete does not cease with the completion of a new structure. All the concrete structures of the Commission are inspected by an expert from the laboratory every two years and a complete record of these inspections is embodied in reports in which necessary repairs are recommended. The Commission's investment in concrete structures is many millions of dollars, and this inspection is considered essential to the proper maintenance of these structures.

The service rendered by the laboratory in controlling the quality of materials in use is well illustrated in the cases of linemen's gloves, oil, and paint.

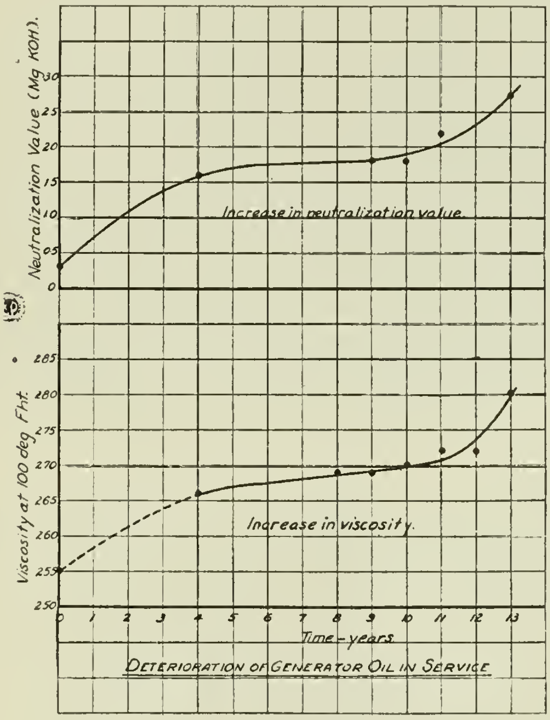

Fig. 4—Deterioration of Oils in Service.

Gloves are purchased under rigid specification and every glove passes through the laboratory not only at the time of its purchase but periodically thereafter, in accordance with a programme determined by the Accident Prevention Department. New gloves are examined and accepted only on the basis of compliance with the specifications. They are shipped from the laboratory after test in special containers bearing laboratory labels. Periodic retests are not as elaborate as the acceptance tests; they involve the application of high voltage (10,000 volts for one minute) and a visual examination. Frequently a glove is rejected even though it passes the high voltage retest, because of mechanical defects which in the judgment of the inspector would involve a hazard to the user and probable failure in the near future.

Oil is used in transformers and circuit breakers, both as an insulating medium and a cooling agent. Its insulating properties are seriously affected by even slight traces of moisture and other impurities. It is also affected in a way not thoroughly understood by high temperatures and by electric stress. It is of extreme importance that its quality be maintained and that evidence of failure be detected before it has proceeded far enough to endanger the equipment. The Commission endeavours to maintain the quality of oil by making monthly dielectric tests on samples carefully selected from all high tension transformers and circuit breakers. The laboratory makes over five thousand tests a year. If moisture or impurities are detected the equipment from which the sample was taken is removed from service and the oil filtered. Supplementing these monthly dielectric tests, a survey of the oils in all high tension transformers is made every three or four years. Samples are tested for acidity, sludge-forming properties and resistance to emulsification, and recommendations made to the Operating Department as to the necessary treatment to restore the oil to operating condition. This procedure is yielding a great deal of information not only on the properties of insulating oil but on the changes which take place in it when subject to operating conditions in transformers and circuit breakers. This subject is very complex and is being given international attention through the efforts of standardizing bodies, such as the International Electrotechnical Commission and the American Society for Testing Materials, in which power companies and purchasers of oil are co-operating in the endeavour to devise reliable tests which may be used to form the basis of specifications covering these qualities. The Commission's laboratory is assisting in this work and as a result of its contacts with these organizations, benefits by the experience of a very large group of oil producers and users.

Lubricating oil used in turbines and generators is subjected to a similar system of control. It is purchased under specifications prepared by the Engineering and Laboratory Departments in co-operation. Its quality in service is determined by annual check tests. Careful attention is paid to acidity, viscosity, flash and fire points and resistance to emulsification. These periodic tests indicate the chemical changes, if any, which will result in deterioration. Figure 4 shows the result of such measurements extending over a period of years and indicates clearly the deterioration of the oil. The determination of the point at which it must be removed from service or treated is a matter of some importance, and recommendations from the laboratory to the Operating Department are based upon these tests.

Paint is an important material used in practically all of the Commission's structures. There is probably no material to which the saying "you get what you pay for" applies with greater force. The laboratory has been studying paints for over fifteen years and when the work was undertaken first there was no method whereby paints submitted for purchase could be quickly compared and a decision formed as to the most desirable. The method then commonly used was to expose samples to conditions duplicating as nearly as possible those which the paint

Fig. 5—Weather Meter for Paint Testing.

would encounter in service. The first step therefore was to set up a rack on the laboratory roof on which were mounted slabs of steel, concrete or wood, painted with samples of the products of various manufacturers. The exposure tests were supplemented by chemical analysis of the paints. Proceeding in this way it was found possible to obtain comparative information on the products of various manufacturers and a system of purchasing paints was worked out in which the laboratory co-operated with the Purchasing Department and with the field. In ordering paints under this system the manufacturer's name is not specified, only the application—for example, concrete floors, steel penstocks, transmission towers, etc. From a list supplied by the laboratory the Purchasing Department chooses satisfactory sources of supply. A committee containing representatives of the Laboratory, Purchasing, Engineering and Operating Departments direct this work in a general way, correlating laboratory tests and field experience. Progress in test methods made within recent years permits obtaining a quick appraisal of the relative merits of various paints for any particular service by means of the weatherometer, a device capable of applying an accelerated life test. The co-operation of the manufacturers of paint has been very helpful in all of this work.

The examples given above have been chosen with a view to illustrating the methods employed by the Commission in determining and controlling the quality of materials. These methods are being extended as rapidly as possible to new materials and they are indicative of the general trend in engineering practice, perhaps insufficiently realized but nevertheless of tremendous importance, viz., the increasing use of laboratory methods. The success of these methods depends, of course, on the invention of tests which will give reliable information concerning the qualities of materials. Not only must these tests be reliable but they must yield information quickly. Accelerated life tests are of particular importance. The development of tests and test methods is a matter for research supplemented by field experience and is work which makes the greatest demands both upon knowledge of the properties of materials and skill in testing technique, and can be carried out successfully only by the co-operative effort of a large group. A survey of the proceedings of organizations such as the American Society for Testing Materials or the International Electrotechnical Commission, as well as the national standardizing institutions in different countries, will indicate the extent of this co-operative effort and the rapid advance which is being made in this field.

Visual inspections by "trial and error" methods were never satisfactory even to the intensely practical man, and are gradually being supplanted as laboratory methods are developed and as confidence is built up in the efficacy of these methods.

Research

The practical nature of the research work carried on in the Commission has been indicated earlier in this paper. The examples which follow have been chosen to illustrate the method of attacking these problems and the limits within which the Commission confines itself. The necessity for close co-operation between laboratory and field staffs is as great as in the case of routine testing and this was taken into account in devising the method of carrying on this work which is now in operation.

A research committee composed of five department heads gives general direction to investigational work. It appoints sub-committees to undertake particular investigations and gives general guidance to their efforts. Each sub-committee contains representatives of the laboratory and of such other departments as may be interested in or capable of assisting the research in question. At the present time ten sub-committees are active.

One of these sub-committees is studying the vibrations of transmission line conductors—a question which is agitating the minds of power transmission engineers and executives all over the world. This phenomenon became apparent only within recent years, following the adoption of longer spans (and consequently higher mechanical tensions) in an effort to reduce the cost of transmission lines. Under certain conditions the conductors vibrate rapidly and eventually fail by fatigue. Millions of dollars have been spent in research and numerous devices have been developed to protect the conductors against the vibrations, but no finality has yet been reached. When the sub-committee began its work the need of improved means of observing and recording the vibrations was quickly apparent and its first efforts were devoted to developing equipment for this purpose. A method has been successfully applied whereby information about the vibrations may be obtained on an oscillograph record. This permits a determination of the bending and stress in the conductor caused by vibration and of the relative merits of vibration absorbers. The solution of the problem of vibration is of immense economic importance to the power companies since it will remove one of the present limitations to conductor spans and will tend to reduce the cost of transmission lines. It is felt that a contribution of value has been made by the work of the committee.

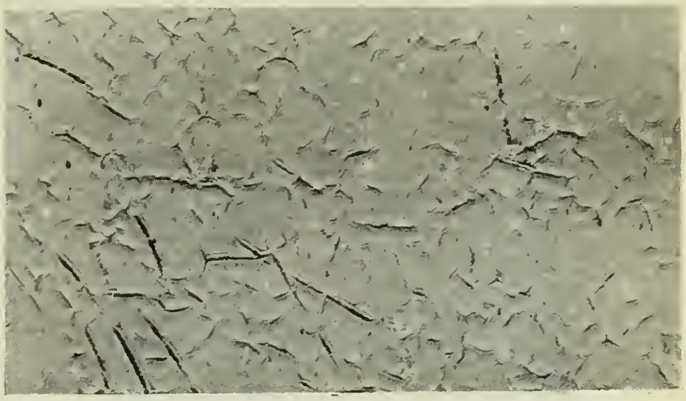

Fig. 6—Sample of Paint taken from Weather Meter.

Another sub-committee is studying wooden transmission structures, having in view the development of means of lengthening the life of such structures. This work involves comparative tests on preservative materials, systematic and detailed inspection of poles in service, the installation and observation of test beds in soils of different types, and the recommendation of measures for the prevention of decay.

Many suggestions have been made to the Commission for the utilization of off-peak power. Some of these, particularly several involving the production of gases by electrolysis, have been studied by the committee.

The application of electric heat to soil has been shown to promote plant growth. This offers an attractive load to power companies, particularly in greenhouses. A sub-committee is studying this subject and has obtained very encouraging results in co-operation with growers and manufacturers of equipment. A good deal of scientific work must still be done to determine the most efficient method of applying the heat, and the co-operation of botanists is being sought.

Other sub-committees are studying insulating and lubricating oils, paint, the efficiency of electrical cooking appliances, methods of remote control of loads, and electrical insulation.

The Commission's water heater campaign introduced a problem in the development of a cheap thermostat capable of breaking a current of 25 amperes. The laboratory in co-operation with a manufacturer succeeded in developing such a device. Studies of thermal insulation, heater efficiencies, etc., in connection with the same question resulted in the obtaining of a high grade electric water heating system at a much lower cost per unit than was possible at the commencement of the campaign.

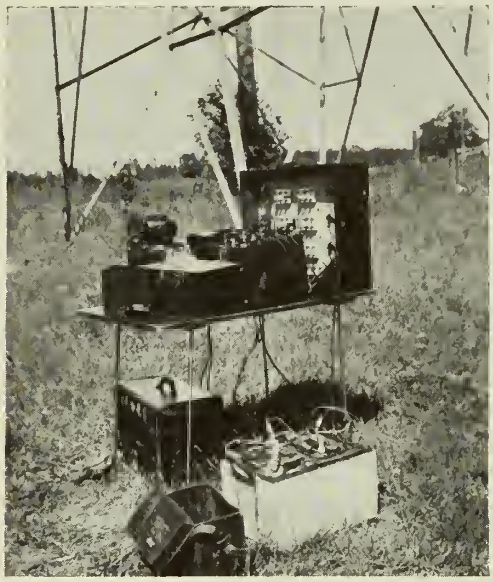

Fig. 7—Equipment for Studying Vibrations of Transmission Line Conductors.

The development of equipment, while not primarily the concern of a power company, is sometimes necessary for various reasons—technical and monetary. Equipment for a specific purpose may not be available at a price which would warrant its purchase, and on the other hand someone on the staff may suggest a solution which appears feasible and economical. Many such cases have arisen in the Commission's history for which solutions have been found. One of the first was a method of testing defective insulators on live lines. Much work has been devoted also to means of indicating and recording abnormal voltages on high tension lines. One of the most recent developments was carried on in co-operation with a manufacturer and resulted in a potential device adapted to 110-kv. and 220-kv. lines. The cost of this, as produced by the manufacturer, is less than one-tenth of the cost of available standard equipment for similar service. While the latter equipment would furnish more information than the device developed—in fact more information than needed—the consideration of price and space occupied rendered its use uneconomical. This is an example of research suggested by a requirement which existing equipment failed to meet economically.

The research work brings the laboratory into contact not only with other departments but with outside organizations. Problems involving the Commission with communication companies arise when power and communication lines run parallel to one another with relatively small separation. The solution of these problems of inductive co-ordination often involves special testing and theoretical investigations. Other troublesome questions often arise when radio owners in the neighbourhood of high voltage lines complain of poor reception. The laboratories have co-operated with the communication companies and the Federal Radio Branch of the Department of Marine in investigating many of these problems.

The department also assisted the Banting Research Institute in an extensive research on the effects of electric shock; its particular part in this investigation being the development of precise methods of controlling the application of electricity.

The investigation of operating problems can scarcely be classed as research, although in many cases it involves the application of mathematical analysis and advanced experimental methods. The failure of equipment often presents problems which demand the application of high technical skill. The cause of failure may be an abnormal stress upon the equipment or a weakening of the equipment material owing to defective design or construction, so that it is unable to withstand the normal stress of operation. These studies often involve the application of the keenest analysis.

The development of research in power companies within recent years is the result of the recognition of the necessity of supplementing investigational work in the development of new equipment by field studies. The greater part of engineering research has in the past been carried on by manufacturers and perhaps in amount it still exceeds that conducted by power companies. In a certain sense the power systems become experimental laboratories for the manufacturers, since progress in the design of new equipment depends upon the observation of its behaviour under operating conditions and detailed knowledge of these conditions. A commercial organization, however, must of necessity have a point of view somewhat different from that of a power company. It is required to show a profit and it cannot carry on research in any line indefinitely without producing something of marketable value. The power company then is frequently under the necessity of choosing between competitive products developed in different research laboratories and submitted as solutions of its operating problems. For these reasons power companies have been forced to carry on research on their own account.

It follows from the considerations which have been presented that testing and research are inseparably connected. The Testing Laboratory even in its routine work encounters problems to which the methods of research must be applied for solution. New test methods must be devised and existing methods must be improved. Testing technique must keep pace with advances in engineering practice, and with the production of new materials and equipment. Thus the problems of routine testing give rise to research and on the other hand, research can only be carried on by making use of routine test methods. In fact, the two are interdependent.

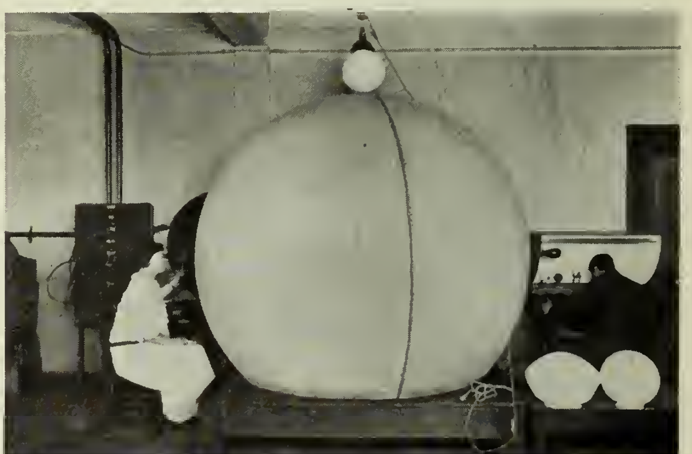

Fig. 8—Integrating Sphere Photometer.

VALUE OF THIS WORK TO A POWER COMPANY

The value of a department, such as has been described, is manifold:

(*a*) It saves money for the organization both in capital cost and in maintenance and operation. In the purchasing of equipment and material a proper balance between price and quality can be obtained in no better way than by following the methods which have been outlined. Certainty, of course, is not attainable, but many uncertainties are resolved, and as test methods are developed and applied more widely the advantage of purchasing in this way will become more apparent. Not only do these methods save money in capital but they also reduce maintenance costs, for it follows that the better the quality of equipment the longer will be its life and the less the cost of its maintenance.

(*b*) Improvement in service naturally follows from the adoption of methods which will improve material and equipment.

(*c*) The laboratory exercises a preventive and protective function which is perhaps one of its intangible advantages and may be called "Preventive Engineering." Although it cannot promise perfect health and indefinite life to equipment any more than preventive medicine can make a similar promise to human beings, yet it is undeniable that important benefits follow the sound application of these methods in the former as well as in the latter case. While definite savings cannot always be estimated or pointed out, there are cases in which this can be done. It is known, for example, to mention a few cases, that several hundred thousand dollars were saved in concrete materials on the Queenston and Chats Falls jobs as a result of laboratory control; that the assistance rendered the Operating Department in connection with painting has produced definite reduction in maintenance costs; that the co-operation of the laboratory and municipal departments in the water heater campaign effected savings in the supply of water-heating equipment; that the recommendations of the Chemical Laboratory for the painting of steel penstocks on one of the Niagara plants reduced the maintenance of these to practically nothing over a period of nine years; that the Chemical Laboratory developed a dressing for tree wounds, which effected a saving of several dollars a gallon over that previously obtainable.

(*d*) The value to an organization of an accumulated fund of information directly applicable to its problems and the skill of a staff trained in its service and familiar with its operation is more than an intangible asset. It becomes in case of emergency a real factor in providing a remedy unobtainable from any outside agency.

(*e*) The centralization of testing and research facilities in a single department has many advantages; it avoids duplication of staff and equipment and provides a specialized service not otherwise obtainable at the same cost.

The cost of the service rendered by such a laboratory is negligible in comparison with the benefits, tangible and intangible, which it returns. It is necessary, however, that the equipment and staff to be of maximum value must be adequate to supply a varied service. This involves a fairly large capital expenditure and can be undertaken only by a moderately large company. It is not necessary thereby to duplicate research facilities existing in universities or in national research institutions. The necessity for familiarity with the organization and its operating problems places a limit upon the direct assistance which can be expected from such institutions. Every effort is made, however, to co-operate with research institutions, so that purely scientific problems may be referred to the proper authorities and the results made available. The power company may suggest problems in pure science the solution of which may have a wide application and the maximum benefit is thus obtained from the union of research in pure science and in engineering.

Report on Tenders and Contracts for Public Works

from the

Council of The Engineering Institute of Canada

to the

Canadian Chamber of Commerce

Montreal, January 1935

Gentlemen:—

The following report has been prepared in response to a request from you for recommendations and comments as to the practice which is desirable as regards the calling of tenders for public works, the manner in which these tenders are dealt with, the interpretation given to contracts in operation, and the inspection and final acceptance of public works carried out by contract.

The report is based upon the findings of a committee appointed by the Council of The Institute, composed of the following five members, two of whom are public officials, two officers of contracting organizations, and one an engineer in consulting practice:—

Chairman—R. E. Chadwick, M.E.I.C.,
President, The Foundation Co. of Canada, Limited, Montreal.

Members —W. E. Bonn, A.M.E.I.C.,
Engineer, Canadian Dredging Company, Limited, Toronto.

Lieut.-Colonel C. S. L. Hertzberg, M.E.I.C.,
Harkness and Hertzberg, consulting engineers, Toronto.

Dr. O. O. Lefebvre, M.E.I.C.,
Chief Engineer, Quebec Streams Commission, Montreal.

D. W. McLachlan, M.E.I.C.,
Engineer, Department of Railways and Canals, Ottawa.

This committee (referred to hereinafter as our committee) has dealt with the subject under two general headings, namely:—

I. The practice as regards the calling of tenders for public works and the manner in which these tenders are dealt with.

II. The interpretation given to contracts in operation and the inspection and final acceptance of public works carried out by contract.

I. Practice as Regards the Calling of Tenders for Public Works and the Manner in which these Tenders are Dealt With.

(1) *Advertising for Tenders.*

In general the present practice in Canada is to call for tenders for public works by advertisement in the daily newspapers of the locality in which the work is to be executed, and in the daily newspapers of the principal cities and in the technical press.

Our committee is of the opinion that in advertising for tenders a great deal of unnecessary expense is incurred through the widespread and repeated publication of advertisements in newspapers that do not in the ordinary course of events reach prospective tenderers. Our committee is of the opinion that where the call for tenders is advertised, sufficient publicity would be given if the advertisement appeared only once in the technical press and in the daily press of the locality and of the capital city of the province in which the work is to be done, including, in the case of the province of Quebec, one French and one English newspaper.

(2) *Selection of qualified bidders.*

Under the existing general practice of calling for tenders for public works in Canada, no serious attempt is made to eliminate tenders from irresponsible contractors, contractors obviously lacking the equipment, organization and skill necessary to carry out the work, and so-called "brokers" who contemplate subletting the work to others in the event of their tenders being accepted by reason of being the lowest submitted. Our committee is of the opinion that tenderers should be restricted to bona fide firms and corporations regularly established in the construction business and controlled within the British Empire for some period commensurate with the importance of the work.

In the case of important engineering works the practice of calling for tenders by public advertisement without requiring evidence of qualification on the part of prospective bidders appears to be a practice established principally in the United States and Canada. The British practice appears to be to call for tenders for important works from a selected list of regularly established British contractors only, who have previously satisfied the authorities that they have the equipment, personnel, experience and financial backing necessary to carry out successfully the work contemplated.

Our committee recommends that a similar system be adopted in Canada in the case of important public works, more particularly in the case of engineering works where a substantial proportion of the cost is represented by work that is underground or under water. It is believed that such a system would result in a higher grade of workmanship at an ultimate cost to the public substantially less than that realized under the present system. Our committee points out that in requiring prospective bidders to submit proof of competency our public authorities would be following well established business principles, and what would appear to be established public practice elsewhere than on the American continent. Our committee observes that the practice of calling for tenders from a list of qualified contractors as suggested, has already been followed with marked success, in the case of important contracts, by some of our public bodies.

It must be recognized that the general practice of restricting tenderers to a selected list of contractors could probably succeed in Canada only if actively supported by public opinion and by the representative engineering or contracting organizations such as The Engineering Institute and the Canadian Construction Association. Otherwise, and without this support, the selection of bidders would doubtless tend to be based on political considerations rather than on merit and an honest desire to secure skilfully executed work at the best possible price.

In order to avoid any possibility of personal influence, the selection for the lists should be made and the lists drawn up by public departments or by such organizations as those just named. Provision should also be made for the addition to these lists from time to time of firms whose standing and resources have developed so as to justify their inclusion.

One member of our committee did not endorse the above in its entirety and his views are submitted in the footnote below.*

(3) *British Empire Organizations.*

Our committee believes that tenders for public works in Canada should be accepted only from bona fide contracting organizations controlled within the British Empire, but recognizing the difficulty of establishing the domicile of the real owners of an incorporated company, suggests as a further condition of qualification that the tenderer be regularly established within the Empire for some length of time commensurate with the importance of the work.

In this connection attention is called to the recent regrettable decision of the Colonial Office, London, restricting tenders for certain harbour work in Trinidad to United Kingdom contractors and declining to permit Canadian contractors to submit proposals for the work.

While recommending that tenders be received only from British Empire organizations, our committee wishes to go on record as being opposed to the practice of certain municipalities in restricting tenderers for important work to contractors of that particular city only. A restriction of this kind is comparable to a customs duty protecting a manufacturer and it does not appear to be in the public interest to set up trade barriers within the limits of the Dominion itself.

(4) *Adequate preliminary investigation needed.*

Our committee remarks that, in the case of construction, a substantial portion of the cost of which is represented by work that is underground or under water, the plans and specifications upon which tenders are asked often fail to give sufficient information in the way of soundings and borings to enable a contractor to submit an accurate tender. Our committee considers it a duty of the authority calling for tenders to have made a proper engineering investigation of the site of the work, including sufficient borings to determine as accurately as practicable the nature of the soil and the subsurface conditions, and that it should be recognized that the tender is based on the information furnished. Suitable provision should be made in all lump sum contracts for adjustment in price either as an increase or decrease, as the case may be, in the event of the level of rock varying from that indicated.

Our committee believes that lack of proper preliminary engineering investigation, borings, etc., increases in the aggregate the cost of public works in Canada by a very large amount, and often leads to unnecessary and costly "extras."

Our committee calls attention to the custom of inserting in public works' contracts various clauses under which the contractor is required to declare that the contract is

* A dissent from the recommendation of the majority of the committee that tenders for public work be restricted to a previously prepared list of approved contractors as outlined in Section I (2) was recorded by Mr. McLachlan. He believes dark horse bidding tends to keep contract prices from becoming unduly high.

He believes barriers should not be thrown in the way of new contractors if they have sufficient financial resources and can show a reasonable procedure for securing the plant and personnel required for the proper execution of the work.

He also believes the statement of the majority as to British practice conforming with their proposal is too sweeping.

based solely on information which he himself has obtained, and that he has not relied upon the borings, tests, surveys, plans, profiles and specifications furnished by the engineer. It is an economical and, in many cases, a physical impossibility for each contractor tendering to duplicate the investigations, borings and surveys of the designing engineer. To do this would add substantially to the cost of construction generally. It does not appear to be in the public interest to ask a contractor to make a declaration in his tender that is not in accordance with the facts, and it is obvious that a contract based on a false declaration leads to claims, extras and litigation, and ultimately increases the cost of our public works. It is obviously necessary that a contractor, before submitting a tender, be required to visit the site of the work and to ascertain for himself the conditions under which the contract must be carried out, and our committee believes that he should be required to make a declaration to this effect.

(5) *Unit price contracts.*

Construction contracts for public works are usually based on a lump sum price for a specific piece of work, with or without provision for increases and deductions, or on a schedule of unit prices for each particular class of work. Either of these types of contract is satisfactory, and the general practice is to use the lump sum form of contract for building work and the unit price form for engineering work in which the exact quantities cannot be accurately predetermined.

Disputes occasionally arise in connection with the award of unit price contracts where through a clerical error the extensions or totals do not check with the quantities and unit prices. In this matter our committee is of the opinion that where an error is made the unit price should be held to be binding and the error in extension and in the total should be corrected, and that to avoid any possibility of dispute the instructions to bidders should state clearly that this rule will be followed.

In the case of unit price contracts involving excavation to any considerable depth below water level or ground level, our committee is of the opinion that the basic price for excavation should be for work to the expected depth, and that there should be a scale of prices for extras and deductions that vary according to the depth to which they are to apply. Otherwise no tender can be said to be "balanced" so far as the excavation items are concerned. The cost clearly increases with the depth, and without a differential scale a variation in depth results in either a loss or an excessive profit to one or other of the parties to the contract, whereas the intention of the unit price contract is that each and every item of work shall be rated at a price that will permit of changes in quantities being made without undue advantage to either the contractor or the public.

Our committee is of the opinion that it should be stipulated in all unit price contracts that tenders must be "balanced," meaning that each unit price must be reasonable in comparison with all others in the same tender. Under this restriction a contractor is barred from quoting a low price on items of work that he thinks may be increased, with the intention of showing the lowest possible figure for the total amount on which the contract is awarded. The principle of unbalanced bidding can be and has been used, through fraud and collusion on the part of the engineer and the contractor, to award contracts to tenderers that are not in fact the lowest bidders. All specifications or instructions to bidders on unit price contracts should contain a clause to the effect that bids which in the opinion of the engineer are unbalanced will be rejected and that this rule should be enforced, even though it results in the acceptance of a higher tender.

It is recommended that in the case of all unit price contracts, the tender form clearly state the engineer's estimate of the quantity of each class of work, and that the several tenders be compared on the basis of these quantities. While this is the practice generally followed, it is not universal. Our committee is of the opinion that the omission of the bill of quantities from the tender form encourages "unbalanced" bidding and collusion.

Our committee goes on record as condemning the practice of including in tender forms prices on alternative types of construction or equipment to an extent that may give rise to doubt as to which of two tenders may in fact be the lower, and which could result in a summation unduly favouring some one contractor. Where alternatives are considered necessary complete plans should in all cases be prepared by the engineer.

(6) *Guarantee that contract will be signed.*

It is necessary that there be some form of guarantee that a bidder, if his bid be accepted, will enter into a formal contract for the execution of the work. The practice as regards the form of this guarantee varies, some public authorities requiring a bond commonly known as a "bid bond," others a certified cheque on a Canadian chartered bank, and others the deposit of securities in the form of bonds of the authority calling for the tenders. In some cases some combination of two or of three of the above types of security is required.

Our committee recommends as the most satisfactory form of security the certified cheque, and is of the opinion that the so-called "bid bond" is not desirable on the ground that it could probably be enforced only after protracted litigation.

Attention is called to the practice of certain of our public authorities of cashing or depositing to their own account bid cheques submitted by contractors as guarantees that they will enter into a contract. This practice should be discontinued. In the opinion of our committee no public authority should appropriate to its own use moneys so deposited.

(7) *Delays in awarding contracts.*

Our committee also condemns the practice on the part of certain public authorities of holding bid cheques for more than a few days pending the award of a contract. This practice should be discouraged.

The practice of holding bid cheques, either cashed or uncashed, for an unnecessary length of time, places on the construction industry as a whole a substantial financial burden which must ultimately be passed on to the public in the form of increased costs. The amount of money deposited in the form of bid cheques and contractors' guarantees during any period will aggregate probably fifty per cent of the total value of work undertaken, and the public doubtless does not realize that it is under present practice paying unnecessary interest charges on this vast sum of idle capital. The practice of cashing bid cheques is particularly objectionable as this in general about triples the carrying charges.

It would appear obvious that if a contract is to be let to the lowest responsible bidder, the award can and should, as a general rule, be made within three days of the time of receiving tenders, and all cheques other than those of the lowest bidders can then be returned. In this connection our committee recommends the practice of the Department of Public Works of Canada, under which the cheques of all contractors whose tenders are obviously not acceptable are returned on the day they are received, the general practice being to hold until the contract is signed the cheques of the three lowest bidders only. If for any reason tenders have to be held over for analysis, the time and date on which the award is to be made should be announced at the time.

(8) *Guarantee for performance of contract.*

It is customary and advisable that there be some tangible form of guarantee that a contractor will complete the work after having signed the contract. The practice in this respect is to provide for monthly payments on account, less a stipulated percentage to be retained until the expiry of the date within which liens can be registered after the completion of the work. In addition it is customary to require the contractor to furnish a bond guaranteeing the completion of the work, or in lieu thereof, to deposit securities in the form of bonds of the authority giving the contract. Our committee is of the opinion that the bond is not a satisfactory form of security owing to the difficulty of enforcement. The requirement for a bond adds at least one per cent to the cost of the work with no commensurate advantages, which additional cost must eventually be passed on to the public. It is considered that a deposit of cash or of securities constitutes the best form of guarantee and offers in itself assurance that the contractor is to some extent financially responsible.

Our committee is of the opinion that the requirement of a performance bond rather than a deposit of cash or its equivalent is wrong in principle, as under the bonding system those contractors who operate their businesses efficiently inevitably, through their bond premiums, make good the losses of those who fail. A tax on the efficient operator for the benefit of the inefficient operator is not in the public interest.

(9) *Fair-wage clauses.*

It is customary for all public works contracts to include a so-called "fair-wage" clause stipulating the minimum rates of wages that are to be paid. Certain public bodies stipulate in general terms that the contractor must pay the union or prevailing rate of wages. Other authorities attach a schedule giving the minimum rates of wages for each trade. Our committee concurs in the advisability of a fair wage clause and recommends in this connection the practice of the Dominion Government in stipulating definitely the rates for each trade, rather than a general requirement to the effect that the contractor is to pay a union or prevailing rate. It is often difficult, on account of the jurisdictional differences between the unions themselves, to determine precisely what the so-called "union" rate is, and it is obviously difficult to say what the prevailing rate may be.

Having stipulated the number of hours constituting a working day or week and a so-called "fair wage" which is the minimum the contractor under his contract is permitted to pay, a public authority should, in the event of its ordering any change in the hours of work or an increase in rates, fairly compensate the contractor for any extra cost imposed upon him on this account. Similarly, if a change in hours of work or in rates of pay is ordered which results in a decrease in cost, the contractor should be required to rebate the amount of the saving effected.

While concurring in the advisability of a fair wage clause, our committee is of the opinion that in many cases the schedule rates are excessive and exceed those actually prevailing in the district in which the work is to be done, and go on record as condemning this practice, feeling that it adds unnecessarily to the cost of public works and tends to establish an artificial rate that has the effect of discouraging private construction.

(10) *Delivery and Opening of Tenders.*

Our committee calls attention to the fact that while under our Canadian practice public works are ostensibly let by public tender, comparatively few of our public bodies actually let their contracts in public, that is, receive and open their tenders in public and disclose the prices tendered. Tenders are in most cases received by mail or by hand up to a given time, to be opened at some later date. This practice frequently results in suspicion that tenders are tampered with between the time they are received and the time they are intended to be opened, and it has been from time to time suspected that favoured contractors have been permitted to submit revised bids after all tenders are in and the original prices known.

In this connection our committee recommends the practice of the Department of Public Works of Canada, under which tenders may be sent by mail or be delivered by hand, at the option of the bidder, up to a given time, and are then immediately opened in the presence of two responsible officials of the Department and in the presence of those bidders who wish to be present, and the figures read out to the assembled meeting. Under this system, which has been firmly established for many years, there can be no suspicion of fraud or of collusion in regard to the tenders. It is suggested that the practice of the Department might be further improved by the requirement that all tenders be delivered by registered, not ordinary mail, or at the option of the tenderer, be delivered by hand at the actual meeting at which they are to be opened.

Our committee strongly condemns the following practice which appears to be quite prevalent in the handling of so-called "public" tenders, viz.:—The practice of receiving tenders up to a given time and holding them, ostensibly unopened, to be dealt with at some subsequent meeting. Provision should be made in all cases for tenders to be handed to the official who is to open them, and for them to be opened then without having passed through the hands of any third party.

(11) *Acceptance of Lowest Tender.*

Our committee is of the opinion that it is not in the public interest that a contract be awarded to the lowest bidder where, by comparing the low tender with the engineer's estimate and with other bona fide tenders it is obvious that the low tender is the result of an error in judgment, lack of experience, or failure to appreciate the requirements of the work, and that the work cannot be executed in accordance with the specifications for the price tendered. In cases of this kind our committee is of the opinion that the low bid should be rejected and the contract given to the next lowest properly qualified bidder. Our committee is strongly opposed to the policy, which has at times been followed, of rejecting all bids and calling new tenders, on the ground that this can serve no useful purpose, delays the work and is obviously unfair to all bona fide bidders and particularly to that contractor who is entitled to the work and whose price is disclosed to his competitors.

II. The Interpretation Given to Contracts in Operation and the Inspection and Final Acceptance of Public Works Carried out by Contract.

(12) *Brevity of documents.*

It is believed that many of the specifications and contract forms presently used could be advantageously shortened and put into simpler language more comprehensible to those to be governed thereby. It is also felt that many of the clauses are unfair to the contractor.

(13) *Unknown sub-surface conditions.*

Our committee is of the opinion that where sub-surface conditions are not known or cannot be determined with reasonable accuracy prior to the calling of tenders, the contract should be so drawn as to provide for the handling on a cost-plus basis of that portion of the work that is affected, as, for example, cofferdamming, unwatering and perhaps also, excavation. A policy of handling such work on a cost-plus basis would, it is felt, give the supervising engineer more direct control over an operation essential to the success of the work as a whole, but the details of which cannot in many cases be accurately specified in the first instance.

(14) *Restrictions in use of machinery.*

Our committee is of the opinion that when restrictions in the use of machinery in place of hand labour are deemed advisable in the public interest, they should be fully and clearly set out in the original specifications and no deviation therefrom should be subsequently used as an excuse for changing the contract prices.

(15) *Enforcement of time limits.*

Our committee draws attention to the desirability of a strict enforcement of the time limits of contracts. In its opinion a reasonable time limit for commencing work and a reasonable rate of progress should be specified and enforced.

(16) *Supervision by qualified engineers.*

Our committee suggests that a decided improvement might be effected in the execution of our public works if they were always, while work is in progress, under the direct supervision of fully qualified engineers.

(17) *Strict adherence to specifications.*

It is the general consensus of opinion that in the administration of public works' contracts there is a tendency on the part of some engineers and inspectors to assist the irresponsible contractor who has, perhaps, in the first instance bid the work at a price that is obviously too low, this assistance being given by granting extras and a more favourable classification than is justified. Our committee is of the opinion that contractors should be required to execute their work strictly in accordance with their contracts, and that no extras should be allowed unless for work that is in addition to that contracted for. When a policy of definitely requiring strict adherence to the specifications is established, this fact soon becomes apparent to all interested contractors and bids are made accordingly, and a better quality of workmanship and a lower ultimate cost to the public results.

(18) *Appeal from engineers' decisions.*

Public works' contracts usually appoint the engineer or architect, as the case may be, the sole and final arbiter in regard to the interpretation of the plans and specifications, and in regard to the quality and quantity of the work done. Our committee is of the opinion that in the final adjustment of a contract there should be provision for appeal from the decision of the engineer or architect to a board of arbitration such as, for example, that provided by the Ontario Arbitration Act, except in cases where appeal is otherwise provided for, as in the case of appeal to the Exchequer Court in the case of Dominion Government contracts.

(19) *Service grounds, disposal areas, etc.*

Our committee is of the opinion that where service grounds, borrow pits, or disposal areas are definitely required for the execution of any given work, they should be arranged for and provided by the public authority in advance of calling for tenders. The term "service ground" refers to any property outside the actual area occupied by the finished work but which is necessary for the purpose of carrying out the work; the term "borrow pit" refers to any area of ground from which it is necessary to take material to be used as fill in the finished work; and the term "disposal area" refers to any property which is necessary for the disposal of surplus excavated material.

It is felt that where service grounds, borrow pits and disposal areas are essential, they can be secured in advance by the public authority at a much lower price than they can subsequently be secured by whatever contractor may be entrusted with the work. Generally speaking, the knowledge that an operation is actually about to commence enhances, often to an exaggerated extent, the value of properties required in its execution, and the cost of the work is often materially increased on this account, and in this connection it must be pointed out that the contractor lacks the power of expropriation usually available to the public authority.

It should be pointed out that this clause refers principally to the larger engineering projects and, as a general rule, is neither applicable nor necessary in the case of building construction.

(20) *Employment of consulting engineers and architects.*

Our committee takes the liberty of expressing its views on a point that appears pertinent to, although perhaps not strictly included in, the several points upon which it was asked to report.

Our committee commends the employment of consulting engineers in an advisory capacity on public works in special cases and for the design of works for which there is no permanent staff available. It also suggests that architects might with advantage be retained in a consulting capacity in connection with our engineering works that include buildings, and in connection with our more important bridges. In the opinion of our committee Canada has reached a stage in her development where æsthetics should assume a more important role in the design of our engineering structures.

The whole respectfully submitted on behalf of the Council of

THE ENGINEERING INSTITUTE OF CANADA

The English Bay Interceptor, Vancouver

G. M. Gilbert, A.M.E.I.C.[1]

DISCUSSION

A. D. Creer, M.E.I.C.[2]

The writer was resident engineer under Mr. R. S. Lea, M.E.I.C., on the preliminary investigation in 1911 and 1912 and was chief engineer to the Joint Sewerage Board from its formation to 1921. It was largely through the efforts of the Hon. H. H. Stevens when he was an alderman on the city council that the Joint Board was formed and at that time it included in its area four municipalities.

Some years were spent on investigations and a preliminary report was presented to the Burrard Peninsula Joint Sewerage Committee, which resulted in the formation by the provincial government of the Vancouver and Districts Joint Sewerage and Drainage Board.

This preliminary report laid down the general lines of a complete scheme for the whole area, with an estimate of the population and ultimate cost of the undertaking. The population was put at 1,450,000 in 1950 and the cost at $10,000,000, the only criticism being that the population was under estimated. (In 1910 the population was 150,000 and in 1934 it was 300,000.) These figures were later cut to 800,000 and the design revised. The question of the separate or combined system for the English bay area was considered thoroughly and while the preliminary report advised the adoption of the former, the Board decided on the combined system. About that time the New York Sewerage Commission had laid down a standard of purity for bathing beaches as "approximating that of drinking water" and as the shore of English bay from False creek to Point Grey is one continuous bathing beach, it was felt that as the additional cost of the separate system was not prohibitive, it would be wise to adopt this system and give the maximum protection to the beaches.

Time will prove that this view was correct. It is likely, however, that as the population increases and the overflows come into more continuous operation, either the bathing beaches will have to be abandoned as such or further provision made for carrying the overflows or trunk outlets considerably further out from the shore.

It is also questionable whether the point of outlet at Imperial street as selected, will continue to be satisfactory. The currents are slow and have little dispersion value. There will be a tendency, when the volume of flow increases, for the sewage to move en masse and become a major nuisance. It would have been wiser to have deferred the construction of the interceptor and lengthened the trunk outfalls watching the results as time went on and the population and flow increased.

It is quite within the bounds of possibility that ultimately an interceptor may have to be carried in the opposite direction, syphoning under False creek to the neighbourhood of Prospect Point where high velocity currents are available for proper dispersion.

Another criticism is that the size of the interceptor at its upper end should have been larger; the cost of excavation for a 4-foot 6-inch tunnel sewer is practically the same as for a 5-foot, and the additional capacity would have been useful in preventing to a greater extent the pollution of False creek.

As regards grit chambers the writer's experience has led to the conclusion that the cheapest and most satisfactory way to get rid of grit is to allow it to go into the sewers and then flush it out. Also, with reference to the cost of the work as compared with day labour work, a considerable saving would have been effected if the work had been done by contract.

J. M. Begg, M.E.I.C.[3]

As this extended paper may from time to time be consulted as an authoritative record the writer would like to incorporate in the discussion some comments suggested by a reading of an advance proof.

The run-off factor (25 per cent) for the Balaclava area may strike the reader as needing some explanation when applied to an area likely to be well built up in the future. It is not strictly comparable with the run-off factor used in storm sewer design. It was little more than an allowance for light summer rainfall and for the first rush of storm water after a dry spell. Its selection was influenced by considerations not all readily expressible in arithmetic. Mr. R. S. Lea reached a similar final result but it was by a different method. It is to be noted that as design was based in an estimate of the flow of sewage for the maximum hour of the minimum day there is at all other times room in the sewer for more rainfall than the amount obtained by the calculation.

In the original 1912 scheme Mr. Lea had recommended the separate system for the area tributary to the interceptor, but this had been abandoned at an early stage in the history of the Board, a step which imposed on the new design a corresponding change in method. Conditions as they are likely to be some thirty or forty years hence were fully realized and provided for.

Some apparent inconsistency in the author's hydraulics may be cleared up by explaining that the formula used in determining the dimensions of the sewer required for a given rate of flow was that of Hazen and Williams. Chezy was used only for preliminary sketches of some subsidiary structures. The statement that the hydraulic radius of an 8-foot horse shoe section is 2, in so far as it suggests that the section was treated as a circle, implies a looser standard of approximation than was in fact maintained whenever possible in all final hydraulic computation.

The estimated maximum rate of flow relative to the average was increased towards the upper end of the interceptor to allow for a greater fluctuation in the discharge from smaller tributary area.

The thorough investigation on which Mr. Lea's 1912 scheme for the whole peninsula was founded included a study of probable future population. It was mainly on this with a few emendations suggested by the passage of time that design was based. The Town Planning Commission's estimate became available before construction began, and the plans, already well advanced, were checked by the new figures, but the results varied little from those already adopted, a slight increase being covered by a small margin of capacity already provided.

The writer hardly hoped to make the butt joint on the outfall watertight in itself. Experience of subaqueous work, and of the human element involved in it, led him to endeavour to design a joint which would, if pulled well home by mechanical means, ensure the beginning of tightness. He was then thinking of lead wool for filling the recesses and had a long eye to the possibility that in such

(1) Paper presented before the Western Professional Meeting of The Engineering Institute of Canada, held at Vancouver, B.C., on July 11th to 14th, 1934, and published in the September, 1934, issue of The Engineering Journal.

(3) Cumnock, Ayrshire, Scotland. Chief Engineer, Vancouver and Districts Joint Sewerage and Drainage Board 1924-1933.

deep and often turbid water the caulking at some joints might be imperfect. The butt joint plus a filling even of the surrounding silt would give a joint of a kind. The discovery of a compound which enabled the filling to be placed with ease was fortunate. The joint is not so much a "tongue and groove" as a development of the bell and spigot type which naturally emerges when one gives the recess a wedge shape in order to hold the filling. The conical shape of the abutting surfaces should be noted. This keeps contiguous pipe concentric when pulled into position. It is necessary that the cradle of steel rails be truly and carefully laid on as carefully prepared caps and piling, a condition which in this particular case only the author's tenacity and meticulous instrument work in all weathers made possible of fulfilment. The writer wishes also to acknowledge his debt on a vital point to published papers on the work of other engineers on the Pacific coast, and to an unknown American contractor with whom he once discussed the subject.

The depression or channel in the silt of the ocean bed at the 2,000-foot point from shore, though a source of anxiety, presented a problem of unusual interest. There was daily a general ocean current across the line of the outfall of about half a mile to five miles per hour as measured at the surface. The presence of a distinct and individual current in the channel 70 feet or so below, more rapid than that in the surrounding sea, was more a matter of inference from the existence of the channel itself than from the inconclusive evidence obtained by direct observation. There was nothing improbable in the formation of a current by the edge of Spanish Banks, but it seemed curious, if not improbable, that after leaving the Banks it should still maintain itself in the open water a mile further east as something in the nature of a submarine stream, a thread comparatively, in the great body of the surrounding water, permeated, as it was, by the complex and involved currents revealed by the floats. This doubt was not lessened by reports of previous dredging operations. It seemed reasonable to suppose that in any case, if it did exist, an intermittent current of any likely velocity, while the danger of its turning right or left was recognized, could be readily enough diverted upwards into the water above by a long sloping fill protected, if necessary, and especially from scour on the lea side by gravel. Even when teredo attacked the trestle there seemed to the writer to be conflicting elements in the evidence as to the cause of exposure of the piling, but the obvious explanation was accepted and in the repair shop it was decided to risk the danger to which creosoted piling would be subject from ships' anchors, and leave, to support the pipe across the channel, an open trestle permitting free passage between the bents. There was the additional consideration that it would the more securely keep the current crossing at a known point. In 1933, two years later, and after two flood seasons on the Fraser, the piling and channel were examined by a diver. There appeared to be no erosion of the channel under the pipe, but the piling itself, due possibly to a dragging anchor, showed signs of damage. The greater part of the rest of the outfall had by now been protected by gravel, this being done gradually as the fill of the silt subsided and packed round the pile foundations or was subject to erosion. The diversion of a possible current was therefore less to be feared than a break in the creosoted surface of the piling permitting the entrance of teredo. The crossing at the channel was accordingly finally filled in with gravel.

The hydraulics of the system were arranged to permit the installation at any time necessary, of a screening plant at the foot of Imperial street, but the excellent results of operation at the outlet selected by Mr. Lea, make it seem unlikely that screening will be required.

One or two calculations such as that based on a figure given in Fowler's work on foundations did not perhaps quite deserve the publicity conferred on them by a formal paper. They were written down in passing to throw a side light on the point under consideration and were not the basis of design. The same applies in some degree to the calculation of the probable concurrence of rainfall and high tide at the foreshore. The writer is not himself enough of a mathematician to be sure whether or not a strict member of that fraternity would demur to an assumption that the alternatives in this instance are equally likely possibilities in the sense required for the computation, or might not go further even and insist on a distinction here between probability and frequency. Some limitation of data in any case there was, and the result of the subsequent calculation, when transformed into probable frequency over a period of time, was accepted only as a rough guide to judgment.

In calculating the heights of the curving weirs approximate values for certain factors such as the coefficient of roughness in the existing sewer were assumed or estimated by inspection, and the weirs so built that they could be readily raised or lowered, the final adjustment of elevation to be determined by the results of prolonged operation.

The disintegration of lead wool in some old joints may have been due to incomplete caulking and consolidation. Part was still of more or less fibrous texture.

The two-inch paving finish contained clean sharp sand as well as pump-sand, being composed of one part cement, one part washed sand, and one part fine pump-sand.

As to the general scheme of which the interceptor is an important item, only an engineer familiar with the drainage problems of some older cities can appreciate the good fortune of Vancouver and district in securing a complete general plan of drainage and sewerage so early in its history. And perhaps only an engineer who, like the writer, has devoted some nine years to its development can fully appreciate the massive grasp and skill behind Mr. Lea's great system of drainage for Vancouver and the Burrard Peninsula.

Chas. Brakenridge, M.E.I.C.[4]

The formation of the Vancouver and Districts Joint Sewerage and Drainage Board reflects great credit on the wisdom and foresight of the public men and officials in office at the time this scheme was conceived. The unfortunate position in which the old city of Vancouver was placed, with rapidly developing areas on the lower slopes adjacent to tidewater urgently requiring the extension of sewerage and drainage facilities and with sparsely developed lands on the higher levels tributary to the same drainage outlets but located in adjoining municipalities, drew attention forcibly to the imperative need of combined action.

The Board is responsible for the provision of trunk sewers and drains for all drainage areas of 400 acres or over, while the member municipalities retain the obligation to provide their own facilities for drainage areas of lesser extent than 400 acres, as well as for all lateral sewers, drains, and property connections.

In the final report submitted by Mr. R. S. Lea, the adoption of the separate system was strongly urged for the area tributary to English bay, notwithstanding the fact that a considerable portion of this area had already been sewered on the combined system. Mr. Lea recommended that the existing sewered area should be rigorously confined to its then present limits, and that any new construction should be carried out on the separate system.

In the preliminary design for an interceptor which was advanced in the Lea report, it was proposed to provide for storm water from those areas already sewered on the

(4) City Engineer, Vancouver, B.C.

combined system up to about one-quarter inch per hour; and the point was strongly stressed by Mr. Lea that unless the balance of the area to be made tributary to the interceptor was sewered on the separate system, there would be grave danger of pollution in the waters adjacent to the foreshore and bathing beaches.

At the time the Lea report was submitted, the limits of the city of Vancouver in the area tributary to the interceptor only extended as far south as 16th avenue, the balance of the territory to the south being within the confines of the municipality of Point Grey. This municipality and the adjacent one to the east, South Vancouver, were not amalgamated with the old city of Vancouver, till the beginning of 1929.

Both the old city officials and those of the Point Grey municipality were favourably disposed to the adoption of a combined system of sewerage for the area tributary to this interceptor; and in a report submitted to the provincial government at the time of the passing of the act by two independent engineers, Messrs. C. H. Rust and R. H. Thompson, it was pointed out that the danger of sewage pollution of the foreshore and beaches had possibly been over-estimated, and the need for adoption of the separate system unduly stressed. Subsequently a resolution was passed by the Sewerage Board and approved by the provincial government, substituting a combined system for the separate one advocated for this area; and the further development of sewerage facilities has consequently been carried out on the combined system.

The experience gained in this city seems to be somewhat at variance with some of the arguments generally advanced in favour of the adoption of the separate system, particularly in regard to the possibility of delaying the installation of storm drains until some time after that of sanitary sewers. It has been found here that in the development of new areas there has often been a greater demand for the early provision of facilities to take care of storm water in districts where household septic tanks are giving reasonably satisfactory service, and where sanitary sewers are not therefore immediately required. It has been the experience in these new districts that more trouble and inconvenience arise from the flooding of low-lying areas and basements, due to the lack of storm water carriers, than from the want of sanitary sewers; while the development of street improvements has often been retarded from the same cause.

Owing to the large areas remaining between the interceptor and the foreshore below a level that could be drained to the interceptor the sewage from such areas must continue to discharge into waters which partially reach the bathing beaches until pumping stations can be installed and the sewage raised to the interceptor level. In this connection it may be pointed out that the city acceded somewhat reluctantly to the proposal to move the head of the interceptor one block further south on Cambie street, as a semi-trunk sewer had been in existence for several years on 7th avenue, discharging into Cambie street trunk at that point. But it was finally arranged that in order to gain an additional 14 feet of head, the interceptor should commence at 8th avenue and Cambie street and this necessitated the construction of a relief sewer on 8th avenue for a distance of approximately 2,750 feet east.

It should be noted that the city of Vancouver was vitally concerned with any economies that could be effected in the construction of this interceptor, as the city's share of the capital cost amounted to approximately 98 per cent of the total amount. The method of assessing the member municipalities of the Sewerage Board finally adopted is to distribute 30 per cent of the total cost of any particular trunk sewer project amongst the member municipalities in the ratio of the total assessed value of the land in the respective municipalities, while the remaining 70 per cent of the cost is distributed according to the relative total assessed value of the lands actually benefited by any such sewer or project in the particular drainage district, irrespective of municipal boundaries. This method of assessment was provided in an amendment to the original act as the result of an appeal lodged by the old city of Vancouver against the first assessment, which was based on a strictly legal interpretation of the original act. The revised method was based on the assumption that the general health of the community might be considered to be benefited to the extent of 30 per cent of the cost of any particular trunk sewer or project.

One of the most interesting features of the paper is that part dealing with the submerged outfall. Great credit was reflected on the engineers responsible for the original report in 1912-13 when it was finally decided some fifteen years later, after spending an additional two years in further extensive investigations and studies, to locate the outfall in substantial accordance with the original plan notwithstanding the fact that considerable development of public bathing beaches had taken place in the vicinity in the meantime.

It may be of interest to point out that before finally selecting Imperial street as the most suitable point for the outfall of the English bay interceptor, Mr. Lea gave serious consideration to the possibility of carrying the interceptor in the opposite direction to that ultimately selected, and fixing the site of the outfall at the First Narrows of Burrard Inlet, where, as it was stated, from the dispersion point of view the ideal condition of discharge existed. But the possibility of a dam being constructed at some future time at the Second Narrows was undoubtedly an adverse influence; and the original report of Mr. Lea finally set forth that "although the actual cost of carrying an outfall there (at the First Narrows) is not prohibitive, it was considered that equally good results could be obtained by discharging at a more accessible point."

The decision to restrict the capacity of the submerged outfall to what was necessary to convey the dry weather flow during the periods of extreme high tides seems to have been well warranted in view of all the circumstances, including the fact of the very infrequent intervals during which the overflow will be likely to discharge during the bathing season. The storm outlets at Balaclava and Maple streets are themselves provided with smaller submerged outfalls discharging below low water; and these will further tend to minimize the disposition of sewage along the foreshore.

The location of a plant in the city equipped to manufacture pre-cast pipe made by the Hume centrifugal process facilitated the adoption of this type of concrete pipe for the submerged outfall. The closeness of grain which marks the Hume pipe in the smaller sizes, so well shown under the microscope, and which, as experiments with acetic acid extending over eighteen months in the city laboratory show, is accompanied by a noteworthy increase of resistance to attack by agents like the carbon dioxide dissolved in the sea-water or in ordinary ground-water, is not so marked in the large pipe sizes, owing to the slower spin and the lesser centrifugal effect during manufacture. There is still, however, an appreciably greater resistance to the accelerated attack by acetic acid of 2 per cent strength on the large sizes of Hume pipe as compared with wet mix pipes of the same size which had been cast without the spinning.

The vital importance of obtaining both good mechanical contact and water-tightness in the joints of the submerged outfall appears to have been fully recognized, not only in the design of the joints, but also in the care taken to secure accurate grade and alignment in the pipe-cradle before the pipe-lengths were placed in position. It is equally reassuring to learn that such good results were obtained with the Sika compound used in caulking the pipe-joints. Engineers will follow with interest the service record of this important installation of pre-cast pipe and its jointing material. But the care which seems to have been exercised throughout in laying and jointing, taken in conjunction with the prompt backfilling of the trench and the numerous and substantial pile-bents, give all reasonable assurance of security at the joints. The thickness of the pipe-shell, 7½ inches, ought to be sufficient to guarantee that the pipe will have long life so far as chemical attack is concerned.

It is certainly disturbing to learn that the teredos were capable of working so much havoc in such a short space of time as was experienced in this case; and engineers are indebted to the writer of the paper for bringing the occurrence to their attention.

It is interesting, though in no way surprising, that total darkness exists at the bottom of English bay. The enormous quantity of fine silt carried down by the Fraser river, which has its origin in the wide and deep masses of glacial material that were deposited in its broad valley during the Ice Age, fully accounts for the darkness at the bottom of the bay, as can be understood by a comparison of the colour of the water in the bay with that from the open sea, especially during the periods of high water in the Fraser river.

G. M. Gilbert, A.M.E.I.C.[5] (Author's Reply.)

There is nothing further to be added to the discussion submitted by Mr. J. M. Begg. He goes more fully into some of the features of design which were mentioned in the paper.

The discussion submitted by Mr. Brakenridge adds considerably to the knowledge of this project and stresses points which were not fully developed in the paper.

(5) Acting Engineer and Superintendent, Vancouver and District Joint Sewerage and Drainage Board, Vancouver, B.C.

Mr. Creer's discussion might be analyzed. He states that in time the bathing beaches along the south shore of English bay will have to be abandoned or provision made for extending the outfalls. He also questions the location of the outlet off Imperial street. The answer to both these objections is that the present outlet is only temporary, provision having been made for the ultimate outlet some 2,500 feet further off shore.

Mr. Creer mentions the possibility that an interceptor may have to be carried in the opposite direction syphoning under False creek to the neighbourhood of Prospect Point to discharge into the high velocity currents there. This is a very remote possibility. A much more likely development will be the extension of the interceptor through the University Endowment Lands to discharge into the Gulf of Georgia somewhere near Point Grey. The interceptor was built with this possible development in mind and the extension westward would continue from the corner of 1st avenue and Imperial street, although the present outfall would no doubt always be in use to carry part of the flow.

While it may be possible to flush grit out of the short outfalls it would only be asking for trouble to allow grit to settle in the long outfall off Imperial street. In fact, as pointed out in the paper, one of the cardinal points of design was that no grit should be allowed to enter the submarine pipe.

The argument of "Contract vs. Day Labour" is a matter of opinion and one in which circumstances play so large a part that it is impossible to make a definite statement one way or the other.

The Sika compound has not been analyzed. The joint shown in Fig. 1 was especially designed to give a butt joint and yet permit of closure. The action of the compound is to increase the hydration and prevent the efflorescence always present in Portland cement. Number 3 Sika, the one used, is a liquid used for making a rapid-setting concrete, and for surfacing floors where an extremely hard and impervious and smooth finish is required. It is largely used for pipe jointing under water.

Streamlining

J. J. Green, A.R.C.Sc., Ph.D.,
National Research Laboratories, Ottawa, Ont.

Paper presented before the Ottawa Branch of The Engineering Institute of Canada, October 18th, 1934.

One of the most vital questions to the engineer is efficiency. In the forward march of applied science this factor becomes increasingly important.

Within the last twenty years the aeroplane has entered into the field of transportation, and the threat of competition has awakened the transport engineer to a realization of all the possibilities for improved efficiency that have been waiting for him ever since George Stephenson built the "Rocket."

The following notes refer to one of these possibilities, viz., the reduction of air resistance by streamlining.

When a body is moving through air or any other fluid, a variety of phenomena can be observed. In order to examine these phenomena in detail, we will travel with the body so that relative to ourselves it is at rest and the fluid is moving past. As the fluid meets the body, it becomes displaced by it and, in being compelled to flow around the body contour, its velocity becomes changed in regions close to the body, the effect being diminished with distance from the body.

Two types of resistance are encountered,—one due to the viscosity of the fluid arising from the frictional forces called into play by the relative motion of the body and the fluid adjacent to it, and the other due to the inertia of the fluid, involving its density and the impressed velocity changes, which give rise to variations of pressure around the contour of the body. These two types of resistance are usually referred to as the "skin friction" and the "form drag."

Suppose that our body is of cylindrical shape of say elliptic cross section and that we have a variety of instruments for examining the behaviour of the fluid. We observe that, depending on the velocity, there are two specific types of flow pattern. At extremely low velocities the flow is said to be streamline, taking place as it does along definite paths with respect to the body which are unchanging with time.

At "A" where the fluid impinges, the pressure on the body rises above the pressure in the remote fluid by an amount $\frac{1}{2}\rho V^2$, where ρ is the fluid density and V its velocity relative to the body, representing the kinetic energy in unit volume which is yielded up by the fluid arrested at "A." From stagnation at "A" the fluid is accelerated due to the constricting action of the body on the stream. The centrifugal tendency of the accelerating fluid to leave the curved surface causes the pressure to fall below the pressure in the remote fluid. From "B" to "C" the velocity is falling and the pressure rising, with the result that the pressure distribution around the cylinder is such as to give rise to a very small pressure resistance or form drag. The major portion of the resistance is composed of skin friction due to the body retarding the adjacent fluid layer through the mechanism of viscosity.

As the relative velocity V is increased, the fluid particles have an increasing tendency to fly off tangentially to the surface of the cylinder and the restraint provided by viscosity is insufficient to maintain this type of flow. At a critical velocity, depending on the shape and size of our body, the second type of flow sets in. On the forebody the flow resembles streamline flow, but the boundary layer between "A" and "B," the thin fluid layer in which the viscous forces between body and fluid are operative, now breaks away from the body and travels downstream. Since the inside of this layer has been retarded by friction over the body surface, a large velocity gradient exists across it, the fluid on the inside moving much more slowly than that on the outside edge. This causes the sheet of fluid to roll up into a vortex which travels downstream behind the cylinder. In this way a wake of vorticity is generated by the body, alternate vortices being shed from either side.*

With this second type of flow, the excess pressure at "A" is again $\frac{1}{2}\rho V^2$, falls to a minimum between "A" and "B," recovers slightly near "B," but remains below the pressure in the remote fluid over the remainder of the surface. This type of pressure distribution naturally results in a large form drag in comparison with which the skin friction is negligible.

It is evident that the breakaway of the flow depends very much on the sharpness of the turn it must make in order to adhere to the surface. By changing the body shape so that it converges gradually to a sharp tail, the breakaway of the flow is delayed and a wide wake with its low pressure is absent. This is the principle involved in streamlining which aims at maintaining always a type of flow similar to the first type discussed. A number of flow photographs have been published which show how streamlining reduces the width of the wake and induces the fluid to follow the body contour, and convincing numerical results can be quoted showing what enormous savings in resistance can be made on simple shapes such as the square and circular section by replacing them by streamlined sections.

Returning to the mechanism of the breakaway of the flow, the pressure distribution around the body is also a controlling factor. From "A" towards "B" the falling pressure urges the fluid of the boundary layer along in the general direction of flow, but having reached a minimum the pressure makes an effort to recover its former value with the result that the boundary layer meets a rising pressure which opposes its motion. This assisted by viscous forces slows it down so that a stagnation occurs and the fluid following on behind is forced to leave the surface.

Now two types of flow are possible within the boundary layer itself, viz., laminar and turbulent flow. In the former type, the motion takes place in definite layers and in the latter type there is an interchange of particles between adjacent layers. If the boundary layer flow changes from laminar to turbulent, some of the faster moving air outside gets mixed into the layer, bringing fresh stores of energy which enable the boundary layer to carry on for a greater distance against the adverse pressure gradient.

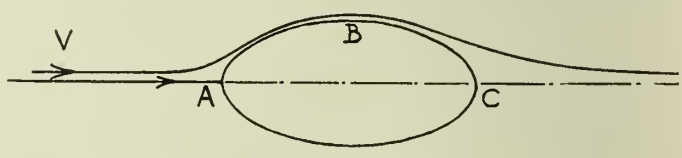

Fig. 1.

This delay of the breakaway reduces the width of the wake and thereby reduces the form resistance of the body. In the case of a sphere for instance roughening its surface actually reduces the drag due to this cause.

The action of a turbulent boundary layer in reducing drag is only operative in cases where the body drag is mainly form drag. In the case of a streamlined body, form drag has been much reduced and the resistance is due

*See Engineering Journal, June 1931, p. 357.

predominantly to skin friction. If now the boundary layer becomes turbulent, its increased energy content will give rise to greater intensity of friction between itself and the body. The increased skin friction will therefore appear as a larger measured total drag and this is found to be the case in practice.

In testing models of streamlined bodies such as airships in a wind tunnel, at some position along the body the boundary layer changes from laminar to turbulent. If the body is a "poor" streamlined shape, the transition occurs more towards the front, most of the boundary layer is turbulent and consequently the measured drag is higher than for a "good" streamlined shape of the same slenderness ratio.

Increasing the scale of the model or the wind speed causes the transition point to move forward on the model. It would appear therefore that due to the size of airships their boundary layers are almost certain to be wholly turbulent and a shape that is considered to be a "good" streamline will have as much skin friction drag as one that is considered a "poor" streamline.

This work on turbulent boundary layers is quite recent. The airships R-100 and R-101 carried concentrated loads at the nose and tail where mooring gear and control surfaces were located, yet due to their streamlined shapes a poor distribution of buoyancy existed which resulted in the presence of large bending moments in the framework. Had it been known at the time that a "poor" streamlined shape would have had as low an air resistance, a more cylindrical shape could have been used resulting not only in reduced bending moments but also in cheaper and more rapid construction due to the use of a large number of identical frames instead of all the frames being different in size as was the case.

For bodies on a less gigantic scale this need not worry us and good streamlined shapes are always desirable.

Having outlined the phenomena which attend the motion of bodies through fluids and having indicated how by controlling these phenomena by the principles of streamlining large savings in resistance can be obtained on simple shapes, existing transport vehicles will be considered to see what steps, if any, have been taken to utilize this knowledge in the quest for economy of power or the attainment of higher speeds.

Air travel is of course the youngest mode of transport and yet we find that the streamlined body is the foundation on which all aircraft design is built. Without streamlining,

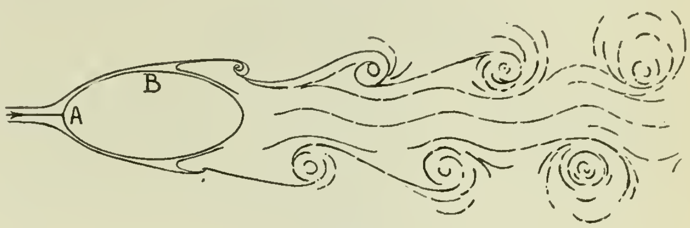

Fig. 2.

air transport would be impossible and for this reason the accumulation of all this knowledge concerning motion through fluids has been done mainly by groups of scientists primarily interested in the development of aircraft.

Turning to a consideration of land transport vehicles, we are at once impressed by the absence of streamlined types and a seemingly total disregard for the saving of power. In the case of steam locomotives, for instance, very little indeed has been done in the way of streamlining and yet the sharp corners and discontinuities of existing railway equipment must at high speeds absorb much power in creating unwanted air resistance.

In the last few years there has been a slight trend in certain directions towards streamlined types. Rail coaches and rail cars have been introduced in which great care has been lavished on the external design, which has in most cases been developed in wind tunnel. In the automobile industry a number of outstanding tests and attempts have been made at producing an efficient streamlined automobile.

VOLUME XVIII MARCH 1935 No. 3

Public Works Tenders and Contracts

The programme of public works which is now being carried out by the Dominion and provincial governments is regarded as an effort to set the construction industry on its feet, and has met with general approval from this point of view.

The considerable expenditure which it involves will naturally be watched carefully by the public, who realize that at a difficult time like the present it is of special importance that the funds provided by the hard-pressed taxpayers shall be wisely and economically administered. It is evident that to attain this end the best possible methods should be followed in letting tenders and supervising the execution of contracts for public works.

Anything that can be done to improve present practice in this respect will meet with the willing support of the engineering profession. The many members of The Institute who are connected with the construction industry will therefore join the Council of The Institute in welcoming the request received last year from the Canadian Chamber of Commerce to furnish, for the information of its committee on Sound Public Finance, recommendations and comments as to the procedure desirable in dealing with tenders for public works, and the measures which should be taken to ensure satisfactory results from the contractors' work. In response to that request a valuable report on this subject has been prepared by a committee appointed by the Council and has been forwarded to the Chamber of Commerce for their information.

Council has directed its publication for the benefit of the membership at large and it will be found on page 131 of this issue of The Journal.

Members who are already familiar with this branch of engineering work will find that this clearly drawn and outspoken document deals with many points on which they have looked for information and in which improvement in the present general practice seems possible. Its publication will give to those who are not engaged in construction work some idea of the many precautions which are necessary in planning and executing public works if a fair deal is to be secured both for the public and the contractor, and if an adequate return is to be obtained when public money is expended in this manner.

The report will repay careful study and should be considered in relation to the Canadian Standard Forms of Construction Contract to which reference was made in our January issue.

It will be seen that the committee appointed by Council was thoroughly representative in its membership. In preparing their report they dealt first with the practice which is desirable as regards the calling of tenders, afterwards discussing the manner in which such tenders are dealt with, the way in which contracts should be interpreted, and a number of important points in connection with the inspection and final acceptance of public works carried out by contract.

Very properly, the committee has not confined its recommendations to technical questions, but has dealt with many considerations affecting the business relations of the parties concerned. In carrying out its task dogmatic methods of presentation have been successfully avoided; its recommendations are backed by reasoned argument throughout.

In dealing with such topics as have been placed before it there has naturally been room for difference of opinion on many points. It is therefore satisfactory to note that with one exception the committee's findings are unanimous. That point refers to the suggestion that tenders for public works of considerable magnitude and importance should only be asked from those contractors who have proved to the authorities that they have the equipment, personnel, experience and financial backing necessary to carry out the proposed work successfully. In this matter, however, one member holds that such selection might militate against the entry of new contractors into the field, even if they did possess the necessary resources to undertake the work.

The wide experience of the committee members has enabled them to suggest means of avoiding many sources of potential difficulty between the owner, the engineer and the contractor; for this reason their remarks on such topics as unbalanced tenders, tenders based on insufficient preliminary investigation of the site and its conditions, the formalities of procedure desirable in opening tenders and awarding contracts, and the thorny subject of contractors' guarantees for the signing of contracts and satisfactory performance of the work are worthy of close attention.

The concluding section of the report rightly draws attention to the way in which an irresponsible contractor may derive an unfair advantage if the specifications are not strictly drawn and closely adhered to. The committee's views on the importance of providing fully qualified engineers for the direct supervision of work in progress, and the desirability in many cases of the employment of outside consulting engineers and architects in the preparation of designs for important buildings, structures and bridges, are all timely and most commendable. While the report deals specifically with the question of public works contracts, many of its recommendations could be applied with advantage in contracts for the purchase of engineering equipment by public authorities.

The committee's work forms an admirable illustration of the fact that the successful outcome of an engineer's efforts does not depend on technical knowledge and ability alone. There must also be a continuous application of sound ethical and business principles throughout the preparation, execution and supervision of the undertaking.

Frederick Arthur Gaby, D.Sc., M.E.I.C.

President of The Engineering Institute of Canada

The long list of past-presidents of The Institute includes the names of men who have distinguished themselves in many branches of the profession. Their wide range of professional experience is in keeping with the diversity of interests of our members and the variety of engineering topics dealt with in our branch and Institute meetings. Looking back over the past five years the presidential chair has been occupied in succession by a a Federal Government engineer, responsible for construction work on a large scale; an officer of a great railway company, who is engaged in irrigation work and the development of natural resources in the west; a civil servant who is an authority on mining engineering and economic geology; an official of one of the provincial governments in charge of the water power resources of the province, and the chief engineer of one of our large bridge companies, versed in the design and fabrication of great steel structures.

The professional career of Dr. F. A. Gaby, who has been elected President for 1935, differs from all of these. For the past twenty years he has served as chief engineer of a publicly owned utility, which is equally remarkable for the magnitude of its operations and the excellence of the service it has rendered to the public. During this period the Hydro-Electric Power Commission of Ontario has expended some $300,000,000 on its various developments, which now carry a peak load of nearly 1,500,000 h.p. and supply electrical energy to more than 750 municipalities in the province. Dr. Gaby has thus had an outstanding career in thie field of engineering, and has established for himself an international reputation as an authority on problems of electrical supply, distribution and utilization.

He was born at Richmond Hill, Ontario, on March 26th, 1878, and graduated from the School of Practical Science, University of Toronto, receiving the degree of B.A.Sc. in 1903, and those of M.E. and E.E. in 1904.

FREDERICK ARTHUR GABY, D.Sc., M.E.I.C.

Following graduation Dr. Gaby became erecting engineer with the Canadian General Electric Company on the Nova Scotia Steel and Coal Company work at Sydney Mines. The next two years found him employed in a similar capacity with the Toronto-Niagara Company, and in 1906 he became chief assistant electrical engineer at the Pointe du Bois power plant on the Winnipeg river. Dr. Gaby joined the service of the Hydro-Electric Power Commission of Ontario in 1907, and acted in the capacity of assistant chief engineer until 1912, when he became chief engineer of the Commission, later acting also as chief executive officer.

Dr. Gaby in 1924 was honoured by the University of Toronto, receiving the degree of Doctor of Science as a recognition of his outstanding work in the field of hydro-electric power engineering in Canada.

Early in 1934, owing to a change in government in the province of Ontario, Dr. Gaby severed his connection with the Hydro-Electric Power Commission of Ontario, and became consulting engineer with Noranda Mines Limited. Later in the year he was appointed assistant to the president of the Canadian Pacific Railway Company, with headquarters in Montreal, and at the same time assumed the duties of vice-president of the Seigniory Club Association of Montebello.

Dr. Gaby became a Member of The Engineering Institute of Canada on February 25th, 1919.

He is a member of many national and international societies, including the American Institute of Electrical Engineers, the Institution of Electrical Engineers (Great Britain), the American Society of Civil Engineers, the American Society of Mechanical Engineers, and is a Fellow of the Royal Society of Arts.

The choice of Dr. Gaby as President for the ensuing year forms a noteworthy recognition of the importance of power engineering among the services through which engineers contribute to the working of the modern state.

Address of the Retiring President

F. P. Shearwood, M.E.I.C.

STRUCTURAL ENGINEERING

Delivered before the Forty-Ninth Annual General Meeting of The Engineering Institute of Canada, Toronto, Ontario. February 7th, 1935.

Before delivering to you the customary Presidential address in the usual formal manner, I want to express my sincere thanks for the hospitable reception given to me by the members of every Branch of The Engineering Institute which I visited throughout Canada.

This kindly hospitality transformed my responsibilities and duties into a pleasure, and it was a gratification to me to find everywhere the eager and vigorous enthusiasm for the well-being and progress of The Institute.

During the year in which I have had the honour of holding the office of President of your Institute, I have been more and more impressed with the fact that The Engineering Institute of Canada is a body which, by its very nature, generates loyalty to the ideals for which it was originally founded. It is true that time and energy have been given to such secondary matters as the methods of our administration, but the general feeling is that the voluntary interchange of knowledge, to which we give of our professional best, is the main characteristic which commands a loyalty and devotion such as no coercive or compulsory organization could beget or develop.

In addition to this, I have observed that the character of the aggregate of our members is determined by the character of the individual. There is expected from each member a zealous study of his own particular line of engineering, and there is also demanded from each individual student a modest effort to transmit to his fellow engineers the ideas and benefits gained from his investigations.

For this reason I venture to address you, not on the methods of conducting the affairs of The Institute or the law and order involved in its temporal affairs, not on the whole vast subject of engineering with all the ramifications which our profession includes, but on the detached branch of structural engineering, a subject in the study of which I have spent practically all my working time for nearly half a century.

Structural engineering, and particularly that which has to do with metal structures, has developed greatly during the last fifty years, and it is interesting to review the trend of this development, not only for the sake of showing the progress, but also to detect or suggest defects or exaggerations which may have crept into design (or rather into the control of design), and to point to lessons to be gained from existing structures, and from those which are now obsolete.

Bridges formed by far the greatest part of structural designing in iron and steel during the latter part of the last century. Considering only Canadian bridges we find that in the year of Queen Victoria's Jubilee steel was beginning to replace wrought iron. Canadian railways then had many different types of metal bridges on their roads. The Grand Trunk Railway and the Intercolonial Railway had bridges of English design which were mostly multiple lattice girders, plate girders and box girders. The most notable of these was the old Victoria bridge, at Montreal, a box type of continuous plate girder, having spans of 250 and 340 feet. It was remarkable not only on account of its long service but even more so because of many features in its construction which might be cited in proving the extravagances of modern designing. The lattice girders with multiple web system of flats and single angles and T-shaped chords which were in service on the Intercolonial main line until 1910 and 1911, and since then have been transferred to highway crossings, evidence the fact that many of the limitations and restrictions of modern designing are unnecessarily severe.

The Canadian Pacific Railway, which was built during the eighties, generally used for long spans the pin and link type of truss, which was very popular at that time. These structures presented a curious mixture of strict conformity to theoretical requirements and flagrant neglect of them. Pin joints were favoured on account of the fact that the members were concentrically grouped and free to turn, while riveted connections were avoided because the fixedness of their joints might induce dangerous secondary strains. On the pin-connected bridges, while their main truss members were concentrically grouped, most horrible eccentric connections were used for assembling all other parts. Perhaps the main reason for the popularity of the pin and link type of construction was not so much the claim of truly articulated joints, but rather that they were easy and cheap to erect. In those days all field riveting was done by hand riveters. This was an expensive process and it was often very difficult to obtain good riveting. Pin-connected spans are now seldom used for new bridges, partly on account of the cheapening of riveted members and their connections as compared with eye bars and pin joints, but more because experience has proved that the riveted truss is the stiffer and that no harm has resulted from the rigidity or fixedness of their joints. Then too the many defects in the design of the pin-connected span bracing and details have been recognized. The old fears of secondary stressing from non-articulated joints have largely disappeared, partly because scientific theoretical calculations prove them to be relatively small, and partly because practical experience shows no undesirable effects.

For railway bridges the present practice is to use rolled beams or plate girders for as long spans as can be fabricated and erected economically. Riveted trusses are used for all medium and long spans, although pin and link construction is occasionally favoured by some designers and fabricators for the longer spans.

For highway bridges, the practice is very much the same as that used for the railways, but trusses are used for shorter spans, owing to the restrictions specified for the thickness of the web plate. This makes plate girder construction heavy and expensive for the comparatively light loadings. The latest tendency is to lengthen the spans of long highway bridges and use the suspension type of bridge, while for the shorter spans the use of light welded steel frames encased in concrete has begun to replace rolled beams and rod reinforced concrete.

Until recent years continuous and other frames which are generally termed indeterminate structures, were rather studiously avoided, principally on account of the uncertainty of the reactions and of the difficulty of computing the stresses. Today, partly because of the superior calculating knowledge of the structural engineers and partly because the benefits of continuity are realized, they are beginning to be more frequently used.

Most of the highway bridges which were built thirty or more years ago were of extraordinary lightness. This was due to the very keen competition between the fabricating shops and the practical absence of any independent engineering check on their designs. The main material, the details and the connections of these old bridges outraged nearly all of the restrictions and limitations demanded by modern specifications, yet practically none of these bridges ever failed, even under the trials of overloading and lack of maintenance; but the lessons which should have been learned from their performances have been sadly ignored.

Most of the earlier bridges were designed by the fabricators and the contract for building them was awarded to the lowest tender, irrespective of quality. Competition (that curse of good engineering and of fair trade) became so keen that all means were used to reduce the costs and therefore designing became a science of reducing the weight of metal to a minimum. The factor of safety was therefore encroached upon so much, through the ignorance and nerve of the bidders, that a demand arose for some means to force bidders to keep within some recognized boundary. This resulted in the issue of standard specifications which were written mainly to prevent a tenderer from cutting down the factor of safety and thus obtaining a low bid.

The early standard specifications controlled only the main material and workmanship. It was soon found that the secondary parts and details could be cut so as to make reductions in the costs at the expense of quality, and so the specifications were amplified to control and restrict practically every part of the structure, while designing became largely a matter of following the letter of the specification. Subsequently designing deteriorated into a computer's task instead of developing the engineer's art. The arbitrary application of these specification rules had led to a demand or fad for stresses to be computed to the exact kip, and material provided to meet an exact definitely specified unit stress. Then followed a craving for so-called determinate structures with exact figured stresses, even when these were based on conjectural assumptions as to the amount and condition of loading. All this has tended to give designers an extravagant faith in figured stresses and in the unlimited and blind application of Hooke's Law. It has also induced a mania for complicated stress analysis, while conditions and straining of the materials during fabrication, erection and service are largely overlooked. The rigid application of Hooke's Law, the limitation of straining to a factor of the elastic limit of the material, the assumption of uniformity in the initial state of all materials, the frequency, severity and likelihood of the loading are all assumed to conform exactly to the basis of the specification, which of course they do not; and yet the specifications are made the prime and often the only considerations in proportioning a structure.

Standard specifications which so completely control every part and detail of modern steel bridges have tended to relieve designers from a sense of responsibility, but have also restricted ingenuity and have prevented the use of mature judgment based on the lessons to be gained from existing structures. Competitive designing has degenerated into a science of fulfilling the demands of a specification most cheaply, rather than of producing the best structure.

The question arises as to whether the science of designing framed structures does not rely upon computations which are based on arbitrary assumptions to too great an extent, instead of allowing engineering judgment based on practical experience to modify and adjust the proportioning of material and arrangement of details to the estimated demands of the forces to be resisted and the stability required.

If the designs and details of many of the old bridges are examined, they will be found to transgress very seriously the requirements of modern standard specifications. Yet no harm has resulted. Such features as the bracing of the chords of pony trusses with T-shaped sections, the thickness of flange, cover and tie plates and the thickness of outstanding legs of angles are constantly found to have conflicted with modern standard specification requirements. The omission of stiffeners on thin plate girder webs, the size and spacing of lacing bars, the slenderness of secondary compression members and compression joints which rely on abutting ends, are other matters in which past experience proves that slavery to specifications has prevented proper economy and balanced strength. The specifications with their arbitrary limitations and restrictions prevent a designer modifying the shape and make up of a member according to the character and conditions of the service, and often lead to extravagance and abnormality.

The conventional or specified practice of calling for a system of bracing to be designed to resist a specified wind force, and relying on it also to serve efficiently in stiffening and stabilizing the structure, is unscientific and often ineffective. The study of many of the old bridges, especially those of the pin and link type, with their inefficient systems of bracing, tends to prove that there are other paths of resistance, besides their lateral systems, which are strained by the horizontal forces and which aid in stabilizing the span and its individual members. This fact should be more fully realized and the structure should be designed accordingly.

The stabilizing of a structure as a whole and of its individual compression members and joints is a problem separate from the resisting of the wind force, and while a common resistance may often suffice, it is important to visualize the two as separate problems.

Lack of proper stability of the whole structure, or of the individual parts, or of the joints has been the cause of a large proportion of the rare failures in steel construction and includes some of the most notable cases.

The habit of treating a strain as a stress in all conditions of designing steelwork has prevented the full utilization of the ductility of steel. This property is greater, far more reliable and more uniform in steel than it is in any other structural material, and yet the use of it is most strictly guarded against. A fuller and more confident appreciation of the ductility of steel should justify a rational and intelligent use of this valuable property.

The rigid practice of treating a strain as a stress in strict accordance with Hooke's Law for all conditions and ranges of service when designing steelwork, has led to erroneous estimations of the real safety or strength of many structures, especially those having more than one path of resistance. Numerous cases exist of steel structures which have had some member or part distorted by overloading, abuse or secondary distortion, but on account of the ductile properties of the material, the excess strain has been absorbed by permanent distortion; or, the deformation has brought less strained paths to take an increased participation in the required resistance, without impairing the combined strength of the structure. Moreover, it is conceded that during the fabrication of the steelwork, this ductility is and must be constantly used, without assuming any reduction in the strength of the steel.

These evidences and the facts that the stress-strain curve of steel deviates strongly from a straight line after it passes the elastic limit, and that in most of the steels used for framed structures there is a large margin of strain between the elastic limit and the ultimate, should indicate that when the stresses do not alternate excessively, a large amount of redistribution of stress in frames with multiple systems can take place before one path of resistance is in danger, and that secondary distortion can generally be safely neutralized. The greater appreciation and visualization of the possible elastic and permanent deformation in structures should tend to the realization of the many inconsistencies in conventional designs. A close study of almost any riveted connection will show many local eccentricities which are neglected in our calculations. Most important of all, this appreciation might make us more careful in avoiding relative planes of weakness, or sudden alterations in sections, which interfere with the even flow of the stresses, particularly at or near points of maximum secondary distortion.

Turning now to the fabrication of steel structures, it may be noted that until quite recently improvements were in the nature of development rather than of radical change.

The advent and recent use of modern welding and the cutting torch are now bringing about a real change in the whole science and art of steel fabrication, and in its design. These changes are, perhaps, fulfilling the dream of many a designer of being able to join the component parts of a structure together without having to pierce the material with holes for rivets, bolts or pins, and being able to use less clumsy and indirect details than connection angles and similar devices.

Electric arc and gas welding, although still presenting many problems to be solved, appears to be destined to wholly, or at least very greatly, replace riveted methods of steel construction, while the quality of the work of the cutting torch is being improved so much by the use of automatic machines and manual skill that it is rapidly replacing shears, saws and other cutting apparatus, and enabling structural steel to be fabricated in a vastly different manner.

Investigation, testing and experience is proving that the distortion from burning and welding on thin material when correctly performed will in many cases leave no significant loss of strength or dangerous brittleness in the material. The engineer is particularly concerned in these latest tools of construction, because progress must demand their adoption if they prove superior, but it is equally certain that they must be used with far more scientific control than the older methods, since they require all superintendence and even some portion of the operation to be undertaken by trained engineers with approved appliances and highly qualified operators.

The subject of æsthetics too has been sadly neglected, especially in steel bridges. This condition is principally due to the fact that price is generally the only consideration when the design is made and the contract awarded for structural steel. Unsightliness has also been caused to a large extent by the restrictions and peremptory demands of standard specifications, and by illogical prejudices.

Beautiful structures can be designed in steel and will, no doubt, materialize in the future. Even in the present day more beautiful outlines are being used and evidence is not wanting to prove that the designers are departing from the angular and over-braced frames of the last half century. They are now adopting the more pleasing forms of the arch, the suspension and the continuous span.

In conclusion the question arises as to whether we have not treated all steel structures too much as a stress-sheet problem, balancing computed stresses which are based on assumed loadings with arbitrarily applied limitations, instead of proportioning the structure as a whole to meet the conditions to which it will be subjected.

If, in this brief review I have partaken of the nature of the critic, it is not the criticism of disparagement or destruction. On the contrary, it is to me a very hopeful sign that there are, throughout Canada, striking examples of steel construction which yield to none in their excellence, and which are designed by Canadian engineers. These examples testify that there is within the membership of our own Institute an ever growing class of efficient engineers, who are capable of designing these works, and who, by co-operation and consultation with fabricators, utilize in a proper way the available records of practical experience, in their effort to attain perfection.

It is to the growth of this class that we look for more freedom in designing and for the removal of undesirable restrictions, so necessary if price is to be the controlling consideration.

It may be that my remarks have been too closely concerned with bridge-building, too circumscribed and confined to the narrow line of steel construction, which incidentally has been to me an engrossing hobby, as well as a means of livelihood for many years; but you will have noticed that at least some of these observations are applicable to other lines of engineering.

Hampering restrictions, similar to those which I have described, have forced themselves on designers of many types of engineering construction, and on those whose work is exposed to the ruling of unyielding standardization.

I have treated the question from the point of view of the engineer engaged in steel construction, in the hope that I may induce representatives of other branches of engineering to dispense more information, derived from the riches of their own experience, and dedicated to the claims of, and the loyalty to, The Engineering Institute, which is the outward expression of our professional service to Canada.

Meetings of Council

A meeting of the Council of The Institute was held at the Royal York Hotel, Toronto, on Thursday, February 7th, 1935, at five o'clock p.m., with President F. A. Gaby, M.E.I.C., in the chair, and thirteen other members of Council present.

R. J. Durley, M.E.I.C., was re-appointed Secretary of The Institute and J. B. Challies, M.E.I.C., was re-appointed Treasurer.

The Finance Committee was re-appointed for the year 1935 under the chairmanship of P. L. Pratley, M.E.I.C., the membership being as follows:

P. L. Pratley, M.E.I.C., *Chairman.*
J. L. Busfield, M.E.I.C.
J. B. Challies, M.E.I.C.
A. Duperron, M.E.I.C.
F. Newell, M.E.I.C.

The chairmen of the other standing committees were appointed as follows, and asked to submit the names of the other members of their committees to the next meeting of Council:

Library and House Committee......E. A. Ryan, M.E.I.C.
Papers Committee..................C. S. L. Hertzberg, M.E.I.C.
Publication Committee.............H. Cimon, M.E.I.C.
Legislation Committee.............A. B. Crealock, A.M.E.I.C.

A report was presented from a special committee which had been appointed to make recommendations regarding the E.I.C. Catalogue, and in accordance therewith the continuation of the Catalogue for the ensuing year was approved.

Mr. Paulin pointed out that in connection with the three papers on "The Status of the Engineer," presented during the afternoon, the General Meeting had passed a resolution requesting the Council to take action to promote security and proper consideration for technically trained employees of the provincial civil services, and he urged that Council should do this without delay.

After considerable discussion, Mr. Paulin was appointed chairman of a committee to draft a brief on the subject to be forwarded to the various provincial governments, and he was requested to organize groups for the necessary supporting action in the different provinces, selecting the other members of his committee from members or councillors resident in the provincial capitals, the suggestion being that provincial legislation should be aimed at of a character similar to that now effective for the protection of Federal Civil Servants.

The Secretary was authorized to forward the thanks and appreciation of Council to the various committees and members who had co-operated in the arrangements for the Forty-Ninth Annual General and General Professional Meeting, and had contributed so greatly to its success.

Seven Students were admitted.

The Council rose at six thirty-five p.m.

A meeting of Council was held at Headquarters on Friday, February 22nd, 1935, at eight o'clock p.m., with President F. A. Gaby, M.E.I.C., in the chair, and nine other members of Council present.

A report was submitted by Dr. Lefebvre, chairman of a committee appointed by Council to submit recommendations for transmission to Major N. B. McLean, M.E.I.C., Chairman of the Interdepartmental Water Levels Board, who had requested an expression of opinion regarding water levels in the Montreal Harbour and the ship channel below Montreal. The committee's report suggested consideration of the possibility of a better control of the flow of the Ottawa river and a revision of the rules set up for the control of the discharge of Lake Superior. The report was accepted and approved, and the Secretary was directed to forward a copy to Major McLean, and to express the thanks of the Council to Dr. Lefebvre and his committee for their work.

Attention was drawn to the resolutions passed at the Annual Meeting in Toronto on February 7th, 1935, relative to the consolidation of the engineering profession in Canada, and the resulting appointment of a committee to develop the possibilities in this connection. Mr. Gordon McL. Pitts, A.M.E.I.C., the chairman, and Mr. R. F. Legget, A.M.E.I.C., the secretary of this committee, attended by invitation, and Mr. Pitts outlined for the information of Council the procedure which his committee proposed to follow.

It was noted that the committee intended to communicate with the branches of The Institute and the Associations of Professional Engineers with regard to this matter. Attention was drawn to the movements already in progress in Nova Scotia, New Brunswick, Quebec, Manitoba and Saskatchewan, looking to closer connection between the branches of The Institute and those provinces of the several Provincial Associations of Professional Engineers. Mr. Pitts explained that the pamphlet which he had prepared, and which his committee was circulating to corporate members of The Institute, was intended as a basis for discussion in the hope that it would elicit modifications or other proposals which would be an improvement on his own.

The following committees were appointed:

Papers Committee:
C. S. L. Hertzberg, M.E.I.C., *Chairman.*
I. M. Fraser, A.M.E.I.C.
C. C. Kirby, M.E.I.C.
C. K. S. Macdonnell, A.M.E.I.C.
A. B. Normandin, M.E.I.C.
J. J. Spence, A.M.E.I.C.
W. G. Swan, M.E.I.C.

Publication Committee:
H. Cimon, M.E.I.C., *Chairman.*
J. A. Duchastel, M.E.I.C.
A. A. MacDiarmid, M.E.I.C.
P. L. Pratley, M.E.I.C.
H. L. Trotter, M.E.I.C.

Legislation Committee:
A. B. Crealock, A.M.E.I.C., *Chairman.*
A. S. Gentles, M.E.I.C.
F. Newell, M.E.I.C.

In regard to the work of the committee appointed under the chairmanship of Mr. Paulin to communicate with the various provincial governments regarding legislation, the Secretary reported that the necessary letters had been forwarded to the members of Mr. Paulin's committee as follows:

H. L. Swan, M.E.I.C., Victoria, B.C.
R. S. L. Wilson, M.E.I.C., Edmonton, Alta.
D. A. R. McCannel, M.E.I.C., Regina, Sask.
F. G. Goodspeed, M.E.I.C., Winnipeg, Man.
A. B. Normandin, M.E.I.C., Quebec, Que.
H. S. Johnston, M.E.I.C., Halifax, N.S.
Alex. Gray, M.E.I.C., Saint John, N.B.

The report of the Finance Committee and the budget for the year 1935 were presented and approved.

Attention was drawn to the fact that so far The Institute had not been able to implement fully the terms of its agreement with the Institution of Electrical Engineers as regards the formation of Radio Sections, and Council approved the formation of a general committee under the chairmanship of Professor G. A. Wallace, A.M.E.I.C., to report as to further possibilities in this connection.

Discussion followed as to the general policy to be adopted in connection with members on the Non-Active List who owe for 1933.

The Secretary having pointed out that the five year period for which The Engineering Institute of Canada Prizes had been originally established had now terminated, it was unanimously resolved that these prizes be continued for a further period of five years.

The Secretary reported that in connection with the discussion on the western water problem which had taken place at the Annual General Meeting in Toronto, copies of the papers presented had been forwarded to the Prime Minister, the Minister of Agriculture, and other Ministers interested, and also to the Premiers of the prairie provinces, with an offer of co-operation on the part of the Council of The Institute.

The attention of these governmental authorities was drawn to the desirability of including an engineer in the membership of any commission or committees appointed to take action on the drought situation.

A letter was presented from Mr. G. A. Gaherty, M.E.I.C., commenting on the valuable information brought out in these papers, and suggesting that Council nominate a committee to follow up the work initiated in the symposium. Such a committee might collect and co-ordinate the relevant data, and might assist in the detailed field investigations which would no doubt be the function of some governmental body. The suggestion was heartily approved and it was resolved that Mr. Gaherty be asked to accept the chairmanship of such a committee.

Six resignations were accepted, a number of members were replaced on the active list, four members were placed on the non-active list, and several special cases were dealt with.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Members	2	Assoc. Member to Member	5
Associate Member	1	Junior to Assoc. Member	5
Students admitted	2	Student to Assoc. Member	4
		Student to Junior	3

The Council rose at twelve fifty a.m.

Annual Fees

Members are reminded that a reduction of One Dollar is allowed on their annual fees if paid on or before March 31st of the current year. The date of mailing, as shown by the postmark on the envelope, is taken as the date of payment. This gives equal opportunity to members residing in all parts of the country.

The Forty-Ninth Annual General and General Professional Meeting

Convened at Headquarters, Montreal, January 24th, 1935, and adjourned to the Royal York Hotel, Toronto, on February 7th, 1935

The Forty-Ninth Annual General Meeting of The Engineering Institute of Canada commenced at Headquarters on Thursday, January twenty-fourth, nineteen hundred and thirty-five, at eight fifteen o'clock p.m., with President F. P. Shearwood, M.E.I.C., in the chair.

The Secretary having read the notice convening the meeting, the minutes of the Forty-Eighth Annual General Meeting were submitted, and on the motion of J. L. Busfield, M.E.I.C., seconded by R. H. Findlay, M.E.I.C., were taken as read and confirmed.

Appointment of Scrutineers

On the motion of H. W. B. Swabey, M.E.I.C., seconded by J. G. Hall, M.E.I.C., Messrs. A. Duperron, M.E.I.C., Fraser S. Keith, M.E.I.C., and Fred Newell, M.E.I.C., were appointed scrutineers to canvass the Officers' Ballot and report the result.

There being no other formal business, it was resolved, on the motion of M. D. Barclay, A.M.E.I.C., seconded by J. A. McCrory, M.E.I.C., that the meeting do adjourn to reconvene at the Royal York Hotel, Toronto, at ten o'clock a.m., on the seventh day of February, nineteen hundred and thirty-five.

Adjourned General and General Professional Meeting at the Royal York Hotel, Toronto

The adjourned meeting was called to order by President F. P. Shearwood, M.E.I.C., at ten a.m. on Thursday, February 7th, 1935. The Secretary having announced the receipt of a number of messages of regret and felicitation, submitted the membership of the Nominating Committee appointed to nominate the officers of The Institute for 1936 as follows:

Nominating Committee 1935

Chairman: L. F. Grant, M.E.I.C.

Branch	*Representative*
Halifax Branch	A. F. Dyer, A.M.E.I.C.
Cape Breton Branch	R. R. Moffatt, A.M.E.I.C.
Saint John Branch	J. N. Flood, A.M.E.I.C.
Moncton Branch	C. S. G. Rogers, A.M.E.I.C.
Saguenay Branch	A. W. Whitaker, A.M.E.I.C.
Quebec Branch	P. Methe, A.M.E.I.C.
St. Maurice Valley Branch	J. H. Fregeau, A.M.E.I.C.
Montreal Branch	H. G. Thompson, A.M.E.I.C.
Ottawa Branch	J. McLeish, M.E.I.C.
Peterborough Branch	A. L. Killaly, A.M.E.I.C.
Kingston Branch	R. A. Low, A.M.E.I.C.
Toronto Branch	E. L. Cousins, M.E.I.C.
Hamilton Branch	J. R. Dunbar, A.M.E.I.C.
London Branch	H. A. McKay, A.M.E.I.C.
Niagara Peninsula Branch	C. G. Moon, A.M.E.I.C.
Border Cities Branch	S. E. McGorman, M.E.I.C.
Sault Ste. Marie Branch	A. H. Russell, A.M.E.I.C.
Lakehead Branch	
Winnipeg Branch	A. J. Taunton, A.M.E.I.C.
Saskatchewan Branch	P. C. Perry, A.M.E.I.C.
Lethbridge Branch	R. Livingstone, M.E.I.C.
Edmonton Branch	H. J. MacLeod, M.E.I.C.
Calgary Branch	H. W. Tooker, A.M.E.I.C.
Vancouver Branch	W. H. Powell, M.E.I.C.
Victoria Branch	J. N. Anderson, A.M.E.I.C.

Awards of Medals and Prizes

The Secretary announced the winners of the various prizes and medals of The Institute. The President stated that the formal presentation of these distinctions would take place at the Annual Dinner in the evening, and announced also that in the unavoidable absence through illness of Past-President R. A. Ross, he would be represented by his daughter, Miss Vernon Ross, who had kindly consented to receive the medal on her father's behalf.

The Sir John Kennedy Medal to Robert Alexander Ross, D.Sc., M.E.I.C., Consulting Engineer, Montreal, Past-President of The Institute.

The Gzowski Medal to W. H. Powell, M.E.I.C., Engineer, Greater Vancouver Water District, Vancouver, B.C., for his paper "The First Narrows Pressure Tunnel, Vancouver, B.C."

The Leonard Medal to D. E. Keeley, M.C.I.M.M., Mines Superintendent, McIntyre Porcupine Mines Ltd., Schumacher, Ont., for his paper "Guniting at the McIntyre Mine."

The Plummer Medal to F. E. Lathe, Director, Division of Research Information, National Research Council, Ottawa, for his paper "The Utilization of Magnesian Carbonates."

Students' and Juniors' Prizes

The John Galbraith Prize (Province of Ontario) to F. A. Masse, Jr.E.I.C., Assistant Chemist, Abitibi Power and Paper Company, Sault Ste. Marie, Ont., for his paper "A History of Paper Making."

The Phelps Johnson Prize (Province of Quebec—English) to C. B. Charlewood, S.E.I.C., Noranda Mines, Ltd., Noranda, Que., for his paper "Steam Distribution in the Newsprint Mill."

Report of Council and Report of Finance Committee

The Report of Council for 1934 was read by the Secretary, and in connection therewith the President drew attention to the number of prominent members of The Institute who had died during the year. As a token of respect a moment of silence was observed while those present stood in memory of the deceased members.

The report of the Finance Committee was presented by its chairman, P. L. Pratley, M.E.I.C., after which it was moved by Mr. Pratley, seconded by J. B. Challies, M.E.I.C., and resolved that the report of Council and the report of the Finance Committee be approved.

Reports of Committees

The report of the Membership Committee was presented by its chairman, D. C. Tennant, M.E.I.C., who concurred in the emphasis given in the report of Council to the necessity for activity as regards new members, after which, on the motion of Mr. Tennant, seconded by R. W. Boyle, M.E.I.C., it was resolved that the report of the Membership Committee be adopted.

The following committee reports, as published in The Journal for February 1935, were presented: Gzowski Medal Committee, Plummer Medal Committee, Leonard Medal Committee, Students' and Juniors' Prizes, Papers Committee, Publication Committee, Library and House Committee, E.I.C. Members of the Main Committee of the C.E.S.A., Committee on Relations with National Societies, Board of Examiners and Education and the Employment Service Bureau. On the motion of C. K. McLeod, A.M.E.I.C., seconded by J. A. McCrory, M.E.I.C., the reports of the above committees were adopted.

The report of the Committee on Unemployment was presented verbally by D. C. Tennant, M.E.I.C., who drew attention to the fact that information received from the branch unemployment committees pointed to a very definite general improvement in conditions of employment of members of The Institute. The adoption of the report was moved by Mr. Tennant, seconded by P. C. Perry, A.M.E.I.C., and carried.

Branch Reports

On the motion of L. F. Grant, M.E.I.C., seconded by H. A. Lumsden, M.E.I.C., it was resolved that the reports of the various branches be taken as read and accepted.

Entrance Fee

The President pointed out that Council's action in reducing the entrance fee from the specified amounts to $5.00 for all classes of members had been effective during 1934 as approved by the Annual Meeting in February 1934, and that Council now recommended that the policy be continued during the year 1935. On the motion of P. L. Pratley, M.E.I.C., seconded by F. Newell, M.E.I.C., it was resolved that for the current year the entrance fee be continued at the sum of $5.00.

Address of Retiring President

The President then gave his address on "Structural Engineering," which is printed in full on pages 144 to 146 of this issue of The Journal, and was received with marked attention.

Election of Officers

On the conclusion of the retiring President's Address the Secretary read the report of the scrutineers appointed to canvass the officers' ballot for 1935, and the officers named therein were declared duly elected as follows:

President	F. A. Gaby
Vice-Presidents:	
Zone A	E. V. Caton
Zone C	P. L. Pratley
Councillors:	
Halifax Branch	H. S. Johnston
Saint John Branch	C. A. Vandervoort
Saguenay Branch	G. H. Kirby
St. Maurice Valley Branch	B. Grandmont
Montreal Branch	A. Frigon
	E. A. Ryan
Ottawa Branch	E. W. Stedman
Kingston Branch	L. F. Goodwin
Toronto Branch	A. B. Crealock
London Branch	J. A. Vance
Border Cities Branch	C. G. R. Armstrong
Lakehead Branch	G. H. Burbidge
Saskatchewan Branch	S. Young
Edmonton Branch	H. R. Webb
Vancouver Branch	A. S. Wootton

Mr. Shearwood then welcomed Dr. Gaby to the Presidency and asked Past-President C. H. Mitchell, M.E.I.C., and Past-President Charles Camsell, M.E.I.C., to conduct the newly elected President to the chair. After this ceremony, in expressing appreciation of the honour done him, President Gaby said that he realized that many important problems faced The Institute at this time, especially those resulting from the period of depression, but he felt that with the sympathetic co-operation of the members he would be able to meet the responsibilities of the office of president. He regretted that in the past, owing to the stress of other work, he had not been able to take as active a part in the affairs of The Institute as he had desired, but he had been able to encourage those associated with him to participate in The Institute's work. He felt that the important questions before The Institute at the present time were, first, the search for a feasible method of consolidating the engineering profession in Canada; secondly, to enhance the value of The Institute to its members and to increase its membership, and finally to balance the budget so as to maintain The Institute in a sound financial condition.

On the conclusion of the President's remarks, on the motion of J. H. Hunter, M.E.I.C., seconded by S. F. Rutherford, A.M.E.I.C., it was unanimously resolved that a very hearty vote of thanks be accorded to the retiring President and members of Council in appreciation of the work they have done for The Institute during the past year.

On the motion of P. B. Motley, M.E.I.C., seconded by G. McL. Pitts, A.M.E.I.C., it was unanimously resolved that the thanks of The Institute be conveyed to the Toronto Branch in recognition of their hospitality and activity in connection with the holding of the Forty-Ninth Annual General and General Professional Meeting.

On the motion of W. E. Ross, A.M.E.I.C., seconded by J. A. Vance, A.M.E.I.C., it was unanimously resolved that a vote of thanks be tendered to the scrutineers for their services in preparing the report on the election of officers, and that the ballot papers be destroyed.

Consolidation of the Engineering Profession

The President remarked that the next item on the agenda was a discussion on the consolidation of the engineering profession, which would no doubt result from a number of resolutions and messages which had been sent in by branches of The Institute and others in regard to this question. The President also pointed out that if, as seemed possible, the discussion proved to be an extended one, it would be possible to have an adjourned meeting to continue it on Saturday morning. The Secretary then read resolutions and messages as follows:

Resolution from the Montreal Branch supporting any movement towards uniting the engineering organizations in each province and ultimately throughout the Dominion.

Resolution from the Ottawa Branch supporting the same object in identical terms.

Resolution from the Executive Committee of the Quebec Branch supporting any renewed efforts which may lead to organizing the Canadian engineering profession on similar lines to the legal, architectural or medical professions.

Telegram from the Executive Committee of the Border Cities Branch approving in principle the proposed consolidation of the engineering profession as set forth in Mr. Pitts' pamphlet.

Telegram from the Lethbridge Branch supporting the amalgamation of associations of professional engineers and The Engineering Institute of Canada, but opposing the method suggested by Mr. Pitts.

Resolution from the Association of Professional Engineers of the Province of New Brunswick recommending that every effort be made to advance the consolidation of The Engineering Institute of Canada and the professional associations of the various provinces.

It was further pointed out that in November last Council had received a resolution on the subject from the Halifax Branch favouring consolidation which had been published in The Journal of November 1934, page 505.

Gordon McL. Pitts, A.M.E.I.C., desired to preface the discussion by a broad motion which he hoped would express the sentiments of the meeting. He would move:

> "that The Engineering Institute of Canada in Annual Meeting assembled, hereby goes on record as being in favour of the consolidation of the engineering profession in Canada."

J. H. Hunter, M.E.I.C., suggested that in view of the number of members who might wish to contribute to the discussion a time limit on speeches should be set. The President inquired whether it was the wish of the meeting that a five-minute time limit should be set for any one individual to submit his views, and this was agreed to.

J. L. Busfield, M.E.I.C., drew attention to a pamphlet, prepared by Gordon McL. Pitts, A.M.E.I.C., entitled "Proposed Consolidation of The Engineering Profession in Canada," copies of which had been distributed to the members present, and inquired whether the term "the consolidation of the engineering profession in Canada" as used by Mr. Pitts, referred to the scheme outlined in the pamphlet in question.

Mr. Pitts replied that the scheme outlined in the pamphlet was intended as a basis for discussion, which he hoped would bring out better suggestions than any of those contained in the pamphlet.

Mr. Pitts' motion was seconded by J. L. Busfield, M.E.I.C.

Dr. O. O. Lefebvre, M.E.I.C., pointed out that the resolution merely asked for the acceptance of the broad principle of affiliation, and he believed there was no ground for diversity of opinion on that point. Differences of opinion would arise when it was necessary to discuss the methods by which the goal could be reached.

The motion was then put to the meeting and carried unanimously, with applause.

Mr. Pitts explained that he desired to make another motion with a view of giving ordinary members an opportunity to express their opinions on some of the details involved in any scheme for consolidation. He would move:

"That in view of the important question as to the policy of The Engineering Institute of Canada raised by the resolutions received from the branches relative to the consolidation of the engineering profession in Canada, and as it has direct bearing on the discussions which were not completed at the last annual meeting, and as the professional papers of this afternoon's session have direct bearing on the subject, therefore be it resolved that this annual general meeting of The Engineering Institute of Canada be reconvened at three thirty p.m. to-day for the discussion of the policy of The Institute with regard to the consolidation of the engineering profession in Canada."

Mr. Pitts remarked that the papers to be read in the afternoon would entail discussion which would have a direct bearing on the method of consolidation to be followed. His motion was intended to combine the discussion on the three papers on "The Status of the Engineer" with discussion on the consolidation of the engineering profession, so that the benefit of full discussion on both matters could be obtained at the same time. Mr. Pitts' motion was seconded by R. F. Legget, A.M.E.I.C.

F. A. Dallyn, M.E.I.C., remarked that in his opinion the principal difficulty was to define what was meant by the "profession of engineering." If, as a body, The Institute proposed to deal seriously with the resolutions that had been proposed, he felt that it would first be necessary to have a committee to decide what is a "professional engineer."

Mr. Busfield suggested that it was an unusual and possibly a conflicting procedure to carry on the discussions of a professional session and the debates of the Annual General Meeting at one and the same time. He felt that if the question of consolidation were discussed in the brief period left after the three papers of the afternoon had been read, there would not be time to get any conclusive result. He was therefore of opinion that the Council should again appoint a committee to study and investigate this question. Such a committee should take the opinions of everybody desiring to express them and take time to study their views. He believed that the matter should be placed in the hands of the Council.

General C. H. Mitchell, M.E.I.C., understood from Mr. Pitts' motion that it was intended to adjourn from this particular meeting and continue the discussion at three thirty p.m.

P. C. Perry, A.M.E.I.C., felt that it would be more satisfactory to carry on the discussion on Saturday morning, and he moved as an amendment to the motion of Mr. Pitts, that the Annual General Meeting be adjourned to Saturday morning. This amendment was seconded by Mr. Busfield.

T. C. Main, A.M.E.I.C., desired to point out, before voting took place, that the titles of the papers to be presented during the afternoon were "The Engineer in Industry," "The Engineer in Private Practice," and "The Engineer in the Public Service." He noted in the first one of these, by J. M. Oxley, M.E.I.C., the following statement: "The Engineering Institute of Canada has no provincial organization, and this question brings up again the necessity for close co-operation between the provincial bodies of engineers and The Institute." He thought therefore that irrespective of the discussion now taking place, the question of consolidation was bound to come up again in the afternoon.

Dr. R. W. Boyle, M.E.I.C., saw no objection to continuing the discussion of consolidation during the afternoon session, and his views were supported by Dr. O. O. Lefebvre, M.E.I.C., who hoped that the mover of the amendment would consent to withdraw it. Mr. Perry having expressed his willingness to do this, the amendment was withdrawn. The original resolution was then put and carried.

At the suggestion of General Mitchell it was decided to continue the discussion of the question of consolidation until the adjournment hour, and Mr. Busfield hoped that speakers would confine their remarks to discussing the manner in which consolidation could be effected.

G. Stead, M.E.I.C., drew attention to the communication from the Saint John Branch, and remarked that the membership of The Institute in New Brunswick was in close and friendly relations with the Professional Association of that province. Both bodies felt that the progress made so far by the Committee of Eight had not been satisfactory, and hoped that this meeting would bring about an improvement in this condition.

Mr. Gordon McL. Pitts asked the members present to give serious study to the pamphlet which he had prepared and of which copies were in members' hands. He pointed out that the scheme outlined a Dominion or central organization whose administrative officers would be chosen by the provincial engineering organizations. The functions of the provincial organizations would be professional in every sense, while the central body would concern itself with the dissemination of professional knowledge with regard to all branches of engineering, the publication of documents and of a professional journal, and the stimulation and support of the provincial organizations, particularly those provincial associations which had not yet attained their full development. He drew attention to the similar system which had been found to work well in the architectural profession and observed that when the Royal Architectural Institute of Canada was organized, it only had five provincial bodies as component societies. The remainder came in at a later stage.

He suggested that members should approach the very debatable question of the qualifications of membership in the spirit of co-operation and compromise.

Major L. F. Grant, M.E.I.C., was inclined to doubt whether there was any desire on the part of the professional associations to meet The Institute halfway. He feared that in any arrangement with the professional associations it would be up to The Institute to make the compromises of which Mr. Pitts had spoken.

He also drew attention to the position of The Institute's branches should a scheme like that proposed by Mr. Pitts come into effect. Major Grant had great respect and affection for The Engineering Institute to which he owed many friends, inspiration for his work, and additions to his professional knowledge, and he was not disposed to support the changes suggested until satisfied that The Institute's members in the smaller branches would get something better than they now have.

A. R. Chambers, M.E.I.C., speaking as a past-president of the Association of Professional Engineers of Nova Scotia, remarked that the idea of co-operation had always been before the Association in Nova Scotia and the Nova Scotia Branches of The Institute. Joint meetings had been held and at the present time the Provincial Association was looking towards an arrangement as regards Nova Scotia somewhat similar to that now advocated by Mr. Pitts.

C. H. Attwood, A.M.E.I.C., drew attention to the close connection between the Winnipeg Branch of The Institute and the Association of Professional Engineers of Manitoba, and believed that the recent proposal for joint control of those two bodies, which had not been accepted by the Council of the Professional Engineers of Manitoba, was still a live question.

Dr. R. W. Boyle, M.E.I.C., thought that before proceeding further with the discussion, some information should be available as to the progress, if any, which had been made by the Committee of Eight, representative of the Associations, which he understood was still engaged in the study of co-ordination of the efforts of the eight professional associations.

The secretary replied that the latest information available indicated that while the Committee of Eight had held a meeting in 1933, their progress was very slow, and seemed likely to continue so.

Dr. O. O. Lefebvre remarked that as regards the Committee of Eight, the expense (some $1,500 to $1,800) involved in organizing a meeting formed a great obstacle to their progress, particularly as it was difficult, if not impossible, to carry on the work by correspondence.

T. C. Main, A.M.E.I.C., desired to add to Mr. Attwood's remarks the information that at a recent annual meeting of the Association of Professional Engineers of Manitoba, the Association indicated their interest in the work of the Winnipeg Branch of The Institute by granting $150 to The Institute's Branch to carry on its technical meetings in Winnipeg.

Mr. Main's announcement was received with applause.

The morning session adjourned at 12.30 o'clock p.m.

The afternoon session convened at 3 o'clock p.m. under the chairmanship of J. B. Carswell, M.E.I.C., who observed that the afternoon discussion would be preceded by three papers on "The Status of The Engineer." These were presented in the following order: "The Engineer in the Public Service," by G. J. Desbarats, M.E.I.C., "The Engineer in Industry," by R. E. Smythe, A.M.E.I.C., and "The Engineer in Private Practice," by J. M. Oxley, M.E.I.C.

Mr. Carswell remarked that from some comments in Mr. Desbarats' paper he gathered that conditions in the provincial government services were not so satisfactory as regards pay and security of tenure as in the service of the Federal Government. He thought this point was worthy of discussion.

Mr. Gordon Pitts pointed out that in accordance with the resolution passed in the morning, this afternoon meeting, after the presentation of the three papers listed in the programme, should be regarded as a continuation of the Annual General Meeting.

R. F. Legget, A.M.E.I.C., remarked that in all three of the papers which had just been presented, attention was drawn to certain faults in present conditions as regards the status of the engineer. He regarded that status as the position of an individual in respect to his professional society and the public. All three papers therefore indicated the necessity for immediate action to improve the present position of the engineer.

The status of the engineer was at present imperfectly realized. For example, the qualifications for a position as director of the Bank of Canada as published, mentioned "lawyers, newspaper editors, doctors, locomotive engineers, printers and the like." Mr. Legget felt that the two main obstacles were, (1) trying to obtain uniformity of legislation before co-ordinating the work of the various associations and (2) attempting to get uniformity of ideas, that is, attempting to get all the provinces to think the same, before any move is made.

This subject had been under consideration for many years and had, in fact, been referred to by Sir Casimir Gzowski at a meeting of the Canadian Society of Civil Engineers in Toronto thirty-seven years ago. Sir Casimir had said that many members then present would be grey headed before all the provinces would agree to do the same thing.

Mr. Legget believed that the scheme proposed in the pamphlet did offer a possible way to attain results, and he hoped that before the meeting broke up some definite step forward would be taken.

The chairman thanked Mr. Legget for his contribution and pointed out that the discussion should primarily follow along the lines of the papers which had been presented. Mr. Carswell drew attention to the figures given by Colonel Smythe as regards the supply of young engineers in this country, and the effect of branch industries coming into Canada from the United States and elsewhere and bringing their own engineers with them. Colonel Smythe had suggested that The Institute should co-operate with the Dominion government in dealing with this situation.

W. E. Ross, A.M.E.I.C., pointed out that in the early days of the development of the electrical industry in Canada, this development went so fast that the supply of engineers was insufficient, hence they had to be imported.

He was struck with the disparity between the large number of engineering graduates as given by Colonel Smythe, amounting to over eleven thousand for the period which he had quoted, as compared with the membership of The Institute, roughly about four thousand.

Mr. H. C. Powell, as a member of the executive of the Ontario Vocational Guidance Association, stated that there was a great many misfits in engineering and that The Institute's co-operation would be valuable in overcoming this difficulty. The problem was, to give preference to engineering graduates without any injustice to the young men trained in the technical schools. This was now a very real difficulty in the province of Ontario.

Professor Haultain, M.E.I.C., remarked that no reference had been made to mining, which was one of the outstanding industries in Canada; many mining graduates were now earning $20,000 a year because of the high status they held in the industry.

F. W. Paulin, M.E.I.C., pointed out in connection with Mr. Desbarats' paper, that possibly beneficial results would follow if a resolution were sent to every provincial government asking them to adopt a system of promotion in the civil service similar to that which exists in the Dominion government. He would move that such a resolution be sent.

At the suggestion of the chairman, Mr. Paulin's motion was left with Mr. Desbarats and the chairman who were asked to frame the wording, and the motion was seconded by K. H. Smith, M.E.I.C., who thought that more recognition should be given to engineers who are public servants. The motion was then put and carried.

Mr. Paulin felt that the motion might have a broader effect if other associations such as the Royal Architectural Institute of Canada, and the Provincial Professional Associations were asked to join. He thought that the resolution might ask that the meeting might authorize the Council to send the resolution instead of the resolution coming from the meeting.

Mr. Busfield thought that instead of waiting for a joint resolution from a number of bodies, The Institute might go ahead with its own resolution and suggest to the other societies that they follow the motion up.

Dr. Lefebvre enquired as to the actual wording of the motion.

Mr. Paulin in reply stated that the motion was:

"That this meeting request the Council to draft a resolution which should be sent to the various provincial governments and to the Dominion government, asking that the provincial governments adopt the system which is in existence in the Dominion Civil Service in connection with appointment and the promotion of engineers in the service."

Dr. Lefebvre remarked that in adopting such a resolution the meeting was taking it for granted that a satisfactory system of promotion did not exist in any of the provinces. This was not the case, particularly in the province of Quebec, and he therefore thought that some distinction should be made, and it should not be assumed pointedly that the promotion system did not exist anywhere in the provinces.

J. M. R. Fairbairn, M.E.I.C., said that any resolution of this kind should emanate from the Council or at least should go to Council and be approved by Council before being sent out as coming from The Institute.

The chairman enquired whether there were any further points in connection with Mr. Oxley's paper on which discussion was desired.

E. M. Proctor, M.E.I.C., desired to lay stress on the necessity for co-operation between the engineer, the architect, and others connected with the design and carrying out of a project. He remarked that the success of the new entrance built into the city of Hamilton a few years ago was obtained by the close co-operation between himself as engineer, the architect, John M. Hill, and the landscape architect, Mr. Borgstrom. No one of the three alone would have been able to secure a result nearly as satisfactory as that obtained by the co-operation of the three.

The chairman drew attention to a further statement in Mr. Oxley's paper suggesting that in the case of errors due to the engineer's carelessness, and involving additional cost on the part of the owner, the engineer should assume responsibility, and pay for the costs involved.

Mr. Proctor agreed with Mr. Oxley in his opinion and Mr. Pitts pointed out that the province of Quebec enforces a five-year responsibility on both the engineer and the architect.

The chairman, as a contractor of twenty-five years' experience, wished that all engineers were of the same opinion as Mr. Proctor.

Colonel C. S. L. Hertzberg, M.E.I.C., did not agree with Mr. Oxley's opinion that the engineer should assume responsibility for mistakes, the contract being between the owner and the contractor. If the owner employed an incompetent engineer he should take the same responsibility as if he had employed an incompetent lawyer. It would be just as reasonable to make the lawyer pay the whole costs of a law suit arising from his faulty legal phrases as it would be to make an engineer pay the whole costs in a contract where a mistake had been made in the engineering advice.

Mr. Proctor replied that his point was not quite that taken by Colonel Hertzberg. The kind of error to which he had referred would be a foolish but serious one, such as would occur if an engineer laid out a sewer with an uphill instead of a downhill grade, so that the sewer would have to be relaid. Such extra cost he thought should be at the engineer's expense.

Clarence M. Pitts, A.M.E.I.C., remarked that at the morning meeting a very important question, the co-ordination of the engineering profession, had been considered, and a scheme for consolidation had been presented for discussion. The morning meeting had resolved that co-ordination is a desirable thing, but Mr. Pitts did not believe that the exact form of that co-ordination could be settled at this general meeting. He thought, however, that the meeting could leave the question in a position from which definite progress could be made, and in order that there might be active prosecution of the matter he moved:

"That it be resolved that the following committee be appointed with power to add to their number, to develop the possibilities of consolidation of the engineering profession in Canada and that they report their findings to Council and to the next annual meeting of The Institute, or to a special general meeting called for the purpose. This is the personnel of the committee: Dr. A. R. Decary, Past-President of The Institute, Mr. G. J. Desbarats, former Deputy Minister of the Department of National Defence, Mr. J. B. Challies, Treasurer of The Institute, Mr. R. F. Legget, representing the junior members of the profession, and Mr. Gordon Pitts."

Mr. Clarence Pitts further remarked that the personnel of the Committee now suggested was largely divorced from Council, and he made this proposal since in his experience the matter had been brought up to Council and had been shelved on every occasion. He felt therefore that the matter should not be part of the ordinary activities of the Councillors who are concerned with the ordinary working of The Institute, and that the suggested committee, highly qualified for this work, should be appointed so that real progress could be made before the next annual meeting.

Mr. Pitts' motion was seconded by Professor R. E. Jamieson, M.E.I.C.

Colonel Smythe pointed out that the members of the Committee were busy men and he thought that secretarial facilities should be provided for them at the expense of The Institute.

Mr. Clarence Pitts thanked Colonel Smythe for his suggestion, but believed that the Committee would be able to function satisfactorily without being subsidized.

Mr. K. H. Smith believed that any arrangement for the consolidation of the profession would not in itself fix the status of the engineer, as he believed that the status of the engineer must depend on his own individual abilities.

Colonel H. J. Lamb, M.E.I.C., hoped that Mr. Pitts' motion would bring some results and was in sympathy with it, but feared that it would take time to obtain the necessary concerted definite opinion from the different associations throughout the Dominion. Colonel Lamb recalled that in 1926 Professor Haultain and himself had spent some time in Montreal representing the Association of Professional Engineers of Ontario at a meeting of representatives of all the Provincial Professional Associations. That meeting worked on this very problem, as it was called to establish ways and means for the fullest co-operation of the provincial associations with The Institute. As a result of the work which followed this meeting there was a general feeling of agreement with the principles of consolidation, but that the efforts of the Associations themselves must first be co-ordinated. In his opinion there existed a feeling of opposition on the part of some members of the Associations which would have to be overcome, and he saw no way of doing this unless the fullest expressions of opinion were obtained from all the Associations, and the scheme finally threshed out over the table.

The chairman reminded the meeting of the terms of the motion as follows:

It has been moved and seconded that a committee be appointed with power to add to their number, to develop the possibilities of consolidation of the engineering profession in Canada, and that they report their findings to Council and to the next annual meeting of The Institute, or to a special general meeting called for the purpose.

General Mitchell enquired whether it was intended that the committee should report to the next annual meeting or would Council do so. He felt that there was danger of a divided responsibility. Mr. Gordon Pitts stated that the committee's responsibility was to report to the Council and report to the annual meeting.

Mr. Fairbairn observed that under the wording of the resolution the committee would report to Council and to the Annual Meeting. He thought this would result in a divided responsibility and in his opinion the committee should report to Council who would report to the Annual Meeting.

Mr. Gordon Pitts thought the membership would be wise to leave the wording as originally proposed. The Council was not appointing the Committee, but the Annual General Meeting was putting the responsibility on them, thus the work done by the Committee should be reported to Council and also be reported to the body laying the charge upon the Committee.

Mr. Fairbairn thought this arrangement open to objection, as it would appear that the Council of The Institute was being ignored by a meeting which was empowering a committee to report back to the meeting. He urged that the motion should direct the committee to report to the Annual Meeting through Council.

The chairman then suggested that two words should be added to the resolution so that it would read: "—and that they report their findings to Council and *through Council* to the next Annual General Meeting."

With this change in the wording the motion was put to the meeting and carried, with two members dissenting.

Colonel Lamb took it for granted that the Committee which had thus been appointed could count on the full support of Council in accomplishing if possible their objective. He thought it was clear that the meeting was very definitely in favour of the Committee's object.

The session adjourned at 5.35 o'clock p.m.

Social Functions

The chairman of the Toronto Branch, Colonel R. E. Smythe, A.M.E.I.C., presided at the luncheon held on February 7th, at which a cordial welcome on behalf of the Mayor of Toronto was extended by Controller Day. He was followed by Mr. J. B. Carswell of Hamilton, whose witty address outlined the subject of the "Status of the Engineer" which was scheduled for discussion at the afternoon session. The luncheon was well attended, and served as an admirable introduction to the various activities which followed.

In the evening the Annual Dinner of The Institute took place in the Concert Hall, President F. A. Gaby, M.E.I.C., in the chair. The prizes and medals of The Institute were presented by the Hon. Grote Stirling, M.E.I.C., Minister of National Defence, and a special interest was given to the presentation by the fact that in the unavoidable absence of Dr. R. A. Ross, M.E.I.C., the recipient of the Sir John Kennedy Medal, he was represented by his daughter, Miss Vernon Ross, who received the medal on her father's behalf.

The presentation of the prizes was followed by an address by Dr. A. S. Eve, C.B.E., F.R.S., Dean of the Faculty of Graduate Studies, McGill University, Montreal, many of whose touches of humour had an evident application to financial and social questions of the day.

The dinner was followed by a reception and dance, the members and guests being received by the President and Mrs. Gaby and by the chairman of the Toronto Branch and Mrs. Smythe.

One of the most interesting functions of the meeting was a tour of the Royal Ontario Museum, which was organized for the ladies. This was personally conducted by Professor C. T. Currelly, curator of the Museum, and the visiting ladies were afterwards entertained at tea at the Museum.

The function was greatly appreciated, as was also the ladies' theatre party held on the same evening. At the smoking concert a large audience greatly enjoyed the attractive programme which had been arranged by the entertaining committee under the chairmanship of Mr. W. E. Bonn, A.M.E.I.C.

Technical Sessions

At the professional sessions held on Friday, February 8th, the papers presented and discussed in the morning were the following:

In Hall D. under the chairmanship of H. V. Armstrong, A.M.E.I.C.:

"Research and Testing Work for the Hydro-Electric Power Commission of Ontario," by W. P. Dobson, M.E.I.C.

"Gaseous Conductor Lamps and Their Applications," by J. W. Bateman.

In the library, under the chairmanship of M. Barry Watson, A.M.E.I.C.:

"Simple Graphical Solution for Pressure Rise in Pipes and Pump Discharge Lines," by R. W. Angus, M.E.I.C.

"The Montreal Neurological Institute and Its Service Equipment," by F. J. Friedman, M.E.I.C., and C. P. Creighton, A.M.E.I.C.

In the Tudor Room under the chairmanship of H. A. Babcock, A.M.E.I.C.:

"The Toronto Waterworks Extensions, a General Description of the Scheme with Details of Some Outstanding Features," by William Storrie, M.E.I.C.

"Three Bascule Bridges of the Simple Trunnion Type," by H. W. Buzzell, A.M.E.I.C., and R. S. Eadie, A.M.E.I.C.

The professional sessions at this meeting were noteworthy in including two discussions of importance. The first, held on Thursday afternoon, dealt with the "Status of the Engineer," and was based on three papers as follows:

"The Engineer in Industry," by R. E. Smythe A.M.E.I.C.

"The Engineer in Private Practice," by J. M. Oxley, M.E.I.C.

"The Engineer in the Public Service," by G. J. Desbarats, C.M.G., M.E.I.C.

In these papers the salient points were first, the situation described by Col. Smythe, arising in Canada from the importation of young technically trained men from the United States and elsewhere, largely by organizations establishing branch plants in this country; second, a question raised by Mr. J. M. Oxley as to the necessity of complete co-operation and understanding between the engineer and the architect in undertakings involving the work of both professions, and thirdly, the fact, brought out by Mr. Desbarats, that the engineering officers in some of the provincial civil services are not so favourably treated as regards conditions of appointment and security of tenure as are their brethren in the Dominion Civil Service.

As a result of the discussion it was decided to ask Council to take immediate action with regard to the last named difficulty.

On the afternoon of Friday, February 8th, a large audience, to accommodate which it was necessary to adjourn to the Ball Room, took part in a discussion on "The Water Supply of the Prairie Provinces and its Bearing on their Economic Development" under the chairmanship of Past-President S. G. Porter, M.E.I.C. No less than eleven papers were presented on various phases of the subject as follows:

"Precipitation in the Prairie Provinces," by John Patterson.

"Surface Water Supply and Run-off of the Prairie Provinces," by J. T. Johnston, M.E.I.C.

"Water Conservation in the Prairie Provinces," by T. C. Main, A.M.E.I.C.

"The Surface Waters of the Canadian Prairies," by P. C. Perry, A.M.E.I.C.

"Rural Water Supply in Alberta," by W. Calder.

"Relationship of Geology to Soil Drifting in Southern Manitoba and Southern Saskatchewan," by W. A. Johnston and R. T. D. Wickenden.

"Some Possible Sources of Ground Water in Southern Saskatchewan," by R. T. D. Wickenden.

"Mineral Character of the Underground Waters in Southern Saskatchewan," by D. C. Maddox.

"Storage on the South Saskatchewan River," by Walter Blue, A.M.E.I.C.

"Tree Planting in Relation to Drought Control," by Norman M. Ross.

"Water Phases of the Drought Relief Programme of the United States Federal Emergency Relief Administration," by Lewis A. Jones.

The active discussion which followed threw additional light on nearly all these phases of the question.

It is intended to publish these papers and the discussion thereon in an early issue of The Journal.

Following the many activities of the first two days of the meeting, a considerable number of members remained for the morning of Saturday, February 9th, and took part in inspection trips to the following engineering works of interest:

New Armouries, Fleet Street.
The Bell Telephone Company, Elgin Building.
Laboratories of the Hydro-Electric Power Commission, Strachan Avenue.
Laboratories of the Ontario Research Foundation.
Water Purification Plant, Victoria Park.

The Annual Meeting Committee of the Toronto Branch are to be congratulated on the undoubted success of the meeting due so largely to their plans and efforts. A considerable proportion of the time usually taken up by purely technical papers was this year devoted to the consideration of topics of more general interest to the public and to members of the engineering profession, and this innovation met with general approval.

OBITUARIES

Robert Angus, M.E.I.C.

It is with deep regret that the death at London, Ontario, on January 16th, 1935, of Robert Angus, M.E.I.C., is placed on record.

Mr. Angus was born at Kingston, Ontario, on January 11th, 1842, and in 1865 he entered upon an apprenticeship with the Hon. Elijah Leonard, who was at that time engaged in the manufacture of sawing machines, threshing machines, water turbines and an occasional steam engine. Books and engineering periodicals were scarce but Mr. Angus was an earnest student and a remarkably ingenious mechanic, and with the aid of a few well-selected books and papers, was able in his early years to make the drawings for a number of steam engines, which were later installed.

When the town of St. Thomas decided in 1873 or 1874 to put in its first pumping engine Mr. Angus made the necessary designs and drawings and supervised the construction of the machine which proved very successful. This was followed in the next year, by a pumping engine for Sarnia, and since that time he has designed and superintended the construction of a very large number of engines and other machines.

For over thirty years he was with E. Leonard and Sons, London, and during a large part of this time he had charge of the shop. He also served as master mechanic with the Standard Oil Company, Cleveland, Ohio, for a few years, and during his later years Mr. Angus had a very busy life as a consultant on engineering matters.

Mr. Angus showed an enthusiastic interest in every engineering cause, and joined The Institute as a Member on April 18th, 1922. He was the first Canadian member of the American Society of Mechanical Engineers.

Professor R. W. Angus, M.E.I.C., head of the Department of Mechanical Engineering, University of Toronto, is one of Mr. Angus' two surviving sons.

R. O. Wynne-Roberts, M.E.I.C.

Robert Owen Wynne-Roberts, M.E.I.C.

Members of The Institute will learn with regret of the death of Robert Owen Wynne-Roberts, M.E.I.C., at Toronto on February 5th, 1935.

Mr. Wynne-Roberts was born at Liverpool, England, on October 12th, 1864, and in 1882-1889 was assistant town engineer of Llandudno, Wales. In 1889-1894 he was borough, water and gas engineer for Caernarvon, and was subsequently, until 1898, borough and water engineer of Oswestry. From 1898 until 1907 Mr. Wynne-Roberts was in South Africa, acting as city and water engineer of Capetown. Coming to Canada in 1910 he entered private practice. and was later retained by the city of Regina and the Saskatchewan government before he settled in Toronto and established the firm of Wynne-Roberts, Son and McLean, consulting engineers. Mr. Wynne-Roberts' practice was chiefly concerned with municipal undertakings, and at various times he was engaged by Belleville, Blenheim, Kincardine, New Liskeard, Niagara Falls, and many other municipalities.

Mr. Wynne-Roberts was a member of the Institution of Civil Engineers (Great Britain) and the American Society of Engineers. He was a graduate of the Royal Sanitary Institute, England.

He joined The Institute as a Member on March 11th, 1913, and took a keen interest in its affairs, having served on Council in the years 1922, 1923 and 1924 and been chairman of the Toronto Branch in 1920.

Albert Henry Pattenden, M.E.I.C.

Deep regret is expressed in placing on record the death of Albert Henry Pattenden, M.E.I.C., which occurred at Montreal, on February 26th, 1935, as a result of burns received in October, 1934, during an explosion which occurred in an oil switch in the power house at the Central Division of the Montreal General Hospital. At the time of the accident Mr. Pattenden, who was building superintendent of the Central and Western Divisions of the Hospital, was supervising the restoration of service after a breakdown.

Mr. Pattenden was born in London, England, on December 23rd, 1889, and from 1903-1907 was apprentice with Everett Edgecumbe, electrical and mechanical engineers in London. Coming to Canada in 1907, Mr. Pattenden was with the Montreal Light Heat and Power Company until 1910, when he became connected with the Monarch Electric Company, Montreal, being engaged on the design, fabrication and installation of power house and sub-station equipment. From 1912 until 1916 he was in charge of the electric car department in the Angus shops of the Canadian Pacific Railway Company. In 1916-1918 Mr. Pattenden was in charge of electrical and mechanical development work with W. J. O'Leary and Company, Montreal, and following this was until 1922 electrical engineer of eastern plants with the Canadian Consolidated Rubber Company, being transferred to the central office as electrical engineer of eastern and western plants at that time. Mr. Pattenden was later industrial engineer in the New Business Department of the Montreal Light Heat and Power Cons., and in 1929 was with Gallard and Company, Montreal. In 1932 Mr. Pattenden accepted the appointment which he held up to the time of the fatal accident.

Mr. Pattenden joined The Institute as an Associate Member on September 18th, 1923, and became a Member on June 15th, 1928.

PERSONALS

J. B. Clark Keith, A.M.E.I.C., chief engineer of the Essex Border Utilities Commission, Windsor, Ontario, has been elected president of the Association of Professional Engineers of the Province of Ontario.

John Stephenson, A.M.E.I.C., has joined the staff of the Canadian Atlas Steel Limited, Welland, Ontario, as plant maintenance engineer. Mr. Stephenson was formerly with the General Engineering Company of Canada Limited, Toronto.

W. J. Lecky, S.E.I.C., is now a demonstrator and sales engineer on the staff of Holman Machines Limited, Noranda, Que. Mr. Lecky, who graduated from McGill University in 1932 with the degree of B.Eng., was for a time with Noranda Mines Limited, at Noranda, and has more recently been with Howey Gold Mines Limited, at Red Lake, Ontario.

C. Hastings Skelton, S.E.I.C., who was formerly with the Nichols Engineering and Research Corporation of Canada, Limited, Montreal, is now connected with the research department of the Consolidated Paper Corporation, Wayagamack Division, at Three Rivers, Que. Mr. Skelton graduated from McGill University in 1930 with the degree of B.Sc.

M. Stuart Nelson, A.M.E.I.C., has recently become connected with Farand and Delorme, Limited, Montreal, as contracting engineer. Following graduation from McGill University in 1915 with the degree of B.Sc., Mr. Nelson was for a short time surveyor with the International Nickel Company, and from January 1916 until May 1917 he was engaged as a chemist, and on industrial inspection, etc. From May until November 1917 he was works engineer with A. F. Byers and Company Limited, and later until June 1918, Mr. Nelson was plant chemist with Canadian Electro-Metals at Shawinigan Falls, Que. From June 1918 until March 1919 he was a lieutenant with the Canadian Engineers. In May 1919 Mr. Nelson again became connected with A. F. Byers and Company Limited, as building foreman and superintendent, and from June 1920 until May 1923 was in charge of purchasing and subcontracts with the same firm. In May 1923 he joined the staff of A. Faustin Limited as assistant manager and secretary-treasurer and remained with that firm until recently.

Member of Institute on Directorate of Bank of Canada

W. D. Black, M.E.I.C., vice-president and general manager of the Otis-Fensom Elevator Company Limited, Hamilton, Ontario, has been elected to the directorate of the Bank of Canada.

Graduating from the University of Toronto in 1910 with the degree of B.A.Sc., Mr. Black was subsequently resident engineer for Gustav Lindenthal on the Kentucky river high bridge. In 1911 he joined the staff of the Otis-Fensom Elevator Company Limited, as manager for the Maritime Provinces and Quebec, and held that position until 1918 when he was engineer in charge of munition production for the company. In 1918-1921 he was manager of construction, and in 1921-1925 works manager, being appointed general manager in 1926.

In 1934, as president of the Industrial Relations Committee of the Canadian Manufacturers' Association, Mr. Black was appointed employers' delegate to the International Labour Conference in Geneva.

J. A. McCrory, M.E.I.C., Receives Important Appointment

J. A. McCrory, M.E.I.C., has been appointed vice-president and chief engineer of the Shawinigan Engineering Company Limited.

Mr. McCrory graduated from Pennsylvania State College in 1907 with the degree of B.Sc. in mechanical engineering, and coming to Canada in 1910, located at Toronto, where he was engaged on the design and construction of the London Hydro sub-station and in general building work. In 1912 he moved to Montreal, and for four years was employed on design and supervision of reinforced concrete construction. Mr. McCrory joined the staff of the Shawinigan Water and Power Company in 1916 as a designer, and on the formation of the Shawinigan Engineering Company Limited, in 1918, was appointed office engineer. During the intervening period he has been actively engaged on the design and investigation of a large number of hydro-electric developments for the Shawinigan Water and Power Company and others.

Mr. McCrory has taken an active interest in the affairs of The Institute since he became an Associate

J. A. McCrory, M.E.I.C.

Member in 1921 and a full Member in 1926, having been chairman of the Montreal Branch in 1929 and having represented that Branch on the Council of The Institute continuously since 1930.

Mr. McCrory is a member of the Corporation of Professional Engineers of Quebec, the Canadian Engineering Standards Association, the Canadian Electrical Association, and the American Society for Testing Materials.

Richard E. Heartz, M.E.I.C., is now assistant chief engineer of the Shawinigan Engineering Company Limited.

Mr. Heartz graduated from McGill University in 1917 with the degree of B.Sc., and immediately after graduation was employed by the St. Maurice Construction Company at La Loutre, on the construction of the Gouin dam. Later in the same year he enlisted with the Royal Air Force, received his commission early in 1918, and was appointed flying instructor, being demobilized in 1919. In that year he joined the Fraser Brace Engineering Company, Ltd., and was employed on the construction of the Big Eddy dam on the Spanish river. Mr. Heartz became resident engineer at La Gabelle development on the St. Maurice river in 1922, having joined the staff of the Shawinigan Engineering Company Limited in 1920. He was resident engineer on the St. Narcisse development on the Batiscan river in 1924-1925, and in 1926 was transferred to Montreal for investigation and preliminary design of hydro-electric developments. In 1927 Mr. Heartz was appointed resident engineer of the Paugan Falls development on the Gatineau river, and since the completion of that undertaking has been connected with the design and construction of different hydro-electric projects.

R. E. Heartz, M.E.I.C.

E. Geoffrey Cullwick, Jr.E.I.C., formerly assistant professor in electrical engineering at the University of British Columbia, Vancouver, B.C., has resigned from that position to join the professional staff of the Military College of Science, Woolwich, England, as lecturer in electrical engineering. It will be recalled that Mr. Cullwick, who graduated from Cambridge University in 1925 with the degree of B.A. in engineering, received honourable mention for his paper on "Engineering Education" submitted for the Past-Presidents' Prize for the year 1930-1931 and also for one on "The Effect of the Development of the Electronic Valve upon Electrical Engineering and Industry" which he submitted for the year 1932-1933. Following graduation, Mr. Cullwick was for a time connected with the Canadian General Electric Company, Ltd., at Peterborough, Ontario.

Dr. F. D. Adams, Hon.M.E.I.C., Honoured

Dr. Frank D. Adams, Ph.D., D.Sc., F.G.S.A., F.R.S., Hon.M.E.I.C., emeritus vice-principal of McGill University and eminent geologist and palaeontologist, has been appointed a foreign member of the Swedish Academy of Science of Stockholm, the body whose duty it is to select each year the person to whom shall be awarded the Nobel prizes in chemistry and physics. This is in recognition of the important contributions which Dr. Adams has made to the science of geology. Dr. Adams has also been elected a foreign member of Academia Asiatica, of Teheran, Persia.

Gordon McLeod Pitts, A.M.E.I.C., Elected President of the Province of Quebec Association of Architects

Gordon McLeod Pitts, a member of the firm of Maxwell and Pitts, Architects, Montreal, has been elected President of the Province of Quebec Association of Architects.

A native of Fredericton, N.B., Mr. Pitts graduated from McGill University in 1908 with the degree of B.Sc., and in 1909 received the degree of M.Sc. In 1916 he received the degree of B.Arch.

In 1906 Mr. Pitts was an engineer on construction with the Canadian Pacific Railway and in 1908 was a senior draughtsman with the Transcontinental Railway at Ottawa, Ont. In 1909 he joined the staff of P. Lyall and Sons Construction Co. Ltd., as engineer and superintendent, and in 1912 was supervising engineer for the construction of the Montreal High School for the Protestant Board of School Commissioners. He was assistant to John A. Pearson, Architect for the Parliament Buildings at Ottawa. In 1919 he joined the firm of Edward and W. S. Maxwell, Architects of Montreal, forming the firm of Maxwell and Pitts in 1923, thereby maintaining one of the oldest architectural practices in Canada.

Dr. R. W. Boyle, M.E.I.C., director, Division of Physics and Engineering, National Research Council, Ottawa, was elected chairman of the Ottawa Branch of The Institute for the year 1935, at the Branch's annual meeting recently.

Dr. Boyle is a graduate of McGill University, having received the degree of B.Sc. in 1905, that of M.Sc. (for research in physics) in 1906, and Ph.D. in 1909, and being awarded the 1857 Exhibition Research Scholarship, he was at Manchester University, England, from 1909 until 1911.

Returning to Canada, Dr. Boyle was assistant professor of physics at McGill University in 1912, and in the same year was appointed professor of physics at the University of Alberta. During the years 1916-1919, Dr. Boyle was in charge of experimental work on, and later consultant on new methods of submarine detection for the Admiralty Board of Inventions and Research. In the autumn of 1919 he resumed the professorship of physics and of electrical engineering at the University of Alberta, and in 1921 was appointed Dean of the Faculty of Applied Science at the same university, holding that office until 1929 when he accepted the appointment which he now holds.

H. G. Thompson, A.M.E.I.C., has been appointed manager of the Toronto sales office of Canadian Vickers Limited. Mr. Thompson completed his course at the University of Toronto following his return from overseas, where he served with the R.N.A.S., graduating in 1922 with the degree of B.A.Sc., and was subsequently engaged on engineering design, estimating and sale of heating and ventilating equipment with the Canadian Sirocco Company Limited, Montreal. From June to November 1923 he was supply engineer for pulp mill equipment with the Riordon Company Limited at Temiskaming, Que., and from that time until 1925 was connected with the Combustion Engineering Corporation Limited, as engineer on erection, service and sale of boilers, mechanical stokers, etc., and later as assistant to the Montreal manager. In October 1925 Mr. Thompson joined the staff of Affiliated Engineering Companies Limited, and in 1930 became associated with F. S. B. Heward and Company Limited, Montreal. At the inception of the E-I-C Engineering Catalogue in 1932, Mr. Thompson was appointed editor of indices. In 1934 he joined the sales force of Canadian Vickers Limited, specializing in the boiler field.

The Sir John Kennedy Medal Awarded to Robert Alexander Ross, M.E.I.C.

Robert Alexander Ross, M.E.I.C., receives the Sir John Kennedy Medal of The Engineering Institute of Canada for the year 1934.

This gold medal was established in commemoration of the great services rendered to the development of Canada, to engineering science and to the profession by the late Sir John Kennedy, past-president of The Institute. It is the highest honour which The Institute can bestow and is given only when the occasion warrants, as a recognition of outstanding merit in the profession or of noteworthy contribution to the science of engineering, or to the benefit of The Institute. Previous recipients of this award have been the late Colonel R. W. Leonard, M.E.I.C., G. H. Duggan, M.E.I.C., and A. J. Grant, M.E.I.C.

Born at Woodstock, Ontario, on August 29th, 1865, Mr. Ross was educated at the University of Toronto, graduating from the School of Practical Science in 1890.

Following graduation he was engineer in charge of the engineering department of the Canadian General Electric Company at Sherbrooke, Que., and Peterborough, Ont., until 1893, when he was appointed chief electrical and mechanical engineer of the Royal Electric Company of Montreal in charge of all engineering in station and shops. In 1896 Mr. Ross was granted the professional degree of E.E. by the University of Toronto, and since that date has been engaged in consulting engineering practice in Montreal, having been responsible for the design of many important electrical and power installations, including the West Kootenay Power and Light plant at Bonnington Falls, B.C., the Huronian Company's plant, and that of the Canadian Copper Company at Copper Cliff, Ont., the West India Electric Company, Jamaica, and many others.

R. A. ROSS, M.E.I.C.

Mr. Ross has acted at various times as consultant to most of the larger cities and municipalities throughout the Dominion and has carried out work in China, India, Straits Settlements, Russia, Finland, Scotland, Australia and the United States.

An interesting feature of Mr. Ross's professional career has been his long connection with the City of Westmount as their consulting engineer. His original commission from the city led to the installation of their well known municipal power plant and refuse destructor. This plant was built in 1905 and its success was largely due to the progressive ideas of the consulting engineer, while its operation as a municipal undertaking did much to bring about successive reductions in electrical rates in the Island of Montreal.

In 1916 at the time of its establishment, he was appointed a member of the Honorary Advisory Council for Scientific and Industrial Research, and later held the office of chairman of that body for some years. He was also chairman of the Lignite Utilization Board (1918-1924).

From 1918 until 1921 Mr. Ross served as a member of the Administrative Commission of Montreal, a body formed by the provincial government to save the city from financial chaos, and in 1921 he received the honorary degree of Doctor of Science from the University of Toronto.

In 1923 Dr. Ross was appointed a member of the Gregory Commission, a Royal Commission instituted by the provincial government of Ontario to investigate and report upon the affairs of the Hydro-Electric Power Commission of Ontario, and in 1932 was a member of the Board of Engineers which carried out an important investigation into power rates in the city of Quebec and reported to the city council thereon.

Dr. Ross has always taken a leading part in the affairs of The Engineering Institute of Canada, having joined the Canadian Society of Civil Engineers as a Member on May 6th, 1897. He served as a member of Council for eight years, was a vice-president from 1914 to 1916, and filled the presidential chair of The Institute in 1920.

He is a Fellow of the American Institute of Electrical Engineers.

Throughout Dr. Ross's career he has been unsparing in devoting time and effort to the service of his fellow engineers and the public. A man of unswerving integrity and clear vision, his independence of character and his professional competence have combined to give special value to his advice, a feature most clearly exemplified during his connection with the management of the affairs of the city of Montreal.

Always generous in his appraisal of others, he has never sought publicity as regards his own achievements, although these have marked him out, both as a distinguished public servant and an outstanding member of his profession.

Award of Medals and Prizes

Gzowski Medal

W. H. Powell, M.E.I.C., has been awarded the Gzowski Medal for the year 1933-1934 for his paper entitled "First Narrows Pressure Tunnel, Vancouver, B.C." which was published in The Engineering Journal for June 1934.

W. H. Powell, M.E.I.C.
Gzowski Medallist

F. E. Lathe
Plummer Medallist

D. E. Keeley
Leonard Medallist

F. A. Masse, Jr.E.I.C.
John Galbraith Prizeman

Mr. Powell graduated from McGill University in 1909 with the degree of B.Sc., and was subsequently first assistant and articled pupil to B. J. Saunders, D.L.S. At the beginning of the year 1910 he was with the Maritime Bridge Company, New Glasgow, as a draughtsman, and in 1910-1911 was assistant on a Dominion Hydrographical Survey in the neighbourhood of Prince Rupert. In the following year Mr. Powell was in charge of a subdivision survey in northern Saskatchewan with the Topographical Surveys Branch, Department of the Interior, and from March to August 1912 was in private practice on miscellaneous surveys. In August 1912 he was appointed city surveyor for the city of Vancouver which position he held for a number of years. In 1928 Mr. Powell became engineer for the Greater Vancouver Water District, and still holds that appointment.

Plummer Medal

The Plummer Medal Committee has awarded that medal for the year ending June, 1934, to Mr. F. E. Lathe, Director, Division of Research Information, National Research Council, Ottawa, for his paper on "The Utilization of Magnesian Carbonates" which appeared in the December, 1933, issue of The Journal.

Mr. Lathe is a graduate of McGill University, having received the degree of B.A. in chemistry in 1904, that of B.Sc. in metallurgy in 1907, and his M.Sc. in metallurgy in 1915.

From 1910 until 1924 Mr. Lathe was chief chemist or metallurgist with copper and nickel companies in British Columbia, Chile, Ontario and Quebec, with the exception of 1914-1915, when he was lecturer in metallurgy at the University of Toronto. From 1925 until the present time he has been with the National Research Council, first as technical assistant to the president, and for the last five years in the position which he now occupies. Mr. Lathe is a Fellow of the Canadian Institute of Chemistry and the American Association for the Advancement of Science, a member of the Canadian Institute of Mining and Metallurgy, the American Institute of Mining and Metallurgical Engineers, and the Canadian Ceramic Society.

Leonard Medal

Mr. D. E. Keeley is the recipient of the Leonard Medal for the year 1933-1934, the award being for his paper on "Guniting at the McIntyre Mine" which appeared in the June, 1934, Bulletin of the Canadian Institute of Mining and Metallurgy.

C. B. Charlewood, S.E.I.C.
Phelps Johnson Prizeman

Mr. Keeley, who is a graduate of Queen's University, Kingston, is mine superintendent of McIntyre Porcupine Mines Limited, Schumacher, Ontario. He is a member of the Canadian Institute of Mining and Metallurgy. Leonard medallists must be members either of The Engineering Institute of Canada or of the Canadian Institute of Mining and Metallurgy.

Students' and Juniors' Prizes

Two of these prizes were awarded this year as follows:

The John Galbraith Prize (province of Ontario) to F. A. Masse, Jr.E.I.C., assistant chemist, Abitibi Power and Paper Company, Sault Ste. Marie, Ontario, for his paper on the "History of Paper Making."

The Phelps Johnson Prize (Province of Quebec, English) to C. B. Charlewood, S.E.I.C., who is attached to the mechanical department of Noranda Mines Limited, Noranda, Que., for his paper entitled "Steam Distribution in the Newsprint Mill."

ELECTIONS AND TRANSFERS

At the meeting of Council held on February 22nd, 1935, the following elections and transfers were effected:—

Members

CAMPBELL, Lorne Argyle, vice-president and general manager, West Kootenay Power and Light Company, Limited, Trail, B.C.

IRWIN, Gifford Melville, B.Sc., (McGill Univ.), city engr. and water commissioner, City of Victoria, B.C.

Associate Member

RIMMER, Ralph Horton, B.S. (Chem.), (Univ. of N.C.), asst. supt., aluminum plant (Arvida works), Aluminum Company of Canada Ltd., Arvida, Que.

Transferred from the class of Associate Member to that of Member

BONN, William Ernest, (Glasgow & West of Scot. Tech. Sch.), engr. in charge, Toronto district, Canadian Dredging Co. Ltd., Toronto, Ont.

CREALOCK, Archie Burgess, B.A.Sc., (Univ. of Toronto), consltg. engr., Kent Bldg., Toronto, Ont.

SMYTHE, Ro. Eric, Colonel, D.S.O., M.C., B.A.Sc., (Univ. of Toronto), director, Technical Service Council, Toronto, Ont.

WILSON, William Stewart, B.A.Sc., (Univ. of Toronto), secretary, Faculty of Applied Science and Engineering, University of Toronto, Toronto, Ont.

WOOD, James Robert, Associate (Civil Engrg.), (Royal Technical College), asst. city engr., Calgary, Alta.

Transferred from the class of Junior to that of Associate Member

COCKBURN, John Macmillan, B.Sc., (Queen's Univ.), engr., telephone systems engrg. dept., Northern Electric Co. Ltd., Montreal, Que.

HICKS, Ben Church, B.Sc., (McGill Univ.), elect'l. engr., Shawinigan Water & Power Company, Montreal, Que.

JUSTICE, Claude Wellington, B.Sc., (Univ. of Man.), asst. to plant engr., Noranda Mines Ltd., Noranda, Que.

LANGLOIS, William Lawrence, B.A.Sc., (Univ. of Toronto), acting asst. district engr., Dept. of Northern Development, Wanapitei, Ont.

MITCHELL, J. Murray, B.Sc., (McGill Univ.), district traffic supt., Bell Telephone Company of Canada, Three Rivers, Que.

Transferred from the class of Student to that of Associate Member

HANGO, J. Raymond, B.Sc., (Univ. of Alta.), asst. elect'l. engr., Duke-Price Power Co. Ltd., Arvida, Que.

JUBIEN, Ernest Burchell, B.Sc., (McGill Univ.), engrg. dept., Canadian Industries Limited, Montreal, Que.

LALONDE, Jean Paul, B.A.Sc., C.E., (Ecole Polytech., Montreal), chief engr., J. M. Eugene Guay Inc., consltg. engr., Montreal, Que.

MILLER, Charles, B.Sc., (Queen's Univ.), engrg. staff, Duke-Price Power Co. Ltd., Arvida, Que.

Transferred from the class of Student to that of Junior

DUTTON, William Lawrason, B.A.Sc., (Univ. of Toronto), engr., Union Gas Company of Canada Ltd., Chatham, Ont.

FISHER, Sidney Thomson, B.A.Sc., (Univ. of Toronto), design engr., Northern Electric Co. Ltd., Montreal, Que.

PIDOUX, John Leslie, B.Sc., (Univ. of Alta.), instr'man., Dept. Public Works of Alberta, Calgary, Alta.

Students Admitted

CROTHERS, Donald Coverdale, (Queen's Univ.), 11 Sydenham St., Kingston, Ont.

DAVIDSON, Arthur Campbell, (Univ. of Man.), 1732-11th St. West, Calgary, Alta.

At the meeting of Council held on February 7th, 1935, the following Students were admitted:—

BAGGS, William Clyde, (McGill Univ.), 3506 University St., Montreal, Que.

BONNELL, A. Robertson, (Univ. of N.B.), 447 Charlotte St., Fredericton, N.B.

BREWER, Douglas Jared, (Univ. of N.B.), 269 Woodstock Road, Fredericton, N.B.

DUNLOP, James Russell, (McGill Univ.), 184 Primrose Ave., Ottawa, Ont.

MAYHEW, Earle Chandler, Lieut., O.M.E., (Grad. R.M.C.), (Queen's Univ.), Headquarters, M.D. No. 3, Kingston, Ont.

MORRIS, Harold Kempffer, (McGill Univ.), 2063 Stanley St., Montreal, Que.

ZION, Alfred Bernard, (McGill Univ.), 5280 Byron St., Montreal, Que.

Studies on the Thermochemistry of the Compounds Occurring in the System CaO-Al_2O_3-SiO_2. V. The Heats of Formation of Tricalcium Silicate and Dicalcium Silicate, by O. K. Johannson and T. Thorvaldson.

BOOK REVIEWS

Report on the Treatment of Welded Structures by the Metallic Arc Process

Published by the Institution of Structural Engineers, London, England, 1934. 5½ by 8½ inches, photos, diagrams, etc. 5 shillings. Paper.

Reviewed by P. L. Pratley, M.E.I.C.*

This report is definitely a notable contribution to the proper appreciation of this comparatively new art—the application of electric welding processes to structural steel fabrication.

Part I, which deals with the process and its technique, is particularly valuable, constituting as it does a clear presentation of the aim, the materials, the methods, the difficulties encountered and the experience gained up to date both in practice and research.

The basic principles are explained with commendable lucidity and there can be no doubt but that a large number of engineers interested in arc welding as a means of accomplishing the connection and physical integration of metal parts will find here just that amount of technical description which will enable them to understand the present state of the art and its rapid development both in respect of direction and concerning the various limiting influences.

---

*Monsarrat and Pratley, Montreal.

The references to flux-coated electrodes, to the functions of their chemical components, to the gases evolved, and to the current absorbed, are concisely expressed and very well illustrated.

The variety of deposited beads, their critical analysis, and some valuable practical hints and suggestions regarding the length of run available or desirable from standard lengths of electrodes of specific gauges, are all treated in this first part and accompanied by useful though simple illustrative diagrams.

Procedure in fabrication may differ as between various shops and individual supervisors, but such informative notes on accepted practice under stated conditions are eagerly sought by those engaged in developing the process, under similar, or even dissimilar conditions. The experiments on distortion which are described in the Report, on pages 35 to 39, are both interesting and instructive and serve to remind the interested reader that experience and study are both necessary and sufficient to avoid trouble in this connection.

The second section of the Report, Part II, deals with the metallurgical aspect and treats of the various electrodes, the preparation of the surfaces, the resulting fusions, and the types of corrosion, slag inclusion, and other sources of defect. Numerous micro-photographs illustrating good and bad beads, the effects of various treatments upon the electrodes, actual joints between weld metal and parent metal, etc., etc., including a series of X-ray exposures and a number of diagrammatic sketches add many valuable and informative pages to this portion of the Report.

The following section, Part III, deals with sundry tests made under shop conditions and is again copiously illustrated with photographs, sketches and diagrams.

Part IV is a very useful section in the nature of suggestions for specifications covering ordinary practice and including recommended working stresses and types of connection.

A glossary of technical terms and a very complete index round out the volume.

Naturally, the references to experiment and practice concern "old country" shops, and one or two features such as the use of a two-number indicator to describe the weld instead of the throat thickness are new to the present reviewer. There may be advantages in this nomenclature and no doubt those actually concerned in production, such as designers, supervisors, and operators, will reach their own opinions as to the desirable means of specifying the sizes of the actual fillets. In the method used, the indication 8/10 means that a No. 8 electrode of the standard 18-inch length would deposit 10 inches of run which is equivalent to a 7/32-inch fillet using the throat dimension as is present common practice in Canada. Earlier in the Report mention is made of the fact that there exists an optimum length of run for each gauge of electrode which produces the best general economy with the greatest ease of operation. The comfort of the operator is stressed as an essential feature in the securing of high class welding and the supply of proper equipment, power plant, electrode holders, eye-shields, etc., is referred to as only reasonable if good workmanship is to be obtained.

The perusal and study of this Report is cordially recommended to all engineers and operators closely concerned with the process or with the acceptance of welding and the Institution of Structural Engineers of Great Britain are certainly to be congratulated on this production.

Les Réseaux de Transmission d'Energie

By Jean Fallou, Librairie-Imprimerie Gauthier-Villars, Paris, 1935. 6½ by 10 inches, 558 pages, 125 frs. Paper.

Reviewed by Dr. A. Frigon, M.E.I.C.*

This is a complete and elaborate theoretical treatment of the most important practical problems encountered by the electrical engineer specializing in the design and operation of power transmission systems. The author, a doctor of science and a graduate engineer of "L'Ecole Supérieure d'Electricité," is now attached as consulting engineer to "L'Union d'Electricité." He is familiar with recent developments in this field and has given due consideration to the practice followed on this side of the Atlantic.

The book has been divided into four sections, each containing all the important essential principles necessary for the understanding of the particular problems involved. The first part, in which we find the general theory of transmission systems, serves as an introduction to the methodical discussion of the various systems of transmission now in use. Their regulation and stability are also considered here.

The second section has been devoted to the study of overloads. After having developed a method for the calculation of short circuit currents, the author reviews the troubles caused by overloads; abnormal heating, surges and excess-voltage induced in telephone communication lines. Special attention is given to the means available for limiting overloads. The different methods of grounding the neutral point are also analysed. The last chapter in this section discusses modern automatic instruments used for limiting and recording short circuits.

*Dean, Ecole Polytechnique, Montreal.

The third part contains the general theory of transient and normal conditions which produce excess-voltage. The author lays down a number of formulae frequently used for the calculation of transient phenomena and indicates the characteristic magnitudes which must be assigned to the different parts of a transmission system in order that they may be assimilated to simple circuits. Several causes of over voltage, such as resonances, ground surges, switch manipulation, etc. are analysed. A special chapter describes the registering of excess-voltage by the klydonograph.

The fourth part treats of protective systems from a theoretical viewpoint. A description of numerous up-to-date devices is also included.

As a whole this is an excellent reference book, well printed and profusely illustrated with diagrams. The reviewer finds it difficult to understand why the author has not considered it advisable to provide such an important work with an index.

BULLETINS

Vitrified Clay Products.—Three booklets have been received from the National Sewer Pipe Company Limited, Toronto, as follows: One 8-page booklet containing particulars on wall coping; another, 16-page booklet dealing with clay pipe, outlining the effect of chemicals on this product, its uses, and methods of laying; and a third containing 16 pages on flue lining, with reasons why flue lining should be used, with typical applications, standard sizes manufactured, and a modern chimney construction by-law.

Underfeed Stoker.—A 16-page booklet received from the Combustion Engineering Company Inc., New York, deals with the new Type-E centre-retort underfeed stoker. Particulars of the drive, automatic control, forced draught equipment, and details of construction are given as well as sample applications to various types of boilers.

Metal Spray Gun.—A 12-page bulletin issued by the Metal Spray Company, Los Angeles, Calif., gives particulars regarding specifications, and application of metal spraying.

Piston Pumps.—The Worthington Pump and Machinery Corporation, Harrison, N.J., have issued a 4-page leaflet giving details of their horizontal, piston pattern pumps, simplex and duplex for petroleum oil refineries. These are made in a number of sizes, capable of handling liquids up to a temperature of 700 degrees F.

Aluminum Foil.—A 4-page folder received from the Alfol Insulation Company Inc., New York, outlines the use and advantages of aluminum foil as a modern fire-proof insulation.

Accumulators.—A 4-page pamphlet received from the Seamless Steel Equipment Corporation, New York, describes the advantages and methods of operation of Hydraulik compressed air accumulators without pistons or floats, also hydraulic presses. This company has recently taken over the representation of the Hydraulik, G.m.b.H. of Duisburg, Germany.

Compressors.—A 4-page leaflet received from the Canadian Ingersoll Rand Company Limited, Montreal, gives particulars of the XVH compressor which is available in capacities ranging from 400 c.f.m. upward.

The Municipal Diesel Plant of the City of St. Hyacinthe

From information supplied by

Nicholas Sauer,

Diesel plant, City Hall, St. Hyacinthe, Que.

In the spring of 1933 the question of building a municipal power plant for the city of St. Hyacinthe came under consideration, as the result of an endeavour to secure lower power rates for the citizens.

Under the direction of the city council, a detailed study of the subject was made, it was decided to install Diesel engines, many Diesel plants on the North American continent and in England and Germany were inspected, and an estimate of the cost of an undertaking of this nature was prepared.

The city council recommended that a bond issue for $310,000 be arranged for the establishment of a Diesel electric plant and a distribution system for the city, and requested tenders on the equipment required in accordance with the city's specifications.

In the beginning of 1934 a contract was awarded to the Montreal Locomotive Works Limited for four 600-h.p. Diesel engines, to be designed by McIntosh and Seymour Inc. of Auburn, N.Y., the contracts for the electrical equipment were placed with the Canadian General Electric Company and the Canadian Westinghouse Company.

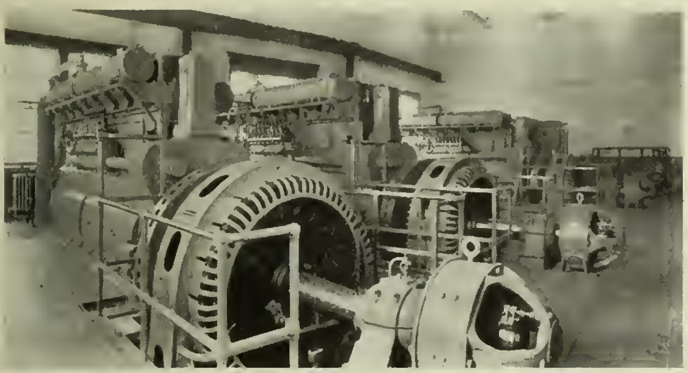
Work on this plant was commenced in April 1934, and operation started on November 30th of the same year, power being supplied for the waterworks and the city street lighting system.

The new plant has been installed in space already available in the city waterworks building, thereby saving the cost of a building and greatly reducing the cost of the equipment necessary for supplying cooling water. On the other hand there is a certain disadvantage in that the plant is not centrally located with respect to the load, and the limited space in the engine room imposed some restriction regarding the arrangement of the engines and auxiliaries.

This engine room is 59 feet long by 34 feet wide, 20 feet high and contains four 600-b.h.p. Diesel electric units and auxiliaries, with provision for one additional unit.

The basement contains the engine sump-tanks, oil-coolers, air receivers, water pumps and fuel oil transfer pumps.

A good deal of consideration was given to the construction of the engine foundations. The sub-soil is clay, and in order to isolate the running machinery it was decided to place a 2-inch layer of cork below each foundation block in the sub-foundation, the foundation blocks being arranged in pairs, each pair standing on a separate concrete mat.



Diesel Electric Units, St. Hyacinthe.

Each engine is rated at 600 b.h.p. at 360 r.p.m. The eight cylinders are 12½-inch bore and 18-inch stroke. The engines are of the 4-cycle, solid injection, vertical, totally enclosed type, direct connected to a.c. generators and exciters. The floor space for each engine is 16 feet 7½ inches by 8 feet 1½ inches, the height is 8 feet 1 inch.

The engines are equipped with Bosch fuel pumps and nozzles, and are regulated by means of a Woodward isochronous governor.

For starting, two 15 c.f.m. 350 pounds pressure air compressors, one driven by a 7½ h.p. motor and one by a 20 h.p. gasoline-engine are provided. The air is stored at 350 pounds pressure in four air receivers. The 20-h.p. gasoline generator compressor set was installed as a safety measure, the generator to act as a spare exciter and otherwise to be connected to an auxiliary power house lighting circuit.

Each engine has its individual oil circulating system, which is forced feed throughout. The oil is stored in a 300-gallon overhead tank.

The cooling water for the engines is obtained from the city mains which deliver to a 5,000-gallon overhead tank. The engines are supplied by gravity from the tank, and the water is then discharged to an underground basin of the city's filtration plant.

To prevent excessively cold water from entering the engine jackets, a motor-driven centrifugal water pump with a capacity of 150 gallons a minute was installed between the main inlet header and the water outlet of the engines to recirculate part of the warm water discharge. A duplicate pump serves as a standby. The recirculating system is automatically controlled by a thermostat and is equipped with an alarm to guard against failure of the water supply.

Suction air is taken from outside through filters, and the exhaust gases pass from the cylinders into a water-cooled manifold, and are then led to a silencer located outside the building in an underground concrete pit. Each engine is equipped with an individual air-filter and silencer.

Fuel oil is delivered to the plant by tank cars and stored outside in a 30,000-gallon steel tank. The fuel oil used at the plant has the following characteristics:

Specific gravity at 70 degrees F.	0.86 to 0.90
Flashpoint p.m.	180 to 200
Viscosity (Saybolt Universal) at 100 degrees F.	35 to 40
B.t.u.'s per pound (gross)	19,500 min.

No provision was made for the recovery of the heat in the cooling water and the exhaust gases, due to the fact that the plant was designed to be operated eventually as a standby for a hydro-electric plant.

The Diesel engines are directly connected to four 500-kv.a., 4,000-volt, 3-phase, 60-cycle, 360 r.p.m. generators.

The direct-connected exciters are 9.5 kw., 125-volt, shunt wound machines and the switch gear necessary for the control of the alternators, feeders and auxiliary circuits is located in a central part of the building adjacent to the engine room.

Before delivery, tests were run on the Diesel generator sets in the shops of the Montreal Locomotive Works, and each engine was observed for twenty-four hours at full load, two hours at 10 per cent overload, and one hour each both at ¾ load and ½ load. The performance of the engines was equally steady at all loads. The fuel consumption was as follows:

B.h.p. developed	Pounds of Fuel per b.h.p. per hour	Thermal Efficiency (b.h.p. basis) gross per cent
660 at 10 per cent overload	0.382	34.3
600 at 1/1 load	0.377	34.8
450 at ¾ load	0.375	35.0
300 at ½ load	0.406	32.2

The fuel used had an average calorific value of 19,430 B.t.u. (gross) per pound.

BRANCH NEWS

Border Cities Branch

C. F. Davison, A.M.E.I.C., Secretary-Treasurer.
F. J. Ryder, S.E.I.C., Branch News Editor.

The November meeting of the Branch was treated to a lecture on "Gasoline" by Mr. J. M. Miller, B.Sc., a graduate of the University of Michigan, and at present lubricating engineer with the Standard Oil Company of Indiana.

Gasoline

Mr. Miller explained that there were two fundamental principles in the production of gasoline. First, the separation of various products contained in crude oil, and second, the purification of these products. Then step by step each phase of the work was explained and discussed.

He then read a brief technical discussion of gasoline, explaining that the automobile, the chief user of gasoline, is a chemical factory on wheels. Its principal function is the manufacture of energy; enough of which is stored in one gallon of gasoline to drive a light car 450 miles, if efficiently used. The creation of energy is brought about by the union of the oxygen of the air and gasoline. The table below gives the figures of this generation of energy in an average engine:

Going In		*Coming Out*			
Gasoline	6.25 pounds	CO_2	10 pounds	87.00 cubic feet
		H_2O	6.9 "	0.83 "
Air	1,200 cubic feet	CO	5.9 "	80.00 "
		H_2	0.2 "	40.00 "
		O_2	0.2 "	2.00 "
		N_2		775.00 "

Due to incomplete combustion, there is a slight shrinkage in the number of volumes coming out. Also, that 6.25 pounds of gasoline makes 6.9 pounds of water in an average engine or 8.95 pounds of water with perfect combustion.

The item of greatest importance is volatility. This factor governs —(1) ease of starting, (2) uniformity of operation (vapour lock), (3) ease of acceleration, (4) uniform manifold distribution and crank-case dilution.

Acceleration is a difficult property of the fuel to ascertain. It is dependent on engine design, manifold design, temperature and carbureter mixture. Any fuel would give as good results as another if the above factors were adjusted or allowed for when using a particular fuel.

The problem of the gas man is to improve on the four main points mentioned above. The automotive designer must improve his fuel systems.

A few statistics in connection with the petroleum industry, show that it is the second largest in the United States (agriculture being the largest). It has $26,000,000,000 capital, employs over 3,000,000 people, operates over 150,000 miles of main line railroad and over 100,000 miles of pipe line, the longest being 1,500 miles. In the Detroit area there is a gasoline station for every 125 cars.

A Steel Mill in Russia

Our December meeting was entertained by Mr. M. J. Wohlgemuth, who is general engineer with the Westinghouse Electric and Manufacturing Company. The speaker spent nearly three years (1930-33) in Russia in conjunction with the installation of steel mill equipment in what is the largest steel mill in Russia. This mill was located at a site where in 1929 there were no people living within a 25-mile radius and in 1932 there were over 150,000 people at the site. The mill is located on one bank of a river. It is 3½ miles long and ¾ of a mile wide. The plant was originally designed for the production of 1,000,000 tons per year which was altered to 1,250,000 tons per year. At present, the plant is producing 500,000 tons per year, 300,000 tons being in structural shapes and the balance in rails and merchant quality. The plant has four large coking ovens and fifteen one-hundred-and-fifty-ton open hearth furnaces. Several reels of moving pictures showing the views of the plant and scenes taken by the speaker were enjoyed.

At the conclusion of the pictures, Mr. Wohlgemuth was bombarded with questions on conditions in Russia.

All food was rationed, although there were special quotas for the specialists. Russian workers are ordered from one job to another the same as a soldier in the army. In this instance, Russian labourers were ordered to the site of the new plant. No provisions had been made for housing them nor had any of the usual sanitary provisions been installed, although the Russian government had provided special accommodations for the imported help. The Russian workers overcame their difficulties by digging into the surrounding hills and erecting long rows of dugouts. The speaker found that the Russian workers were very incompetent but quite anxious to learn. Practical universities have been established in all such undertakings to help educate the workers. The rate of pay varies from $25 per month minimum to $400 per month maximum. However, this difference is partially offset by the fact that different classes must trade at certain class stores and the prices of goods vary accordingly. There is a good deal of propaganda against religion, the common slogan being "Religion is Opium for the Soul." However, the speaker added that there were still groups of young people to be seen in the churches.

Calgary Branch

J. Dow, M.E.I.C., Secretary-Treasurer.
H. W. Tooker, A.M.E.I.C., Branch News Editor.

On Monday, January 14th, 1935, over fifty members of the Calgary Branch and their friends heard Wm. Storrie, M.E.I.C., of Gore, Nasmith and Storrie, consulting engineers, Toronto, give a most interesting illustrated address on "Engineers and Public Health."

Engineers and Public Health

In his opening remarks, Mr. Storrie expressed his delight in being in Calgary again and meeting old friends, he also expressed satisfaction in his visit to the Glenmore dam.

The speaker declared that under no consideration in matters of the public health should a city or consulting engineer allow a city council to "run him" in regard to technical matters. A council has every right to interfere in matters of policy, but it was the duty of the engineer to guide the council. The real live public health engineer affords protection to the public, and it is his privilege to design, construct and control all schemes designed to bring about conditions which have the welfare of everyone at heart.

Public health engineering might be defined as the art of directing the forces of nature in the direction of public health in which there are large fields.

Purification of water has now become a well defined art from which there is not a great deal to learn, but there is a great deal of knowledge to be gained regarding sewage disposal which is now in, more or less, the experimental stage.

Stating that typhoid fever is the index of the nature of the water supply, chlorination of water has reduced the death rate by this disease almost 90 per cent. Mr. Storrie then cited several projects which have caused a great deal of experimenting and study. Toronto was a case in point, where 10 per cent more chlorine is used than in ordinary plants; the water was then de-chlorided before use. Comparisons were also made between Ottawa and Hull plants. In 1914 when Ottawa first used chlorine in the water supply there were only twenty-eight cases of typhoid fever, as against Hull with two hundred cases which did not use chlorine, though the two cities obtain their water supply from practically the same point in the Ottawa river, and Ottawa has five times the population of Hull.

Sewage treatment is difficult, the speaker said, on account of the continual variation of the sewage to be treated.

Mr. Storrie suggested a good slogan for the water-works engineer; it is "To know your sewage before designing a plant."

The address was illustrated by interesting slides, showing water supply plants of Toronto and Ottawa, and several large sewage disposal plants recently constructed.

Following this, a short discussion took place, after which a vote of thanks was given the speaker by H. J. McLean, A.M.E.I.C.

At the meeting of the Calgary Branch of The Institute held on January 24th, 1935, two thirty-minute addresses, with organized discussion, were presented.

The first, by H. B. Sherman, A.M.E.I.C., was on "Power Distribution in Alberta" and was illustrated by a number of interesting lantern slides, and the second by J. H. Ross, A.M.E.I.C., was on "The Fundamentals of Engineering Education and Vocational Training."

Power Distribution in Alberta

Mr. Sherman described the ideal power distribution system as one sufficiently comprehensive to make electricity available to every resident at rates which would permit the full use of the service being made. However, owing to the sparseness of the population in some sections of Alberta it was not economically feasible to extend transmission lines to them.

Mr. Sherman then went on to describe the Calgary Power Company's system with main generating stations at Kananaskis, Horseshoe and Ghost, giving the main load centres, transmission voltages, step down transformer stations, and details of the distribution system generally. This included something on the design and construction of transmission lines and a few of the main causes of trouble.

The Fundamentals of Engineering Education and Vocational Training

Mr. Ross stated that the three phases of the engineer's education beyond the secondary or high school were (*a*) general education, (*b*) general engineering education and (*c*) vocational training. Under (*a*) was included all those studies which had no direct application to engineering, in (*b*) were included those studies taken by all students in applied science and engineering courses in universities, and (*c*) included all work or studies having a direct application to the particular branch of engineering to be followed.

The speaker then gave an outline of what was being done now and what in his opinion should be done to improve the present training and assist the engineer in placing himself in his proper status in a civilization based largely on science. He further outlined the qualities necessary in a young man if he was to be a successful engineer.

Mr. Ross concluded by stating that "whether a man was a civil, a mechanical, or a chemical engineer was not fundamentally important so long as his basic training was sound." In other words, an engineer should be trained as an engineer and specialization should be the same as in other professions, viz. by training and experience after graduation from university.

At the conclusion of the meeting a hearty vote of thanks was given both speakers by P. F. Peele, A.M.E.I.C.

Lethbridge Branch

E. A. Lawrence, S.E.I.C., Secretary-Treasurer.
J. E. Hawkins, S.E.I.C., Branch News Editor.

The Lethbridge Branch of The Engineering Institute of Canada held its first meeting of 1935 at the Marquis hotel on January 12th, at 7.30 p.m., with C. S. Donaldson, A.M.E.I.C., in the chair, and about forty members present.

A short business meeting was held, during which the annual report was presented and passed.

A motion picture film dealing with the metallurgical plant at Trail, B.C., was then shown. The complete operation of the plant, from the preliminary crushing of the lead zinc ore, through to the final casting of the lead and zinc, and the recovery of the silver and gold from the residue, was shown.

Development of The Turner Valley Oil Fields

R. S. Winter then introduced the guest speaker of the evening, S. E. Slipper, chief geologist of the Canadian Western Natural Gas Co., who spoke on "The Development of The Turner Valley Oil Fields." He outlined the history of Turner Valley from the time of the Dingwell discovery in 1913 down to the present time, when it has become Canada's greatest gas and petroleum field.

Turner Valley, situated approximately forty-five miles southwest of Calgary in the foothills of the Rocky Mountains, is a longitudinal valley lying parallel with the Rockies, cut laterally by the north and south branches of Sheep Creek. It is classed as an eroded sandstone anticline; leaving the valley with sandstone ridges.

It was in 1924 that the main horizon was struck in the limestone by the Royalite No. 4. Of particular interest was the speaker's description of the geology of the valley, with the use of a log of a typical well.

Mr. Slipper pointed out that the oil in the limestone is unique in that it does not come directly from the wells as oil but comes out as gas which must be condensed. This is done by means of separators and absorption plants. The use of absorption plants has increased the production of naphtha per unit of gas considerably, especially with the lower pressures now prevailing.

The wells were not closed in completely from 1924 to 1932 and consequently the original rock pressure is not know, but it has been estimated from observations as about 2,000 pounds per square inch. The first closed pressure obtained was 1,835 pounds per square inch. The great waste of gas from 1929 until 1932 amounted to about 500 million cubic feet daily, having a heat value of 1,100 B.t.u. The field was closed in 1932, and restrictions placed on this waste. In this regard the speaker mentioned the work of the Conservation Board, illustrating his remarks with a number of contour maps. He pointed out that a drop in pressure has taken place in certain places in the valley from 2,000 pounds in 1924 to 900 pounds in 1934.

Mr. Slipper answered a number of questions; Messrs. Donaldson, J. B. deHart, M.E.I.C., and Thrall taking part in the discussion. C. S. Clendening, A.M.E.I.C., moved a vote of thanks to the speaker.

Mr. Slipper's talk was followed with a film on the development of Turner Valley, showing the work involved in bringing a well into production. The processes of refining and distribution of the gasoline concluded this interesting subject.

The programme was followed by a delightful buffet lunch.

Democracy at the Crossroads

On December 15th, 1934, the Branch held a dinner meeting at the Marquis hotel, Lethbridge, taking the form of a ladies night. The speaker, Mr. D. H. Elton, K.C., addressed the meeting upon the subject: "Democracy at the Crossroads." Mr. Elton was introduced by C. S. Donaldson, A.M.E.I.C. Some forty members and guests attended.

The speaker stated that all found themselves in a dilemma to-day; nearly everything was at a standstill, social, business, industrial and even educational activities.

One did not know whether the radical left or the reactionary right was the road to follow or whether both could be avoided.

He outlined many of the causes of this state of perplexity and the difficulties confronting governments of the day. In his opinion there was only one way of solving these difficulties, and that was through obedience to constituted law and authority by increased individual responsibility, the shaking off of indifferent attitudes and the assuming of those duties which the fulfilment of citizenship imposed.

Mr. Elton then observed that three things were essential to good government; things the individual should do, namely, to vote intelligently, to vote unselfishly, to vote honestly. He closed by saying that democracy would prosper in the degree in which it knows good citizenship.

Mr. F. A. Rudd thanked the speaker on behalf of the Branch for his very able address and following this, bridge was played for the remainder of the evening.

London Branch

S. G. Johre, A.M.E.I.C., Secretary-Treasurer.
J. R. Rostron, A.M.E.I.C., Branch News Editor.

The annual dinner meeting of the Branch was held on January 23rd, 1935, at the Highland Golf Club house, the retiring chairman of the Branch, Frank C. Ball, A.M.E.I.C., presiding.

The guest speaker of the evening was Professor P. H. Hensel, of the department of business administration of the University of Western Ontario.

Some Relations Between Technical and Business Training

Professor Hensel's address was regarding "Some Relations Between Technical and Business Training," in which he sketched the difference in outlook brought by training in the business world and in schools of technical engineering.

Much of the progress of business was due to the expansion of engineering knowledge.

At the same time feats of engineering had brought about the large industrial plants which required large orders to keep them working and here business training of the heads of industry was essential to regulate the industry so that the demand would not be overstepped by supply.

Although the two systems of training, for business life and for engineering, were widely separated, there was an interrelationship necessary to keep stability in world conditions.

Because of the variation in the outlook that was created by the two schools of training, the successful engineer seldom became the executive head of even an engineering firm. At the same time the old school business executive with no understanding of the laws of technology was unable to cope with the intricate mechanism that business had become.

The two departments of science and business training were more nearly associated than ever before. Even those with technical education were finding it necessary to learn the laws of business men to acquire the technical knowledge of an engineer to properly gauge business expansion.

A vote of thanks was proposed by W. C. Miller, M.E.I.C., seconded by J. A. Vance, A.M.E.I.C., and unanimously carried.

The evening was enlivened by cards and music provided by Colonel Murray Dillon and his Vimy Orchestra.

About sixty members and guests were present.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

The Montreal Branch Unemployment Relief Committee wishes to acknowledge, with thanks, receipt of an anonymous subscription for twenty dollars.

Machine Gas Cutting in Fabrication

On the evening of January 7th, 1935, the members of the Montreal Branch were the guests of the Montreal Chapter of the American Society of Metals at a practical demonstration and lecture held at the Dominion Bridge Company plant at Lachine.

The demonstrations included actual production work on oxy-acetylene gas cutting machines and metal spraying. Mr. R. F. Helmkamp, of the Air Reduction Sales Company, New York, later gave an illustrated talk on machine gas cutting. About five hundred attended. Previous to the meeting a dinner was held at the Windsor hotel at which F. P. Shearwood, M.E.I.C., the President of The Institute, gave a short address.

Annual Meeting—Montreal Branch

The annual meeting of the Montreal Branch was held on January 10th, 1935. Dr. A. Frigon, M.E.I.C., the chairman of the Branch, presided. J. G. Hall, M.E.I.C., chairman of the Papers and Meetings committee, spoke on the work of his committee during the past year, expressing the hope that members would continue to offer suggestions with regard to subjects for meetings, new activities, etc.

H. G. Thompson, A.M.E.I.C., read the report of the scrutineers, advising that F. S. B. Heward, A.M.E.I.C., had been elected chairman, J. B. D'Aeth, M.E.I.C., vice-chairman, and R. H. Findlay, M.E.I.C., B. R. Perry, M.E.I.C., and J. A. Lalonde, A.M.E.I.C., members of the executive for the year 1935.

After a vote of thanks to the outgoing executive, the newly-elected chairman gave a short talk on the progress of engineering during the past century.

G. McL. Pitts, A.M.E.I.C., then spoke on his proposed scheme for the consolidation of The Engineering Institute and the various professional associations. The details of this were further outlined by R. F. Legget, A.M.E.I.C. Due to the late hour it was decided to call a special meeting to deal with the discussion of this subject.

Refreshments were served at the close of the meeting.

Junior Section Annual Meeting

H. J. Leitch, A.M.E.I.C., presided at this meeting held on January 14th, 1935. The Secretary read the minutes of the last annual meeting, and a report of activities for the past year. Mr. D'Aeth, vice-chairman of the Montreal Branch, then spoke briefly on ways in which the section could be of assistance to The Institute.

The elections of officers resulted as follows: E. R. Smallhorn, A.M.E.I.C., chairman, L. A. Duchastel, Jr.E.I.C., vice-chairman, C. E. Frost, secretary, and the committee of Messrs. P. Poitras, A. Shearwood, S.E.I.C., J. S. Lochhead, McGill representative, L. P. Cousineau, S.E.I.C. and Felix Racicot, Ecole Polytechnique representatives, H. J. Leitch, A.M.E.I.C., and C. K. McLeod, A.M.E.I.C., ex-officio.

The new chairman, Mr. E. R. Smallhorn, presided at the discussion introduced by Mr. P. Poitras on "Codes of Ethics for Engineers." This provided a lively discussion during which many of those present expressed their views.

At the close of the meeting refreshments were served.

Noise Limit in Communication

Dr. O. E. Buckley, Director of Research in the Bell Telephone Laboratories, New York, spoke on the subject of noise on January 17th, 1935.

According to the speaker it was noise more than sensitivity that set the limits of hearing and serious attempts were being made to cut out this nuisance at its source. Radio static, telephonic and radio communication were also discussed.

Surveying and its Relation to Property

The first surveyor to receive a commission as such in Canada was Jean Bourdon, in 1634, stated C. C. Lindsay, A.M.E.I.C., of the firm of M. D. Barclay, Inc., in a talk before the Montreal Branch on January 24th, 1935. The speaker gave a summary of the laws affecting real property, discussing such questions as land titles and squatters' rights and the rights of property owners to what was above and below the soil.

Electrical Section—Boulder Dam Transmission Line

On January 25th, 1935, Mr. E. W. Titus, chief engineer of the Canada Wire and Cable Company, spoke on the manufacture and tests of the hollow core conductor as used in the Boulder dam transmission line. Slides and moving pictures illustrated the construction of the dam and line.

Mr. J. L. T. Martin was in the chair.

Junior Section—Plant Visit

On the evening of Monday, January 28th, 1935, the Junior Section of the Branch visited the Fire Alarm Control Headquarters of the city of Montreal on Fletcher's Field. Fifty members attended and these were divided into groups and conducted over the building by members of the staff.

This visit was arranged through the kindness of C. J. Desbaillets, M.E.I.C., chief engineer of the Montreal Water Board.

Special Meeting—Montreal Branch

On January 30th, 1935, at 8.30 p.m., a special meeting of the Branch was held in The Institute hall to discuss the proposals of G. McL. Pitts, A.M.E.I.C., for the consolidation of The Institute and the provincial professional associations.

R. F. Legget, A.M.E.I.C., outlined the proposal stating that measures should be taken along the lines suggested, at once.

F. P. Shearwood, M.E.I.C., President of The Institute, then spoke giving a résumé of his views, information and ideas he had obtained from his visit to all the branches of The Institute throughout Canada during the past year. In his opinion, Mr. Pitts was much too pessimistic of the outcome of negotiations when following the present procedure of Council.

P. L. Pratley, M.E.I.C., who was unable to be present, had prepared a résumé of Council's activities over the past fifteen years in endeavouring to secure uniformity of ideas between The Institute and the professional associations with a view of eventually forming a Dominion body. In this connection The Institute had taken the initiative throughout. This was read by F. Newell, M.E.I.C., for Mr. Pratley.

J. L. Busfield, M.E.I.C., then pointed out some of the likely stumbling blocks in Mr. Pitts' scheme and proposed an alternative.

This led to considerable discussion after which a motion was carried that a resolution should be sent to the coming Annual Meeting of The Institute recommending that immediate steps be taken to approach the professional associations with a view to obtaining a co-ordination of activities of the two bodies.

F. S. B. Heward, A.M.E.I.C., presided.

Modern Arc Welding

David Boyd, A.M.E.I.C., assistant works manager of the Dominion Bridge Company, Lachine, discussed, on January 31st, 1935, the properties of the electric arc, electrodes, weld metal and outlined fields of application. The qualifications and training for operators and inspectors were also set forth.

H. J. Roast, M.E.I.C., acted as chairman.

Niagara Peninsula Branch

P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

The Branch held a dinner meeting at Thorold on January 22nd, 1935, gathering at the new plant of "Spun Rock Wools Ltd." and later being addressed by Mr. C. R. Buss on the subject of "Insulation."

PLANT VISIT

The plant, which is a new industry to this country, is quite compact; containing two electric furnaces that alternate in producing the fluffy material which is now being used for house and other forms of insulation. The stone is obtained locally and is used without any additional ingredient. Although the process appears to be extremely simple yet a great many experiments had first to be made in order to achieve the exact furnace temperatures, lining materials and speeds whereby these results were attained. It differs from previous methods in that the rock is electrically smelted and the wool fibre formation is effected by means of a rapidly rotating disc instead of air or steam blowing. The result is a fine light fibre practically free from any impurities or non-insulating matter, being fire and insect proof, with a weight of 6 pounds per cubic foot and a conductivity of 0.25. It is shipped in bulk form or in bats and rolls.

An evening meeting of the Branch was held at Thorold on February 15th, 1935, at which Mr. J. M. Barclay, vice-president of the southwestern branch of the Amateur Athletic Union, spoke upon the subject of games as an aid to character building.

Children are particularly helped by organized games, they learn to give and take, to be fair, to develop their will power and to acquire balanced power and judgment.

When the children absorb true principles of sport, the nations to which they belong become great. The Greeks and Romans were examples of nations which achieved greatness at a time when the chief honours were showered upon athletes. The process of decay started when sport became subservient to the flesh pots. "Waterloo was won upon the playing fields of Eton," and Britain will remain in the lead so long as she lives up to this tradition.

Chairman W. R. Manock, A.M.E.I.C., conveyed the thanks of the meeting to the speaker and then brought forward a discussion upon the merits of the E.I.C. Employment service. Several suggestions were advanced for possible improvements and it was resolved to bring these to the attention of the General Secretary and seek his advice.

L. P. Rundle, M.E.I.C., then gave a résumé of the activities at the annual meeting in Toronto, which was followed with close attention by those of the members who were unable to be present at that gathering.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

ANNUAL BRANCH MEETING

The twenty-fifth annual meeting of the Ottawa Branch of The Engineering Institute of Canada was held at the rooms of the Canadian Government Motion Picture Bureau, Sussex and John streets, on the evening of January 10th, 1935. About sixty-seven members were present, the retiring chairman, A. K. Hay, A.M.E.I.C., presiding. F. C. C. Lynch, A.M.E.I.C., Branch secretary, was present to carry out the duties of that position.

The chairman, in presenting his address, reviewed the activities of the Branch for the past year, and paid tribute to the work of his immediate predecessor, Group Captain E. W. Stedman, M.E.I.C. During the year the attendance at the luncheons had been well maintained, and at the evening meetings had been beyond expectations.

The chairman referred to the fact that all branches of The Institute had received suggestions that more consideration should be given to the younger members. This matter had been carefully thought over and constructive suggestions on this point would be welcomed by the management committee. More written contributions or papers from younger men would be most desirable and the Proceedings committee would arrange for meetings where any group of members might discuss some particular subject, whether of general interest or otherwise.

The secretary-treasurer's report revealed that the finances of the Branch were in good condition with a cash balance (including bank balance, cash on hand and Government Bonds) of $1,669.54 and total assets of $1,733.44. Deaths, resignations and members removed from the roll, resulted in a decrease in membership of 21, the total now being 326 resident and 59 non-resident members. The death was recorded with deep regret of two members: S. Bray, M.E.I.C., and W. C. Treanor, A.M.E.I.C.

The secretary-treasurer's report also recorded that in accordance with the motion passed at the last annual meeting, the Branch donated two sets of draughting instruments to the Ottawa Technical School for presentation as prizes for proficiency in draughting, and a copy of "Standard Handbook for Electrical Engineers" to the Hull Technical School for presentation as a prize to a student in the Department of Electricity. John McLeish, M.E.I.C., on behalf of the Branch, personally presented the prizes to the successful students at the annual commencement exercises of the Ottawa Technical School on December 7th last.

Twelve luncheon meetings were held by the Branch, five evening meetings including the annual Branch meeting, and one afternoon was devoted to a visit to the studios and transmitting station of CRCO. The average attendance at the luncheons was sixty-nine and at the evening meetings sixty-two. Some suggestions were put forward in the report of the proceedings committee for the consideration of the incoming executive with regard to luncheon arrangements.

The aeronautic section held eight meetings of their own and were also extended invitations to attend eight other meetings held under other auspices in which subjects of direct interest to them were presented. With this section, which has a membership of ninety-five, is incorporated the Ottawa Section of the Royal Aeronautical Society. It receives a small grant from the Ottawa Branch of The Engineering Institute of Canada. During the year the chairman was Group Captain E. W. Stedman, chief aeronautical engineer of the Department of National Defence, and the secretary was K. F. Tupper, of the National Research Council.

The reports of committees presented, after the chairman's address and the secretary-treasurer's report, were:—

Proceedings committee by J. H. Parkin, M.E.I.C.
Membership committee by W. F. M. Bryce, A.M.E.I.C.
Unemployment committee by G. J. Desbarats, M.E.I.C.
Rooms and Library, Branch By-laws and Reception committee by J. G. Macphail, M.E.I.C.
Advertising committee by A. V. Gale, A.M.E.I.C.
Aeronautic section by E. W. Stedman, M.E.I.C.

After the committee reports a resolution was passed to the effect that the policy be continued for the school year of 1934-35 of donating prizes to students of the Ottawa Technical School and the Ecole Technique de Hull for proficiency. A resolution was passed that the thanks of the Branch be conveyed to the Ottawa Journal, the Ottawa Citizen, and Le Droit for the publicity given to proceedings during the year.

Following a suggestion by C. Klotz, S.E.I.C., that greater attention be paid to new members, a discussion took place with regard to how interest amongst these new members could be encouraged. Group Captain Stedman advised the meeting of the procedure followed by societies in England and out of the discussion certain suggestions were put forward for the consideration of the incoming executive with a view to effecting this result.

C. M. Pitts, A.M.E.I.C., reported as councillor on the work of the Council, the main item of which during the past year was the work of the Development Committee. He expressed the opinion that it was most important to The Institute that the matter of greater cooperation between our Institute and other engineering bodies should not be allowed to drop. To this end he presented a resolution, seconded by John Murphy, M.E.I.C., to the effect that the Ottawa Branch go on record as supporting any movement towards uniting the Professional Engineering organizations in each province and ultimately throughout the Dominion of Canada; also that the General Secretary of The Institute be sent a copy of this resolution and an expression of support of the Ottawa Branch to any movement along this line, the General Secretary to be requested to present such communication to the Annual Meeting of The Institute to be held in February next. After some discussion the motion was carried.

The report of the election for the ensuing 1935-36 year was then announced.

Mr. Hay then introduced Dr. R. W. Boyle, M.E.I.C., the chairman for 1935, who took the chair and expressed his thanks for the honour which had been conferred upon him by the Ottawa Branch. After a vote of thanks had been moved for each of the retiring officers of the Branch, the annual meeting closed with the showing of a motion picture "Flying over the Empire" secured through the courtesy of the National Council of Education, after which refreshments were served.

HIGH TENSION DIRECT CURRENT TRANSMISSION

The first evening meeting of the new 1935 term took place January 24th at the Auditorium of the National Research Laboratories. B. G. Ballard, B.Sc., A.M.E.I.C., of the National Research Council, was the speaker, his subject being "Some Aspects of High Tension Direct Current Power Transmission." Dr. R. W. Boyle, M.E.I.C., newly elected chairman of the Branch, presided.

Of all the methods in practical use for the transmission of power, stated Mr. Ballard, electric transmission is the only one employing alternating or oscillating forces. The reasons for its adoption are well known. It would not be impossible to transmit mechanical power in a similar manner using alternating impulses but the fact that inertia effects would demand larger equipment for the same amount of power input would be a much greater disadvantage relatively in alternating mechanical transmission than in alternating electrical transmission.

In alternating current transmission, the power flow in any one element varies from zero to some maximum value which, of course, is somewhat higher than the net effective value. This factor has little importance when currents are considered but with voltages it is different. It necessitates that the system insulation must be capable of withstanding the maximum peak voltages encountered. In practice it is found that direct current effective voltages may safely be as much as 100 per cent higher than alternating current effective voltages.

Another apparent advantage in direct current high voltage transmission is that corona losses are less than with alternating currents. This reduction may be as much as 50 per cent less for a given effective voltage in the case of 25 cycle lines.

Thury developed the direct current system in Europe and in one instance built a line over 100 miles in length, operating at 70,000 volts. The system operates at a constant current rather than at constant voltage, and, incidentally, avoids much of the trouble due to surges so frequently encountered on direct current systems for railroad electrification. The advantages are: higher effective voltages; unity power factor; and no dielectric losses. The disadvantages are: generating units economically too small, owing to limitations imposed by commutators; generators require insulated bases and couplings; and full load line copper loss at all times.

These handicaps have prevented any appreciable extension of the Thury system.

Recent developments, however, have renewed activity in direct current power transmission. Among those giving most promise is the vapour discharge tube. With this it is hoped to rectify alternating currents at high voltages, transmit over long lines by direct current, then invert through other vapour discharge tubes to alternating current which could be stepped down in ordinary transformers to usable voltages.

At present, currents of many amperes may be controlled with tubes little larger than radio tubes. Moreover, in addition to rectifying, the tubes may be made to control voltages without losses and to operate as circuit breakers with either instantaneous or time delay overload trips.

At this point the speaker demonstrated the use of such tubes with apparatus specially set up for the occasion. He also referred to advantages and disadvantages of the vapour discharge tube as opposed to the high vacuum tube, and the limitations of commutator design which prevented rotating direct current machines from operating at voltages much higher than 5,000. There are possibilities that such limitations may be met in a practical way by operating the machines in a vacuum.

At present research is mainly along the lines of overcoming these limitations and of minimizing the effects of surges so commonly prevalent in direct current systems.

The address was followed by a period of discussion after which refreshments were served.

Peterborough Branch

H. R. Sills, Jr.E.I.C., Secretary.
E. J. Davies, Jr.E.I.C., Branch News Editor.

MODERN ARC WELDING

The principles and practice of the manual art of arc welding was the subject of an address by Mr. David Boyd of the engineering staff of the Dominion Bridge Company, Montreal, to this Branch at the regular monthly meeting on Thursday, January 10th, 1935.

Engineers of to-day have developed welding by the use of oxy-acetylene gas, thermit and electricity and with virtually all metals.

As is generally known, arc welding has displaced riveting in many directions. Its application in the manufacture of tanks, hoppers and also in general shop work, in the fabrication of large sized pipe, in replacing steel castings and especially in structural iron work, covers a wide range of successful adaptations. Mr. Boyd rather pointedly declared that some designing engineers have been slow to recognize the effectual use of arc welding in its fuller scope of replacing riveting, and cited from his own extensive experience examples of detail work, particularly in joints, in which welders have turned out more perfect jobs.

In the field of iron pipes of larger diameters electric welding is supreme. It has revolutionized the manufacture of high pressure vessels especially in the petroleum industry, where high pressures and high temperatures are required in what are called "cracking" stills. Danger of leakage of petroleum and crude oil products from the vessels in which they are reduced has been eliminated by welding, which also has permitted the use of heavier plates in such vessels, thereby paving the way for higher pressures and greater heat.

Welded joints behave consistently under tests, Mr. Boyd said, giving a uniform performance in any structure. The designing of welded joints is a new art that is being continuously improved. Mr. Boyd's screen slides illustrated much of his subject matter, and its practical phases were thoroughly appreciated by the men who are engaged in this work.

There was an exceptionally good attendance including members and many visitors who are welders from the local factories, and others interested in welding. A vote of thanks and appreciation of Mr. Boyd's very interesting address was tendered by O. R. Thompson, M.E.I.C., of Belleville.

Saskatchewan Branch

S. Young, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Saskatchewan Branch of The Engineering Institute of Canada, was held in the Saskatchewan hotel on Thursday evening, January 24th, 1935, at 7.45 p.m., being preceded by a dinner. The total attendance was twenty-five. The guest speaker of the evening was William Storrie, M.E.I.C., consulting engineer, Toronto.

Immediately following the dinner several songs were contributed by Mr. Sam Swayze.

Dr. B. C. Riley, of the staff of the General Hospital, spoke for a few minutes on the treatment of frozen parts of the body by the mechanical application of positive and negative atmospheric pressures, an entirely new method.

The Secretary read a letter from R. J. Durley, M.E.I.C., advising of the election of H. S. Carpenter, M.E.I.C., as a life member of The Institute and another advising of the temporary continuation of the five dollar entrance fee for the grade of Junior and higher classes, thus eliminating the transfer fee when transferring from Junior to Associate or from Associate to Member.

S. R. Muirhead, A.M.E.I.C., reported for the Papers committee, stating that arrangements had been completed to have E. E. Lord address the annual meeting in March on his experiences in engineering work in China.

The acting chairman, A. P. Linton, A.M.E.I.C., then introduced the guest speaker, William Storrie, M.E.I.C., his subject being the "Engineer and Public Health."

After briefly outlining the work of the engineer in its relation to public health, Mr. Storrie proceeded to detail the activities of the engineer in respect of water supply and sewage disposal. Following this numerous lantern slides were shown depicting the construction of waterworks and sewage disposal plants at various points, particularly the city of Toronto where Mr. Storrie was engaged as consultant. The address was provocative of considerable discussion, following which a hearty vote of thanks was tendered to Mr. Storrie on motion of D. A. R. McCannell, M.E.I.C., and R. H. Murray, A.M.E.I.C.

Sault Ste. Marie Branch

H. O. Brown, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Sault Ste. Marie Branch was held at the Windsor hotel on Wednesday, January 23rd, 1935, in the form of a dinner-meeting with Frank Smallwood, M.E.I.C., the new chairman, in the chair.

Twenty-six sat down to dinner at 6.45 and about a dozen more came later for the business meeting and address.

After the business of the evening had been transacted the chairman called on O. A. Evans, Jr.E.I.C., of the Sault Branch, to address the meeting on "Theory and Practice of Assaying."

Mr. Evans is assayer for the Mines Department of the A.C.R. and is, therefore, well qualified to discuss his chosen subject. Samples of typical Algoma ores which are sent in for assaying and samples of assays in various stages of the process were shown throughout the paper.

A historical outline of the assaying of precious metals and the development through the ages was first presented. This was followed by a detailed description of the present "dry system" of assaying of gold and silver ores. The size of sample used; the crushing; and flux elements used and the heating and segregation of "the button" were all explained very thoroughly, and as previously mentioned were illustrated with actual working samples.

At the close of the paper various questions were asked and explained by Mr. Evans. After the discussion a very hearty vote of thanks was tendered Mr. Evans by the members and friends present.

Mr. Smallwood then spoke briefly and solicited the support of the members for the coming year by their attendance and help on the various committees. He also made reference to the prospects for new members and in this connection the membership committee would appreciate having members submit the names of any who are eligible to become members.

Winnipeg Branch

E. W. M. James, A.M.E.I.C., Secretary-Treasurer.
E. V. Caton, M.E.I.C., Branch News Editor.

A meeting of the Winnipeg Branch of The Engineering Institute of Canada was held in the University Buildings, Broadway, on Thursday January 3rd, 1935.

At the request of the acting chairman, Professor A. E. Macdonald, A.M.E.I.C., introduced the speaker of the evening, Rev. A. E. Kerr, pastor of Augustine Church, Winnipeg, who delivered a most informative and entertaining address under the title "Personal Impressions of Russia."

Mr. Kerr began by stating that he laid no claim to being an authority on Russia, but that he had been able to gratify a long-felt wish by visiting Russia in the summer of 1934; entering by way of Leningrad, visiting Moscow and the Ukraine, and leaving by way of Odessa. He had been able to come into fairly close contact with the people of Russia, other than officials, and had therefore been able to gain some very interesting sidelights on the conditions of the country.

In 1928 the Five Year Plan was launched, with the remarkable result that at the end of the first five years heavy industry in Russia had been doubled. But it is to be noted that in spite of the pressure that was brought to bear upon agriculture and with the advent of thousands of tractors and modern farm implements, at the end of the Five Year Plan the amount of livestock in the country had been reduced to 50 per cent of what it had been in 1917. The reason given for this was that the individual farmers failed to co-operate with the government in the manner and to the extent that had been expected of them. Several incidents related by Mr. Kerr touching on the treatment of the farmers left no doubt as to the cause of such lack of co-operation.

At the close of his address Mr. Kerr very kindly answered numerous questions asked by the members. J. W. Porter, M.E.I.C., moved a hearty vote of thanks to the speaker.

A special meeting of the Winnipeg Branch of The Engineering Institute of Canada was held on Friday, January 25th, 1935.

The speaker of the evening was William Storrie, M.E.I.C., of Messrs. Gore, Nasmith and Storrie, consulting engineers, Toronto, who gave an extremely interesting address on water supply and sewage disposal, describing installations with which he had been connected in Toronto and other eastern cities; also in Calgary. The address was illustrated by lantern slides.

Mr. Storrie pointed out the work done by the engineering profession in preventative medicine and in the improvement and protection of public health, both as regards to supply of safe drinking water and the adequate disposal of sewage. His discussion of the difficulties to be met in different installations was extremely interesting and at the close of his talk the active discussion which took place indicated the interest of the members in the matter.

A hearty vote of thanks was tendered the speaker for his interesting address.

Association of Professional Engineers of the Province of Manitoba

The annual meeting of the Association of Professional Engineers of the Province of Manitoba was held in the Hudson's Bay dining room on Thursday, January 17th, 1935.

Previous to the meeting a dinner was held.

The guest speaker of the evening was the new Chief of Police, Mr. Geo. Smith, who gave an interesting address on police matters.

The report of the scrutineers showed that 134 valid ballots were received, and Messrs. J. N. Finlayson, M.E.I.C., J. W. Sanger, A.M.E.I.C., J. A. Meindl, A.M.E.I.C., and G. E. Cole, A.M.E.I.C., were elected as the new Councillors for the term ending January, 1937. The three members of Council still having one year to serve are Messrs. E. W. M. James, A.M.E.I.C., A. L. Cavanagh, A.M.E.I.C., and C. S. Landon.

Following the report of the scrutineers Council retired from the general meeting and held its Organization Meeting.

The report of Council showed that the membership at December 31st, 1934, stood at 202.

The report of the secretary and auditors showed very satisfactory condition of the finances; the bonds of the Association having a par value of $10,100.

Council appointed J. W. Sanger, A.M.E.I.C., as its representative on the Committee of Eight for 1935.

The Association and Institute Joint Committee on Unemployment had during the year continued the very valuable work commenced three years ago and had been successful in securing work for a number of unemployed engineers, and felt that as a result of their negotiations the reputation of the engineering profession had been enhanced, particularly with certain departments of the government.

The question of ways and means of more active co-operation between the two organizations in Manitoba was thoroughly discussed, following which the incoming Council was instructed to appoint a committee to further this work.

A Committee from Council reported that they had interviewed provincial government officials as regards seeing that engineers employed in the mining industry in the province were registered members of the Association where their work came within the meaning of the Act.

W. M. Scott, M.E.I.C., chairman of the University Scholarship Committee, reported that the annual scholarship of the Association granted to the student of the second year in engineering of the University of Manitoba who obtained the highest aggregate on the results of the first and second years, was awarded this year to Mr. Eliot R. Davis, of Winnipeg.

The new President, Professor J. N. Finlayson, then took the chair, and in a few well chosen remarks closed the meeting.

The meeting adjourned at 11.40 p.m.

The McCharles Prize, 1935

Announcement is made that an award of the McCharles Prize, instituted by the University of Toronto, will shortly be considered. This is a distinguished prize for engineers, inventors and scientific research workers. It carries not only a very high honour but a cash value of one thousand dollars.

This prize was established in connection with the bequest of the late Aeneas McCharles of the value of $10,000 and is awarded on the following terms and conditions contained in the bequest and authorized by the governors of the University of Toronto, namely, that the interest therefrom shall be given from time to time, but not necessarily every year, like the Nobel prizes in a small way:

(1) To any Canadian from one end of the country to the other, and whether student or not, who invents or discovers any new and improved process for the treatment of Canadian ores or minerals of any kind, after such process has been proved to be of special merit on a practical scale; (2) or for any important discovery, invention or device by any Canadian that will lessen the dangers, and loss of life in connection with the use of electricity in supplying power and light; (3) or for any marked public distinction achieved by any Canadian in scientific research in any useful practical line.

The term "Canadian" for the purpose of the award means any person Canadian born who has not renounced British allegiance, and for the purpose of the award in the first of the three cases provided for by the bequest, domicile in Canada is an essential condition.

Every candidate for the prize is required to be proposed as such in writing by some duly qualified person. A direct application for a prize will not be considered.

No prize will be awarded for any discovery or invention unless it shall have been proved to the satisfaction of the awarding body to possess the special practical merit indicated by the terms and spirit of the bequest.

The committee of award announces that it will receive nominations for candidates up to the 1st April next. Nominations may be made direct to Dean C. H. Mitchell, M.E.I.C., chairman of the committee, at the University of Toronto.

Engineers and The Empire

The novelist and the poet not uncommonly regard their outpourings, when they have been translated into type, with a coldness and even an aversion that the layman finds astonishing. It is not surprising, therefore, to find that the engineer, while he may pore for hours over his drawings and exercise all his energies in seeing that construction is carried out in accordance with his ideas, is by no means always willing to set down what he has done on paper for the benefit of his colleagues, still less to expatiate to a lay public. Moreover he has not been too well treated by the historian and, with almost the single exception of Mr. Kipling, the novelist has also neglected that romance which, in the widest sense "brings up the 8.15." It was therefore fitting that the Royal Empire Society should have devoted their meeting in London, on January 15, to a consideration of what engineers have done for the Empire, and that they should have called on such distinguished representatives as Mr. Ralph Freeman, Mr. Julian Tritton, Brigadier-General Hammond and Colonel Pollard-Lowsley to tell them something about their work. The result must have been to show how much such structures as the Sydney Harbour Bridge, the Willingdon Bridge at Calcutta, the Hardinge Bridge over the Ganges, and the Zambesi Bridge, the development of such ports as those at Haifa, the construction of many miles of railways in India, Ceylon, Malaya, West Africa and Uganda and, perhaps above all, the lay-out of extensive irrigation systems in more than one of the King's Overseas Dominions, have done to save life, and both materially and morally to raise the standard of living. To illustrate this opinion, only one quotation, taken from Colonel Pollard-Lowsley's address, is necessary. In India, he said, as the result of the work of British engineers, an area of 49,451 square miles had been irrigated, constituting one eighth of the cultivated area of the sub-continent.—*Engineering.*

International Housing and Town Planning Congress

The fourteenth International Housing and Town Planning Congress is to be held in London, England, on July 16th to 20th, 1935. This is arranged by the International Federation for Housing and Town Planning, 25 Bedford Row, London, W.C.1. The Congress has the support of the British Government, the Corporation of the City of London, the London County Council, other leading municipalities and the national associations concerned with housing and town planning.

A most interesting programme of meetings and inspection trips has been arranged.

Canadian Institute of Mining and Metallurgy

The 1935 Annual Meeting of the Canadian Institute of Mining and Metallurgy is to be held at Winnipeg, Man., on March 12th to 14th next. The visitors will be entertained at the Royal Alexandra hotel in Winnipeg by the local mining group, who are now of substantial numbers, and an excursion by special train to Flin Flon has been arranged.

The first annual meeting of the Canadian Institute held in Winnipeg was in 1929, when the mineral industry of the province of Manitoba was just beginning to be firmly established. During the intervening six years one of the world's great mines has been put into operation at Flin Flon, and San Antonio and other gold mines have become a substantial and dependable source of gold. Thus the return of this important annual convention to Winnipeg marks the definite entry of Manitoba into the mining history of the Dominion.

The General Motors of Canada report that on February 1st, 1935, their Oshawa plant showed an increase of 45 per cent over the number of men employed on the same date of 1934. At the Walkerville engine plant of the company, employment showed a gain of over 48 per cent. The McKinnon Industries unit of General Motors, at St. Catharines, producer of gears and electrical units, showed an increase of 24 per cent. The total number of direct employees on the payroll of General Motors of Canada at January 31st, was sixty-six hundred.

Preliminary Notice

of Applications for Admission and for Transfer

February 26th, 1935

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in April, 1935.

R. J. Durley, Secretary.

*The professional requirements are as follows.—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

CHENEVERT—JOSEPH GEORGES, of 555 Querbes Ave., Outremont, Que., Born at Montreal, March 19th, 1900; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1923; From 1923 to date, with Arthur Surveyer & Company, Consltg. Engrs., Montreal, on design and supervision of numerous large bldgs., filtration plants, aqueducts and sewage disposal plants, valuations, studies re establishment of various plants, investigations and reports, also expert in court cases, etc., and at present consltg. engr. with above company.

KERR—SAMUEL LOGAN, of 30 E. Mt. Pleasant Ave., Philadelphia, Pa., Born at Philadelphia, July 15th, 1899; Educ., B.S. in M.E., 1921, M.E., 1924, Univ. of Penn.; 1917 (summer), dftsman., I. P. Morris Co.; 1918-19, with U.S. Army, A.E.F. in France; 1920 (summer), asst. in charge of hydraulic testing lab. I. P. Morris Dept., Wm. Cramp & Sons Ship and Eng. Bldg. Co., Philadelphia; 1921-27, with I. P. Morris Dept. of above company as follows: 1921-22, research asst., special investigations and lab. testing in connection with hydraulic turbine manufacture. Also research investigation water hammer theory; 1921-24, engrg. investigations, proposals and estimating work on hydraulic turbines, field tests and investigations; guarantees and acceptance tests on turbines, including Queenston plant, H.E.P.C. of Ont., Great Falls plant, Manitoba Power Co., Station 3C, Niagara Falls Power Co., etc.; 1927-29, asst. chief engr., I. P. Morris Corpn., responsible charge hydraulic governor design; also field engrg. and testing completed installns. Developed "Automatic Operator" for speed and load control in hydro-electric generating plants; 1929-31, research engr., I. P. Morris & DeLavergne Inc., in responsible charge of research and experimental labs. for hydraulic turbines, pumps, governors, Diesel engines and refrigerating machy. Designed and constructed hydraulic turbine and governor labs. In responsible charge field testing all products and field service and constrn. hydraulic turbines and design of hydraulic governors. Member, N.E.L.A. Committee on Hydraulic Governors. Appointed Capt., Specialist Reserve, Ordnance Dept., U.S.A.; 1931 to date, research engr., I. P. Morris Divn., Baldwin Southwark Corpn., Philadelphia. Responsible charge lab. and field testing hydraulic turbines, governors and water works equipment; also design hydraulic governors and automatic control equipment. Responsible charge design and testing automatic water works valves. Development of new types and applications. Specializing in ana yses and solution of water hammer problems in water works systems. Chairman, A.S.M.E. Committee on Water Hammer; Member, A.S.M.E., Member, A.S.C.E.

FOR TRANSFER FROM THE CLASS OF JUNIOR

BOWMAN—RONALD FRASER PATRICK, of Lethbridge, Alta., Born at Lethbridge, March 17th, 1904; Educ., B.Sc. (Civil), Univ. of Alta., 1928; 1920-25 (summers), rodman and chainman, Lethbridge Northern Irrigation Dist., New West Irrigation Dist., and Dept. Public Works. Alta., during 1925 doing instrument work; Summers 1926-27, and 1928-30, transitman, and 1931 to date, roadmaster, C.P.R., at present at Lethbridge, Alta. (*St. 1926, Jr. 1930.*)
References: R. S. L. Wilson, F. W. Alexander, T. Lees, J. M. Campbell, H. R. Miles, G. N. Houston.

BREAKEY—JAMES, of Brentwood Rd., Toronto, Ont., Born at Sheffield, England, Sept. 19th, 1901; Educ., Associateship in Engrg., Sheffield Univ., 1921; 1922, student in erection shops, Brightside Foundry & Engrg. Co., Sheffield; 1923-25, college ap'tice, at Metropolitan Vickers Electrical Co. Ltd., Manchester, England; 1925-27, with same company as asst. engr., on erection and inspection of mech'l. and elect'l. apparatus, and on design of power plants; 1927-29, sea-going engr. with A. Holt & Co., Liverpool, owners of the Blue Funnel Line (2nd Engr's. Board of Trade Cert. (Marine); 1929, dftsman., industrial drawing office, Canadian Vickers, Montreal; 1929 to date, editorial dept. of technical publications of the MacLean Publishing Co., being editor of Modern Power & Engineering and associate editor of Canadian Machinery and Manufacturing News. (*Jr. 1931.*)
References: C. B. Hamilton, Jr., R. E. Smythe, M. B. Watson, R. Ramsay, G. Agar.

RIDGERS—ARTHUR COURTNEY, of Rossland, B.C., Born at South Queensferry, Scotland, April 29th, 1901; 1916-22, H.M. Dockyard School, Portsmouth, England, and Technical Institute, Portsmouth. I.C.S. Course in Civil Engrg., 1924. Elected Struct'l. Engr., Assn. of Prof. Engrs. B.C. by Exam., Nov. 1934; 1916-22, ap'tice in constrn. dept., H.M. Dockyard, Portsmouth; 1922-24, asst. engr. at Havant, England, sewerage works constrn.; 1924-26, detailer, and 1926 to date, designing dftsman., Consolidated Mining & Smelting Co. of Canada Ltd. Responsible to chief engr. for design of zinc oxide leaching plant, phosphate fertilizer bldg., reconstrn. of zinc melting plant, design of structure, mercury arc rectifier bldg., proposed electrolytic zinc plant, for eastern Canada, design of all structures and layout of plant and equipment, etc. (*Jr. 1929.*)

FOR TRANSFER FROM THE CLASS OF STUDENT

BOWLES—WILLIAM SHEDDEN, of Westmount, Que., Born at Vancouver, B.C., June 12th, 1906; Educ., B.Sc. (Civil), McGill Univ., 1930. 1932-33, grad. studies, McGill Univ. leading to M.E. degree (not yet recd.); 1926-27 (summers), chainman and rodman, C.P.R.; 1928 (2 mos.), asst. operator, Cedar Rapids Power plant; 1929 (3 mos.), dftsman., Shawinigan Engrg. Co., Montreal; June 1930 to Nov. 1931, with A. F. Byers & Co., as manager of the Lamella Trussless Roof Co., sales, design and constrn. of Lamella roofs. Supervision during constrn. of swimming pool roof at Lucerne-in-Quebec. Layout engr. during constrn. of Foundry for Jenkins Bros. at Lachine. Business mgr. at Moncton, N.B., during constrn. of rink; Sept. 1933 to date, asst. to E. F. Tucker, A.M.E.I.C., Manager, Canadian Stebbins Engrg. & Mfg. Co. Ltd., estimating, design and gen. office work. (*St. 1929.*)
References: E. F. Tucker, A. F. Byers, E. V. Gage, C. H. Timm, J. A. McCrory, E. Brown, B. R. Perry.

MACDONALD—ARDEN MORRIS, of Londonderry Stn., N.S., Born at Truro, N.S., July 8th, 1912; Educ., B.Sc. (Mech.), N.S. Tech. Coll., 1933; 1929 (summer), asst. topographer, C.N.R., Moncton; May 1933 to June 1934, machinist installn. and mtce. of mining machinery for Prof. A. E. Flynn, N.S. Technical College, Halifax, N.S. (*St. 1931.*)
References: F. R. Faulkner, H. W. McKiel, F. L. West, A. S. Gunn, J. B. Hayes.

OGILVY—JAMES ANGUS, of 3129 Peel St., Montreal, Que., Born at Westmount, Que., June 7th, 1907; Educ., B.Sc. (Mining), McGill Univ., 1930; 1926 (summer), labourer on constrn. of Gatineau mill; 1927 (summer), rodman and temp. instr'man., Dome Mines Ltd.; 1929 (summer), machineman and slusher operator, Sullivan Mine, Cons. M. and S. Co. Ltd., Kimberley, B.C.; 1928 (summer), prospector, Nipissing Mining Co. Ltd.; 1930 (summer), inspr., mech. dept., Aluminum Co. of Canada, Arvida, Que.; With McIntyre Porcupine Mines Ltd., as follows: 1930-31 (6 mos.), helper, machineman; 1931 (Feb.-Apr.), engr. in charge of Birch Lake property during diamond drilling; May 1931, engr. in charge of party examining a staked area; Aug. 1931-Jan. 1932, sampler; 1932 (Feb.-July), engr. in charge of tests on rock drills, keeping cost and performance records; Aug. 1932 to Jan. 1933 and July 1933, acting shiftboss; 1933 (Feb.-June), shiftboss; Aug. 1933-June 1934, stope boss; 1934 (July-Nov.), mine supt., Thompson-Cadillac Mining Co. Ltd., Amos, Que. (*St. 1926.*)
References: A. Stansfield, A. D. Campbell, R. E. Jamieson, H. Idsardi, R. F. Ogilvy, W. L. McFaul.

PAMENTER—ARCHIBALD FRANCIS, of 14 James St., Dartmouth, N.S., Born at Liverpool, England, Aug. 2nd, 1905; Educ., B.Sc. (C.E.), N.S. Tech. Coll., 1932. N.S.L.S., 1925; With Hollingsworth & Whitney Ltd., Bridgewater, N.S., as follows: 1923 (3 mos.), chainman, rodman and instr'man., 1924-27, instr'man and land surveyor; 1927-28, N.S. land surveyor; 1929 (summer), N.S. land surveyor for N.S. Power Commn. on Mersey hydro line; 1930-31 (summers), dftsman., Acadia Gas Engrs. Ltd.; 1932 (3 mos.), N.S. land surveyor, Scott Paper Co. Ltd., Charleston, N.S.; 1932-33, private work as N.S. land surveyor; 1933 to date, in testing laboratory, Imperial Oil Co. Ltd., Dartmouth, N.S. (*St. 1931.*)
References: F. R. Faulkner, R. L. Dunsmore, S. Ball, H. W. Mahon, H. S. Johnston, C. Scrymgeour.

PETURSSON—FRANKLIN, of Kenora, Ont., Born at Foam Lake, Sask., April 16th, 1906; Educ., B.Sc. (C.E.), Univ. of Man. (Thesis to write for M.Sc. degree); 1927 (summer), concrete inspr., Over & Munn, Winnipeg; 1928 (summer), concrete inspr. for C.N.R. water supply, western provinces; 1928-29, demonstrator in engrg. dept., Univ. of Man.; 1929-30, instr'man on location and constrn., C.N.R., western provinces; With Dept. of Northern Development, Kenora District, as follows: 1930-31, engr. in charge of location party, Trans-Canada highway; 1931-34, res. and divn. engr. on constrn.; 1934 (5 mos.), res. engr. in charge contract work; 1934-35 (5 mos.), divn. engr. in charge of contract work; Jan. 1935 to date, location engr. (*St. 1928.*)
References: J. N. Finlayson, G. H. Herriot, T. C. Main, R. R. Moffatt, A. E. MacDonald.

RONEY—GERALD VAN LUVEN, of Montreal, Que., Born at Kingston, Ont., Sept. 4th, 1903; Educ., B.Sc., Queen's Univ., 1926; 1921-25 (summers), chainman, rodman and instr'man., engrg. service, Canadian National Parks, Banff; 1926 (summer), struct'l. detailer, Canadian Bridge Co., Walkerville, Ont.; 1926-27, senior dftsman., Pennsylvania State Highway Dept.; 1927 (May-Oct.), struct'l. detailer, Pittsburgh-DesMoines Steel Co., Pittsburgh; 1927-28, checker and later squad boss, F. L. Hughes & Co., Rochester, N.Y.; 1928-29, designing dftsman., on struct'l. design, Chesapeake and Ohio Rly. Co., Richmond, Va.; 1929-32, checker on struct'l details, Manitoba Bridge and Iron Works. Transferred to Dominion Bridge Co., Winnipeg, in same capacity, when these firms amalgamated; 1934 (Apr.-June), dftsman. on design drawings of new unit, McColl Frontenac Oil Co., Montreal; Since June 1934 in full charge of engrg. dept., and at present chief engr., Farand & Delorme Ltd., steel fabricators, Montreal, Que. (*St. 1925.*)

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situations Vacant

CITY ENGINEER

A. H. Evans, clerk, will receive applications for the position of City Engineer, city of Port Arthur, up to 5 p.m. Thursday, March 21st, 1935. Applications to state qualifications, experience, etc. and to be in sealed envelopes marked "Application for position of City Engineer."

ELECTRICAL DESIGNER, experienced in the design of single phase fractional horsepower motors. Also capable of taking charge of motor department. Location western Ontario. Apply to Box No. 1114-V.

Situations Wanted

ESTABLISHED SALES ENGINEER. Univ. of Toronto '24, with plant and manufacturing experience, wishes to represent manufacturers of technical equipment. Connections with automobile and electrical equipment dealers, throughout Canada. Will make small investment if necessary. Apply to Box No. 1-W.

MECHANICAL ENGINEER, Canadian, with technica training and executive experience in both Canadian and American industries, particularly plant layout, equipment, planning and production control methods, is open for employment with company desirous of improving manufacturing methods, lowering costs and preparing for business expansion. Apply to Box No. 35-W.

MECHANICAL ENGINEER, graduate McGill Univ. Experience on hydro-clectric power construction and design and installation of equipment of pulp and paper mills. Desires position as mechanical engineer in an industrial plant or pulp and paper mill, or as representative on the eale of heavy machinery. Apply to Box No. 142-W.

PURCHASING AGENT. Graduate mechanical engineer, Canadian, married, age 36, with fourteen years experience in industrial field, including design, construction and operation, eight years of which had to do with the development of specifications and ordering of equipment and materials for plant extensions and maintenance; one year engaged on sale of surplus construction equipment. Full details on request. At present employed. Apply to Box No. 161-W.

SALES ENGINEER, S.E.I.C.; B.Sc. C.E., 1930 (Univ. New Bruns.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ELECTRICAL ENGINEER, B.Ec., A.M.E.I.C., Am.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

CIVIL ENGINEER, B.A.Sc. and C.E.; A.M.E.I.C., Jun. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.Sc. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

MECHANICAL ENGINEER, B.Sc. Age 31. Married. Last ten yeare includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

Situations Wanted

CIVIL ENGINEER, Canadian, married, twenty-five years technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.Ec., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment. Four summers as instrumentman on surveying and highway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern where the combination of technical and business experience will be of value. Apply to Box No. 564-W.

MECHANICAL ENGINEER, A.M.E.I.C. Experienced on plant maintenance, steel plant, cement plant and mining plants. Available on short notice. Apply to Box No. 571-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

Employment Service Bureau

This bureau is maintained by The Engineering Institute of Canada for the benefit of members and organizations employing technically trained men.

An enquiry addressed to 2050 Mansfield Street, Montreal, will bring full information concerning the services offered. Details can also be obtained from Branch secretaries who are located in the larger centres throughout Canada.

Brief announcements of men available and positions vacant will be published without charge in The Engineering Journal and the Bulletin. Replies addressed in care of the required box number will be forwarded to the advertiser without delay.

An additional service also offered those who are unemployed or wish to change their positions, is the opportunity of placing their names and records on file at 2050 Mansfield Street for consideration by employers wishing to employ engineers. This is of great assistance as many employers will not advertise or wish to locate a suitable man on short notice. If desired the information contained in these records can be kept confidential.

Forms for registration purposes may be obtained from The Institute Headquarters of Branch secretaries.

CHEMICAL ENGINEER, E.E.I.C., B.Ec., University of Alberta, '30. Age 31. Single. Six seasons practical laboratory experience, three as chief chemist and three as assistant chemist in cement plant; one year's p.g. work in physical chemistry; three years experience teaching. Desires position in any industry with chemical control. Available immediately. Apply to Box. No. 609-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W

ELECTRICAL ENGINEER, B.Ec. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. **Location immaterial.** Apply to Box. No. 651-W.

Situations Wanted

ELECTRICAL ENGINEER, Univ. Grad. 1928. Two years Students' apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660 W.

ELECTRICAL AND RADIO ENGINEER, B.Sc. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experiences includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.Ec., Elec., '29, B.Sc., Civil '33. Age 27. Jr.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.Sc., '27, Jr.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.Ec., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), E.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.Sc. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box. No. 729-W.

MECHANICAL ENGINEER, E.E.I.C., B.A.Ec., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location **immaterial.** Apply to Box No. 740-W.

Situations Wanted

CIVIL ENGINEER, B.Sc. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten years diversified electrical and mechanical experience in the industrial field. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.Sc., A M.E.I.C., with fifteen years experience mostly in pulp and paper millwork, reinforced concrete and structural steel design, field surveys, layout of mechanical equipment, piping. Available at once. Apply to Box No. 825-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

BRIDGE AND STRUCTURAL ENGINEER. A.M.E.I.C., McGill. Twenty-five years experience on bridge and structural staffs. Until recently employed. Familiar with all late designs, construction, and practices in all Canadian fabricating plants. Desirous of employment in any responsible position, sales, fabrication or construction. Apply to Box No. 851-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

Situations Wanted

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box. No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, B.A.Sc. in C.E., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.Sc. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

Situations Wanted

CIVIL ENGINEER, B.Sc., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C. '29); M.S. Age 27. Single. Four years experience in research work in applied mechanics and materials testing. Desires position involving analytical work in design, development or testing. Available on short notice. Apply to Box No. 1123-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box. No. 1127-W.

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.Sc., Queen's '33 Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.Sc., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.Sc., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Write and speak both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211 W.

CIVIL ENGINEER, B.Sc. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

COMBUSTION ENGINEER, A.M.E.I.C., with extensive experience in all phases of combustion engineering, including plant layout, piping, etc. Lately connected with prominent firm of automatic oil burner manufacturers. Apply to Box No. 1224-W.

MECHANICAL ENGINEER, B.Sc. McGill. Experienced as supt. of plant manufacturing home appliances—purchasing of supplies and equipment of technical nature. Plant engineer of works for manufacture of railway equipment and of copper and brass rolling mill and seamless brass and copper tube mill and brass cartridge cases. Designing engineer on special machinery, maintenance engineer, plant layouts. Apply to Box No. 1241-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet and tissues. Apply to Box No. 1246-W.

CIVIL ENGINEER, B.Sc. '29, Jr.E.I.C., age 29, single. Experience in all types of surveying including use of aerial photographs. Three years on hydro-electric power development in field and office. Instrumentman on concrete road construction. Location immaterial. Apply to Box No. 1254-W.

CIVIL ENGINEER, Univ. Toronto '33, age 24, married. One year as instrumentman with provincial department of highways. Experience in concrete and retread construction grading, culverts, etc. Also draughting, estimating and general office practice. Apply to Box No. 1265-W.

THE

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

Entered at the Post Office, Montreal, as Second Class Matter.

The Institute as a body is not responsible either for the statements made or for the opinions expressed in the following pages.

Volume XVIII — Montreal, April, 1935 — Number 4

The Water Supply of the Prairie Provinces

Leading points in the papers presented at the Annual Meeting in Toronto on February 8th, 1935, with notes on the discussions which followed.

In dealing with the subject of precipitation, *Mr. John Patterson's*[1] paper points out that the rainfall over a continental area like the prairie provinces is not determined by local conditions, but by world-wide forces causing the movement of great masses of polar and tropical air; thus its amount and general distribution cannot be altered by human effort.

In reference to the matter of surface water supply and run-off the paper by *Mr. J. T. Johnston*[2] gives statistics indicating the severity of the present drought, since the run-off from prairie sources during the past six years has been only 20 to 30 per cent of the twenty-year mean. The run-off from mountain sources has been better maintained, but has nevertheless shown a marked decrease.

The availability of ground water depends largely on its distribution and *Mr. R. T. D. Wickenden's*[3] contribution indicates that the bedrock formations of West and South Saskatchewan are capable of yielding considerable supplies which, however, have to be pumped. There are also artesian areas which are not yet completely known, and require further investigation as to their extent and yield, before proper conservation methods can be developed.

Ground waters in the prairie provinces are especially liable to mineralization, and the paper by *Mr. D. C. Maddox*[4] states that while artesian waters are generally potable, they often contain a fairly high proportion of soluble salts. The waters from the shallow wells in surface deposits or glacial drift vary greatly in mineral content, but as a rule contain smaller amounts of soluble salts, and are the most satisfactory for drinking purposes. Investigation is desirable as to the possible improvement of the artesian waters by mixture or possibly by chemical treatment.

Mr. W. Calder[5] in his paper dealing with well drilling in Alberta draws attention to the importance of controlling rural well sinking so as to avoid the pollution or mineralization of otherwise potable supplies.

Messrs. W. A. Johnston and R. T. D. Wickenden[6] consider that soil drifting is largely the result of dry-farming methods and single crop farming, combined with the general absence of wind breaks. The character, extent and mode of origin of soils in Manitoba and Saskatchewan south of 52 degrees are discussed in relation to soil drifting, and references are given to the valuable information on this subject contained in the soil survey publications of the University of Saskatchewan.

As a result of his long experience, *Mr. N. M. Ross*[7] believes that there is little basis for the claim that tree planting changes the climate of a large area, or will increase the rainfall. The local benefits to be derived from shelter belts and tree planting are, however, quite definite. To grow trees successfully in the prairies requires considerable care, cultivation and the proper choice of varieties. Trees *can* be grown where there is sufficient moisture for wheat, but successful results will not be obtained without proper attention. They should be planted at the commencement of a period of normal precipitation, not during severe drought. Great assistance has been given in this matter by the Dominion Forest Nurseries Station, which has distributed nearly one hundred and forty million seedlings to more than fifty thousand farmers.

The paper by *Mr. P. C. Perry*[8] gives the results of his study of drainage basins in southern Alberta, Saskatchewan and Manitoba. He points out that in the prairie generally the annual evaporation from open water is about twice the precipitation, and that the final run-off of prairie streams does not exceed about two per cent of the precipitation. He is of the opinion that the theory of regular climatic cycles due to sun spots, etc., has little weight. He advocates the construction of storage reservoirs wherever possible, varying in size from small dugouts for individual farms to large lakes. He also points out that in the utilization of available water supplies, problems of administration are likely to arise.

In his general study of water conservation *Mr. T. C. Main*[9] draws attention to the waste of surface water which has occurred in the past. He believes that there has been a steady, though small, rise, say about 2 to 4 degrees, in the average temperature in the prairie regions for the past sixty years, although it appears that the trend is now reversed. He emphasizes the importance of adequate water supply in maintaining a proper standard of living, and holds that the water available should not be used for wheat

irrigation but for individual farm supply. As regards major schemes for water conservation, he refers to proposals which have been made for dealing with the South Saskatchewan river, the Frenchman river in southwestern Saskatchewan, Swift Current creek, the Qu'Appelle river at Buffalo Pound Lake, and the Souris river in southeastern Saskatchewan, together with projects for preserving and enlarging various lakes such as Big Muddy Lake, Willow Bunch Lake and Goose Lake. He points out that these and other similar schemes have not yet been studied in detail as engineering projects. Such study is necessary before opinions can be expressed as to their economic feasibility.

The paper by *Mr. Walter Blue*[10] gives some results of his preliminary study of the possibility of damming the South Saskatchewan river near the Elbow. This glacier-fed river is the principal large-scale source of possible supply in the drought region, and could probably furnish over two million acre-feet annually. Construction work would have to be on a large scale and would be costly, as the maximum discharge of the river is some 130,000 second feet. The development would make power available for pumping, and in his opinion, the scheme deserves a complete engineering study.

In regard to conditions in the United States, the memorandum by *Mr. L. A. Jones*[11] supplies information on the Federal Emergency Relief Administration activities in the drought areas of North Dakota and Montana during the year 1934-1935. The large sums made available by the F.E.R.A. have been devoted largely to direct relief and the provision of food, fodder for livestock, and seed for farms, but have also provided for considerable expenditure on tree planting, the development of water supply improvements and irrigation systems, and the construction of small reservoirs. Ground and surface water surveys have been made and work has been provided for a large number of men who were on the relief rolls. The assistance thus afforded has enabled many farmers to remain on the land who would otherwise have been forced to leave it.

* * *

In the discussion based on these papers much additional information was given. The following notes refer to written discussions received, as well as to those presented orally at the meeting.

These discussions are printed on pages 221 to 231 inclusive, of this issue.

Mr. H. G. Cochrane pointed out that the drought problem resolved itself into the question of how to make the prairie area more habitable. A great deal of information is already available, and more should be secured, as a basis for systematic investigation, for which funds might be supplied partly by investors interested in the area, such as railways, insurance companies, manufacturers and so on. He would suggest the formation of a committee to approach such bodies for contributions, to undertake the study required and to report to the contributors and to the various provincial governments concerned.

Mr. C. H. Fox agreed that the majority of proposals for engineering works so far made had been insufficiently studied technically, for example, the proposed Riverhurst diversion of the South Saskatchewan river for the purpose of distributing water over 8,500 square miles. This would involve a dam 2,000 feet long, 200 miles of distributing channel or pipe and 80,000 h.p. for pumping. He would prefer to consider a less ambitious scheme such as that suggested by Mr. Blue. He was heartily in favour of minor engineering works for the control of drainage, flood and run-off water, and also the provision of shelter belts for the benefit of the individual farmer.

Mr. Perry considered that Mr. Main's condemnation of drainage was too sweeping, and he was unable to support Mr. Main's theory of the effect of ratio of water to land area on climate. He did not think this was tenable except in regard to continental masses and oceans. He drew attention to the changes which had occurred in the areas of sloughs and lakes, as for example a lake near Lampson, which in 1927 covered 3,000 acres. This area was dry in 1912, partly filled in 1916, dry again in 1922, completely filled in 1927, and is now dry and has been dry since 1930. These changes took place irrespective of drainage ditches or any artificial factor, and he did not think the drainage measures taken over most of the prairie areas had had any appreciable effect on climate. He was strongly in favour of water conservation by means of farm ponds and small reservoirs on local streams, but thought that the larger schemes, such as that proposed for Buffalo Pound Lake, for the Souris river, and for the South Saskatchewan, should certainly be deferred.

Mr. Attwood summarized the views of Premier Bracken as expressed in the speech delivered on October 25th, 1934, at Winnipeg. This admirable presentation of the rehabilitation problem described the situation and pointed out that immediate action is necessary if we are not to witness similar distress at recurring periods in the future. The Premier of Manitoba had remarked that in approaching such a problem the basic facts must first be discovered, and that reforestation, power, drainage practice, soil management and cropping methods must all be taken into consideration. A reclamation programme should provide for a thorough survey of the area affected and should result in specific recommendations regarding agricultural production and conservation plans for each separate soil zone.

Mr. Patterson, supplementing the information given in his paper, stated that conservation methods could not affect the climate of the region as a whole. He believed that the slow increase in temperature observed in Manitoba was not confined to the prairies but was possibly world wide.

Mr. Main drew attention to the various meanings assigned to the term "climate" but thought that it would be useful to follow Geiger in distinguishing between macroclimate and microclimate. The former term referred to the general climate of a whole area, and the latter to the climate close to the ground or in small areas as affected locally by the presence of ponds, shelter belts and the like. Microclimate is therefore amenable to human control to a certain extent.

Mr. F. K. Beach was doubtful whether there really had been the 20 per cent increase of evaporation of which Mr. Main had spoken, and whether there was a real cyclical variation of run-off due to sun spots or other causes. He desired to point out that Mr. Main's proposal to furnish water to individual farmers in amounts sufficient to supply 15 acres per quarter-section would involve immense expenditure, and judging from past experience this would all have to come from the public purse. He believed that the most pressing immediate needs were the withdrawal of unsuitable land from cultivation, the provision of dams and reservoirs, and the control of well digging and the use of ground water.

Mr. F. W. Caldwell drew attention to the work of the various state planning boards in the United States. These now exist in forty-one states, and there are, in addition, two regional planning boards. Their function is to plan for the utilization of the natural resources of the state or region regarded as an economic whole, and he would suggest the desirability of similar measures as regards Canada's arid regions.

10 Storage on the South Saskatchewan River. See page 218.

11 Water Phases of the Drought Relief Programme of the United States Federal Emergency Relief Administration. See page 220.

Professor Chandler, as a result of thirty-two years' experience of run-off conditions in North Dakota, had obtained figures which agreed substantially with Mr. Perry's. In prairie land run-off does not form any definite proportion of the precipitation but consists mainly of water which runs away after sudden storms before it has had time to sink in, or of spring flow-off resulting from rapid melting of snow when the ground below is still frost-bound; This is available in the spring, and its amount varies greatly in different years. The storage of such waters is one of the most important items in a water conservation programme.

Mr. J. W. D. Farrell was in agreement with Mr. Main in considering that the feature of primary importance is not irrigation but the provision of the necessary supply on the farms for human and animal use. He doubted whether many local reservoirs would survive prolonged drought, although they would undoubtedly better conditions in the intervening periods. He cited the case of Wascana Lake at Regina, which covers an area of 200 acres and was full up to the spillway in 1928, was nearly empty in 1931 and in 1934 was full again.

Mr. D. A. R. McCannel pointed out that the time of the year at which precipitation occurs is as important as the amount which falls. Frequent moderate rainfall during the growing season, June and July, is the most beneficial. He considered that in the construction of small and medium sized reservoirs or dams, engineering advice is essential, and works of this character are the first necessity. The economic feasibility of large and expensive schemes should be thoroughly investigated before they are embarked upon.

Mr. C. J. McGavin quoted various divergent opinions on the effect of forests on climate. The annual rings in trees laid bare by the recession of lakes in North Dakota indicated that wet cycles have come and gone for over one hundred years. He considered that the shape of a drainage basin, whether long and narrow or round, had marked effect on the amount of run-off and the intensity of floods originating in that drainage area. Mr. McGavin was unable to follow Mr. Main in tracing a relation between run-off and sun spot cycles. He thought that a ten-year period was generally considered sufficient for hydrometric records except in the case of the design of major structures, where longer records, say fifty to sixty years, were almost essential. Mr. McGavin suggested a formula for mean temperature taking care of longitude, latitude and altitude. He agreed that the primary need is for dams for domestic and stock watering, and believed that an inventory should be taken of the water resources of each township, together with considerable further investigation of the ground water resources of the dry areas.

Dean C. J. Mackenzie considered that there are two schools of thought: one holding that climatic conditions can be affected to some degree by man's efforts, and that precipitation may be increased by tree planting and the creation of reservoirs, also that large-scale projects such as Mr. Main outlined in his paper are desirable and practicable. The other school believes that such measures are impracticable, that the remedy lies rather in the field of improvement of agricultural and tillage methods for the purpose of reducing evaporation and lessening soil drifting, and that a reorganization of our social and political institutions, perhaps in the form of an insurance scheme for relief purposes, is more practical and economically justifiable, for the purpose of tiding over the periods of drought which will inevitably return. He favoured this view.

Dean Mackenzie felt that Mr. Main's scheme of bringing water to individual farms by pipes is a bold conception, but on investigation would be found impracticable under present economic conditions. He considered that the most promising course would be a system of planning and insurance which would cover all areas against drought, and agreed with Mr. Main that there is urgent need of a commission of enquiry of a broad nature to bring together the opinions of meteorologists, agriculturists, engineers and statesmen.

Mr. R. W. McKinnon was of the opinion that while tree belts would have no appreciable effect on the amount of precipitation, they would be helpful as regards soil drifting. The present, however, is not the time to start tree planting on a large scale, by reason of the deficiency of ground water. In all forestation or tree planting schemes the individual co-operation of the farmers is essential, and this is also the case in regard to the formation of ponds and dams, which in dry years he felt would be in danger of filling with drift soil if unprotected. He was of the opinion that there are still places where drainage and reclamation is desirable, and did not think that drainage due to the efforts of farmers and highway constructors and the railways had had the prejudicial effect which some speakers had mentioned.

Mr. Perry remarked that as regards the construction of dams and reservoirs, something had already been accomplished. Last year nine municipal reservoirs had been built in Saskatchewan under proper engineering supervision, while about forty others were now contemplated. He drew attention to the successful establishment of reservoirs by the railways. Mineralization of reservoir waters had not been found serious by the railways. He believed that large scale irrigation is not a paying proposition on the Canadian prairie. Mr. Perry disagreed with Mr. McGavin as to the effect of tree planting, and considered that the chief use of shelter belts would be to concentrate water in desirable spots and help to supply and protect reservoirs and reduce evaporation from them.

Mr. L. P. Rundle suggested the formation of a commission by the Federal government which would be in touch with an engineering representative of each province. The ideas and methods of rehabilitation work in the United States should be studied. Meteorological data should be secured and recorded by an international meteorological clearing house for the North American countries. The government commission should study individual areas as to their fitness for agriculture, grazing and tree planting. There should be proper regulation of drainage, uniform legislation as to water rights, and the various legislatures and the public should be informed by the commission as to desirable conservation schemes. The commission would also make recommendations as to finances.

Mr. R. S. Stockton, in an address made before the Calgary Branch of The Institute, had drawn attention to the way in which the fertility of large areas in the prairie provinces had been destroyed, and remarked that the principal remedies available appear to be strip farming, seeding of considerable areas to grass or other selected suitable plants, the employment of live stock so that manure would be available, the diversion of perennial streams for irrigation where possible, the conservation of run-off water, the provision of shelter belts, and the adjustment of land taxation. Much of the work involved would need engineering supervision, as for example the construction of dugouts and dams for the storage of storm water in farms and the control of well digging and pumping to ensure proper utilization of available ground water resources.

Precipitation in the Prairie Provinces

John Patterson,
Director, Meteorological Service of Canada, Toronto, Ontario.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

A symposium on the water resources in the prairie provinces necessarily involves the question of rainfall in these provinces or on the drainage basin of which they form a part. Meteorologically the two factors to be considered are evaporation and rainfall, but the disposal of the rainfall after it reaches the earth must be dealt with by those who have made a special study of the problems. This paper will be confined entirely to the question of precipitation, evaporation and temperature in the prairie provinces.

There are many erroneous ideas prevalent in regard to precipitation as it may be affected by opening the country up for settlement. The ideas seem to change according as the rainfall is abundant over a period of years, or the opposite. In the period of abundant rainfall there was a prevalent idea that the opening of the country up to agriculture increased the rainfall; now the pendulum has swung violently in the opposite direction, and many people believe that the cultivation of the land and the drainage of sloughs, ponds, lakes, etc., has decreased the rainfall, and has been a very important factor in producing the drought that has prevailed for the last number of years.

It would be well therefore to consider first of all the actual physical processes that are in operation to produce precipitation. The first question naturally is whether the processes that produce precipitation are entirely local in their origin or world wide. If the former, then we would naturally expect that decreased evaporation and decreasing water areas might have an appreciable effect on the precipitation. On the other hand, if the processes are the result of the operation of world wide forces then the local conditions would play, at the very most, a very insignificant part. The fundamental facts are as follows:

The air receives its supply of water vapour by evaporation from all water surfaces, and from moisture in the surface soil, and from transpiration from vegetation. Naturally the greatest source of moisture is the tropical regions where there are enormous water areas and high temperature. On the other hand, the lowest evaporation occurs in deserts and in the arctic regions where it is very cold and largely continental. There is thus passing into the air an enormous quantity of moisture from evaporation, and this moisture is distributed by the air currents over the face of the earth, but after getting the moisture into the air the next question is "how is the moisture to be taken out." This is probably the factor which leads to erroneous conceptions about the effect which evaporation has on rainfall in a region. Apparently many believe the only question is that of getting the moisture into the air, completely forgetting the means by which it can be taken out, and the incomprehensible amount of energy required to carry through the weather processes.

In connection with getting the moisture out of the air, it is necessary first to consider the physical facts about the atmosphere on which these processes are based. They are:

(1) The higher the temperature the more moisture the air can contain.

(2) There is a definite amount of moisture that can exist in the form of vapour for any given temperature. Experiments show that at a temperature of 32 degrees F. the air can hold about 22,000; at 70 degrees F. 85,000; and at 100 degrees F. 210,000 tons of water per cubic mile, in the form of vapour.

(3) The temperature decreases with height above the earth's surface. Experiments show that on the average the temperature decreases about 3½ degrees per thousand feet of elevation.

These are the physical conditions in the atmosphere on which the weather processes operate in order to get the moisture out of the air. There is always a certain amount of moisture in the atmosphere, and from what has just been said if the air can be cooled sufficiently the temperature will be reduced below the saturation point and thus the excess moisture will be condensed into fog, cloud, or precipitation. If much rain is to be obtained the air must be cooled on an enormous scale, as the only amount of moisture that can be taken out is that between the saturation point and the final temperature to which the air is reduced; thus if the air saturated at 70 degrees F. could be reduced to 60 degrees F. there would only be 24,000 tons of water per cubic mile of atmosphere taken out, and that would give about one-third inch rainfall per square mile. This is a very extreme case, but it gives one some conception of the enormous supply of vapour that is necessary in order to produce rainfall on an extensive scale.

The only method in nature whereby this cooling can be produced on a scale sufficiently great to produce extensive precipitation is to force the air to rise in the atmosphere,

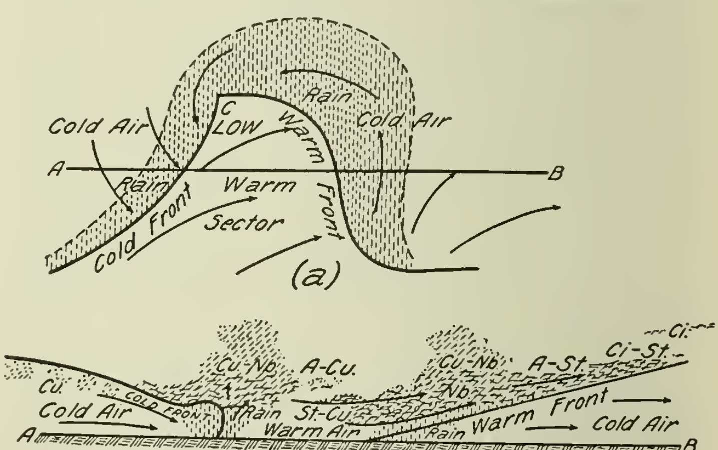

Fig. 1—Horizontal and Vertical Section of an "Idealized Cyclone."

thus cooling it at the rate of about 3½ degrees per thousand feet of elevation; at the same time a continuous supply of moist air has to be provided. How can this air be forced to rise? One of the familiar means by which forced ascension can take place is that of moisture-laden winds blowing up against the side of a mountain. Here the mountain compels the air to rise and thereby cools it, so that the moisture is precipitated, but away from the mountain we must have something in the atmosphere itself that will take the place of the mountain. This has been the subject of long investigation, especially of the conditions existing in the upper atmosphere, and as a result we now know that there exist in the temperate regions at any rate two great air masses or air currents. They are known as "the polar current" or polar air mass, and "the tropical current" or tropical air mass. Their names give some idea of their characteristics, that is, the polar current is cold and comparatively dry, as it originates in the polar regions; the tropical current, coming from the tropics, is warm and generally moist.

While these are the distinguishing features of the two air masses, yet each may be sub-divided into a great many different types, according to their origin over land or over water, and their subsequent history; if over land, they would naturally be dry whether tropical or polar; if over the water they would contain a considerable amount of water vapour depending of course on the temperature. These currents can preserve their identity for a long time, being gradually modified of course by the region over which they are passing. Probably their most striking feature is that they can exist side by side for great distances without any appreciable mixing.

The operation can be explained most easily by means of a diagram of what we may call "the idealized cyclone." The tropical current, by some means which is not yet understood, forces its way into the polar air current, and once this action is set up it goes on to completion.

As the cyclone or low pressure area develops we find the condition illustrated in Fig. 1. Here the tropical air current on one side drives into the polar current and the line of intersection is known as "the warm front" since it is the warm front that is advancing against the cold. On the other side of the tropical current the polar air mass is advancing against the tropical and this is known as "the polar front" or cold front. Some idea of the extent of this area may be gained from the knowledge that the distance from the front to the rear of the idealized cyclone as measured along the line A-B may exceed 1,000 miles.

In Fig. 1 the tropical current drives back the polar air current along the warm front. At the same time it runs up over the cold current which may be likened to an enormous wedge with a slope of about 1 to 200 and impenetrable to the warm current so that the warm current is forced to flow up along this wedge. It is easily seen what happens as the current advances farther and farther up the slope. The warm current is lifted higher and higher until first there is cloud, then higher still, rain. After the rain has been taken out we get the higher cloud, the alto, and higher still the cirrus, thin wispy clouds which are often seen spreading across the sky, the harbinger of an approaching disturbance.

It is thus not a case of simply lifting up the air over the place of observation, to the region where it can be condensed into cloud or rain, but the flowing of a continuous supply of warm moist air up this slope, so that the abundance of rainfall in the region will depend on the amount of moisture in the air and the degree of cooling to which it is subjected. This will determine whether it is mere drizzle, moderate rain, or heavy rain, while the duration of the rainfall will depend on the rate at which the polar air current is driven back.

Thus it will be seen that in such cases the surface air over the region where rain is falling is acting as the wedge up over which the warm moisture laden currents are flowing and consequently no rain can be obtained out of the surface air and thus evaporation at the place plays no part in the rainfall over the region.

As we pass back along the line B-A into the tropical current we come into higher temperature, high humidity, and a region usually very muggy and oppressive, even more so than when it was raining in the warm front region. There is no precipitation, probably no cloud, because in this region there is nothing that will force the ascension whereby the air mass may be cooled.

As we pass farther westward towards A we come to the cold advancing front which impinges against the warm current and undercuts it, forcing the warm current up to enormous heights and causing tremendous turbulence in the atmosphere. It is generally along this line that we have

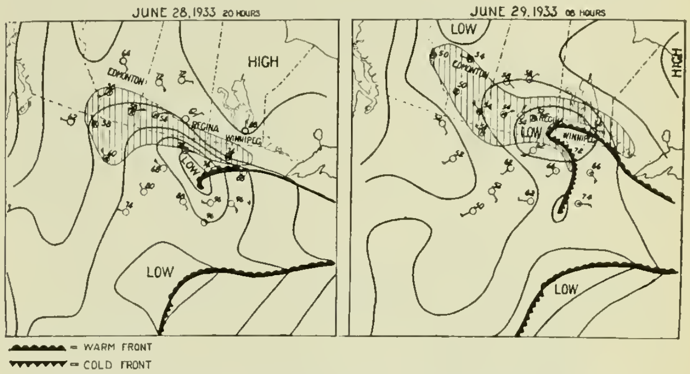

Fig. 2—Weather map for June 28th and 29th, 1933.

showers, violent thunderstorms, hailstorms and violent line squalls.

This front of advancing cold air has a slope of about 1 in 100 with a sort of round nose, as indicated in the diagram. The strip is comparatively narrow, and as it sweeps by, we emerge into clear polar air.

As the cold advancing front arrives suddenly and undercuts the warm tropical current it might appear as if here is a place where evaporation over lakes, ponds, sloughs and from the ground generally, would play an important part in the amount of precipitation received. In this connection it must be remembered that there is always a certain amount of wind, especially in the higher levels, and the moisture is thus carried away as rapidly as it is evaporated, probably travelling over 200 miles in the course of a single day. If it could possibly be imagined that the air remained perfectly calm for a space of say six hours, before the advent of the cold front, it would be found that the greatest amount of evaporation that could occur in that time would be about .06 of an inch from a free water surface, and very much less from comparatively dry land. Consequently, even admitting that this evaporation was returned as rainfall to the surface, the amount would be infinitesimal, in fact it is so small that it would be evaporated while falling through the air. This however, is not what happens. There are as already stated two great air currents, one the polar and the other the tropical. Along the line of the polar front, we have the meeting of two strong opposite currents, each of them converging along a common line, and it is this piling up of the air from both directions along the junction that causes such a tremendous turbulence in the atmosphere, giving the heavy thunderstorms, etc., that are often experienced. Thus even in this particular case, one can see that evaporation over a region plays no part whatever in the amount of precipitation that may be received.

That this idealized cyclone which has just been described represents what is actually taking place in the atmosphere when the weather systems are well developed is illustrated in Fig. 2, which shows the actual meteorological conditions existing on June 28th and 29th, 1933, in the prairie provinces. During the summer months there is what is called a "quasi stationary front" which extends practically across the continent, a portion of it being shown in Fig. 2, at the bottom of the diagram. This front moves from north to south in the eastern part but there is very little motion in the western part especially near the mountains. There is in addition to that in the summer time another frontal system which moves down from the north and ultimately joins up with it. In the particular cases here given on the 28th of June this second or northern front is shown in Dakota, the warm front being specially well

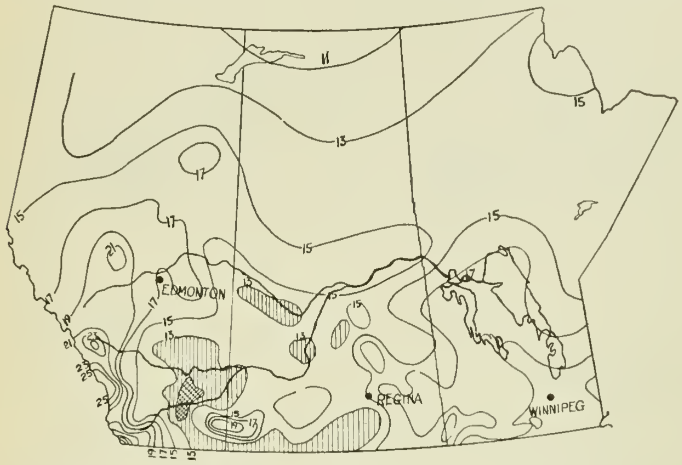

Fig. 3—Average Annual Total Precipitation in Inches.

developed. Here the warm air from the south is over-running the cold, so much so that it has given rain over the hatched area. This is typical of what is shown in the northern part of the idealized cyclone. Notice that the temperature in the rainfall area or in the cold air mass is comparatively low, whereas in the region to the south of the warm front it is high. To the north of the front the winds are east, north-east or north, while those to the south are generally southerly in direction.

On this particular day the cold front was not definitely marked, but it developed during the next twelve hours so that the weather map of June 29th looks very much like the diagram for the idealized cyclone. Here again there is a tremendous over-running of warm air over the cold, so that precipitation has actually extended as far north as Edmonton and Jasper. There is also well marked rain to the east of the warm front, but most of it is to the north and west. The wind system is again much the same, and the usual marked difference of temperature between the cold and the warm air masses. The cold air mass contributes practically no moisture to the general precipitation, as it forms the wedge over which the warm and moist air current from the south is running. In this particular storm there was very general and heavy rain generally without thunderstorms over all the region represented by the hatched area. It must be remembered however that in all systems there is every gradation from those that are well marked in this example to others where it is with great difficulty that any distinction can be made between the air masses. Moreover, much of the rainfall received in the prairies is of the cold front type instead of the warm front as illustrated and consequently comes more frequently in sudden showers than in any other way. These showers are often very local; just what sets up the mechanism in the cold front region, thus starting the process in many different places, it is difficult to say. There are probably local topographical features involved, and it is usually in the place where there is greatest instability in the atmosphere causing a greater uprising of the air currents when the cold front arrives. Of course, hills of a moderate size would be very favourable for starting these uprising currents and thus accelerating the production of the rain.

In these cases there is not a great amount of moisture available in the atmosphere, and consequently we do not get rain on a very extensive scale. It must be remembered that the extent of the rainfall depends on the amount of moisture in the tropical current, and the amount of cooling to which it is subjected. In the case where there are just local showers it is probable that the convective action has been carried far enough to produce the shower, while in other places it has not been carried sufficiently far to produce rain.

It may be noted further that the prairie area forms one of the most interesting regions meteorologically that there is for the study of weather processes. Mountains to the west impose such a great barrier on the advancing fronts that they are broken up at the surface as they hit the mountains and are apparently carried across high up in the atmosphere, and thus do not show themselves at the earth's surface until they have advanced some considerable distance from the mountains. This is a subject which it is hoped to investigate very specially as soon as the necessary means are available for that purpose.

The foregoing is an attempt to explain the process by which precipitation on an extensive scale is produced. Unless these two great air currents meet over the region, it is utterly impossible to get rainfall of any account, that is, there will not be rainfall of any appreciable amount in a region which is entirely under the influence of either the tropical or polar current. Thus when drought conditions appear, either one or other of these currents is very weak, and generally this is the polar current, so that the prairies are largely under the domination of the tropical or warm air current during years of drought; this being the case, there is usually more moisture in the air per cubic foot than there is in years of good rainfall, but as there is no means by which the ascension of the air can be forced, there is in consequence no precipitation. This also explains why as you go north in the prairies, rainfall becomes more certain and droughts much less frequent. It is the region where the tropical and polar air currents meet more frequently.

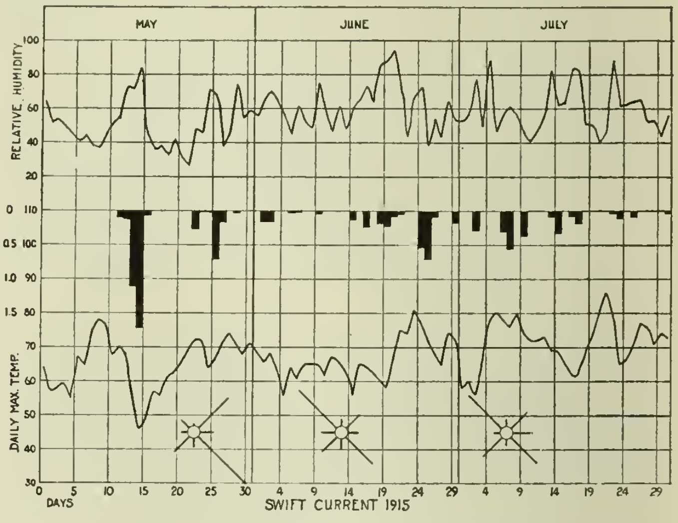

Fig. 4—Daily Rainfall, Maximum Temperature, Relative Humidity, and Prevailing Wind Direction.

Having discussed the cause of precipitation and the general world meteorological conditions that exist during years of drought and years of good rainfall, the actual weather conditions over the prairie provinces will now be considered very briefly.

In Fig. 3 the average annual precipitation in inches is shown, by lines for every 2 inches of rainfall. The hatched area represents the region where the average fall is between 11 and 13 inches and the double hatched less than 11 inches. It is shown that precipitation varies all over the world from year to year and generally the deficiency in places where the normal rainfall is abundant would have no very serious effect but in places where it is scanty it is all the difference between years of drought and years of plenty. Thus there is the rather interesting fact that the greatest amount of precipitation recorded in one year in Toronto was two and a half times greater than the lowest. This same ratio holds for Qu'Appelle, and Swift Current,

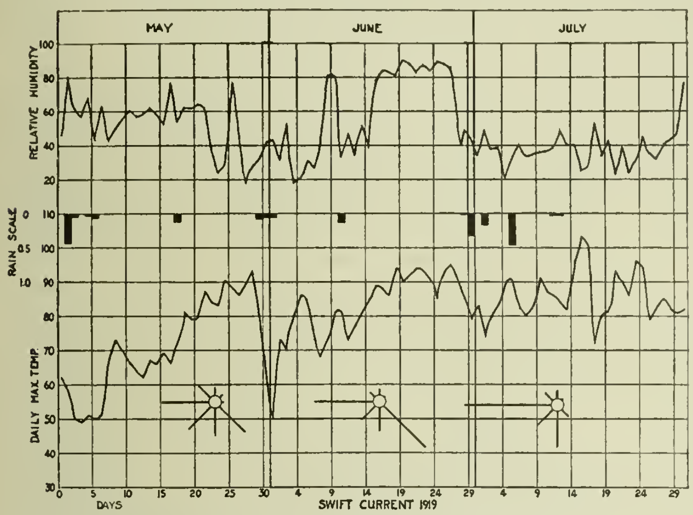

Fig. 5—Daily Rainfall, Maximum Temperature, Relative Humidity and Prevailing Wind Direction.

while at Prince Albert one was four times greater than the other. This being the common experience all over the world one must expect that in regions where normal rainfall is scanty there will be years of drought and years of plenty.

Precipitation in the prairie provinces is generally considered to be the all important meteorological factor in determining the character of the year as regards drought or plenty, but there is also to be considered its distribution in time, as well as the temperature, wind and humidity. All these are important factors in determining growing conditions.

In order to illustrate this, two years have been selected, taking Swift Current as typical of the region. One of the best years was 1915, and Fig. 4 shows day by day for the three months, May, June and July, the rainfall, maximum temperature, relative humidity at the time of maximum temperature, and the direction of the wind from the different quarters. It will be noticed that the rainfall was frequent but only on one occasion was it at all heavy. Again there were no high temperatures, the thermometer only going above 80 degrees Fah. on three occasions. Probably the most surprising part of the record is that in spite of the good rainfall, the relative humidity was fairly low. This, however, is to be expected, as in this year the prairies were dominated largely by polar air masses which as already explained have usually a small moisture content. The predominating wind direction during May was southeast and during the other months northwest, the northwest winds indicating the inflow of cool air from the Arctic. Thus the rainfall was just about normal with frequent but not heavy showers throughout the growing season, and the temperature was low, thus providing ideal conditions for a good crop.

One of the worst years on record was 1919 (Fig. 5). During this year showers were very light and infrequent and only on two occasions, and these far apart, did it exceed .45 of an inch; temperatures were high, being well over 90 degrees for nearly two weeks in June. Notice however the rather surprising feature that the humidity at this period was exceedingly high, contrary to general expectations. It indicates an inflow of warm, tropical air, but as the polar current was lacking there was nothing to force the ascension and thus produce rainfall. There is a predominance especially during July of westerly winds, indicating that the air masses were coming from the Pacific, and in these Pacific air masses the humidity was quite low.

Many more examples could be given to show the difference between a good and a bad crop year, but they would have the same general characteristics as shown for the years 1915 and 1919 at Swift Current.

The characteristics then of a good year are frequent showers, low temperature, moderate to low humidity, and a prevalence of northwest winds. On the other hand, the characteristics of a drought year are infrequent showers or showers so light as to be of little use, high temperature, prevailing southwest and west winds and moderate or low humidity.

When rainfall was good it was generally felt that these conditions would continue. Now people have gone to the other extreme, and the question is being asked, are droughts owing to the cultivation of the land a permanent condition and will years of good rainfall never return. The only answer that can be given to this question is to refer to the past and see what has happened before. This is generally called the "trend of precipitation." One of the best means to show this is to take the five-year moving mean. This mean is obtained by taking five consecutive years, dividing by five, and crediting it to the middle year; then dropping the first year, adding the next in succession, dividing by five, and crediting the result to the following year. In this way a moving mean is obtained. It sums up the average rainfall for five-year periods and it thus shows the general trend of the precipitation over long periods.

This moving mean for Prince Albert, Swift Current and Qu'Appelle is shown in Fig. 6 for the period for which records are obtained, amounting to about fifty years. At Swift Current it is noticed that there is no definite trend there having been periods of good rainfall together with periods of deficient rain. On the other hand at Qu'Appelle from about 1897 until 1925 the rainfall on the whole was good apart from occasional bad years, but since that time the rainfall has been on the whole decreasing. It will also be noticed that from the beginning of the observations in the early 80's up to 1897 there was deficient rainfall.

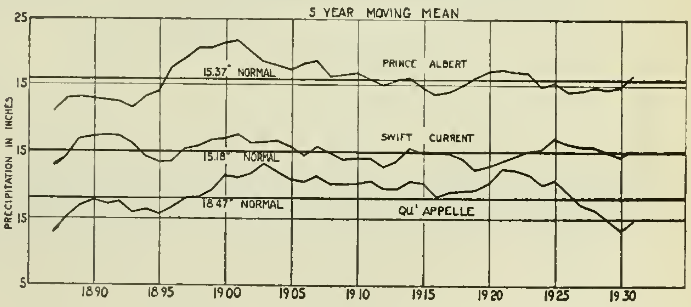

Fig. 6—Five-Year Moving Mean.

Prince Albert ever since 1905 has been characterized by rainfall not departing very much from normal.

Another method of indicating precipitation trends is that of accumulated excess or defect, that is the normal rainfall for the period is taken and beginning at the first year the deficit or excess is taken, then add the deficit or excess in the next year to the preceding and so on. In this way you build up the total accumulation or deficiency of rainfall from year to year. It must be remembered in this connection, however, that the curve must end on the normal line for the last year of the series, and thus it only indicates the trend of the rainfall.

St. Paul, Minn., which is fairly close to the Canadian border, is one station that has a long record. It extends back for nearly one hundred years. In Fig. 7 the trend is indicated in this case by a six-year moving mean and accumulated excess or defect. There was a period previous to about 1865 when it was more or less in defect, from 1865 to 1883 in excess, in defect again for a short period up to about 1893, then a fairly long period up to 1907 and since that time it has been hovering around normal.

The six-year moving mean for Qu'Appelle has been plotted on the same curve to show its similarity during the period for which there were observations from Qu'Appelle. The normal line is taken as the same in both cases, but for St. Paul the normal is 27 inches while for Qu'Appelle it is 18.6 inches. It illustrates the similarity of the trend between the two places. Considering the variation of these curves, it will be seen that they are too irregular to make any deduction from them as to the future prospects.

There has always been much discussion as to the relationship of weather to the sunspot period. There is plotted in this figure the excess or defect of rainfall for each sunspot period during the past one hundred years. The maximum is taken as the zero position and the precipitation is plotted for one, two, three, four, five and six years before and the same number of years after the maximum. It is noticed that there are about as many on one side of the normal as the other, a sort of crowding together during the periods of sunspot maximum when the deficiency or excess did not seem to be as great except in one particular year and a widening out again as the period approached the sunspot minimum. It will be seen from this that such curves could not with safety be used for any forecasting purposes, although the smoothed mean for all the curves would indicate a slight trend of rainfall in excess preceding the sunspot maximum and a deficiency for a few years following it.

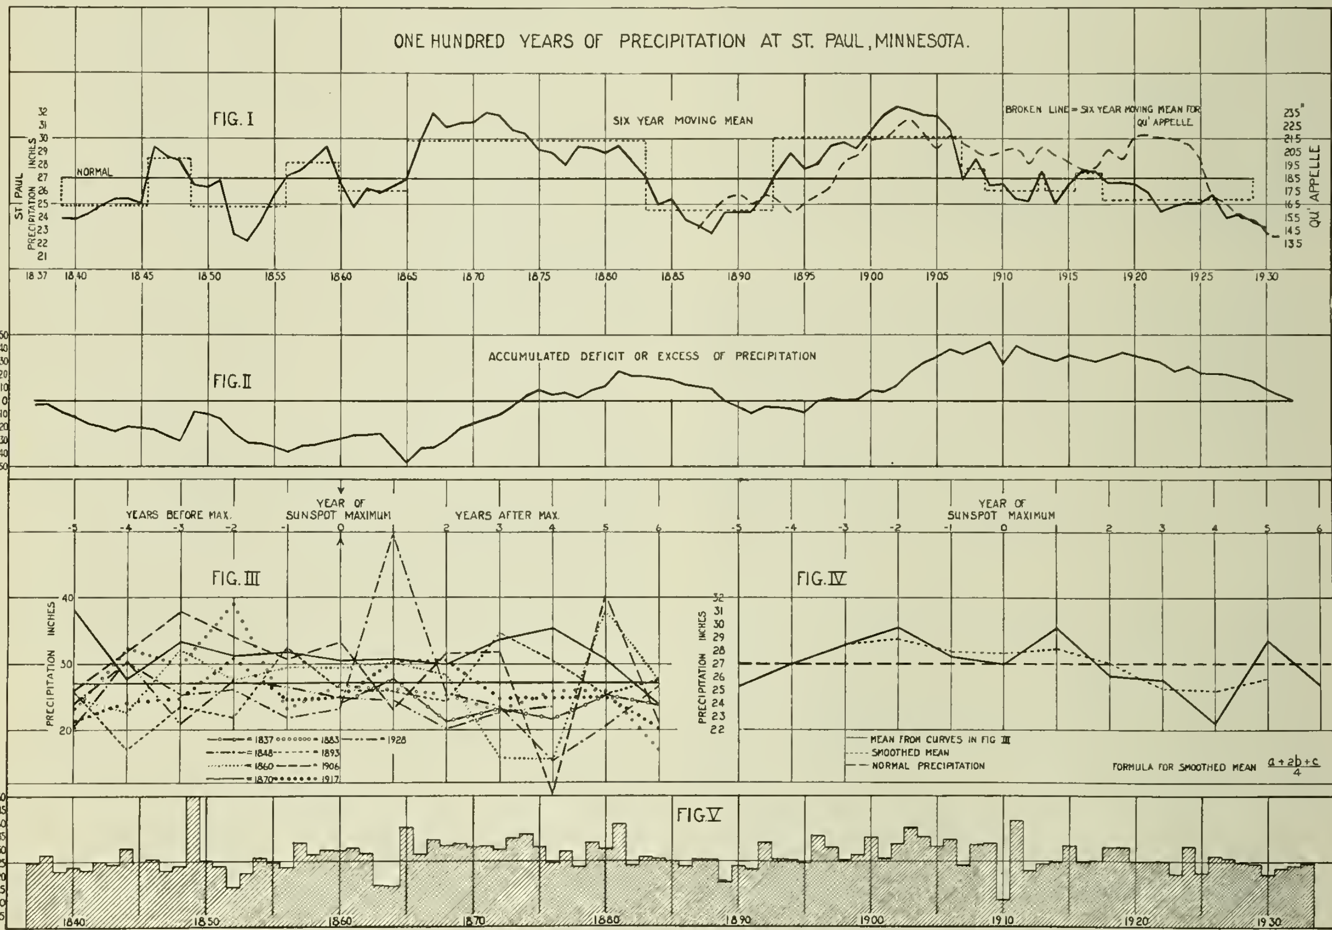

Fig. 7—One Hundred Years of Precipitation at St. Paul, Minnesota.

Surface Water Supply and Runoff of the Prairie Provinces

J. T. Johnston, M.E.I.C.,

Director, Dominion Water Power and Hydrometric Bureau, Department of the Interior, Ottawa, Ont.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

SUMMARY.—This paper analyzes the records of the Dominion Hydrometric Survey as obtained by the Dominion Water Power and Hydrometric Bureau of the Department of the Interior during the past twenty years, in the southern half of the three prairie provinces. The records at eighteen typical stations have been analysed in such a manner as to distinguish between the runoff of the mountain areas, the foothill areas, the prairie and drought areas. This permits of an immediate comparison of the total supply from year to year and by cycles. The runoff from mountain sources has been fairly consistent although it has decreased somewhat during the past six years. On the other hand the runoff from prairie sources has decreased excessively during the past six years, the mean of these years being only from twenty to thirty per cent of the normal quantity, and this condition has been even more accentuated in the drought area.

The drought conditions which have obtained in the southern and central areas of the prairie provinces have concentrated attention upon the area affected and upon the various factors which have a bearing upon the situation as a whole. From the very nature of the problem the question of the water supply available, is one of paramount interest.

The purpose of this paper is to analyze the run-off conditions in the southern half of the three prairie provinces during the past twenty years. The period of twenty years is taken because hydrometric records at some of the gauging stations are incomplete before 1914. The runoff which is studied is from the two main drainage systems, the Saskatchewan river and Red river, which—except for 10,000 square miles lying along the international border and forming a part of the Mississippi Drainage Basin—drain approximately 280,000 square miles of the area extending from the Rocky Mountains to Lake Winnipeg and from the International Boundary to the 54th parallel. The attached map covers the area in question and indicates the location of the hydrometric stations, the records of which are analyzed.

Runoff records represent simply the actual runoff water which finds its way by river and stream to its ultimate goal in the ocean. In other words, it is the residual left from the sources of original supply, after losses from seepage and evaporation and from waters used in the growth of vegetation and diverted for specific purposes have been subtracted. The original sources of supply for the area in question are the ice-capped Rocky Mountains which supply a very constant and dependable runoff throughout the summer season, and the precipitation which falls in varying amounts from month to month.

It is recognized that this paper can be but a partial study of the water supply of the area in question. A complementary study of the meteorological records of rain and snowfall is necessary to properly interpret the runoff figures in relation to all sources of supply. However, the runoff records are of themselves directly indicative of water supply conditions as they obtain and as they are available for dependable utilization, and their study provides an essential background for a study of the drought conditions as a whole.

Physical Characteristics of the Prairie Provinces and of the Drought Area

As might be expected in so vast an area, the physical conditions are greatly varied and consequently exert different influences upon the runoff in different sections.

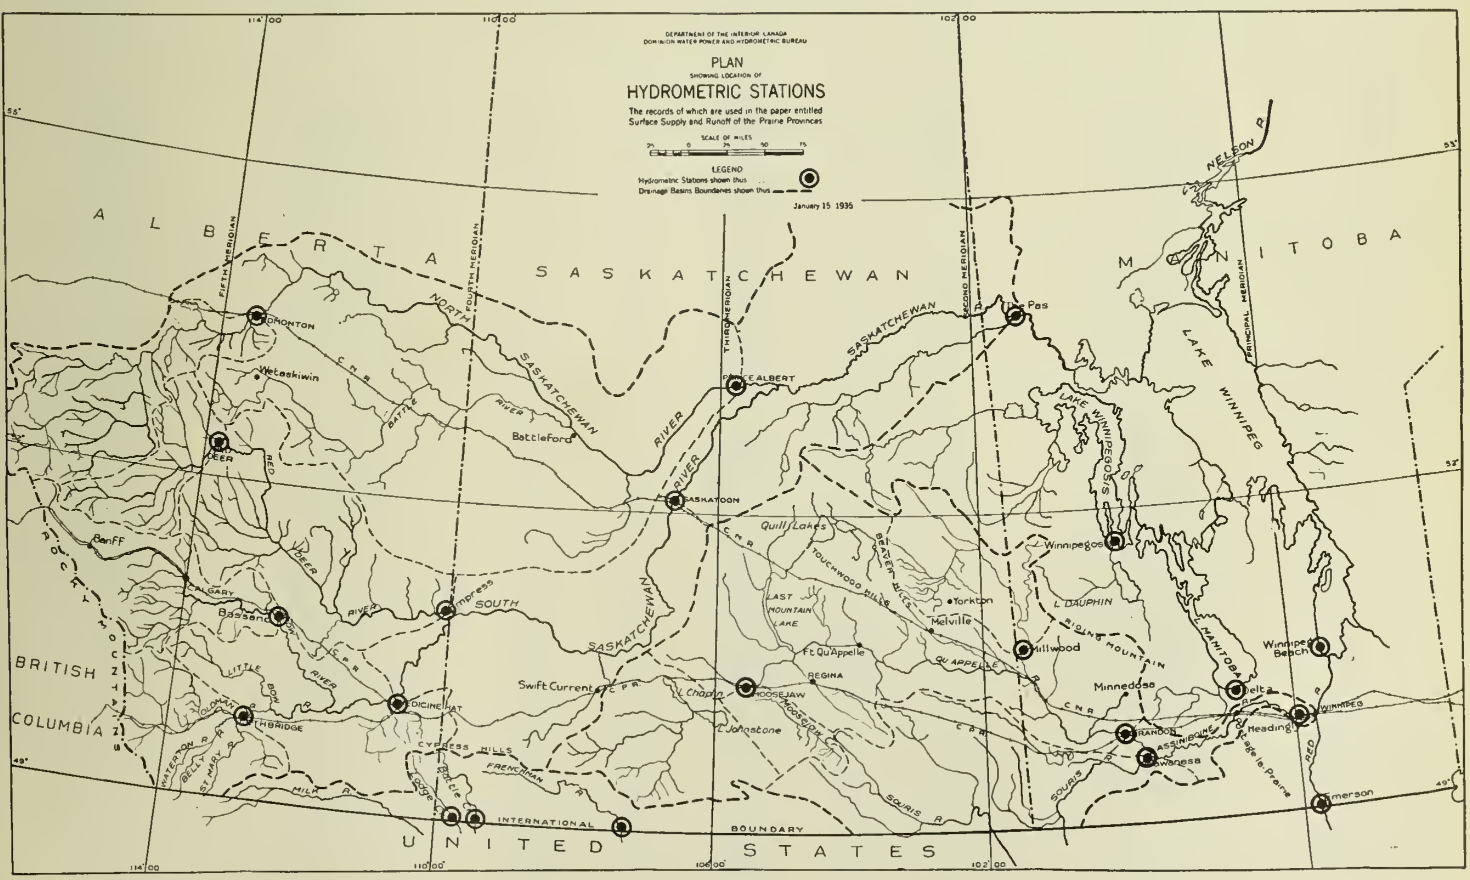

Fig. 1—Location of Hydrometric Stations in Canada.

The towering snow-capped peaks of the Rocky Mountains form the extreme western portion of the area under consideration and supply the source of the Saskatchewan river drainage system. From the mountain area the land drops through a rolling foothill region through the park-like areas of eastern Alberta, merging into the level prairie region of Saskatchewan and then into the lake area of Manitoba.

The runoff from the mountain area, depending upon climatological conditions, is subject to quick and great fluctuations. Floods occur regularly in May and June, after which the flow in the streams gradually decreases until its minimum is reached, in mid winter. The glaciers and perpetual snows provide a dependable runoff throughout the warm weather season. In the lower mountain and foothill area the dense tree growth and thick carpet of vegetation shields the snows of the winters from the spring sun, retarding the runoff and decreasing the liability of the quick and great changes of flow found in the mountain area. From the areas of eastern Alberta the runoff is very small—dependent as it is upon local precipitation.

The runoff from the Saskatchewan plains which include the drought area, is through typical prairie streams. These streams flow in narrow canyon-like channels, in places 300 feet below the original plains. The sparsely wooded hillsides and valleys offer slight resistance to the runoff from the surrounding area. The runoff in these prairie sections, dependent on the local precipitation, is very seasonable. The winter snows rapidly melt in the warm winds and rising temperatures of the spring giving an excessive runoff for a short time. The runoff quickly decreases as summer approaches and is only revived by a heavy local rain.

Data Available for Study

During the past twenty-five years the Dominion through the Department of the Interior has conducted a survey known as the Dominion Hydrometric Survey for the systematic collection and compilation of stream flow of the prairie provinces. This work was initiated as early as 1894 in the provinces of Alberta and Saskatchewan. In the early years it was conducted on a small scale in connection with certain irrigation projects and was confined to summer measurements. In the spring of 1909 the hydrometric survey of the Irrigation Branch was organized on a modern basis and the systematic collection of data pertaining to stream flow of the prairie provinces was begun. In 1912 similar work was initiated by the then Dominion Water Power Branch in the province of Manitoba. In 1920 the responsibility for the Dominion Hydrometric

Survey work was consolidated under the service now known as the Dominion Water Power and Hydrometric Bureau. With the transfer of the natural resources to the prairie provinces the work has been continued by the bureau under co-operative arrangements made with the provinces.

The stream flow records which have been secured constitute a dependable and invaluable record of the surface water supply of the three provinces.

Basis of Study

To analyze the runoff conditions in the drought area it is necessary to determine the flow in the streams derived from other areas.

In this study, the runoff from the mountain and foothill area of Alberta is determined in the North Saskatchewan river from the stream flow records at Edmonton; in the Red Deer river by those at Red Deer; in the Bow river by those at Bassano and in the Oldman river by those at Lethbridge. The runoff from the prairies of eastern Alberta is found in the records of the Red Deer river at Empress and the South Saskatchewan river at Medicine Hat. The runoff from the drainage basin of the Saskatchewan river in western Saskatchewan is found from the records of the South Saskatchewan river at Saskatoon and those of the North Saskatchewan river at Prince Albert, while the records of the Saskatchewan river at The Pas give the runoff from the whole basin.

The records of Moose Jaw Creek at McCarthy's farm near Moose Jaw and those at the International Boundary on Lodge Creek, Battle Creek and Frenchman river give typical runoff from southwestern Saskatchewan.

The runoff from the central and eastern parts of Saskatchewan and southwestern Manitoba is found from the records of the Assiniboine river at Millwood, at Brandon and at Headingly and of the Souris river at Wawanesa. The runoff from southern Manitoba is found in the records of the Red river at Emerson.

Before proceeding with the discussion of the runoff conditions found from these stream flow records, it appears advisable to give a brief description of the individual drainage basins.

Saskatchewan River

The Saskatchewan river may be considered a mountain stream with a more or less dependable source of supply. It consists of two main branches, the North Saskatchewan and the South Saskatchewan, which join just east of Prince Albert to form the main Saskatchewan river which empties into Lake Winnipeg.

North Saskatchewan River

The North Saskatchewan river draws its principal water supply from the eastern slope of the Rocky Mountains between the 52nd and 53rd parallels. The general direction of the stream is easterly. The drainage basin is bounded on the south by those of the Red Deer and South Saskatchewan rivers and on the north by those of the Athabaska and Churchill rivers.

For a study of the runoff conditions in the North Saskatchewan river, the basin should be divided into three principal areas, but because the records at Edmonton and at Prince Albert are the only complete records of flow in the river for the twenty years, it will be discussed under two areas.

The first area is that part of the drainage basin above Edmonton and includes the mountains and foothill area. From this section which contains the glaciers and the perpetual snows of the mountains and the well wooded slopes of the foothills, the runoff per square mile is greater than from any other section of the basin.

The second area extends from Edmonton to Prince Albert. Its contribution of runoff to the main stream is chiefly through the Sturgeon river which drains the wooded country to the north, the Vermilion and Battle rivers which drain the park-like lands of Alberta and the prairie lands of Saskatchewan south of the main stream.

South Saskatchewan River

The South Saskatchewan river also draws its principal supply from the eastern slope of the Rocky Mountains through its main tributaries, the Red Deer, the Bow and the Oldman rivers. The headwaters of this river extend from the 52nd parallel to south of the International Boundary.

The runoff conditions in this basin are somewhat similar to those in the North Saskatchewan basin and may be divided into the three areas, although because of the size of its mountain tributaries, they have to be considered separately. Considering first the mountain and foothill areas; the mountain flow of the Red Deer is determined at the town of Red Deer; the mountain and foothill flow of the Bow river at Bassano; and the mountain flow of the Oldman river and its tributaries at Lethbridge. The runoff from the second area, or that section of the drainage basin in Alberta other than the mountain and foothill section, is determined at Empress and Medicine Hat. The runoff from the third area, that is to say the open prairie of western Saskatchewan, is recorded at Saskatoon.

Main Saskatchewan River

Below the junction of the north and south branches, the main Saskatchewan river passes through central Saskatchewan and is joined near The Pas by the Carrot and Pasquia rivers which drain the open prairies to the south of the river.

Red River

The Red river may be considered as a typical prairie stream, whose flow—because the source of supply is from the winter snows, from springs and from prairie areas where the precipitation is low—is not as dependable as that of the Saskatchewan river.

The Red river, one of the most important flowing in the province of Manitoba, has its source near the central part of the state of Minnesota. It crosses the International Boundary at the town of Emerson and flows in a northerly direction to empty in Lake Winnipeg. The drainage basin of the river is 116,347 square miles, of which 50,500 are in Saskatchewan and 23,300 are in Manitoba. As the Red river is the oldest district in Manitoba and practically all settled, little standing timber is to be found.

Assiniboine River

The main tributary to the Red river in Canada and of more interest in this discussion, is the Assiniboine river which joins the main stream at Winnipeg. Its source is in the province of Saskatchewan from the southeastern slope of Beaver Hills. It flows in a southeasterly direction through Saskatchewan and Manitoba. Of the total drainage area of the Assiniboine river, 37,700 square miles are in Saskatchewan and 13,050 square miles in Manitoba. The area drained varies between open prairie found in its southern reaches to the well wooded areas in Duck and Riding Mountains. This river is important as a source of water supply and as a means of drainage and sewage disposal in the most densely populated part of Manitoba where the natural water supply is limited. The principal tributaries to the Assiniboine river are the Qu'Appelle and Souris rivers.

Moose Jaw Creek and Runoff from Cypress Hills

In addition to the two main drainage systems, two minor representative drainage basins of differing physical characteristics in southwestern Saskatchewan have been investigated. The Moose Jaw creek, a tributary to the headwaters of the Qu'Appelle river, drains the open prairie south of Moose Jaw, and its runoff is entirely dependent on local precipitation. The runoff in Lodge Creek, Battle Creek and Frenchman river, which has been taken as from one drainage basin, has its source in the wooded slopes of the Cypress Hills.

Table IV

Central Saskatchewan

Analysis of Records

As mentioned in the foregoing the period under investigation in this paper is a twenty-year period—from October 1st, 1914, to September 30th, 1934. The material is compiled by water years, i.e. each year extending from and inclusive of the month of October to the month of September in the following year, thus taking cognizance of that portion of each season's winter precipitation which is held in frozen form to augment the runoff of the succeeding season.

In the tabular matter compiled herein records have been taken for the full water year—October to September—on the main streams. On the tributaries the records tabulated include only open water flow during April to the end of October, while on the Souris river they only include May to the end of October.

It is unfortunate that, as a result of the curtailment of field operations owing to the administrative retrenchment made necessary by economic conditions in the past few years, continuous runoff records are not available at a few of the stations involved in the analysis. Where such records were missing it has been necessary to prepare an estimate of the flow based upon such records as were to hand backed by the experienced knowledge of the hydrometric engineers on the ground.

For the purpose of presenting the material in a form that can be readily studied by those concerned in the drought situation, a series of tables has been prepared and is included herewith. The runoff has been compiled in the form of total acre-feet per water year and the depth in inches per square mile to which this runoff would be equivalent if applied to the area drained. This permits of an immediate comparison of the total supply from year to year, and by cycles.

The material has been compiled by five-year means in order that general comparisons or trends, if any, may be noted. The twenty-year mean is also recorded. Following the initial tabulations it became evident that in certain areas the low runoff cycle commenced in 1929; it has continued for the last six years. Taking cognizance of this, the tables have been extended to record the mean for the fourteen years before the period of low runoff and also the mean of the six years of low runoff.

Comment on Tables

Tables I to X, inclusive, deal with the runoff from the various individual areas under review and show the areas in square miles, the annual or seasonal runoff in acre feet and equivalent depth in inches per square mile of the drainage basin and the means for the different periods men-

1929-34 Mean	5,755,000	5,135,000	10,890,000	14,630,000	3,740,000	1.336

tioned. Table XI is a summary of the first ten tables and shows the runoff in inches depth per square mile of the drainage basin in the different areas studied.

Table XII is the tabulation of the mean annual water level in the three lakes, Winnipegosis, Manitoba and Winnipeg.

Saskatchewan River Basin

An analysis of the tables reveals that the runoff from the first or mountain area was fairly consistent during the first fourteen years of the twenty years record, but during the last six years, while nearly normal in the North Saskatchewan basin, dropped to 59 per cent of the twenty-year mean in the Red Deer basin and to 75 per cent in the South Saskatchewan.

Table I, column 2, indicates that the flow of the North Saskatchewan river at Edmonton during the past six years was 81 per cent of the twenty-year mean and 77 per cent of the mean of the preceding fourteen years. Table II, column 2, indicates that the flow of the Red Deer river at Red Deer during the last six years was 59 per cent of the twenty-year mean and only half of the mean for the preceding fourteen years. Table III combines the flow of the flow of the Bow river at Bassano with that in the Oldman river at Lethbridge, and column 4 indicates that this combined flow from the mountain area, during the last six years was 75 per cent of the twenty-year mean and 68 per cent of the mean for the preceding fourteen years.

The second area considered on the North Saskatchewan river lies between Edmonton and Prince Albert, consequently, the increment between these stations indicates the runoff from eastern Alberta and western Saskatchewan. During the last six years, this increment as determined in Table I, column 6, was only 58 per cent of the twenty-year mean and 49 per cent of the mean of the preceding fourteen years.

In the South Saskatchewan river basin, the runoff from the second area considered, which is in central and southern Alberta, is shown from Table II, column 5, and from Table III, column 6.

Table II, column 5, indicates that the mean inflow to Red Deer river between Red Deer and Empress during the last six years was 53 per cent of the twenty-year mean and 44 per cent of the mean of the preceding fourteen years.

Table III, column 6, indicates that the mean inflow to the South Saskatchewan river from the drainage area in the Bow river between Bassano and Medicine Hat and on the Oldman river between Lethbridge and Medicine Hat during the last six years was considerably greater than both the twenty-year mean and the mean for the preceding fourteen years. Column 6 also indicates that the mean runoff from

this area for the period 1915 to 1928 is a negative quantity, showing that the losses during this period exceed the inflow. It may be explained that the large irrigation projects in southern Alberta are located in this particular area and the runoff records are influenced by the use of water on these irrigation projects.

The increment to the South Saskatchewan river between Medicine Hat and Saskatoon is contributed from southwestern Saskatchewan and has been fairly consistent. Table IV, column 6, shows that the mean of this increment during the last six years was 80 per cent of the twenty-year mean and 76 per cent of the mean of the preceding fourteen years.

The inflow to the main stream east of Prince Albert as seen in Table V, column 6, has been fairly consistent as the mean for the last six years was 87 per cent of the twenty-year mean and 82 per cent of the mean of the preceding fourteen years.

Mississippi River Basin

The runoff from the Cypress Hills as determined in Table VI, column 8, during the last six years was 45 per cent of the twenty-year mean and 38 per cent of the mean for the preceding fourteen years. The records show that approximately 70 per cent of the open water flow from this basin occurs before May.

Red-Assiniboine Basin

The mean runoff from Moose Jaw creek near Moose Jaw as shown in Table VII, column 2, during the last six years was 15 per cent of the twenty-year mean and 11 per cent of the mean of the preceding fourteen years, while the flow of 1934 was only 2 per cent of the twenty-year mean. The records show that 73 per cent of the runoff from this basin occurs before May.

From the Assiniboine river basin may be determined the runoff conditions in eastern, central and southeastern Saskatchewan and from southwestern Manitoba.

The runoff during the open water period from southeastern Saskatchewan and southwestern Manitoba is recorded in the Assiniboine river at Millwood. The mean runoff from this area as indicated in Table VIII, column 2, during the last six years was 39 per cent of the twenty-year mean and 30 per cent of the mean of the fourteen preceding years.

The mean runoff from the Qu'Appelle river as determined in Table VIII, column 6, during the last six years was 33 per cent of the twenty-year mean and 26 per cent of the mean of the preceding fourteen years, while the mean runoff from the Souris river at Wawanesa as shown in Table VII, column 4, during the last six years was 22 per cent of the twenty-year mean and 16 per cent of the mean of the preceding fourteen years.

1929-34 Mean	4,570	0.050	26,400	0.021

The runoff of the Red river as recorded at Emerson also shows a falling off during the last six years. Table X, column 2, indicates that the mean of the last six years was 29 per cent of the twenty-year mean and 22 per cent of the mean of the preceding fourteen years.

Manitoba Lakes

The levels of Lake Manitoba, Lake Winnipegosis and Lake Winnipeg as recorded in Table XII, during the last six years all show about one foot lower elevation than the mean level of the twenty-year period and about one foot and a half lower than the mean of the preceding fourteen years.

Summary

The foregoing review of runoff records for the twenty-year period 1914-1934 indicates that the flow of streams having mountain supply as their source, such as the tributaries of the Saskatchewan river, has not suffered during the recent dry years to anything like the extent experienced in the streams fed from prairie drainage in southern Saskatchewan and southwestern Manitoba.

The runoff from mountain sources has been fairly consistent, and, although it has decreased somewhat during the last six years, an average of approximately 80 per cent of normal flow has been maintained in these years. In other words the snow-capped mountain areas have constituted a fairly dependable source of supply throughout the drought period, to the river systems originating therein.

On the other hand, the runoff from prairie sources has decreased excessively during the last six years, the mean of these years being from 20 per cent to 30 per cent of normal quantity. This is particularly the case in southern Saskatchewan and southwestern Manitoba where flows in some of the streams during the open water period of 1934 have been as low as 5 per cent of the twenty-year mean, and all streams have shown an extraordinary diminution in flow.

Some Possible Sources of Ground Water in Southern Saskatchewan

*R. T. D. Wickenden**
Assistant Geologist, Geological Survey of Canada, Ottawa, Ont.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., Feb 7thand 8th, 1935.

SUMMARY—Possible sources of ground water in southern Saskatchewan are from some of the bedrock formations and in places from the glacial drift and recent alluvium. Bedrock formations that are known to yield water are mostly confined to the western and southern parts of the province. The water from some of them is mineralized. The water in the surface deposits or glacial drift occurs in buried stream channels, in sand and gravel beds covered by lake clay or boulder clay, in glacial outwash and gravel and in recent alluvium in the present stream valleys. In places artesian water occurs in sands and gravels overlain by clay.

The study of ground water problems in southern Saskatchewan has been a subject of investigation by the Geological Survey for several years. Thus far a preliminary study has been made; the surface deposits and bedrock formations have been mapped and detailed surveys made of areas around Moose Jaw, Regina and the district covered by the Rush Lake sectional sheet and part of the Elbow sheet. The area around Regina was studied by Professor Howard E. Simpson.[1] W. A. Johnston[2] and the present author reported on the underground water conditions in the vicinity of Moose Jaw. Two reports by D. C. Maddox[3] described ground water conditions in the Rush Lake sheet and the eastern part of the Elbow sheet.

Most of the information used in this paper has been obtained by the author while mapping the surface deposits between longitude 102 degrees to 109 degrees and latitude 49 degrees to 52 degrees. These are practically the limits of the area referred to as southern Saskatchewan in this paper. W. A. Johnston[4] in his report on the Winnipeg map area has reported on the district between the Saskatchewan-Manitoba boundary and the second meridian.

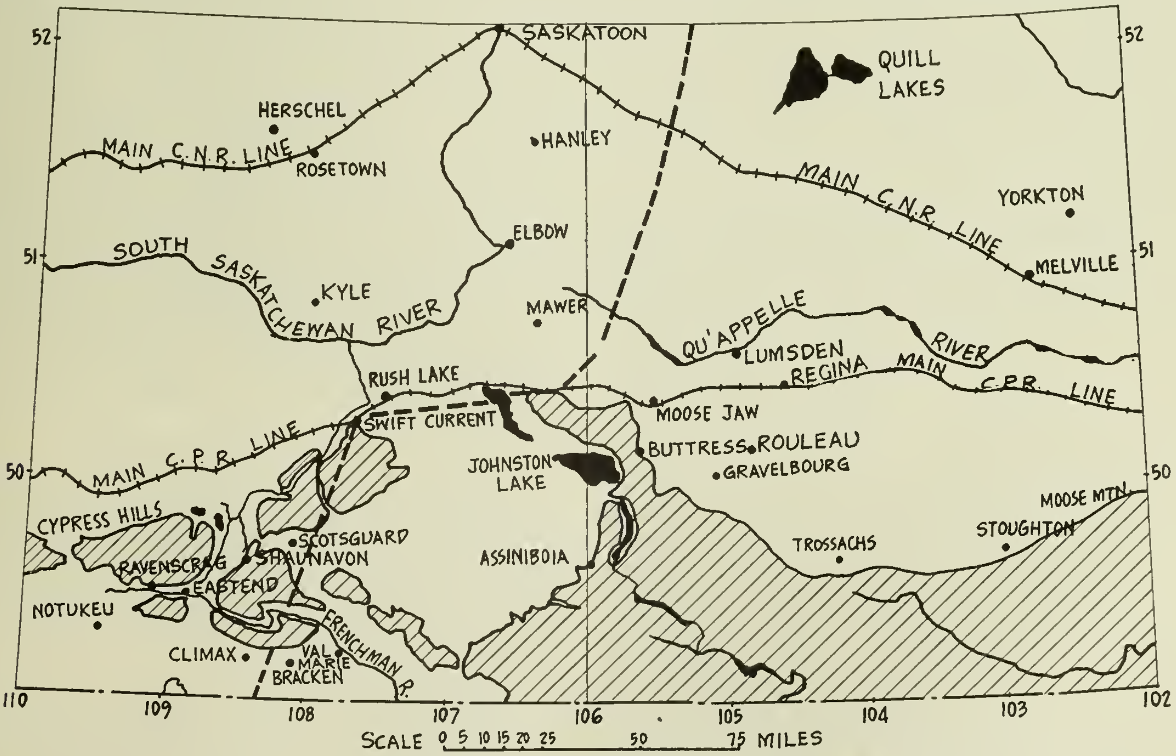

Fig. 1—Sketch Map of Southern Saskatchewan: shaded area underlain by Ravenscrag and Tertiary Formations; broken line indicates approximate eastern limit of area in which water bearing sands occur in the Belly River and Bearpaw Formations.

The present paper gives only a general account of the modes of occurrence of ground water in parts of the region. Much more work needs to be done before it will be possible to state in what areas water may be obtained by drilling and in what areas it is not possible. It is known that in some areas little or no water is obtainable by drilling.

Bedrock Waters

Ground waters in southern Saskatchewan may be considered as belonging geologically to two general classes: those that occur in the bedrock and those that occur in the glacial drift and recent alluvium. The term bedrock as used in this paper refers to the formations of fairly uniform character and wide distribution that underlie the glacial drift. These formations are not made of hard rock such as one finds in many areas, but rather of soft clay shales or partially cemented or loose sands.

Bedrock waters occur in the formations of late Mesozoic or early Tertiary age such as the Cypress Hills, Ravenscrag, Whitemud, Eastend and in slightly older rocks of Belly river and Bearpaw age. The distribution of the Ravenscrag and Tertiary formations is shown on Fig. 1. The Whitemud and Eastend formations are practically confined to the same areas. So far as known at present potable water in the bedrock occurs chiefly in the western and southern parts of the province in the Belly river and younger formations.

In the central and eastern parts of the province the bedrock waters in wells that have been drilled are scanty owing to the fact that the bedrock consists almost entirely of shale to a considerable depth, or the waters have such a high mineral content that they are not used for drinking except locally by mixing them with good water.

The oldest formations that are known to carry potable water are the Belly river and the Bearpaw. In Fig. 1 the approximate eastern limit of the area in which water may be found in the Belly river and Bearpaw formations is indicated by a broken line. In the vicinity of the Canadian Pacific Railway line between Notukeu and Valmarie, at Climax and at Bracken, water can be obtained from a sand that probably is at the top of the Belly river series. At Climax this water is used but at Bracken the mineral content, consisting chiefly of sodium sulphate and sodium carbonate, is so high that the water is not considered to be usable by the town. The source for the water at this horizon probably is a long distance to the west. This seems to be indicated by the high mineral content of the water. It is probable that water can be obtained at this horizon in the area to the west of Climax but the depth of drilling in many places may involve too great an expense for individuals.

In the vicinity of Rosetown and Herschel there are a number of deep wells that yield water from the Belly river formation. At Rosetown the water is reached at a depth of 600 to 800 feet, and occurs in very fine sand. In some places shale occurs with the sand and the amount of water obtainable is very small. Screens are easily clogged because of the presence of very fine sand. The water in one of the wells rose to 9 feet from the surface and in another to 120 feet from the surface. It probably enters the sand in higher areas to the west where formations of Belly river age are exposed at the surface.

At Herschel a well drilled for oil and gas passed through an artesian water horizon at 190 feet. Beds of the Belly river series are exposed at the surface near Herschel and it is probable that the water horizon is in this series. Probably water can be obtained from the bedrock throughout the Herschel and Rosetown districts. The water, however, contains sodium carbonate and this renders it practically useless for irrigation. In the district around Mawer and north to Hanley and west to Kyle water has been found in horizons that are either in the Belly river formation or in the lower part of the Bearpaw. A detailed description of these occurrences has been given by Johnston[5] and by Maddox in reports already referred to.

Little is known as to the possibilities of obtaining water in formations of Bearpaw or Belly river age to the east of the areas mentioned. Apparently to the east the sands of these formations are replaced by shale to a great extent so that they may not be water-bearing or the water may have too great a mineral content to be potable.

A number of sand horizons occur in the formations above the Bearpaw. The Eastend formation is a fine sand which may carry water in some places, but the sand is so fine that the flow of water from it probably would be very slow. There may be some wells that get water from this horizon but they are not known to the author. In many places where the formation is present and might serve as a water-bearing horizon, younger beds that are much more porous are present and there is no need of drilling through these beds into the Eastend formation.

Sands in the Whitemud formation may carry some water in localities where they have not been changed to kaolinized sandstones. It is difficult to tell whether this formation or a similar looking sand in the Ravenscrag is the water-bearing horizon in some areas in the southwestern part of the province.

The Ravenscrag formation furnishes water of good quality in many places in the southwestern part of the province. The water is generally soft due to the presence of sodium carbonate so that it is useless for irrigation. Generally the water is found at the top of coal seams and in some places small streams issue from sands overlying coal seams. There are slight structures in the Ravenscrag and where the top of an anticline occurs there is likely to be no water. This is very good for coal mining but unfortunate for a rancher or farmer who happens to be situated on one of these structures.

Drilling in the Ravenscrag generally presents no difficulties and in most places water, if present, can be reached within 200 to 400 feet from the surface.

Stansfield[6] outlined an area in which water might be found in the bedrock as lying south and west of a line from Stoughton to Trossachs and from Trossachs to Buttress. Much of the country west of the boundary, as shown in Fig. 1, is not underlain by Ravenscrag (called Fort Union by Stansfield). The western boundary is about on a line from Assiniboia to the eastern end of Lake Johnston and extends west along the northern part of the Wood Mountain highland to north of Valmarie. In much of the country in the vicinity of Gravelbourg and along the Canadian Pacific Railway line between Assiniboia and Scotsguard there is no worthwhile water-bearing horizon in the bedrock so far as known. In the vicinity of Shaunavon and south as far as the Frenchman river and south of the Frenchman river for about twelve miles the country is underlain by Ravenscrag beds which carry water. West from Eastend and in the area covered by the Cypress Hills the Ravenscrag also contains water-bearing horizons. The Tertiary formations of the Cypress Hills also have good water-bearing beds.

Glacial Drift Waters

The finding of adequate supplies of water in the glacial drift presents a more difficult problem on account of the haphazard disposition of this material and the irregular mode of occurrence of porous horizons in it. A brief review of the mode of formation of this material is necessary in attempting to explain the various ways in which water occurs in the glacial drift.

6 Stansfield, J., Geol. Surv. Canada, Summ. Rept. 1917, pt. B., pp. 41-52 (1918).

Previous to the advance of the Pleistocene ice sheets over Saskatchewan the country on the whole probably had little relief except for flat top highlands in the areas now occupied by the Missouri Coteau, Moose Mountain, Cypress Hills and other highlands. There were undoubtedly many stream valleys and some badlands along the sides of these highlands. Very likely these stream beds were filled in part with gravel and sand. When the ice sheet advanced these gravels and sands were either eroded or were buried beneath glacial drift and new gravels were laid down by glacial streams in valleys that existed at that time. During at least two interglacial stages probably new valleys were made and more stream gravel and sand deposited. Thus in a number of localities there are buried stream beds of a dendritic or tree-like pattern heading in the highland areas. Such buried stream beds heading in the more or less porous morainic areas of the highlands concentrate the ground water of a wide area into a rather confined space and give rise to artesian water supplies in the drift. A number of such occurrences of water are found along the south side of the Missouri Coteau and in other areas. The one that is best known is the Boggy Creek area that furnishes a part of the water supply for Regina. An area in the vicinity of Rouleau is somewhat similar to the Regina area. The gravel and sand from which the water comes is buried beneath impervious clay and is practically on top of the bedrock. Some reaction of the salts in the water with the minerals in the shale or drift has caused this water to be fairly soft which is very unusual for water occurring in glacial drift in the province. In the vicinity of Rouleau the water seems to be confined in a bed of gravel and sand not over a mile wide extending in a northeast and southwest direction with the centre a little east of the town. Places to the east and to the west of this old stream bed can only get a very limited supply of poor quality water in the boulder clay. Whether this water comes from the north or from the north slope of the Missouri Coteau to the south is uncertain. The facts that north of Rouleau more water-bearing gravels occur and that the mineral content of the water decreases to the north from 2,000 parts per million to 1,700 parts per million seems to indicate a source to the north. No accurate series of elevations of the wells have been made so that the slope of the water-bearing horizon is not known.

Locating of buried stream-bed types of artesian water is difficult because of the irregular pattern which the beds may have. In some areas the channels are very close to the sites of the present valleys leading from the higher morainic belts. The Mound Spring and Boggy Creek areas that furnish water for Regina are examples of this type. In places cold springs may indicate that the water is coming from an artesian basin of this character. Such artesian sources might be located by electrical methods after a geological study of the locality had been made, but the cost of such a survey by a reliable method is high.

Another type of ground water supply associated with the glacial deposits is that found in places where outwash sand and gravel occur at the surface. The sand and gravel allow the water to penetrate deep enough to prevent large losses by evaporation, so that a large part of the rainfall of an area underlain by these deposits may be stored underground. Usually, however, the areas are not very large and the supply of water found in outwash sands and gravel is not great, but the quality as a rule is very good. The town of Melville gets most of its supply from a broad belt of outwash sand and gravel north and northwest of the town. The water table is only ten or fifteen feet from the surface and the water is obtained by means of a collecting gallery. Part of the supply used by Moose Jaw comes from the Sandy Creek area and is of a similar nature except that the sand and clay probably were deposited in a glacial lake.

Another type of supply is found where glacial outwash sand and gravel underlie clay. The Yorkton supply appears to be of this type. The water is not under pressure and apparently the sand and gravel act simply as an underground reservoir; as the supply is used the water level drops and unless the source is replenished at the same rate at which it is used, in time such a supply may become practically exhausted.

In the material that forms the valley bottoms of the present stream valleys there are in places porous horizons of sand and gravels which may yield a fair supply of water. These water-bearing beds may be largely post-glacial in age but there are some also that are Pleistocene or Glacial in age. In many places considerable sediment has been deposited even since the coming of white men to the country, as is shown by the remains of horses and cattle buried under twenty to thirty feet of alluvium in some small stream valleys. The Qu'Appelle valley is an example of a valley with a thick bed of alluvium and drift. Near Lumsden in this valley a well passed through two hundred feet of sediments above the bedrock.

Summary and Conclusions

In drilling for water in southern Saskatchewan a knowledge of the geology is useful. Areas where water may be obtained from the bedrock are mostly in the western and southern parts of the province. Bedrock formations from which potable water may be obtained are the Belly River, Bearpaw, Whitemud, Ravenscrag and Tertiary (Cypress Hills beds, etc.). The water in the Belly River and Bearpaw formations is generally much mineralized and the farther east it is found the greater is the mineral content. Artesian water also occurs at places in the glacial drift. More work is necessary to determine the extent of the artesian areas and the amount of water available. As a result of such work proper methods of conservation could be developed.

Mineral Character of the Underground Waters in Southern Saskatchewan

*D. C. Maddox**

Associate Geologist, Division of Water Supply and Borings, Geological Survey of Canada, Ottawa, Ontario.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

SUMMARY—The artesian waters of southern Saskatchewan, except those that come from a considerable depth, are generally usable for drinking purposes, although they contain a fairly high proportion of soluble salts. The deep well waters that come from below the Belly river beds, so far as known, are saline. The artesian waters, as a rule, contain so much of the salts of sodium, especially the carbonate, that they are not well adapted for irrigation purposes under the conditions of precipitation, evaporation, topography and soil found in southern Saskatchewan. The waters from the shallow wells in the sandy beds of the surface deposits or glacial drift overlying the bedrock, as a rule, contain smaller amounts of soluble salts and are the most satisfactory for drinking purposes. Improvement of the artesian waters by mixture with other types of water, with possibly chemical treatment, is a problem that requires investigation.

Relation Between Chemical Composition and the Principal Uses of the Underground Waters

For human consumption water must not have so high a content of dissolved salts as to render it unpalatable or injurious to health. The temperature of a water high in sodium salts has a marked influence on the taste of the water. In some of the artesian areas of southern Saskatchewan water containing up to 1,500 or even 2,000 parts per million of sodium salts is quite palatable if drunk at the temperature at which it issues from the well—45 degrees to 48 degrees F. Such water, however, if allowed to warm up in a city supply system would have a decidedly flat "soda" taste. If the water contains a large proportion of the sulphates of sodium and magnesium it may be too laxative for constant use although within reasonable limits the continued use of the more laxative waters appears to build up a certain degree of resistance.

Many waters, especially the highly saline water often found in shallow wells in the "drift" (this term being used in this paper to include all types of glacial and post-glacial deposits) that are not considered fit for human consumption, are used for stock. It is generally considered that waters containing fairly large amounts of dissolved salts may be used for stock. Should the water be so bitter, however, due to the presence of magnesium sulphate, or should it cause scouring, due to the sulphates of sodium and magnesium, it becomes unusable for stock. The presence of common salt in most of the artesian waters obviates the use of salt licks for cattle and the mildly laxative action of the sodium and magnesium sulphates is of value during the winter months when dry foods such as hay are used. High sulphate content of water has been considered to be the cause of degeneration of the bones of cattle by abstraction of lime, but this is doubtful and further research on the question is needed.

For irrigation purposes in an area of such small rainfall as southern Saskatchewan water should not contain a high proportion of dissolved salts. The safe upper limit varies with the nature of the salts, the soil, drainage conditions and the crop. It is generally considered to be about 700 parts per million but in exceptional cases it is 1,000 parts per million. In Australia 700 parts per million of alkaline salts are considered to be the upper limit. Most of the artesian waters of southern Saskatchewan far exceed these limits. In the Sahara, however, water containing up to 8,000 parts per million of solids, about half of which is sodium chloride, has been used for irrigation under special conditions. The toxicity of the sodium salts to plants varies in the approximate proportion of 10:5:1 for the carbonate, chloride and sulphate respectively; of these the carbonate forms the dreaded black alkali, the chlorides and sulphates white alkali. In the Central Butte district in south central Saskatchewan, the singular spectacle was seen of a farmer, in a very dry year, suing the owner of a flowing well because water from that well was flowing through his farm.

For laundry purposes the water from the drift is almost invariably too hard. Many of the artesian wells yield waters that are soft but contain a good deal of sodium carbonate. For use in boilers the generally high content of calcium sulphate in the drift waters renders them likely to cause hard scale. The soft artesian water is likely to cause foaming. A well at Mawer Station in the Darmody-Mawer artesian basin has a large flow but the water is not used for boiler purposes. It is reported, however, that the water causes foaming only when mixed with hard, drift water. The corrosive action of water is important in the case of waters used for municipal purposes. It would seem probable that the artesian waters would be corrosive.

Special Conditions Affecting the Chemical Composition of the Underground Waters

The small rainfall, the absence in much of the area of through drainage to the sea, the generally flat topography and the presence of many undrained hollows due to uneven deposition of the glacial drift, all tend to prevent the removal from the soil and subsoil of mineral salts and favour the rise of salts to the surface by capillarity and deposition of salts from spring waters. The extreme limit of concentration of salts is the alkali-lake deposit but many of the waters from wells in the drift contain a high proportion of salts. It is evident therefore that the drift contains a great deal of salts and the presence of numerous crystals of selenite-calcium sulphate at many outcrops of the Cretaceous shales shows that these rocks also contain salts.

The chief dissolved salts that have marked influence on the uses of the underground waters are the sulphates, chlorides, and carbonates of sodium, calcium and magnesium.

Sodium sulphate or Glauber's salts is a mild laxative, the dose for this purpose being one half to one ounce of the hydrated salt. It is the least harmful of the common salts when present in waters used for irrigation.

Sodium chloride or common salt in moderate amounts has little action on the body functions. In quantities of over 500 parts per million it gives a brackish taste to water and at high concentrations it produces a water that will not quench thirst. In water used for irrigation it is intermediate in toxicity between the sulphates and carbonates.

Sodium carbonate, which in the artesian waters seems to occur always as the bicarbonate, has no harmful effect on humans if used in moderate amounts. If present in the water used for irrigation, however, it is the most harmful of the sodium salts, the safe limit for this purpose being about 100 to 200 parts per million of the normal carbonate. Calcium and magnesium carbonates and bicarbonates give temporary hardness to water. They were for a long time considered to cause gall stones and other troubles but are now thought to be quite harmless in this respect. They are more abundant in waters from the drift than in those

*Published with the permission of the Director, Bureau of Economic Geology, Department of Mines, Ottawa.

from the older rocks. In water used for irrigation they are much less harmful than the sodium salts.

Calcium sulphate in moderate amount in drinking water is not so harmful as the sodium salts. Waters with very high calcium sulphate content occur in regions in which gypsum is found and are used for human consumption. Unless present in very large amounts it is not harmful for irrigation purposes; gypsum is often added to the soil to counteract the effect of sodium carbonate by converting it to the less harmful sodium sulphate.

Magnesium sulphate is a slightly stronger laxative than sodium sulphate, the dose for human use for this purpose being ¼ to ½ ounce of the hydrous salt. It is much more harmful to the system than sodium sulphate, however. In the artesian waters that come from the bedrock it is generally quite subordinate to the sodium salts but in the waters from the drift it is much more prominent although usually being less in amount than the calcium sulphate. In water for irrigation it appears to be less harmful than sodium carbonate.

As regards taste imparted to water by the dissolved salts, calcium sulphate and calcium and magnesium carbonates are practically tasteless. Sodium sulphate in small amounts is nearly tasteless, sodium bicarbonate gives a "soda" taste to the water and magnesium sulphate in large amounts gives a bitter taste.

Chemical Classification of the Main Types of the Underground Waters

The waters from wells in the drift show great variation in the amount and composition of salts even within short distances. They may perhaps be roughly classified into those that are derived from the more argillaceous type of deposits—boulder clay, lake clays, etc.—and those derived from the more sandy types of deposits, outwash sands, dune sands, etc. In the former type the salts are seldom less than 1,000 parts per million and are often several times this figure. The composition of the salts varies widely, but in general calcium and magnesium sulphates are the chief salts, with sodium chloride subordinate and sodium sulphate and carbonate variable. Calcium and magnesium carbonate are generally present but are usually subordinate to the corresponding sulphates. These waters are very hard and many of them are not well adapted to irrigation even were they found in sufficient quantities for this purpose. The water from the sandy type of drift in places is very hard and is high in salts, but in very sandy areas it is likely to be less hard than the previous type, some waters from very sandy areas being even reported as soft. Some of the waters from shallow wells or collecting galleries in the sandy areas contain only 600 to 700 parts per million of soluble salts and are the best underground waters so far found.

The waters from wells in the Tertiary and Cretaceous rocks, with a few exceptions, show less wide variation in salt content than do the drift waters and are generally not so hard. Two general types are very common, at least in the Rush Lake and Elbow quadrangles and in parts of the Regina and Touchwood quadrangles. The sodium sulphate-carbonate-chloride type may be regarded as the "soft normal" type and water containing these salts with calcium and magnesium sulphate in addition may be referred to as the "hard normal" type. The sodium chloride type is comparatively rare but the waters frequently contain large amounts of this salt, 10,680 parts per million being reported in one well, and are commonly found at considerable depths in the bedrock, for example in the deep wells at Moose Jaw and Simpson. Many intermediate types between the above mentioned ones are found. Many of the waters are absolutely soft. The salt content varies but most of the analyses available show 1,250 to 2,500 parts per million.

Waters of Artesian Areas

The Carnduff area in the southeastern corner of the province, described in Memoir 174, Bureau of Economic Geology, pages 13-14, covers about 400 square miles over most of which area flowing wells are found. Analysis of water from Cornduff creamery, close to the limit of water flow, shows a very unusual combination of sodium and magnesium carbonates with sodium chloride, total solids being 1,044 parts per million.

The Darmody-Riverhurst area described in Summary Report, Geological Survey, Canada, 1931, Part B, pages 58-71, covers at least 500 square miles. It is one of the most clearly defined artesian basins in Saskatchewan that have been studied to date. The underground surface of the water is generally at a very uniform level and analyses show that the water is very uniform in salt content—1,250 to 1,650 parts per million. With the exception of a few wells, considered as marginal, the water is all of the "soft normal" type. Flowing wells are obtained in the eastern part of the artesian basin.

Twelve detailed analyses show that the average quantity of salts in solution in the water is 1,615 parts per million, almost entirely consisting of sodium chloride, sodium carbonate (probably existing as the bicarbonate) and sodium sulphate in the approximate proportion of 1:3:4 respectively.

The sources or intake beds of the water are not definitely known, but it is possible that the water enters the basin in sandy beds in the valley of Swift Current creek, 60 miles to the southwest.

In the east half of the Elbow quadrangle, described in Summary Report, Geological Survey of Canada, 1932, part B, pages 75-89, the ground water is much less uniform in amount and composition of salts, than in the Darmody-Riverhurst area. In the southern and central parts of the quadrangle, including the Brightwater Creek area of artesian water flow, most of the water is of the "soft normal" type but the total solids are generally about 50 per cent higher than in the Darmody-Riverhurst area. In the northern part of the quadrangle a flowing artesian area occurs in which the water is of the "hard normal" type.

An artesian area in the western half of the Rush Lake quadrangle described in Summary Report, Geological Survey of Canada, 1932, part B, pages 76-79, has water of the "soft normal" and "hard normal" types. South of Beechy, two small flowing artesian areas occur; in one the water is the "soft normal" type and in the other the water is very hard.

Several artesian areas, found in the vicinity of Regina, are described in Geological Survey of Canada Summary Report 1929, part B. The most important of these areas are the valley of Boggy creek, Mallory Springs valley and Flying Creek basin. The water occurs in sandy beds in the drift and is hard. An analysis of the Boggy creek water, the chief source of supply, shows total solids 995 parts per million, the sodium salts being 115 parts per million and sodium carbonate 101 parts per million. Analyses of well water from the Mound Spring area and from the Mound, Cooper and Dickson springs show a wide variation but they all show the water to be hard. The sodium salts vary from 201 to 449 parts per million, sodium carbonate being reported only in the Mound Spring.

The underground water conditions near the city of Moose Jaw are described in Geological Survey of Canada Summary Report 1930, part B, pages 50-64. The sources of supply are Snowdy Springs, Sandy Creek gallery, the Forsythe well and the Sandy Creek well. The first three contain 486 to 686 parts per million of total solids in solution, with sodium from nil to 98 parts per million, and are hard. The last named is much higher in total solids—1,218 parts per million. The Sandy Creek well water is only moderately hard—186 parts per million. The difference between the shallow water in sandy beds, near the surface and that obtained at even so small a depth as 80 feet is well shown by a comparison of analyses of the water from Sandy Creek gallery and from No. 1 well at Sandy Creek. Total solids in the former are 486 parts per million and in the latter 1,218 parts per million. Analyses show the water from Sandy Creek gallery to be the best so far found in the Regina and Moose Jaw districts, both for drinking and irrigation purposes.

Mode of Origin of the Soft Artesian Waters

The softness of the water in the Darmody-Mawer artesian basin may be due to base exchange of calcium to sodium by minerals of the glauconite type in the water sand. Glauconite[1] is known to occur in Cretaceous sandstones at places in the prairie provinces. A solution of calcium sulphate left for twenty months in contact with Cretaceous sand that occurs in the valley of Swift Current creek and may form part of the intake beds for the artesian water, showed a marked softening. Bentonite as well as glauconite is known to be capable of softening water by the base exchange process. Bentonite[2] bands are of frequent occurrence in the Cretaceous shales and it is probable that a good deal of bentonite is distributed through the Cretaceous strata and through the glacial drift which is largely derived from these beds. Water softening therefore may have occurred also as a result of the base exchange properties of bentonite.

Possibilities of Improving the Character of the Well Waters

Fairly large quantities of artesian water, sufficient for the irrigation of farm gardens, are available in the Darmody-Mawer basin and in other areas but these waters are so high in sodium that they cannot be used for this purpose. They are also unsatisfactory for drinking. Whether these soft, sodium waters can be altered by some simple and inexpensive method so as to render them suitable for irrigation and other purposes; and whether their mineral character would be improved by mixing them with hard waters are problems that require investigation.

1 Glauconite—a naturally occurring mineral from which zeolites are prepared as used for water softening.

2 Bentonite—a type of china clay used for filters and as filtration agents.

Rural Water Supply in Alberta

William Calder,

Director, Petroleum and Natural Gas Division, Department of Lands and Mines, Alberta, Edmonton, Alta.

Paper presented before the Edmonton Branch of The Engineering Institute of Canada, March 14th, 1934.

To the average city or town dweller, water requirements rarely present any worries, as his needs are efficiently catered for even to the extent of the water being chlorinated to remove dangerous contamination. Should, however, the supply at the tap fail, he has only to communicate with the district water department and it is not long before the service is again available—that is always provided the service has not been deliberately cut off on account of the non-payment of a water bill.

The rural dweller, however, has seldom a benevolent water board to serve his needs, which must be supplied by his own efforts. Failing a convenient surface source, his supplies are obtained from underground deposits by wells from which the water has to be lifted by either mechanical means or manual labour. A rural supply of water is not usually available under any co-operative scheme, as distances between source and consumption points are so great that this would necessitate prohibitive capital expenditure. It is however a barren, waterless country where the requirements of a household cannot be obtained at a comparatively shallow depth by means of dug wells.

The sinking of these wells is done by manual labour, in the majority of cases by persons with little or no experience in this class of work. As a result the protection of well walls is often inadequate and the material used is poor, resulting not only in the need for frequent repairs and the cleaning out of silt, but also in pollution of the underground supply by the seepage downward of surface water carrying detrimental and even insanitary material. These wells are seldom located where water contamination would be minimized, the selection usually being one of convenience irrespective of the risk of contamination from house garbage dumps, cattle sheds or domestic conveniences, from all of which there occurs continuous soakage. Such contamination can be considerably minimized if the well neck is made of brick, concrete, or stone masonry carried well above the surrounding surface and extending downwards below any sub-surface beds through which polluted surface soakage can easily flow.

To be of long usefulness, dug wells should have a masonry lining for the full depth, but this is expensive as such work has to be done by well sinkers. Here in Alberta such experienced labour is not available except at extraordinary wages to which must be added the excessive cost of the material for the lining. Therefore, it is correct to assume that these costs are beyond the means of the majority of rural dwellers here, resulting in their supplies of water having to be obtained in most cases from wells, the sides of which are inadequately protected by softwood linings which not only soon deteriorate but never effectually shut off polluted water inflow.

An advance on hand-dug methods is the drilled well, sometimes sunk by manual or horse power but more frequently by mechanical means. These wells being of small diameter, are cased with metal pipes extending from the surface downwards for approximately the full depth to the water horizon and, if properly completed, would prove a permanent asset. Unfortunately, it is seldom that such wells would be passed by an engineer, since for reasons of economy, the pipe is usually cut off flush at the surface and, further, none of the pipes used are ever cemented for soakage exclusion purposes, nature apparently being expected to carry out this—one of the most important details in the construction of a drilled well.

It is well known that in many parts of Alberta the immediate sub-surface water carries considerable quantities of alkali, rendering the water unpalatable for drinking, and in most cases, unsuitable for cooking. Usually below such unpleasant sub-surface water horizons, comparatively good water can be met at lower depths, with the result that well sinkers and drillers frequently dig to these deeper sources of supply and in doing so, on account of their inexperience, they permit the non-potable sub-surface water to pass downward and mingle with the lower water, thereby altering the latter to the same unsatisfactory condition in a very short time.

Confirming such unintentional pollution and underground wastage of surface water, there are many places in Alberta and other parts of the prairie provinces, where sloughs or small lakes have completely dried up within recent years. Frequently, close to such dried out areas, there are to be found dug wells of varying depth and these may have served as the channels whereby the surface water escaped underground.

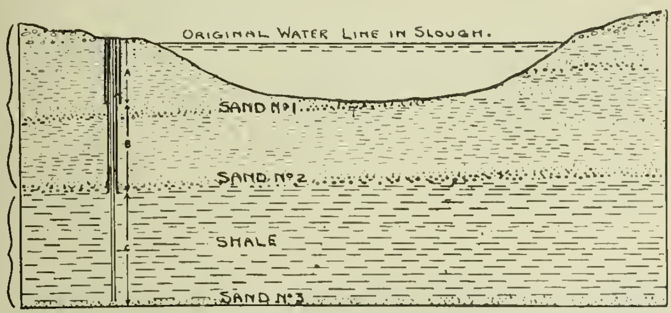

Fig. 1

An example of the presumed downward water seepage is shown in Fig. 1. The initial hand-dug well is represented at *A*, the wall sides being usually protected by a wood lining. On the water from the No. 1 horizon becoming unsatisfactory for use further deepening is carried out as at *B;* this being done either by hand work or by bucket auger operated by horse power, the well sides again being protected by wood in the form of circular cribbing usually built up and lowered from the surface.

On the quality of the second water stratum changing, the well is in the majority of cases abandoned without being filled in. This not only permits the continuous downward passage of water from the slough and any water horizons that may have been passed through, but also presents a continuing danger to persons and livestock. In a few cases deepening may be continued either by bucket auger or drilling machine and metal well casing inserted so as to permit the elevation of the water by manual, wind power or mechanically operated pump.

The further deepening and the use of metal casing is a correct procedure and would be permanently satisfactory if the casing is properly cemented and the depths *A* and *B* filled in with rubble and mud slurry. Unfortunately few, if any, water well drilling contractors have experience in well cementing and lack the necessary pumping and other equipment essential for such work. They are, therefore, obliged to rely on undesirable water being excluded by debris from the clay or shale formation settling around the inserted pipe. Owing to bored and drilled wells not always being truly vertical and frequently more elliptical than circular; both of which defects may happen on account of the varying hardness of the formation drilled, the settlement of debris and formation on the casing cannot be uniform and voids must remain, down which there always occurs a flow of water thereby causing ever-increasing channelling.

Thus many of these faulty wells are serving as channels by which horizons of good potable water are rendered unusable. That the use of well-drilling machines for water supply will be considerably extended in the near future needs no emphasizing, and there is an immediate and imperative need of efficient control to ensure that contamination is not allowed to continue, otherwise all good water horizons underlying Alberta may, in a few years, be rendered unsatisfactory for use.

In Alberta it would be interesting to see the results of prolonged controlled tests of underground water levels made at different points in the province. In all probability it would be found that the sub-surface water table is dropping rapidly—in fact it is very possible that in some areas the top water horizons may be found to have disappeared completely and required supplies of water have to be searched for at greater depth.

From the findings obtained in the drilling of deep wells in the south and midnorth of the province, there is ample proof that several prolific horizons of good water are to be found down to 1,000 feet from the surface and it is, therefore, safe to forecast that there is no immediate fear of a water famine in the areas above cited, provided means are available for reaching the water and lifting it to the surface. Below 1,000 feet the chances of good potable water being found are speculative, as most deep horizons carry a considerable mineral content which precludes the use of the water for human or animal consumption.

At present all over the North American continent great stress is being laid on the conservation of natural resources, and, water being an absolute necessity for sustaining life, must be classed as the most valuable of these. How seldom do we hear any call for its conservation and protection. As already noted, any tyro is allowed to sink wells and thereby not only permitted to pollute underground water sources but also drain surface deposits, thus apparently interfering with the work of nature in augmenting supplies by rainfall. The author believes that government interference in private effort should be the least possible, provided individuals are efficient in their enterprises, but where waste is rampant it appears imperative that governments should control the selfish and incompetent. It is, therefore, considered that the search for and development of potable water should be under some form of supervision which will control all sources of contamination, and in a measure discipline those carrying out the engineering work to insure its being carried out efficiently.

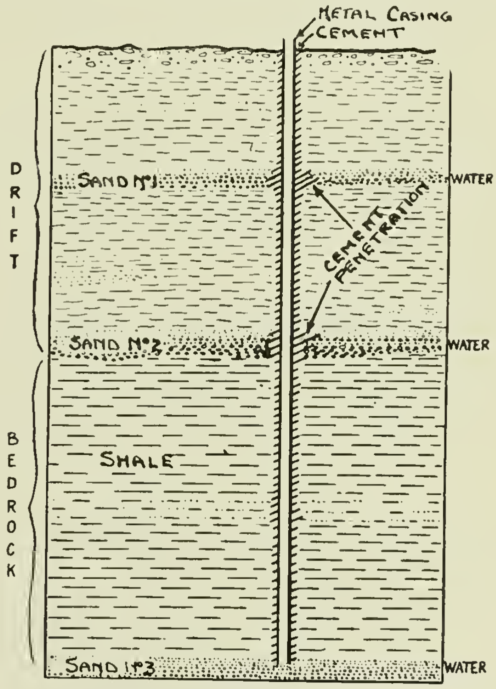

Fig. 2—Section of Drilled Well Showing Cement Protection.

This last requirement would require the registration of all contractors and others engaged in the digging or drilling of water wells, and that no well should be commenced without the specification of the projected work being first scrutinized and authorized by a recognized body. With such control the construction of all wells would be regulated—the necks of dug wells would be protected by proper linings carried above the surface and below the sub-surface porous strata to prevent pollution. In deeper wells where pipe is used all unsatisfactory water would be shut off by cementation or such method as would insure a lining behind such pipe which would prevent undesirable infiltration even should the metal of the pipe entirely disappear through corrosion.

The suggestion will perhaps appear premature and too advanced for these times but inasmuch as water in many places at this moment is at a premium on account of its scarcity, all rights to underground water should be reserved to the Crown. In the author's opinion no natural resources below the surface should ever be placed under the control of individuals who may permit their dissipation to the detriment of the public interests.

The author wishes to state that he is not a specialist in ground water problems and in presenting this paper has done so solely to make known personal observations of what is apparently one of the serious dangers likely to interfere with the prosperity of the prairie provinces; also to create in young engineers an interest in drilled well contracting, a class of work which has been somewhat neglected in the past by the trained engineer.

Relationship of Geology to Soil Drifting in Southern Manitoba and Southern Saskatchewan

W. A. Johnston, Geologist in Charge, Division of Water Supply and Borings,
and
R. T. D. Wickenden, Assistant Geologist,
*Geological Survey of Canada, Ottawa, Ont.**

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

SUMMARY—Dry farming methods and single crop farming, together with the prevalence of high winds in times of drought, and general absence of wind breaks, are the chief causes of soil drifting. In the present paper the character, extent and mode of origin of the materials on which the soils are developed in Manitoba and Saskatchewan south of latitude 52 degrees, are discussed in relation to the question of soil drifting.

Soil drifting in the Prairie Provinces began after the period of intensive settlement, from 1906 to 1910, and has gradually increased since that time but has been most pronounced in times of drought. Previous to this period there were, however, in the drier southern and southwestern parts of Saskatchewan large areas of "burn-out" where the surface soil had been removed in patches probably in part by wind action.

Dry farming methods and single crop farming, which demand excessive cultivation of the soil, together with the occurrence of high winds in times of drought and the general absence of wind breaks are the chief causes of soil drifting. The causes have been well discussed in the Soil Survey publications of the University of Saskatchewan and it has frequently been pointed out in these publications that the permanent solution of the problem is to be sought in the adoption of systematic crop rotations, though much can be done by careful management of the soil, by the use of protective crops and by strip farming, that is, farming of the land in narrow strips, cultivated cross-wise to the direction of the prevailing winds. There are, however, large areas where sufficient water for live stock farming may not be obtainable, so that in these areas the problem is a difficult one. The planting of hedges to act as wind breaks and to collect snow, and the storage of spring run-off water for farming and municipal purposes has been advocated by T. C. Main (Engineering Journal, June 1932).

As some parts of the region are much more affected by soil drifting than other parts it may be of value to discuss briefly the character, extent and mode of origin of the materials on which the various soils of the region are developed. Map 254A published by the Department of Mines, Ottawa, shows the general character of the surface deposits of Manitoba south of latitude 52 degrees and of a small part of eastern Saskatchewan. The Regina sheet in course of preparation describes the surface deposits of Saskatchewan south of latitude 52 degrees. Both maps are on the scale of 8 miles to the inch.

*Published with the permission of the Director, Bureau of Economic Geology, Department of Mines, Ottawa.

Dune Sand Areas

In Manitoba dune sands occupy 1,250 square miles of a total area of 43,380 square miles that has been mapped. The largest single area, much of which is included in the Spruce Woods forest reserve, extends along the Assiniboine river for fifty miles east from near Brandon. There are other fairly large areas south of Portage la Prairie and in the Souris valley near Hartney and Oak lake. Live dunes occur at places in the dune areas, but for the most part the surface has a protective covering of vegetation and there is comparatively little soil drifting except locally. The occurrence of remains of an extinct bison at a depth of only a few feet in dune sand near Douglas shows that some of the dunes are very old. There are few occurrences of buried soils and it seems probable that the dunes have not been active to any great extent since they first became clothed with vegetation several thousand years ago.

Around the margins of the sand dune areas and in places in the Souris valley, that was once a lake bed, there are areas of dune silt and very fine sand. This material somewhat resembles loess but differs from true loess in that it is not compacted or cemented and is very easily eroded. These soils drift badly once the protective sod is destroyed by cultivation, but the areas are comparatively small.

In southern Saskatchewan the largest tract of dune sand, covering an area of approximately 1,500 square miles and known as the Great Sand Hills, lies north of the Canadian Pacific railway between Maple Creek and Swift Current and extends north nearly to Lancer on the Empress branch of the Canadian Pacific railway. Only about 20 square miles of the area are included in the Seward forest reserve as the region has little forest growth. In the vicinity of the elbow of the South Saskatchewan river a dune area of about 100 square miles is included in forest reserves. Another tract of about the same extent lies on the east side of the South Saskatchewan river, south of Saskatoon and is included for the most part in the Dundurn forest reserve. Many smaller tracts occur throughout the region except in the extreme south.

In the Great Sand Hills there are many live dunes that appear to have developed in recent years, and some damage to adjacent farm lands has been done by drifting of the sand, but the greater part of the dune area is protected from drifting by vegetation. Around the margins of the dune areas and particularly on the south and east sides there is a belt a few miles wide of very fine sand and silt that has been deposited from the air. These areas drift badly after a few years cultivation.

Considered as a whole the sand dune areas do not enter largely into the problem of soil drifting at the present time as they have been cultivated to only a slight extent and are not drifting except locally. The dune areas of very fine sand and silt require protective measures to prevent soil drifting, but are of no great extent.

Lake and Alluvial Clay Areas

In Manitoba and adjacent parts of Saskatchewan stoneless clay areas that were once lake beds cover nearly 5,000 square miles, the largest single area being in the Red River valley and along the lower part of the Assiniboine river.

In southern Saskatchewan lake clay forms the Regina plain, extending northwest from near Weyburn to Moose Jaw and south from Qu'Appelle valley nearly to Avonlea. Another large area lies on the west side of the South Saskatchewan river and extends from Outlook north nearly to Saskatoon and west to Rosetown. In the south there is a fairly large area in the vicinity of Gravelbourg and in the west scattered areas to the east of the Great Sand Hills. The total area is approximately 6,120 square miles.

These clay areas are generally considered as forming the best farm lands. They are affected by soil drifting to some extent, particularly in the southern drier parts of the provinces and where the soils have been cultivated longest. The very factors which render the soils easily cultivated and highly productive, namely their finely-granular texture due to the high organic matter content in the form of humus and the calcareous character of the soils, also render them easily affected by soil drifting. Small rounded clay grains, which at first glance appear to be sand grains, drift before the wind, fill ditches and accumulate along fences and other barriers. Drifting of the black clay soil of the Red River valley is well shown near Morris and at other places in southern Manitoba; and of the Regina brown clay soil at many places along the highway east of Regina and between Regina and Moose Jaw. Soil drifting in the lake clay areas is not so serious as might be supposed, for it occurs chiefly in times of drought and the great depth of the humus soil prevents exposure of the subsoil. There is no question, however, that soil drifting in the lake clay areas has increased during the past few years and in time will demand remedial measures for its prevention.

Lake Sand and Silt Areas

Areas of sandy and silty soils in Manitoba occur around the margins of the lake clay areas and are widespread in the ancient delta of the Assiniboine river extending from Brandon to Portage la Prairie and in the Souris valley. They cover an area of 8,340 square miles.

In southern Saskatchewan similar surface materials occupy areas in the former lake beds along the Qu'Appelle and South Saskatchewan rivers. They are widespread in the Rosetown district near Mortlach, west of Moose Jaw, around the borders of the Great Sand Hills, and in the vicinity of Saskatoon. Altogether there are about 1,800 square miles of sand and silt deposits in southern Saskatchewan.

These areas are easily affected by soil drifting because of the loose friable nature of the soils. On account of their character and extent they particularly demand remedial measures for the prevention of soil drifting. In Manitoba only parts of these areas are affected particularly in the Souris valley and in the Assiniboine delta region, whereas in Saskatchewan nearly all the areas are affected.

Boulder Clay Areas

In southern Manitoba soils developed on boulder clay or glacial till are the most widespread and are only slightly affected by soil drifting. The few areas that are affected lie in the drier southwestern part of the province.

In southern Saskatchewan the boulder clay areas are also the most extensive and are affected by soil drifting particularly in the drier southern part of the province and where the boulder clay has a thin covering of sand. Boulder clay forms the surface materials over all the region except in the former lake beds, in comparatively small areas where glacial sands and gravels occur, and in parts of the Wood Mountain region where there is practically no glacial drift. The boulder clay varies in composition to some extent according to the type of local material from which it has been derived. In places where there are extensive sand formations underlying the drift or where older glacial outwash deposits have been reworked the boulder clay is very sandy. It is in this type of deposit that drifting does the most damage, for generally there is nothing but a cobble pavement left at the surface after the top soil has been blown out. Such areas may be observed in the vicinity of Aneroid and near the Moose Jaw reservoir at Snowdy Springs. There are between 65,000 and 70,000 square miles of boulder clay area in southern Saskatchewan and about a quarter of this is the rolling moraine type of country. The outstanding moraine areas are the Missouri Coteau, Moose Mountain, Touchwood Hills and Allen Hills. The moraine areas are not cultivated extensively and have not been affected by drifting except very locally. Large parts of the more even ground moraine type of country particularly in the region south of the Qu'Appelle and South Saskatchewan river valleys are affected by soil drifting, but in places also to the north of these valleys.

"Burn-out" Areas

Areas in southern and southwestern Saskatchewan where the surface of the ground is characterized by shallow depressions having little or no humus soil and containing in many places accumulations of soluble salts are known locally as "burn-outs" or "blow-outs." They occur in the drier southern and southwestern parts of the province, chiefly in boulder clay tracts that have a thin covering of fine sand and silt deposited from the air. The depressions are a few inches deep, and are roughly circular or oval in shape, varying from a few feet to twenty or thirty feet or even more across; and as the bare subsoil is exposed and there are accumulations of salts, chiefly sulphates of sodium and magnesium, in them, they are not productive under cultivation except in very favourable seasons.

Development of the "burn-outs" appears to have antedated the period of intensive settlement judging from the accounts of early settlers who state that after ranching began in the region and measures were taken to prevent the spread of prairie fires, the result of protection from fires was that the soil became covered with a thick mat of prairie grasses and when fires did occur the surface soil in places was destroyed. During the past thirty years, however, there have been comparatively few prairie fires and the "burn-out" areas appear to have remained in about the same condition or to have been extended. Similar soils occur in semi-arid regions in other parts of the world and are known as saline, white alkali or solontshak soils. It is possible that prairie fires may have had something to do with the formation of the depressions but the main factors probably are the dry climatic conditions, the effects of high winds, and the character of the materials on which the soils are developed.

The "burn-out" areas occur chiefly in two regions, in a belt ten to twenty miles wide along the International boundary and extending for one hundred miles east of the Alberta boundary; and in a belt about ten miles wide between Avonlea and Estevan in south-central Saskatchewan. Farming of these areas has been attempted at many places but with no great success. Owing to the unusual soil conditions the areas present special problems not entirely connected with soil drifting.

Tree Planting in Relation to Drought Control

Norman M. Ross,

Chief of Tree Planting, Forest Nursery Station, Department of Agriculture, Indian Head, Sask.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

The present situation in many large areas of the prairie provinces, brought about by successive seasons of drought, is a most serious one. Much concern is being felt regarding the future, should similar conditions recur, as past history would indicate to be almost a certainty.

Drought conditions, coupled with the common practice of bare summer-fallowing of immense acreages with repeated cultivation of the soil, has so depleted the natural fibre and humus that soil drifting has become a serious menace. It is doubtful whether soil drifting in these areas can now be controlled, even in seasons of normal precipitation, unless some radical change is made in cereal farming methods.

The daily press, farm papers and even popular magazines have been carrying numerous articles dealing with the situation which is recognized as a national calamity, calling upon governments to do something about it.

Suggestions to counteract the effect of drought have been freely offered, often by those not sufficiently conversant with the practical problems involved, advocating schemes of a wholesale nature the carrying out of which would involve enormous expenditures, and setting forth extravagant claims as to the benefits which would result. Most of these suggestions have included wholesale planting of trees, with the claim that by so doing rainfall would be increased and the climate changed. Unfortunately such claims are not justified by available data and immediately invite adverse criticism. This is most unfortunate, for in the resulting controversy, the very great economic benefits which might follow the systematic establishment of practical shelter belts are sidetracked and more or less overlooked.

For the benefit of those not familiar with prairie conditions the problems of tree planting in these areas may be briefly considered. In passing, the author may mention that the facts submitted and the opinions expressed are based on over thirty-seven years actual residence in Manitoba and Saskatchewan, the last thirty-four of which have been spent in supervising a scheme which has for its object the establishment of plantations on prairie farms.

During this period one hundred and thirty-nine and a quarter millions of seedlings and cuttings have been sent out from the Dominion Forest Nursery Stations into the three prairie provinces, distributed amongst approximately fifty-four thousand farmers. Over fifty per cent of these are in Saskatchewan. Some failures have naturally occurred but are only a small proportion of the whole.

On account of a minimum of precipitation and extremes in temperature certain methods in establishing plantations must be followed out. One cannot, as in the east, just go ahead and dig holes in the ground, plant the trees and then leave them to become established. Before planting the soil must be carefully prepared, to eradicate native perennial grasses and weeds and also to store up a reserve of moisture to give the new plantings a reasonable start. After planting the belts must be given systematic cultivation to conserve the very limited supply of moisture and prevent the growth of grass and herbaceous weeds which would compete with the trees for such little moisture as is available. Then a wise choice of varieties must be made, using only such kinds as experience has shown to be hardy and capable of standing up under prolonged periods of drought. Unfortunately choice is thus limited to a very narrow list and in dealing with the areas most subject to drought the selection is practically confined to three varieties of broad leaf species, namely, caragana, ash and elm and a few varieties of hardy spruce and pine. This does not mean that there are not other kinds of trees and shrubs hardy enough to withstand severe conditions, but availability of seed and comparatively cheap production costs must be considered when dealing with any extensive scheme of planting. Even in unfavourable districts there are often locations where, owing to a high water table or topographical features favouring the retention of surface drainage moisture, other kinds such as Manitoba maple and varieties of the poplars and willows can be used with good success. In the so-called park area tree planting is not so much of a problem, but even here periodic dry spells are experienced and proper methods must be followed out to secure successful results.

Fig. 1—An isolated Plantation on a very exposed Site South of Swift Current. Trees up to 40 feet high, planted 4 by 4 feet enclosing Garden Plot. Photo taken in July 1934 following a series of abnormally dry seasons.

As a result of many years experience and observation the author is convinced that trees *can* be grown anywhere on the prairie where cereal crops can be raised successfully in seasons of normal rainfall. Plantations can be established when moisture conditions are favourable and from actual experience will survive several successive seasons of drought even when moisture is not sufficient to produce even a poor grain crop. The fact should not be overlooked that many comparatively old plantations have, during the last four dry years, been very seriously set back and in some cases have failed completely. But these failures are due mostly to neglect, to the planting of unsuitable varieties, to insect and rodent damage and in some cases to being buried by drift soil. These are factors, however, which can be controlled. Such failures, while naturally a source of great discouragement to the owners of the plantations, nevertheless are of considerable value in demonstrating what to avoid in the future.

Assuming therefore that it is not impractical to grow plantations in the agricultural areas of the prairies, the question arises whether belts can be established on a wide enough scale to appreciably ameliorate drought conditions, and if so would the accruing benefits compensate for the labour and expense? In trying to find an answer we are confronted by an uncertain quantity, namely, the human factor. Success really depends more on this particular factor than on anything else. Where a man has the inborn desire to grow trees and has the necessary knowledge, he will make a success of it under the most trying circumstances. But without such will to succeed no amount of legislation or government assistance is likely to bring about the desired result. If a government organization could have complete control of all factors, namely both the land and labour involved, then, with a well thought out plan, a very reasonable degree of success might be anticipated. Under our system of government this is hardly possible. What then is the most promising procedure? If it could be clearly demonstrated that field shelter-belts were a paying proposition it might not be difficult to induce farmers to undertake such plantings with confidence and with success. Unfortunately there is at present but little reliable information available on the beneficial effects of field shelters. There are, it is true, numerous instances on record where shelters have not only saved crops from drifting, but have greatly increased the yields within their influence. Every one who has lived on the prairies concedes the benefits resulting from tree-sheltered gardens and fruit plots. The field shelter idea is only going a step further and those who have had the opportunity to make extended observations are generally convinced that the idea of such plantings is basically sound.

Carlos G. Bates, Senior Silviculturist of the United States Forest Service, in a recently published statement, discussing the American shelter belt project, says, "There is an obvious reason for scepticism as to the effects which the retention of moisture through the reduction of wind movement and evaporation has upon crops. . . . The Forest Service has conducted no systematic investigations along the line of these particular problems since 1908. While innumerable examples of striking benefits to crops from shelter belts have been recorded . . ., we fully realize the extreme difficulty of finding physical situations in which 'Fair experimental conditions' are at all well satisfied. . . . What is needed for satisfying experiment and observations is an immense field laboratory with all soil conditions under control, shelter belts built to satisfactory specifications, etc." Mr. Bates further states that actually a portion of the million dollars already voted by Congress will be used in establishing such a field laboratory or demonstration area and carrying on research elsewhere when opportunity is afforded.

Exactly the same sort of thing is needed in Canada, viz.: The creating of one or more demonstration areas in each of our prairie provinces where blocks of land of a suitable size (say not less than 9 sections in a square) can be secured by the governments concerned and handled under complete control as large-scale illustration stations. In such areas all the best theories for cultural practice, local water conservation by dams, and shelter-belt plantings could be combined and maintained for a sufficiently long period of years so as to afford absolutely conclusive data.

Fig. 2—Grain field at Hugendon, Alta., June 1929. Note how the shelter belt only 3 to 4 feet high has completely stopped the drift soil and saved the crop. This field gave a good yield of grain, while the crop in that adjoining was a complete failure.

Such projects would not require immense expenditure, as in most cases the lands, already reasonably equipped with buildings, have reverted to the municipalities for taxes. After a few years of preliminary treatment, such areas should return sufficient from crops grown to carry the greater part of the cost. Would not such projects be more valuable to the west than the expenditures of huge sums in public buildings and other so-called relief projects of a non-revenue-producing nature? Such demonstration areas, if successful, would do more to encourage and stimulate the general practice of the systems advocated than anything else. If not successful, the sooner that is determined the better.

It is impossible in a short paper to take up the beneficial effects of shelter belts which have been well demonstrated already in a limited way in scattered individual examples. Suffice it to say that practical foresters with experience in prairie planting do not expect even the most extensive plantations, which it would be possible to establish artificially, either to increase precipitation or change the climate. What they do claim is that plantings would make the prairie more livable, would tend to check winds, thus conserving at least some moisture, and in some degree help to check soil drifting and would also tend to conserve winter snowfall from which some increase of moisture may be expected as against a complete run off.

It is hard to tell what the economic value would be, but there is reason to believe it would not be inconsiderable. Tree planting on the prairies, irrespective of field shelters, has already proved itself and in any event is worthy of every encouragement. In addition to the establishment of the large-scale illustration areas already referred to, all necessary assistance should be extended to individual farmers to continue planting around their building sites and to those, increasing in numbers year by year, who are actually setting out field shelters on their own initiative.

The Surface Waters of the Canadian Prairie

P. C. Perry, A.M.E.I.C.,
Division Engineer, Canadian National Railways, Regina, Sask.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ontario, February 7th and 8th, 1935.

SUMMARY.—The paper deals with a number of drainage basins in southern Alberta, southern Saskatchewan and south-western Manitoba, covering about 130,000 square miles, most of the area being treeless prairie with an average precipitation of about 15 inches.

The general relations between precipitation, absorption, evaporation and run-off are discussed, and possible methods of flood control and storage to provide local supplies are indicated.

PART I.—CLIMATE AND SURFACE WATER

The development of any area, where climatic conditions approach aridity, depends very much upon the way its water is conserved and used. It is important, therefore, that the closest possible study of our water supply should be made. This paper will deal with the relationship between surface water and climatic phenomena, and also touch briefly upon the use and physical control of our waters.

The area dealt with consists of the watersheds of the Souris and Qu'Appelle rivers; the tributary basin of the South Saskatchewan between Saskatoon and the foothills; that part of the Mississippi watershed in Canada; and a number of smaller drainage areas adjoining the above. Many of the smaller drainage basins have run-off only to lakes which have no outlet. The map, Fig. 1, shows the drainage basins referred to above, those without outside drainage being shaded. For this paper the areas outlined, being about 130,000 square miles, will be considered as the Canadian prairie. This includes practically all of the open or treeless prairie; some partially wooded hill areas such as the Cypress Hills in south-western Saskatchewan; and part of the park or grove belt to the north and east of the prairie.

The average annual precipitation[1] over this area varies from 12 to 20 inches, most of the area having between 13 and 16 inches with heavier precipitation in all ranges of hills. Fifteen inches is an approximate figure for average precipitation over the area. Mean monthly temperatures for January, the coldest month, range from 16 degrees in the south-west corner to −6 degrees in the north-east. For July, the hottest month, mean temperatures range from 62 to 68 degrees. Strong winds are common at all times, humidity is low, and evaporation is very rapid, particularly in the south-west. Most of the surface soil is very fertile, and when there is sufficient moisture, plant growth is rapid in the long days of early summer.

The waters of local origin may be divided into two classes—streams and lakes. Only these local waters are studied here, but in addition there is another important class in the streams of mountain origin flowing through the prairie. The local waters are maintained by precipitation falling upon the prairie area. The third class, consisting of the Saskatchewan river and some of its tributaries, is maintained chiefly by the precipitation falling upon the eastern slope of the Rocky Mountains. Most of the local streams contain water suitable for irrigation and industrial purposes, and with treatment could be used for domestic and municipal supply. All of the lakes are mineralized to some extent, the mineral content being higher in the lakes without outlet and increasing during years of drought. While the mountain-fed streams may eventually prove to be of more economic importance than those of local nature, the local streams are more easily utilized.

Disposal of Water Coming in Precipitation

In order to arrive at a better understanding of the relationship between surface waters and precipitation, it is suggested that the whole process of the disposal of water arriving as precipitation be considered. That process is illustrated in the diagram in Fig. 2. When water comes in the form of rain or snow, some of it is evaporated directly from the surface upon which it falls, some soaks into the

1 Where the term "annual precipitation" is used, or the word precipitation is used in a general way, it is intended to refer to all the water received as snow or rain. Ten inches of snow is assumed to ontain one inch of water.

*Indicates open water record only.

surface soil and some runs off over the surface. This initial division is shown at the top of the diagram as direct evaporation, soil absorption, and initial run-off. The water absorbed by the surface soil does not remain there and should be followed further. In fertile soil, a large proportion of the water absorbed by the soil is reached by the roots of vegetation; and through transpiration is turned back to the atmosphere. As surface soil dries out, some moisture is brought up from the lower strata by capillary action and is then evaporated. These processes account for a very large percentage of the water entering the surface; but where soil is unusually porous, a portion continues to penetrate into the ground. Such water then becomes ground water. This may be added to by water from initial run-off penetrating the ground from beds of streams or ponds.

On the Canadian prairie there is an evaporation from open water equal to approximately twice the precipitation and every stream and lake loses from its surface through evaporation. Small streams also lose water through absorption along their banks, which water is turned into the air as described for soil absorption. The surface water not accounted for in the foregoing, and leaving the area in surface streams, then becomes final run-off. This run-off is generally measured as depth in inches over the drainage area.

Water which penetrates the ground beyond surface influences where it fell has been described as ground water, but such water is continually being brought to the surface again. A large percentage of it works through nearly horizontal strata and appears in valleys as springs, or it may be brought to the surface by artificial means. It is then either evaporated, or becomes part of the run-off. A part may continue to move underground until it leaves the area studied, when it becomes deep seepage.

The diagram shows typical final disposal, with the same divisions as for initial disposal, but with greatly changed proportions. The upper part of the chart is not drawn to scale for usual prairie conditions. The lower line shows the division which the author believes to exist for the Canadian prairie as a whole. It is believed that the amount lost through deep seepage is extremely small when expressed as a percentage of precipitation, and is offset by water received from mountains to the west through underground sources, and is, therefore, ignored in a study of the entire area. As will be shown later, the final run-off is about two per cent of the precipitation, some 98 per cent being returned to the atmosphere over the entire prairie area. There is a marked tendency for the percentage of water taken away by deep seepage and run-off to decrease as the drainage basin increases in size and naturally there is a corresponding increase in amount taken by evaporation. No consideration has been given in the foregoing to storage, as average conditions are being considered. Storage will take place in a year of higher than normal precipitation, or perhaps in a normal year following extremely dry conditions. When storage does take place, the proportion will be higher for the larger drainage areas.

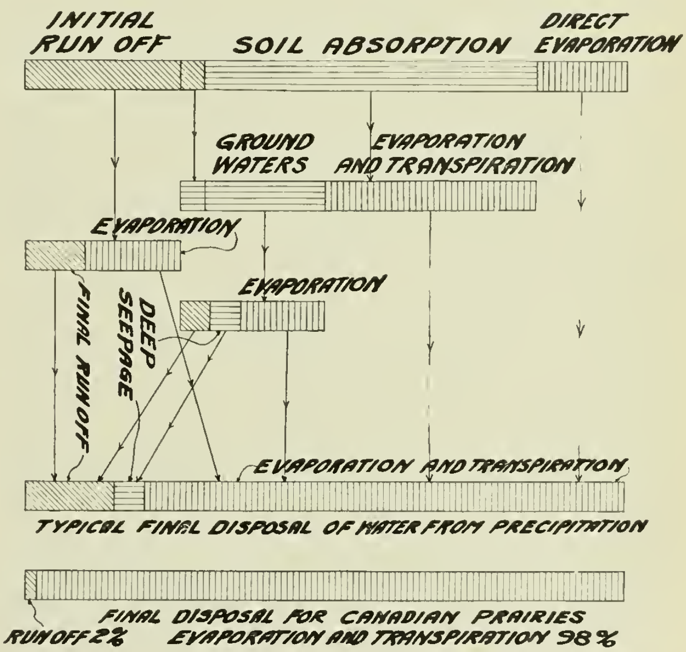

Fig. 2—Final Disposal of Water from Precipitation.

This is another factor tending to decrease the run-off (as depth over drainage area or percentage of precipitation) as the drainage area is increased. This tendency is clearly shown in run-off statistics, and while it may be significant only in semi-arid regions, its importance in these regions should be more generally recognized.

It is appreciated that even the prairie streams generally have their headwaters in ranges of hills where the precipitation is higher than the average for the whole area and topography is more rugged. This tends to increase the run-off for small streams as compared with that for large watersheds. There is, however, ample evidence to show that the average run-off is greater for small watersheds than for larger, other conditions being similar.

Run-Off and Precipitation

Table I gives the run-off for a number of prairie streams and a few in adjoining wooded areas for the ten water-years from October 1st, 1919, to September 30th, 1929, taken from the Water Supply Papers of the Dominion Water Power and Hydrometric Bureau. While the measurements for Qu'Appelle and Souris rivers cover the open water period only, it is believed that the winter flow would be very small when expressed as depth over drainage area, and that the total run-off is little over two-

Fig. 3—The Souris River Near Estevan, Sask.

tenths of an inch. The Souris river, measured at Minot for twenty-two years by the United States Geological Survey, gives an average of twenty-three hundredths of an inch. Smaller streams of the Mississippi and South Saskatchewan river watersheds show higher run-off, but on the other hand, there are large areas where there is no outside run-off. Taking all drainage basins into consideration, the author has suggested three-tenths of an inch as a figure covering the total run-off from the area, and is satisfied that it does not exceed this amount. This would be two percent of precipitation if an estimate of fifteen inches is accepted for the average value.

While the stream-flow data available are valuable in any study of waters, in most instances the figures cover a very short period, and there are streams for which there are practically no data. Meteorological records are not as comprehensive as one would like, but they cover the prairie area better and for a longer period than the hydrometric records do. It is important then that an endeavour should be made to establish the relationship between meteorological records and stream flow.

The author has endeavoured to study available literature as well as the prairie records in a search for this relationship. A number of simple formulae and graphs are available which attempt to give the approximate relationship between annual precipitation and run-off. Most of these are clearly inaccurate with a light precipitation. Some seem to give approximately correct results for small drainage areas, say under 500 square miles, but none are of value for the larger basins. Unquestionably the proper approach is to think of the run-off as a residue of precipitation after deducting the losses for evaporation, transpiration and seepage. Professor E. F. Chandler[2] of Grand Forks, N.D., suggests 20 inches as the approximate requirements for evaporation and transpiration in northern states and thinks that, generally speaking, when precipitation exceeds 20 inches, the amount over 20 inches will be found in run-off.

2 "What Becomes of Rainfall in North Dakota," University of North Dakota Quarterly Journal, January 1925.

This rule may not be of direct help as our precipitation is under 20 inches, but it does bring out an important fact concerning run-off, namely, that *the average precipitation does not meet the normal demands of transpiration and evaporation.* The streams originating in the prairie and lake levels, then, are dependent upon water from snow which melts and runs off when the ground is frozen; a small run-off from unusually heavy rains falling on small areas faster than it can be absorbed; and a very small discharge from ground water accumulated in unusually porous soil deposits.

The most complete general study of the subject which the author has found is contained in a paper[3] by Mr. Meyer who also deals with the matter and gives his charts in his book.[4] His method is to compute all losses from precipitation, taking into consideration the physical features of the watershed as well as all meteorological data.

Mr. E. G. Marriott, A.M.E.I.C., of Victoria, B.C., states[5] that he found Mr. Meyer's method worked out well with streams near Kamloops, B.C., where annual precipitation is as low as ours. The author has not been as successful in applying the method to prairie streams, though it may be that the data used were not complete enough. Certainly Mr. Meyer's approach to the subject is scientific and logical, but it is doubtful if results would be accurate enough to warrant the work involved. Methods which might be entirely practicable in areas where precipitation is greater, and where twenty to fifty per cent of precipitation finds its way into streams, may not be feasible

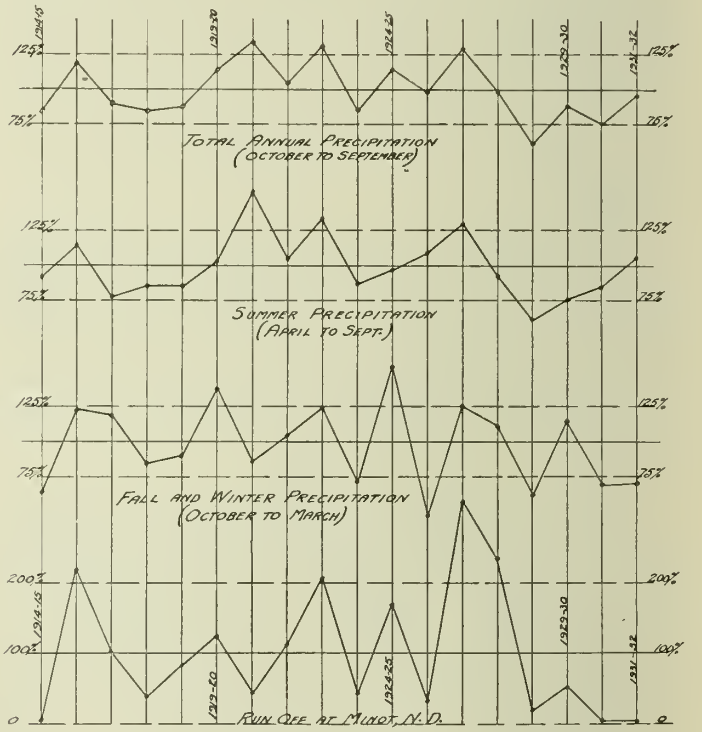

Fig. 4—Precipitation and Run-Off, Souris River above Minot, N.D.

in an area where run-off is only two to five per cent. Changes in meteorological conditions which would be hard to record might easily make a difference of one or two per cent in the amount of the annual precipitation reaching streams. Such variations would approach fifty per cent of our run-off, but would be barely noticeable in some humid districts.

3 "Computing Run-Off from Rainfall and other Physical Data," by A. F. Meyer, Vol. 79, Transactions of the American Society of Civil Engineers, 1915.
4 Elements of Hydrology, A. F. Meyer, Wiley, New York.
5 The Engineering Journal, September 1927.

All who have studied prairie conditions will agree that the dependable surface flow from small areas is from winter precipitation. The author believes that the flow of the larger local streams is dependent chiefly upon snowfall and fall rains. The fall rains probably affect the run-off in two ways. Professor Chandler suggests that when the surface soil freezes in a wet condition, it is more effectively sealed, and a larger portion of water from melting snow runs off in the spring. It is believed too that more of the fall rain penetrates the ground than any other precipitation. From this ground storage some water finds its way into streams for flow in the winter (where any exists) or during the following summer.

No formula is suggested here for determination of run-off from precipitation but it is believed that our stream flow is primarily dependent upon fall and winter (October to March inclusive) precipitation. Where the water year (October 1st to September 30th) is used, it is suggested that the flow of the prairie streams is dependent upon the precipitation of the first six months. As the winter flow is extremely small, the calendar year may be used instead, and stream flow considered as dependent upon the precipitation of six months beginning the preceding October 1st.

Heavy rains in September seem to affect the run-off for the following year also, probably through increased yield from the ground waters. September rains are usually light, however, and for convenience, the six months beginning October 1st has been adopted as the period during which precipitation has the controlling effect upon stream flow.

Figure 4 is a diagram showing the approximate relationship between fall and winter precipitation, summer precipitation, total precipitation and run-off for the Souris river at Minot, N.D. Run-off is shown as measured by the United States Geological Survey and is expressed as a percentage of the average for the period. Precipitation is estimated from the records published by the province of Saskatchewan and state of North Dakota, and is expressed in the same way. While run-off does not follow fall and winter precipitation closely, there is a much closer relationship than that existing between total precipitation and run-off. During some years, the summer and winter precipitation shows the same trend, in which case it is difficult to see which affects the stream flow. Where they show opposite trends, the winter precipitation unquestionably is the important factor. For instance, during 1925 and 1926 the fall and winter precipitation is 72 per cent of the average, the summer precipitation is 109 per cent and the total 98 per cent; yet the stream flow is only 34 per cent. For 1927 and 1928, the fall and winter precipitation is 112 per cent, the summer 93 per cent and the total 99 per cent while the run-off is 185 per cent of the average.

The curves in Fig. 5 are submitted as an approximate guide in estimating run-off from fall and winter precipitation. It is believed that size of watershed is the factor next in importance to precipitation in estimating run-off; that feature, and also to some extent topography of basin has been allowed for by giving separate curves for different sizes of drainage area. This chart has been prepared by plotting a large number of run-off figures from the Dominion Water Power and Hydrometric Bureau reports, and those secured by the Canadian National Railways engineers. Needless to say, stream flow records will be found which differ widely from the chart, but it is believed that the chart will be of value where few data are available on which to base an estimate. Small drainage basins, particularly those in rolling prairie or hilly areas, will in some years have additional run-off from sudden summer showers. Such run-off is not dependable, however, and probably has little, if any, effect on streams of over one thousand square miles drainage area.

Other Factors Affecting Run-Off

Some of the other factors affecting stream flow should be considered. Probably the nature of the spring thaw is as important as anything else, for when the thaw is continuous and abrupt, a larger proportion of water from snow joins the run-off. Where the thaw is gradual and broken by spells of cold weather, the water is largely evaporated or absorbed by the soil. Unusually high temperatures continued through the season will naturally reduce the run-off, as evaporation will be greater.

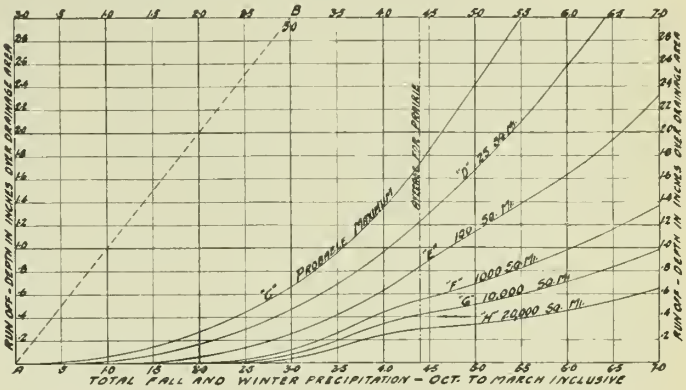

Fig. 5—Run-Off from Canadian Prairie, Regina, Sask.

Note:—C, D and E will apply to rolling prairie or hills, clay soils and quick melting of snow. F, G and H will apply to watersheds consisting of part level and part rolling prairie, average soil and temperatures.

The rolling or hilly watershed will give a greater average flow and more dependable run-off than the more level prairie. Under some conditions, however, the prairie with very gentle slopes will produce run-off from melting snow nearly equal to that from hilly areas. Lakes and sloughs tend to greatly reduce the run-off from any prairie area. The nature of soil may have little effect for drainage basins in excess of one thousand square miles. If sandy soils are present, more water will be absorbed, but this may be offset by the increase in stream flow from springs.

When the influence of forests on stream flow is touched upon, a field is entered where a very wide divergence of opinion exists. Persons interested in effect upon climate will tell of the vast amount of water returned to the atmosphere through transpiration from trees, and express the belief that this tends to decrease the run-off. On the other hand, there are those interested in water supply who tell of the way tree growth stops evaporation from ground and water surfaces, and suggest that stream flow is increased by this effect. Most of the opinions of meteorologists give little weight to the effect of trees on climate or stream flow. For example, Professor Willis Moore of the United States Weather Bureau[6] observes that deforestation, drainage and cultivation has not materially altered climatic conditions and referring particularly to floods states that effect of deforestation is limited to small area of mountain districts. However a different attitude is represented by Geddes,[7] who states that evaporation takes place more rapidly from a surface covered with vegetation than from a free water surface, other things being equal.

Engineers differ also but it appears that those who have given most careful study to the subject do not credit forests with having as great an effect as is commonly supposed. Mr. Meyer[8] points out the wide difference in claims for effect of vegetation and gives the following as his estimate of water used in transpiration—9 to 10 inches for grains and other agricultural crops; 8 to 12 inches for

6 "Descriptive Meteorology."
7 Meteorology, A. E. M. Geddes, Van Nostrand, New York.
8 Elements of Hydrology, A. F. Meyer.

deciduous trees; 6 to 8 inches for small trees and brush; 4 to 6 inches for coniferous trees.

Those who have observed the behaviour of single trees or shelter belts planted in the drier areas of the prairie are ready to believe that they will return large quantities of moisture to the atmosphere when it is available. The tendency for roots of trees to run a long distance and draw moisture from large areas is quite remarkable, but when we study the stream records of the prairie and adjoining areas, it would appear that tree growth increases the run-off. The author wishes to support the doctrine that forests are primarily the result of certain climatic conditions rather than the cause. It should be admitted then that there are some natural climatic differences between the naturally forested area and the open prairie. This makes it difficult to compare the behaviour of streams in the open prairie with those in the forest or park belt, but nevertheless, the comparison is interesting.

Swift Current creek measured at Swift Current is one of the prairie streams having considerably heavier run-off than many of its neighbours, but comparison with the Swan river in the forest area to the north is quite surprising. For the ten-year period covered by Table I the average run-off for the former is 0.918 inches while the latter has 3.97 inches. Drainage areas are about equal, while information available concerning soil and topography lead to the belief that these factors would be similar in their effect. Meteorological records indicate that the Swan river watershed received about one and one half inches greater annual precipitation for the period considered. There is a marked difference in mean temperature, particularly for the winter months. The mean monthly temperature for January at Swift Current is 7 degrees, while at Swan river it is − 6 degrees. The higher average temperature at Swift Current is largely brought about by pronounced warm waves coming with the Chinook winds, when the snow is often melted and water evaporated, leaving little for absorption or stream flow.

It should be remembered that the run-off in the prairie and adjoining streams comes entirely or very largely from the fall and winter precipitation. At that time, trees are dormant and will not be drawing upon the supply of water. Probably the shading of trees and the reduction of wind reduces evaporation, and it is the author's belief that the presence of trees in or near the prairie area tends to increase the run-off. If it is possible to materially increase the tree growth on the prairies, it should bring about a slightly increased average flow of streams or, at least, offset any reduction brought about by cultivation of part of the surface drained.

Are Permanent Changes Taking Place?

This brings us to the important question of permanent or progressive change. There is a common belief in the theory that our streams are now much smaller and the lakes lower than they were one or two hundred years ago. While there may have been some change, it certainly is not as great as is popularly supposed. The only authentic record of any permanent or progressive change in streams or lakes in or near the Canadian prairie, which the author has found, is that for Devils Lake in North Dakota. Professor Chandler[9] states that the lake level has fallen twenty-two feet in the past fifty years, while no appreciable decline in precipitation has occurred. He suggests in explanation that the cultivation of the surrounding prairie has slightly decreased the run-off. Professor Howard E. Simpson, State Water Geologist of North Dakota, believes too that the cultivation of the prairie has slightly reduced run-off.[10]

Probably some of the streams and lakes are being affected in a similar way, though statistical evidence has not been found. The year 1915 saw an extremely low flow in local streams, the flow for the Qu'Appelle and Souris rivers being the lowest recorded until the severe drought of 1929 occurred. There are some gauge records on Lake Johnson and Quill Lakes but unfortunately the record is very short, and has not been maintained during recent years. At Lake Johnson, the level held about uniform from 1918 to 1924, then rose 3 feet from 1924 to 1928. A drop of 2 feet occurred during the years 1929 to 1930, leaving the level one foot higher in 1930 than in 1918 when the record was started. The level has continued to drop during the severe drought, probably at the rate of one foot per year, and it is believed that the water is now 3 feet lower than in 1918. The record, however, is too short to show whether it is a progressive lowering, or whether it is a matter of fluctuations.

Some interesting notes on the Qu'Appelle river are contained in the report of Professor H. Y. Hinds[11] who explored this area in 1857. He referred to the Qu'Appelle Lakes as "full of weeds and having a disagreeable odour," and described the river above Craven as a stream "nineteen feet wide and one and one half feet deep." Altogether his notes lead the author to believe that the lakes and streams were much the same in 1857 as we find them today.

Variations

Needless to say, wide departures from the normal or average flow of streams must be anticipated. During the recent drought the Qu'Appelle and Souris rivers have had for five consecutive years discharges less than 25 percent of the long time mean. The variations in smaller watersheds are greater, and where there is only gently rolling prairie, no run-off has occurred in several of the past five

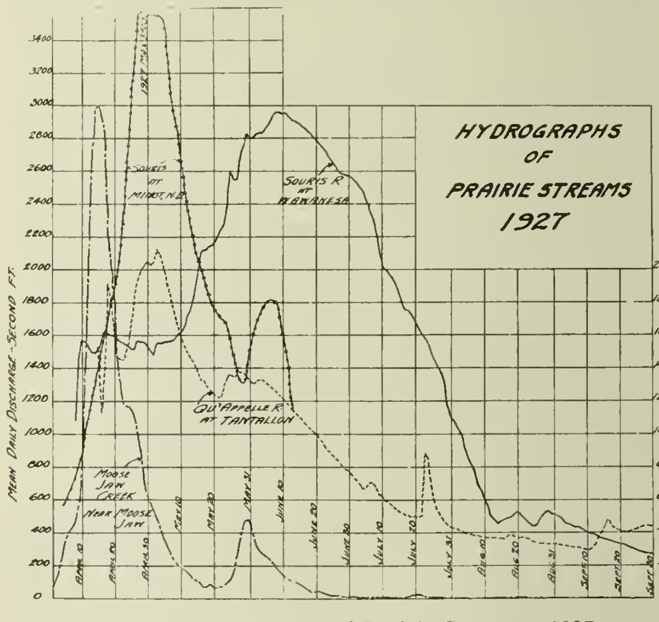

Fig. 6—Hydrographs of Prairie Streams, 1927.

years. With rugged topography, some run-off occurs almost every year. The author has had under observation reservoirs on coulees near Avonlea, Tilney, Darmody and Central Butte during the recent drought, and found that some run-off was secured each year, and reservoirs have been satisfactory for railway service.

Precipitation for the Canadian prairie shows some tendency to follow the sun spot cycle of eleven and one quarter years, recent dry periods of from two to four years having centred upon the years 1909, 1920 and 1931. The flow of streams, however, is likely to be more irregular than the

11 Report on the Assiniboine and Saskatchewan Exploring Expedition, 1859.

annual precipitation, and it is doubtful if the theory of regular recurring cycles can be relied upon.

Flood Stages

The maximum and minimum flow of streams are as important as total discharges. The maximum flow is of particular interest, for it becomes the flood stage in years of heavy flow. Figure 6 shows hydrographs of the Souris, Qu'Appelle and Moose Jaw rivers for part of the open water period of 1927, giving the mean daily discharge in cubic feet per second. It will be found that in years when the average or more than average flow occurs, hydrographs follow somewhat similar curves. This then may be taken as typical of the high water flow for many of our streams. The Souris river at Wawanesa usually has its high stage much earlier than in 1927. The maximum recorded was about double the highest for 1927, and occurred April 19th, 1916. This early and high stage of the Souris in 1916 was probably an important factor in bringing the record flood for the lower Assiniboine that year. It is interesting to note that the Moose Jaw creek with a drainage area of 1,960 square miles had a higher flood stage than the Qu'Appelle with 20,600 square miles; and the Souris had a higher stage at Minot with 10,270 square miles than at Wawanesa with 23,400 square miles.

To facilitate comparison between the flood flow of our streams and those of other parts of the continent, Table II has been compiled showing the flood stage of typical streams. It is recognized that flood stages, when expressed as cubic feet per second per square mile, will be greater for small watersheds than for larger, other things being equal. The streams listed have, therefore, been divided into five groups on the basis of drainage area. In each group the first one or two streams are on the Canadian prairie, and the remarkable difference between our floods and those in more humid districts is evident. No attempt is made to describe the climatic features affecting each stream, and little is submitted concerning the physical characteristics of the drainage area. Nevertheless, certain conclusions are quite obvious. For the first three groups, it is evident that the flood stage is the result of the combined climatic conditions and physical features of the watershed. For the larger watersheds in groups four and five, it is believed that the nature of the watershed has little effect as compared with the climatic conditions. For instance, the watershed of the Qu'Appelle river above Lumsden is made up largely of rolling prairie and hills with clay and loam soils. Judged on the basis of topography, lake storage, soil and vegetation, one would expect it to produce greater floods than the Assiniboine above Millwood, Manitoba, or the Gatineau in Quebec. On the contrary, the flood stage for the Qu'Appelle is only 0.408 cubic feet per second per square mile, while the other streams have 2.345 and

Table II.—Flood Stages of Typical Streams

Group No.	Stream	Location	Drainage area sq. m.	Maximum Recorded Stage Second-Feet	Maximum Recorded Stage Second-Feet per sq. mile	Date	Ref.	Remarks
1	McEachern Creek	Near International Boundary, Sask.	160	1,050	6.281	Apr. 3, 1927	A	Rolling prairie

6.768 respectively. In the central and southern states, streams of approximately the same drainage area produce floods of 37.1, 61.7 and 92.3 cubic feet per second per square mile.

It is evident, then, that our streams have extremely light flood stages due to climatic conditions. However, as the record is a short one, is there not a possibility of some year in the future producing floods very much in excess of those now recorded? It is the author's opinion that this

Fig. 7—A town in the Dry Belt, Hodgeville, Sask., 1927.

is not only a possibility but a probability. A very little difference in meteorological conditions as compared with previous years, when records were established, may bring floods considerably higher than those of the past.

It is interesting to note that Meyer's flood formula[12] intended for Minnesota conditions seems to agree roughly with records of the prairie streams of drainage areas under five hundred square miles, and the streams in wooded areas to the east and north. For the large prairie watersheds, Mr. Meyer's formula would give results two to five times greater than the maximum recorded. This, of course, shows that the formula does not apply to the large prairie drainage areas, but it may also be taken as another indication that we should expect greater floods.

Mr. Meyer suggests that for the northern states the maximum floods for streams with drainage areas under one thousand square miles will occur from excessive rain, while for areas larger than one thousand square miles, melting snow (sometimes accompanied by rain) will cause the extreme stage. The author would suggest 500 square miles as the dividing line for prairie streams. For the smaller watersheds, soil and topography are important as well as the nature of the storm. For drainage basins over 500 square miles, the factors affecting flood are similar to those affecting total discharge; namely, condition of the watershed at the time of freezing during the preceding fall; the amount of snow; and nature of the spring thaw—the quick continuous thaw, of course, being most productive of flood waters.

A study of Table II shows conclusively that forests cannot have the effect generally credited to them in preventing flood. Rather, it would appear that they tend to increase the stage for large watersheds. Mr. Meyer has arrived at similar conclusions, for he says: "The available information on the subject does not indicate that forests have any material effect upon the extreme flood flow. They have a tendency to reduce the ordinary flood flow somewhat. In northern Minnesota forests have aggravated spring floods by retarding the melting of snow until warm April rains set in."

PART II.—USE AND PHYSICAL CONTROL

Flood Control

This is a subject which has not been given much attention on the prairie during recent years, but as suggested above, may come to the fore in the future. Some water courses have become partially blocked during dry years from soil drifting, deposit of silt, and growth of brush, which will tend to increase trouble when high water comes again.

Three general methods are adopted in flood control work—storage reservoirs, dykes and flood channels. The first is of greater interest to residents on the prairie, because it is frequently suggested that reservoirs can be combined for flood control and other utility. While it is evident that it is impossible to secure maximum flood benefit from a reservoir and at the same time secure satisfactory service for other purposes, it is true that every reservoir used for impounding spring run-off will tend to reduce floods on large watersheds.

Drainage

Drainage is also a subject that has not been considered a great deal on the prairies during the past few years. It is believed, however, that some drainage work may be justified and where it is undertaken, the closest possible study of climate should be made.

One phase of the subject is the matter of culvert and bridge openings to be provided in highway and railway grades and spillways for dams. This is one place where the average engineer has not been guided by experience in more humid areas. Generally, waterway openings have been based on appearances, and observation of stream or water-course for a short period. Where observations were made during the dry part of a cycle, the openings were often made very small for the drainage area.

Probably the most widely quoted rule for determining culvert openings is the Talbot Formula.[13] This, with lowest factor (for flat land), gives openings as follows:—

1.25 square miles drainage, 30 square feet of opening.
12.5 square miles drainage, 169 square feet of opening.
25 square miles drainage, 285 square feet of opening.
125 square miles drainage, 951 square feet of opening.

It is true that that formula was intended for the Mississippi valley where rainfall is heavier. On the other hand, there is sometimes heavy rainfall over small areas, and our soil as a rule does not absorb rainfall quickly. The extreme run-off may occur so infrequently that one may not be economically justified in providing sufficient waterway to handle it in every case. However, where insufficient waterway opening is likely to result in serious damage, it is believed that waterways at least twice as large as those commonly used on the prairie should be provided.

Fig. 8—C.N.R. Track West of Hodgeville, Sask., 1927.

Storage

Mention has been made of the extremely low run-off from the prairies when expressed as a percentage of pre-

12 A. F. Meyer, "Elements of Hydrology," 2nd ed., p. 369.

13 American Civil Engineers Handbook, 5th edition, p. 2009.

cipitation. It should be remembered, however, that drainage areas are great, and there are large quantities of water available for local use. Storage may be made in various types of reservoirs, from the small dugout in a farm yard to comparatively large artificial lakes; or through control of levels in existing lakes such as Last Mountain Lake (Long Lake). The uses may be just as varied, including domestic, municipal, industrial, irrigation and recreational purposes. The author believes that one of the best fields for the use of surface water is in reservoirs of from 10 to 1,000 acre feet capacity, made by constructing dams in coulees, which are ordinarily dry but have a spring flow from melting snow. The smaller reservoir of this type would be for individual farm use, supplying water for the home (filtering and other treatment would make such water suitable for domestic use if well water is not available), for stock and irrigation. The larger sizes would be suitable for municipal or government reservoirs and might be used in some cases for industrial purposes, and in most cases for recreational purposes. A lake or reservoir of this kind, especially when improved by planting trees around its shores, would make an attractive recreational centre, providing swimming, boating and auto camps. Where sufficient flow exists, it would be advisable to have two or more reservoirs on the same coulee, the level of the lower maintained by letting the water down from the upper storage. The lower would, of course, be the one improved. The quality of the water in such reservoirs depends very much upon the amount of deep water. Wide expanses of marsh and shallow water make excellent breeding places for water fowl, but tend to lower the quality of the water for industrial and recreational purposes. Where the quality of the water is important, it is suggested that as much deep water (over eight feet) be obtained as possible. This could be done by excavating channels through parts of the reservoir which would naturally have only shallow storage. The earth removed would form islands or steep banks around the outside of the reservoir. It is the conviction of many who have studied the matter carefully that such artificial lakes, properly maintained for recreational purposes would be of great value to the prairie. Everything which tends to make the country a more attractive place in which to live is of practical value.

Another type of reservoir which might be used in places is an imitation of the "oxbow" lake or slough, sometimes found in river valleys. Where a creek or river meanders through a wide valley, a channel could be excavated between two adjoining bends, and earth used for dams at both ends of the channel cut off. A pipe with check valve, or gate valve manually controlled, would permit the severed channel to fill to the height of the flood water but would hold such water after the flood recedes. This type of reservoir would eliminate the necessity for an expensive spillway, and avoid obstruction to the stream.

In connection with all reservoirs, it is felt that more could be done in using water for irrigation of small areas. It is realized that irrigation in general is not a paying proposition, especially with existing prices for agricultural products; but a small area irrigated for garden and feed, especially if that area is adjoining the farm home, would remove much of the hardship experienced during years of drought.[14]

The larger projects for reservoirs should not be carried out without proper engineering advice, but engineers who have an opportunity to advise on matters of this kind will have to be careful to avoid unnecessary expense on any undertaking.

Many agricultural leaders and engineers are advocating more extensive use of the small reservoir to insure a farm

Fig. 9—A Beach on one of the Qu'Appelle Lakes near Lebret, Sask.

supply. The Hon. Mr. Weir in a letter which appeared in Regina papers stated: "A thick shelter belt around a small trench or reservoir for water supply should make it possible for any farm to handle stock (sufficient to be self-sustaining) in this way." Mr. T. C. Main, A.M.E.I.C., has strongly urged, among other things, the use of small reservoirs for farms in the dryer areas.[15]

A type of irrigation practised extensively in Montana, and in the south-west Canadian prairie area, is known as "flood irrigation."[16] This primarily consists of diverting or temporarily impounding the spring flood water to give the land a spring irrigation. Mr. H. L. Lantz, County Extension Agent, Malta, Montana, in a letter of February 11th, 1932, advises that this work has been very successful in that area. He states "To date, I have personally surveyed out one hundred and sixty-seven systems covering over 14,000 acres." Professor M. L. Wilson, Head of the Department of Agricultural Economics, University of Montana, in a letter of January 30th, 1932, states that flood irrigation was included in their programme for betterment of dry areas started ten years earlier, and was found to be constructive.

No attempt is made in this paper to deal with the administration of our waters except to mention that it is illegal to impound or divert any surface water without government permission. Problems of administration will become greater as more water is utilized. It is important that the taking of hydrometric records should be continued and extended, and that the material secured since 1929 should be published at an early date.

The author hopes that the foregoing notes will aid by showing the need for careful study, and thus help towards the better utilization of our surface waters.

---

14 Literature is available to those interested in the subject. Bulletin No. 5 of the Reclamation Service of Canada on "Farm Water Supply" was obtained from the Dominion Water Power and Hydrometric Bureau recently, and probably is still available. The United States Department of Agriculture Farm Bulletin No. 828 on "Farm Reservoirs" contains similar information. The reports of the Dominion Field Husbandman, Agricultural Department, Ottawa, for 1928 and 1930 describe small reservoirs constructed for watering stock at the Range Experimental Station, Manyberries, Alberta. The Department of Agriculture Bulletin No. 125—"Use of Irrigation Water on Farm Crops" and bulletin No. 7 of the Dominion Water Power and Hydrometric Bureau give valuable data on this phase of the subject.

Water Conservation in the Prairie Provinces

T. C. Main, A.M.E.I.C.,
Assistant Engineer, Water Supply, Canadian National Railways, Winnipeg, Man.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

SUMMARY.—The paper deals with conservation of water, which, together with improved methods of cultivation, and the planting of trees and hedges is a possible means for rehabilitation of the drought area. The author touches on the waste which has occurred in the past and considers that increased evaporation over a long period is the chief cause of the drought. He objects to general irrigation for cereal crops and refers to the economics of the situation. A number of specific conservation projects are described, and it is urged that action be taken without delay by appointing a small commission of technical men to make a definite study and co-ordinate the work of government departments, universities and private individuals.

A paper by the author entitled "Drought and Soil Drifting in Western Canada" appeared in The Engineering Journal of June 1932. In that paper the distressing condition of the so-called drought area was described. The situation now is much worse than it was then and the affected area is larger. The problem is now of more than local or provincial interest and is being looked upon from the national point of view. This attitude is logical, as it is difficult to visualize a high degree of prosperity for Canada as a whole while the great agricultural area of western Canada is in its present serious condition.

It is the author's opinion, after many years of serious study of this problem, that man must assist nature if this area is to be rehabilitated and the disastrous effects of future drought periods minimized. Three principal ways in which man can assist appear to be (1) improved methods of cultivation, (2) planting trees and hedges, and (3) conservation of water.

In the present paper it is proposed to deal chiefly with the reasons for, and the possibilities and limitations of water conservation. It is hoped to present to the country, through the engineering profession, a practical basis for the conservation and utilization of moisture in this semi-arid, but otherwise fertile country.

Deciding where the boundary of the drought area lies is a difficult task, as there are no definite lines of demarcation. Moreover, there are oases of practically unaffected country in drought territory, and miniature deserts in normal districts. The area shown shaded on the map in Fig. 1 is the author's idea of that part of the prairie provinces which may be considered as the present drought region.

It must be pointed out, however, that drought is a potential enemy to the entire country from the Rocky Mountains to Ontario and from the international boundary to as far north as agriculture may go. Records show that precipitation in general decreases from south to north in our western country. Furthermore the land north of the North Saskatchewan river is for the most part lighter than in the south; hence, with lighter land and less precipitation, the north country is in greater danger than the south of becoming desert, once the tree growth is eliminated.

Waste of Surface Water

It is an axiom of climatology that the ratio of water to land has an important effect on climate. The natural corollary is that an acre of water or marsh, in a semi-arid region, must be more valuable than an acre of high class wheat land. Nature unfortunately was niggardly in providing water areas in the drought region and indeed in the southern, central and westerly portions of the three prairie provinces considered as a unit.

In spite of nature's parsimony, man has lost few opportunities of draining lakes, sloughs and marshes in order to increase his land holdings in a country where the ratio of water to land was already too small. There has been a general idea that the bed of a lake or marsh must necessarily be exceedingly fertile. As a rule the contrary is true, as it usually takes many years for a former lake bed to sweeten up sufficiently to grow high class crops. This is particularly true in western Canada where most of the lakes are inclined to be saline.

Normal drainage due to the construction of highways and railways has also contributed to loss of ground and surface water. This loss was more or less unavoidable; although the author believes that road drainage has been overdone; in fact, was frequently part of reclamation schemes.

Loss Through Evaporation

The climate of a region is usually classified according to its mean annual precipitation. Frequently the evaporation factor is somewhat neglected. As a matter of fact

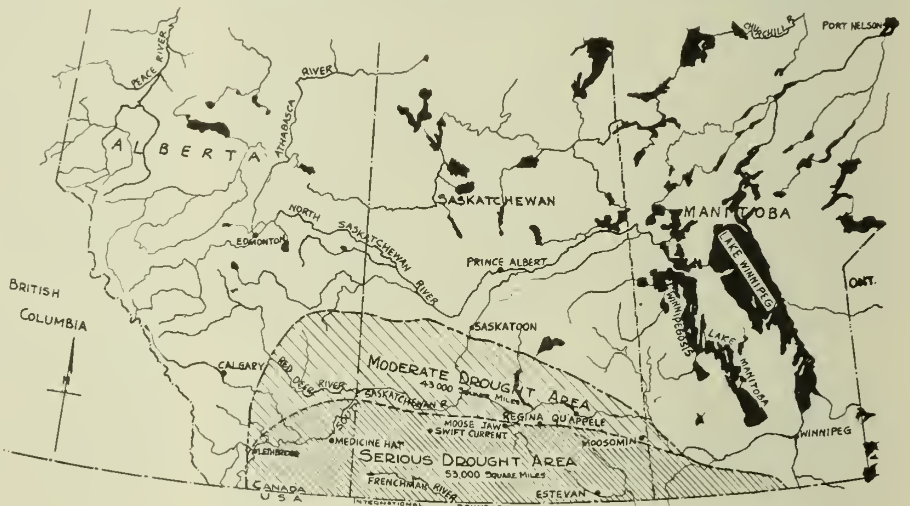

Fig. 1—Drought Area in Western Canada.

evaporation, next to precipitation and temperature, is the most important factor in climate. It cannot, of course, be divorced from temperature, though not entirely dependent on it.

The layman, in thinking of the recent drought in western Canada, lays the blame entirely on lack of precipitation. It is true that precipitation was low for several years, and undoubtedly this was a factor. On referring to the graphs in Fig. 2, however, it will be seen that while in general precipitation was low from 1928 to 1931, the past two years have been normal or above normal in this respect over a considerable portion of the drought area. It is interesting and encouraging to note that the twenty-year moving averages shown in the figure do not indicate any tendency toward lower precipitation in the prairie country. Winnipeg seems to be an exception; but apart from a comparatively small area in the south and west, Manitoba has not suffered from lack of precipitation.

Increase in evaporation, caused in turn by an increase in temperature, is perhaps quite as important a factor in our drought situation as the more obvious decrease in precipitation.

The twenty-year moving summations of yearly mean temperatures plotted in Fig. 3 indicate what has been happening in western Canada in the period during which temperature records have been kept. It will be noted that the mean daily temperature in Winnipeg for the twenty-year period ending 1931 was 3.9 degrees F. greater than for a similar period ending 1892. All through the prairie provinces, except at Edmonton, this temperature increase approximated that of Winnipeg. In the Edmonton district it increased, but not to the same extent.

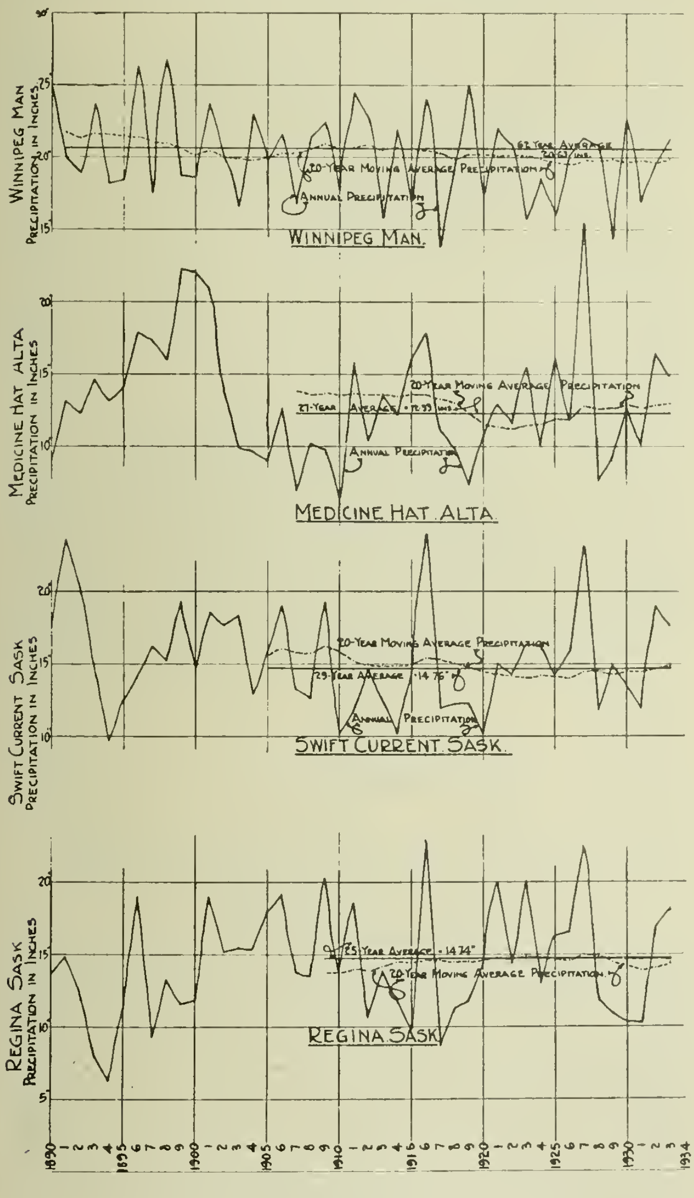

Fig. 2—Total Precipitation from 1890 to 1933.

Now temperature is the most important factor in evaporation. According to Meyer[1] it appears that the rate of evaporation doubles for an increase of approximately 18 degrees F. other factors remaining the same, hence we may assume that the increase of 3.9 degrees F. in Winnipeg represented an increase of approximately 21.6 per cent in the rate of evaporation.

1 Elements of Hydrology, by A. F. Meyer, Wiley, New York.

Sunspots and Run-off

While the relation between sunspots and precipitation is very difficult to trace in a continental climate, there seems to be an actual association between sunspot count and stream discharge.

Figure 4 shows the apparent connection between the sunspot cycle and the discharge of the Red river at Emerson. It will be noted that the sunspot culminations are high and low alternately; that there is a high river discharge one year before all sunspot maxima, also three to four years after the high peaks, but not after the low ones.

This apparent relation was particularly interesting during the period 1901 to 1913. The sunspot cycle should have attained its maximum in 1906. Actually two summits of approximately equal intensity appeared in 1905 and 1907. It seems more than coincidence that the river discharge was high in 1904 and 1906, just a year prior in each case to the two unexpected sunspot maxima.

It is possible that this phenomenon is not due to increased precipitation but rather to reduced evaporation, or possibly more effective precipitation, either of which would provide more water for run-off.

The above offers an interesting field for further investigation. It must be admitted, however, that in Canada, and particularly in western Canada, such work is greatly handicapped due to the comparatively short periods during which records have been kept. Further, our records, meteorological and hydrometrical, leave much to be desired. For example there are no continuous humidity records; wind velocity is only recorded at one elevation, and not frequently enough to make it worth while. The object of stream measurement seems to have been to get a ten-year average. Usually, on minor streams, measurements cease after this has been obtained. Many fairly important streams have not been measured at all.

This is not a criticism of the several departments that are responsible for collecting such data, as no doubt they are doing the best they can with the funds at their disposal.

Temperature, Precipitation and Run-off

The effect of temperature, precipitation and other factors on the discharge of the Red river can be observed in Fig. 5. All records are on a twenty-year moving average basis, and in order to be comparable, have been calculated as a percentage, using the twenty-year period ending in 1910 as 100 for all three phenomena.

Temperatures rose more or less steadily from 1901 to 1931, and precipitation tended to increase during the period 1902 to 1909. River discharge during this period, and until 1910, increased in sympathy with the increase in precipitation, and in spite of increase in temperature, because the rate of effective precipitation increase was apparently greater than that of temperature. From 1910 to 1919 precipitation on the average changed very little, but river discharge was reduced, apparently due to increased evaporation. Since 1919 temperatures have continued to climb and precipitation to lower on the Red river drainage area, while the river discharge, due to these two unfavourable factors (and probably to others such as increased demand of vegetation) has quickly been reduced until for the twenty-year period ending in 1933 it was only 63 per cent of that recorded in a similar period ending 1910.

It will be seen from Fig. 3 that since 1931 temperatures have been coming down. 1934 will lower this graph still further. It seems probable that there is a more or less definite temperature cycle and that 1931 was the top of the curve. Thus lower temperatures are likely over a fairly long period of years, and therefore lower evaporation, and hence more moisture for the growing crops.

In Fig. 4 the sunspot cycle and discharge in the Red river have been forecast up to 1945 using the same pattern that has occurred in the past. The probabilities are that the sunspot curve will approximate that forecast, and that the river will also more or less follow the pattern it has followed in the past. But in order for the river to do this, a great deal of precipitation must be received during the next three years, and a considerable amount for three or four years after the maximum sunspot year of 1938. The water table is now low and one year of heavy precipitation would have little effect on stream flow.

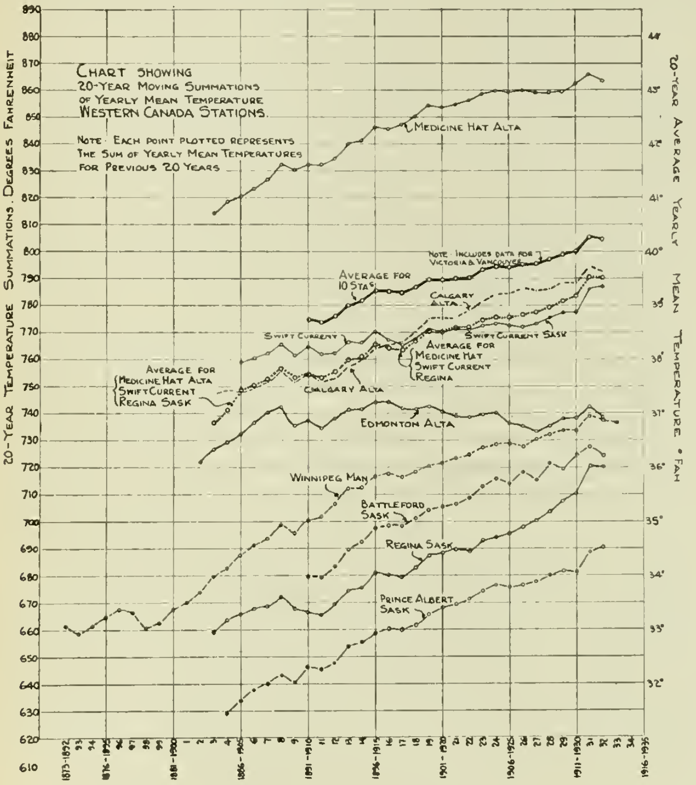

Fig. 3—Twenty-Year Moving Summations of Yearly Mean Temperature.

Importance of Water

A high standard of living without the provision of a plentiful water supply of good quality is out of the question. Most engineering work is concerned with water; either getting rid of it, harnessing it or conserving it. A city or country with a restricted water supply is a city or country of restricted growth.

An outstanding feature of the prairie provinces is a shortage of water, so the conservation of this valuable commodity becomes an exceedingly important factor in any scheme for their economic improvement.

The minimum flow of the Saskatchewan river at La Corne is approximately 1,900 second-feet. As Alberta will develop along with Saskatchewan, the draught on both branches of this stream in Alberta will be heavy, hence this minimum flow will be reduced. As some water must be allowed to discharge into Manitoba, the amount available for use in Saskatchewan at minimum discharge might only be a few hundred second-feet. It is obvious therefore that some day storage of spring flow in the Saskatchewan river will be necessary.

If the standard of living improves, and people become more exacting as to the quality of water, and particularly as irrigation is extended (as seems inevitable), this minimum flow, plus the conveniently usable ground water, will not do more than take care of the present population; hence, any increase in industrial activity, or population, or both, will mean that some part of the flood waters of the Saskatchewan river, and other streams, must be conserved.

It would seem then that the population of the prairie regions, say south of the 54th parallel, may ultimately be limited by the amount of water that can be conserved rather than by the amount of food that can be produced. It may be noted that up to the present the average production of cereal products in Saskatchewan alone has been sufficient to furnish a population of at least forty million people with that important part of their daily ration.

Standard of Living

A striking paradox in this land of plenty, potentially one of the wealthiest countries in the world, is the present disparity in the standard of living as between urban and rural citizens. The standard of living on many farms of the prairie provinces is much too low; lower in many respects than that of the peasantry of Europe. The latter at least enjoy a community life, social intercourse, the æsthetic advantages of trees, streams, lakes and natural or artificial beauty in many forms. These, for the most part, are denied to the denizens of our western prairies.

Modern methods of farming, where one or two men with the aid of machinery can cultivate at least half a section of land, tend to produce a scattered rural population, not dense enough to sustain an interesting community life. Lack of good drinking water is a hardship; lack of sufficient water for stock, in many large areas, compels the farmer to concentrate on cereal crops. A sparse population makes it economically difficult to provide electric energy, water, rural mail delivery, playgrounds, community halls and other amenities or services, common to denser rural populations, and of course to urban communities.

Housing conditions in some portions of the prairie country are exceedingly bad. Apparently the settlers in general did not appreciate the importance of having good homes and pleasant surroundings. The craze for more land of course had something to do with this tendency, but undoubtedly the uninviting appearance of the "bald-headed prairie" created in settlers the feeling of temporary tenure.

The standard of living must be raised if we are to have permanent settlement of desirable citizens on a large scale in this vast area.

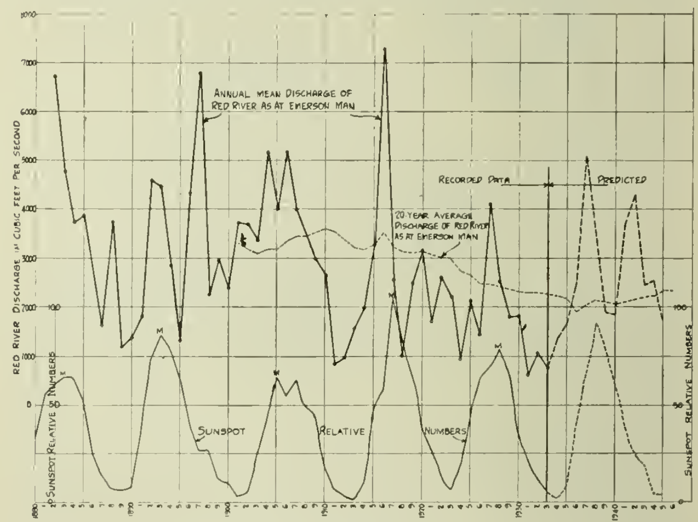

Fig. 4—Flow of Red River at Emerson, Man., and relative Sunspot Numbers.

Living conditions could be greatly improved by conserving surface water; by forming artificial lakes and by creating water districts to serve rural communities with that precious commodity in much the same way as urban communities are now served.

Utilization of Water

The average precipitation in the country considered is between 15 and 16 inches per annum. The final run-off, after deducting amounts that must be allowed to discharge in the United States and Manitoba, represents approximately 3 inches over the adjacent territory suitable for mixed farming. This would indicate that irrigation on a large scale is out of the question.

There is too much tendency to think of western Canada in terms of wheat. If present methods of farming continue, very little increase in prairie population can be expected. Producing large quantities of wheat alone on the prairies may help the growth of population in eastern Canada and possibly in British Columbia, but does not tend to increase population greatly in the prairie provinces.

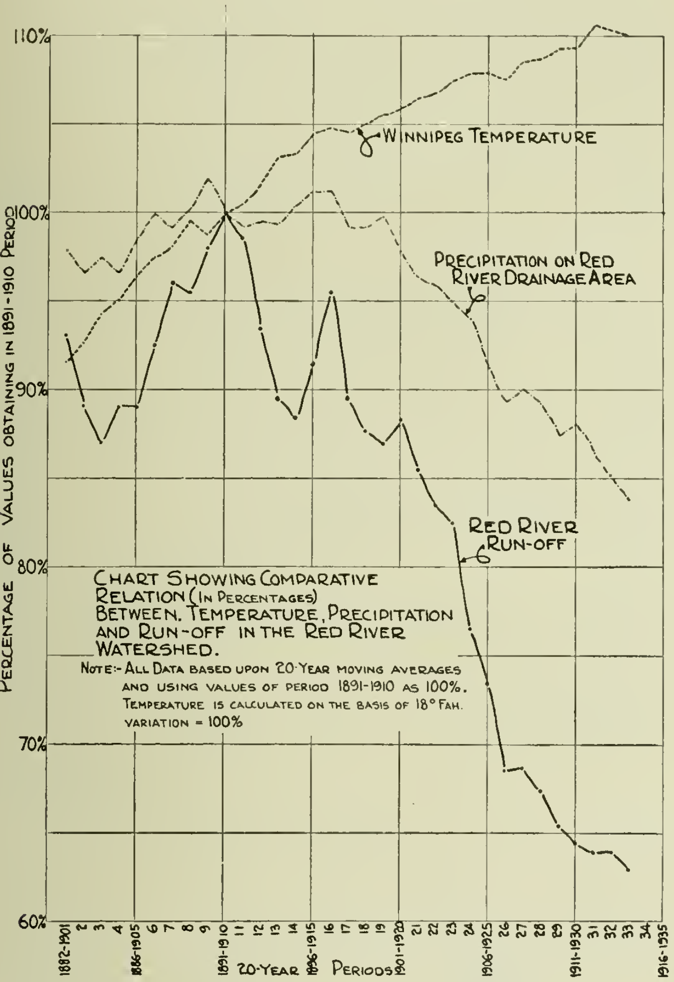

Fig. 5—Relation Between Temperature Precipitation and Run-Off in the Red River Watershed.

It is the author's opinion that available water should not be used for wheat irrigation. Indeed the prairie soil produces excellent wheat without irrigation. It is suggested that an ideal arrangement would be to provide water under pressure say along each alternate north and south, or east and west, road allowance, in a given water district. Water would be furnished first for domestic use in the home, thus tending to raise the standard of living; secondly, it would be piped to the barn and elsewhere for the use of stock; thirdly, water would be available for say an acre or two of garden, providing vegetables for home consumption and for sale, and roots for hogs, etc. Fourthly, sufficient water should be made available for irrigating from 15 to 25 acres of hay land per quarter section. Thus a farmer and his family on half a section could produce say 100 acres of wheat annually. When the market for wheat was poor, or in the event of a periodical drought, they would still have their garden truck, a few head of stall-fed beef steers, some fat hogs, poultry, eggs, milk and cream to carry them through. Even in the event of a depression, when such produce is difficult to dispose of at a profit, they would at least have enough to eat and so would not be a burden on other taxpayers for relief, as at present.

The tragedy of the drought area is not that farmers failed to produce large quantities of wheat; indeed it was a godsend in disguise that they did not do so, as the world supply was apparently too great. The sad part is that they had nothing to eat, chiefly due to lack of water for stock and for growing vegetables for themselves and feed for cattle, hogs, and poultry. Under the system proposed above, water would be available in the cities, towns and hamlets, as well as in the rural areas, and it is calculated that on the average 120 acre-feet of water per annum for each section of land would supply the rural requirements.

Economics of Rehabilitation

Seventy-five per cent at least of the rural population of this vast area, with their horses and machinery, have been practically idle for several months each summer for two, three and even four years. If this power could have been utilized during that period, all the projects suggested below, and many more, could have been completed, and each completed project would have added to the real wealth of the nation.

As it is the residents have remained in idleness, much against their will, and millions of money have been poured into these areas for relief purposes for which there is no added wealth to show. Further, during this period, the people to some extent have lost their moral fibre and independence.

It must be admitted that our economic system justified the course we have followed, so we have at least been consistent; however, in the opinion of the writer, any economic system that prevents needed projects being constructed when otherwise idle labour, willing and anxious to work, is available; when a large proportion of the material required for such improvements is at hand, and the balance available in other parts of the country where using it will provide work for other idle people, and when the alternative to doing such work is to keep the idle people on relief at the expense of taxpayers; then that system of economics should be overhauled as there must necessarily be something basically wrong with it. This is not a plea for either socialism or fascism but rather for common sense.

It may be argued that the above discussion is departing from the realm of engineering for that of economics. Engineering cannot be divorced from economics and it would seem that engineers, whose bounden duty is to serve mankind, should be jealous of anything that prevents or weakens that service.

Specific Water Conservation Projects

To indicate the possibilities and limitations of water conservation in the prairie country, a few specific projects will be discussed. These proposals are marked on the map in Fig. 6. They were studied by the author during a reconnaissance trip made for the Saskatchewan government in 1931. As no field work was done, the description in each case is necessarily a general outline of possibilities. As no such reconnaissance was made either of Alberta or Manitoba the following schemes suggested for further study are limited to Saskatchewan. One major project only will be mentioned.

The average annual discharge of the South Saskatchewan river at Saskatoon is approximately eight million acre-feet, or over twelve times as much as the aggregate of all the other central and southern Saskatchewan streams. This is a measure of the relative importance of the South

Saskatchewan river and the other streams. In other words this large stream must be tapped if any considerable portion of the drought area is to be provided with water. The other streams are important enough locally, but even if all of them were developed, only a relatively small proportion of the country would be benefited.

The amount of water which can be taken from the South Saskatchewan river depends on negotiations with the adjacent provinces, the desire of the people for water and their ability to solve power and economic problems.

Riverhurst Proposal

It is worth while studying the possibility of holding about 100 feet of water on a dam across the South Saskatchewan river near Riverhurst. It appears possible here to develop enough power from such a dam to lift say one million acre-feet per annum into a reservoir in the Vermilion Hills where the head would be sufficient to discharge water to the international boundary, say south of Estevan. This water could be used for the cities of Moose Jaw, Regina, and Weyburn; for the numerous towns and hamlets in this region and for farms. If this were done an area of approximately 10,000 square miles would be served with excellent water. Each section of land to which water is served should of course bear part of the cost; on the other hand as the community itself would be wealthier because of available water, it should also bear part of the cost. Again the economics of this proposal should be viewed from the standpoint outlined above, where it was shown that labour is going to waste now and should be harnessed.

Cypress Lake Project

For many years the advisability of holding water in Frenchman river, just north of Robsart, and irrigating the Robsart-Vidora areas, has been under consideration. A combination scheme of diverting some water from Battle creek into Cypress lake, holding here with a small dam and having a main dam north of Robsart on the Frenchman river, has also been suggested. As the country has a very definite fall to the south and east from the site of the proposed dam there would be no need for pumping if the water were carried to farms by pipe lines instead of ditches. Furthermore, maintenance costs would be very much less. On the basis of providing 120 acre-feet per annum to each section as already suggested, a large area of this part of Saskatchewan would be made more or less independent of drought as far as normal living is concerned. Again, this area produces some very fine wheat crops without irrigation.

Swift Current Creek

Since 1931 Rush Lake and Morse Lake have been dry, while Lake Chaplin probably has not more than one-tenth of its normal volume. The last mentioned lake gets very little water from the surrounding country but is dependent almost entirely on overflow from Lake Johnston. When dry seasons come, Lake Johnston is able to hold the total discharge of Wood river, so there is nothing left for Lake Chaplin. The normal area of this latter lake is about 22 square miles. Surrounding the lake, and to the south east of it, there is at least an equal area that is so low and marshy that it also should be classified as lake bottom.

It is proposed to divert practically the total discharge of Swift Current creek into Rush Lake creek about 2 miles north and 3 miles east of Waldeck. This would be accomplished by constructing a relatively small diversion dam on Swift Current creek and tunnelling through the ridge to the east. There is a fall of about 35 feet between the two streams, Rush Lake creek being the lower of the wo. Normally there would be sufficient water to raiset Rush Lake 3 or 4 feet and Morse Lake about 5 feet. During wet years the surplus water can be stored in Lake Chaplin.

It is expected that sufficient water would be available to maintain the three lakes with the following area at least:—

Rush Lake	7 square miles
Morse Lake	14 " "
Lake Chaplin	32 " "
Total water area	53 square miles

Fig. 6—Suggested Water Conservation Projects in Saskatchewan.

This is probably 45 square miles more water area than at present.

Of course it might be better to use this excellent water for domestic use for stock and for irrigating gardens and small areas of alfalfa as described elsewhere. Some 600 square miles of mixed farming country could be salvaged in this way; however, the country needs the water areas described, and serious consideration should be given this proposal before the alternative, or any other scheme, is agreed to.

The pond ducks and other water fowl of this continent are decreasing, due partly to the scarcity of prairie sloughs and lakes for suitable breeding grounds, and partly to bad water conditions in lakes that have not yet dried up. It must be remembered that the solid matter in solution changes in inverse ratio to the change in volume of water, up to the point of saturation. As some of our prairie lakes now contain from one-quarter to one-tenth of their normal volume, their saline content must now be four to ten times as great as formerly.

As this particular project would add a greater water area suitable for prairie waterfowl than any other suggested, it is probable that the water should be used for this purpose.

Buffalo Pound Lake Project

The Qu'Appelle river is one of the larger streams whose flow at present is of very little value to the country. In the early spring it often goes in flood, damaging much property along its valley and causing high water in the Assiniboine river, thus being largely responsible for the flood damage between Brandon and Winnipeg. In other seasons of the year it is often dry as far east as the Manitoba-Saskatchewan boundary.

It is proposed to construct a dam across the Qu'Appelle river immediately below its confluence with Moose Jaw creek. This reservoir would be capable of impounding the total flow in any one year of Moose Jaw creek and the Qu'Appelle river up to that point. A lake would be formed in the Qu'Appelle valley some ¾ mile wide and 24 miles long, flooding out Buffalo Pound lake which has been practically dry since 1931.

The advantages of such a proposal are many. Between 6,000 and 8,000 acres of excellent sandy loam land in the Qu'Appelle valley could be irrigated by gravity from the proposed reservoir. As this area is adjacent to good markets in Moose Jaw and Regina, no doubt it would develop into a vegetable and small fruit growing district, for which it is exceptionally well fitted.

Floods in the Qu'Appelle valley would be prevented and a beneficial effect on the flood conditions in the Assiniboine may be expected. Low water flow in both the Qu'Appelle and Assiniboine rivers could be increased, a boon to the settlers along their banks.

In this same project it is also proposed to improve the small dam at Craven and construct another on the outlet from Long Lake. By so doing Long Lake can be maintained at a pre-determined level, thus improving an already popular summer resort.

The several other beautiful lakes along the Qu'Appelle valley below Craven would be kept full also, which would be a source of pleasure to the people of the lower valley. Buffalo Pound lake itself would provide a summer resort for boating, bathing, etc., less than twenty miles from the city of Moose Jaw.

Souris River

The Souris river has an average annual discharge of about 60,000 acre-feet at the international boundary. Nearly two-thirds of this passes through the valley during six weeks in the spring. The city of Minot, North Dakota, is interested in the conservation of water in this stream, as it would help to prevent floods in spring and to increase low water flow, chiefly for the dilution of sewage.

Tentative offers of contributions towards the cost of controlling the Souris river in Saskatchewan have been made by representatives of the city of Minot and the state of North Dakota.

By damming the Souris river itself some three miles west of Estevan and its two chief tributaries, i.e., Long creek and Moose Mountain creek, at Estevan and Alameda respectively, the flow of the Souris river could be entirely controlled.

As this portion of Saskatchewan is underlain by thick seams of lignite coal, while clay for brick making and other purposes is close at hand, it is probable that the available water should be conserved chiefly for industrial purposes.

If the Souris river and Long creek near Estevan are dammed, sufficient water would be impounded to provide for steam plants of several hundred thousand horse power; considerably more than southern and central Saskatchewan will require for many years in the future.

The water impounded in Moose Mountain creek near Alameda could be used for farm purposes as described elsewhere. Water is urgently needed for this in the district around Frobisher, Oxbow and east, at the present time, which is an excellent wheat growing country.

Many other projects could be mentioned, particularly for preserving at a high elevation many of the larger lakes, such as Big Muddy, Willow Bunch and Goose Lake; all of which are practically dry at the present time. Such projects would raise the level of the ground water table in their general vicinity; would provide water for cattle and other stock, breeding ground for water fowl, recreational areas for residents, and would in general make the prairie a more desirable country in which to live.

Ground Water

Too little is known about the ground water resources of the three prairie provinces. Farmers, engineers and others are wasting a great deal of money and effort in costly experiments trying to find satisfactory ground water in various parts of the country.

A comprehensive report on the geology and ground water resources of the prairie provinces should be prepared. While some information is already obtainable for isolated areas, it is inadequate as a basis for rehabilitation projects. The farmer, industrialist or engineer should be able to tell directly from such a report where water is obtainable, the quantity, quality and probable depth at which it will be found.

It may be stated however that our ground water resources in this territory are not very impressive. Very few important artesian areas exist. For the most part also the quality of ground water is far from satisfactory.

Professor Simpson has given one hundred and ninety-six analyses of typical ground waters in North Dakota.[2] Comparing these with the specifications for drinking water issued by the United States Treasury Department, it is found that only 2 per cent are good, 11 per cent fair, 11 per cent poor, and 76 per cent unfit for human consumption. About the same ratio holds in general for the prairie country in Canada.

While a great deal of improvement can be made in the quality of these ground waters by suitable treatment, many cannot be made potable, due to heavy concentration of the sodium salts.

This is another reason why surface supplies should be developed to the fullest extent possible in our prairie country.

Conclusion

Drought conditions are serious in the prairie provinces. The area affected is getting larger. While natural factors

2 U.S. Geological Survey, Water Supply Paper No. 598.

appear to be changing for the better (i.e., increased precipitation and lower evaporation), man must take action to rehabilitate the stricken country and to create conditions that will minimize the effects of another serious drought period when it comes, as it surely will. Much depends on the technical agriculturist in developing more suitable vegetation and farming methods; much depends on the farmer in using these weapons and others intelligently and energetically. A great deal can be done by intelligent forest protection, reforestation, afforestation and the planting of hedges, etc. Perhaps the largest amount of responsibility lies with the engineer in connection with the conservation and utilization to the best advantage of all available surface and ground waters.

The problem as a whole is one that cannot be solved by the engineer alone, or the agronomist, or the forestry expert, but rather by a small commission of technical men co-ordinating the work of government departments, universities and private individuals.

In conclusion an excerpt is quoted from an article written for the author by Mr. J. Dewey Soper, Chief Federal Migratory Bird Officer for the western provinces, which shows how important such proposals are from the standpoint of bird life on this continent.

"Drastic steps are required to save both the farming interests of the dry belt and the waterfowl which one day so abundantly populated its innumerable ponds and sloughs. The time has come for a profound consideration of these problems. Drainage operations must be abolished and every effort made to restore vanished lakes and suspend the gradual subsidence of others—if that is at all possible. The restoration of ponds, lakes and sloughs, and the planting of trees should go far to bring back a normal farming community, and coincidentally the waterfowl population. Tree belts, while preventing the devastating effects of soil drifting and conserving moisture with a heightening of the water table, will attract a great army of insectivorous birds beneficial to agriculture. *Upon an adequate and prolonged restoration programme will hinge important inter-related and profitable consequences.*"

Storage on the South Saskatchewan River

Walter Blue, A.M.E.I.C.,
Manager, Development, Gatineau Power Company, Ottawa, Ont.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

During the past four years parts of southern Manitoba and sections of southeastern Alberta, and particularly southern Saskatchewan, have suffered from a severe drought, with a consequent loss and hardship to the inhabitants in particular and to Canada in general. To relieve this situation, the various governments have been providing relief in the form of money, food and clothing. While this method may be the most economical, it will not prevent a recurrence of the present situation and it is now realized that measures for the conservation of the water supply in the prairie provinces will have to be taken before any permanent relief can be effected.

Sources from which water might be drawn for irrigation in southern Saskatchewan are the streams rising in the province and the South Saskatchewan river.

It has been suggested that many small local reservoirs should be built to conserve the spring runoff of streams having their sources within the drought area. The writer has not sufficient knowledge of the country to say how feasible this would be, but it is quite apparent that this supply is not dependable. The chief source of supply must therefore be from streams having their source and main water supply outside of the area affected. The Saskatchewan river fulfills this condition, as about three quarters of its flow is of glacial origin from the Rocky Mountains. The precipitation in the prairies adds little to its flow.

The Saskatchewan river is one of the largest in western Canada. Both its north and south branches rise in the Rocky Mountains and flow easterly through the provinces of Alberta and Saskatchewan, the south branch through the drought area, joining about thirty miles below Prince Albert at the Forks, then continuing east and north to The Pas, Manitoba, finally emptying into Lake Winnipeg. The construction of a storage dam on the south branch warrants serious consideration, and while it would not relieve the whole drought area, it would have the decided advantage of providing permanent relief each year to over 800,000 acres of dry land. Other benefits attributable to storage will be mentioned later.

While it is impossible, without more information to decide definitely on a location for the dam, a study of reliable contoured maps indicates that a site in the vicinity of The Elbow, or upstream from it, depending on where the lands are that require irrigation and can be irrigated, would have many advantages. As an example, if a dam could be constructed on the South Saskatchewan river, below its junction with Aiktow Creek, the natural level could be raised about 140 feet from elevation 1650 to 1805, and the deeply eroded valley of the South Saskatchewan river used as the storage reservoir, having a capacity of 200 billion cubic feet. If this location were finally chosen, a secondary dam would have to be constructed on the height of land between the waters of Aiktow Creek and the Qu'Appelle river, and a third at the outlet of Buffalo Pound lake, creating a supplementary reservoir having a capacity of 115 billion cubic feet to elevation 1775, would make water available in that valley for irrigation, grazing and water supply. This supplementary reservoir would be filled by the excess of the requirements for 200 billion cubic feet.

The total drainage area at the mouth is 155,000 square miles, and at The Pas 149,000 square miles. The drainage area at Saskatoon, situated on the South Saskatchewan river, with which branch this memorandum mainly deals, is 50,900 square miles.

The records of stream flow at Saskatoon for the South Saskatchewan have been kept by the Dominion Water Power Branch since 1911 and show that the river at this point has a discharge varying from a minimum flow of 765 to a maximum of 131,000 second feet, or a ratio of 1 to 170.

A calculation, using the monthly mean flows for the period 1911 to September 1933 indicates that there has been sufficient water in the river to fill annually a storage reservoir of 200 billion cubic feet, based on the lowest period of record. This water so stored and the flow regulated as required would have been enough to irrigate 800,000 acres of land each year, at the rate of 3 feet per acre, and, in addition, would have increased the low flow of the river from a monthly minimum of 1,300 second feet to 4,000 second feet, as well as increasing the low flow of the Qu'Appelle river by some 400 cubic feet per second, or more, and providing sufficient water for a population double the combined population of Moose Jaw and Regina.

The flows of the South Saskatchewan and the Qu'Appelle rivers are entirely dissimilar. The South Saskatchewan at Medicine Hat has a drainage area of 20,600 miles and on the Qu'Appelle at Tantallon, 120 miles east of Regina, the drainage area is the same. An examination of the monthly mean flows shows that in April 1925, when the South Saskatchewan at Medicine Hat was flowing 11,600 cubic feet per second, the discharge on the Qu'Appelle was only 1,950 cubic feet per second. For July of the same year, the flow of the South Saskatchewan at Medicine Hat was 10,600 and the Qu'Appelle 250. In July 1926 the flow at Medicine Hat was 7,340 and on the Qu'Appelle, 76.

The Qu'Appelle flows just north of Moose Jaw and north of Regina. Both these towns draw their water from wells. An increased flow in this river would give assurance of a constant increased supply of water for these two cities and to the lands along its route.

A scheme was proposed some years ago for the pumping of water from the Saskatchewan river over the height of land down Thunder Creek valley, for a water supply to Moose Jaw and Regina by the construction of a small storage dam on this river.

With the larger scheme of storage on the South Saskatchewan, as proposed by this memorandum, it might be possible to extend pipe lines or canals and supply water to smaller storage reservoirs located throughout the affected area.

From the standpoint of reclamation, it is reported that in the Carrot river triangle and the Pasquia river section, upstream and downstream from The Pas, an area of land exceeding one million acres is annually inundated by the flood waters of the Saskatchewan river. It is nearly impossible, from an economic standpoint, to create sufficient storage to totally store peak flows and reduce them so that they would never occur, but the creation of storage does reduce the duration of peak and so would assist in reclaiming this huge area.

While some power for pumping could be developed at the storage dam itself, the variation in the head would be a serious factor and it is quite probable that power would need to be developed at plants downstream from the storage dam where the head would be constant and the minimum flow greater.

The increase in the potential power of the river, due to the storage, from the probable dam site down to a point about 150 miles upstream from The Pas would be about 200,000 h.p. at 100 per cent load factor and 85 per cent efficiency. Some of these sites are a considerable distance below the proposed storage reservoir, but with proper operation and the succession of ponds caused by the power developments, nearly the full effect of the storage would be obtained at the lower sites.

The construction of power plants primarily for pumping would not interfere with existing power systems. At certain times during the year there would be power available for sale. The population of Saskatchewan is some 951,000, the third largest of any province in Canada, and yet, possibly due to the lack of large manufacturing industries, the power at present developed by plants having power for sale within the province is only 126 h.p. per 1,000 of population. The developed power within the province consists of water power 42,035 and power developed by some 140 odd fuel oil and steam stations, amounts to some 78,400 h.p. Practically all of the water power is produced in the plant on the Churchill river, and is exported to Manitoba for use in the mines.

The above figure of 126 h.p. per 1,000 of population appears to be far from the saturation point. Ontario has 668 h.p. per 1,000 of population, Manitoba 541 h.p. per 1,000 and British Columbia over 1,000 h.p.

Similar storage schemes can no doubt be built on the North Saskatchewan, the Red Deer and other tributary streams rising in the mountains, with consequent benefits to irrigation, reclamation, water power and navigation.

At the present time, irrigation is of paramount importance. The other uses for water mentioned above should not be lost sight of in future plans, and it is felt that the scheme suggested by this paper also serves these other three demands.

A complete inquiry should be made as to the economic possibilities of relieving in part the drought by irrigation and no scheme should be gone ahead with until a thorough examination has been made of the water resources of the Saskatchewan river drainage area. As the river is interprovincial, a committee might be formed consisting of a proper member from each of the provinces affected and from the Dominion government to report on the construction of a storage dam or dams to benefit irrigation, reclamation, power and navigation. If it was decided that storage dams were the proper practical solution, a legal agreement could be entered into between the three provinces and the Dominion, based on their respective rights, to carry the project to a successful conclusion.

Water Phases of the Drought Relief Programme of the United States Federal Emergency Relief Administration

Lewis A. Jones, Staff Engineer,
Federal Emergency Relief Administration, Washington, D.C.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ontario, February 7th and 8th, 1935.

In June 1934 the Congress of the United States made available to the Federal Emergency Relief Administration the sum of $525,000,000 to be expended on drought relief in areas designated by the U.S. Department of Agriculture as suffering from drought, the funds to remain available until March 31st, 1935. The Federal Emergency Relief Administration allotted these funds to the various State Emergency Relief Administrations in the drought area to be expended by these agencies under general policies established by the Federal Administration.

A number of states have set up State Planning Boards or State Conservation Boards each having a federal representative associated with them. These federal representatives are expected to assist in co-ordinating the work of the various state boards with the plans of the National Resources Board working under the Public Works Administration. In some states the State Committees are called State Planning Committees and in others State Conservation Boards or Committees.

The programme as carried out has included all types of relief such as direct payment of funds to distressed families, the purchase of livestock that could not be maintained in the drought area because of shortage of feed and water, the furnishing of seed for late forage crops, etc., and work projects such as the processing and canning of meats for distribution to people on relief rolls and the development of water supplies in the drought areas.

Because of the comparatively short time the drought relief funds would be available, and the urgent need in many areas for immediate water supplies, it was decided in planning the water programme to limit the work to projects that would promptly make water available, and that could be completed within the limited time during which drought funds would be available. In other words, the object was to meet the existing drought situation rather than to start on a long time water conservation programme.

On the national forest ranges and public grazing land the work has been confined largely to the cleaning out and improvement of springs, the digging of wells, the furnishing of windmills and tanks, and the construction of dams to form stock water holes. The improvements are more or less of a permanent nature and the increased carrying capacity of the range resulting from the work will ultimately pay the cost.

On privately owned land, both in the range and dry farming areas, the same types of projects have been carried on, but in every case before construction work has been started, the landowner has been required to sign an easement granting the general public access to the water developed during periods of drought.

In the irrigated areas ditches have been cleaned out and lined to reduce seepage losses, reservoirs and other irrigation structures have been repaired, small reservoirs have been constructed and pumping from streams has been carried on to furnish supplemental water for crops. This work has resulted in the saving of large areas of crops that would have otherwise been killed by the drought, and has enabled the landowners to take care of themselves during this winter instead of being dependent upon the relief rolls. The cost of carrying the benefited people over the winter on the relief rolls would have in most cases exceeded very materially the cost of the work and the landowners have been able to maintain their self respect.

In some instances the water supplies for towns and villages have been supplemented by the digging of wells, the improvement of reservoirs, the construction of pipe lines and the pumping of water from nearby streams, etc. In practically all cases where assistance has been rendered to incorporated towns the local communities have been required to furnish most of the materials required for the work, and the drought funds have been expended in the employment of labour that would otherwise have been on the relief rolls.

In a few of the drought states bird refuges and recreational lakes have been developed as a phase of the relief work, the size of the lakes varying in area from about 80 to 10,000 acres. The bird refuges have been developed on public lands and entirely at public expense. In developing the recreational lakes the local people have been required to furnish the lake site and all or part of the materials and equipment required for the work. The relief funds have been devoted primarily to the employment of labour from the relief rolls. In visiting the field the writer has been impressed with the popularity of such developments. They appeal especially to the residents of the semi-arid states where bodies of water for recreational uses are non-existent.

In addition to the construction projects outlined above a number of the State Relief Administrations have conducted ground and surface water surveys to determine the extent of such resources. Such projects have furnished employment to engineers and geologists in need, and the results obtained will be of great value in planning long time programmes of water conservations. Several of the states have established Water Conservation Boards and the State Relief Administrations have co-operated with these boards by furnishing technical personnel to assist ni developing state-wide plans for water development. If a general public works programme should be undertaken the plans that have been prepared will be of great value in expediting the work.

In Montana the water programme has been limited primarily to the development of water supplies on the range lands. Numerous springs have been cleaned out and equipped with suitable water troughs; wells have been dug; and small dams constructed to form stock water ponds. As a result of the work it has been possible to retain a large amount of livestock in the state that would otherwise had to have been sacrificed. In some instances supplemental water has been made available to irrigated lands and repairs made to irrigation systems to reduce seepage losses. Assistance has also been rendered to the State Conservation Board by furnishing employment to technical employees engaged in developing a long time plan of water development and conservation for the state.

In North Dakota work in the rural region has been limited primarily to the construction of dams for stock water ponds. It is expected that more than four hundred such dams will be completed before the end of next March. In addition to the stock water ponds a considerable number of small recreational lakes and municipal reservoirs have been completed ranging in size from 30 to 40 acres up to 600 or 700 acres. Five large bird refuges are also under construction covering a total of more than 150,000 acres. The refuges on the Des Lacs lakes and the Souris river, located north of Minot, are expected, when completed, to be the most valuable wild life refuges in the United States. In localities where municipalities and rural communities have suffered from shortage of water, wells have been dug to relieve the situation.

The state has organized a Water Conservation Board and the Emergency Relief Administration has co-operated with the board by furnishing technical personnel from the unemployed lists to conduct a state-wide survey of ground water conditions which will be of value in planning a water development programme for the state.

The Federal Emergency Relief Administration feels that the water development and conservation projects carried on under the drought relief programme have not only been of great value in relieving the immediate drought situation but that much of the work is of such permanent character that benefits will continue to be derived for years to come. The value of the crops and livestock saved during the past season have enabled large numbers of farmers to maintain themselves who otherwise would have had to appeal for relief during the present winter. The reduction thus obtained in the relief load will go a long way toward paying the cost of the work. The programme has also provided an opportunity for work to large numbers on the relief rolls, thus enabling them to maintain their self respect by working instead of accepting a dole.

Under the Public Works Programme it is planned to plant a shelter belt extending from north central North Dakota south into the state of Texas. The belt is to be made up of strips of timber a few hundred feet wide placed a mile apart, the entire belt having a total width of approximately 100 miles. It is expected that $25,000,000 will be available for the work during 1935. Planting will be started this spring and it is expected that all of the tree stock available will be planted. Nurseries will be started to supply further stock for the belt.

The National Resources Board has prepared a long-time programme of the development of National Resources that it is expected will be used as a guide in planning for public improvements under plan of Public Works passed by Congress. Congress is now engaged in considering what shall be spent on public works in the immediate future. Final action has not been taken so that it is impossible to advise what authority will carry out the work that is authorized.

The Water Supply of the Prairie Provinces and its Bearing on their Economic Development[1]

DISCUSSION

S. G. Porter, M.E.I.C.—*Chairman*[2]

The criticism is sometimes made that The Institute is indifferent to the actual, the practical economic problems that the country has to meet. However, the arrangement for this discussion should tend to remove any ground for such criticism. The question under discussion is one of pressing economic concern, as well as having its engineering and scientific phases.

All of these papers are on the one general topic of the water supply of the prairie provinces and their bearing on economic development and with the discussions will form an accumulation of data and ideas that should be of practical assistance to our governments or other bodies who are interested.

H. G. Cochrane, A.M.E.I.C.[3]

The problem Mr. Main presents is, not how to grow more wheat, but how to make this area more habitable, and to conserve the investment already made in it, so that it will not eventually be given back to the Indians.

No "blanket remedy" can be applied to the drought area. Different districts require different treatment. Nor can the remedies be put into effect at once, or on a large scale. There must be piecemeal application.

The question has three aspects—social, economic and engineering, and must be considered from all three.

It appears that the various governments at the present time have neither the funds nor the inclination to make an exhaustive study, nor does an undertaking of this kind appear sufficiently attractive to private capital to warrant a private investigation of its possibilities. But viewed as *a measure to salvage investments already made*, the matter assumes a different aspect.

Who are the investors chiefly interested? Primarily, the railway companies, the insurance companies, loan and mortgage companies, grain and elevator companies, the larger merchants, farm implement companies, the larger cities and towns in the drought area. And if the list were broadened to include other bodies interested in the question, the names of the Canadian Chamber of Commerce and the Canadian Manufacturers' Association might be added.

Were these bodies approached, it is probable that all or many of them would be willing to contribute sufficient funds between them to enable a thorough consideration of the question to be carried out. Moreover, by the time such a study or appraisal were completed, it might readily be that the governments would be in a better position to take such steps as might be found necessary and recommended by such a study.

There are almost unlimited sources of information and statistics available for such an appraisal. The universities, agricultural colleges, experimental farms, grain and elevator companies, city water departments, all have statistics bearing on the subject. Crop statistics are available from the railways, and from the existing irrigation districts in operation in Alberta, the Dominion Water Power Branch and the Provincial Natural Resources Departments have available sufficient engineering surveys to form an intelligent basis for preliminary estimates. This collection of data and the consideration of it, could be undertaken and substantially completed in a preliminary way, within a year or eighteen months, with an expenditure of a few thousand dollars. Each of the variously proposed remedies could be considered one at a time, estimates of costs made, delimiting the area under consideration, and an approximate assessment made of the economic and social benefits to be gained. Even the social benefits can be partly valued by determining the amount of "relief expenditure" to be saved. Each project could be examined to see to what extent it might be self-liquidating and how.

The Engineering Institute deserves praise for bringing this question into the limelight of professional discussion. But if it merely draws such comments from its members as "Very interesting problem, someone ought to do something about it!"—nothing much will have been accomplished.

The following suggestion is therefore presented—that a strong committee of The Institute be formed at this meeting, composed mostly of its western members, empowered to approach the bodies above suggested, for contributions, to undertake such a study and

[3] Senneville, Que.

report, within limits made possible by funds obtained, and to circularize any of the profession now in possession of any pertinent information asking their co-operation. Copies of such a report could be made available to contributors and governments, and as much publicity as possible given to the subject, through the daily press, bearing in mind that ultimately governments must provide the funds for whatever is done, and informed public opinion is the only motivating force which will cause such action.

In such a way, The Engineering Institute could materially assist in the solution of a thoroughly Canadian problem of the first magnitude.

C. H. Fox, M.E.I.C.[4]

Most of the major proposals in popular discussions seem to miss the mark and it is important that engineers should stress the necessity for an exhaustive study of the actual benefits which will be derived before any scheme is put into effect.

To refer briefly to the projects. One was the diversion of the South Saskatchewan river, close to Riverhurst, to irrigate or to be distributed over an area of 8,500 square miles, all the way down to the south boundary of Saskatchewan. That project would require a dam construction across a valley 2,000 feet wide, underlain with a considerable depth of sand and silt, at least 200 miles of main distribution with reservoirs, and in addition to that, the suggested diversion of a million acre-feet of water per annum, and elevating to a sufficient height to be used over that area would require a continuous pumping plant of 80,000 h.p. capacity. That is more than the capacity available from the Saskatchewan during a great part of the season and such a pumping plant would therefore require a capacity of about 200,000 h.p. to do the work successfully.

The elevating of such large quantities as suggested in the Riverhurst diversion is an expensive undertaking. A less ambitious plan might be to make the diversion near Elbow, following the old overflow course down the Qu'Appelle.

With regard to the suggested impounding of Buffalo Pound Lake from Moose Jaw creek area. It seems strange to suggest letting water flow out of Moose Jaw creek area and impounding it in Buffalo Pound Lake, and at the same time to suggest diverting the Saskatchewan and elevating water three to four hundred feet to be used in the Moose Jaw creek drainage area.

The total precipitation on the average in most farming districts if conserved is sufficient for ordinary needs. The difficulty is that a good deal runs off at times when there is an excess. The important thing is to retain this moisture actually on the farms. The impounding of run-off in the beds of creeks is of secondary importance, while the creation of lakes at the low levels of major stream beds is of little value.

The development of at least one or two ponds on every farm surrounded with shelter belts of trees should be encouraged. To reduce evaporation losses such ponds should be as deep and of as small an area as local conditions and cost of construction will permit.

Mr. Main's paper showed some interesting charts on temperature, but those charts were all prepared on data obtained in cities or places where the amount of radiating surface had possibly increased during the period under consideration. Has that increase in temperature been general throughout the prairie lands?

P. C. Perry, A.M.E.I.C.[5]

Mr. Main has rendered a service to the prairie provinces through his efforts to arouse public interest in conservation; however, on some points our opinions differ. His introductory remarks would imply that drainage work on the prairie is to be condemned for its adverse effect on climatic conditions, while conservation schemes may be justified, in part at least, because of their value for ameliorating climate. Those who have studied the matter carefully believe that such an attitude should not be entertained in a study of conservation.

Mr. Main states "It is an axiom of climatology that the ratio of water to land has an important effect on climate. The natural corollary is that an acre of water or marsh, in a semi-arid region, must be more valuable than an acre of high class wheat land." This is quite a sweeping statement which should not be accepted unless clearly supported by the opinions of outstanding climatologists or from evidence from actual conditions. We do agree that climatologists dwell on the importance of the ratio of land to water in as far as great land masses and oceans are concerned. Mr. C. E. P. Brooks* refers to the effect of land masses as "continentality" and all writers on climatology refer to the inland type of climate as "continental." Some writers do refer to the effect of large bodies of water but the outstanding works on meteorology and climatology do not support Mr. Main's statement. Ocean currents, prevailing winds and mountain ranges are shown to be factors which far overshadow other local conditions. Mr. A. E. M. Geddes† writes "the chief factor in determining the distribution of precipitation and also of humidity is the prevailing wind system."

[4] Engineer of Water Service, Canadian Pacific Railway Company, Winnipeg.

[5] Division Engineer, Canadian National Railways, Regina, Sask.

* "Climate Through the Ages."

† "Meteorology," page 380.

A study of actual climatic conditions supports this stand. In Florida, a peninsula projecting into the Atlantic, humid conditions prevail with annual precipitation of 50 to 75 inches. In the same latitude on the other side of the continent, the peninsula of Lower California projecting into the Pacific has an annual precipitation of 10 to 25 inches and near desert conditions.

It is certain that our prairie aridity is due primarily to the presence of the mountains and the prevailing westerly winds. Conditions which bring about the precipitation of the moisture in the air, seem to be more important to us than the conditions which put the moisture there. This is shown by the way precipitation is increased by hills, where in some cases it is 75 per cent greater than on surrounding prairie.

To make clearer the natural conditions of our sloughs and lakes, the behaviour of one large slough under observation will be described. When the G.T.P. railway line from Regina to Northgate was constructed in 1912, it passed through what was described as a "dry lake bottom" near Lampman. In 1916 this slough or marsh partly filled but the water was not retained. It was dry again until 1922 when water began accumulating. The areas and depth increased until 1927, the maximum water surface being an irregular area of about 3,000 acres. It was necessary to raise the railway grade considerably and place riprap, while some highways were abandoned. The water began to recede rapidly in 1928; the entire area was dry again before the end of 1930, and has remained dry since that time. Drainage or other artificial factors had nothing to do with the disappearance of the water from this slough.

This sort of behaviour is typical of thousands of sloughs and marshes of various sizes and many lakes. The lakes containing considerable deep water are not so greatly affected and the larger ones do not disappear entirely.

It is the writer's conviction that the drainage of such areas, where local benefits justify, does no harm to the country in general, and that the forming of additional water surfaces of this kind will not be of general value. The natural slough or lake usually forms in a wide shallow depression of saucer shape and an attempt should be made to substitute reservoirs of "cup" shape. This will mean less water surface during wet years, but reservoirs which will stand the drought periods.

Even from the standpoint of providing dependable breeding grounds and resting places for water birds, one may be justified in draining some areas while at the same time constructing artificial lakes or ponds. For both drainage and storage, one need not consider effect on climate but each proposal should be judged upon basis of direct and tangible benefit.

Surface water conservation projects may be divided into three general groups: First, the small units on local streams, such as private and municipal reservoirs. Second, larger units on local streams such as the Buffalo Lake and Souris river schemes. Third, the still larger schemes dealing with the diversion of water from the Saskatchewan river.

Mr. Main's recommendations in his paper deal with the second and third classes, but at other times he has shown the possibilities of the first class. His mention of the inferior standard of living of rural populations should also be noted, the need for water for all citizens and the desirability of providing work in rural areas, all point to the local units as the type of work which should be given preference. Provincial and Dominion legislation controlling water stipulates that domestic requirements which include water for farm stock, are to be considered first in allotting waters and the justice of such a provision is self-evident. This too would indicate that the small unit development for use of local waters must be given first place. Prior use is, and should be, a claim recognized and the supply of water for those lakes which are now improved and in use should not be restricted because of the development of other projects unless the purpose for which the water is to be diverted is much more important.

In regard to cost, it should be remembered that labour should be employed on those undertakings which will be of greatest value to the country. If the situation is carefully studied with the foregoing principles in mind, it will be found that efforts should be confined chiefly to the small unit programme, that many of Mr. Main's larger proposals are not feasible and that work on others must be deferred for many years.

E. M. Proctor, M.E.I.C.[6]

S. G. Harding, Professor of Engineering in the University of California states* three things which have a bearing on this subject and may be summarized as follows: First, within tne last thirty to sixty years the Great Salt Lake area in Utah has apparently experienced the most moist period of the last three hundred years. Second, the last one hundred years has been continuously more moist than the preceding one hundred years. Third, the period of deficient water

[6] President, James, Proctor and Redfern Ltd., consulting engineers, Toronto.

* The Civil Engineer, February 1935.

supply since 1917 has not resulted in as great an accumulated deficiency as in the past.

This may indicate that possibly conditions in Canada may still become worse.

C. H. Attwood, A.M.E.I.C.[7]

Premier Bracken has taken a keen interest in the drought problem. In fact, he has stated* that "The spectacle of shortage of food in large farming areas, and the necessity of shipping livestock away from hitherto prosperous and productive communities, and of shipping in thousands of carloads of feed for animals and scores of carloads of food for human consumption, in order to prevent widespread distress and abandonment of land on a wholesale scale—this spectacle is not a pleasant one to contemplate, and one that you and I and two million others on these plains must try as far as possible to prevent in future." . . . .

"If we are not to witness similar distress at recurring periods in the future, we must pool our brains and our experience, and in the light of past history, formulate such policies and execute such plans as will adequately meet the contingencies, which are sure to arise occasionally in the future, just as they have in the past." . . . .

"Is it better, as some have said, to let time and economic conditions determine the future of these areas at whatever price in abandoned farms and disappointed human lives? Or can we rehabilitate the vast areas now temporarily in a state of partial desert? Can we prevent a recurrence of these conditions? Can we avoid the still further encroachment of the drought area upon adjoining lands?

"These are vital questions which challenge the practical wisdom of this generation. They are a challenge to our scientific skill, to our statecraft and to our administrative ability. They are a challenge to you and to me and to half a million others directly affected in these areas."

Mr. Bracken says further: "That in approaching such a problem, it is essential first to discover the basic facts. Unless this is done, faulty conclusions are sure to be drawn from wrong premises. Opinions and hopes are a poor foundation upon which to build a structure expected to stand the storms and vicissitudes of a dry and somewhat variable climate."

He also observed that: "In my judgment some of our forestry policies, some of our drainage practices, and some of our soil management and cropping methods need reconsideration and redirection in the light of the apparently increased danger of drought.

"We have been cutting trees and burning forest; we must plant trees and protect the forests. We have over-drained some of our lands; we must commence to regulate and maintain the water table rather than to lower it further. We have tilled some of our virgin soils until we have injured their texture; we must modify our tillage methods now, having their altered condition in mind. We have ploughed some soils that should never have been broken; we must correct that error and prevent as far as possible its repetition."

In dealing with this it is suggested that: "The reclamation programme should provide for a thorough survey of the area affected or likely to be affected. Such a survey should include a soil survey, a topographical survey, a survey of the native vegetation, a survey of the precipitation, temperature and other climatic records, and a review of the record of agricultural production. The report should be accompanied by specific recommendations regarding agricultural production plans for each separate soil zone.

"The reclamation programme should also provide for the creation of forest or grass land reserves on any obviously inferior land areas; it should provide for tree planting for protective purposes on the open land; it should provide for the construction of dams in streams, wherever economically feasible, and it should provide for the construction of dugouts for water storage purposes on lands where stream water is not available and where well water is not obtainable or is for any reason unsuitable. It should provide for an intensive programme of education on the best methods of soil management and crop production in areas of low precipitation and where the soil is likely to drift. It should emphasize the necessity of saving the run-off water and of lessening evaporation and wind velocity."

This is a problem that needs very careful study by all scientific men—scientific agriculturists, physicists, and so on, gathering together the knowledge that is available from these sources, and that you may make an historical review of the droughts that have occurred in the past ages. Having made this study of all the facts that can be obtained, having analyzed all the information, then decide on what the plan should be and what the programme should be for the reclamation or protection of the drought area. When the plan is made it is then time to start on the work and as the work is done, each piece becomes a unit of the final completed scheme.

John Patterson[8]

From some of the remarks that have been made it would appear as if there is an idea that the proposed conservation methods will affect the climate of the province or country. It may be well to point out therefore, that the climate in any place or region is made up of the average weather conditions that prevail from day to day or even from hour to hour. The weather at any particular time and place is dependent upon the operation of world wide forces, and consequently it would be impossible to change the climate of the place by any conservation methods that might be adopted.

With regard to the creating of reservoirs and dams, etc., for the storing of waters, it would appear from the paper dealing with the mineral salts contained in the water that there might be a concentration of salt sufficient to render the stored water unfit for use. Possibly this is not a problem in the areas involved, but at the same time it is one that should be carefully examined before the reservoirs or dams are constructed.

Mr. Main in his address pointed out that there was a gradual increase of temperature in certain places in the west. This however is not only characteristic of the west, but has been noticed in eastern Canada and in many other places. It seems to be a world wide movement, and there is no doubt that in other regions the reverse is taking place. The mean temperature over the world is probably very constant and these fluctuations at different places will in the end balance out.

T. C. Main, A.M.E.I.C.[9]

The large amount of discussion of this paper is believed by the author to indicate the tremendous interest taken in this serious national problem. This is a source of satisfaction as the chief object of his paper was not the solution of a problem forthwith, but rather to stimulate interest, study and discussion so that in time a satisfactory formula might be found.

Adverse criticism in general may be summed up under two heads, i.e. (1) Denial that conservation of water and planting of trees and hedges will have any effect on climate, and (2) Belief that we cannot afford to carry out some of the larger projects suggested.

Regarding the first, it must be stated that there was no intention of suggesting that conserving water and planting trees and hedges would have any considerable effect on the general climate of the country. There is plenty of evidence, however, to show that water, trees and hedges do have a marked and beneficial effect on plant life within a comparatively narrow radius of influence and therefore must effect the microclimate with which plant life is so intimately associated. In the case of trees and hedges (and particularly the latter) this is due first to a reduction in wind velocity to a distance of approximately 20 times the height of the hedge on the lea side and 5 times the height on the windward side. With a reduction in wind velocity comes a reduction of evaporation and hence more moisture for the growing crop. In addition of course some snow is trapped during the winter and this again means more moisture and heavier yields.

In the case of water areas, vegetation is benefited by the maintenance of a higher water table thus making moisture available to plant life around the perimeter of lake or reservoir. The chief reason for impounding water of course is for the more obvious reasons given in the paper itself.

Regarding the second major criticism, i.e., the economic problem involved in the construction of some of the larger proposals, it is admitted that some of these projects cannot be justified by our present economic theories. It is perfectly evident, however, that these theories at the moment are being subjected to the most critical inspection they have ever undergone. It seems probable that the apparently static quality of the current depression primarily is due to the fact that problems are considered chiefly from the financial point of view. In the present case the fact that sufficient men-days have been wasted during the past five years to complete all the projects involved seems to be entirely ignored, and it would seem to be of primary importance.

It seems probable that eventually a system will be evolved whereby only two criteria will decide whether a given project should be constructed or not, i.e. (1) Will the proposed works be of sufficient social benefit? and (2) Is there sufficient surplus labour available to insure completion of the project? If the answer to both of these questions is in the affirmative the project will be constructed.

This philosophy appears to be the only justification for many of the larger projects under construction in the United States at the present time. Judged by our current economic theories many of these projects are shown to be unsound* and therefore should not be seriously considered. Surely it is far more unsound to have millions of able-bodied man, willing and anxious to work, on the relief rolls? It would seem that this is another national problem that might be studied by the members of our profession with benefit to our country and ourselves.

Again, the chief reason for suggesting a large number of projects was not the desire that they should be undertaken forthwith, but rather the hope of stimulating interest in water conservation in general, to the end that our water resources might be thoroughly studied and plans evolved for scientific conservation and use of our second most important natural resource.

F. K. Beach, A.M.E.I.C.[10]

Mr. Main has presented the results of careful study and research in his Figs. 3 and 4. It is news to many and to the writer that there has been a progressive and long time increase in mean temperature. The general agreement among numerous widely separated stations is too consistent to be attributable to local vagaries, while the consistently increasing curve rather washes out speculations as to mutual effects between temperature and evaporation.

Whether there has actually been a 20 per cent increase in evaporation concurrent with a 4-degree rise in annual mean temperature is somewhat problematic considering how closely evaporation is tied in with per cent humidity of the air and freedom of movement of air over a surface of evaporation. Some years ago the writer made a study of an irrigation reservoir, measuring all water passing in and out during the season, collecting rainfall records and carefully estimating natural inflow, and making an allowance for evaporation based on an experimental evaporation pan a few miles distant. In the course of the enquiry into evaporation data, it was found that records were being obtained in a second pan not far distant, but the records were not at all comparable. Temperatures and air humidity were quite comparable, but at the second pan a shelter belt of trees had grown up and over a period of four or five years this tree growth had most strikingly decreased the evaporation rate. Since over most of the prairie where drought has become an increasingly serious problem there has been no general increase in magnitude of windbreaks, one is inclined to put considerable weight on the progressive increase in temperature as a contributing factor in drought conditions, and this fact finding is distinctly to Mr. Main's credit.

Respecting the plotted relation between sun spot numbers and run-off, the writer is interested but doubtful as to the acceptance of any easily formulated relation applicable to the prairies in general. It might be suggested that it was merely a chance that the Red river at Emerson was selected for comparison, for if any stream rising in the Rocky Mountains and flowing eastward had been chosen, the picture would have been different. To quote only one year, 1915 was just an average run-off year in Red river, but it was a maximum year in all the mountain tributaries of the Saskatchewan river. The rainfall was heavy eastward as well, and numerous fields produced 65 bushels of wheat per acre around Swift Current, Vanguard and Gull Lake. The prairie farmer would very much like to know before seeding time whether rainfall is likely to be adequate for a crop. If there is any way of foretelling this, by all means let us have it, but it is to be feared that this is not possible. That there may be a relation for various localities between sun spot number and rainfall is just possible. In connection with both relations shown, that is, progressive temperature change and sun spots, it is of interest to note a publication by the United States Geological Survey.*

Varves are deposits of mud laid down in still water which by alternations of colour indicate spring freshets and summer inflow and thus become analogous to annual rings of tree growth. Since the thickness of each layer is proportional to run-off, they give a long time record of inflow to the lake where they were laid down. This author in studying the Green river formation of Colorado, Wyoming and Utah, found three cycles of run-off suggested. One cycle appears to have the frequency of sun spot numbers, but the interval between maxima varies from seven to seventeen years. A second cycle appears to have a frequency of about fifty years, while a third cycle corresponds with the precession of the equinoxes or about twenty-one thousand, six hundred years.

Under the heading "Utilization of Water" Mr. Main suggests "an ideal arrangement would be to provide water under pressure" at intervals of two miles, and contemplates such water in quantities sufficient to irrigate 15 to 25 acres per quarter section, as well as for other domestic purposes. That picture might well have been amplified as for the Riverhurst proposal alone this would call for steel pipe on the order of half a million tons. With this business in sight one could possibly have a steel industry in western Canada. Think of the men that would be put to work in British Columbia mining and smelting camps, in Alberta and British Columbia coal mines, in railway train service. Clothing—overalls, boots and gloves—would boost eastern Canada's factory output, and how many others would indirectly benefit.

But——who pays for all this programme? It is only when the economics of the proposal are reached that difficulties are encountered. In Alberta when wheat was worth $1.50 a bushel, it was known that the farmer could not afford to irrigate wheat. When other prices were on a par with $1.50 wheat, the irrigation farmer was hard put to it to find $100 a year for water rights on 40 acres. Can a farmer on a quarter section with 15 to 25 acres of hay watered be expected to find any more than $100 or $200 a year for water? In one irrigation scheme in Alberta where there was no extraordinary engineering structure to build up the cost, where the water is carried in earthen canals cheaply and quickly to the user, where soil conditions and climate are as favourable as can be found in the Canadian prairies, capital charges have all come from public revenue.

The psychological factor cannot be ignored. An irrigation scheme is not expected to yield a profit. Therefore its bonds will not be purchased by a person who has savings on which he wants interest with security. If the scheme is larger than a very small project, it must be financed from public credit, and once it is so financed the water users organize themselves to resist paying. Where a bank or mortgage company would evict and put in a new tenant, the water users make a political issue of all efforts to collect. With this general premise, it is therefore suggested that before recommending so large a scheme as the Riverhurst proposal, or the William Pearce project, it should be suggested to the sponsors that they must expect to supply all the capital cost without hope of repayment, that they be prepared to maintain and operate the scheme in perpetuity without ever recovering more than a fraction of the cost of operation, and in all probability they may be called on to subsidize crops raised by the water supplied.

The writer feels that it is hardly fair to ask the farmer in humid parts of Canada to subsidize the drought areas to compete with him, and if the farmer in humid areas is not to contribute, many other classes dependent on him must be exempt. If it was certain that by constructing vast water supply systems lasting prosperity might be brought to the whole of Canada, a demand could be made that the farmer of humid districts and those dependent on him waive their objections to such subsidizing of the drought areas. Major Duncan Stuart, K.C., of Calgary, in a recent pamphlet*, shows that Persepolis was built in a steppe resembling our Canadian prairie, and that pulverization of the soil from farming operations coupled with a rainfall that could not be depended on, ended in shifting dunes and total desert. If the financial support of the Ontario farmer is demanded to pipe water widely over drought areas, or to lead it in canals, and then it is found that soil drifting has merely been invited, have engineers been true to their creed?

If wholesale reclamation is condemned, what can be recommended? The answer is not simple. No one answer can be given offhand. It does seem certain, however, that the desert or semi-desert of our drought areas must call for a culture of living as well as a culture of land which differs from the habits of humid areas. The wheat farmer expected to work sixty days in the year. That is out. Much of the drought area must go back to grass and grazing. Small reservoirs easily constructed from simple labour can be developed. In Alberta considerable progress is already under way along both these lines. Control of water well drilling and a kindly, scientific guidance in the individual efforts of the inhabitants who choose to remain, will help to develop ground water supplies where they are available, and prevent to some extent any over exploitation of this valuable resource, or its contamination or dissipation from bad drilling practices. Permanent retention of geological personnel and co-ordinated records of water wells would not be costly and Mr. W. Calder has made a suggestion along this line.

To summarize, the mean annual temperature has been increasing over a cycle greater than the cycle of sun spot numbers. Possibly it is on the turn and may be a 50-year cycle that will in a few years decrease natural evaporation to a point where crops can again be raised, but this is not definitely known as yet. Wholesale reclamation is bad from a psychological standpoint, and probably bad from a soil drifting standpoint. Small reservoirs to delay run-off and thus encourage retention of moisture in the air can properly be sponsored but they should be done by local effort. Well drilling should be supervised and guided by geological advice and records. Much of the drought area must go back to grazing, and those who remain on the land must adopt a culture suited to the climate in which they live. Those who demand a higher standard of living than the climate will support should go to a climate that will support the standards they set for themselves.

F. W. Caldwell, M.E.I.C.[11]

Premier Bracken's views as described to the meeting must command attention of all members of The Institute and economists and physicists. Here is a great opportunity for engineering activities in planning for the future of the prairie provinces. To set out all their natural resources is to plan for all Canada. Now in the United States there are forty-one State Planning Boards, besides two Regional Planning Boards, one of the latter being the Mississippi Valley Committee. Preliminary plans for a state may cost from $50,000 to $75,000 at the present time. This small amount of money will be made up by the saving of a few farms from bankruptcy or even be disposed of in the water supply of only one small town. These boards plan for the economic whole of a province or district and not only for water or weather. The entire natural resources are considered.

In the report of the Mississippi Valley Committee of the Public Works Administration, information is found as to the lowering of ground water from 10 to 20 feet in North and South Dakota and special comments on artesian well laws. Areas of the Hudson Bay basin below the international boundary are shown in social and economic status as well as in water supply classification. This report states the Red

[10] Petroleum Engineer, Petroleum and Natural Gas Division, Department of the Interior, Edmonton, Alta.

* "The Canadian Desert."

[11] New York State Planning Board, Albany, N.Y.

river of the north valley is from 30 to 50 miles wide on either side of the river (referring of course to the portion in the United States). The valley is a flat surface of alluvial soil left in the basin of geological lake Agassiz. The mean annual precipitation is 20 inches. A land use plan must consider this valley subject to the humidity of the east and the aridity of the west. The problem is to adjust the most favourable relation of factors included in this climatic area.

The Red river receives waste from Wahpeton, Fargo, Morehead, Grand Forks and lesser cities. At Grand Forks, with a drainage area of 25,000 square miles, it reaches a volume of 43,000 cubic feet per second or about one tenth the flood flow of that of our eastern streams with the same watershed area, but in October 1932, the flow was only 13 cubic feet per second and it became an open sewer. In the winter it freezes to the bottom. A careful balance between uses of surface water, underground water, and drainage must be maintained. This river is, of course, in the eastern edge of the dry climate section, but it is also important on account of having such large portions of its basin both above and below the boundary line between the two countries.

The assembling of maps of the entire arid area, all drawn to one scale so they can be readily superimposed for study, would be a progressive step. In Mr. Main's paper are two maps and in Messrs. Perry and Johnson's one each. It is to be hoped that more information can be collected and presented at future meetings of The Institute on this important subject, which is really basic to the planning of a very large portion of Canada's future.

E. F. Chandler[12]

An enthusiastic desire to endorse almost every statement in the paper by Mr. P. C. Perry is aroused in the study of it by anyone who, like the writer, has had for thirty-two years detailed continuous knowledge of the behaviour of all the typical surface streams in the region adjoining on the southeast, the entire state of North Dakota and considerable surrounding area. In this district many of the rivers have conditions similar to the district described in Manitoba, Saskatchewan and Alberta; and one river station in particular, maintained for more than thirty years at Minot, North Dakota, is on one of the streams listed, the Souris river, where it loops south into North Dakota.

If there is no difference in opinion from the statements made by the author, perhaps it is superflous to discuss them. But mention may be made of the excellent agreements in our figures. In North Dakota, a prairie region where the average annual precipitation is about 20 inches at the eastern end and 15 inches at the western end, the long extended records have shown for all the streams rising within the state average annual run-off of less than one inch, and for those most closely resembling such Canadian streams as the Souris an annual run-off from a quarter inch to a half inch.

For the ordinary gross evaporation to be expected from average lake or reservoir surface, the writer's own figures are 33 inches for each twelve-month period. For evaporation and vegetal-transpiration from land surface in this region, 20 inches per year if as much as that is supplied by precipitation and is thus available giving "evaporation opportunity."

In this region run-off cannot logically be considered as a percentage or fraction of the annual precipitation; although its amount is so small as in most years to be only between one and five per cent of the rainfall; but it is really not a fraction but a remainder, after evaporation has taken away 20 inches or thereabouts if there was opportunity.

As rainfall is usually less than 20 inches, the run-off is merely such accidental portion of precipitation as runs off quickly from sudden storms before it can be clutched by the dry soil or taken by evaporation, or as flow off in spring when deep wet snowdrifts melt quickly or when the soil spaces are largely sealed by frost, or under other special temporary conditions. This run-off is usually merely a very small portion of the local precipitation, likely to be almost inappreciable except in early spring. On such streams in many of the years more than half of the total annual run-off passes within two or three weeks of the spring.

The total amount depends therefore so much on accidental local temporary conditions that it is difficult here to set definite figures in prediction of floods more than a few days in advance. Most predictions are merely rough guesses.

The variation between different years is very great. For example, on the Souris river at Minot the total flow of the worst flood year recorded, 1904, was about a hundred times as much as the total flow for the twelve months of 1915, although 1915 was not a so-called drought year; it was merely a year in which the total rainfall was slightly deficient because it included no heavy cloudbursts, but was composed of well-separated gentle rains giving a reasonably good supply for agriculture. And in some of the recent years of extreme drought the run-off has been still smaller.

Nevertheless there is some flow every year, and in occasional years a large flood. Hence such storage projects as recommended by the author are very desirable. The reservoir storage may be a ridiculously small fraction of the total annual precipitation, but it can easily be a very considerable portion of the total run-off even of a "flood year." Besides lessening to some slight extent the danger of flood-injuries along the valleys below, such reservoirs hold for the general benefit of the region a part of the run-off from one month to the next or one year to the next, into the dry seasons, providing a permanent supply that is in many ways very advantageous. One of these benefits that at first thought often escapes attention is the ease with which trees can be grown near such reservoirs, totalling a very considerable acreage which may add greatly to the comfort or enjoyment of life for all in the neighbourhood.

The benefits of such reservoirs, smaller or larger, in the prairie regions are so many that their construction ought to be encouraged wherever feasible.

J. W. D. Farrell, A.M.E.I.C.[13]

Mr. Main's excellent paper should have a tonic effect on the most discouraged dweller of the southern prairies, and also put fresh energy into those vigorous persons who are determined to find ways of making the next drought less devastating. If the indicated improvements in climatic conditions materialize, it is to be hoped that the almost certain prospect of a return of drought conditions in ten to twenty years will not be overlooked. If an incentive to prepare against drought is needed, the author provides it in pointing out that remedial measures are also those needed to bring ordinary living conditions in rural communities up to a more tenable standard.

The author's data showing that climatic conditions productive of drought occur in recognizable though irregular periods are a valuable feature of the paper. In looking at drought conditions of the past few years, it must not be overlooked that the climatic records show that periods of three or four years of low precipitation are separated by much longer periods of sufficient moisture. That is, drought is the exception and there are now several years in which to adopt measures which should greatly moderate the effect of the next drought. It should be particularly noted that Mr. Main does not claim that remedial measures will change the climate but will moderate its effect. A personal recollection of previous periods of low precipitation shows that some of the worst features of the recent drought, such as soil drifting, were absent. Recovery was also more rapid. The waste of surface water combined with heavy cropping have undoubtedly made the recent drought far more serious and prolonged than previous droughts.

In attempting to discuss some features of the paper, one is almost irresistibly drawn to the economic side of the question and not without reason. In the area affected there is a capital investment of millions of dollars represented by railways, elevators, highways, telephone systems and all the buildings and appurtenances of the cities, towns, villages and farms. In the past, this area has produced a great deal of wealth. On the human side there are thousands of people living in the area. The economic and humanitarian reasons for adopting suitable measures of rehabilitation are more than sufficient. An important item in any such measure is certainly the conservation of water resources.

World economic conditions should assist the plan for water conservation. A limitation in our exportation and therefore in our production of wheat is a recognized situation. Reduced production means less acreage so that the land needed for water storage can be readily yielded. With more water available more livestock may be kept and land needed for pasture and fodder crop would further reduce the wheat acreage, and the area subject to soil drifting. If the area under consideration is due for a shrinkage both in population and production, it will surely be better that readjustment take place along organized lines, retaining the occupants of lands that can be reached by the proposed improvements and assisting others to move.

Those paragraphs of Mr. Main's paper under the heading "Economics of Rehabilitation" should be particularly arresting to the attention of taxpayers and governing bodies, alike. If the present financial system is not capable of providing the necessary funds to float useful work projects to completion, then there is need for reform. Money and credit should be recognized as a utility and administered as a government monopoly.

Turning to the engineering features of the paper, it is interesting to note that irrigation is not intended in the usual sense of the word. Instead of supplying water to field crops in a large way during the growing season, the term as Mr. Main uses it, indicates the provision of limited quantities of water for some crops and the year round provision of water for human and animal consumption. In a country that can already produce more wheat than it can sell, there would be no justification in an irrigation scheme for producing still more wheat.

In considering water conservation by the means suggested, mostly by surface storage, one must beware of expecting too much. In regulating spring flood conditions on a recognized water course, much

[12] Professor of Civil Engineering (and Dean-emeritus College of Engineering), University of North Dakota, University Station, Grand Forks, N.D.

[13] Superintendent of Waterworks, City of Regina, Sask.

tact and care would be needed to avoid depriving the lower part of a water course of what might be considered its rightful supply. The spring flooding of a hay flat, wasteful though it may be, could not be replaced by the gradual flow confined to the stream bed during the summer.

Many of the proposed reservoirs would not survive a prolonged and severe drought such as that of 1928 to 1931 but they would do much to better conditions between droughts and would likely survive short droughts and shorten their effect. For these reasons and for the improvement to living conditions between droughts, they would be well worth while.

As an example, Wascana Lake is an artificial lake, mostly in the city of Regina; it has an area of some 200 acres and is supplied by the run-off from quite a large watershed. In June of 1928 rain was very plentiful and the lake was full. In 1931 it was necessary to conserve all the inflow in the upper third of the lake for the benefit of the city power house, and by the fall of 1931, the lower two-thirds of the lake was so nearly empty that the remaining water was run out and the bottom of the lake was cleaned and deepened. In 1932, although precipitation was above the average, the lake was only partly filled and it was not until the spring of 1934 that the lake was again full to the spillway. During 1929 and 1930, some water was used from the lake for sprinkling the adjoining parks but none was available for running down stream. If there had been any irrigation scheme dependent on this lake, water taken for its purposes would have hastened the day of the lake being empty. During the minor drought of 1917, 1918, and 1919, Wascana Lake did not go dry. The experience of Wascana Lake during 1928 to 1931 was duplicated to a less degree at the Canadian National Railways reservoir near Condie.

John C. Hoyt[14]

The paper by Mr. L. A. Jones on water phases of our drought relief programme indicates concisely conditions in the United States. The indications are that as droughts are liable to occur at frequent intervals, damages from them can be arrested only by adjusting development, both as to extent and character to available water supplies. This will require more detailed studies of available supplies and of the possibilities for their conservation and use. As the disastrous effects of droughts, in the main, relate to agriculture, the problem will require special studies as to the fitness of land areas to various types of agriculture. In fact, it is largely a land use problem.

D. A. R. McCannel, m.e.i.c.[15]

The extent of precipitation is not as important as the time of year during which it occurs, in so far as its effect upon cereal crops is concerned. Cereal crops have in the past, and will continue in the future, to be the main crop for the prairie provinces. Frequent moderate rainfall during the growing season—June and July—will provide for the production of a normal crop and the benefit of such conditions were borne out by the bumper crop of 1916. The increasing daily mean temperature, referred to by Mr. Main, may not seriously effect the evaporation of useful moisture for cereal crops provided the rise in temperatures are experienced during the winter months, and such is largely the case. Under such a condition, the increased rate of evaporation of 21.6 per cent may not seriously affect the crop yield.

Concerning the use of water—in the past the tendency in farming has been towards larger holdings, and with cereal crops remaining the major product, this tendency will continue assisting the farmer to combat low prices, by reducing his overhead and cost of production. Such a tendency would not appear to demand an increase in the use of water by the rural areas.

Irrigation will result in intensive farming and would appear to be limited to restricted areas where the cost must be comparatively low. The utilization of water delivered through pipes appears to be prohibited from a cost standpoint. With the excessive low temperatures demanding expensive construction to overcome liability for frost and the high cost of long life pipe, the use of water delivered through pipes would be on a very restricted scale.

Mr. Main has outlined the economics of rehabilitation and to utilize this potential power to the full, the writer would suggest the first step be towards conservation of water by the construction of a large number of small works or dams, which should be located close to the potential power available, and would be of immediate and direct benefit to those adjacent to their construction. Engineering advice on their location and construction should be sought and provided. Such local works could be scattered throughout the drought area and could be undertaken with a minimum of time for preliminary work. The large projects suggested for consideration have received some study, but many of them are of such magnitude as to demand considerable further detailed study of their possibilities and costs before they should be undertaken. Those that are found to be advantageous will demand time and expense for investigation and acquiring of property, and the time required to get them under way might prevent the possibility of utilizing the potential power now available. Works providing the greatest good to the greatest number should be a primary consideration, and small projects which include dams and reservoirs, including dug-outs, should be the first undertaking, and would utilize this potential power to the best advantage.

[14] Hydraulic Engineer, Geological Survey, U.S. Department of the Interior, Washington.

[15] City Engineer, City of Regina, Sask.

C. J. McGavin, a.m.e.i.c.[16]

There appears to be a great tendency on the part of recent investigators to prove from the established eleven-and-a-quarter-year cycle (sun spot data) the effectiveness of this cycle in relation to terrestrial phenomena.

The writer made a study of comparison of run-off and precipitation records for seven stations, viz.: Winnipeg and Brandon in Manitoba; Qu'Appelle and Battleford, Saskatchewan; Medicine Hat, Edmonton and Calgary, Alberta; for the thirty-year period 1891 to 1920, with the Winnipeg records dating back to 1872. Normals were arrived at and the percentage of precipitation for each based on normals was analyzed with the following result.

Only during the four years 1898, 1901, 1911 and 1916 did the records show increased precipitation over the normal at all seven stations. Only during the five years 1892, 1894, 1910, 1917 and 1918 did the records show precipitation at all stations below the normal.

By applying all the experience gained from the practice of jig-saw puzzles and with the defined purpose of making "The Punishment Fit the Crime" it was impossible to prove the relationship of our precipitation records to the cycle.

The study suggests, however, cycles of wet and dry years, which do not correspond for different parts of the three provinces, local variations occuring at comparatively short distances with no exact ratio between the precipitation at one point and the run-off conditions.

It was further found that forecasting on the basis of the data obtained shows:

That three years as dry as 1919 may be expected in a period of thirty-nine years, i.e., one year in thirteen.

That five years as wet as 1916 may be expected in thirty-nine years, i.e., one year in 7.8.

According to Dr. W. S. Adams, Director of Mount Wilson Observatory, there is evidence of a correlation between cycles and atmospheric temperatures, but further than that he is reluctant to go. An examination of records appears to show lag and distortion. The warm years of 1921 and 1922 show synchronizing with the 1923 sun spot "low."

Mr. Main has apparently found correlation with the eleven-year cycle and stream flow on a Manitoba stream.

In considering the years of maxima sun spot data shown on Mr. Main's report, 1883, 1893, 1905, 1917, 1928, 1938, it is found that, while they are no doubt conscientiously chosen, even the sun spot data has a tendency towards elasticity with different investigators. J. W. Shuman, Minneapolis, chose the years 1861, 1871, 1882, 1893, 1906, 1918 and only in the year 1893 does the maximum harmonize with Mr. Main's.

The writer found that, where the Red river, studied by Mr. Main, showed a steady decrease in discharge from 1927 to 1933, the Churchill river records show a decided yearly increase during the same period. It would therefore appear advisable as suggested by Mr. Main to give further study to the subject before accepting his interesting results.

In order to secure consistency in estimate of run-off the period 1911 to 1920 inclusive was chosen tentatively as a standard decade. The assumption that the period will give a true normal is based on a comparison of long term precipitation records as follows:

	Calgary	Medicine Hat
Normal annual precipitation for period of 30 years..................(Inches)	15.84	12.91
Mean annual precipitation for decade 1911 to 1920 inclusive...........(Inches)	15.44	12.71
Percentage..........................	97.5	98.5

Verification was also made with long term precipitation records at Edmonton, Qu'Appelle, Grenfell and Swift Current. The general average for Alberta and Saskatchewan, respectively, shows that the decade is practically the same as that for the long term periods.

The adoption of the period has given generally satisfactory results, but hydrometric records show that a term of fifty to sixty years is necessary in connection with expected flood discharge for the design of large expensive structures. Until further records are obtained it will be necessary to assume certain relations between the maxima for ten, fifteen and thirty years respectively based on a comparison of available data.

Stream records when supplemented by the use of lake levels and precipitation indicate that the areas of very high and very low run-off in any one year are probably smaller than might be assumed from the stream records alone. There is therefore, a limit to the safe use of the ordinary methods of correlation, as direct stream records only cover a relatively small portion of the provinces.

[16] Water Rights Engineer, Department of Natural Resources, Government of the Province of Saskatchewan, Regina.

Studies in connection with maximum run-off show that stream records do not indicate the potential maxima or even a constant proportion of such maxima. The maximum rate per square mile of drainage area varies considerably according to size and shape of the drainage basin, as referred to later, so that true or consistent coefficients cannot be obtained by merely dividing the flow by the discharge area.

Streams even in flat country are likely to experience unprecedentedly high potential maxima. Some progress is being made by the writer in preparing maps showing the run-off for the areas in the different drainage basins.

Davis creek draining south-east from the Cypress Hills shows the heaviest run-off south of the bush country being 165 acre-feet to the square mile and Eyehill creek near Yonker the lowest with 2 acre-feet per square mile.

In estimating losses from lakes and reservoirs in the prairie provinces where it is necessary to use fairly close estimates of evaporation it is found that with the relatively few summer records the normal depth of evaporation in inches per year corresponds approximately to the mean temperature over a number of years. As a result the method of estimating the mean temperature by altitude and location when actual records are inadequate gives fairly satisfactory results.

Local variations of temperature being chiefly due to altitude may be estimated on the basis of one degree decrease for every 300 feet of altitude,* but there is a further loss of about one degree temperature for every degree of latitude, and in Alberta and Saskatchewan a gain of about one-half a degree in temperature for every degree of longitude. The latter correction is due to the relative distance from the Pacific Ocean. These conclusions suggest a convenient means of estimating temperature embracing altitude and location by the following formula:—

$$T = C + M - 2L - \frac{A}{300}$$

where T = Mean temperature
C = A coefficient of about 38 (Manitoba 39)
M = Meridian
L = Latitude
A = Altitude in feet.

The value of "C" is derived from thirty years records as follows:

Stations	Mean Temp. for 30 yrs.	Correction for location $114°_M\ 50°_L$	Correction for sea level	"C"	Per cent for 38
Calgary	37.80	−11.97	+11.43	37.26	−2
Medicine Hat	41.70	−10.35	+ 7.06	38.41	+1
Edmonton	36.90	− 6.40	+ 7.02	37.52	−1
				37.73	−0.6
Swift Current	38.10	− 7.08	+ 7.97	38.99	+2.5
Qu'Appelle	34.50	− 2.78	+ 7.05	38.77	+2.0
Prince Albert	31.70	+ 0.70	+ 4.83	37.23	−2.3
				38.33	+1
Minnedosa	33.80	+ 0.67	+ 5.63	40.10	+5.5
St. Albans	35.40	− 0.18	+ 3.93	39.15	+3
Hillview	33.20	− 0.63	+ 4.67	37.24	−2
				38.83	+2.0

It is often necessary to estimate monthly evaporation where only temperature records are available and it is found that if we assume other conditions to be equal the approximate relation of evaporation to temperature is as follows: $\text{Log } E = \frac{T - C}{62}$

where E = Evaporation in water for one month
T = Mean temperature
C = Coefficient depending on relative humidity, etc., and other local factors.

Actual records naturally vary from this equation which was based on average or records extending up to eleven years at several stations. For mass curve estimates they afford a ready means of applying the available data to normal conditions in other respects than temperature. The formula further provides a standard by which to compare data affected by unusual wind and other conditions.

Practically no records of winter evaporation are available and this formula can be used with the average value of "C" denominator (62) for completing partial records to include winter evaporation from monthly records of temperature.

* Meyers "Hydrology," p. 23.

The formula gives the following comparative figures:—

Temperature Degrees Fah.	Evaporation Inches
−20	0.31
−10	0.45
0	0.65
+10	0.93
+20	1.35
+30	1.95
+40	2.85
+50	4.10
+60	6.10
+70	8.50

While temperature is a very important factor in the study of evaporation, equally important is the effect of wind action, removing as it does the protective vapour blanket from above the water surface. The rate of evaporation is caused by wind and in the southern part of our provinces the evaporation opportunity, through the effect of wind, is high.

As one interested in conservation and its attendant factors for many years, and with the experience of administering "Water Rights" in the province of Saskatchewan for the past four years, the writer feels that our most urgent need is the construction, under supervision, of domestic and stock-watering dams together with a plan which would, by contact, assist the farmer in fostering existing irrigation schemes (44,000 acres). It might be also possible to locate and develop small projects that prove on examination to be economically feasible.

Mr. Main in his report proposes the investigation of several large projects many of which will no doubt prove to have merit, particularly from the standpoint of regulating low flow and increasing ground water supply by percolation.

It is suggested that if money becomes available an inventory be made of the possible supply, from wells, creeks, lakes and other sources in each township throughout the drought area. The requirements for a township, accepting the average farm in the grain growing district as one half section, and allowing for losses, are 60 acre-feet per annum.

The quantity required is not large and the cost of construction for low dams would not be great. Where no natural creek beds or depressions are found dugouts might be constructed on suitable sites 200 by 60 by 12 feet. With four to a township a supply of 2,203,368 gallons could be made available after allowing for losses. The quantity would provide a supply for seventy-three days, without considering wells.

It would be of particular interest to this province to have a continuance of the excellent work performed in the Carnduff district by Kirk and Wickenden extended over other areas, should money be made available for such purpose.

While the writer is in agreement with Mr. Perry that our stream flow is primarily dependent upon fall and winter precipitation, it is felt that in compiling his curves as from October 1st to September 30th thus eliminating the month of September as not being dependent he is not in accordance with views now to be set forth.

A study of soil moisture shows that there are two opposing forces, gravity and capillarity—one downward and the other upward. Any added water applied at the surface will unbalance equilibrium and release water to the ground water table. The capillary water assists in controlling the downward movement of additional water as it fills the minute channels, and it acts as a buffer when increased flows are applied.

In September our early frosts stop most plant transpiration. Any precipitation has a chance of filling the capillary pores and has little chance of being affected later by evaporation as October is generally cool, and while there are snows in October they usually evaporate. September on the basis of the above would appear to be the important month for ground water storage.

Spring floods are related to annual temperature, and winter temperature curves closely parallel the annual because they make up a large part of it. The main factors for spring floods are available moisture (usually in March), late springs, with intermittent thaws, sudden and warm weather or hot rains, and a soil previously filled with moisture from fall rains.

There appears to be enough water in a normal winter's snowfall to make a flood if other factors are favourable.

The last floods at Minot, North Dakota, occurred when the average was less than normal. In fact according to figures given by R. E. Kennedy, state engineer, North Dakota, the lowest point on the curve of 2.4 inches.

So, for watersheds not subject to summer floods, the annual temperature has a definite connection with the flood occurrence.

Concerning deforestation, Mr. J. C. Stevens, Portland, Oregon says:

"After many years of guessing and useless argument some authentic information has been produced at last as to the effect of forests on stream flow. The final conclusions are exceedingly simple. They might have been—in fact, actually were—anticipated many years ago. The forest, like every other vegetable crop, consumes large quantities of water for its growth. Unlike some plants, however, it also dissipates large quantities of water by mechanical means. It prevents a substantial portion of rain and snow from reaching the soil, permitting rapid evaporation from branches and leaves. When the forest is removed the water thus consumed by it appears as run-off. As new growths appear the run-off gradually diminishes again in proportion to this crop and mechanical consumption."

Professor D. W. Mead, University of Wisconsin, quotes from experiments made in Wisconsin in 1929:

"The highest average percentage of run-off found was less than 2 per cent for forest covering, 20.1 per cent for pastures, 24.1 per cent for oat lands, 25.6 per cent for corn lands, and 21.5 per cent for hay lands, the last three being probably somewhat reduced by the less average slopes."

The inference is "that sod yields less run-off, consumes more water and returns more to the atmosphere than certain cultivated crops do."

Professor Mead says referring to Devil's Lake: "Since the land around the lake has been settled and cultivated there has been a considerable decrease in run-off and a marked shrinkage in the height and area of the lake, evidently due to the opening of the lands by cultivation."

A paper prepared by Raphael Zon, Director, Lake States Forest Experiment Station, is of particular interest, bringing together impartially all the well-established scientific facts in regard to the relation of forests to water supply and his summing up is as follows:

1. The total discharge of large rivers depends upon climate, precipitation and evaporation. The observed fluctuation in the total amount of water carried by rivers during a long period of years depends upon climatic cycles of wet and dry years.

2. The regularity of flow of rivers and streams throughout the year depends upon the storage capacity of the watershed, which feeds the stored water to the streams during the summer through underground seepage and by springs. In winter the rivers are fed directly by precipitation, which reaches them chiefly as surface run-off.

3. Among the factors, such as climate and character of the soil, which affect the storage capacity of a watershed, and therefore the regularity of stream flow, the forest plays an important part, especially on impermeable soils. The mean low stages as well as the moderately high stages in the rivers depend upon the extent of forest cover on the watersheds. The forest tends to equalize the flow throughout the year by making the low stages higher and the high stages lower.

4. Floods which are produced by exceptional meteorological conditions cannot be prevented by forests, but without their mitigating influence the floods are more severe and destructive.

While Professor Chandler states that Devil's Lake has fallen 22 feet in the past fifty years, R. E. Kennedy is of the opinion that the lake has several times been dry or nearly so. Stump Lake, 25 miles from Devil's Lake, was so named according to Mr. Kennedy because uprooted, fire marked, waterlogged oak trees are slowly emerging in certain places around the shore as the water recedes. These trees are not petrified and one examined showed one hundred and sixteen rings about 12 inches in diameter, and he concludes the ground was dry for at least one hundred and sixteen years. It would appear that wet cycles have come and gone.

With respect to Johnston Lake referred to by Mr. Perry, the writer found that by getting a check-up on this lake in August and allowing for subsequent evaporation the lake has receded about 10 feet since 1883.

While it is agreed that the size of a drainage basin is a factor with precipitation in estimating run-off (with topography) the shape is also considered as being a most important factor. When one examines Moose Jaw Creek Drainage Basin it is found to be about 23 miles wide and 60 miles in length, short and narrow and similar in shape to Swift Current Creek Drainage Basin which is about 16 miles wide. Both being narrow, flood waters reach the point of discharge quickly. The area drained in both cases is partly from hills, whereas the Qu'Appelle basin is about 100 miles wide and the Souris approximately 108 miles. If one considers the length of the radiating lines from the boundaries of the drainage basin to the point of discharge it is thought that the losses would be proportionately greater and the flood stage proportionately less.

Again with the higher stage recorded at Minot with its 10,270 square miles as against Wawanesa with 23,121 square miles, an examination of the basin shows that the flood waters reaching Minot will have time to flatten out before reaching Wawanesa. Meantime the larger part of the 23,121 miles being tributary to Wawanesa will have had every opportunity of passing Wawanesa before the Minot peak reaches there.

Considering the shape of the Wawanesa basin the waters will have to come from a distance of approximately 108 miles north and 100 miles east and one would expect that the long basin, releasing all the way along will give time for the waters to get away with less chance of a peak occurring and before the Minot waters reach there.

With Swan river showing only a difference of 1.5 inches in rainfall over Swift Current creek, Mr. Perry finds the relation of run-off to be:

Swift Current....................	0.918 inches
Swan river......................	3.97 "

As temperature and winds are the principal causes of evaporation one would expect less run-off from the Swift Current district. The temperature of the air and water in the Swan river drainage basin is found to be less. Similar data on file on the two above-mentioned streams shows the run-off in second-feet per square mile to be:

Swift Current..................	5.43
Swan river......................	6.96 for the period.

Many formulae have been used for ascertaining methods of obtaining flood coefficients, a few of the better known exponents being Dickens, Walker, Ryves, Fanning, Meyers and Lillie. It is found however, that the Lillie formula* gives the most satisfactory result for the provinces under consideration.

Mr. Lillie finds that the potential maximum flood cross-section varies as a coefficient multiplied by λ for size and $\Sigma\theta L$ for shape.

In considering maximum discharges in western Canada it was found by the late Mr. Spreckley, Dominion Government Service, Calgary, that λ varies as the fourth root of the area in square miles, and $\Sigma\theta L$ is the sum of the radial distances in miles from the gauging station to the boundary of the watershed at intervals of 1 degree. It is, therefore, possible to reduce any maximum discharge to a common basis of c.f.s. per square mile as if the drainage area were 100 square miles of standard shape thus:—

If C = coefficient for 100 square miles of a shape giving $\Sigma\theta L$ = 1,000. A = drainage area, and P = maximum discharge.

Then $$P = 100\,C\left(\frac{A}{100}\right)^{\frac{1}{4}} \times \frac{\Sigma\theta L}{1000}$$

Therefore $$C = \frac{10\,P}{\frac{\sqrt[4]{A}}{100} \times \Sigma\theta L}$$

and the flood divisor used instead of the actual drainage area will be

$$\frac{\frac{\sqrt[4]{A}}{100} \times \Sigma\theta L}{10} \text{ or } \frac{\lambda\,\Sigma\theta L}{10}$$

In estimating $\Sigma\theta L$ a tracing of radial lines at intervals of 10 degrees is used.

In extending the records for short periods a straight line curve from percentages of "median" yearly maximum discharge is used and the percentages are read off on the line corresponding to the maximum (fifteen years).

C. J. Mackenzie, m.e.i.c.[17]

When Mr. Main states that "man . . . must take action to create conditions that will minimize the effects of another serious drought period when it comes, as it surely will," he expresses the "drought" problem as it appears at the moment to westerners. That the problem is one of more than local significance is realized when it is noted that in six years, 1922 to 1928, the "drought stricken" area of Saskatchewan alone produced new wealth greater than the present total indebtedness of every kind in the entire province. The question of the moment is "what conditions must we create?" Generally speaking, during the past few years there have been in western Canada two schools of thought as to what can be done. One school suggests that climatic conditions can be affected to some degree by man's efforts; that planting trees and hedges, creating large reservoirs and lakes will increase precipitation; that large scale projects, covering extensive areas, for carrying water to the treeless prairies, are desirable and practicable measures. The other school, which has the support of scientific agriculturists, in Saskatchewan at least, believes that there is no possibility of doing anything to affect measurably the rainfall or climate on the prairies; that it is quite impracticable to grow trees in extensive belts in a semi-arid, short grass country where even hard wheat, which is a semi-arid form of growth, can not survive in periods of deficiency of rainfall; that large scheme irrigation or water projects, while perhaps possible from an engineering standpoint, are not feasible from an economical point of view. The remedy, claim adherents of this school, lies rather in the field of cultural and tillage methods for the purpose of reducing evaporation on cultivated lands to a minimum, and lessening soil drifting, and on an intelligent reorganization of our social and political institutions so that all lands would be used only for purposes indicated by the soil and climatic conditions in each particular area. It has been suggested that farming operations must be planned in future on the basis of the inexorable natural laws of variation, which indicate that here, as in any country of semi-arid nature, the wide and quite natural variations in rainfall will bring again periods of drought as have occurred during the past three to five years and which, evidence

* "Discharge from Catchment Areas," Vol. 217 of the Proc. Inst. C.E. September 1924.

[17] Dean of Engineering, University of Saskatchewan, Saskatoon, Sask.

indicates, have occurred in equally severe form in past years before the country was settled. The writer feels that the latter view is the sounder, and the envisaging of a general scheme which would provide at all times an actual storage of seed grain and feed supplies in every section of the country sufficient to meet the requirements of say two drought years with perhaps an actual monetary reserve in the form of an insurance scheme for relief purposes is certainly quite as practical and probably more so than the schemes now in use and under consideration for National Unemployment Insurance. Moreover, such a scheme would involve no large initial expenditures and could be initiated very quickly.

Mr. Perry gives a sound picture of the controlling factors and character of run-off from streams draining prairie watersheds and his conclusion that only about 0.3 inches of rainfall runs off per year is significant, as it can be seen that if all of this were conserved, which of course would be impossible, and applied to the areas from which it comes, the addition would mean little in a country where the rainfall is even as limited as in Saskatchewan. The writer does not suggest that many small storage dams would not serve local farms or even small communities as suggested, and feels that, just as the railways have so successfully developed many water supplies, this effort is one that should be encouraged, but as has been indicated they must be relatively local in nature and cannot be considered as a broad national scheme for the rehabilitation of the treeless prairies considered as a whole.

The major scheme suggested by Mr. Main is of sufficient size to qualify as a broad national scheme, covering as it does an area of about five to six million acres. The water in this case is to be drawn from the South Saskatchewan river, a source uninfluenced by run-off from the prairies, but dependent on the melting snow from the mountains. The scheme of delivering water to individual farms by pipes laid along alternate road allowances, as suggested, is a bold conception, but one who has had experience with waterworks systems for small towns knows that a community of one thousand people living within the area of a village or town, with a supply at hand, can scarcely bear the overhead expense of such a system, and consequently must feel that under present economic and political conditions, when it is found to be economically impracticable to supply individual farms scattered over a large area even with electric light and power, there is not much possibility of having any such scheme in effect in time to meet the next drought. Moreover, while 6,000,000 acres is an area of some magnitude, it is a relatively small proportion of the Saskatchewan grain growing acreage, most of which is liable to years of crop failure. It is true that while in the tree belt of the north, generally speaking, the precipitation is not greater than in the south, the lower temperature and freedom from hot winds with consequent decreased evaporation make conditions quite different from those in the south, and while drought conditions are not so much to be feared, there is always the possibility of a succession of years of late spring or early fall frosts, which would mean a crop loss. There are, however, large areas between the northern limits of the present drought area and extending well into the park belt which are liable to periods of deficient rainfall and drought conditions, and to cover all this latter area, so exposed, with a waterworks system would be an undertaking of gigantic proportions to say the least.

On the other hand, a system of planning and insurance as suggested above, would cover all areas against both drought and frost, and as in all forms of insurance the greater the area covered and the numbers involved, the cheaper and safer it would be. Naturally such insurance rates would vary with the risk in different localities, but most insurance schemes are so adjusted to varying risks.

One agrees with Mr. Main that there is urgent need of a commission of enquiry of a broad nature, to bring together the expert and studied opinions of meteorologists, agriculturists, engineers and statesmen, so that all the scientific and other available information may be pooled and a plan evolved that will be authoritative and acceptable. It should be stated that several interested governments have already taken steps in this direction.

R. W. McKinnon, A.M.E.I.C.[18]

Drought conditions, in the areas now affected, are not new conditions although attended by a great deal more hardship and suffering than was experienced on previous occasions due to increased population and greater cultivation than in past years which has drawn heavily on the ground water supply during periods of low precipitation.

In this semi-arid area, the success or failure of a crop is as dependent on the time of precipitation and the condition of the soil to take advantage of such precipitation, as it is upon its amount. This condition applies to the prairie provinces as a whole and is not particularly confined to the drought area.

The study of conditions throughout Manitoba has led the writer to the conclusion that the year following a comparatively wet fall with early frost and late snow is one in which without early normal summer precipitation, crop conditions are poor. Frozen condition of the earth in the early spring makes it impossible for the soil to take advantage of or store-up the early spring run-off. On the other hand, a dry fall with early frosts and late snow or early snows and late frosts enable the soil to take full advantage of the spring run-off. In the case of the comparatively dry fall and early frosts, large cracks form inlets through which the water is absorbed. In the case of early snows and late frosts, absorption takes place with little movement of the water.

The extensive planting of shelter (tree) belts and the excavation for artificial ponds throughout the drought area, together with the damming up of various creeks and rivers, has been advocated by many as a solution for increased precipitation. While the writer considers the proposals a decided improvement towards the living conditions in the area, he does not consider that they will have any appreciable effect on precipitation in the area referred to.

Shelter belts will collect and hold any winter precipitation in the form of snow and tend to retard their melting in the spring thereby giving the soil in their immediate vicinity better chance of absorbing the collected moisture.

This, together with cultivation and selection of crops tending to replace the fibre in the soil, which has been removed by years of cultivation in one case and the supplying by proper selection of crop and proper working the fibre which is lacking in other sections, will do much towards the prevention of soil drift.

Where no water supply is available, the excavation of ponds for collection of water for domestic use, and for stock watering purposes where only sufficient potable water is obtainable for domestic use is one which has been in use in Manitoba for some years. In the writer's opinion, a good pond on any farm not situated on a creek bank or lake having an all-around water supply, is one of the best assets a farm can have.

Ponds for this use, it will be easily seen, are not of much use for any other purpose. The very object for which they are excavated, namely, that of retaining an all-around water supply, excludes them from the category of a percolation bed and evaporation must be kept at a minimum.

The conclusions arrived at relative to the effect of trees and water have been reached after a number of years of observation of the area situated between Lakes Manitoba and Winnipeg where evaporation surfaces and bush are provided by nature to an extent that it is economically impossible to equal by artificial means and yet in this area lakes and sloughs are drying up without artificial drainage and drought conditions existing, although not on as large a scale as in the dried out areas of the prairie provinces.

The present is not the time for the launching of an extensive tree planting programme as sufficient moisture to start growth of any tree is lacking. However, experiments should be carried on to decide on the tree which will thrive on the minimum of water. When the selection of suitable trees and shrubs has been made, seedlings should be started at once in such numbers than when conditions in the drought area are suitable for proceeding with the project the necessary supply will be available.

On this, together with the attention which the individual is prepared to give, will depend the success of the venture, otherwise the amount of water required to secure a shelter belt may outweigh its usefulness in prevention of soil drift.

The excavation of ponds under present soil and moisture conditions is not feasible. Before sufficient water to fill ponds is available excavations will be filled with drift soil. When ponds are excavated spoil banks should be levelled at once, seeded and surrounded by trees for dual purpose of catching snow and that of preventing soil drift reaching the excavation.

The problem is one of national importance and should have the support of all governments, Federal, provincial and municipal, together with that of the individual.

The attention of the best engineers, agriculturists and geologists should be given to the correlating of all available data and the securing of additional information to arrive at a sound basis for the conservation of available moisture. Particular attention should be paid to the sources by which the ground water of the upper or crop producing strata is supplied, the manner in which it can be conserved and made available to the residents in various areas, also to advise on the best farming methods whereby the individual can co-operate to the utmost in securing the desired results. In the writer's opinion the co-operation received from the individual in carrying out the corrective measures decided upon as being necessary will have more to do with the success or failure of the undertaking than will the major works such as damming of creeks and rivers which will have to be undertaken by one of the governing bodies.

The effect of cultivation on the amount of moisture in the soil was demonstrated last fall during the laying of some two miles of water main. A record was kept of the moisture conditions and the following found to exist:—

On cultivated land which was cropped the same year, moisture was down 8 inches.

On a section which has had a grass coverage for the last twenty years, moisture was down 23 inches.

[18] Chief Engineer, Reclamation Branch, Department of Public Works, Manitoba, Winnipeg, Man.

On a section which was well cultivated, in fact was a large root garden and which had not been cropped for two years, but with the soil well worked and in good condition, the moisture was down 8 feet.

These results were obtained in the vicinity of Winnipeg on approximately a one-quarter section of land.

Another phase which has been greatly emphasized and more particularly in respect to Manitoba, is that of drainage. In the writer's opinion, there are two classes of water:—

That of which the conservation would increase production.

That which is collected in basins or depressions and serves no useful purpose relative to the productiveness of the adjoining lands.

In Manitoba the change in evaporation surface due to artificial means has been less than one-tenth of one per cent. Of this amount the greater portion was in an area where the water was not of any benefit to agricultural pursuits tributary to it. The reclaiming of this area has produced some of the finest and most productive lands in western Canada and even with drought conditions as they are to-day, one would be justified in recommending their drainage. In the years of favourable percolation conditions there is little run-off. In years when conditions are not favourable for percolation the retention of the water on the various farms would have to be of such duration that crop grown would, of necessity, be one of rapid growth and early maturity.

Drought is not a new condition in the area under discussion but one which is recorded by many of the early explorers and which will occur again. Therefore, the present problem is that of devising ways and means whereby during the coming period of ample and possibly of excess moisture, such as have always followed drought periods, the excess water over requirements can be conserved to be used in reducing hardships in future drought periods to a minimum.

P. C. Perry, A.M.E.I.C.

Probably the keynote of the discussion has been the urging of thorough study by experts in the various sciences involved, and citizens in general are probably in agreement with that viewpoint. Some of those participating in the discussion suggested that nothing should be done until a complete study had been made. The writer, however, is convinced that considerable work in connection with development of local water supplies can be proceeded with immediately while the general situation is being more carefully considered. A programme somewhat similar to that carried on by the United States Federal Emergency Relief Administration and described by Mr. Jones can be carried on in the prairie provinces with reasonable assurance of success. A particularly attractive field exists in the construction of municipal reservoirs to supply water and ice for residents of the district. At least nine such reservoirs were constructed in Saskatchewan with engineering supervision last year and it is believed that more were developed without expert advice. Investigations have been made for about forty reservoirs on which work could be done early this year.

It is appreciated that the run-off from the prairie is light and that it can not be depended upon every year. Nevertheless, successful reservoirs have been used for many years by individuals, municipalities, and the railways. The possibilities of this type of work have been demonstrated by experience gained from the time the west was first settled, while the value of these local supplies is beyond question.

The proposals for utilization of the Saskatchewan river are made more attractive because of the more dependable flow of that stream. On the other hand, the river does not possess natural storage basins and the storage of the flood waters will be extremely costly. It seems to be the opinion of those best informed on the matter that large scale irrigation can not be made to pay its own way on the Canadian prairie. The advocates of irrigation in some instances urge that the country at large can bear part of the cost because of the general benefits. In this connection, however, it should be remembered that it is impossible to provide irrigation water for every farm, and if the country assumes part of the cost of irrigating some areas, the farmer without water will be paying (through taxes) part of the cost of the water used by the irrigationist.

Mr. Patterson raised the question of possible mineralization of water in prairie reservoirs, and it may be mentioned that the railways have given careful consideration to that phase of the question, and believe that it is not a serious drawback. The lakes and sloughs have probably developed their mineral content through thousands of years and ground water acquires its mineral salts by slow movement through highly mineralized soil. The greatest help in avoiding mineralization in artificial reservoirs, is to have them located in coulees where the run-off occurs early and for a short time in the spring. A minimum of mineralization occurs when the water runs over frozen ground.

A further great help can be provided in most cases by installing a scour pipe in the dam. Such a pipe is provided with a valve which may be opened when the fresh water begins to enter the reservoir in the spring. In this way an accumulation of salts from year to year is avoided.

Mr. McGavin draws attention to the variety of opinions concerning effect of trees on run-off. Probably the difference in conclusions of observers are due to the differences in other conditions. It is possible that in tropical areas where tree growth is rapid and continuous throughout the year that they may use in transpiration more water than is conserved by shelter in which case the net results would be a reduction in run-off. In higher latitudes the shelter of the trees conserves water for six or seven months and use in transpiration during the remaining part of the year is not great, the net result being an increase of run-off. Further study has led the writer to believe that throughout most of the Canadian area the presence of trees tends to increase the flow of streams. The quotations which Mr. McGavin gives from Professor D. W. Mead, can hardly apply to annual flow for he gives a table* of run-off and precipitation which shows run-off for the Wisconsin river as being 65 per cent of precipitation. In that table, the streams having partly forested watersheds show much heavier percentage of run-off than the prairie streams. The lowest percentage given is for the Platte river of Nebraska where only 8 per cent of the precipitation is included in run-off.

In regard to hedges and shelter belts for the prairie, it is agreed that they will use some water in their growth, and conserve some through reduction of wind. The difference of opinion lies in the question as to which may be the greater, but an important consideration, perhaps not fully recognized, is that the shelter belt may be used to concentrate moisture from the snow-fall in a desirable location. A plot of ground enclosed with hedges or tree belts may collect snow from a large adjoining area not protected. If the topography is favourable, the water from the melting snow may be held, providing the required moisture from the shelter belt and a surplus for crops on a small area or the filling of a small reservoir. The possibility of success in such work will, of course, decrease with attempts to protect all fields with hedges.

L. P. Rundle, M.E.I.C.[19]

Proper remedies for drought conditions are a problem for science and engineering, and the writer offers the following suggestions:

The Federal government to form a commission consisting of expert engineers and scientists, experienced in hydro-electric engineering, forestry, meteorology, irrigation, water conservation and agriculture.

This commission to keep in touch with an engineer representative of each of the provinces involved, and to investigate and correlate all scientific and engineering data, no matter from what source, and to formulate formal recommendations and to finally supervise and direct whatever measures are decided on.

To study reclamation works that have been completed and to exchange ideas with those bodies who are now doing similar works in the United States.

To form an international meteorological clearing house for Canada, the United States, Mexico and the Central American states.

To investigate the effect of hedge and tree planting and the filling of sloughs and swamps, of drainage, etc.

To study the possibilities of vegetation and long root grasses that require a minimum of moisture for those sections that may be determined as being unfitted for settlement or farming.

To determine what areas are not fitted for agricultural purposes with the idea of closing these for settlement and to consider the feasibility of planting trees in such areas.

Outside of proved yearly wheat belts, that is those not subject to drought cycles, to forget wheat and concentrate on mixed farming of a suitable type.

To study regulations with the idea of prohibiting the draining of sloughs, swamps, lakes, etc., with an extensive study made of the geology of the drought areas as it affects the source of ground water, and the scientific regulation of the drilling of wells.

A complete survey of the possibilities of the generation, transmission and distribution of electric energy in conjunction with storage dams and regulating works and other reclamation works.

An intelligent study of road design and engineering to form part of the whole work.

To formulate standard practices and uniform legislation among the various provinces concerned in regard to the handling of water in its various phases.

To formulate an intelligent understanding of the problem by our legislators and the public at large. Where conservation of water by storage dams, etc., and reclamation of land by irrigation and other means in our western drought areas can be proved to be a desirable national undertaking, the public should be shown that any such projects properly directed represent a constructive policy of social development.

Since any reclamation work is a matter that concerns several provinces, it must be engineered by the Federal government with the help of the provinces concerned and a proper division of work decided upon.

The financing of any such work could be fairly divided between the Federal and provincial governments in proportion as the work is purely Federal in scope or local and provincial, though fitting in as part of the general scheme.

---

[19] Senior Assistant Engineer, Welland Ship Canal, St. Catharines, Ont.

R. S. Stockton, M.E.I.C.[20]

The agricultural utilization of the dry belt of Alberta and Saskatchewan is of outstanding importance and is an engineering as well as a farm problem. In this great area, nearly 400 miles east and west and perhaps 200 miles wide, there are millions of acres of prairie soil that have been broken by the plough and continuously farmed for grain production.

In many places one-crop grain farming has been so extensive and continued over so many years that the humus or vegetable fibre in the soil has been used up and the result is reduced fertility and drifting soil. Such exhausted soils are also much less retentive of moisture, which is a vital matter in this region. Destruction of the productivity of large areas is taking place, mainly through soil drifting, and the most basic resource of the country is being rapidly dissipated.

This problem is of great concern for the future, since the productive value of the soil is the foundation on which the population may be supported.

The problem of soil drifting extends into the area of greater rainfall and is most serious throughout the great plains region to the south, as well as in the north.

The following remedies have been proposed:—

(*a*) Strip farming for grain, cover crops, and proper cultural practices that will keep the soil furrowed or rough.
(*b*) Building up humus by seeding large areas to native and tame grasses as a permanent method of utilizing the land and also as a crop rotation with grain.
(*c*) Carrying a reasonable number of livestock on the farms and using the manure to build up the soil.
(*d*) Conservation of the available run-off water from all streams and rivers and all drainage areas and using it, as far as possible, to promote plant growth.
(*e*) The planting of trees and shrubs to break the winds, as well as for beauty and for the timber produced.
(*f*) The scientific and careful classification of the land for its best use. The division of the land into farm units of such size that a family can do well on them and adopt the system more useful in each case. It may happen that 40 acres of good irrigable land is worth as much as a township of desert or mountain grazing land.
(*g*) The introduction, selection, breeding and propagation of plants most suitable to our climate and conditions. Some wonderful things have been accomplished but the field is only scratched along these lines.
(*h*) Reducing and adjusting land taxes so as to encourage proper land use and make up any deficiency in necessary tax revenue by increasing the tax on expenditure and dividing this increase, as required.

The conservation and disposal of the water resources of the country is largely an engineering question and includes a wide field of usefulness in the land utilization.

There is first, the proper diversion of perennial streams for direct irrigation of the most suitable areas, with emphasis on economical use and spreading the water over large districts, with maximum production for water and district rather than maximum yields per acre irrigated as the goal.

A second problem has to do with the construction of reservoirs to retain flood water for irrigation and for domestic and power use. It is usual to consider domestic use as first, irrigation as second, and power as the third use, with some allowance for riparian rights, unless these have been abrogated by law in the interest of the state.

A third method of water conservation consists in the proper storage and utilization of storm water on the farms, particularly in the drier portions, where much of the land should be kept in grass and only the choicest portions farmed. In such districts small reservoirs should be built and the gentle slopes and depressions protected by contour dikes about 18 inches to 24 inches high so that there is no storm water run-off lost. The topography should be studied and suitable depressions converted into shallow springtime ponds that later in the season become hay meadows.

The fourth development consists in digging or boxing wells wherever groundwater can be found to yield a supply. A rate of pumping should be adopted that will utilize, but not exhaust, the perennial supply.

The recent public attention to soil drifting, drought and water conservation is most opportune and will greatly strengthen the hands of those who have been working for years to arouse this public concern in order that action may be taken and our country saved.

The farmer on irrigated land does have some particular problems of his own.

In the first place, he must grade, smooth and ditch his land for economical irrigation; he must see that water is applied to his crops at the right time and in approximately the correct amount and without undue waste. Later he may be faced with seepage, water logging and the rise of alkali which results in the loss of some land or an expenditure for drainage and reclamation. Many farmers in a new country, such as this, are greatly hampered by lack of capital; sometimes they lack knowledge of irrigation and in the semi-humid areas they often prefer to follow an extensive system of grain farming on a dryland summerfallow system using irrigation as a last minute resort in a dry season. This is a very crude system of irrigation farming, and except on the best natural slopes, results in very moderate returns, especially as such farmers are nearly always late in irrigating. Such irrigation on rough land increases seepage and alkali difficulties. The best remedy is a small farm unit, or at least a small irrigable area, on which the operator will be forced to strive for the high yields and varied crops that are to be had from properly irrigated farms. Alfalfa and forage crops are usually the basis for irrigation farming, because they require about twice as much moisture for maximum returns as do grain crops and therefore make full use of this control of moisture in the soil. Irrigation lends itself to raising fruit, sugar beets and a great variety of special crops.

The irrigation farmer has the problem of co-operating with his neighbour and the ditch-rider in order to secure water in proper rotation and in quantity to permit of rapid and effective irrigation.

The problems of the irrigation farmer are closely related to the problems of the irrigation district or ditch company and the operating staff. There is not time to discuss these problems in detail, except to say that they centre upon the effort to give good water service at low set cost and to collect the costs of operation and maintenance and pay off the bonded debt, if such exists. The tendency is more and more, as it should be, to place operation of the project and all responsibility on the farmers that use and benefit from the water delivered. They should be organized as an irrigation district and run the irrigation system.

In conclusion, it may be said that the problems of the farmer, in general and as related to irrigation and water conservation, which have been outlined so briefly here, do deserve study, analysis and the working out of practical reforms for they involve the development and safeguarding of our great natural resources. A planned development based on technical surveys and information of the most scientific and complete character would be of the greatest benefit to this vast region.

VOLUME XVIII APRIL 1935 No. 4

The Technical Aspect of the Western Drought Problem

The interest shown by members of The Institute in questions vitally affecting national welfare was strikingly shown by the large attendance at the professional session of February 8th, 1935, at the Annual Meeting in Toronto, when a series of papers on the water supply of the prairie provinces was presented and discussed. These papers, which are published elsewhere in this issue of The Journal, together with the discussions thereon, were contributed by engineers and technical authorities well qualified to speak on their respective subjects. They dealt with questions of climatology, physiography, and water conservation, rather than with the strictly agricultural or economic features of the drought problem. In fact, the primary object of Council in arranging for this symposium was to bring out the basic facts in regard to the technical side of the question, and to present them for the guidance of the public in considering and appraising the various schemes of rehabilitation which have been proposed.

It is now realized that a considerable proportion of the southern part of the prairie provinces consists of semi-arid land, in which the water supply in normal years is barely sufficient for the staple crop, wheat, and which is subject to recurrent periods of less than normal, and greater than normal, precipitation. A period of the former kind has now lasted for some six years, with serious consequences to the three prairie provinces and to Canada as a whole, and it is necessary, in the words of the Premier of Manitoba, "to plan now or suffer again." Mr. Bracken has pointed out that the problem of drought is no longer one for individual farmers or a few communities, nor a problem for individual provinces or states, but is a matter of concern to the nation. A glance at conditions in southern Alberta, southern Saskatchewan and south-eastern Manitoba will show the magnitude of the problem in Canada; the extent of the difficulty in the drought area of the United States, which extends from the Canadian boundary to Texas, may be gauged from the fact that the Federal Emergency Relief Administration appropriated over $500,000,000 for relief measures during the year 1934-35 in that region. It is true that the rehabilitation of such areas is essentially an agricultural question, in that much of the necessary remedial work will involve agricultural adjustment, changes in farming practice, the reversion of some arable land to pasture, and possibly even the abandonment of certain cultivated areas. These matters are the concern of the agriculturist rather than the engineer.

The agricultural side of the question has naturally been given prominence in addresses by public men, both Federal and Provincial, and in the many articles which have appeared in the public press. Mistakes in land utilization and development have been made in the past, and it is believed that present cropping methods need reconsideration and redirection in the light of present knowledge. "Some of the virgin soils have been tilled," says Mr. Bracken, "until we have injured their texture. Some soils have been ploughed that should never have been broken." Further, the public has been rightly concerned with the provision of immediate relief for the farmers in the drought area, involving aid for human beings as well as for livestock, and there has been a generous response to the appeals for help which have been issued.

It is obvious that since agriculture in the west is dependent on the available water supply, such relief measures and changes in agricultural policy, however desirable in themselves to alleviate present suffering, will not provide security for the future. For this purpose the available water supply must be conserved and utilized to the best advantage, and this is where the engineer can help.

There are those who believe that unless proper measures are taken without delay, particularly with reference to the conservation of water and the limitation of soil-drifting, there is real danger that extensive areas of actual desert may develop in our Canadian west. An active programme of water conservation and utilization is therefore needed, and is receiving attention. In planning such a programme many technical problems arise, to solve which the aid of the scientist and the engineer is required. In order that reliable technical advice may be prepared, it is necessary first to ascertain the basic facts as to the amount and nature of the water supply available, and, secondly, to indicate the lines along which efforts for the conservation and utilization of that supply must be directed. In some cases schemes involving extensive engineering works and corresponding expense have been put forward without adequate preliminary study by any qualified persons. In other cases projects have been suggested whose feasibility seems very doubtful when they are examined in the light of technical knowledge. Thus general support is sometimes secured for the expenditure of public money on schemes advocated by persons who have no idea of the engineering and financial difficulties which their execution would involve. It is in connection with such matters that the engineer and technical expert can render invaluable service to the public.

There are many debatable questions which arise when the water conservation problem in the west is studied. For instance, to what extent has artificial drainage of the land contributed to our difficulties? During the past twenty years large areas have been drained for reclamation purposes (two million acres in Manitoba). Further, the farmers have drained their land with a view of making it possible to commence tillage operations as early as possible in the spring. The run-off has also been increased by the drainage operations incidental to the construction of highways and railways. To what extent have these operations contributed to our difficulties, should they be limited in the future, and if so, to what extent? As another example take the question of the degree to which the ground-water supply in the drought area is being depleted or polluted by uncontrolled well-drilling. Is this a serious matter, and if so, how can it be dealt with?

Again, how can sufficient water be made available for the individual farmer in the dry area to enable him to grow vegetables, raise live stock, and enjoy a more comfortable standard of living? Is any general scheme of rural water supply feasible, and, if so, from what sources and over what areas?

These and other similar questions must be considered before giving detail study to the major and minor water conservation projects which have been proposed.

Following a suggestion made during the discussion at Toronto, the Council of The Institute has appointed a representative committee who are asked to follow up the work of the Annual Meeting and collect relevant data on the various technical aspects of the subject in consultation with engineers who are in a position to give authoritative information. It is also thought that the committee should confer with agriculturists, foresters, geologists, meteorologists and other experts as may be found necessary, and then give consideration to the various methods of water conservation and utilization which have been suggested. In this way The Institute committee can be of assistance in advising as to those engineering features of the programme for alleviating conditions in the affected area which would be the most promising of success. In doing so, those projects could be indicated which seem feasible and worthy of detailed planning and investigation on the part of the governmental bodies concerned. The carrying out of any programme based on such schemes would of course not be the work of the committee, but of the technical officers appointed by the various governments for that purpose. The assistance of the committee is being offered to the Federal and Provincial authorities, with the intimation that although the problem is primarily agricultural, engineers can help in collecting reliable information and expressing opinions on those remedial measures which involve engineering work or investigation.

Past-Presidents' Prize 1934-1935

The subject prescribed by Council for this competition for the prize year July 1st, 1934, to June 30th, 1935, is

"The Co-ordination of the Activities of the Various Engineering Organizations in Canada."

The rules governing the award of the prize are as follows:

The prize shall consist of a cash donation of the amount of one hundred dollars, or the winner may select books or instruments of no more than that value when suitably bound and printed, or engraved as the case may be.

The prize shall be awarded for the best contribution submitted to the Council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by the Council at the beginning of the prize year, which shall be July first to June thirtieth.

The papers entered for the competition shall be judged by a committee of five, to be called the Past-Presidents' Prize Committee, which shall be appointed by the Council as soon after the Annual Meeting of The Institute as practicable. Members and Honorary Members only shall be eligible to act on this committee.

It shall be within the discretion of the committee to refuse an award if they consider no paper of sufficient merit.

All papers eligible for the competition must be the bona fide work of the contributors and must not have been made public before submission to The Institute.

All papers to be entered for the competition must be received **not later than June 30th, 1935**, by the General Secretary of The Institute, either direct from the author or through a local Branch.

Students' and Juniors' Prizes

Students and Juniors of The Institute are reminded that five prizes each of the value of twenty-five dollars, may be awarded to Students and Juniors of The Institute for the prize year 1934-1935 as follows:

The H. N. Ruttan Prize in the four Western Provinces.

The John Galbraith Prize in the Province of Ontario.

The Phelps Johnson Prize for an English Student or Junior in the Province of Quebec.

The Ernest Marceau Prize for a French Student or Junior in the Province of Quebec.

The Martin Murphy Prize in the Maritime Provinces.

Papers in competition for these prizes must be received by Branch Secretaries before June 30th, 1935. Further information as to the requirements and rules may be obtained from the General Secretary.

The Work of the Committee on Consolidation

The Committee appointed at the Annual Meeting of The Institute held in Toronto on February 7th, to develop the possibilities of consolidation of the engineering profession in Canada, held its first meeting in the Royal York Hotel, Toronto, on the evening of February 8th. This meeting was attended by the President, four members of the Committee and representatives from several provinces. Gordon McL. Pitts, A.M.E.I.C., was appointed chairman of the Committee, and Robert F. Legget, A.M.E.I.C., secretary, and there was a general discussion of the procedure to be followed by the Committee.

A further meeting was held in Montreal on February 16th, at which the programme of the Committee was considered, and Professor R. E. Jamieson, M.E.I.C., was added to its number. It was decided that a letter be issued to the Secretaries of the Branches of The Institute and of the Professional Associations, advising them of the functions and programme of the Committee, together with a review of the action taken by the various Branches and Associations throughout Canada on the matter of consolidation.

The chairman and secretary of the Committee were invited to attend a meeting of Council held at headquarters on Friday, February 22nd, at which time the proposals of the Committee were explained to the Council and its progress to date reviewed.

The third meeting of the Committee was held in Montreal on March 1st, and Dr. O. Lefebvre, M.E.I.C., was added to its membership. It was reported that the brochure on the "Proposed Consolidation of the Engineering Profession in Canada" had been distributed to all the members of The Institute, with a covering letter explaining that its purpose was to provide a basis for discussion. It was decided that the Committee should circulate as widely as possible all suggestions or criticisms that they may receive from various engineering organizations, with the idea of crystallizing a majority opinion into a workable scheme for presentation to The Institute.

The letters suggesting a general method of procedure in the consideration of this question, together with a report on the resolutions on this subject from the various engineering bodies throughout Canada, and a chart indicating the organization of the Provincial Committees for discussion and suggestions, have gone forward. Replies to the above indicate that Nova Scotia already has a Joint Committee on Amalgamation, and has, by an almost unanimous vote, made a definite move toward the setting up of one engineering organization in that province which will include members of the Branches of The Institute and of the Professional Associations.

In New Brunswick the Professional Association has gone on record as being in favour of consolidation, and the Annual Meeting of the Saint John Branch will be held on May 9th, at which time their action on this matter will be considered.

In Quebec The Institute Branches in Montreal and the city of Quebec have passed resolutions favouring consolidation. The Saguenay Branch has expressed itself as favouring such action. The Annual Meeting of the Corporation of Professional Engineers of the Province of Quebec held on March 27th, received the unanimous report of a Committee which took the form of a resolution to the meeting favouring co-ordination of the various engineering bodies in Canada with The Institute functioning as the national organization. This motion was passed with few dissenting.

In Ontario, organization work has been slower, but the sentiment expressed is strongly in favour of the principle of consolidation and definite approval of that principle has been received from the Border Cities Branch, the Hamilton Branch and the Ottawa Branch.

In Manitoba, the attitude of the profession towards consolidation, as reflected in the recent referendum, is well known, and the Winnipeg Branch has recently appointed a Committee of five, to represent them in discussions on this subject.

In Saskatchewan, probably greater progress has been made than in any other province with the exception of Nova Scotia, and a Joint Committee has already been formed under the chairmanship of D. A. R. McCannel, M.E.I.C., who is also a member of the Associations' Committee of Eight and appointee to the Central Committee on Consolidation. The Saskatchewan Branch went on record on March 22nd, as being in favour of a national engineering body to represent the whole engineering profession in Canada.

In Alberta, the Lethbridge Branch are strongly in favour of consolidation and the other organizations in that province have indicated that they have this matter under consideration. The Calgary Branch of The Institute has just appointed a Committee of five on consolidation under the convenership of Mr. R. S. Trowsdale, A.M.E.I.C.

With regard to British Columbia, the Victoria Branch of The Institute has passed a resolution strongly in favour of consolidation between The Engineering Institute of Canada and the various Provincial Associations of Professional Engineers.

Mr. R. F. Legget, the secretary of the Committee, has just returned from a two weeks' trip to the Maritime Provinces, during which he visited Moncton, Cape Breton, Halifax and Saint John. He reports the Maritime Provinces strongly in favour of consolidation.

The Committee urgently requests every Branch to meet as promptly as possible to discuss this question and to form their Joint Committees to co-operate with the central Committee, and to forward their suggestions and criticisms for circulation to other bodies, and otherwise to maintain a constructive consideration of this important matter so that a decision may not be delayed and that the provinces may be in a position to act concurrently.

The Committee solicits the co-operation of members of The Institute, individually and collectively, in the best interests of the profession throughout Canada.

E.I.C. Prizes for Canadian Engineering Colleges

At the February meeting of Council it was decided to renew for a further period of five years The Engineering Institute of Canada Prizes, which The Institute has given during the last five years to eleven of the principal engineering schools in the country. Council has received letters of appreciation regarding the award of these prizes, which have a value of Twenty-Five dollars each, and are offered annually for competition among the registered students in the year prior to the graduating year in the following universities and colleges:

University of Alberta
University of British Columbia
Ecole Polytechnique, Montreal
University of Manitoba
McGill University
University of New Brunswick
Nova Scotia Technical College
Queen's University
Royal Military College
University of Saskatchewan
University of Toronto

Meeting of Council

A meeting of the Council of The Institute was held at Headquarters on Tuesday, March 19th, 1935, at eight o'clock p.m., with President F. A. Gaby, M.E.I.C., in the chair, and twelve other members of Council present.

Discussion took place on the proposals which have been made in Nova Scotia for the closer union of the Association of Professional Engineers of Nova Scotia and The Institute branches in Nova Scotia, during which it was pointed out that the problem of co-ordination of the engineering profession in Canada was referred by the last Annual Meeting to a committee under the chairmanship of Mr. Gordon McL. Pitts, A.M.E.I.C. The Secretary was directed to draw the attention of The Institute branches in Nova Scotia to this fact, and to place such information as is available regarding the situation in Nova Scotia in the hands of Mr. Pitts' committee.

The membership of the committee appointed by Council to develop activities in The Institute of interest to communication engineers, as submitted by Professor Wallace, was approved as follows, it being noted that additional names would be submitted at a later date:

G. A. Wallace, A.M.E.I.C., *Chairman.*
J. L. Clarke, M.E.I.C.
S. T. Fisher, Jr.E.I.C.
W. A. Steel
J. H. Thompson, A.M.E.I.C.
H. J. Vennes, A.M.E.I.C.

Letters were noted from the deans of the engineering schools in the several Canadian universities expressing appreciation of Council's action in continuing the award of The Engineering Institute of Canada Prizes for a further period of five years.

It was noted that the following members of The Institute had been asked to serve on the committee appointed by Council to give further consideration to the study of the western water problem:

C. H. Attwood, A.M.E.I.C., Winnipeg, Man.
Dr. Charles Camsell, M.E.I.C., Ottawa, Ont.
L. C. Charlesworth, M.E.I.C., Edmonton, Alta.
Dr. T. H. Hogg, M.E.I.C., Toronto, Ont.
Dr. O. O. Lefebvre, M.E.I.C., Montreal, Que.
Dean C. J. Mackenzie, M.E.I.C., Saskatoon, Sask.
S. G. Porter, M.E.I.C., Calgary, Alta.

The membership of the Library and House Committee was approved as follows:

E. A. Ryan, M.E.I.C., *Chairman.*
J. L. Clarke, M.E.I.C.
F. E. V. Dowd, A.M.E.I.C.
W. G. Hunt, M.E.I.C.
J. H. Landry, A.M.E.I.C.

The examiners for the Students' and Juniors' Prizes were appointed as follows:

H. N. Ruttan Prize	E. V. Caton, M.E.I.C., *Chairman.*
	H. R. Webb, A.M.E.I.C.
	A. S. Wootton, M.E.I.C.
John Galbraith Prize	E. G. Cameron, A.M.E.I.C., *Chairman.*
	F. W. Paulin, M.E.I.C.
	A. E. Pickering, M.E.I.C.
Phelps Johnson Prize	P. L. Pratley, M.E.I.C., *Chairman.*
	C. B. Brown, M.E.I.C.
	E. A. Ryan, M.E.I.C.
Ernest Marceau Prize	A. B. Normandin, M.E.I.C., *Chairman.*
	H. Cimon, M.E.I.C.
	B. Grandmont, A.M.E.I.C.
Martin Murphy Prize	A. Gray, M.E.I.C., *Chairman.*
	H. J. Crudge, A.M.E.I.C.
	H. S. Johnston, M.E.I.C.

Discussion took place on the general policy to be pursued in the case of members in arrears or on the Non-Active List.

Consideration was given to a request from the Calgary Branch that the payment for branch news in The Journal be resumed, but on a report from the Finance Committee it was decided that such payments could not be resumed as yet.

A number of suggested revisions to the Niagara Peninsula Branch By-laws were noted and approved.

Twelve resignations were accepted, a number of members were placed on the Non-Active List, several special cases were considered, one member was reinstated, and one member placed on the Life Membership List.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Members	3	Assoc. Member to Member	2
Associate Members	6	Junior to Assoc. Member	5
Affiliate	1	Student to Assoc. Member	4
Students admitted	24	Student to Junior	3

The Council rose at eleven fifteen p.m.

ELECTIONS AND TRANSFERS

At the meeting of Council held on March 19th, 1935, the following elections and transfers were effected:

Members

DUFRESNE, Alphonse Olivier, B.A.Sc., M.E., (Ecole Polytechnique, Montreal), B.Sc., M.Sc., (McGill Univ.), director, Quebec Bureau of Mines, Quebec, Que.

MARTINEAU, Joseph Omer, B.Sc., (Queen's Univ.), asst. chief engr., Dept. of Roads, Quebec, Que.

PARADIS, Alphonse, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), chief engr., Dept. of Roads, Quebec, Que.

Associate Members

COXWORTH, Thomas Walker, B.Sc., (Univ. of Man.), asst. engr., McClintic Marshall Corpn., Chicago, Ill.

GAGNON, Ludger, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), asst. city engr., Quebec, Que.

GALE, Melvin Lambeth, B.Sc., (Univ. of Alta.), assessor, Province of Alberta, 12021-97th Street, Edmonton, Alta.

HESLOP, Wilfrid Gibson, B.A.Sc., (Univ. of Toronto), P.O. Box 196, Kirkland Lake, Ont.

MATTHEWS, Samuel, B.Sc., (Univ. of Sask.), ceramic engr., Dominion Fire Brick & Clay Products, Ltd., Moose Jaw, Sask.

SCRYMGEOUR, Donald Stuart, (Royal Technical Institute), chief dftsman., London Structural Steel Co. Ltd., London, Ont.

Affiliate

MacFARLANE, Peter William, supt. engr., bldgs. and grounds, McGill University, Montreal, Que.

Transferred from the class of Associate Member to that of Member

BENNETT, Harry Frederick, B.Sc., (Univ. of N.B.), district engr., Dept. of Public Works of Canada, Sault Ste. Marie, Ont.

LINTON, Adam Pearce, B.A.Sc., (Univ. of Toronto), chief bridge engr., Dept. of Highways of Sask., Regina, Sask.

Transferred from the class of Junior to that of Associate Member

CARRUTHERS, Clarence D., B.A.Sc., (Univ. of Toronto), designer and dftsman., for Gordon L. Wallace, A.M.E.I.C., Toronto, Ont.

DAVIDSON, John Knox, B.Sc., (Univ. of St. Andrews, Scotland), A.M.I.C.E.; chief engr., Electric Reduction Co. Ltd., Buckingham, Que.

GRAHAM, Walter White, B.Sc., (McGill Univ.), elect'l. designer, Shawinigan Engineering Company, Montreal, Que.

LAIDLAW, Douglas Staunton, B.A.Sc., (Univ. of Toronto), struct'l. engr., in partnership with Catto & Catto, architects, Toronto, Ont.

LOVETT, Percy Arthur, B.Sc., (N.S. Tech. Coll.), consltg. engr. and sec. treas., Engineering Service Co. Ltd., Halifax, N.S.

Transferred from the class of Student to that of Associate Member

ARMSTRONG, Owen Fred Calder, B.Sc., (N.S. Tech. Coll.), asst. to gen. employment supervisor, gen. traffic dept., Bell Telephone Company of Canada, Montreal, Que.

COSTIGAN, James Percival McDougall, B.Sc., (McGill Univ.), engr., T. Pringle & Son Limited, Montreal, Que.

HURST, William Donald, B.Sc., (Univ. of Man.), C.E., (Virginia Polytechnic Inst.), asst. engr. (in charge of water works operating branch), City of Winnipeg, Man.

SCANLAN, Jeremiah Joseph René, B.Sc., (McGill Univ.), engr., Milton Hersey Co. Ltd., Montreal, Que.

Transferred from the class of Student to that of Junior

LEWIS, Edmund Keith, B.Sc., (N.S. Tech. Coll.), in charge of meter dept., Imperial Oil Refinery, Dartmouth, N.S.

STRIOWSKI, John Benjamin, B.Sc., (Univ. of Man.), 257 Beverley St., Winnipeg, Man.

WICKWIRE, Lawrence David, B.Sc., (N.S. Tech. Coll.), engrg. dftsman., Mersey Paper Company, Liverpool, N.S.

Students Admitted

ANGEL, John Bartlett, (McGill Univ.), 3609 University St., Montreal, Que.

BEACH, John Edward, (Univ. of Alta.), 10957-90th Ave., Edmonton, Alta.

BEATH, Laurence Raymond, (McGill Univ.), 1492 Bishop St., Montreal, Que.

BURKE, Eric Vincent, (Memorial University College), 38 Bonaventure Ave., St. John's, Nfld.

CHEESEMAN, Edgar W., (Memorial Univ. Coll.), 66 Fleming St., St. John's, Nfld.

DOBSON-SMITH, Charles Fredrick, (Univ. of Man.), Dundurn Camp., Dundurn, Sask.

DUNCAN, Gaylen R., Jr., (McGill Univ.), 1550 Mackay St., Montreal, Que.

ERICKSON, Martin Adolph, (Queen's Univ.), 27 Clergy Street West, Kingston, Ont.

FRIZZLE, Harold Robert, B.Sc., (N.S. Tech. Coll.), Berwick, N.S.

GODDEN, Charles J., (Memorial Univ. Coll.), 55 Cochrane St., St. John's, Nfld.

GORDON, John Edward, (Queen's Univ.), 113 King St. W., Dundas, Ont.

INNES, Edward Patrick N., B.Eng., (McGill Univ.), 56 Charlton Ave. W., Hamilton, Ont.

KENT, A. Douglas, (Queen's Univ.), 148 Barrie St., Kingston, Ont.

McDONALD, Alexander John, (Queen's Univ.), 537 Albert St., Kingston, Ont.

MOAKLER, John J., (Memorial Univ. Coll.), 11 Maxse St., St. John's, Nfld.

MORRIS, S. Rupert, (Memorial Univ. Coll.), Trinity, Nfld.

POWELL, Robert M., (R.M.C.), 290 Coltrin Road, Rockcliffe, Ottawa, Ont.

PARSONS, Clarence Walter, (Memorial Univ. Coll.), Bell Island, Nfld.

REES, Frederic, (Memorial Univ. Coll.). Bell Island, Nfld.

SCHEAR, Philip Maurice, (McGill Univ.), 4215 St. Urbain St., Montreal, Que.

SMITH, Owen Leonard, (Memorial Univ. Coll.), Angle Brook, Glovertown, Nfld.

SOLES, William, (Queen's Univ.), Rock Island, Que.

TATHAM, William Carlyle, (McGill Univ.), 3647 University St., Montreal, Que.

YORK, Frederick Gilbert, (McGill Univ.), 1441 Drummond St., Montreal, Que.

OBITUARIES

Frederick Young Harcourt, M.E.I.C.

We regret to announce the death of Frederick Young Harcourt, M.E.I.C., at London, Ontario, on February 14th, 1935.

Mr. Harcourt was born at Welland, Ontario, on July 31st, 1879, and graduated from the University of Toronto with the degree of B.A. in 1900, and from the School of Practical Science in 1903.

Following graduation he was until 1905 rodman and instrumentman and chief of field party with the Ontario Power Company at Niagara Falls, Ont. In 1905-1907 he was on the Georgian Bay canal survey as instrumentman, and in 1907 he entered the service of the Department of Public Works, Canada, as senior assistant engineer of the Port Arthur district. In 1911-1915 Mr. Harcourt was district engineer of the same district, and from 1915 to 1919 served overseas, returning to the same position at the end of the war. From 1921 to 1930 he was district engineer for the Department of Public Works of Canada of the Port Arthur and Fort William districts, and in 1930 he was transferred to London, Ontario, where he was in charge of the district until the time of his death.

Mr. Harcourt joined The Institute as a Member on May 22nd, 1922, and took a keen interest in Institute affairs, having been elected a Councillor representing the Lakehead Branch in 1930, and served on the Executive committee of the London Branch.

Joseph O. Bonin, A.M.E.I.C.

Regret is expressed in placing on record the death at Cedars, Que., of Joseph O. Bonin, A.M.E.I.C.

Mr. Bonin was born at Lanoraie, Que., on July 29th, 1879, and graduated from Laval University with the degree of B.A. in 1902.

In 1904 Mr. Bonin was rodman with the Canadian Pacific Railway Company and in 1905-1906 was leveller with the New Canadian Company, being engaged on railway construction in summer and surveys in winter. In 1907-1908 Mr. Bonin was again with the Canadian Pacific Railway Company, as transitman on grade reduction, and in 1909-1910 he was resident engineer on railway construction with the New Canadian Company. In the following year he was with the Bishop Construction Company as contractors' engineer. For over twenty years Mr. Bonin has been located at Cedars, Que.

He became a Student of The Institute on October 12th, 1905, and on May 11th, 1912, transferred to the class of Associate Member.

Alfred Boydell Lambe, A.M.E.I.C.

It is with regret that we have to record the death of Alfred Boydell Lambe, A.M.E.I.C., at Ottawa, Ont., on March 15th, 1935.

Mr. Lambe was born at Toronto, Ont., on February 9th, 1873, and received his early education at the Woodstock College where he took a science course, later taking a student's course with the Canadian General Electric Company at Peterborough, Ont.

From 1895 to 1896 Mr. Lambe was superintendent and engineer with the Peterborough Street Railway, and in the following year was assistant chief engineer with the London Street Railway. In 1897-98 he was superintendent and engineer with the Lima (Ohio) Street Railway and from that time until 1903 was engaged on designing, estimating and constructing electric plants of all descriptions as assistant to the chief engineer of the Canadian General Electric Company. From 1903 to 1909 Mr. Lambe was supply department engineer with the same company, and in 1909 he became manager and engineer of the company's Winnipeg district. In 1911 Mr. Lambe became assistant to the chief electrical engineer with the Department of Inland Revenue, Ottawa, and in 1919 he was with the Dominion Power Board. In 1925 he became attached to the Dominion Water Power Branch of the Department of the Interior, Ottawa.

Mr. Lambe was widely known in electrical circles throughout Ontario, and was very active in the affairs of the Association of Professional Engineers of the Province of Ontario, having been president of the Association in 1933.

Mr. Lambe joined The Institute as an Associate Member on April 8th, 1911. He took a keen interest in Institute affairs, and was a member of the Executive committee of the Ottawa Branch in the year 1922-1923.

PERSONALS

C. W. Deans, S.E.I.C., is now connected with the Western Bridge Company, Vancouver, B.C. Mr. Deans graduated from the University of British Columbia in 1930 with the degree of B.A.Sc., and in 1933 received the degree of M.Sc. from Iowa State College.

Lawrence H. Armstrong, A.M.E.I.C., Science 1922, McGill University, son of Professor Henry F. Armstrong, sailed on March 30th on the S.S. Southern Cross for Rio de Janeiro, Brazil, where he will be employed on special work by the Brazilian Telephone Company.

Mr. Armstrong was for eight years with the International Telephone and Telegraph Corporation in Cuba and Spain, most of which time was spent on toll transmission work, and the last two years on trans-Atlantic radio telephone development.

E. L. Dilworth, A.M.E.I.C., of the Canadian Blower and Forge Company Limited, has been transferred to the company's head office in Kitchener, Ont., as assistant sales manager for the company and its associate, Canada Pumps Limited. Mr. Dilworth graduated from Queen's University in 1925 with the degree of B.Sc., and was subsequently with the Buffalo Forge Company at Buffalo, N.Y. He returned to Canada in 1926, and in 1927 took charge of the Montreal office of the Canadian Blower and Forge Company Limited, holding that position until recently.

CORRESPONDENCE

The Editor, Toronto, February 26th, 1935.
The Engineering Journal,
2050 Mansfield Street,
Montreal, Que.

Dear Sir:—

At the recent annual meeting of The Institute in Toronto Mr. J. B. Carswell, M.E.I.C., in his luncheon address, introducing the discussion on the "Status of the Engineer," made some very pertinent and timely observations which merit more attention than they received in the subsequent discussions.

Mr. Carswell in a courageous and forceful speech pointed out that The Institute is devoting all its time to routine matters and the discussion of technical subjects. It is neglecting entirely to interest itself in the general affairs of the community. It offers no opinion, for example, on such matters of urgent national importance as the railway problem; unemployment insurance; relief work and other similar matters on which the government seeks and needs guidance and advice.

He urged a change in policy which would enable The Institute to act as the mouthpiece of the engineering profession in such matters; and he expressed the opinion that the resulting enlargement of "the stature" of the engineer in the public eye would automatically effect an improvement in the status of the engineer in industry, in the public service and in private practice.

Unfortunately the reading and discussion of the three subsequent papers left no time for adequate comment on Mr. Carswell's introduction. It would be unfortunate if his challenging and thought provoking utterances were allowed to pass without further discussion. I would suggest, therefore, that through the medium of The Journal, members would be invited to express their views on this important subject, which has a direct bearing on the declining influence of The Engineering Institute of Canada in recent years.

Unquestionably members of the engineering profession do not occupy the same position nor wield the same influence in public affairs as do the members of other professions. A cursory glance at the constitution of the present House of Commons at Ottawa—or indeed the constitution of any national or local government body—will indicate the negligible representation of our profession in public life.

Admittedly, the nature of the engineer's work, and the fact that so many engineers are employed directly or indirectly by public bodies, railways, public utilities, universities and large corporations, make individual participation in public life impracticable for most of us.

Is it not therefore all the more necessary to have a strong corporate body, fully cognisant of the views of engineers, and capable of presenting and advocating the considered opinion of the engineering profession on questions of the day?

When any matter of great public concern is attracting the attention of the country, it is customary for Boards of Trade, Chambers of Commerce, Manufacturers' Associations, Agricultural Organizations, and similar bodies to convey their views to the government.

Engineers, however, remain inarticulate because they have no mouthpiece through which they can speak, and yet by the nature of their work engineers are brought into intimate contact with every branch of human activity—production—distribution—consumption. Surely they should have something useful to contribute towards the solution of the problems that threaten our social structure—and surely The Engineering Institute of Canada should lead the way.

To the average member, I venture to think, The Institute has ceased to be a live entity—and we have ourselves to blame. With most of us our interest starts and finishes with a perfunctory attendance at a few meetings during the winter months, when we listen to the reading and discussions of technical papers which could generally be more effectively presented in The Journal or in the technical press.

Apart from that—there is little to stimulate interest—little social intercourse—no political aspirations—no contact with public affairs—none of those human relations which are so necessary to build up and sustain an interest in any objective—and which have been instrumental in raising other professional men to their higher standing in the community.

However, if The Institute will arouse itself from its torpor, give ear to the demands of changing conditions, and step out from within the bounds of professional reticence, I am convinced that it can be made useful and influential, not only professionally but also nationally.

Mr. Carswell has indicated the first step. Let us take it.

Yours truly,

(Signed) W. E. P. Duncan, A.M.E.I.C.

Dominion-Crossley and Dominion-Crossley-Premier Diesel Engines

An association has been formed between Dominion Engineering Works Limited, Crossley Brothers Limited of Manchester, and Crossley-Premier Engines Limited of Sandiacre, as a result of which Dominion Engineering Works Limited will manufacture and sell Dominion-Crossley and Dominion-Crossley-Premier Diesel and Gas engines for Canada and Newfoundland.

Engines which may be offered by Dominion-Crossley-Premier will have behind them the long experience of Crossley Brothers and the Crossley-Premier Engine Company as builders of Diesel engines for a great variety of services.

Dominion Engineering Works hopes through its manufacturing facilities in Canada and through its branch offices and associate companies throughout the country, to render a service to users of Diesel engines in Canada and Newfoundland which cannot be rendered so well from abroad.

BOOK REVIEWS

The Stone Industries

By Oliver Bowles, McGraw-Hill Book Co. Inc., New York, 1934. 6 by 9¼ inches, 519 pages, photos, diagrams, etc. $5.00. Cloth.

Reviewed by L. H. Cole, M.E.I.C.*

Few people realize the important part played by stone of all kinds in industry. Its application to practical use was one of the oldest human activities, extending far back before the earliest records, for the name "stone age" is applied to that period of history, our knowledge of which has been conveyed to us only by the crude tools and implements of stone that have been unearthed from time to time.

It is a far cry from the lowly stone hammers and flint arrow heads of our earliest ancestors to the beautifully designed and intricately carved modern buildings to be seen in all our larger cities, and likewise the difference between early quarrying and our present day methods of excavating stone is so great and the advances made in recent years so marked that it is with pleasure that we welcome this volume, giving a comprehensive picture of the stone industry to-day, especially from the pen of an author who has made the subject one of extensive research for so many years.

The volume is divided into three parts: the first part covering the general features of the stone industries; the second, dimension stone, and part three, crushed and broken stone.

Part I deals with the generalities of the industry, has a brief chapter on the minerals and rocks and their classification, and discusses the factors governing rock utilization as well as methods of prospecting and development, points which are common to all classes of quarrying.

Part II, on the production of dimension stone, occupies well over half of the book and deals in detail in separate chapters with the various stones used for the production of dimension blocks, such as limestone, sandstone, granite, marble and slate.

Part III, covering the crushed and broken stone industry, treats principally with crushed and broken limestone, at the same time not neglecting other stones than limestone.

The book, while dealing principally with the stone industry of the United States, contains a brief but well written chapter on Foreign Building and Ornamental Stones.

For engineers and architects, the book has a direct appeal, dealing as it does with the composition, physical properties, structural features, methods of preparation and uses of the various classes of stone.

One criticism that might be offered is the lack of a comprehensive glossary of terms used in the stone industry, a defect that the present volume shares with most other textbooks on the subject. Most of the definitions are given in the text, but if they were compiled in a glossary as an appendix at the end of the volume, this would be of great value.

The bibliographical references at the end of each chapter are wisely chosen and enable easy research over a much wider area than is possible to compress into a volume of this size. The volume is very well indexed, making it extremely valuable as a ready reference book, not least to Canadian engineers interested in the subject, the author having received his engineering education at the University of Toronto.

**Mining Engineer, Mines Branch, Department of Mines, Ottawa.*

An Introduction to Structural Theory and Design

By Hale Sutherland and Harry Lake Bowman, John Wiley and Sons, New York, 1935. 5¾ by 9¼ inches, 318 pages, diagrams, etc. $3.50. Cloth.

Reviewed by W. Chase Thomson, M.E.I.C.*

This is primarily a text-book for use in colleges: but portions of it will be found of interest and value to the practising engineer. As stated in the preface, the reader is assumed to be familiar with the principles of statics and of the strength of materials. It is well written and illustrated.

Simple structures are dealt with very fully in Chapters I to VI inclusive.

In Chapter VII slope and deflection of beams and trusses are treated comprehensively by various methods, including those of work, elastic weights and moment areas, also by the Williot-Mohr diagram.

Chapter VIII deals with rigid frames, introducing the theorem of three moments, also the methods of least work, slope deflection, moment distribution and column analogy.

Chapter IX gives approximate methods only for calculating wind stresses in frames of tall buildings; but, for comparison, includes results derived by the slope-deflection method for a particular example. The authors recommend approximate methods for calculating wind stresses, because of the cumbersomeness of the so-called exact methods, because of the lack of knowledge concerning the proportion of the wind shears carried by walls and partitions and their distribution by the rigid floor construction, also because the girders in steel construction have usually been proportioned as though they were simple spans when carrying vertical loads. With the Cross method of moment distribution now available, which greatly simplifies the layout and by which the same degree of accuracy may be obtained as by the slope-deflection method, there would seem to be no reasonable excuse for approximate methods, either for vertical or horizontal loads. In the meantime, until curtain walls and partitions are better designed to act in unison with the steel

**Consulting engineer, Montreal.*

frame, and until it is possible to make reasonably reliable assumptions regarding the proportion of shears transmitted by such curtain walls and partitions, it would seem advisable to continue proportioning the columns and girders to resist the entire assumed wind loads.

Chapter X deals adequately with indeterminate trusses, employing methods of least work, deflections and influence lines. It closes with a reference to mechanical analysis.

In Chapter XI, secondary stresses are treated primarily by the slope-deflection method as modified by Mohr, using a Williot diagram to determine the movement of the end of a member perpendicular to its axis. Reference is also made to the Cross method, in which the fixed-end moments are obtained by a Williot diagram, as before, but without rotation of joints. Moments are then distributed in the usual manner. The calculation of secondary stresses by the latter method becomes a very simple matter; and, as mentioned by the authors, the accuracy attainable thereby may be as great as desired, or as can be obtained by the Mohr method.

The book closes with Chapter XII, dealing with space framework. This section will be found particularly useful in the design of transmission towers, which are frequently subject to eccentrically-applied loads.

Diesel Engine Design

By Harold F. Shepherd, John Wiley and Sons, New York, 1935. 6 by 9¼ in., 224 pages. $3.50. Cloth.

This publication is well printed and clearly illustrated, but obviously such a big subject cannot be fully covered in a comparatively small volume of this type. It is, however, extremely refreshing to find a treatise on Diesel engines which nowhere contains catalogue descriptions of different makes of Diesel engine.

The first chapter of the volume is entitled "Historical" and might perhaps have been omitted without seriously impairing the value of the book, especially as some of the references are incomplete, for example those dealing with the types of combustion chamber for small engines, in which there is no reference to the direct injection system.

The other chapters deal with such features as combustion, fuel, nozzles and pumps, governing, cylinder heads and valve gear, lubrication, inertia of reciprocating parts, the flywheel and crankshaft with an appendix for reducing calculations in designing crankshaft members, and generally speaking, the whole volume is based on giving short descriptions of the principles involved in the design of each component part of the engine, followed by, in many cases, references to the necessary calculations for solving the problems connected therewith. Some of the illustrations, such as of men lining a room with cork insulating material, or of an exploded crankcase, seem superfluous.

The book is worthy of a much fuller index than is provided. The author cites a number of features in design or material upon which successful operation depends, discussing for example the form and proportions of piston which are needed to secure an optimum working temperature of piston face, and the points to be borne in mind when designing the starting gear for marine engines which are required to manoeuvre constantly in service.

The volume may be recommended as of considerable value to engineers interested in Diesel engines, either from the design or operating viewpoints. It must not be overlooked, however, that there are probably hundreds of different manufacturers of Diesel engines, every one of whom has at least one distinctive method of dealing successfully with some specific problem, and that it is impossible in a volume of this size to refer to more than the small proportion of these many methods which may be personally known to the author.

The 1935 E.I.C. Engineering Catalogue

The third annual edition of the E.I.C. Engineering Catalogue is now in the press and will be distributed shortly. The present volume is considerably extended both as regards the information descriptive of engineering equipment and materials and the index reference data.

The many appreciative letters received following the issuance of the first two editions, and the evident desire of manufacturers to include greater detail regarding their products is indicative of the better understanding and appreciation of the service which The Institute is rendering by the publication of such a comprehensive and authoritative reference book.

In the present issue the arrangement of the data follows that of the previous editions, which is believed to provide the most convenient arrangement for ready reference.

The Catalogue is designed to serve the requirements of those responsible for the specifying and purchase of engineering equipment and materials in every branch of industry and engineering, so that it includes reference information covering electrical equipment, mechanical equipment, construction equipment, building products and special machinery used in such basic industries as mining, pulp and paper manufacture, textiles, etc.

Copies of the Catalogue will be supplied to all members of The Institute who will fill in and return the enquiry cards which will be sent out in the course of a few days, and the remainder of the issue of five thousand copies will be distributed to a carefully selected list of those officers of important firms or organizations who can best make use of the reference information which it contains.

BRANCH NEWS

Calgary Branch

J. Dow, M.E.I.C., Secretary-Treasurer.
H. W. Tooker, A.M.E.I.C., Branch News Editor.

On Thursday, February 7th, 1935, the members of the Calgary Branch were fortunate in hearing an address by Mr. A. Hannah, K.C., on "Democracy or Dictatorship." This meeting was also chosen for the finals of the ten minute speeches in the competition for the younger members of the Branch. Those participating were I. Abramson, Jr.E.I.C., and R. W. Dunlop, Jr.E.I.C.

Cement Testing

The chairman first called upon Mr. Abramson, whose subject was "Cement Testing."

The tests usually applied to cement may be roughly classified as mechanical or chemical in nature, the most common being for the determination of tensile or compressive strength. Fineness, normal consistency, time of set etc., soundness, are also observed and for some purposes porosity and permeability of mortars may be investigated.

However, one test method, the study of electrical properties of cement, seems to be overlooked.

Modern atomic theories regard all matter as electrical in nature and chemical properties of any element may be explained in terms of grouping of the electrons about the atomic nucleus and the resultant internal and external forces. Therefore, a study of the variation in electrical characteristics of a chemical mixture should yield information on the changes taking place in it.

A similar conclusion may be reached by a different form of reasoning, viz. from practice we know that the ohmic resistance of an electrical conductor of given dimensions depends on its chemical composition, thus if chemical changes take place in a given conductor its chemical resistance must vary.

To prove this, a number of experiments were carried out with test pieces having electrodes inserted in the ends of each. After curing in moist air the specimens were transferred to various solutions. At daily intervals they were removed from the solutions, the surfaces dried and the resistance measured by observing the voltage necessary to pass a given current.

Principles of Orifice Meters

The chairman then called upon Mr. R. W. Dunlop for his discussion on the "Principles of Orifice Meters."

To give a very short outline of the principles of orifice meters the subject may be divided into the following general headings:

Uses. Orifice meters have a wide range of application, chiefly in large scale commercial measurements of liquids and gases, and are used for total quantity and rate of flow measurements.

Development and Principles. The orifice meter has been developed from the characteristics of fluid flow through a circular orifice in a diaphram inserted in a pipe. Connections are made on the pipe for measuring differential pressures at the upstream and downstream faces of the plate as well as the static or line pressure at the downstream face. By determining differentials for various flow rates with any orifice we can establish an orifice meter. For compressible fluids it is necessary to measure static pressure at the down stream face.

General Considerations. To obtain consistently accurate results the following considerations must be taken into account: size of orifice relative to pipe size; the fittings should be ten pipe diameters up stream and five diameters down stream from the orifice; position of differential connections; orifice shape.

Following Mr. Dunlap's address the chairman introduced the speaker of the evening, Mr. A. Hannah, K.C.

Democracy or Dictatorship

In his opening remarks Mr. Hannah stated that there was nothing political in what he was about to say and also that he wished to review the subject of democracy in the first place, as this form of government has developed under the British constitution.

One of the first beginnings in history and perhaps the one which comes most readily to one's mind in thinking of democracy is the Magna Charta.

The most significant features of democracy have been the results which have flowed from democracy as developed under the English constitution, namely: Freedom of the people; development of education; administration whereby justice is swift and sure; purity and lack of corruption in our law courts and regard for private rights.

With all these things, why the cause for the outcry to-day against existing conditions? The world war shook the world to its foundations and possibly it has been good for all of us to be shaken out of self-complacency and satisfaction. We are forced to the admission that if there have been beneficial growths as democracy has developed there have also been growths of a virulent and undesirable type. Who is to blame for this condition and how could undesirable conditions originate when so much that is desirable has been brought to pass?

The speaker believed that the solution of our present day difficulties will be solved not by revolutions nor any new-fangled schemes, but by finding out what is wrong with our systems and the why and the wherefore of our having gone astray.

Democracy, like any other form of government, involves primarily the relationship between the state and the individual and the question whether the individual is to be left full freedom to develop his life, as he will, subject to respect for the rights of others, or to have it ordered for him by the regimentation of some arbitrary power exerting authority in the name of the state.

To defend the liberties we prize against encroachment demands perpetual vigilance, and nothing can so much stimulate it as the spectacle of other countries where liberty as we know it has disappeared.

A hearty vote of thanks was given to the three speakers by the chairman of the Branch, G. P. F. Boese, A.M.E.I.C.

Hamilton Branch

A. Love, M.E.I.C., Secretary-Treasurer.
Alan B. Dove, Jr.E.I.C., Branch News Editor.

The Hamilton Branch of The Institute met in the Science Hall, McMaster University, on the evening of Tuesday, February 19th, 1935. W. Hollingworth, M.E.I.C., chairman of the Branch, occupied the chair. After preliminary remarks, W. J. W. Reid, A.M.E.I.C., was called on to introduce the speaker of the evening, Mr. Balmer Neilly, B.A. Sc., C.E., one of Ontario's best known consulting mining engineers and one fully qualified to deal with the subject of "Mines and Miners."

Mines and Miners

Mr. Neilly stated that all the facts of mining were not evident from the information given by the promoters of mining stock; the difficulties were not mentioned, and the good points, if not absolutely magnified, greatly predominate. Since 1903, charters have been issued by the provincial government to forty-three hundred mining concerns, of which only forty-two have reached that stage of development which requires payment of government tax. Again, only one in three hundred is able to pay taxes, return of capital and hazard investment and actually reach the stage of being a successful mine.

The speaker expressed the opinion that mining was destined to assume the place in economic importance formerly held by our agricultural resources, in opening up new areas and attracting colonial settlers.

The value of the products of Canadian mines for 1934 was 278 millions. This showed an increase, of 26 per cent over 1933, and 25 per cent over 1929, the previous peak year.

Canadian mines employ over twenty-two thousand men in the mines and about one thousand prospectors. The mines are operated on three shifts of eight hours each. The miner works a six day week, but there is always a call for extra men, and many work the seven days. The average pay for the miner is $5.10 per shift.

Contrary to popular opinion, the foreign element does not predominate in the mining industry. Statistics show the following percentages, British stock 64 per cent, Italian 7.6 per cent, Slavs 7.2 per cent, Finns 4.2 per cent, Poles 2.9 per cent, and others 14.1 per cent, and it is interesting to note that of the 36 per cent classed as foreigners, 80 to 85 per cent of them are naturalized Canadian citizens, and in the second or third generation their children do not differ from Canadian boys and girls.

The advantages of a mining advance are manifold and include colonization, railway extension, development of water power and sales of the city products. Of the total value realized for the gold of Canada, one third goes to compensate labour, one third for supplies and equipment, and the rest to capital and funds. The cost of supplies with their attendant value to cities like Hamilton may be imagined when it is realized that every ton of ore ground necessitates about 4½ lbs. of steel in the form of balls for the grinder.

Mining taxes must be very carefully considered, for if the tax is raised then much ore must be left undeveloped. Government taxes here amount to $1.26 per ton of ore mined and reduced, and the cost of production is $4.16 including the tax.

In order to give an insight into the conditions met with in mines and the methods employed in obtaining the ore, Mr. Neilly showed two Ontario government films of the workings of the Hollinger Gold Mines at Timmins, Ont.

R. M. Dilly, of the Babcock-Wilcox & Goldie-McCulloch Engineering Society, Galt, brought greetings from his society and an invitation to attend their meeting Friday night. He proposed a vote of thanks to the lecturer for his splendid address. This was endorsed by all present.

Announcements were made and Mr. Milne was thanked for his services with the projector. The meeting then adjourned and refreshments were enjoyed in an adjoining room.

Lethbridge Branch

E. A. Lawrence, S.E.I.C., Secretary-Treasurer.
J. E. Hawkins, S.E.I.C., Branch News Editor.

The Lethbridge Branch of The Engineering Institute of Canada held its regular meeting in the Marquis hotel on Saturday evening, February 2nd, 1935, with C. S. Donaldson, A.M.E.I.C., in the chair, and about forty-five members present.

The Production of Rubber

An interesting film kindly loaned by the Dominion Rubber Company on the production of rubber was shown. This dealt with the company's rubber plantations in the island of Sumatra, showing the initial work of clearing the jungle, planting, and grafting of the young trees and the tapping of the trees to obtain the sap or "latex" as it is called. The factory operations for converting the latex to rubber were then shown; the Hopkinson spray process being clearly explained by means of an animated drawing. Of particular interest was the fact that almost all the labour was done manually, due no doubt to the cheapness of native labour.

Century of Progress

Through the courtesy of the Ford Company and the Ford Motor Sales of this city, an interesting film dealing with the "Century of Progress" World's Fair at Chicago, and a trip through the Ford building was shown.

Concrete Highway Construction

Following this, a film on "Modern Concrete Highway Construction," furnished by the Canada Cement Company, was shown. The quarrying, washing, and screening of the coarse aggregate was first dealt with. Then came the weighing of the proper proportions of the coarse aggregate, the fine aggregate, and the cement, and the transportation to the mixers. The mixers performed the work of mixing and laying of the surface. The method of properly allowing the concrete to "set" and dry and the provisions made for expansion joints were shown. Finally the government supervision and testing work was outlined.

The meeting was followed by a buffet luncheon, which concluded a very interesting evening's entertainment.

The Lethbridge Branch of The Institute held its regular meeting in the Marquis hotel on Saturday evening, March 2nd, 1935, with C. S. Donaldson, A.M.E.I.C., in the chair.

Dinner was served to about thirty members. During the dinner Mr. and Mrs. George Brown and orchestra entertained the members with several very delightful numbers. Following the dinner community singing interspersed with vocal solos was enjoyed. Mr. Donaldson called upon W. L. McKenzie, A.M.E.I.C., the incoming chairman, to say a few words. Mr. McKenzie traced the growth of the electrical industry in the past forty years, concluding by mentioning some of the ideas held at that time which are entirely disregarded to-day.

Mr. Donaldson then introduced Mr. W. Pratt of the Otis-Fensom Elevator Company, and two excellent films supplied by that company were shown, the first dealing with the construction of the Empire State building and the second with the construction of the George Washington bridge.

The film dealing with the construction of the Empire State building traced the construction through from the fabrication of the columns in the Carnegie Steel Company's plants to their final assembly in the building. There are sixty-seven elevators in the building; the main elevators travelling to the eightieth floor where a transfer is made to the eighty-sixth floor, and finally one elevator travels to the observation tower, equivalent to the one hundred and second floor, 1,212 feet above street level. The whole building is 1,250 feet high.

The next film dealt with the construction of the George Washington bridge across the Hudson river, New York. This is a suspension bridge, being suspended from four cables, each 36 inches in diameter, which in turn are fastened to two towers 600 feet high, and anchored in bedrock at each side of the river. A very clear illustration of the spinning of the cables was given. The wire used in the cables totals a length of 107,000 miles or more than four times around the earth.

On behalf of the meeting Wm. Meldrum, A.M.E.I.C., moved a hearty vote of thanks to Mr. Pratt and the Otis-Fensom Company for their courtesy in connection with these films.

The meeting then adjourned to the mezzanine floor for a short business meeting, during which the result of the election of officers was announced.

Mr. Rudd spoke briefly on the work of the League of Nation's Society. The annual report was presented and passed. The report of the Programme committee was presented by Mr. Meldrum, and after a short discussion of the programme for the next season the meeting adjourned.

London Branch

S. G. Johre, A.M.E.I.C., Secretary-Treasurer.
Jno. R. Rostron, A.M.E.I.C., Branch News Editor.

The regular monthly meeting of the London Branch of The Institute was held on February 20th, 1935, in the City Hall auditorium, the speaker being Mr. C. E. Simpson, of the All-Weld Company of Toronto, and his subject "Spray Metallizing."

In the absence of S. W. Archibald, A.M.E.I.C., chairman of the Branch, J. Ferguson, A.M.E.I.C., vice-chairman, presided.

Spray Metallizing

The speaker told how by ingenious methods cold metal can be taken into a spray gun in the form of wire, and instantaneously sprayed onto another metal surface like paint and done economically. The idea itself was not new, it was used extensively during the World War in somewhat the same way.

With the use of motion pictures, Mr. Simpson illustrated his address, showing graphically how the gun works making use of any metal that can be drawn into wire. Zinc, tin, copper, lead, iron, even stainless steel is now sprayed on. For instance it was possible now to spray the inside of water tanks to prevent rust, and the speaker went on to outline innumerable uses for the gun. It is a cold process, one's hand could be put right through the spray and come out metal plated but not burned. The metal wire is melted just as it leaves the gun, with the use of oxy-acetylene, and is made permanent on the surface by impact.

The process was particularly useful to engineers, contractors and manufacturers, as well as electrical workers. Mr. Simpson said, showing how worn parts, shafts particularly, can be built up to their original size and shape, thus saving the cost of new parts, or in some cases the possible scrapping of the machine.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

Methods of coal testing employed by the Canadian National Railways formed the subject of a very instructive paper read before a regular meeting of the Branch on January 29th, 1935, by David Hourston, Branch Affiliate. J. G. Mackinnon, M.E.I.C., chairman of the Branch, presided.

Coal Tests

Inasmuch as ten cents of every revenue dollar is spent by the railways for fuel, the importance of fuel tests cannot be overestimated. Laboratory tests are useful as a check but locomotive running tests are required to take care of all the factors entering into the steaming value of any given grade of coal.

The run should be over a subdivision of from seventy-five to one hundred miles long, where at least a three hour run may be expected. The physical characteristics of the subdivision chosen should be such that the engine will have to be worked most of the time and where very little drifting and braking will be encountered due to down grades. The class of train essential to bring out the best results will be one with full tonnage on a run with very little detention. The conditions under which each test is made should of course be as nearly identical as possible.

The speaker described, at length, the test instruments attached to the locomotive and the readings taken.

A vote of thanks to Mr. Hourston was moved by T. H. Dickson, A.M.E.I.C., seconded by R. H. Emmerson, A.M.E.I.C.

Modern Arc Welding

On February 19th David Boyd, B.Sc., A.M.E.I.C., of the Dominion Bridge Co. Ltd., Montreal, delivered an illustrated address on "Modern Arc Welding." J. G. Mackinnon, A.M.E.I.C., was in the chair.

Mr. Boyd described the materials and types of electrodes used in welding. With the aid of slides he showed illustrations of correct design and also the more common errors in the design of welded connections. A brief description was given of the annealing process for reducing internal stresses. In the opinion of the speaker, at least one year is required to train a welder. An inspector should not only be a welder but a qualified engineer as well.

In answer to questions, Mr. Boyd stated that in buying a welding machine, he would suggest a capacity of at least 300 amperes and a potential at the electrode of not less than 40 volts.

The welding of locomotive boilers was not yet permitted but when it is, the speaker was of the opinion that boiler pressures could be doubled and the steam locomotive compete to better advantage with the oil electric.

The electric arc is not suitable for welding rail ends. The thermit process is the one found most satisfactory.

A vote of thanks to Mr. Boyd was moved by C. S. G. Rogers, A.M.E.I.C., seconded by H. J. Crudge, A.M.E.I.C.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

Mechanical Section—Arc Welding

On February 4th, 1935, David Boyd, A.M.E.I.C., further developed his paper as given on the Thursday evening previous, illustrating his talk with slides and models.

H. J. Roast, M.E.I.C., was again in the chair.

Economics and Design of Air Compressors

The history, design, economics and types of air compressors were described on the evening of February 7th, 1935, by F. G. Ferrabee, sales manager of the Canadian Ingersoll Rand Company Ltd., in a talk before the members of the Branch. The variety of uses for compressors were commented upon and examples given.

R. H. Findlay, M.E.I.C., presided.

Junior Section

On February 11th, 1935, two papers were presented before the Section: One by W. L. Thompson, Jr.E.I.C., engineer with the Bailey Meter Company, on "Flow Meters," and another by J. Royer, S.E.I.C., a student at McGill University, on the "Treatment of Copper Ores at Noranda."

Paul Vincent, S.E.I.C., was in the chair.

Broadcast Network of Canadian Radio Commission

Lieut.-Colonel W. A. Steel, M.C., Commissioner of Canadian Radio Commission, on February 14th, 1935, spoke on the broadcast network in Canada. He explained the complex networks used by the Commission to send out its programmes and the many technical problems involved in broadcasting. Some comparisons were made with British, European and American procedures, the speaker stating that due to the uneven distribution of the Canadian population the problems arising from broadcasting coverage were much more complicated in Canada than in most other countries.

H. J. Vennes, A.M.E.I.C., acted as chairman, and previous to the meeting an informal dinner was held at the Windsor hotel.

Lightning

On February 21st, 1935, Mr. A. C. Monteith, engineer with the Westinghouse Electric and Manufacturing Company, Pittsburgh, presented a paper on lightning problems, reviewing the present knowledge of natural lightning and factors to be considered in the design of transmission lines and substations. His address was illustrated by a number of excellent lantern slides.

Previous to the lecture an informal dinner was held at the Windsor hotel. Professor C. V. Christie, M.E.I.C., was chairman of the meeting.

Student Night

Two members of the Junior Section of the Montreal Branch presented papers at the meeting held on Thursday, February 28th, 1935.

Horace Young, a student in fourth year mining at McGill University, spoke on "Mineral Production in Canada and Effect in Industry," and Yvon Tasse, S.E.I.C., in his first year at the Ecole Polytechnique, who spoke in French, his subject being "Le Vent pour Electrifier nos Campagnes."

Recent Developments in Sound Pictures

S. T. Fisher, Jr.E.I.C., engineer in the special products engineering department of the Northern Electric Company, gave an exceedingly interesting address and demonstration on March 7th, 1935. He outlined the history, thecry and practice of sound reproduction as applied to moving picture theatres and to public address systems. Recent improvements have been mainly in three ways: the successful transmission of low- and high-pitched voices and other sounds, by improvements in the volume of sound and by reduction in the noises created by the reproducing mechanism.

J. L. Clarke, M.E.I.C., presided.

Junior Section

On Monday, March 11th, 1935, papers were presented before this section on "Technical Advance in Russia," by E. I. Wigdor, S.E.I.C., and "Air Conditioning for Comfort and Industrial Purposes," by Andre Michaud, S.E.I.C.

Mr. Wigdor is in his final year in electrical engineering at McGill University, and Mr. Michaud was a graduate in 1934 from the Ecole Polytechnique.

W. S. Bowles, S.E.I.C., acted as chairman.

Air Conditioning in Industry

Mr. Walter L. Fleisher, consulting engineer, of New York, and editor of the "Guide" of the American Society of Heating and Ventilating Engineers, spoke to the members of the Branch on March 15th, 1935. He pointed out that the future of air conditioning in Canada, as distinguished from that in the United States, was a winter problem rather than a summer one, and consequently any equipment used should be designed with this in mind. Interesting data regarding air conditioning in general was furnished.

Brian R. Perry, A.M.E.I.C., occupied the chair, and previous to the meeting an informal dinner was held at the Windsor hotel.

Stainless Steel

On March 21st, 1935, C. M. Carmichael, general manager of the Shawinigan Stainless Steel and Alloys Limited, presented a paper on the history and application of stainless steel. This was discovered by accident at Sheffield, England, during experiments on gun linings and is now used extensively in many industries.

C. R. Whittemore, A.M.E.I.C., presided.

Niagara Peninsula Branch

P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

The Branch held a well attended dinner meeting at the King Edward hotel, Niagara Falls, on March 13th, 1935, at which Mr. David Boyd, assistant works manager of the Montreal fabricating shops of the Dominion Bridge Company, spoke on the art of "Arc Welding."

Arc Welding

"Although welding has been practised from time immemorial," said Mr. Boyd, "it is only within the last fifty years that the development of electricity and the improved science of metallurgy has allowed its use to be extended to the field erection of bridges, ships, buildings and to the shop welding of huge members used in various engineering designs, some of which weigh ten tons and over.

"Most of the metals and alloys can now be successfully welded with joints that are practically unnoticeable and being as strong, or stronger than the original metal. At least one half of the test bars will break outside of the weld.

"Metallic arc welding is being used more and more for the fabrication of gear wheels, machinery frames and bases, column footings and other shapes which, until a few years ago, were made entirely of cast iron or steel.

"In structural steelwork, welding has not altogether taken the place of rivets, principally on account of the difficulty in making tests of work which has been field connected. Many of the principal joints are therefore riveted whereas the secondary connections may be welded."

Lantern slides were shown of the new Caughnawaga and Isle d'Orleans bridges, in the construction of which welding was employed extensively. Another novel use was the fabrication and erection of the light reinforcing steelwork for an eleven-storey concrete building: the metal work being entirely completed before any concrete was poured thus saving much of the supports for formwork and allowing the allied trades to instal the necessary pipes and electric wiring conduits.

After a vote of thanks to the speaker had been tendered by chairman W. R. Manock, A.M.E.I.C., the amount of local interest was shown by a discussion which lasted until nearly midnight.

Mr. Boyd has addressed several of our Branches during the past winter and is preparing an article on the subject of welding which will appear in The Journal.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

THE PRESENT STATUS OF TIDAL POWER

At the first noon luncheon of the 1935-1936 year, held at the Chateau Laurier on February 21st, 1935, H. E. M. Kensit, M.E.I.C., M.A.I.E.E., spoke upon "The Present Status of Tidal Power." Dr. R. W. Boyle, M.E.I.C., chairman of the Ottawa Branch, presided, and in addition head table guests included: J. L. Busfield, M.E.I.C., of Montreal; Hon. T. G. Murphy, C. A. Magrath, M.E.I.C., Dr. A. E. Cameron, R. A. Gibson, Norman Marr, M.E.I.C., Prof. A. S. Cudmore, G. S. Wrong, J. A. Rodd, J. L. Stiver, L. S. McLaine, and Victor Meek, M.E.I.C.

Tidal power utilization, Mr. Kensit stated, is not new. Probably the earliest tidal plant was the water-wheel installed by a Dutchman, Peter Morice, in one of the arches of London Bridge in 1582, to operate a pump for water supply—this was in use, with extensions, for over one hundred years. Other more recent examples of small installations have been in existence for many years in America. The question really is not so much can power from tidal sources be developed, as, is such development commercially practicable on a larger scale? At present both capital and production costs of tidal power appear to be slightly above the best obtainable from fuel or from possible available undeveloped water powers.

Also the technical aspect of tidal power production is more involved than is the case with the usual water power development.

Several types of tidal power development are possible: the single basin type, either unassisted or used in conjunction with other power stations; the single basin type supplemented, where possible, by elevated natural water storage to which water may be pumped by the surplus power at high tide, the combination furnishing continuous power; the single basin type supplemented by fuel auxiliary; and various forms of the multiple basin type that can be operated to give continuous power without either elevated storage or fuel auxiliary.

Large scale projects for the development of tidal power have been under investigation in various parts of the world: on the eastern coast of the Argentine; on the coast of Brittany; on Passamaquoddy bay and at the junction of the Petitcodiac and Memramcook rivers in Canada; and on the estuary of the Severn river between England and Wales.

Two of these that have received most thorough investigation are those on the Severn in England and on Passamaquoddy bay in Canada. The latter, in addition to examination and estimates by private interests, has been investigated by the Board of Engineers of the United States Army. This board estimated it could provide for an ultimate installation of 1,087,000 h.p. at a cost of $100,000,000 or $92 per horse power, which is a substantially lower figure than that so far estimated for any other large tidal power project.

Probably the controlling factor in holding back the development of large tidal power projects has been the advances that have been made in recent years in reducing both the capital and production costs of fuel power. The coal required for a given output, for instance, has been more than halved in the last fifteen years.

Peterborough Branch

H. R. Sills, Jr.E.I.C., Secretary.
E. J. Davies, Jr.E.I.C., Branch News Editor.

ARTIFICIAL ILLUMINATION AND ITS PART IN MODERN LIFE

The story of illumination was told to the members of the Peterborough Branch and their friends on February 21st, 1935, in the auditorium of the Peterborough Collegiate and Vocational School, and was presented by the Canadian General Electric Company, the Canadian Westinghouse Company and the Ontario Hydro-Electric Power Commission.

The first part of the programme was covered by a talking picture entitled "The Science of Seeing," featuring H. F. Barnes of the Nela Park laboratories of the General Electric Company. Lecturing from the screen, Mr. Barnes outlined the fundamentals in the relationship of illumination to healthy vision.

Four factors in regard to satisfactory illumination were urged. Rooms should first be illuminated with light of an intensity high enough to serve the specific needs. Whereas relatively dim light is satisfactory for stairways and hallways, very bright light is required for sewing and the reading of small types. Rooms should be lighted in such a way that little lighting contrast is permitted, and lighting systems should be such that glares are avoided, it was pointed out.

A practical demonstration on lighting was staged by Mr. G. F. Mudgett of the Westinghouse Company, in which he demonstrated different kinds of lights and the contrast between glaring and non-glaring lights. He showed that by covering a glaring light with a transparent shade that the glare was eliminated and yet the light intensity received by a meter was not diminished.

Mr. G. G. Cousins of the Hydro-Electric Power Commission spoke on the fundamental principles of illumination covering the light intensity required for different uses of the eye. He demonstrated the ideal student reading lamp, designed by the Illuminating Engineering Association to cover the requirements of students. The bottom of the shade of these lamps is at a distance of from 18 to 20 inches from the table. The light used is 100 watt, part of which is thrown directly to the ceiling and the balance through a transparent secondary shade to the table. Mr. Cousins made a special appeal to the parents on behalf of the boys and girls who have homework to do, and urged the parents to see that young people were supplied with suitable lighting in order to preserve their good health and their eyes.

An animated cartoon film urging the importance of modernized lighting systems in city streets rounded out the programme. Mr. R. Wilde of the Canadian General Electric Company officiated in the projection of the pictures, while Mr. Wm. Dickson assisted Mr. Mudgett with the series of slides depicting properly and improperly lighted rooms in homes. The meeting, under the chairmanship of Ross L. Dobbin, M.E.I.C., was attended by more than three hundred persons who thoroughly enjoyed the programme.

Quebec Branch

Jules Joyal, A.M.E.I.C., Secretary-Treasurer.

SOME CONSIDERATIONS GOVERNING THE UNDERTAKING OF HYDRO-ELECTRIC POWER DEVELOPMENTS

"The author has endeavoured in this paper to give some idea of the problems to be encountered when any hydro-electric power development is under consideration. The science of hydro-electric power engineering has made great advances in recent years, but the difficulties to be surmounted become greater all the time. The engineering profession has also increased its knowledge and it is hard to conceive of any problem that will remain unsolved for long. Certainly things are being accomplished to-day that would have been mere pipe dreams a few years ago."

This was the conclusion of the paper presented by E. D. Gray-Donald, M.Sc., A.M.E.I.C., superintendent, Power Division, Quebec Power Company, at a luncheon meeting of the Quebec Branch held at the Chateau Frontenac on January 14th, 1935.

"In Canada the greater amount of power is developed by hydraulic means; the installed horse-power at the end of 1933 was 7,332,000 h.p., the output was estimated as the equivalent of 15 million tons of coal. In a country where the few available coal deposits are far from the centres of industry it is a very important factor."

The speaker said a few words on the trends in hydro-electric power development and briefly described the Boulder Dam project on the Colorado river.

"The popular belief that electricity generated by means of water power is always cheaper than that generated in steam plants, is a fallacy. The reason for this is the tremendous capital cost of hydraulic works, the cost of storage water as an operating charge, and the long distances over which hydro-electric power usually has to be transmitted, involving high investment in transmission lines and continuous loss of power. Except in special cases careful analysis must be made to find which is the more economical method of generation."

"In any undertaking for the supply of electric power there are a great many factors to be considered, the two fundamentals of which are demand for power and available source of water supply."

The speaker mentioned the manufacture of newsprint paper as one of the greatest industries using electricity in eastern Canada and gave some information in this connection; he then gave valuable information in regard to the projects under construction or to be executed in the future on the St. Maurice river.

The question of water supply was fully dealt with and geological considerations were mentioned as a very important factor governing the location of a dam.

The last paragraph of Mr. Gray-Donald's lecture was dealing with the construction organization and the line of communication with the construction force.

LA ROUTE MODERNE

Tel fut le sujet d'une très intéressante causerie qui fut donnée à un déjeuner de notre section, le 18 mars, 1935, par M. Alphonse Paradis, Ingénieur en Chef au Ministère de la Voirie de la Province de Québec.

Le conférencier fut présenté à l'auditoire par M. Hector Cimon, M.E.I.C., président de la section, puis M. L. P. Méthé, A.M.E.I.C., Directeur de l'Ecole Technique de Québec, proposa un vote de remerciements chaleureusement secondé par les applaudissements.

Nous croyons que la causerie de M. Paradis sera publiée prochainement dans ce "Journal".

Sault Ste. Marie Branch

H. O. Brown, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Sault Ste. Marie Branch was held at the Windsor hotel on Friday evening, February 22nd, 1935. The usual form of dinner meeting was followed, and about sixteen sat down to the dinner preceding the business meeting.

F. Smallwood, M.E.I.C., the chairman, presided, and the regular business meeting was held at the close of the dinner. The members of the Branch were interested in the "Proposed Consolidation of the Engineering Profession in Canada" as referred to in the resolution of the Montreal Branch presented at the annual meeting held in Toronto, and also the resolutions passed at the Toronto meeting.

The Branch asked that the Executive review the correspondence and proposals received and be prepared to present a resolution to the Branch at a later meeting.

The speaker of the evening, Mr. James Kelleher, of the Fitzgerald Laboratories, was introduced by H. F. Bennett, A.M.E.I.C., and the subject of his address was "Research Work in the Ceramic Industry."

Research Work in the Ceramic Industry

The speaker pointed out that the ceramic industry covered a very large field when defined as the art of making pottery, china and porcelain wares. As it may be naturally divided into coarse products such as brick, tile and terra-cotta, and fine products as chinaware and porcelains, the paper was confined to the fine products.

An outline of the origin of the clays, the preparation of the clays, the moulding of the various types of articles, the firing or baking, the decorating and glazing were all described very fully by Mr. Kelleher and illustrated with large diagrams.

The special research work carried out at the Fitzgerald Laboratories a few years ago and with which Mr. Kelleher was associated was principally in connection with the porcelains for spark plugs for motor cars.

A special electric furnace was developed for the research work and the various problems met with such as irregular baking and shrinkage and "blistering" were finally overcome. The final results attained were a more durable product, a greatly reduced manufacturing time and shrinkages controlled within the limits allowed.

Reference was also made to some research work carried on in the baking of "abrasive" wheels in the electric furnace and also other articles which presented difficulties in the ordinary gas or oil-fired furnaces.

The meeting was thrown open for questions at the close of the paper and the subject proved to be of great interest to all the members present.

A very hearty vote of thanks was extended to Mr. Kelleher by the members of the Branch for the presentation of his paper.

Winnipeg Branch

J. F. Cunningham, A.M.E.I.C., Secretary-Treasurer.
H. L. Briggs, A.M.E.I.C., Branch News Editor.

Annual Supper Dance

In no small way were the Winnipeg Branch of The Institute together with the Association of Professional Engineers of Manitoba successful with their ninth annual supper dance, held in the Royal Alexandra hotel on the evening of February 21st, 1935.

The main dining room was most effectively decorated for the occasion. The entire ceiling was draped with gold, scarlet and blue. From a setting in silver stars a golden moon shone down upon a Venetian scene, while the orchestra in a scarlet and gold gondola supplied the latest dance music for a capacity gathering of carefree engineers, their wives and friends. Lantern lights from gay gondola pontoons and coloured tapers lit up the flower-decked supper tables.

S. E. McColl, A.M.E.I.C., and his committee are to be highly complimented on their efforts, which truly warranted the successful evening.

Report of Annual Meeting

The annual meeting of the Winnipeg Branch of The Institute was held at the University of Manitoba on Thursday, February 7th, 1935, at 8.40 o'clock p.m. Major A. J. Taunton, A.M.E.I.C., occupied the chair.

The minutes of the previous meeting were read by the Secretary and adopted. The chairman reported that as the proposals for the joint Executive Control of the Branch and of the Association of Professional Engineers of Manitoba had not become effective, the amendments to the By-laws of the Branch were unnecessary, and that amendments affecting the method of securing the consent of nominees for candidature at elections were being considered by F. G. Goodspeed, M.E.I.C.

The chairmen of the following committees read their reports: Joint Committee on Unemployment, Professor J. N. Finlayson, M.E.I.C.; Library and Publication, J. F. Cunningham, A.M.E.I.C.; Programme Committee, G. E. Cole, A.M.E.I.C. The Secretary read the report of the auditors, Messrs. J. C. Trueman, A.M.E.I.C., and Alex Campbell, A.M.E.I.C., and that of the scrutineers, Messrs. G. Affleck, A.M.E.I.C., and F. E. Umphrey, A.M.E.I.C.

The following chairmen of committees were elected: Advisory Committee, E. W. M. James, A.M.E.I.C.; Library and Publications Committee, L. M. Hovey, A.M.E.I.C.; Programme Committee, W. D. Hurst, S.E.I.C.; Research and Investigation Committee, F. G. Goodspeed, M.E.I.C.; Branch representative on The Institute Nominating Committee, A. J. Taunton, A.M.E.I.C. Auditors, G. M. Pearston, A.M.E.I.C., and J. T. Rose, A.M.E.I.C.

The retiring chairman then made his address, after which he announced that the secretary, Mr. E. W. M. James, was also retiring, and made very appreciative remarks in connection with Mr. James' long term of office.

The incoming chairman then took the chair and introduced the speaker, Professor Wardle, professor of zoology of the University of Manitoba, who gave a "New Discourse on a Stale Topic," in which he dealt with the place of the imagination in scientific observations, particularly in the field of mediæval pharmacy, zoology and medicine and surgery.

Professor G. H. Herriot, M.E.I.C., moved a vote of thanks to the speaker and the meeting adjourned at 11 o'clock p.m., after which refreshments were served.

Explosives in Peaceful Pursuits

A good audience of engineers made their way through Winnipeg's record fall of snow to hear Mr. J. S. Morrey, Explosives Division, Canadian Industries Limited, present a paper entitled "Explosives in Peaceful Pursuits" on March 7th last.

Mr. Morrey defined an explosive as a substance which by the application of friction, heat, spark, or shock would instantly be converted into an enormous volume of gas.

Liquid and highly dangerous nitroglycerin was made comparatively safe by Alfred Nobel, by dissolving gun cotton in it, thereby producing gelatinized dynamite. The new product opened the gateway to the commercial use of high explosives.

When explosed, the first dynamites gave off large quantities of poisonous gases. Today, dynamites can be obtained which include ingredients which make the gas products almost entirely harmless.

The percentage of a dynamite means the percentage strength of the dynamite, compared with pure nitroglycerin. The speed of explosion of a dynamite is known as its velocity of detonation, and is as high as 12,800 feet per second.

Black powder is a mixture of charcoal 16 per cent, sulphur 11 per cent, and saltpetre 73 per cent. It is used chiefly in coal mines for its 'heaving' action, where a fast explosive would shatter the coal.

In mines where gas is met with, a 'permitted' explosive is used. This is a low grade dynamite, which because of its reduced burning time as compared with black powder, minimizes the possibility of the explosion igniting the mine gas.

The hour of questions and discussion which followed the presentation of Mr. Morrey's paper showed the general interest in the subject. A hearty vote of thanks was tendered the speaker, after which those present enjoyed light refreshments and a social half hour.

Association of Professional Engineers of Saskatchewan

The fifth annual meeting of the Association of Professional Engineers of Saskatchewan, was held at the Hotel Saskatchewan, Regina, on February 15th, 1935. The afternoon was taken up with a Council meeting and the general meeting of the Association, at which general business was transacted.

At this meeting, Mr. D. A. R. McCannel, M.E.I.C., chairman of the committee for co-ordinating the activities of engineering organizations in the province, presented a report which contained the following recommendations which were adopted by the meeting:

(1) That the Professional Association in Annual Meeting to-day approve the following resolution—"resolved that the Association of Professional Engineers of Saskatchewan in Annual General Meeting assembled hereby goes on record as being in favour of the consolidation of the engineering profession in Canada.

(2) That the Council of the Association and the Saskatchewan Branch, Engineering Institute of Canada, give early consideration to the appointment of a joint Secretary, preferably a member of both societies, who is in private practice.

(3) That the Association of Professional Engineers of Saskatchewan arrange annually for a general meeting of all Saskatchewan engineers to consider and promote the interests of the engineering profession and of the province.

(4) That the Council of the Association of Professional Engineers endeavour insofar as possible, to arrange for its Council meetings at a date that will coincide with meetings of engineering societies in Regina.

The result of the ballot for election of officers was as follows: President, H. C. Ritchie, A.M.E.I.C.; vice-president, D. A. R. McCannel, M.E.I.C.; Councillors, H. Forbes-Roberts, S. T. Lewis, A. P. Linton, A.M.E.I.C. These, with the following, who remain in office for one year constitute the new executive. Those remaining in the Council: H. R. MacKenzie, A.M.E.I.C., W. W. Perrie, A.M.E.I.C., J. J. White, A.M.E.I.C., and Professor W. E. Lovell, A.M.E.I.C. And one member from the faculty of the University to be appointed by the Lieutenant-Governor-in-Council.

An audited financial statement presented showed cash on hand of $702.62 and a Dominion Government 5 per cent bond for $1,000.

The evening was given up to a banquet presided over by the new president, Mr. Ritchie, and musical and other entertainment was provided by the entertainment committee.

Preliminary Notice

of Applications for Admission and for Transfer

March 23rd, 1935

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in May, 1935.

R. J. Durley, Secretary.

*The professional requirements are as follows.—

A Member shall be at least thirty-five years of age, and shall have been engaged in some hranch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not alresdy passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BOWEN—HENRY BLAKE, of 3018 Breslay Road, Montreal, Que., Born at Chapel-en-le-Frith, Derbyshire, England; Educ., 1903-05, Manchester School of Technology: 1900-03, Crossley Bros., Manchester, England: With the C.P.R. as follows: 1905-06, special ap'tice, Angus Shops; 1906-07, dftsman., Winnipeg; 1908, foreman, loco. shops, Winnipeg; 1909-11, shop engr., Winnipeg; 1911-19, chief dftsman., Winnipeg; 1920-27, works manager, Winnipeg shops; 1928, asst. supt., motive power, and 1928 to date, chief of motive power and rolling stock.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

ARCHIBALD—SAMUEL WALLACE, of London, Ont., Born at Seaforth, Ont., May 13th, 1894; Educ., B.A.Sc. (Civil), Univ. of Toronto, 1922. O.L.S., 1925. R.P.E. Ont.; 1916-18, overseas, Major, C.E.F.; 1919, chainman, and 1920, instr'man. on location, res. on constrn. rly. spur and transmission line, Nipissing district, with Lang & Ross, Ltd., Sault Ste. Marie, Ont.; 1921, instr'man., with H. J. Beatty, O.L.S., Pembroke, Ont.; 1922-23, instr'man. in charge of party, Sudbury district, with J. W. Fitzgerald, O.L.S., Peterborough; 1922-23, instructor in engrg. drawing and maths., Sault Ste. Marie Tech. School; 1923-24, demonstrator, dept. of drawing, Faculty of App. Sci., Univ. of Toronto; 1924, instr'man. in charge of party, highway location, Lake Superior east shore, with Lang & Ross, Ltd.; 1925 to date, in practice as consltg. engr. and surveyor, at Seaforth, Ont., and at London, Ont., and the following winter work: 1927, in charge of party, flooded area survey, Wicksteed and Martin lakes, for Lang & Ross, Ltd.; 1928, transitman, transmission line location, Algoma District, and 1928-29, in charge of party, transmission line location, Flin Flon, Man. to Island Falls, Sask., for same company; Consltg. work includes: surveys, awards and reports under the Drainage Acts of Ontario; topographic surveys, subdivisions, re-surveys, compiled plans, reinforced concrete design. (*A.M. 1928.*)

BEACH—FLOYD KELLOGG, of 10957-90th Ave., Edmonton, Alta., Born at Hesperia, Mich., Dec. 30th, 1884; Educ., One year univ. work; Corres. School and private study. Admission to corporate membership E.I.C. by exam. 1913; D.L.S.; 1902, rodman, Mich. Cent. Ry.; 1906-09, transitman and dftsman. on D.L.S. work, irrigation surveys and rly. mtce.; 1910-13, private practice, highway, irrigation, rly. surveys, topographic mapping, etc.; 1913-16, irrigation and hydrometric surveys; 1916-19, overseas, Can. Rly. Troops, Lieut. Later Capt. and Major, 13th Field Co., Can. Engrs., Militia Staff Course; 1919-27, divnl. engr., hydrometric survey, and dist. engr. (irrigation); 1927 to date, petroleum and natural gas engr., Dept. of Lands and Mines of Alberta, Edmonton, Alta. (*St. 1910, A.M. 1913.*)

References: R. S. L. Wilson, G. N. Houston, S. G. Coultis, S. G. Porter, P. J. Jennings, P. M. Sauder, F. W. Alexander.

CORMIER—ERNEST, of Montreal, Que., Born at Montreal, Dec. 5th, 1885; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1906; 1906-08, struct'l. steel design, city office, Dominion Bridge Company, Montreal; 1915-18, with Considere, Pelnard, Caquot, Paris. Engr. in charge of concrete designs for French Govt.; 1925 to date, professor, Ecole Polytechnique, Montreal, and 1918 to date, private practice as architect and engr., reinforced concrete, heating, ventilation, refrigeration, elect'l. designs for churches, schools, public bldgs. and the Univ. of Montreal. (*St. 1904, A.M. 1909.*)

References: O. O. Lefebvre, G. M. Pitts, A. Frigon, A. D. Harrison, F. S. B. Heward.

FARRELL—JAMES WARDROPE DICK, of 3025 Rae St., Regina, Sask., Born at Smiths Falls, Ont., Sept. 20th, 1890; Educ., B.A., 1912, B.Sc., 1915, Queen's Univ.; 1913-14, asst. to dist. surveyor and engr., Dept. Highways, Regina; 1914-19, Can. Engrs., R.F.C., R.A.F., Overseas, Capt.; 1919, dftsman., dept. of irrigation, Calgary; 1920-24, asst. supt., and 1924 to date, supt. of waterworks, Regina, Sask., supervision and planning plant constrn. as well as charge of operation and mtce. (*Jr. 1920, A.M. 1921.*)

References: L. A. Thornton, D. A. R. McCannel, H. S. Carpenter, C. J. Mackenzie, A. C. Garner.

LAFLECHE—ALPHONSE, of Ottawa, Ont., Born at St. Martin, Que., Dec. 5th, 1884; Educ., Civil Engr., Ecole Polytechnique of Montreal, 1909; 1909-11, city engrg., Montreal; With Dept. of Marine as follows: 1911-17, junior engr., 1917-25, asst. engr., 1925-29, senior asst. engr., 1929 to date, asst. chief engr., River St. Lawrence Ship Channel. (*St. 1909, A.M. 1916.*)

References: N. B. McLean, F. Anderson, J. A. L. Dansereau, D. W. McLachlan, J. P. Leclaire, J. A. Smith.

MOTT—HAROLD EDGAR, of Brantford, Ont., Born at Winnipeg, Man., Dec. 4th, 1897; Educ., B.Sc., McGill Univ., 1922; With Canadian Marconi Co., Montreal, as follows: 1922, test engr.; 1923, engr. in charge, test dept.; 1923, supt. of works; 1924-27, works engr.; 1927-28, chief engr., De Forest Crosley Radio; 1928-33, mgr. of engrg. and production, and chief engr., Rogers Majestic Corpn.; 1933-34, consltg. engr.; 1934 to date, president and gen. mgr., H. E. Mott Co. Ltd., Brantford, Ont., designers and manufacturers of industrial equipment, etc. (*St. 1919, A.M. 1926.*)

References: C. V. Christie, J. H. Thompson, G. A. Lindsay, J. F. Plow, W. S. Stewart.

YOUNG—STEWART, of 2822 Rae St., Regina, Sask., Born at Owen Sound, Ont., Sept. 2nd, 1884; Educ., Diploma, S.P.S., 1911, B.A.Sc., 1912, Univ. of Toronto. D.L.S. and S.L.S. 1913. Summers: 1910, inspr., waterworks and sewers, Cobalt; 1911, dftsman., G.T.P., Winnipeg; 1912, triangulation surveys, B.C.; 1912-13, checking plans, asst. surveyor, Dept. Public Works, Sask.; With the Province of Saskatchewan as follows: 1913-16, misc. surveyor; 1916-17, acting district surveyor; 1917-24, district surveyor; 1924, res. engr.; 1924 to date, director of town planning (*A.M. 1917.*)

References: H. S. Carpenter, H. R. MacKenzie, D. A. R. McCannel, A. P. Linton, J. J. White.

FOR TRANSFER FROM THE CLASS OF JUNIOR

CHANDLER—EDWARD SAYRE, of Charlottetown, P.E.I., Born at Charlottetown, July 17th, 1901; Educ., B.Sc. (E.E.), N.S. Tech. Coll., 1931; 1917-19, meter reader, and 1925-30 (during vacations), supt.'s asst., Maritime Electric Co.; 1931-32, acting supt., Wolfville Electric Commn.; 1932 to date, Provincial Electrical Inspector, Charlottetown, P.E.I. (*St. 1930, Jr. 1932.*)

References: F. R. Faulkner, H. F. Laurence, H. E. Miller, H. W. McKiel, W. A. McLaren.

FOR TRANSFER FROM THE CLASS OF STUDENT

LAWRENCE—EDWARD ARTHUR, of Lethbridge, Alta., Born at Sydenham, London, England, July 5th, 1909; Educ., Junior Matric., Univ. of Alta., 1927; prep. course, struct'l. engrg., Wilson Engineering Corporation, Cambridge, Mass.; 1927 to date, with the C.P.R., Dept. of Natural Resources, Irrigation Branch, Lethbridge, Alta. Hydrometric work, misc. surveys, including gen. field, topog'l. and compass surveys; classification of land for irrigable area, cross-sectioning and profiles. Prelim. and final survey of new canal extensions. Instrument and office work in connection with building of earthwork dam for storage purposes. Office work in connection with above, also calculations for yardage and estimates. Dfting in connection with irrigation works. Present position, instr'man and hydrographer. (*St. 1932.*)

References: G. N. Houston, G. S. Brown, J. T. Watson, W. Meldrum, J. B. deHart.

FOR TRANSFER FROM THE CLASS OF AFFILIATE

SAMUEL—MYRON, of Toronto, Ont., Born at Libau, Latvia, Nov. 8th, 1898. (British Subject since 1932.) Educ., Engrg. Diploma, Engrg. College of Danzig, 1924. Member, V.D.I., 1931; 1919-20, ap'ticeship, Matisons Machine Works, Libau, and Danziger Shipbldg. and Engrg. Co.; 1923 (Apr.-Aug.), Sawmill and Lumber Transport and Shipping Co., Danzig, consltg. work in connection with new additions, preparing plans and estimates, testing and appraising of equipment; 1926-27, S. Behr & Mathew, Shanghai, China. Cold storage, refrigerated ships and produce packing. In charge of frozen egg mixing, filling and freezing plant and tin-box factory. Supervision of operations, time studies, lab. testing work, modernization of operations and plans for new installns.; 1927-32, J. I. Bernitz, Inc., New York and Toronto. Engrg. Sales and Service. Canadian representative in charge of preparing plans and estimates for additions to existing plants and new installns., installn. of equipment, acceptance tests, estimating cost of necessary repairs and directing the reconditioning of equipment, advising on engrg. problems. Making plans and designs for special purpose equipment, investigating breakdowns; April 1932 to date, proprietor of the Empire Engineering Company, Toronto. Plans and estimates for additions to present plants, new installns., modernization of existing equipment, supervision installns., directing acceptance tests, estimating costs of repairs and reconditioning, etc. Equipment sales and service. (*Affil. 1931.*)

The Bristol Company of Canada Limited announces that on March 1st, 1935, it doubled its factory space at 64 Princess Street, Toronto. This Company was incorporated a little over a year ago, both to serve the Canadian market for Bristol's instruments and to expand and consolidate the service laboratory that for twelve years previously had been maintained in Toronto.

The factory is equipped with facilities for making and testing gauges, thermometers, controllers, voltmeters, recording ammeters and other instruments of the Bristol line.

Canadian distributors of Bristol's products are Powerlite Devices, Ltd., Montreal and Toronto; Gorman's Limited, Edmonton, Alta.; and Filer Smith Machine Company, Winnipeg, Man.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Civil Service Vacancies

List No. 617

The Civil Service Commission announces open competitive examinations for the following positions:

ASSISTANT OFFICE ENGINEER (MALE)

23866.—An Assistant Office Engineer (Male), in the Chief Engineer's Branch, Penitentiaries Branch, Department of Justice at Ottawa, at a salary of $2,160 per annum, subject to such deduction as may be provided for by legislation.

Duties.—Under direction, to assist in the work of the Chief Engineer's Branch, Penitentiaries Branch, Department of Justice; to prepare plans, estimates, specifications and bills of materials, and to perform other related work as required.

Qualifications.—Education equivalent to high school graduation; either graduation in engineering from a school of applied science of recognized standing with at least three years of experience in field or office engineering construction work, or five years of experience in field or office engineering construction work including in each case at least one year in a position of professional responsibility; considerable experience in preparing estimates, specifications, and bills of materials; accuracy, thoroughness and good judgment.

While no age limit has been set age may be a determining factor in making a selection.

While temporary appointment only may be made at the present time this examination will qualify for permanent appointment. In the event of permanent appointment the initial salary of $2,160 per annum may be increased upon recommendation for efficient service at the rate of $120 per annum until a maximum of $2,580 is reached.

ASSISTANT MECHANICAL ENGINEER (MALE)

23865.—An Assistant Mechanical Engineer, in the Penitentiaries Branch, Department of Justice at Ottawa at a salary of $2,220 per annum, subject to such deduction as may be provided for by legislation.

Duties.—To assist in designing and preparing plans and estimates of various engineering and construction projects, including mechanical heating and ventilation equipment, steam power plants, installation of electrical equipment of various kinds, and to perform other related work as required.

Qualifications.—Education equivalent to High School graduation; either graduation in Mechanical Engineering from a school of applied science of recognized standing with three years of experience in Mechanical Engineering, one year of which shall have been in a position of professional and supervisory responsibility; or, five years of Mechanical Engineering experience, one year of which shall have been in a position of professional and supervisory responsibility; preferably experience in general construction engineering; tact and good judgment.

While no age limit has been set age may be a determining factor in making a selection.

While temporary appointment only may be made at the present time this examination will qualify for permanent appointment. In the event of permanent appointment the initial salary of $2,220 per annum may be increased upon recommendation for efficient service at the rate of $120 per annum until a maximum of $2,700 is reached.

Nature of Examination.—A rating on education and experience will be given from the sworn statements, supporting documents and other evidence submitted by applicants on and with the application forms. Applicants must give full particulars concerning their technical training and experience, especially as they bear on the qualifications for and duties of these positions.

An Oral Examination may be given if necessary in the opinion of the Commission. An eligible list valid for one year may be established.

Application forms properly filled in must be filed with the Civil Service Commission, Ottawa, **not later than April 18, 1935.**

Application forms may be obtained from ths offices of the Employment Service of Canada, from the Postmasters at Prince Rupert, Vancouver, Victoria, Edmonton, Calgary, Regina, Saskatoon, Winnipeg, Quebec, Fredericton, Saint John, Charlottetown, and Halifax, the Secretary of the Civil Service Commission, and from The Engineering Institute of Canada, Montreal.

Situations Wanted

ESTABLISHED SALES ENGINEER. Univ. of Toronto '24, with plant and manufacturing experience, wishes to represent manufacturers of technical equipment. Connections with automobile and electrical equipment dealers, throughout Canada. Will make small investment if necessary. Apply to Box No. 1-W.

MECHANICAL ENGINEER, Canadian, with technical training and executive experience in both Canadian and American industries, particularly plant layout, equipment, planning and production control methods, is open for employment with company desirous of improving manufacturing methods, lowering costs and preparing for business expansion. Apply to Box No. 35-W.

Situations Wanted

ENGINEER, A.M.E.I.C., Univ. Grad. '27, age 31, with ten years' experience in the design and construction of paper mills and hydro-electric plants, modernization of sulphite pulp mills and industrial plants, and general engineering. Available immediately. Apply to Box No. 150-W.

PURCHASING AGENT. Graduate mechanical engineer, Canadian, married, age 36, with fourteen years experience in industrial field, including design, construction and operation, eight years of which had to do with the development of specifications and ordering of equipment and materials for plant extensions and maintenance; ons year engaged on sale of surplus construction equipment. Full details on request. At present employed. Apply to Box No. 161-W.

SALES ENGINEER, S.E.I.C.; B.SC. C.E., 1930 (Univ. New Bruns.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.SC., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ELECTRICAL ENGINEER, B.SC., A.M.E.I.C., AM.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

CIVIL ENGINEER, B.A.SC. and C.E.; A.M.E.I.C., JUN. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.SC. Univ of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

MECHANICAL ENGINEER, B.SC. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrumsnt work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.SC., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment. Four summers as instrumentman on surveying and highway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern where the combination of technical and business experience will be of value. Apply to Box No. 564-W.

CONSTRUCTION ENGINEER, age 26, unmarried, graduate C.E. Experience includes hydro-electric, railroad, highway, and industrial plant construction, both field and office, including cost accounting, estimating, stores, layout, general engineering and supervision, as well as practical work in mechanical trades. Apply to Box No. 567-W.

MECHANICAL ENGINEER, A.M.E.I.C. Experienced on plant maintenance, steel plant, cement plant and mining plants. Available on short notice. Apply to Box No. 571-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

Situations Wanted

CHEMICAL ENGINEER, S.E.I.C., B.SC., Univsrsity of Alberta, '30. Age 31. Single. Six seasons practical laboratory experience, thres as chief chemist and thres as assistant chemist in csment plant; one year's p.g. work in physical chemistry; three years experience teaching. Desires position in any industry with chemical control. Availabls immediately. Apply to Box. No. 609-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty ysars experiencs in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; thres years construction engineer on industrial plants; fourtesn ysars in chargs of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as sxecutive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W

ELECTRICAL ENGINEER, B.SC. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouss Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box. No. 651-W.

ELECTRICAL ENGINEER, Univ. Grad. 1928. Two years Students' apprenticeship at Can. Westinghouss Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660 W.

ELECTRICAL AND RADIO ENGINEER, B.SC. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can bs verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC., Elec., '29, B.SC., Civil '33. Age 27. JR.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.SC., '27, JR.E.I.C. Four years maintsnance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.SC., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.SC. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.SC. (McGill Univ.), O.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box. No. 729-W.

Situations Wanted

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No 735-W

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.Sc. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten years diversified electrical and mechanical experience in the industrial field. Apply to Box No 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

Situations Wanted

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box. No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, B.A.Sc. in C.E., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.Sc., O.P.E Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.Sc. (Queen's, '14), A.M.E.I.C., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, B.Sc., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

Situations Wanted

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C. '29); M.S. Age 27. Single. Four years experience in research work in applied mechanics and materials testing. Desires position involving analytical work in design, development or testing. Available on short notice. Apply to Box No. 1123-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box. No. 1127-W.

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.Sc., Queen's '33 Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.Sc., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

CIVIL ENGINEER, B.A., B.A.Sc., S.E.I.C., Canadian, age 27, single. Experience includes eighteen months in general building construction. Write and speak both French and English fluently. Available at once for any suitable position in general engineering. Apply to Box No. 1211 W.

CIVIL ENGINEER, B.Sc. '34 (Univ. of N.B.), age 24. Experience includes construction and highway engineering. Desires position with contracting or manufacturing firm. Interested in design. References. Will consider any location. Apply to Box No. 1214-W.

COMBUSTION ENGINEER, A.M.E.I.C., with extensive experience in all phases of combustion engineering, including plant layout, piping, etc. Lately connected with prominent firm of automatic oil burner manufacturers. Apply to Box No. 1224-W.

MECHANICAL ENGINEER, B.Sc. McGill. Experienced as supt. of plant manufacturing home appliances—purchasing of supplies and equipment of technical nature. Plant engineer of works for manufacture of railway equipment and of copper and brass rolling mill and seamless brass and copper tube mill and brass cartridge cases. Designing engineer on special machinery, maintenance engineer, plant layouts. Apply to Box No. 1241-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet and tissues. Apply to Box No. 1246-W.

CIVIL ENGINEER, B.Sc. '29, Jr.E.I.C., age 29, single. Experience in all types of surveying including use of aerial photographs. Three years on hydro-electric power development in field and office. Instrumentman on concrete road construction. Location immaterial. Apply to Box No. 1254-W.

CIVIL ENGINEER, Univ. Toronto '33, age 24, married. One year as instrumentman with provincial department of highways. Experience in concrete and retread construction grading, culverts, etc. Also draughting, estimating and general office practice. Apply to Box No 1265-W.

INDUSTRIAL ENGINEER, B.Sc. in Mech. Eng. (McGill '31), Rockefeller Research Associate in industrial engineering on economic and statistical analysis. Previous experience in manufacturing plants. Desires connection with industrial firm. Apply to Box No. 1269-W.

MECHANICAL ENGINEER, B.Sc. (Queen's Univ. '29). Age 28. Six years experience in automobile office and plant; two years as supervisor of inspection in body assembly. Good understanding of modern business methods applied to manufacturing. Desires position with production department of smaller Ontario industry. Good references. Interviews anywhere in central Ontario. Apply to Box No. 1270-W.

ELECTRICAL GRADUATE, S.E.I.C., B.Sc. '32, M.Sc. '34. Experience includes four years as part time operator and announcer for a radio broadcast station. At present employed in radio repair dept. of a large wholesale firm. Apply to Box No. 1283-W.

The New Gaseous Conductor Lamps and their Applications

J. W. Bateman,

Manager, Lighting Service Department, Canadian General Electric Co. Ltd., Toronto, Ont.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ontario, February 8th, 1935.

SUMMARY.—This paper discusses the new sodium and high intensity mercury vapour lamps, giving a description of their design and characteristics, and outlines their present and possible future applications. These new light sources have created wide interest, and this paper is intended to cover their advantages and disadvantages, and the effect they may have on lighting practice. In general, it is considered that these sources are new tools for the lighting industry that will meet with increasing use. They seem, as far as the present goes, to be unlikely to supplant, to any great extent, the incandescent tungsten lamp for general lighting service.

Many types of gaseous conductor lamps have been developed and serve a wide variety of purposes. The scope of this paper is confined to a description of the new sodium and high intensity mercury vapour lamps and their application to lighting service.

Since the days of Edison's first practical incandescent lamp, scientists have been continually striving for light sources with higher and higher efficiencies. Much progress has been made in incandescent lamps, from the 1.4 lumens per watt of the first carbon lamps to the 10 to 20 lumens per watt of our standard general service tungsten lamps today. Little can be hoped for in greater efficiency with the present types of lamps.

It has long been known that some gases, particularly sodium, gave high luminous efficiencies, but previously these were treated largely as experimental laboratory curiosities. Mercury vapour has been used for many years as a light source in low pressure tubes for photographic and general industrial lighting, since the start of the development of practical gaseous conductor lamps by Peter Cooper Hewitt in 1902. The commercial application of the newer types of lamps was first begun in Europe in the summer of 1932. The first installation given publicity was the lighting of a mile of highway in Holland with Philips sodium vapour lamps, July 1st, 1932.[1] The lamps used had a rating of between 5,000 and 6,000 lumens. They were spaced 83 feet apart and mounted 26 feet high. Leaving out of consideration any peculiar features of the sodium lighting, the installation was such as to provide a good level of illumination by means of properly placed lighting units. Comments on the lighting were favourable, as "so intense is the illumination along the roadway that, driving a car at 50 or 60 miles per hour without headlights, one feels perfectly safe."

At about this same time trials were being made of a new type of mercury lamp in England and an official opening of a street lighting installation at Wembley was held on November 9th, 1932.[2] The lamp used was a 400-watt unit with a rating of 40 lumens per watt. On December 1st, 1932, the first installation of sodium lamps for public lighting in England was announced at Croydon.[3]

Progress in the development of the sodium vapour lamp was also being made in the United States early in the year 1932, and the General Electric Research Laboratory at Schenectady announced a practical 100-watt direct current lamp giving an over-all efficiency of 34 lumens per watt, in August, 1932.[1] These announcements of new light sources created much general interest. Many people, particularly those connected with the electric light industry, wondered to just what extent past practices in lighting would be revolutionized. Some of the general public gained the impression that these new sources would become immediately applicable to all classes of lighting. Now, after two and a half years of development work and experience with these new gaseous conductor lamps, more is known of their uses and their limitations.

The Sodium Lamp

Sodium vapour lamps are now available in this country in 500, 4,000, 6,000, 10,000 and 15,000 lumen sizes for operation on a.c. circuits. The 500-lumen lamp is designed for use in a Lab-arc unit for laboratory experimental purposes. The lamp on which most development work has been done on this continent is the 10,000-lumen lamp. This is used in most of the present installations here, so that for the purpose of this paper the description given will refer specifically to this lamp, which is typical, however, of sodium lamps in general.

The present form of 10,000-lumen a.c. sodium lamp consists of a long bulb of special glass enclosing at each end an oxide coated filament which serves as a cathode, and a metal cylinder surrounding the filament which serves as an anode. Thus this lamp has two cathodes and two anodes which serve during the appropriate half-cycle. A small quantity of metallic sodium and some neon gas at a pressure of about 1.5 mm. or more are included in the bulb. When the lamp is first turned on the discharge takes place through the neon gas which serves to start the sodium discharge by heating and vaporizing the sodium. Thus the appearance at first is that of a neon lamp, but the characteristic yellow glow develops as the sodium warms and becomes predominant in about five minutes. However, it takes from twenty to thirty minutes for the lamp to come up to full candlepower.

The bulb containing the sodium is coated on the interior with a sodium resistant glaze of borosilicate to prevent the attacking of the glass by the sodium and the resulting discoloration of the bulb. The development of sodium-resistant glasses or glazes to be applied to commercial glasses, was one of the chief problems in the making of a practical sodium lamp. Not only was it necessary to produce a glass that would resist the attacks of the sodium, but this glass had to have the quality of being workable

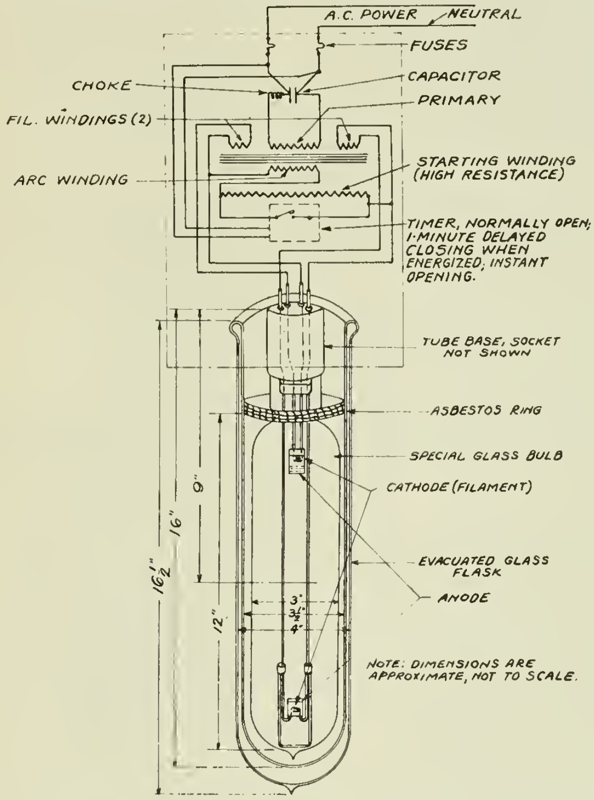

Fig. 1—Schematic Diagram, 10,000 Lumen A.C. Sodium Lamp

so as to permit fabrication of lamps. The best solution seems to be that described above, of coating the interior of a commercial hard glass bulb with a sodium-resistant glaze which prevents penetration by the sodium atoms. This glazing gives to the bulb the appearance of the familiar inside frosted bulbs of incandescent lamps.

The sodium lamp bulb which is approximately 3 inches in diameter by 12 inches long, is enclosed in a double-walled vacuum flask having an outside diameter of 4 inches and an over-all length of 16½ inches. Asbestos washers around the neck of the bulb fill the open end of the vacuum flask to prevent heat loss. The vacuum flask is indispensable to the operation of the lamp, since a temperature of about 220 degrees C. is required to provide the most desirable vapour pressure of the sodium, of about 0.2 microns.[4] The attainment of maximum light output and maximum efficiency depends upon this critical temperature. When equipped with the vacuum flask and as used in commercial luminaires, most of which have a heat-conserving influence, the variations in efficiency are not great for even the wide ranges of summer and winter temperatures. The result of one test showed a decrease in lumens of only 6 per cent for a change from room temperature to −30 degrees C.[5]

Operating Characteristics of 10,000 Lumen A.C. Sodium Lamp

Three inherent properties of the sodium vapour lamp govern the design of the electrical circuit whether for a.c. or d.c. operation[6]:—

1. Sodium vapour lamps, like all gaseous discharges, have an arc volt-ampere characteristic, that is, the voltage drop is independent of current or else it decreases with increase of current. This property of a gas or vapour lamp necessitates the use of special series elements of reactance or resistance for the purpose of limiting the current to the desired value.
2. The cathode requires a heating current and must be "pre-heated" before the arc is started.
3. The starting voltage of the lamp is higher than the operating drop.

The 10,000-lumen arc lamp is designed for operation on a 6.6 ampere street lighting circuit. Figure 1 gives a schematic diagram of this lamp and auxiliary equipment for series circuit operation. The 6.6 amperes for arc current can be supplied from a transformer with 6.6 ampere or any other normal primary current rating. Inasmuch as a cathode heating period of about a minute is required before the arc is struck, a time-delay device is incorporated in the equipment to delay the starting by this length of time. A radio filter condenser and ratio-frequency choke coil are included to eliminate any radio interference.

The 10,000-lumen a.c. sodium lamp can be operated directly from a 115 volt a.c. multiple circuit by means of a device to provide an inductive kick for starting and the necessary auxiliary equipment for controlling the current and voltage.

High Intensity Mercury Vapour Lamps

The new mercury vapour lamps are now available in 250-watt and 400-watt sizes. The 400-watt lamp was initially developed and has been used in most installations up to the present and the description given in this paper will be confined to this size.

The 400-watt high intensity (high pressure) mercury vapour lamp consists of a tubular light source surrounded by a heat-conserving jacket, fitted wtih a mogul screw base. The high intensity mercury lamp differs from the familiar Cooper-Hewitt type or low pressure lamp, in that the pressure of the new lamp runs much higher, though still not above atmospheric, and the lamp is of smaller dimensions. (See Fig. 2.)

The light source is contained in an inner glass bulb 1⅜ inches in diameter and 9 inches in length. This inner bulb is mounted concentrically in an outer glass bulb which is filled with a low pressure of nitrogen to prevent too rapid dissipation of heat. The complete lamp is 2 inches in diameter by 13 inches overall in length. The inner bulb contains a small amount of mercury and a low pressure of argon gas for starting. A band of wire gauze placed on the outside of this bulb near one electrode facilitates starting. No preheating of the electrodes is required and the lamp will operate on a 230-volt a.c. circuit with no other regulator than a choke coil in series to provide the reactive steadying effect. For operation on 115 volts a transformer to step up the voltage may be used, and equipment of this design is now available.

The arc appears as a brilliant pencil of light at the centre of the cylindrical tube. This is in contrast to the sodium and low pressure mercury lamp where the glow seems to fill the entire diameter. It is necessary to operate the lamp in a vertical position to prevent injury to the glass from the heat of the arc, although lamps of this type for horizontal burning have now been announced.[7] The control of the luminous stream so as to prevent it impinging on the glass and consequent overheating is effected by means of electro magnets placed in proximity to the tube.

Efficiency

It is the high actual and even higher theoretical efficiencies of these new light sources that are of most interest in regard to their applications. If all the energy of a light source were emitted at a wave length of 5,550 *A*, the peak of the relative luminosity curve, the luminous efficiency would be 670 lumens per watt. For sodium, one-quarter of the energy is emitted in the infra-red and small amounts in other lines besides the sodium *D* lines. The maximum possible luminous efficiency of a sodium source is about 360 lumens per watt, and this has been reached in the laboratory.[2] However, a value as high as this is not practical, but under good conditions efficiencies of 70 lumens per watt seem possible. In practical sodium lamps of present manufacture 40 to 50 lumens per watt are assured, and there is good reason to believe that higher efficiencies can be secured with further experience and improvement. The present 10,000-lumen a.c. series lamp is rated at 40 lumens per watt.

Theoretically, mercury arc lamps do not offer as high possible efficiencies as the sodium lamps on account of the spectral character of the luminous flux. However, comparatively high efficiencies have been obtained in experimental lamps and the present practical 400-watt high intensity mercury lamp is rated at 35 lumens per watt or overall lumens per watt of about 32 when the reactor is included. The high intensity mercury lamp as generally used here and in Europe is a 230-volt lamp. This lamp shows a greater improvement in efficiency over the standard Mazda lamps in England, which are generally of 230 volts rating, than over Mazda lamps in this country which are designed for 115-volt circuits. Incandescent lamps of the

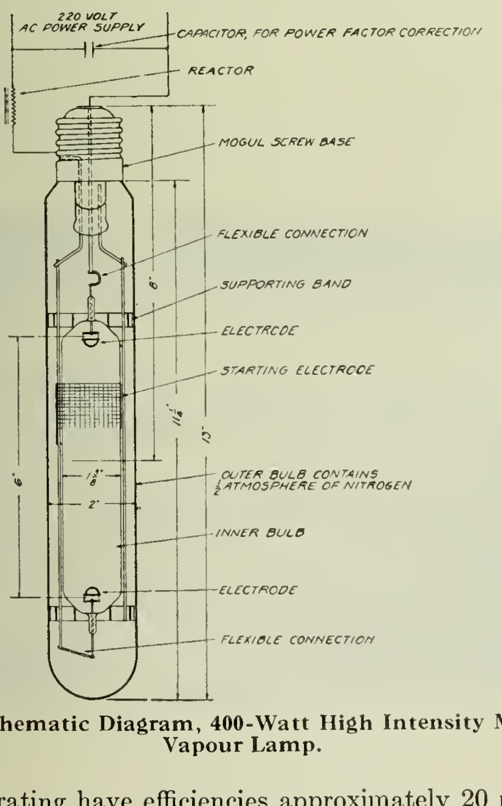

Fig. 2—Schematic Diagram, 400-Watt High Intensity Mercury-Vapour Lamp.

115-volt rating have efficiencies approximately 20 per cent higher than 230-volt lamps. This explains to some extent the more extensive use of these new sources in Europe.

Consideration must be given as well to the economic efficiency in a practical installation as well as the efficiency of the source itself. As compared to incandescent lamp installations, the cost of auxiliary equipment and installation is higher with these new units. In addition the average lumens maintained throughout life is a lower percentage of initial lumens for the gaseous-conductor lamp than for Mazda incandescent lamps. In general, the new gaseous conductor lamps fall off in candlepower, so that the average efficiency throughout life is approximately 80 per cent as compared to an average efficiency of 90 per cent or better for incandescent lamps.

In making a final comparison of the new lamps and the present-day incandescent lamps it is largely the average or effective lumens on the work that should be considered.

The Colour of the Light

The sodium lamp has a characteristic orange-yellow colour, quite similar to that produced when common salt is dropped into a flame. It is practically a monochromatic light source with most of the light in the sodium *D* lines of the spectrum equivalent to the wavelength of 5,893 Angstrom units. Thus, under this light all of the other colours are distorted. This distortion may be an advantage for certain particular operations, but in general is a distinct disadvantage for the usual visual tasks.

The spectrum of the mercury vapour lamp consists of lines or bands characteristic in wavelength and energy content of mercury. The light of the high intensity mercury vapour lamp has a higher percentage of green and yellow than the familiar low pressure tubes. While the light has the same bluish-green characteristic, the appearance is that of a "whiter" light source. This light is comparatively monochromatic in character in that most of the luminous flux is in the yellow-green band.

The high intensity arc has a small amount of red light although still quite deficient in this portion of the spectrum to give satisfactory renditions of objects with red colours. The red component can be improved by the addition of cadmium or zinc, but the gain in colour is secured at a sacrifice in efficiency. Estimating the red from the incandescent lamp at 25 per cent, from daylight at 15 per cent, and from the high intensity mercury vapour lamp at one per cent it has been found that the latter could be increased through additions of cadmium and zinc by one per cent gain in red at a loss in efficiency of about 10 per cent.[8] In view of the fact that the deficiency in red can be so easily made up by the use of incandescent lamps, the above modification of the mercury arc hardly seems justifiable.

Flicker

Both the new sodium and mercury arc lamps fall off in candlepower during the passing of the current through zero on alternating current circuits. On 60-cycle circuits this fluctuation is hardly noticeable and not at all objectionable for most applications. It is only in the case of the illumination of high speed machinery that care needs to be taken in providing illumination from these sources in order to avoid stroboscopic effects. However, it is found that safety guards and surrounding equipment of this nature are likely to quite effectively eliminate any annoyance from this character of the light.[9]

On 25-cycle circuits the flicker is quite pronounced, and so objectionable as to be impractical in ordinary interior lighting installations. The effect out of doors, however, has proved to be acceptable and it may be that these lamps can be used on 25-cycle, particularly where 3-phase is available in large interiors, and where some flicker is not a serious handicap.

Power Factor

The power factor of the 10,000-lumen a.c. sodium lamp is about 90 per cent.

The power factor of the 400-watt multiple high intensity mercury lamp on 220 volts with reactor only is approximately 60 per cent. This value can be corrected to above 90 per cent by the use of a condenser.

The Applications of Sodium Lamps

Since the first installations in Europe the new sodium lamps have found their application in highway lighting largely. There are perhaps three particular reasons for this. In the first place, highway lighting is one of the undeveloped fields of lighting where a high efficiency source like the sodium lamp offers an incentive to provide lighting and so correct the uneconomic condition of dark highways. Secondly, the sodium lamp is particularly adapt-

Fig. 3—Model Highway for Laboratory Experimental Purposes.

able to series circuits which have an advantage in control and distribution for this service. And thirdly, the colour of the light not only seems less objectionable in this application but actually appears more satisfactory than incandescent lamp lighting. This general impression is due perhaps largely to the different effect of this lighting which causes the highway to stand out distinctly and to the lower brightness of the light sources with the resultant minimized glare.

While it is known that the monochromatic sodium light is better than light of all colours of the spectrum where visual acuity is concerned, it is not definitely known that this is the reason for the favourableness of the sodium lamp for highway lighting. It has been estimated that visual acuity is three times as good under sodium illumination as under incandescent lamp illumination. In fact investigations by Luckiesh and Moss indicate that 5 foot-candles of this light are as effective in revealing fine detail as 20 foot-candles of incandescent light.[10] However, visual acuity is a factor that plays little part in visibility on highways. What one is more interested in here is the contrast between objects and the background, and in this latter regard sodium light seems to have an advantage for objects of some colours and for silhouette vision.

In an effort to determine the relative advantages of sodium light for highways where conditions could be carefully controlled and numerous observations taken, a model roadway on a ⅛ scale was constructed at Nela Park, Cleveland, last summer.[11] The road surface is 250 feet long and therefore represents approximately 2,000 feet of street. (See Fig. 3.) It is equipped with several similar systems of incandescent lamps and sodium lamps which give substantially identical illumination values on the street and equal candlepower toward the eye. When observations are made, the subject is seated at the end of the street in a position relative to the road surface, similar to that which he would occupy in the driver's seat of an automobile. Now several thousand observations indicate that there is no substantial difference foot-candle for foot-candle between the sodium and incandescent lighting in revealing objects according to the engineers who have been conducting the test.

In a true comparison of sodium and incandescent lighting, it is necessary to take into consideration not only the cost per lumen delivered on the roadway, but also such factors as glare, contrast, reliability, simplicity, etc.

In Canada there are two trial installations of sodium lamps, one just outside Three Rivers, where ten lamps are installed[12], and one near Stoney Creek on the Toronto-Niagara highway, where four units are used. Other installations of a small number of units may have been made.

As more satisfactory sodium lamps for multiple circuits are developed it is not unlikely that they will be extended in their use to other fields than highway and street lighting. For the lighting of large areas the increased efficiency may be found advantageous. Such fields as railway yards, athletic grounds, parking areas, racetracks, etc., are possible applications. When the higher levels of illumination are required and persons come within the range of this illumination in their activities, the sodium lamp is at a distinct disadvantage. Persons look singularly unattractive when viewed under this light. This colour disadvantage places a great handicap on the sodium lamp for extended application outside the fields mentioned above. It is particularly unsuited to home and commercial lighting.

Reflectors for Sodium Lamps

This new light source not only brought to the illuminating engineer new ideas of an illuminant, but also new requirements in reflecting and distributing equipment. The sodium lamp may be burned horizontally, as well as in any other position, so that its extended light source offers a particular advantage for highway lighting and also demands a new design of reflecting medium.

One type of equipment that has proved effective is the airplane design of unit illustrated in Fig. 4. It is interesting to note, as well, that the reflectors of this luminaire are made of aluminum treated with the new "Alzak" process which provides not only high efficiency but also good permanence in its reflecting power, since the surface is impervious to atmospheric conditions. The initial reflecting efficiency of this surface is about 82 per cent.

A few other types have been produced on this continent, and in addition, standard street lighting units

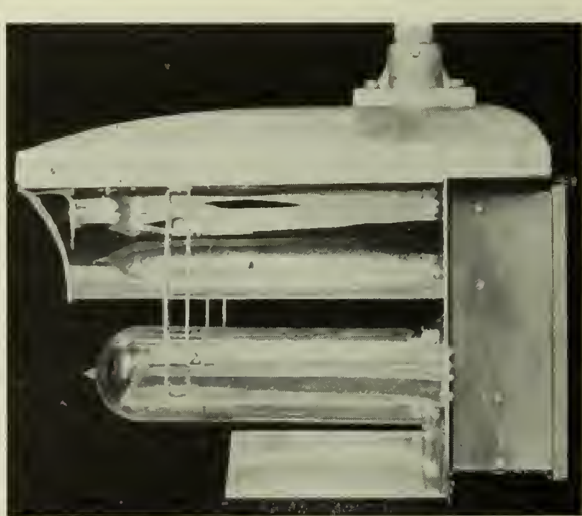

Fig. 4—Sodium Luminaire.

have been adapted to accommodate the sodium lamps. Many new designs of equipment have been developed in Europe for sodium lamps.

Applications of High Intensity Mercury Vapour Lamps

For many years mercury vapour lighting has been used successfully in various industrial applications and in other specific fields, such as the photographic. The advent of the new high intensity mercury lamp did not constitute as marked a change from past practice as did the introduction of the sodium lamp. The new mercury lamp, however, has a much higher efficiency, a somewhat whiter appearing light, and a form and size more akin to the common incandescent lamps than the elongated low pressure mercury vapour tube. These three different characteristics make the new lamp applicable in many fields where the older type was unsuited.

For the present the new uses seem to be largely in street lighting and in high bay lighting in factories and larger buildings. For street lighting the mercury arc is not so radically different from the carbon arc street lights still used to good advantage in many cities. The mercury light is lacking in red, but this deficiency can readily be corrected or relieved by the use of incandescent lamps in combination with the mercury lamp. The incandescent lamp serves two further purposes, particularly as used in this climate, first improving starting conditions of the mercury lamp in cold weather, and second, serving as a standby light source in case a momentary power interruption causes the mercury lamp to cease functioning for a time, until it has cooled sufficiently for the pressure to drop to a value where the lamp will start. While complete data are lacking it is generally considered for the present that as far as cold weather operation goes, the high intensity mercury lamps may not start at temperatures much below 15 degrees F.

The enclosing of a single 200-watt lamp or combinations of more than one lamp in a semi-enclosing globe with the mercury lamp serves to provide sufficient heat to bring the temperature to a satisfactory point for the starting of the mercury lamp.

Similar to the sodium lamp the high intensity mercury lamp requires from fifteen to twenty minutes or longer to build up to full candlepower.

Lighting Equipment for High Intensity Mercury Lamps

While in a few instances manufacturers in America have given some consideration to the design of new reflectors and luminaires for the new mercury lamp, for the most part the use of these lamps up to the present time has been confined to either standard equipment or that equipment with slight adaptations. Satisfactory distributions of light can be obtained from standard high bay units, industrial and commercial units of some types and street lighting equipments of proper size. In England many new designs of equipment have been developed, chiefly for street lighting.[13]

In the design of equipment the chief problem is that arising from the long narrow light source as distinct from the small source of the incandescent lamp which for many purposes may be considered as approaching a point source.

Combination Units

The incompleteness of the spectra of the gaseous conductor lamps, particularly in red radiations, has led to the idea of combinations of these lamps with incandescent lamps for general lighting purposes. The incandescent lamp has a complete spectrum and has an abundance of red and yellow rays.

Since incandescent lamp light is yellow as compared to daylight or white light, the addition of this to the already predominantly yellow light of the sodium lamp does not constitute much in improvement in the general quality of the illumination. Therefore little use has been made so far of combinations of incandescent and sodium lighting.

The condition however is very different where the new mercury lamp is concerned. The addition of incandescent light to the mercury light completes the spectrum in a relatively satisfactory manner. Experiments to date indicate that for a daylight effect a mixture in the proportion of 60 lumens incandescent to 40 lumens high intensity mercury is about right. This means that from two and a half to three times as much wattage in incandescent lamps is required as in high intensity mercury lamps. The effect, of course, of the combination is to produce a luminous efficiency somewhere between that of the two different light sources, so that in this regard the combination unit is in a much less advantageous position than the mercury lamp by itself. No combinations of mercury vapour and Mazda lamps exactly reproduce daylight, and so are not satisfactory for accurate colour matching.

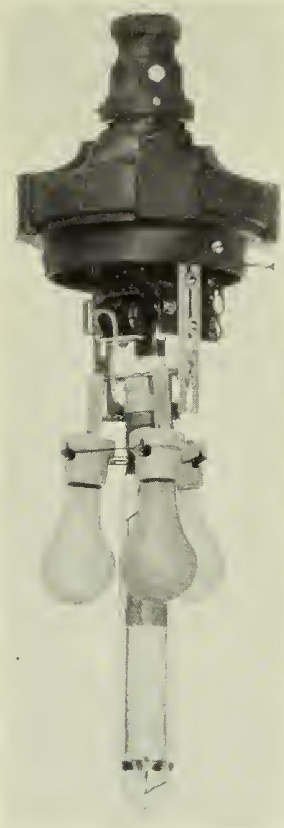

Fig. 5—Bracket Type Mercury Arc Incandescent Luminaire, without Globe.

The following is a table of overall efficiencies of generated light for combinations of lamps, bare lamps only considered.

	Generated Lumens	
Mercury lamps alone (400 watts)	35	lumens per watt
Mercury-Mazda Combination— equal watts (2-200 watts)	26	" " "
Mercury-Mazda Combination— equal lumens (4-200 watts)	23	" " "
Mercury-Mazda Combination— 43-57 lumen ratio (4-250 watts G-30)	23.4	" " "
1,000 watt Mazda Lamp alone	20.8	" " "
500 " " " "	19.5	" " "
200 " " " "	16.7	" " "

While the overall efficiencies of combination units are lower than that of the high intensity mercury lamp alone, they are nevertheless much higher than the efficiency of Mazda Daylight Lamps. Thus where a daylight appearance without accurate colour discrimination qualities is required, the combination units permit the illumination to be obtained much more efficiently than by daylight lamps or luminaires.

In general, multiple lamp units involve greater difficulties in the efficient reflection and distribution of the light so that from the standpoint of effective light control and utilization combination units are usually at a disadvantage to single lamp types.

Some very satisfactory experimental indirect combination units have been developed. By mixing the light in an indirect manner, good distribution is obtained and good mixing of the light. Luminaires of this type with mercury and Mazda lamps will find application in store lighting where an abrupt change between the colour of daylight and the artificial lighting in the interior is undesirable. It will also be found that the light from combination units mixes better with daylight, so that these combination units will provide ideal sources for supplementing daylight in office buildings, schools, exhibitions, etc.

Likewise, combination units of mercury and Mazda will find acceptance in industrial plants, arenas, and like places. The Glassteel Diffuser type of luminaire has been adapted in an experimental way to accommodate four or five 150-watt incandescent lamps with one 400-watt mercury lamp. Other arrangements in specially designed reflectors are possible.

Combinations of two separate systems of lighting—one for mercury lamps and one for Mazda lamps—have already been used in a number of installations. This plan is perhaps best suited to high bay lighting, where the units are mounted well above the work. The high mounting makes possible a reasonable mixing of the light without an extremely close spacing of the lighting units. In some instances the layout is planned for a standard Mazda lamp system and then high intensity mercury vapour units substituted for alternate units. The incandescent lamp system serves to provide better colour rendition and also as a standby during the retarded starting of the mercury units in the case of a circuit interruption. The high intensity mercury light adds any improvement in visibility due to the mercury spectrum, gives a more "daylight" effect to the illumination, and increases the efficiency of the lighting system.

The providing of a daylight effect by the additive method by using mercury and Mazda illumination together is a more efficient method than by the use of daylight glass or daylight bulbs with incandescent lamps.

Conclusion

It is difficult to predict what will be the ultimate place of the gaseous conductor lamp in the lighting of the future. That they will occupy an increasingly prominent position seems certain. As experience is gained in their uses and in their manufacture, improvements will be accomplished. While during the introduction of these light sources up to the present the installations have been considered largely of an experimental nature, now the practice regarding their use has become quite well established and installations of any magnitude are being undertaken.

Improvements in the near future in life, average efficiency, uniformity, colour of light, simplicity of operation, and in cost of production, are hoped for. Whether or not they will eventually supplant the incandescent lamp for general lighting is a question that only the future will answer. For the present it appears that they offer an additional type of light source that will find application in the extension of artificial lighting into new fields and in present uses where alone or in combination with Mazda lamps more effective lighting results are obtained. The gaseous conductor lamps seem to have, inherently, limitations which will prevent their taking the place in any large measure of the simple and convenient electric lamps as known today.

DISCUSSION

L. P. Rundle, M.E.I.C.[1]

There is a highway lighting installation on the Hamilton-St. Catharines highway at Stoney Creek, consisting of four 10,000-lumen sodium type lamps on 66 cycles. The writer has passed through this installation several times late at night in both bus and automobile. In the lighted zone headlights were turned off and it appeared that with the present installation one would be more safe in driving around 40 to 50 miles an hour than with the usual automobile headlights. The driver of the car, however, thought conditions better with his dim lights on as these lights, having a wide beam spread, helped light the ditches. Other motorists state that sodium lamps are the only light of any practical use when driving in heavy fog. Objects stand out quite clearly and a man walking ahead of a car is distinctly outlined and has no appearance of fading into the background at the sides of the highway, thus indicating clear contrast. There appeared to be no noticeable cycle flicker. However on 25-cycle there might be some flicker under certain conditions. If the lamps on 25-cycle were fed alternately from a two- or three-phase supply it is likely that the average illumination would tend to neutralize any flicker and consequent eyestrain. The Stoney Creek illumination appears to be easy on the eye and remarkably free from blinding points of light reflected from the polished road surface and engine hood of the automobile as compared with the ordinary lamps and lighting.

The writer is of the opinion that the lighting would be improved if the units were mounted higher, and if the unit itself had more area, thus decreasing the intensity of the light per unit area. Some people take exception to the colour of the light, others do not. There is no doubt that further research and experiment will improve these lights in both colour and efficiency as well as simplify and reduce the auxiliary equipment now necessary for their operation. The writer is of the opinion that lighting of the more congested highways is necessary to reduce the heavy toll of accidents and fatalities due to night driving, and of all the schemes this type of lamp appears to be considerably superior to any other practical type of lighting unit now in use, including the best of present-day automobile headlights.

A. J. Hodgson[2]

When in England a few months ago, the writer had the opportunity of viewing some of the new lighting installations there.

[1] Senior assistant engineer, Welland Ship Canal, St. Catharines, Ont.

[2] Hydro-Electric Power Commission of Ontario, Toronto, Ont.

Forty thousand units were in use in England last year and a large number in the process of construction. There were also a number of installations of the mercury vapour method used in large stores with a most pleasing effect. Further different councils were arranging for imposing schemes for their respective areas.

One particular feature which was noticed, was the high, even brightness of the roadways, with an absence of glare. The type of fixture used appeared to throw more light in the direction in which the traffic was proceeding than it did toward the traffic. In actual test on a highway, a pedestrian could be seen 2,000 feet away.

It would be difficult to find a better system of lighting to reduce accidents on highways than the system that has been described.

J. A. Langford, A.M.E.I.C.[3]

In connection with the slides of highway lighting installations in England shown by Mr. Hodgson, there seemed to be much less glare coming from the lights themselves. Is this due to the reflectors designed for and used with those lamps?

[3] Electrical Engineer, Canadian and General Finance Company, Toronto, Ont.

J. W. Bateman[4]

In reply to Mr. Langford's question the author observed that there are perhaps two reasons for the lack of glare. In the installation shown in England the intensity of illumination is higher and the spacing of the lamps is closer than in the highway lighting installations here. It must be remembered that the slides shown of the English installations were real street lighting installations where the units were spaced closer together so as to obtain a more even light along the street than in the slides showing the installations here where you have the units placed much farther apart for highway lighting. Also, the English units have not quite the same directive character as far as directing the light in a wide beam, because the particular unit illustrated has an opal glass side which cuts down the brightness to some extent. Then too, the design of the unit is such as to throw the higher candlepower away from the approaching driver. There are units on both sides of the street so that the unit on the side on which one is driving would tend to throw the light away rather than towards you.

The Status of the Engineer

A luncheon address by J. B. Carswell, M.E.I.C.,

Delivered at the Annual General Meeting, Toronto, February 7th, 1935 (Abridged)

With regard to the status of the engineer in his own profession, it is the speaker's opinion that the heading for the papers which follow should not have included the word "status" at all. It would have been better to discuss the "stature" of the engineer, because there is a great difference between his stature and his status.

This abstract thing called "status" indicates someone at rest, someone who has ensconced himself in a certain position, and surrounded himself with barriers and fortifications, and who is not likely to move out of that position for some considerable time.

The other word, "stature," which is a materialistic and concrete quality is more appropriate; you can have stature and still be growing and walking forward amongst your fellowmen, but stature in the engineering profession or in any other profession can only be acquired by hard unselfish service to the public.

Why are we, as engineers, always so worried about our status in the engineering profession? Is there not a little nervous fear that our importance may be overlooked? Many engineers are fond of analyzing the position of the engineer in society and it is an interesting occupation to prove conclusively to yourself that without the engineer society could not exist. However, if you happened to be a law student, you could similarly analyze the situation and prove that society could not exist if it were not for law and order controlled by the legal fraternity. The truth of the matter is that all occupations are merely cogs in the wheels of industry, their usefulness is measured in units of co-operation, and that is where the average engineer falls down.

Last year the speaker criticized the agenda of the annual meeting of The Engineering Institute, and this year it should again be criticized.

Engineers are lacking in perspective. This is the year 1935, when the political pot is boiling as it never boiled before, and when the economic structure of Canada, and every country in the world, is under a severe strain. The old established orders are changing; the capitalistic system is being attacked from every side; in some countries of the world the capitalistic system has ceased to exist. Our government in Ottawa has facing it at the moment problems of vital importance which will affect every man and woman. To-day, the representatives of four thousand professional engineers in the Dominion of Canada meet, a group which is supposed to contain—and does contain without doubt—some of the best trained minds in the country. Now, the government in Ottawa is after all just a group of business men, who are at this time seeking for good intelligent public opinion as a guide for them in their actions. And what do the representatives of four thousand engineers do? The first day of their meeting is devoted to a discussion of gaseous conductor lamps and bascule bridges. What interest has the government in these subjects? And the third session—the third session is much better—something is actually being done for the public in the way of discussing the water situation and the irrigation problems out west. Incidentally there was an editorial in the paper a couple of days ago congratulating The Engineering Institute upon tackling this problem.

But, where does this group of four thousand men stand in connection with such items as unemployment insurance, old age pensions, and all the other social problems confronting the country at the present time? What are their views on the railway problem? It has been said on the best authority that the railway problem will wreck the credit structure in this country, unless a reasonable solution is found. Where do engineers stand on the housing problem. Substantially the same class of houses are being built to-day as one hundred years ago. The modern method of mass production which has made such vast changes in the production of everything else in this country has never yet been applied to the building of houses. Yet it is quite possible to build a house or a factory and apply the same method to its construction as is applied to the building of a Chevrolet car, and still erect a structure which will last and lose none of its originality.

Why is it necessary to go to Indiana, quarry tons of stone out of the solid rock, haul it a thousand miles, and finally hoist it three hundred feet into the air to form the wall of a modern hotel, when fifty other materials could be mentioned which would serve the purpose better, would be cheaper, and would impose on the steel supporting structures only about one-tenth of the weight? Why is this done? The answer is two-fold. First, because our fathers and our grandfathers and our great grandfathers did it before us, and secondly because the engineer, who should be tackling this problem, has for generation after generation treated the subject with contempt and neglect.

Who built the aqueducts in Rome? History says that Claudius Cæsar built them, but while Cæsar was in Britain fighting the Picts and the Scots there was somebody in Rome who knew the first principles of design and hydraulics, and built the aqueducts leading into Rome which stand there to-day, yet his name does not come down in history.

The engineer was then and is to-day for some reason or other always taking a back seat, retiring in modesty. Why does he do so, when at the same time he is faintly conscious of his own superiority over his lay associates. Out of that faint consciousness develops a little cynical attitude towards humanity, a feeling sired by introspection and mothered by idealization.

And so, in introducing this series of discussions this afternoon, the speaker wishes to make a plea that at the next or ensuing meeting of The Engineering Institute an attempt be made to arrange the agenda so that the public, and particularly those in authority, will welcome the coming of our annual meeting, and will look forward to some constructive guidance on the part of this great group of engineers.

Of course, it is necessary to untangle the status of the engineer in Canada, and the papers that you are going to hear are necessary, and will be very interesting, but if the average professional engineer in this country would get away from the detail of his profession sufficiently long to show the man in the street that he has real stature, then he would not have to spend time worrying about his status.

It is no doubt a pleasure to submerge oneself completely in a technical problem, to wallow in a mass of detail, and after weeks and months of concentration to emerge triumphantly with the solution—a solution which can be proved backwards and forwards, and all carefully drawn to the scale of one-half inch to the foot. When you solve a problem of that kind, it really does not matter if you have not been out of the house for a week, or read a daily newspaper for two weeks. You have solved this thing and you know it is right.

Meanwhile, England may have gone off the gold standard; Germany may have turned communistic, or Fascist, or Nazi. One doesn't really care. Possibly the future of some huge industry may be trembling on the brink; it may be the corporation for whom one is working out this problem, but what does it matter. And, frankly, one did not have to care very much in the past. There were always more and more problems to be attacked, lots of work to do, intensely interesting work, and the wheels were going around merrily.

But things are different in 1935; in fact they have been different for the last four years. The wheels of industry have largely stopped running, and the supply of problems has lessened. There are thousands of engineers in this country who have been out of employment for years, and are still out, although the wheels of industry are beginning to move again.

When this depression started there was considerable noise about "technocracy"—that is up in the attic now with other fads of the past, Mah Jong, crinolines and silent pictures. But there was a warning in technocracy which the average engineer failed to grasp. The theory the technocrat handed to us was that too much energy had been devoted to production and there had not been enough guidance and efficiency in distribution; criticism should not have been aimed at production, but at the more inefficient part of the industrial structure, lack of guidance.

Who has been responsible? Just a group of engineers, ourselves, who sit down and discuss at annual meetings the details of bascule bridges, when they should be out performing some good service for the public, and giving the public the benefit of their training and their brains.

Every engineer should be wakened up to the fact that in this mechanical age of progress, if he is ever to acquire real stature in this country, he will have to get out in front of the business mess in which all find themselves to-day, a mess for which he is in a great measure responsible. Away out in front, applying the same logical principles to the present problems as in the past have been applied to production problems. The engineer may have to learn a new language. He may have to discover his lay-associates, to find out who these strange creatures are, before he can be much use, but having served his apprenticeship out in front, where he is performing a real service to the Dominion of Canada, then, and only then, can he look in the mirror, once in awhile, and congratulate himself, not on the status of the engineer in his profession, but on the stature of the engineer in the economic life of Canada.

The Engineer and Industry

R. E. Smythe, M.E.I.C.,
Director, Technical Service Council, Toronto, Ont.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

This paper is an attempt to discuss briefly a number of factors related to the whole subject of the "Engineer and Industry," rather than to deal exhaustively with only one phase of it.

Definition of an Engineer

Just who is the engineer in modern industry?

From general observation, it might be said that he is that man who supplies, and applies, technical and scientific information and direction, wherever complexities of discovery, production, design, processing or distribution exist.

This definition covers a wide field of technology; it includes many new developments in Canada, and the use of men with engineering and scientific training in these new branches is increasing year by year. The demonstrated ability of engineers to adapt their technical training to the ever-changing requirements of industry and business is indeed amazing, and as industry becomes larger, the call for men with an engineering training becomes greater. More specialization is required, and administration becomes more involved.

Status of Engineers in Industry

The great variety of endeavour now followed by engineers in industry, makes training a complex procedure; likewise, it makes any attempt to set standards of professional status almost an impossibility.

The engineer in industry is a professional man, and no doubt exists on that point. He professes and makes open declaration that he is in possession of knowledge over and above that possessed by Mr. Average Citizen. Lives of thousands depend on his skill, and industries constantly advertise this applied knowledge as a feature of their products, whether motor cars or paint. Yet the engineer becomes part of his industry, and largely relinquishes any professional title he may hold. The terms are recognized at once, supervisor, superintendent, manager or president. These titles gives indication of the status of the man in the industry, but not of his status in his profession.

In the past engineers have adopted several ideas to maintain and make known their technical status. They use university and professional degrees. This Institute has had experience in the adding of A.M.E.I.C. and M.E.I.C. after members' names. In one country, engineers have attempted to add the word "engineer" before plant titles, such as engineer-superintendent, or engineer-manager. In industry the titles of plant engineer, maintenance engineer, designing engineer, production engineer and sales engineer are used, but these titles do not indicate status or seniority, as much as specialization. They all, however, do suggest that the man involved professes a knowledge of engineering or technology.

It is not easy to see how professional engineering status can be indicated in industry by title, nor is it clear that this is essential. The point one should be concerned with is the engineer's real status; in other words, how can such an organization as The Engineering Institute of Canada serve the engineer, enable him to give greater service and better leadership to his industry, and to the people depending on him in that industry.

The growth of industry in Canada, in recent years, is well known, and it is unnecessary to quote figures on this side of the question; but the increase in the number of technical graduates from universities in response to the growing demands of industry, is not so well known.

The following figures show the trend towards the more industrial branches of engineering, such as chemical, mechanical or electrical, and this trend has increased enormously in recent years.

The average number of students graduated per year in civil engineering during the period 1900 to 1904, was twenty-two. During the period 1910 to 1914, however, the number graduated rose to an average of one hundred and fifty. The peak was reached during this period, for during the next ten years, the number dropped to one hundred and seventeen; and in the last ten years, has shown a further decrease to an average of one hundred and six.

The number of graduates in mining has been relatively constant since 1910, as compared with the changes in other fields. Before 1910, the average graduating class in mining for all of Canada was eighteen per year. From 1910 to 1934, however, there is a slow rise from fifty to sixty-three.

In the comparatively new fields of chemical, electrical and mechanical engineering is shown most clearly the effect of the demands of a more industrialized country; the phenomenal increase in the number of electrical graduates to meet the needs of the great utilities, private and public, the steadily increasing demand for chemical engineers in the metal industries, food, textiles, oil, rubber, paper and research in every field, is most marked; and then, of course, the steady increase in the use of mechanical engineers as processing becomes more mechanized.

In the period from 1900 to 1904, the average number graduated in electrical engineering from the whole of Canada was two, although there were some combined courses with mechanical engineering; from then till the period 1910-1914, there is a sudden rise to an average of forty-two per year, a tremendous increase.

In the next ten years, ending 1924, the number in electrical engineering more than doubled. For the period from 1930 to 1934, there was an average of one hundred and twenty a year, compared to ninety-four in the 1920-1924 period. It will be seen at once that an apparent peak for electrical engineering was reached in 1930 to 1934, and it may be that this figure will decrease, because employment in electrical industries fell off in these years.

In 1900 to 1904, there was an average graduating class of three in chemical engineering in Canada; the number quadrupled in the 1910 to 1914 period, and during the next ten years increased from twelve to sixty-seven, or 500 per cent. In the last four years, the average is somewhat higher than seventy per year, and this figure does not include graduates in pure chemistry from arts colleges, which would probably increase the number to over ninety per year.

In mechanical engineering, there is a steady but rapid increase in the number graduated. The average in the period 1900 to 1904 was twenty-four; in the last four years, the average number graduated is ninety per year. The average increase from period to period is about 400 per cent.

These figures give some indication of the increasing number of young engineers entering industrial engineering fields. To keep their status in industry high, their training must be thorough, but one must guard against training more men than industry can absorb with profit.

The question of training consists of two principal factors: scientific and theoretical training in universities, and practical experience training in the industry itself. Canadian industry would do well to attach much greater importance to the building up of a junior staff and to training these young men after they are employed.

Changes in economic or national policy greatly affect engineers, both those in industry and consultant engineers serving industry; and one major factor is the growth of the international industries, with centralized research in larger countries, resulting in the enormous growth of branch plants, with their head offices lying outside Canada, where most of the technology is developed and designed.

These changes are not of long standing, but are recent and present developments. In 1920, there were about two hundred branch plants in Canada; today, there are some fifteen hundred—an increase of thirteen hundred in about fourteen years. If the status of the Canadian engineer gives concern, one must study the effects of these changes on his position and future in industry.

It happens that for many branch plants, research, development and training are largely carried on in the parent plant, and when engineers or administrators are required, they are moved from the parent plant to the branch. In isolated cases, this may not affect Canadian engineers, but with fifteen hundred branch plants, it will be seen that the problem becomes vitally important, especially if it is considered that about five hundred young engineers are graduated each year in Canada, and this number is steadily increasing.

Many branch plants are thoughtful on this point, and have a broad viewpoint, taking into consideration the local or national effects of such a policy; but others, overwhelmingly concerned with profits, take a narrow view and tend to ignore national welfare—at least, the welfare of a section of people such as engineers—and it is important that such a stratum of people be considered.

At the present time, when a branch plant wishes to import an engineer from its parent company, application is made to the Department of Immigration, Ottawa, giving the reasons for such a request. The Department then seeks advice on the question from available sources, and grants or refuses entry on the merits of the case, at the time of application. In many companies this need might have been foreseen, and Canadian engineers given the necessary training; in other words, many importations are merely a matter of immediate convenience.

It would appear that this Institute should establish a "Rule of the Road" in co-operation with the Dominion government on such problems, so that branch plants would either send young Canadians to their parent plants—to be brought back later on—or give them training in the branch plant. These companies would at least know what was expected of them; for as it is now, some find it difficult to understand why an application for the importation of a foreign engineer is refused. It is infinitely better to create a definite understanding between countries than to allow a great many small differences to arise and grow.

Imported Design

Again, a definite understanding should be arrived at concerning the importation of design for both structures and machines. Engineering design should not be imported into Canada, when it can be supplied competently in Canada at a comparable cost. To be specific, a plant should not import a design for a building when competent Canadian engineers and architects are available. Yet this was done on many occasions last year.

It should be possible to establish rules for the guidance of all concerned in these matters, and an organization like The Institute might accept leadership in this regard.

There is a secondary effect to be considered when industrial design is imported into Canada. Suppose a Canadian industry maintains an engineering and development staff, and is later subjected to competition from a branch plant where these costs (sometimes as high as 15 per cent) are charged to a market many times as large. It is obvious that the Canadian industry cannot compete for long, and will be forced to give up its technologists in Canada, and import its design at less cost. Thus opportunities for employment of engineers and development of engineering skill in this field are lost to Canada.

Some of these problems are very complicated and solutions far from simple, but they constitute a handicap to the Canadian engineer, if they are not controlled, and seriously affect his status.

How can the engineering organizations assist in improving the real status of the engineer in industry?

1. Our engineering organizations should face the fact that Canadian interests cover an enormous and detailed field, and they should encompass as much of it as they can. They should be ever-ready to enlarge their horizons, whenever they see that service can be rendered to our members, or to the nation and its people. Engineers in Canada must stop doing things by halves; they must do them wholly and find the necessary funds.

2. An organization such as The Institute should give assistance to smaller group of engineers, where it is to the nation's interest to promote the particular specialized knowledge concerned. That assistance should be given with a thoroughness that will enable our engineers to be leaders in these fields.

3. The Institute should promote whole-heartedly the use of competent engineering services to our people. Perhaps heating is more important to Canada than to most countries. A man building or buying a home who does not call in a professional heating engineer for advice loses both money and comfort in the long run. Our cities are filled with cold houses. They could be well heated, with the same or even less fuel, if systems were properly designed. However, people think it too costly to consult engineers specialized in this field. The Institute should, as an association, tell them what can be done for them, and in doing this for them, we assist ourselves.

4. The Institute should be in a position to advise universities where specialist training is needed, and certainly should be able to provide engineers in industry with a constant supply of the best technological literature pertaining to his specialty, arising in any country.

5. The Institute and interested associations, should establish, in conjunction with the government, definite understandings concerning importations of engineering services from other countries, and assist in providing the necessary information on these problems to enable fair rulings to be established.

6. The Institute and interested associations should establish definite understandings, approved by the government of Canada, pertaining to the control of importations of engineering design.

7. The Institute and other associations should lend their best talents to assist in the stabilization of the widely fluctuating durable goods industries, for the lack of such stabilization has created much hardship and a lowering of engineering status during recent years.

Conclusion

To raise the status of the engineer in industry, studies must be made of his problems, and so organize engineering associations that he can be assisted economically and thoroughly, or protected, in whatever way it can most fairly be effected. This is not the work of a year, but of years; but in this way, The Institute can serve the nation and its people, and its own members in industry.

The Status of the Engineer in Private Practice

J. M. Oxley, M.E.I.C.,
Chapman and Oxley, Architects, Toronto.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935.

This paper is to some extent a matter of joint authorship. The chairman of this session and several others have taken an active part in suggesting the points to be considered, and while they cannot be held responsible for the conclusions, they should share in whatever credit there may be for the subject matter.

The subject will be discussed from the possibly limited point of view of the engineer engaged in the design and construction of buildings, including the structural, mechanical and electrical engineer. This should serve to illustrate most of the difficulties and the desires of engineers engaged in other types of private practice.

The status of the engineer depends on his relationships to those with whom his work brings him in contact:—

First— The client.

For the consulting engineer the direct contact may be with either the owner or the architect.

Second—The contractor.

Third— The public.

The principal objects to be attained may also be classed under three headings:—

First— Ability to carry out the responsibilities involved in a competent manner. This is to be attained by natural aptitude; academic and office training; experience in the office and in the field.

The last item is often lacking, resulting in impracticable design and details being called for at an increase in cost with no benefit in the final result.

Second—Full co-operation from inception to completion of the project.

This involves by each of the three parties to the production of the job, architect, engineer and contractor, a full appreciation of the functions and responsibilities of the others; and an active co-operation by means of discussion and consideration so that full advantage may be taken of the special knowledge of each of the three.

Third— Adequate remuneration for the services given. This involves the establishing of and *adherence to* reasonable schedules of fees by the architect and the engineer, with provision for severe disciplining by the governing bodies of those who do not maintain the schedule.

The faults in present conditions are well known, but our main desire at the moment is to seek ways and means of approaching to ideal conditions, instead of bemoaning present failings.

What methods are to be applied to obtain these objects? The essential thing, the basis of all improvement, is undoubtedly uniform and effective legislation developed in co-operation with our colleagues, the architects. Effective legislation will enable us to deal properly with the first and the third of the objects set forth above, i.e., qualification and remuneration.

The architects are ready and eager to co-operate in this regard, in the province of Ontario at any rate, and the author believes prompt and definite action should be taken, by the appointment of representatives of the engineers to meet with the architects and arrive at conclusions as to how best to further the desires of each profession in regard to legislation.

As a matter of practical politics it would appear that this action must be taken by the Ontario Association of Professional Engineers. The Engineering Institute of Canada has no provincial organization, and this question brings up again the necessity for close co-operation between the provincial bodies of engineers and The Institute.

The second of the objects to be attained—full co-operation in the design and execution of the job—is more involved as to method but perhaps easier of accomplishment, in that it does not involve the action of outside bodies—the Provincial Legislatures.

The main difficulty here is probably lack of mutual appreciation. The engineer is not merely a structural designer. The architect is not merely a decorator.

When an architect calls in a structural engineer as a consultant it should not be merely to give him information as to size and detail of a series of beams and columns for which the location and material is already fixed. The engineer's useful functions can and should begin at the stage when the general layout is being determined. His knowledge can be of much greater value in making comparisons as to the advantages and disadvantages of different layouts and different materials than it can be in the relatively simple, almost mechanical, computation of sizes of members, and preparation of details for their connections and so on.

This fact is not appreciated by many architects and some method of impressing it upon them is a necessary preliminary to fuller co-operation.

The same lack of appreciation is noticeable in the opposite direction. Engineers have been known to prepare plans for a great hydro-electric plant, and after everything of apparent importance was settled, to call in an architect and ask him to "pretty it up" for them.

Surely every great engineering work, bridge, dam, hydro plant or industrial plant, should be designed with real consideration to its appearance as well as its efficiency, and to give this consideration the co-operation of the architectural mind should be used, starting at a very early stage of the project.

This full and mutual co-operation is essential to true economy. The major part of large building to-day is commercial in its nature. It must earn its keep. To do this the first cost must be kept as low as possible, the operation of the building must be efficient, and the character and appearance must be such as to attract customers or tenants. To obtain all of these features a full co-operation of the two types of mind, the two methods of approach to the problem, is necessary.

We must also consider the question of the responsibility of the engineer and architect to the contractor and of proper co-operation with him. For the moment we may assume the architect and engineer as one, the designer of the building, and the contractor as the man or organization which produces the finished structure from the design.

Again the value of co-operation from an early stage is apparent. The designer may visualize what he wants, but often the question as to whether it is practicable or obtainable within the cost appropriation is a question on which the contractor can give valuable advice. Or perhaps he can suggest how to obtain the desired result by some other means that has advantages.

Having determined what is to be done, the next stage is to describe this by plans and specifications. Here it is desirable to define what should be included in specifications. The essential thing is that they, along with the plans, should set forth clearly and fully what the final product is to be, including all matters of finish, strength, durability, etc. Generally speaking they should not attempt to fix the methods by which these results are to be attained.

A specification never attempts to direct what type of hoisting equipment shall be used to set a unit of the structure, and yet it may devote two or three pages to a detailed description of the method of making a given mix of concrete, which could just as well be covered by a statement of the strength and finish required.

There are several traditional phrases or clauses often used in specifications which require analysis and correction or deletion.

"To the approval of the engineer" may be a reasonable requirement when it is applied to a matter of taste such as the shade of a finishing coat of paint or the assortment of bricks of varying shades in a wall. It is not reasonable when applied to something which can be definitely described and the variation in which may have an effect on the cost of the work.

"The decision of the engineer shall be final." Of course, there must be one master in control of the job, and the engineer is the logical man for that responsibility. The finality of his decisions should control procedure during the progress of the work, but should always leave open to the contractor an appeal from the decision after completion. Compliance with the engineer's decisions during progress, should be recognized as not in any way prejudicing the contractor's case in making appeal after completion on any items which affect his costs or time.

Another point to consider is the engineer's responsibility for errors. These may be roughly divided into three classes:—

(*a*) Errors in judgment.

(*b*) Errors involving changes which do not increase the final cost beyond what it would have been if the error had not occurred.

(*c*) Plain ordinary mistakes, due to carelessness at some stage by the engineer, and resulting in additional cost without any benefit to the owner.

For the first class, errors of judgment, there can be no financial responsibility held against the engineer. He has presumably given the best of which he is capable. If he was wrong, he will suffer in his reputation and by the loss of future commissions.

For the second class there is usually not much difficulty in rectifying the trouble. The engineer may have an embarrassing interview with the owner to explain matters, and may suffer in his standing with the owner, but that is the extent of the damage.

For the third class, errors due to carelessness which involve additional cost to the owner, my own conviction is that the engineer should assume the responsibility and pay for the cost involved. However, there is evidently a wide difference of opinion on this matter and a free discussion might help to clarify the position.

Regarding the engineer's relations with the public a few words might be said. The title "engineer" has rather a vague significance in the public mind. There is a general knowledge of the functions of the doctor, lawyer or architect, but the "engineer" is usually visualized either as a man peering through a little telescope on a tripod, or the operator of a locomotive or steam shovel. The designing engineer is little known and little thought of by the public in general.

Possibly the public mind can be educated by connecting the personality of the engineer more directly with his work. Every important work should carry a plate giving the names of those chiefly responsible for its production. Every description of an important structure, whether in news paragraph, technical article or advertisement should also carry those names.

If the engineers themselves work persistently for these objects I am confident that a great deal can be accomplished.

A summary of some of the chief items required to improve the status of the engineer follows:—

1. Proper qualification by aptitude, training and experience.
2. Co-operation with architect and contractor in design and execution of the work.
3. Co-operation between the representative bodies of the engineers and architects in obtaining adequate and effective legislation.
4. Co-operation with the architects, by means of periodic discussions, as to rules of practice, division of functions, etc.
5. Recognition of the true responsibilities to owner and contractor.
6. Education of the public by persistent publicity.

The Engineer in the Public Service

G. J. Desbarats, C.M.G., M.E.I.C.,
Ottawa, Ontario.

Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., February 7th and 8th, 1935

The engineers who come under the above heading comprise that large and growing class working in the various branches of government. They may be divided into three groups:—

A. Those employed by the Dominion government
B. Those employed by the various provincial governments
C. Those employed by the governments of the cities and towns and the smaller municipalities throughout the country.

The term government will be used to cover these three classes of administration.

To these should be added the engineer officers of the defence forces who work under different conditions and should be considered separately.

The engineering activities of these governments cover the whole field of engineering and practically every variety of engineering specialist is to be found on the government staffs. The young engineer graduate wishing to engage in any particular branch of the profession can find an appropriate office in one of the government administrations.

Conditions of Employment

The conditions under which engineers are appointed and hold positions in the three classes of public service vary greatly but one feature is common to all and that is the continuing nature of the work to be done. The business of the country must be carried on, it cannot be interrupted. This business tends to grow and expand; in some cases this is due to the growth of the country and to new services which are required to meet increase of population and settlement; sometimes this is due to new inventions as was the case with radio and aviation, in both these cases the Federal government took over an infant which it nursed and developed, it carried on trials and experiments which private enterprise could not have financed and from small beginnings sprang two important government services; in other cases government has taken over services already established by private industry, as in the case of the Ontario Hydro Commission where the government took over a private electrical power plant and built up one of the most remarkable publicly owned utilities in the world, one which has covered Ontario with a network of power lines, and supplies current to its customers at record low rates.

While government administrations add frequently to their activities they never discontinue work which has once been undertaken. There may be temporary periods of slackness or of retrenchment, but once having put its hand to the plough a government administration cannot turn back, it must continue, it has established vested interests which insist on the work being continued and such pressure is difficult for a government to resist.

The young engineer entering government service is therefore justified in looking forward to continued employment in that service, he hopes for promotion in due course and expects that new activities of his department will furnish him opportunities for further usefulness and advancement.

Dominion Government: In the Federal government service this hope for security of employment is quite justified. The engineering staff of the Dominion government is under The Civil Service Act and subject to the terms of that act. The first Civil Service Act of 1908 exempted engineers, largely at their own request, and when the 1918 act included the engineers some indignant protests were made, it being contended that professional men would not compete for appointments or submit to examinations and that it would not be possible to obtain the best men or even well qualified men under a system of public competition. Experience has shown that these fears were groundless and excellent results have followed the application of this act to the engineering staff. The basic principle of The Civil Service Act is the merit system, the principle that every government position should be given to the best qualified man available irrespective of his political affiliations, that promotions should go to the most deserving and that no dismissals should be made except for cause.

The Civil Service Commission has a list of some eight hundred permanent classified engineering positions on the establishment of the Dominion government departments and appointment to these positions is vested in the commission and is required to be made without political or personal bias and purely on merit.

The conditions for examinations and the procedure for appointment to the engineering staff has varied from time to time. Last year after discussion with representatives of The Institute and of the Professional Engineers the commission adopted the following as the fundamental requirements for engineering appointments to positions of responsibility. The candidate for appointment must have "corporate membership in The Engineering Institute of Canada, or membership in a Provincial Association of Professional Engineers, or professional qualifications which would permit of such membership." To these general qualifications are added the special experience or knowledge needed for the position to be filled.

Power of dismissal exists and during the depression years had to be largely exercised. Reduction of staffs took place owing to the general financial conditions and the decrease in parliamentary appropriations, owing to reorganization in some departments and to transfer of certain activities to the provinces. The hardships incident to all these reductions were mitigated to a large extent by the working of the Superannuation Act which provides a pension for employees with ten years of service. A certain discretion was given to the chiefs of branches in the choice of dismissals and every effort was made to minimize the distress caused by these dismissals. It was provided that in the case of vacancies which had to be filled preference would be given to men who had been laid off. The good results attained were shown in the records of the Unemployment Committee of the Ottawa Branch of The Institute. Although the membership of the branch is very largely composed of Dominion government employees there was not a single case shown of an ex-government-employee in urgent need of relief and only three or four applied for employment. The unemployed list of the Ottawa Branch was made up mainly of engineers who had worked with commercial companies.

The Superannuation Act for Dominion government employees is working out satisfactorily. The employees and the government contribute equally to it, the tax on the employee being 5 per cent of his annual salary. It provides for an annual retirement allowance of one-fiftieth of the average salary for the last ten years up to a maximum of thirty-five fiftieths. The widow will draw half as much. This act has only been in force since 1924 so its financial results have not yet appeared, but the fund at present shows a large reserve.

The Dominion government has built up a strong engineering service in its different departments. The morale is good, co-operation between different branches is assured by inter-departmental committees which avoid duplication of effort. The men of many years of service who have attained experience and skill are attached to the service and retained by the Superannuation Act so that they hesitate to accept positions in commercial life though the financial conditions attached are frequently very attractive.

Provincial Governments: Conditions of employment with the provincial governments are not as satisfactory as with the Dominion government. Civil Service Acts in the provinces are incomplete or lacking and do not provide for the employee the protection extended to him by the Federal Act.

A few provinces recognize membership in their Professional Association as qualification for appointment and this is a step in the right direction, but most of them have no definite standard for appointment and promotions and these are frequently made for personal or political reasons and not for merit. The provinces have power to legislate in social service matters and have all passed acts providing protection for various classes of labour. They have generally failed to apply the same principles to their own employees and have left them exposed to the hazards of political patronage.

The engineers in provincial services are protected to some extent by the fact that an incoming administration can hardly proceed with wholesale dismissals in the engineering staff owing to the difficulty of building up a new technical staff, but this is no comfort for the individual engineer who is removed for political reasons or to make way for a political appointee. Provision for superannuation in provincial service is generally lacking or is elementary and does not provide sufficient definite safeguards in the case of removal or old age.

Municipal Governments: In Canadian cities party politics are replaced by ward politics. Engineering appointments are largely determined by considerations of personal friendship and family influence. Promotions and increases of salary are not entirely the result of merit, they have to be voted by council and are therefore subject to wire pulling and all kinds of local influences. On the other hand municipal engineers are seldom dismissed except for cause. Once an engineer has been in office for several years and has established friendly relations with the controllers and the aldermen his position is reasonably secure, but he needs to avoid friction with the members of council and to secure their goodwill.

Superannuation systems are generally lacking in municipalities, an old official may be pensioned but only as a special case, it needs a vote of council and is therefore dependent on its goodwill.

In the large cities the engineer has good scope for his abilities and reasonable chances for promotion. In the small municipalities there are fewer opportunities and hope of advancement is based on transfer to the larger town or city.

Standing in the Community

The engineers employed by Dominion and provincial governments at headquarters suffer from lack of personal recognition of their work, most of their work is anonymous; advertisements calling for tenders are signed by the secretary of the department, the contracts are signed by the minister. The engineer who designed the structure very seldom gets any recognition. In this they share the fate of the engineer employed by a large corporation whose work is credited to the corporation. There are a few exceptions to this rule; the Marine Department publishes charts which, following the practice of the British Admiralty, carry not only the name of the chief hydrographer but also the name of the chief of party and his assistants who made the survey; the Department of Mines issues reports signed by the engineer who made the survey; but as a rule the engineer on a large headquarters staff gets very little publicity for his work, his recognition only comes from his inner consciousness and the regard of the small circle around him.

Notwithstanding these drawbacks the government headquarter staffs as a body stand well with the public. In Ottawa, the headquarters of the Federal Service, its engineers are leaders in Civil Service councils. The Ottawa Branch of The Institute whose members are largely drawn from the service sees its luncheon addresses attended by members of the Dominion Cabinet, Deputy Ministers of Departments and prominent citizens, its meetings are well reported in the local press. Outside of Ottawa, superintending and district engineers of the Dominion and provincial governments are prominent in their localities. As representatives of the central authority they wield considerable influence and in their dealings with contractors and business men their position is recognized.

Government engineers have occasionally opportunities of attending international gatherings of a technical or diplomatic nature as representatives of their government. They may even take a part in negotiating conventions or treaties with other countries. At these meetings the Canadian representatives profit by the prestige of their country. The work at these conferences may be difficult and entail large responsibilities but it is always most interesting and cannot fail to have educational value besides reflecting honour on the delegates.

In municipal administration the engineering staff have good standing on the list of corporation employees. The heads of the various engineering sections are well known in the community, their work is under the eye of the citizens and they generally enjoy the esteem of the public. The individual members of the staff are well advertised, the daily press, which is very personal, records their professional activities and each one is well known to the public in connection with his work. When the town is under the engineer-manager system this official is the most prominent member of the administration.

At election time the works department of a city is generally a target for criticism and the medium of attack on the civic administration but the engineers are seldom attacked personally. If however anything goes wrong in any of the public works of a city, if any accident occurs, the press and the public are liable to visit their displeasure on the engineering staff and call for the dismissal of the engineer in charge of that branch. A man with an unblemished record of years may thus lose his position as the result of public clamour over an accident which he could not control with ordinary precautions. The same is true in a lesser degree in Dominion and provincial staffs. The result is that the public service engineer has to play safe in design, construction and maintenance, he cannot afford to cut as close as his colleague in commercial practice; while this is desirable if kept within limits it should not be stressed unduly as it leads to unnecessary cost and expenditure of public funds.

An engineer in public service needs to be something of a diplomat, he has to keep on good terms with his numerous employers, the Ministers of the Crown, Members of Parliament or of Legislature, city controllers or aldermen and while maintaining friendly relations with these and other influential persons, and endeavouring to meet their views, the engineer must have as his first object the carrying out of his work with efficiency and to the best of his ability and must not allow himself to be diverted from the straight path by considerations of party politics or of personal preference.

Remuneration

The rates of pay for engineers in public service are as a rule low. In 1929 a commission headed by Mr. E. W. Beatty, president of the Canadian Pacific Railway, investigated the salary scale of the Federal Civil Service. The commission recommended substantial increases to the rates of pay of the engineers. The commission found that pay given to juniors, young men fresh from the university with little or no practical experience was fair enough, but the pay of men with some fifteen or twenty years of service occupying positions of responsibility was decidedly inadequate. The pay of the chiefs was low and this affected the rates paid to all the intermediate classes. The government seemed to concur generally with the report of the commission and was disposed to favour a revision of rates of pay. Unfortunately the country's finances dropped at that time and no action was taken, but when the depression has passed the recommendations of the Beatty Commission may be considered.

Salary rates in provincial governments and city administrations are guided generally by the Dominion government rates and are also low. They are not as a rule so well defined nor do they provide so clearly for periodical increases. They are much more dependent on the decision of the minister or of the board of aldermen. This lends itself to political influence, to wire pulling and to the exercise of political patronage which is a detriment to efficiency in the service.

It is this political patronage which is the chief drawback to the position of the public service engineers. While the engineers with the Dominion government are protected from patronage in their appointments and salary they have to deal with this evil in their handling of contracts and work by day labour. The contractors' political friends are liable to bring pressure on the engineer to influence his judgment and obtain favoured treatment for the contractor. In the case of day labour, if the engineer has any control of the hiring and dismissal of the labour force he is expected to see that friends of the party in power are given preference and may find himself in trouble if men holding opposite views are placed on the pay list.

Engineers with provincial governments and municipalities suffer from these troubles to an even greater degree. The conscientious engineer, striving for economy and efficiency has often great difficulty in steering a course which is safe as well as straight.

Recent events have shown that the positions of engineers in some provincial administrations are held subject to political considerations. If this principle is admitted it destroys the feature of continuity which is advanced as a compensation for the low rates of pay current in government positions.

Engineers of the Defence Forces of Canada

The three arms of the defence forces, the navy, the army and the air force carry engineer officers trained as specialists in their own particular branches.

The permanent forces in Canada are small and are maintained mainly for the training of the non-permanent units and as a nucleus which could be expanded in time of emergency.

The naval engineers specialize as marine engineers. They are responsible for the construction and maintenance of the naval ships, have charge of the repair facilities of the navy yards at Halifax and Esquimalt and of the engine rooms of war vessels and act as consulting engineers to other government departments on questions of ship construction and repair.

The air force engineers are specialists in the construction of aeroplanes and air ships, they are responsible for the inspection and maintenance of the planes of the air force and also act as technical officers for the civil aviation administration, they have charge of the air repair depot at Ottawa and of the technical equipment of the air force.

The engineers of the army permanent force are listed in the Corps of Royal Canadian Engineers who are the construction engineers and the Royal Canadian Corps of Signals which is the electrical section; the mechanical engineers, who are few in numbers, will increase with the growing mechanization of the forces.

The typical officer of the Corps of Royal Canadian Engineers is a graduate of the Royal Military College and a Bachelor of Applied Science of one of the universities, he follows a course of one year at the School of Military Engineering at Chatham and may be attached for a period to the Ordnance Survey in England. As an officer of the permanent force he attends Staff College courses in England and qualifies for his various promotions. He is a highly trained engineering and military officer with his mind broadened by study abroad.

His main occupation as a military officer is training the non-permanent engineering units in military procedure and in their special duties in time of war. He must also enlarge his knowledge as an engineer and acquire practical experience in design and construction work.

Unfortunately his opportunities for carrying out engineering work are very limited. The practice of the Canadian Corps follows the example of the Royal Engineers in England, whose only activity outside of care of military property is the Ordnance Survey of Great Britain. The Canadian officer may serve on the survey staff on topographical survey; or as a district engineer officer he will have charge of repairs and maintenance of armouries, barracks, rifle ranges, fortifications, ordnance buildings and occasionally have some construction of military works. Recently the Engineering Corps has laid out and supervised the work carried out by the relief camps of the Department of National Defence and is performing a remarkably good job of work. The engineering officer has very few opportunities of carrying out any important engineering works, his engineering faculties lie fallow and the country receives little return for the expense of his engineering education.

Various methods have been proposed to remedy this undesirable situation, It has been suggested that officers of the Engineering Corps should be seconded for a few years to a construction department of government or to some of the large contracting firms of the country to give them more intimate knowledge of construction work on large and difficult undertakings conducted with special attention to cost and time, and to acquire experience of estimating cost of work under competitive conditions. While it has not been found practical to carry out these suggestions it may be possible to put them in execution when construction revives and more engineering work is available.

The officers of the Corps of Signals fare better, as the Department of National Defence operates through them a chain of radio stations through the Mackenzie Valley to Dawson and Aklavik. They also installed radio beam stations for the airways across the prairies, these are dormant but may be revived when the trans-Canada airways become operative.

General

In this paper stress has been laid on conditions of Dominion government service and more space has been given to this service. This is because the Dominion government is far ahead of the others in the application of the merit system and of superannuation.

It is probable that a majority of Canadians are in favour of the merit system in government service but attacks are still made on it occasionally by parties who wish to restore political patronage, and these attacks are most to be feared when there is a change of administration. The present conditions of unemployment has intensified the demand on ministers for jobs for party workers.

There is unfortunately no national organization to bring the weight of public opinion to bear against the pressure of political job hunters. Several efforts to organize a public service reform league have failed and such a society is much needed. The Ontario government minister who recently declared that he considered the patronage system the curse of every administration in the country would welcome the support of such an organization to strengthen his hand in his fight against the patronage evil. Engineers should take a part in promoting this movement and in urging the adoption of necessary legislation.

Provincial governments stand to-day in their civil service methods where the Dominion government stood some twenty years ago. They lag behind in the application of the best methods of building up an efficient staff for the administration of the business of the province and therefore cannot attain the best results. Employees who know that their success and advancement depend entirely on their skill and application are keen and anxious to carry out their work with the utmost efficiency, but if they feel their success depends more on political favour than on professional attainments they are liable to become indifferent and not to give that full measure of their ability to which a good employer is entitled. Employees who know that their position is secure and that when their period of usefulness is over there will be a pension for their declining years and provision for their family have minds free from care and are able to concentrate all their faculties on their professional work.

The principle of superannuation is recognized by commercial companies. The banks, the railway companies and many large industrial concerns have effective pension schemes in operation. The Dominion government was early in the field; at the time of confederation it had a superannuation act based on the British act. The act has been amended from time to time and the present act embodies the experience gained in its operation. It has proved a most useful help to good administration.

The trend of modern legislation is towards old age pensions, unemployment insurance, minimum wage requirements and other provisions for the protection of employees. Governments who pass this legislation should set a good example to industry and provide similar protection for their staffs. The drawback to government service is the operation of political patronage. This has been fairly well eliminated from Dominion government service where the merit system is well established. In provincial and municipal governments the patronage evil still prevails and until it is eliminated and the merit system adopted efficient administration will be difficult.

Government service does however present an attractive career for the engineer. It offers great variety of employment, it provides good scope for his ability and enterprise; while salaries are low, continuity of employment is general, and security of tenure is assured, at least in Dominion government departments, together with reasonable retiring allowances.

The government engineer has a dignified position in the community, has opportunity for improvement and advancement, has the satisfaction of taking part in the administration of the country and of advancing the interests and contributing to the welfare of his fellow citizens.

Simple Graphical Solution for Pressure Rise in Pipes and Pump Discharge Lines

Robert W. Angus, M.E.I.C. [1]

DISCUSSION

A. W. F. McQueen, A.M.E.I.C.[2]

This interesting paper has made available not only a useful tool by the aid of which the solution of water hammer problems may be materially expedited but also an elucidation of the work of Allievi.

Water hammer phenomena, thanks to the researches of Joukovsky and Allievi and to many others who have expanded the work of these writers, are susceptible of definite analysis. But, in practice, conditions are usually anything but simple. Pipes are branched or have off-takes, they vary in size and have plates of different thickness at different sections. The forces producing water hammer are also seldom of a uniform nature. All of which makes a computation exceptionally difficult and laborious. Under conditions such as these a graphical solution may often have decided advantages over an arithmetical one.

As far as the writer can discover the work of both Allievi (as translated by Halmos) and the author have been predicated on a horizontal pipe. In an earlier paper by Allievi, the equation $H - H_0 = F + f$, which is the author's equation (6), was developed from an inclined pipe and is given as $H - H_0 = F + f - x \sin \alpha$ where α is the angle which the pipe makes with the horizontal. The writer would like to inquire if the graphical method of the author will apply equally well in this case.

In the section headed "Pump Discharge Lines" where an illustrative problem is being discussed, the author makes the statement "It is, however, unable to do so because a perfect vacuum exists at A 15.2, and yet there is a velocity of 3.86 feet per second toward the reservoir, so that an empty space will form on the reservoir side of the valve and the pressure will remain at absolute zero during the whole of this 3.8-second interval......". The writer wonders how true a picture this is of the phenomena that will obtain for the conditions assumed. When the pressure drops below atmospheric and tends towards absolute zero it seems that the condition known as "cavitation" will take place, i.e., the minute air bubbles always present in any but absolutely pure water will form focal points for the formation of water vapour and the freeing of gases contained in the water. So that, instead of having an "empty space" there will be a fluid composed of water, water vapour and gases the elastic properties of which will be sufficiently different from water as to render necessary a change in the physical constants employed.

If a word of criticism may be permitted, it is to be regretted that the author did not adhere wholly to the recommended symbols as published by the American Society of Mechanical Engineers in their Water Hammer Symposium. For instance the Greek letter ψ, for the author's G, is not only the recommended standard of the above mentioned body but has been used by Allievi to designate the ratio between the effective variable gate opening and the area of the pipe throughout his work.

S. Logan Kerr, M.E.I.C.[3]

Professor Angus has done the engineers of Canada and the United States a great service in presenting at this time these most interesting developments in the solution of water hammer problems. The general concept of graphical solutions was set forth by Professor Allievi in his classic work on this subject. Several more recent studies by engineers in Germany, Switzerland and France have improved upon the technique, and have forged a most efficient weapon with which to attack the complexity of the usual water hammer investigation.

The laborious formulae of Allievi and others, simplified by Mr. Norman R. Gibson in his "arithmetic integration method" were improved upon still further by Mr. Ray S. Quick in his paper before the American Society of Mechanical Engineers in 1927* and have been the bases of most water hammer studies. The simple problems which involve only a uniform conduit and a uniform rate of velocity extinction can be solved readily as far as the maximum surge is concerned by using one of the charts prepared by Professor Allievi or Mr. Quick. The complex problems that must take into consideration the shape of the curve of pressure with respect to time, or which concern conduits that are of different thicknesses, materials or diameters, or in which the flow is cut off at variable rates, these problems require long calculations and much time and skill in their solution.

The graphical method at once cuts through much of this cloud of detail and presents an elegant solution that is simple and straightforward in its application. This new tool has permitted the exact solution of problems involving surge chambers and air reservoirs which could only be approximated by any other method.

Still further work has been done in the amplification of the graphical method for surge problems by Dr. Schnyder of Switzerland and Professor Bergeron of France. Among others, the case of water hammer in pump discharge conduits has been brought to the fore by the use of motor

driven centrifugal pumps and automatic check valves, but even this most involved and difficult investigation can be simplified greatly by the use of the graphical method. In the recent studies which the writer has been making on the application of surge relief devices to pump discharge lines, the graphical method has been invaluable in reducing the time required for the analysis, and in avoiding the confusion that might easily result from some minor error in the laborious computations by the "arithmetic integration method."

It was gratifying to find that Professor Angus has followed with few exceptions the generally accepted symbols of the A.S.M.E. Committee on Water Hammer. These were prepared for the Symposium held in 1933 in an endeavour to avoid the confusion which has been all too prevalent among writers on this subject. It seemed as each author took up his task that he searched out new and unused symbols, usually drawing quite heavily upon the Greek alphabet. There seemed to be no urge for uniformity, and it was quite difficult for the ordinary engineer to compare the expressions and formulae of two or more authors for this reason. It would have, perhaps, been a contribution toward standardization if Professor Angus had retained Mr. Gibson's expression for the index of gate opening B instead of introducing a new symbol G, and the nomenclature of Messrs. Billings, Dodkin, Knapp and Santos, in their excellent paper on "High Head Penstock Design"* for the head and velocity ratio seems to have a greater significance by using h_{xt} and v_{xt} respectively rather than X and Y.

The graphical method offers the most convenient method for investigating the importance of the initial gate or velocity condition from which closure starts. This question was emphasized by Allievi in one of his charts, and studied by Compte de Sparre in France. It was the subject of many researches by Camichel, Eydoux and Gariel in their work on water hammer, parts of which were presented in English by the writer recently.† Too much emphasis can not be placed upon this phase of water hammer, as the usual calculation deals with the cutting off of maximum flow, while the most dangerous surge can generally be produced by cutting off only a small fraction of this flow at a proportional rate.

In the problem cited by Professor Angus, in Fig. 6, the writer has prepared a simplified chart that illustrates the surge intensity that would result from cutting off fractional flows in proportional times, each case considering the closures from some partial opening to zero. The charts (Fig. 14) *d*, *e*, *f*, show the surges resulting from the closures from 80 per cent opening to zero in 80 per cent of the time for full gate closure, 60 per cent gate opening to zero in 60 per cent of time, and 40 per cent to zero in 40 per cent of time respectively. It is interesting to note that the closure from 40 per cent gate to zero is made in exactly the critical period of the pipe line, that is $2\ l/a$ seconds. The pressure rise is far greater than would be the case for full gate closure, and thus might produce a very dangerous condition, particularly in cases where branch pipes or compound conduits are encountered.

In considering the closures from greater values of gate opening, and hence greater discharges than the one considered by Professor Angus, another interesting relation is found, namely, that greater flows can be cut off in proportionally greater times without increasing the maximum surge by any significant amount. The following table gives the ressult of this investigation.

Table I

	Percent Quantity	Percent Time	From Charts Percent Pressure Rise	From Graphical Method Percent Pressure Rise
a	400	400	56.3	55.5
b	200	200	56.5	56.6
c	100	100	61.9	63.0
d	80	80	68.3	67.5
e	60	60	76.0	76.5
f	40	40	90.0	90.0

It may be noted that the maximum surge for this conduit is nearly 50 per cent greater than the apparent surge based on Fig. 6 of Professor Angus' paper.

In following Professor Angus' exposition of the graphical method, attention must be directed toward the function ρ or K as the writer prefers to call it. In fixing 2ρ as the slope, the value of ρ corresponding to the value of v at $E = 1.0$ must always be used, hence, the slope will vary with each different value of initial flow.

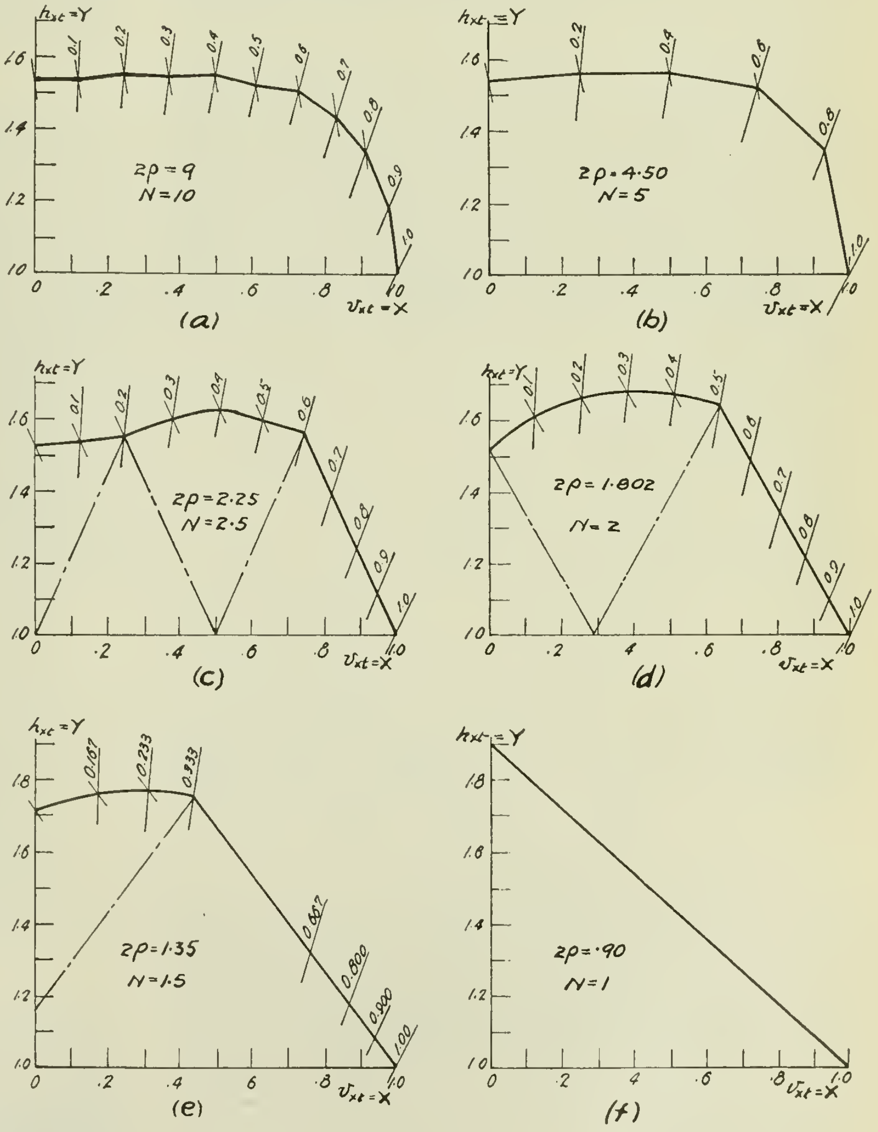

Fig. 14

* Am. Soc. Mech. Engrs., Symposium on Water Hammer, 1933.
† New Aspects of Maximum Pressure Rise in Closed Conduits, Am. Soc. Mech. Engrs., Annual Meeting, 1928.

In other studies it has been customary to use the value of ρ for the maximum conditions, and use a constant slope, and adjust the value of X or E accordingly. Great care must be exercised to use the correct values of these ratios, or serious errors will result.

In conclusion, the writer has compared the results of the graphical method with the solutions by the more usual means (Table I) and has found in every case that the check is exceedingly close. This is not surprising, for the basic formulae are the same and the solutions, therefore, should be the same. The graphical method deserves the careful study of every engineer concerned with water hammer problems, and while it is a longer method than the solution of the charts for uniformly retarded water columns in simple conduits, it is a great simplification for many of the more involved problems encountered in actual practice.

The activities of the Water Hammer Committee of the American Society of Mechanical Engineers are being continued as a semi-permanent committee under the Hydraulic Division of that Society. A second Symposium on Water Hammer is being planned for 1936, and special arrangements have been made whereby associate members have been designated from certain foreign countries to assist the A.S.M.E. in their programme, and it is hoped that The Engineering Institute of Canada will feel free to co-operate with this work so that two members of their Society can be designated as the associate members of the Committee for Canada.

E. B. Strowger[4]

Professor Angus has presented the graphical method of water hammer computation in a manner which makes it quite simple, and the numerous applications given add to the usefulness of the paper. He first develops the pressure wave curves for a simple pipe by referring to Joukovsky and to the "arithmetic integration" method of computing, published by N. R. Gibson, and then introduces the Allievi equations by considering the summation of the upward travelling direct waves and the downward travelling indirect

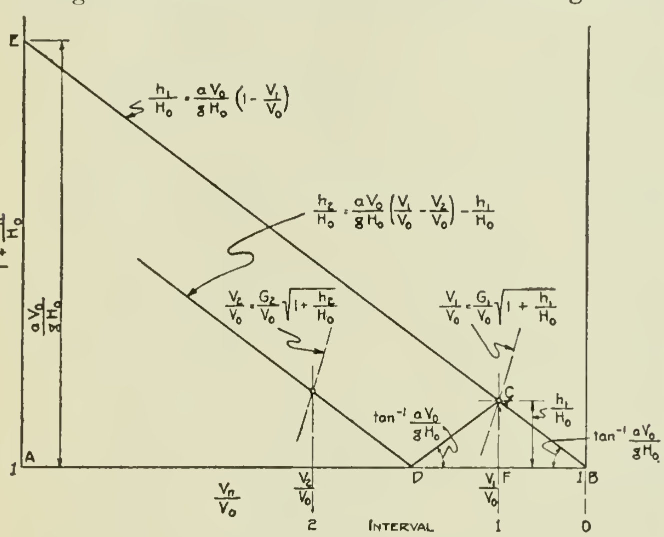

Fig. 15

waves. The method of simultaneous equations is then developed and the graphical method, of course, follows. This is a logical method of development and it is interesting to find that the arithmetic integration computations are used in developing the proper concepts of the problem. The speaker has taken exactly the same method in analyzing the five Allievi equations given in Mr. Halmos' abstract of the 1902 Allievi paper before finally deriving them by a rigorous method.*

[4] Buffalo, Niagara and Eastern Power Corporation, Buffalo, N.Y.

The writer wishes to call attention to some pioneering work done on the subject which may have been overlooked since it was not published as a complete paper in itself. In July 1926 F. M. Wood, of the Civil Engineering Department of McGill University, introduced a graphical method in his discussion of the A.S.M.E. paper† entitled "Speed Changes of Hydraulic Turbines for Sudden Changes of Load" written jointly by S. L. Kerr and the writer. Wood's method is based upon the Gibson equations for water hammer which have been shown to agree exactly

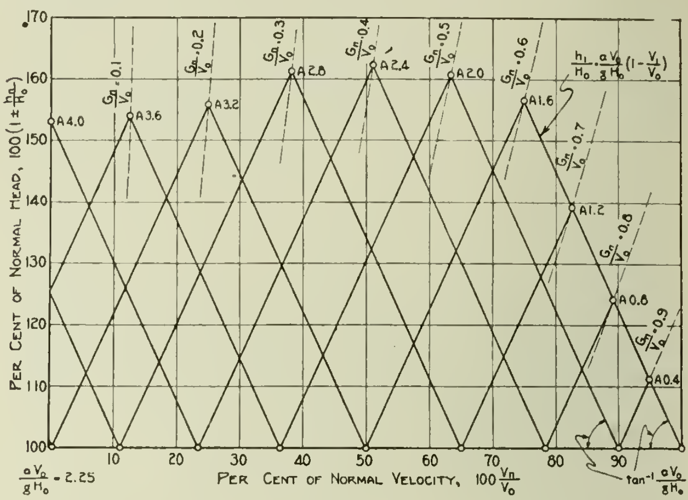

Fig. 16

with the Allievi equations. Basically Wood's graphical method is identical to that given in the Angus paper, as may be seen from the development of the Wood chart given later on. About the same time that Wood published his graphical method Mr. H. Kreitner‡ published in German an account of the graphical method based upon the Allievi equations. His work was described by Loewy in the latter's book on water hammer, to which Professor Angus refers, and was used by Professor Bergeron in his 1931 paper and by Professor Angus in the paper at hand. Both Wood and Kreitner were, to the writer's knowledge, the originators of the graphical method of solution and deserve mention.

Wood has taken the formulae of N. R. Gibson and arranged them to form for each interval two simultaneous equations which lend themselves to a graphical solution. These are for the first interval

$$\frac{v_1}{v_0} = \frac{G_1}{v_0}\sqrt{1 + \frac{h_1}{H_0}}$$

$$\frac{h_1}{H_0} = \frac{av_0}{gH_0}\left(1 - \frac{v_1}{v_0}\right)$$

for the second interval

$$\frac{v_2}{v_0} = \frac{G_2}{v_0}\sqrt{1 + \frac{h_2}{H_0}}$$

$$\frac{h_2}{H_0} = \frac{av_0}{gH_0}\left(\frac{v_1}{v_0} - \frac{v_2}{v_0}\right) - \frac{h_1}{H_0}$$

and for the nth interval

$$\frac{v_n}{v_0} = \frac{G_n}{v_0}\sqrt{1 + \frac{h_n}{H_0}} \quad \ldots\ldots (23)$$

$$\frac{h_n}{H_0} = \frac{av_0}{gH_0}\left(\frac{v_{n-1}}{v_0} - \frac{v_n}{v_0}\right) - \frac{h_{n-1}}{H_0} \quad \ldots\ldots (24)$$

* See discussion No. 5 A.S.M.E. Symposium on Water Hammer, page 133.

† Trans. A.S.M.E. Vol. 48, page 243.

‡ Druckschwankungen in Turbinenrohrleitungen, Die Wasserwirkschaft, 1926, No. 10.

where the symbols used correspond to those of Professor Angus. The first of the two simultaneous equations when plotted gives a family of parabolic curves and the second a family of straight lines. Referring to Fig. 15 the point C, the intersection of the first line with the first parabola gives the head and velocity values at the end of the first interval. A line drawn through C with a slope of $\frac{av_0}{gH_0}$ intersects the axis at D. A line drawn through D parallel to BC represents the straight line for the second interval, etc. It should be noted that the distance AE on the Y axis is equal to $\frac{av_0}{gH_0}$ or 2ρ, this being the Y intercept of the straight line equation for the first interval considering the origin of coordinates to be at A. The point D may be located, without drawing the line CD, by laying off FD equal to BF and then drawing the line through D parallel to CB.

The quantity G may be determined from the relation between gate opening and velocity for the particular device, such as the turbine, under consideration. This relationship is usually assumed to be a straight line but it may be based upon one of the characteristic curves of the turbine. Figure 16 gives the Wood chart for the example given by the author in his Fig. 6. Uniform variation of velocity with respect to gate opening is assumed. The result is seen to be identical to that given by the author

It should be noted that by substituting $(h_n + H_0)$ for H_n, equation (24) given above may readily be derived from

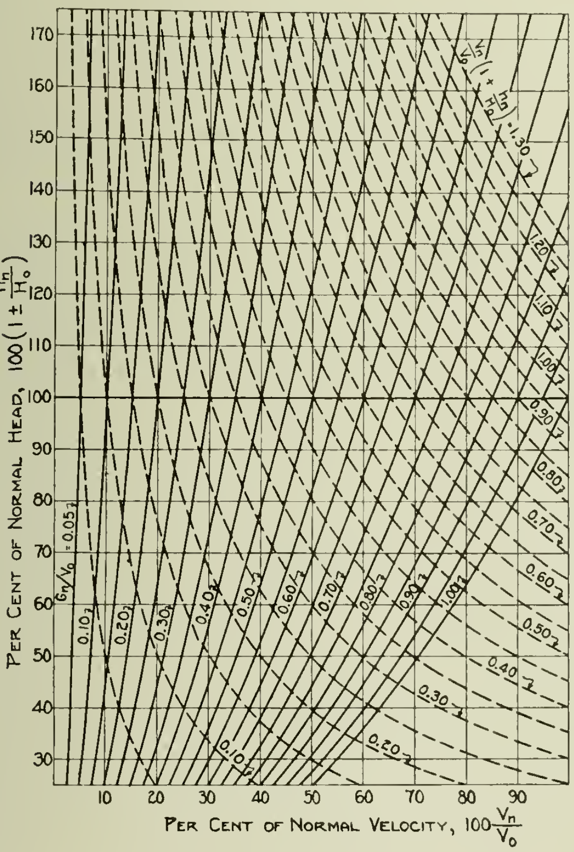

Fig. 17

equation 8 of the paper, showing that the chart given by Professor Angus is essentially the same as that given by Wood.

Figure 17 presents a general chart which the writer has used for facilitating the graphical determination of pressure rise or pressure drop problems in connection with the usual hydroelectric turbine installation. By drawing on the chart light lines with the proper slope and intersecting with the proper set of parabolas, interpolated if necessary between the ones given, the pressure curve can be obtained. This chart was made for general application and can be used with any gate discharge characteristic obtaining with a particular type of runner. The chart has been extended below the point of normal head to cover the field of pressure drop and curves for $\frac{v_n}{v_0}\left(1+\frac{h_n}{H_0}\right)$ have been included to facilitate speed rise computations. For this purpose the values of this product adjusted for part gate efficiency determine the horsepower input to the turbine at the end of each interval and thus when integrated over the time of gate closure give the energy producing excess speed in the rotating parts of the turbine and generator.

These charts for solving the water hammer problem involving the simple type of hydroelectric layout are shown here primarily for the purpose of calling attention to the origin of the graphical method. Professor Angus has succeeded in extending the application of the method beyond the simple case to many problems which, without the chart method, would be very intricate, and in so doing he has added considerably to the simplification of this subject.

F. M. Wood, A.M.E.I.C.[5]

This paper in its application of graphical methods to the study of pressure rise problems is of distinct value to the hydraulic engineer. The study of resonance conditions in particular, is greatly simplified, and evidently there are many other allied problems to which the method may be applied.

An article entitled "Speed Changes of Hydraulic Turbines for Sudden Change of Load" by Mr. E. B. Strowger and Mr. Logan Kerr, was presented before the American Society of Mechanical Engineers at their spring meeting in 1926. In a discussion of this paper the writer developed a similar graphical method for the solution of the pressure rise equation. The method was applied particularly to speed changes in hydraulic turbines, but the fundamental nature of the charts is the same in both cases. This agreement is necessarily due to the fact that both are the graphical equivalents of the same algebraic equations.

The accuracy of the graphical method is dependent on the correct position of the intersecting lines, and on the correct determination of points of intersection. In cases where the quantity ρ is large, great accuracy is not to be expected. This, however, should not deter one from the use of this method when one considers its simplicity, clarity and rapidity.

F. Knapp[6]

The author is to be commended for his effort to bring the graphical method of determining pressure rises to the attention of a greater circle of engineers. However, it would have been better if he had adopted the symbols for water hammer formulae recommended by the A.S.M.E. Committee on Water Hammer.

A reader without detailed knowledge of the surge theory would be inclined to consider Dr. Schnyder's approximate method of taking friction into account, as shown by Fig. 13, to be of the same degree of accuracy as the simultaneous or conjugated equations 13 and 16. This is not the case.

The method of taking friction into account as shown by Figs. 11 and 13 assumes that the friction losses are concentrated at the intake. A closer study of the Y-X diagram

[5] Assistant Professor of Civil Engineering and Applied Mechanics, Engineering Building, McGill University, Montreal.

[6] Assistant hydraulic engineer, The Sao Paulo Tramway Light and Power Company Ltd., Sao Paulo, Brazil.

indicates that this method over-estimates the influence of head losses. This view is confirmed by tests. More accurate results are obtained by assuming that only a certain percentage of the friction loss is concentrated at the intake. This percentage is not constant, but varies with time of closure and characteristics of the pipeline and so must be estimated in each case. A computer without actual experience and not guided by test results most likely will not make the correct assumption. Reliable results may be obtained independently of such assumptions, if the total friction loss is divided into parts and each part assumed as concentrated at several intermediate sections of the line. The necessary changes in the *Y-X* diagram are apparent and need not be discussed here. It may be mentioned, however, that the paper would have gained in clearness by emphasizing the "end-conditions," e.g., the pressure and velocity conditions at the two ends of a pipe section with constant characteristics. This notion of end conditions, together with combined sets of equations similar to equations 13 and 16, permits extending the graphical method to more complicated cases as, for example, bifurcated pipelines. The present status of the water hammer theory permits pressure rises in complicated water works distribution systems to be computed with but little effort. Actual practice has shown, that from the point of view of decreasing the magnitude of surges, and hence increasing safety of operation, the design of such systems may be improved.

The question of the influence of head losses as far as water hammer is concerned, might appear to be of academic interest only inasmuch as it scarcely needs to be considered for the computation of ordinary surges in turbine penstocks. But as soon as exceptional or emergency conditions are considered, neglect of this influence may lead to entirely incorrect results. In such cases, the question becomes of outstanding economical importance.

The author discusses the surge problem from the following point of view: "What is the maximum surge in a penstock of known characteristics caused by an assumed gate movement?" From the point of view of the designer, however, the important question is: "What should be the characteristics of a pipeline designed to resist an assumed accidental surge condition with minimum annual total charges?" The exact meaning of this question will become clear from the following.

In the paper "High Head Penstock Design" by A. W. K. Billings, O. H. Dodkin, F. Knapp and A. Santos Jr., a turbine penstock with diameters increasing towards the powerhouse was proposed. The characteristics of this design were such that at the changes of diameters the "transmission-coefficient" was equal to unity. Compared with a penstock tapered in the usual way, the suggested "inverse taper" design promised considerable savings. However, the comparison is incomplete to the extent that friction losses were neglected and also because the diameters and lengths of each section of the "orthodox taper" design adopted as a basis had been arbitrarily selected. Of course, the two designs had equal friction losses for the weighted average discharge and were also designed for exactly the same exceptional or emergency condition.

	Maximum pressure rise in the third positive interval in percent of Joukovsky's surge	Difference in percent
Neglecting friction	111	+19.7
Test result*	93	0
With 100 per cent of friction concentrated at intake	74	−19.1
Ditto with 50 per cent	85	− 7.9
Friction concentrated in five sections of penstock	93	0

* Courtesy of Mr. H. L. Doolittle, Chief Designing Engineer, Southern California Edison Power Co.

The preceding table of nearly instantaneous pressure rises for a two-diameter penstock, tapered in the usual way and in which the head loss amounts to only 0.45 per cent of the static head, shows the influence of friction in such an exceptional case.

Thus under certain conditions the maximum pressure rises in an orthodox taper penstock are not far greater, or may even be smaller than the absolute minimum Joukovsky surge.

For this reason the conditions which would cause minimum pressure rises under very quick closure were investigated, and it was found that equal reflection times and equal transmission coefficients were necessary requirements. The table below compares the maximum water hammer in an orthodox taper three-diameter penstock, having equal reflection times computed without taking friction losses into account.

Transmission Coefficient	Maximum surge in percent of Joukovsky's surge
1.0	100
0.98	144
0.96	162 (absolute maximum)
0.90	153
0.80	141
0.70	132
0.50	119
0.25	107
0	100

As already stated, friction losses reduce these maximum surges to a greater or lesser extent, depending on conditions. For example, with friction losses amounting to 2 per cent of the static head and with a transmission coefficient of 0.80, the maximum surge is equal to the Joukovsky value and the rise in the third positive interval attains only a value of 96, instead of 141 per cent without friction.

Thus, it is seen that instead of the inverse taper penstock with its several disadvantages, a pipeline with the usual taper and judiciously chosen characteristics, may be designed to resist more economically any accidental water hammer.

In this connection it is interesting to refer to the test results published in the paper already mentioned and which showed maximum surges of 172 per cent of the Joukovsky value†. The good agreement between test and computation obtained without taking into account the head losses is due to the fact that the tests were carried out on a full-size penstock, shutting off exceedingly small water quantities.

It is unlikely that modern and properly designed governors will be so carelessly adjusted as to hunt in such a way as to cause the gate movements shown in Fig. 10. Cases are known where, due to lack of maintenance, the linkage system of double governors with needle and deflector, had so much play as to cause hunting movements, which were, however, of far smaller magnitude than those shown in this figure.

Experience has shown that resonance between load variations and the natural pressure oscillations in the penstock may produce surges which are considerably greater than those caused by shutting off the unit. In the Spullersee high head plant of the Austrian Federal Railways resonant surge action was repeatedly observed which resulted in water hammer of about 300 per cent of that caused by closing the turbine normally. Gate movements as shown by Fig. 9 may be produced by hand operation but never by a governor under automatic control.

Some remarks as to the historical development of the method discussed by the author may be of interest. The basis of this graphical method was first developed by Mr. F. M. Wood of McGill University, Montreal, although he did not recognize the full importance and the pos-

† See Symposium on Water Hammer, page 58, figure 8.

sibility of extension of his method. In 1928, Dr. Loewy of Vienna, Austria, independently developed the same method, which is, however, only applicable for the computation of pressure rises at the gate. Loewy's proposal for computation of surges at intermediate sections of a simple penstock is erroneous. The first published account of the method as discussed by the author together with the important simultaneous equations appeared in 1932 by Dr. Schnyder of Klus, Switzerland, and is the basis for a general graphical method for computation of water hammer not only in simple, but also complex and compound conduits with end-conditions determined by reaction or Pelton turbines, pumps, reservoirs, surge tanks or valves at intermediate sections.

A. Santos, Jr.[7]

The author's paper consists of the presentation of part of the existing knowledge of water hammer. It does not add to our knowledge of the subject, as no new problems are solved and no new methods are introduced. Notwithstanding, it has commendable features, one of which is the clarity imparted by the several numerical examples.

Regarding Allievi's writings on the subject of water hammer, the author did not make it sufficiently clear that Halmos translated into English only "Allievi's Additional Notes," but not his original paper.

There is room for considerable divergence of opinion as to whether the Notes contain too much mathematics. Neglecting the abstract of Allievi's original paper, which precedes the Notes and which contains certain partial differential equations from hydrodynamics, the rest of the work involves only the use of algebra. Perhaps the reason why Allievi's writings are not much read by engineers is to be found in the fact that his conclusions, formulae and diagrams lack general applicability, inasmuch as they are all based on the assumptions of uniform diameter and thickness of the pipes. Most of them are also based on the further assumption of linear closure of the gates. These conditions hardly ever obtain in actual commercial installations.

With respect to the paper by Miss O. Simin, cited by the author, it is to be noted that "it involves no original research" on water hammer, and is "merely a compilation of existing information respecting this subject, including especially a digest of the notable work of Professor N. Joukovsky, at Moscow..."

From Fig. 5 of the author's paper it is not clear how to determine the starting point of the inclined lines representing equations (20) and (21). If friction is neglected these lines always start from the intersection of the horizontal line $Y = 1$ with the parabola representing the gate opening at the beginning of the disturbance or gate motion.

Of course the conditions assumed for the interesting example shown in Fig. 9 could never be observed in a hydraulic turbine installation under automatic governor control. In such a practical case the generating unit would be synchronized, with the valve at the "speed-no-load" position, before any further opening of the valve could take place. In commercial installations a valve can be made to go from the fully closed to the fully open position and then closed again entirely, only if this be deliberately done by hand.

The method shown in Fig. 11 for solving surge tank problems is instructive but lacks somewhat in accuracy, owing to the assumption of friction losses totally concentrated at the intake. Further, the smallness of the angles of intersection of the lines is not conducive to precision. Surge tank problems of this kind can be more expeditiously and more accurately solved by the diagrams given by Calame and Gaden in their book "Théorie des Chambres d'Equilibre."

[7] Assistant hydraulic engineer, The Sao Paulo Tramway Light and Power Company Ltd., Sao Paulo, Brazil.

J. B. Macphail, A.M.E.I.C.[8]

The author, in the second paragraph of his paper, is properly enthusiastic about the work of Allievi, but appears to be unfamiliar with an excellent historical account by Professor R. Neeser, of the University of Lausanne, which is sufficiently authoritative to warrant some correction of, and addition to, that paragraph.

In 1903 Allievi published a monograph, not a book, in Italian: and in 1904 he published a French translation of it in the Revue de Mécanique. A German translation was published by Dubs and Bataillard in 1909.

This monograph, as Allievi himself has said, was merely the mathematical tool and not the theory, but in 1913 he published in Italian his "Theory of Water Hammer, Notes I to V."

A French translation of Notes I and II, together with a summary of the original monograph and a preface containing a good historical account of the subject and an appreciation of the work of Allievi was presented by Neeser in the Revue de Mécanique in 1914, but publication of the subsequent notes was stopped by the war. In 1921 Daniel Gaden republished in French in Paris in book form this work of Neeser, adding thereto his own translation of Notes III, IV and V. The foregoing information comes from this French text. The English book prepared by Mr. Halmos in 1925 contains a translation of Notes I to V and a translation of Neeser's summary of the original monograph, together with a part only of the Neeser preface.

Quoting this preface, the oscillatory character of water hammer had been recognized long before then by M. J. Michaud in 1878, among others, as being due to the elasticity of the conduit and the compressibility of the water; but "all the authors who preceded Allievi believed this influence could be introduced in the calculations by supposing the elasticity of the walls and of the liquid to be concentrated, so to speak, at a determinate point of the conduit in the form of an elastic reservoir of suitable capacity." Accordingly Allievi "disregarding the paths broken by his predecessors...commenced by systematically and voluntarily ignoring all that had been done before." This seems to be a great deal more than having merely "simplified the work previously done" according to Professor Angus.

It is agreed that Joukovsky made extensive experiments in Moscow in 1898, but only in the limited field of valve closures which were practically instantaneous; and that he established the relation that the maximum pressure rise following such a closure is av_0/g, which incidentally is not quite equation (1).

Does not the author then do him too much honour in attributing to him the place of having "established the general theory and certain fundamental equations" of the complicated problem defined in the first paragraph of the paper?

Figure 1 shows a conduit having a portion of its length inclined, and a warning should be given that page X of the Halmos translation supposes the conduit to be horizontal. True, some of the equations can be applied to inclined pipes, but others, particularly those dealing with head-ratios, cannot.

The notation is not consistent. For example, the symbol H is defined as the head close to the gate, whereas in equations (6) and (7) it is correctly used for the head at a distance x from the gate, in a transcription of equations V on page IX of Halmos. In equation (8) however, which is a transcription of equations (6) on page 6 of Halmos, the symbol H_n must refer to the gate. Also the suffix A is defined as applying to the gate, whereas in Fig. 3 it applies to some other place. Again, in the development beginning

[8] Power Engineering Company Ltd., Montreal.

with equation (12) there are several cases where H_{At1} and similar symbols are used, whereas H_{At_1}, is actually meant. Also there are four different equations with the number (20), and several other cases of duplication. For clearness, equations (18) might perhaps have been given the numbers (17) because they come from equation (13). Equations (17) would then bear the numbers (18) because they come from equation (16), and they also refer to the reflected wave, Fig. 4b. The subscript t at first refers to the larger of two times and a little later to the lesser. A warning might be added, to the paragraph following equations (17) and (18), that the equations can not be used to get the waves past the section where the pipe characteristic changes, because certain wave reflections occur at this section.

These difficulties of notation are not very serious, but they obscure the argument in a difficult subject; and delay the reader because it usually takes a little time, first to decide that some notation is wrong and then to infer what the author meant to say.

However, once past these troubles, the method seems very attractive, particularly because of the speed with which it can be applied. A full understanding of the principles, and of the difficulties involved can be obtained only by working through a number of examples. Some question may be raised about the accuracy obtainable, but it can be answered by remarking that the method is probably better than the knowledge of the physical data requires. And at the worst it will be useful in indicating what maximum conditions should be examined in more detail.

Concerning the surge tank problem, something might properly have been done to show why equation (8) is applicable to circumstances so different from those for which it was derived. It will further be recalled that the customary differential equations for designing surge tanks give very satisfactory results, though their derivation involves assumptions from which can be derived a value of $a = \infty$. There is good reason for believing that the value

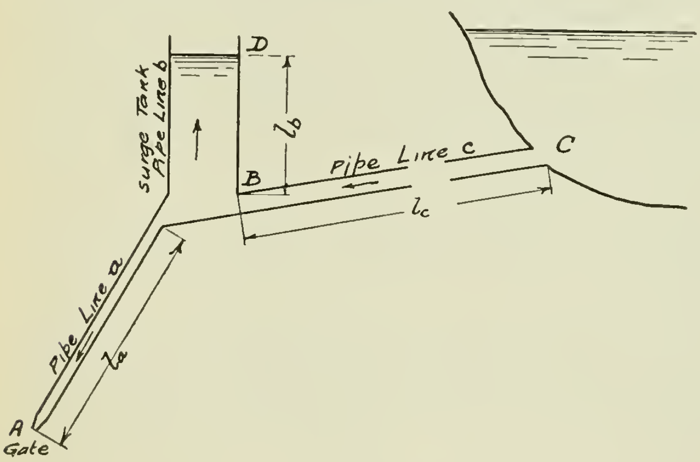

Fig. 18

of a should enter surge tank calculations, but the equations should be such that substitution of the value $a = \infty$ leads to determinate results which, in many cases, have been very satisfactorily confirmed by tests. The terms containing a would be expected to be of relatively small order, and neglecting them might be considered to involve the same errors as in those cases where second differentials are properly discarded. It would be interesting to test equation (8) with three different values of a in some simple case to see if there is some approach to a limit, and to compare that limit with the result given by Jakobsen's rapid method of arithmetic integration.

Dr. O. Schnyder[9]

Professor Angus has developed a graphical method for the determination of water hammer pressures in pipe lines and has demonstrated, by means of very interesting examples, the breadth of its application.

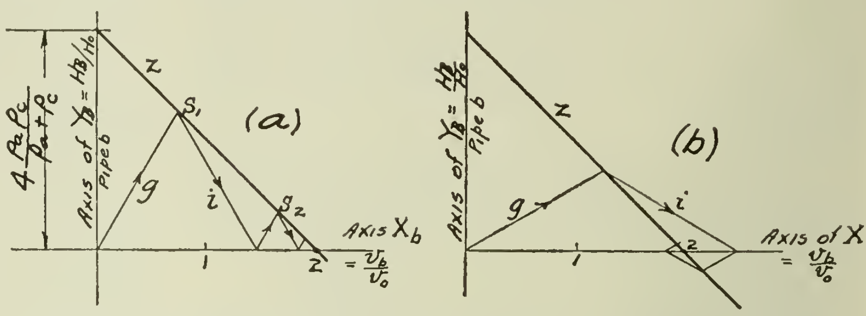

Fig. 19—Water Hammer at Surge Tank for Instantaneous Gate Closure.

The advantage of the graphical method lies in the fact that it is possible to establish, without much additional work, the pressure conditions at any point in a pipe line. Furthermore, this method gives full information as to the changes of velocity that occur. This is of great importance, and as one example the case of the closing devices on pipe lines may be mentioned. These devices are used to protect pipes which are endangered by an extremely large flow of water due to accidental failure of the pipe; they go into operation as soon as the pipe velocity exceeds that corresponding to maximum demand for power or other normal service. The pressure-velocity diagram shows when the velocity exceeds the normal value at the inlet end, due to sudden load demand, and the flow may be further augmented by the opening of the relief valves, caused by resonant movement of the turbine gates. The extent of this increase is important in the regulation of the above mentioned closing devices if they are not to produce bad conditions on the pipe and if the danger of an undesirable rate of closure is to be avoided.

Moreover, the knowledge of the dynamical variations of the velocity is desirable in the case of a pressure pipe line protected by a differential velocity device, i.e., by a mechanism which measures the mass of water at the inlet and outlet of the pipe line, and which effects the closure of the inlet gate if a certain difference exists.

The author has also given us an original presentation of the conditions in a surge tank, and for such a study the graphical method is an excellent one, and its possibilities of application are very large.

The writer wishes to enlarge further on this case and will limit his consideration to a surge tank of uniform area, as shown in Fig. 18, consideration being given to the conditions in the tank resulting from water hammer following quickly after the operation of the gate.

For the point B the following relations are true

$$Y_{Ba} = Y_{Bb} = Y_{Bc} = Y_B \quad \text{(25)}$$

$$X_{Bc} = X_{Ba} + X_{Bb} \quad \text{(26)}$$

again $$Y_{Bat} - Y_{At1} = 2\,\rho_a\,(X_{Bat} - X_{At1}) \quad \text{(27)}$$

and $$Y_{Bct} - Y_{Ct3} = -\,2\,\rho_c\,(X_{Bct} - X_{Ct3}) \quad \text{(28)}$$

adding (27) and (28) gives

$$Y_{Bt}\left(\frac{1}{2\,\rho_a} + \frac{1}{2\,\rho_c}\right) - \frac{Y_{At1}}{2\,\rho_a} - \frac{Y_{Ct3}}{2\,\rho_c} = -\,X_{Bbt} - X_{At1} + X_{Ct3} \quad \text{(29)}$$

[9] Société des Usines de Louis de Roll, Klus, Switzerland.

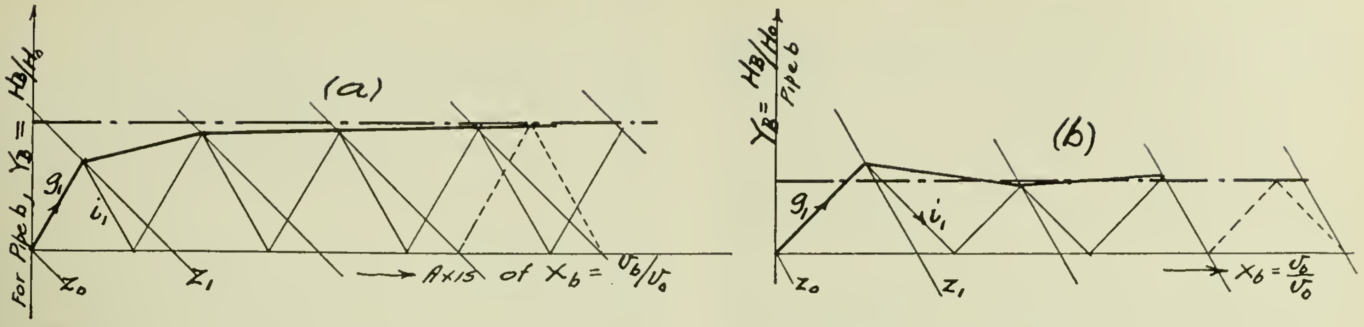

Fig. 20—Water Hammer at Surge Tank for Straight Line Gate Closure.

This equation gives a relation between Y_B and X_{Bb} since the values of Y_{At1}, Y_{Ct3}, X_{At1} and X_{Ct3} are known from other considerations.

The equation evidently represents the hydraulic condition for the surge tank at B and is therefore of fundamental importance for the study of events in the surge tank. On the graphical diagram, this equation is represented by a series of straight lines and the latter may easily be related to the water hammer lines corresponding to equations (27) and (28) by subtracting the values of X_{Ba} from X_{Bc} at the same value of the ordinate, as shown by equation (25)

$$X_{Bb} = X_{Bc} - X_{Ba}$$

Equation (29) represents a series of "limit lines" which are straight and parallel and spaced to suit the time interval, and their application to selected cases will now be made.

(1) *Sudden closure of the gate at A.* In this case,

if $t < \frac{3\,l_a}{a_a}$ the values are $X_{Ct3} = 1$; $Y_{Ct3} = 0$*

$$X_{At1} = 0 \quad \text{and} \quad Y_{At1} = 2\,\rho_a{}^*$$

so that (29) gives

$$Y_{Bt} = (2 - X_{Bbt})\left(\frac{2\,\rho_a\,\rho_c}{\rho_a + \rho_c}\right)^* \ldots\ldots\ldots (30)$$

this equation being represented on Fig. 19 by the straight line Z.

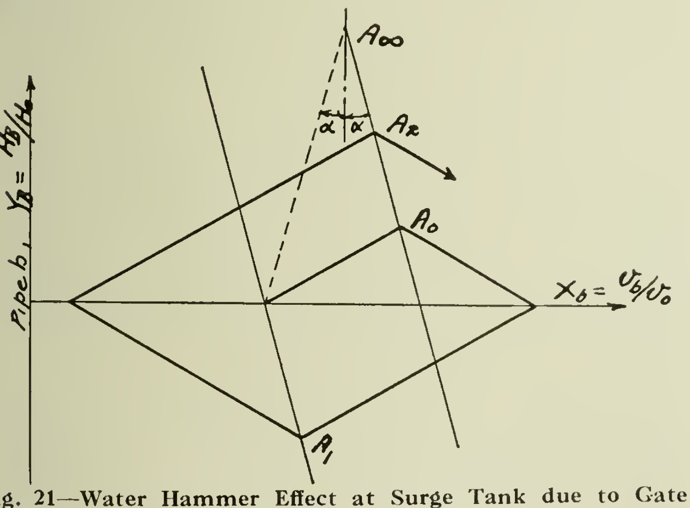

Fig. 21—Water Hammer Effect at Surge Tank due to Gate Swinging Continually, Each Swing Taking $\frac{2\,l_b}{a_b}$ sec.

The water hammer lines for the surge tank will have the equations

$$Y_{Bt} - Y_{Dt2} = 2\,\rho_b\,(X_{Bbt} - X_{Dt2}) \qquad \text{for (g)}$$

and

$$Y_{Dt} - Y_{Bt4} = -\,2\,\rho_b\,(X_{Dt} - X_{Bt4}) \qquad \text{for (i)}$$

At the time $t \leq \frac{l_a}{a_a}$ if no account is taken of the change of water level, $Y_D = 0$* and $X_{Dbt} = 0$ and this locates the first line g and the point S gives the water hammer at B in the tank. The impacts die away periodically or aperiodically, according to the value of

$$\frac{2\,\rho_a\,\rho_c}{\rho_a + \rho_c}$$

as shown in Fig. 19 (a) and (b).

(2) *Linear valve closure.* If gate closure is at uniform rate, often referred to as straight line closure, the results will be as shown on Fig. 20 (a) and (b). In this type of closure, and taking the time interval as $t = \frac{2\,l_b}{a_b}$ the "limit lines" Z are equally spaced, and as this spacing is easily determined, it will not be discussed further.

The relative slopes of the "limit lines" and water hammer lines determine whether the pressures are aperiodic as in Fig. 20 (a) or periodic as in Fig. 20 (b).

(3) *Rhythmic movements of the gate with a time of oscillation*

$$t = \frac{2\,l_b}{a_b}$$

This case is shown in Fig. 21, the lines Z_1 and Z_2 representing in alternate order the conditions at the base of the tank, and to these the water hammer lines have been drawn as shown. If the water hammer lines have a smaller slope than the "limit lines" the pressure oscillations will increase up to a certain value $A\infty$, but for the opposite case these oscillations die away.

The graphical method is applicable not only to pipe lines with surge tanks, but also for any branched piping system. Unfortunately, lack of space prevents the discussion of this matter.

M. Barry Watson, A.M.E.I.C.[10]

The author has stated that the variations of pressure could be found for any particular point on the pipe desired. Does the maximum pressure always occur at the gate, or might it be at some other point further up? If so, does this method lend itself to a determination of that point, so that the pipe designer may calculate the allowable thicknesses of pipe.

E. W. Dill, S.E.I.C.[11]

In view of the reference Mr. Kerr has made as to the variation in pressure changes due to thickness of pipe, would the author say whether the elasticity of the pipe material comes into this question at all? That is, if all steel or concrete.

Professor R. W. Angus, M.E.I.C.[12]

The nature of the discussion shows that the paper has dealt with a subject of live interest, and the author thanks all those who have presented constructive criticism.

---

*See author's closure—page 273.

[10] Consulting Engineer, Toronto, Ontario.
[11] British American Oil Refineries Limited, Toronto, Ont.
[12] Head of Department of Mechanical Engineering, University of Toronto, Toronto, Ont.

Most of the comments on the symbols used are very just; the author tried to use the A.S.M.E. symbols as far as possible, but in order to shorten the paper, he referred to a problem given in a text-book written in 1930, and thought it would simplify the matter to use the symbols there. He did, however, use Allievi's ρ in place of the K recommended, because the latter letter is so commonly used for such a variety of constants. It might have been better to have kept more closely to the A.S.M.E. recommendation.

The general statements of the paper are true for sloping and horizontal pipes, although the interpretation of the results should be made with care. The solution gives the ratios H/H_0 for the pressures where H is the total head, i.e. the sum of the elevation and the pressure head above a datum through the nozzle. The actual static pressure in the pipe at any point Z feet vertically above the gate is $H_0 - Z$ and the pressure there when water hammer occurs is $H - Z$.

Mr. McQueen suggests that the pump problem, Fig. 12, might be affected by cavitation and the presence of water vapour and air. No doubt water vapour and a little air do exist in the cavity on the reservoir side of the valve, and this would modify the water hammer, but the effect should be small because of the extremely low pressure of the vapour; cavitation could scarcely take place in any marked way.

The author agrees with Mr. Kerr in practically all of his discussion and commends him for the information brought out in his Table I. By repeatedly calling attention to the effects of closure from part gate, he is giving a warning as to pressure rises that might not have been expected. The N on Mr. Kerr's figures refers to the number of intervals of $2\,l/a$ sec. required for closure. Mr. Kerr's point as to the method of computing ρ is well taken, and his figures show, what the author omitted to say, that the pressure ratio at the gate for instantaneous closure is the value of H/H_0 where a sloping line at angle with tangent $-\,2\,\rho$ through A_0 (such as $A_0 A_{1.6}$ Fig. 6) intersects the axis of H/H_0.

In the discussions by Professor Wood, Mr. Strowger and Mr. Knapp, reference has been made to an article which was not known to the author till after he had actually read his paper. Undoubtedly, Professor Wood described the principle of intersecting parabolas and lines on which the paper is founded, but it can fairly be inferred that he did not realize the general application of the method, or he would have explained further uses of it in the nine years since his discussion first appeared. The author regrets, however, not having given Professor Wood credit for the work he did.

The broad application of Professor Wood's work, as described by Mr. Strowger, does not seem to be justified. Undoubtedly, equation (8) would fit certain parts of the author's paper, as Mr. Strowger has shown in Figs. 15 and 16, but in Fig. 16 the author's Fig. 6 has been redrawn and the notation of equation (8) applied to it. All of the writers consulted on the subject have developed the graphical construction from equations (6) and (7), and this is essential, because the use of equation (8) is limited to points at the ends of the pipe, whereas the others are not. The complete construction given in the paper could not have been developed from equation (8), but on the other hand, the author has shown how this equation fits such a case as the surge tank, Fig. 11, where the ends alone are considered; but equations (6) and (7) are very much simpler in this case also. The example, however, shows that both methods agree.

The author may perhaps be pardoned for quoting from a letter he received from Mr. Strowger: "I think you have made a distinct contribution to the engineering profession in giving such a complete analysis of so many special problems involving water hammer."

It may be remarked that Bergeron's solution, while giving the same results as in the paper, is slightly different to that used, and does not appear to be quite so easy to work out. Referring to Fig. 6, Bergeron omits all lines sloping parallel to $A_{1.6}\ C_{2.4}$; he finds the image of $A_{1.6}$ with reference to the axis of X and then draws $C_{2.4}\ A_{3.2}$ through this image, and so on.

The limitations of the constructions of Figs. 11 and 13 are ably described by Mr. Knapp, who is himself expert in the use of the construction described. The author appreciates the caution with reference to the correction for friction and agrees with it; he cannot, however, see that it makes any great difference in the problem of Fig. 11 as to the distribution of the friction, since only the ends of the pipe are being considered. His comments on Figs. 9 and 10 are correct, but the author never meant to suggest that a governor would give the results dealt with in these two cases. The paper was prepared to bring before English speaking engineers a graphical construction used abroad for water hammer, and to show how general it is by means of a wide variety of illustrations. As the cuts are naturally much reduced, conditions had to be assumed that would leave the illustrations clear, and that was done in these figures and in Fig. 12 as well.

The author also found that Loewy's construction was incorrect for intermediate points on a pipe, but is correct for end points.

Mr. Santos states that the author's paper does not add to our (meaning probably his own) knowledge of the subject, as no new problems are solved, and he reminds one of the sage who said that "there is nothing new under the sun." The author's "conclusion" makes his position clear, and Mr. Santos' remark would have been much emphasized if he had said where one could see these problems dealt with, as the author does not know. Further, in reply to Mr. Santos, the first sentence in the third paragraph of the paper expresses a statement made to the author many times by engineers who find Allievi's charts useful, in spite of their limitations, and the author points out that no difficulty of a mathematical kind does exist beyond the hydrodynamic equations. The arithmetical illustration was inserted to remove this difficulty.

With the limitations as to the effect of friction, Fig. 11 gives a very accurate and quick way of solving the surge tank problems. All intersections are made by lines very nearly at right angles, and the acute angles between the sloping lines do not determine such points. The author checked its accuracy with the arithmetic integration method and found it most satisfactory. One might criticize the fact that each step has to be made for $2\,l/a$ second intervals, whereas the time intervals for integration may, in some cases, be made very much longer.

The author knew the general historical facts mentioned by Mr. Macphail, and some of them are in the Halmos translation, but felt that he could not enlarge upon them as he wished, and therefore, wrote his own introduction and has no regrets regarding it. He has a great respect for the work of Allievi and of Joukovsky, and the evidence is that the modern water hammer theory is due to them. It looks like quibbling when one is criticized for calling a publication, the German translation of which occupies 155 printed pages, a book, even though Mr. Halmos calls it a paper and also a monograph. The translation by Mr. Halmos of Notes I to V occupies 132 printed pages and 45 full page cuts and also looks like a book.

Nothing is to be gained by answering Mr. Macphail's statement that the notation is not consistent. He has omitted parts of the author's definitions of certain terms, such as H, to prove his points, and some of his criticism is of little help to the engineer trying to understand the paper. Anyone wishing help from the paper would not waste his time trying to show that "some notation is wrong and then to infer what the author meant to say"; he would read what the author did say and would have no trouble. The author is still trying to find out what Mr. Macphail "meant to say" in his last paragraph. The notation is as perfect as the nature of the subject permits.

To Dr. O. Schnyder the author is again indebted and it is hoped that some time he will put all his solutions of problems together in printed form so that they will be readily available, because his ingenuity has enabled him to use the graphical construction for some very difficult cases. His discussion here, on the surge tank, provides a decided addition to the paper, as he has solved a much broader problem than the author did. The author only dealt with the conduit carrying water from the forebay to the surge tank and assumed the turbine to be very close to the tank, while Dr. Schnyder has taken into account also the effect of a long penstock from the tank to the turbine, and used an elegant solution simple in application. His exposition requires no further comment.

Dr. Schnyder appears to have made a mistake in equation (30). Where $t < \frac{3\, l_a}{a_a}$ the values of X are correctly stated but the values of Y should be $Y_{Ct3} = 1$ and $Y_{At1} = 1 + 2\ \rho_a$ and by substituting in equation (29) the left hand member of equation (30) should read $Y_{Bt} - 1$; although the right hand member of equation (30) and the construction of Fig. 19 are correct.

Also at the time $t \leqq \frac{l_a}{a_a}$ the value of Y_D should be unity and not zero.

Several persons have referred to the accuracy of the graphical solution, but there need be no anxiety on that score. The ordinary solutions are fully as accurate as arithmetic integrations made with a 10-inch slide rule, and greater accuracy may be obtained by enlarging the drawing and changing the relative scales till the intersecting angles are not much below 45 degrees. The author has found that mechanical schemes which enable the lines to be drawn parallel quickly are a great help, but these need not be mentioned.

In answer to a question raised by Mr. M. B. Watson, A.M.E.I.C., at the meeting, the author stated that the maximum pressure rise occurs at the gate, and the construction shows how to find the pressure rise at any point on the pipe. The author also replied to E. W. Dill, S.E.I.C., that the wave velocity a depends on the material of the pipe as well as on its diameter and thickness. A formula showing the relationship of the quantities is derived in the author's text, reference (3) of the paper.

VOLUME XVIII MAY 1935 No. 5

The Structure of the Engineering Profession

To-day one of the major difficulties in the successful operation of any engineering society or institution having to do with engineering education arises from the innumerable special branches into which engineering work is dividing itself. The resulting complexity is so bewildering that it is often hard to see the lines, if there are any, which divide the engineer from the physicist, the chemist or the mathematician on the one hand, and the technician, the industrialist or the business man on the other.

The profession or calling of the engineer is frequently looked upon as being essentially similar in structure to that of the architect, lawyer or medical man. The analogy, however, should not be carried too far, for none of these professions has both the highly developed system of specialization and the general limitation of the practitioner's work by commercial or economic considerations which exist in the case of engineering work.

An engineer's work must be based on his knowledge of fundamental scientific principles, but he must also take account of the information gained by experience in construction or manufacture, and his labours should ultimately lead to the production of something that can be beneficially operated or profitably sold. This requirement makes his work largely dependent on the exigencies of industrial life and enterprise, to an extent which does not exist in other professions.

Thus the profession of engineering is one which cannot be easily studied or classified, although such study is evidently necessary before any answer can be given to the question "what is the engineering profession?"

Addresses and papers such as those on the Status of The Engineer which appear elsewhere in this issue are evidence of the live interest which members of The Institute are taking in questions affecting the profession as a whole. These articles, however, deal with such topics as the engineer's concern with public affairs, the opportunities existing for him in industry, the consultant's relations with client and contractor, and the conditions of his employment in the public service. Studies of a somewhat different kind are necessary if a survey is to be made of the many technical branches which constitute the profession.

Classification, we are told, is the collection, under a common name, of a number of objects which are alike in one or more respects. When engineers are the "objects" considered, it is perhaps easier to find the respects in which they differ than the characteristics which they have in common. It is, therefore, not surprising that so little progress has been made in defining clearly the various classes under which professional engineers may be ranged, or even in deciding upon a satisfactory definition of what constitutes a professional engineer.

It seems evident that a general classification of engineering occupations must be made before those which are professional in character can be named, but on attempting such a task it is at once found that confusion arises between a man's professional title, the nature of his occupation and the designation of his official position, all of which are freely used in replies to enquiries as to a man's career. The question may arise, for example, as to whether an "assistant city engineer" is to be classed as a "highway engineer," or under what branch of engineering, if any, should we place a man who calls himself a filtration engineer, or a sound recording engineer.

Further, classification of some kind is necessary if engineers are to be licensed or registered, and at first sight the astonishing list of titles used by engineers or would-be engineers makes the task almost impossible.

Educational authorities have difficulty in framing their courses. They are confronted by such questions as, what is an acoustical engineer, what should he be able to do, and what course of training is desirable for him? Specialization has made headway even as regards the main divisions of engineering work, and some specialized sections which have arisen have attained almost to the dignity of the time-honoured civil, mechanical, electrical and mining branches of engineering. Educational programmes have become correspondingly complicated, particularly in the United States, where we are informed that in the state of New York alone, colleges and schools award over forty different degrees in engineering.

Mindful of all these difficulties, but driven by a scientific man's urge towards systematic classification, a well-known American authority on engineering education has recently made a gallant attempt to tackle this problem of engineering classification, which, indeed, is of primary interest in his field, where there is a continual conflict between the student's desire for early specialization and the claims of the broad fundamental subjects common to all branches of engineering.

In a paper* from which the title of this article is taken, Dr. Hoover gives the results of his studies of this subject. He took the modifying adjectives employed by 10,542 engineers listed in a well known biographical handbook, and found that they used 2,518 different titles in describing themselves. On analysis it appeared that these indicated 337 special branches of engineering. Some of the titles had reference to the users' general field of work, such as civil, electrical, metallurgical and the like, some indicated branches of technology, structures, materials, or products with which the specialist was concerned, as in the case of traffic engineer, ceramic engineer, or drying engineer, and a third category described the user's particular function, such as research, valuation, inspection, managing, sales, or distribution. It was found that nearly six hundred different significant words appeared in the titles studied.

The object of the investigation was to try to establish some standard scheme by which the recognized branches of the profession and the proper titles of engineers devoting

*The Structure of the Engineering Profession, Journal of Engineering Education, January, 1935.

themselves to specialized branches might be defined, and it was felt that, in the United States at least, a scheme of this kind might well be the task of a joint committee of the main national engineering societies.

In this connection Dr. Hoover suggests that all who are primarily engaged in work of an engineering nature, as distinguished from pure scientists and non-professional technicians, should use the word engineer as part of their professional titles; further, that all engineers should be asked to make a distinction between their professional title indicating their branch of engineering, and their present position indicating their place and rank in an organization. All professional titles should be based on two types of adjective: first, those indicating the field of work or zone of interest, and second, those indicating the function performed, as for example, electrical research engineer.

The paper gives lists of suggested adjectives respectively designating field of work, zone of interest, and function, by the use of which it is possible to make up more than ten thousand different combinations or descriptive titles whose meanings are clear.

So far, no systematic attempt at work of this kind has been made in Canada, although the matter is of undoubted importance both to the professional associations and to educational bodies. Further progress in the study of this difficult subject will be watched with interest.

A comprehensive and accurately descriptive list of recognized engineering titles would be of great assistance in connection with the licensing and registration of professional engineers. It seems remarkable that in Canada some of the Provincial Associations of Professional Engineers, as in the Province of Quebec, make no official distinction between the various branches of engineering, and in granting a license to practise do not state the particular line of work for which the holder is legally qualified. In contrast to this there are other associations, as in British Columbia, who recognize as many as seven main technical divisions of the profession, and have even begun to draw up schemes of functional classification for their members.

The matter is of interest in The Engineering Institute also, since our system of examinations for non-graduate applicants for corporate membership must provide for some degree of specialization. Actually, our examination programme recognizes civil, electrical, chemical, metallurgical, mining and structural engineering as main divisions, and this broad classification, with as many as four subdivisions in each case, has been found to work satisfactorily under present conditions. It remains to be seen whether we shall find it necessary to replace this comparatively simple list with a more complicated one based on some such study as that mentioned above. It seems doubtful, however, whether a further elaborate inquiry, along the lines suggested in Dr. Hoover's paper, would be of general advantage, but it would at least aid in showing the futility of some of the extraordinary titles assumed by persons who have no engineering training but who wish to take advantage of the public ignorance of the boundaries of legitimate engineering work.

Committee on Consolidation

The Committee appointed at the Annual Meeting of The Institute held in Toronto on February 7th, to develop the possibilities of the consolidation of the engineering profession in Canada, held its fourth meeting on Tuesday, April 16th, and reviewed the progress being made in organization in the various provinces for the discussion and compilation of data on the subject of Consolidation.

The Committee was of the opinion, from the information before it, that the engineering profession throughout Canada strongly approved the general principle of consolidation. It now becomes necessary to develop certain of the essential broad principles and to obtain the views of the various interested bodies as to the most acceptable procedure involved in such a reorganization. The consideration of these matters was unfinished when the Committee adjourned at 7.30 p.m.

The fifth meeting of the Committee was held in the University Club on the evening of Monday, April 22nd, and the general programme of the Committee was fully discussed and determined. It was decided to communicate with the various Branches and Provincial Committees in the near future, with reference to certain specific points involved in proposals for consolidation. The compilation of and report on the replies to this communication will be the Committee's next objective.

The Committee strongly urges Branches and Associations to meet as soon as possible for a discussion of this communication and the framing of a reply setting forth their views.

Meeting of Council

A meeting of the Council of The Institute was held at Headquarters on Tuesday, April 23rd, 1935, at eight o'clock p.m., with Vice-President P. L. Pratley, M.E.I.C., in the chair, and six other members of Council present.

The Council received resolutions regarding the consolidation movement from the following branches: Halifax, Cape Breton, Quebec and Niagara Peninsula. A report was also presented from a joint committee of the Association of Professional Engineers of Nova Scotia and The Engineering Institute branches in that province, and a report from a similar co-ordinating committee in Saskatchewan. Both favoured the principle of consolidation. Council also received a copy of the Bill amending the Engineering Act in Manitoba, which has recently been passed.

It was noted that the April 1935 number of The Engineering Journal, containing papers and discussions on the western water problem, had been widely distributed to Dominion and Provincial Ministers, Senators, Members of Parliament, newspapers, and other public men and organizations interested.

The following committees were appointed:—

Past-Presidents' Prize Committee:
R. W. Boyle, M.E.I.C., *Chairman*
A. R. Chambers, M.E.I.C.
W. P. Dobson, M.E.I.C.
A. Frigon, M.E.I.C.
S. G. Porter, M.E.I.C.

Gzowski Medal Committee:
R. S. L. Wilson, M.E.I.C., *Chairman*
F. W. Alexander, M.E.I.C.
J. B. deHart, M.E.I.C.
H. J. MacLeod, M.E.I.C.
A. S. Wootton, M.E.I.C.

Leonard Medal Committee:
L. L. Bolton, M.E.I.C., *Chairman*
A. O. Dufresne, M.E.I.C.
G. V. Douglas, A.M.E.I.C.
B. S. McKenzie, M.E.I.C.
G. G. Ommanney, M.E.I.C.

Board of Examiners and Education:
H. M. White, A.M.E.I.C., *Chairman*
E. P. Fetherstonhaugh, M.E.I.C.
J. N. Finlayson, M.E.I.C.
N. M. Hall, M.E.I.C.
J. W. Sanger, A.M.E.I.C.
W. Walkden, A.M.E.I.C.

An amendment to the Saskatchewan Branch by-laws was submitted by the Branch Executive committee and duly approved.

Discussion took place as to the desirability of The Institute suggesting names of prominent engineers for inclusion in the proposed Economic Council of Canada, and it was decided to take steps with this end in view.

President F. A. Gaby, M.E.I.C., was asked to represent The Institute at the Annual General Meeting of the Royal Society of Canada, to be held at McMaster University, Hamilton, on May 21st to 24th, 1935.

The financial statement to March 30th, 1935, was presented and approved.

Fifteen resignations were accepted, four reinstatements were effected, six members were replaced on the active list, one Life Membership was granted, and three members were placed on the Non-Active List.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:—

Elections		*Transfers*	
Members	4	Assoc. Member to Member	3
Assoc. Members	4	Junior to Assoc. Member	3
Junior	1	Student to Assoc. Member	2
Students admitted	39	Student to Junior	4

The Council rose at eleven thirty p.m.

OBITUARIES

Joseph Hunter, M.E.I.C.

Members of The Institute will learn with regret of the death at Victoria, B.C., on April 8th, 1935, of Joseph Hunter, M.E.I.C.

Mr. Hunter was born at Aberdeen, Scotland, on May 7th, 1842, and received his early education there, at Marischal College. After completing his apprenticeship with James F. Beattie, C.E., he was engaged in railway work, surveying, building, etc., and in 1864 went to British Columbia, his route being by way of the Panama canal. Following his arrival in Victoria Mr. Hunter started for the Cariboo goldfields and there worked for seven years as miner and surveyor, in 1872 joining the Canadian Pacific Railway surveys. In 1873 he took a pack train from the head of Howe Sound up Cheakamus river through to Lillooet river, and in 1874 examined the region between the wagon road and Blue river on the North Thompson. In 1875 Mr. Hunter located for the Dominion government the Island Railway from Nanaimo to Mill Bay, linking up with the section located from Victoria to the latter point. In 1876 he was in charge of Y division of the C.P.R. and surveyed a line from the head of Salmon river across the summit and down the Nechaco towards Fort George. In 1877 Mr. Hunter was selected from the engineering staff of the C.P.R. by the Dominion government to lay off a provincial boundary line on the Stikine river between the Dominion of Canada and the Territory of Alaska in accordance with the terms of the Convention between Russia and Great Britain in 1825. Copies of his plan and his report are to be found in the archives at Ottawa, at Washington and in Downing Street, being accepted by the respective governments interested. In 1883 Mr. Hunter joined the Esquimalt and Nanaimo Railway as chief engineer, and remained with the railway for twenty years, being at various times, vice-president and general superintendent. He surveyed the route and all the structures of the railway were built from his designs. He also designed and built the waterworks system for the town of Ladysmith. In 1898 he was given leave of absence to design and build a dam across the Quesnel river at the outlet of Quesnel lake, a piece of engineering work which Mr. Hunter used to describe as the most satisfactory in his whole career. In 1905 Mr. Hunter was appointed chief engineer of the Wellington Colliery Company and Canadian Collieries Dunsmuir Limited. Following his retirement Mr. Hunter retained his active interest in the welfare of the Island.

Mr. Hunter joined The Institute (then the Canadian Society of Civil Engineers) as a Member on March 11th, 1913, and on June 15th, 1934, was made a life member.

Frank Welcome McCrady, A.M.E.I.C.

Regret is expressed in placing on record the death at Vancouver, B.C., on March 13th, 1934, of Frank Welcome McCrady, A.M.E.I.C.

Mr. McCrady was born at Lyn, Ontario, on November 7th, 1856, and received his early education at the High School, Brockville, Ont. Later he studied mechanical engineering, draughting and architecture.

After a number of years of junior work in Ontario and with the Canadian Pacific Railway, Mr. McCrady went to New Westminster in 1886, and after a year, during which he was engaged on engineering and draughting, he worked on the steel swing bridge for the Esquimalt and Nanaimo Railway, Victoria, B.C. He was also in charge of gas plant improvements at Victoria, and on soundings of the Fraser river at New Westminster, B.C. In 1893 Mr. McCrady was superintendent and manager of the Victoria Electric Light and Railway Company at Victoria. Later on he turned his attention to mining, but in 1904 was head of a party on the demarcation of the Canadian-Alaska boundary. The years 1905 to 1907 were again devoted to mining. From 1907 to 1912 Mr. McCrady was engaged on consulting engineering, covering a variety of work, and later, after four years' of illness, he became draughting demonstrator at the University of British Columbia. From 1920 until 1925 he was assistant in mechanical engineering at the same university.

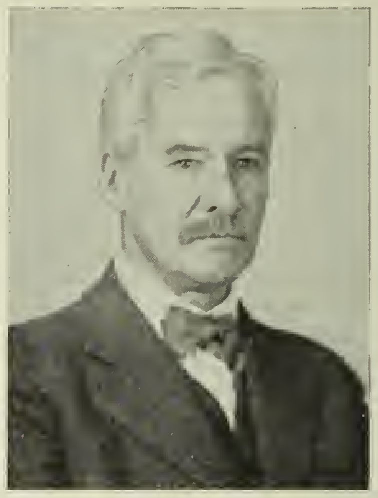
He was granted Life Membership in the Association of Professional Engineers of British Columbia.

Mr. McCrady joined The Institute (then the Canadian Society of Civil Engineers) as an Associate Member on February 17th, 1898, and on December 22nd, 1925, was made a Life Member.

Thomas W. Lesage, M.E.I.C.

Regret is expressed in recording the death at Montreal on April 7th, 1935, of one of our senior members, Thomas W. Lesage, M.E.I.C.

Born at Montreal on December 29th, 1861, Mr. Lesage entered the service of the city in 1887 as assistant engineer in the waterworks department. In 1890 he was



Thomas W. Lesage, M.E.I.C.

transferred to the department of roads, which at that time managed the sewers also, and on January 1st, 1901, was appointed assistant superintendent of waterworks. Ten years later, in 1911, Mr. Lesage became superintendent of the aqueduct, and held that office until 1921 when he resigned, but was retained as consulting engineer to the department until January 1st, 1933, when he retired.

Mr. Lesage was one of the original members of the Canadian Society of Civil Engineers, having joined as an Associate Member on January 20th, 1887, and became a Member on December 21st, 1899. He was made a Life Member of The Institute on February 4th, 1930.

Charles-Edouard Gauvin, A.M.E.I.C.

It is with regret that we place on record the death at Quebec on April 10th, 1935, of Charles-Edouard Gauvin, A.M.E.I.C., one of the early members of the Canadian Society of Civil Engineers.

Mr. Gauvin was born in Quebec in 1853, and received his early education at the Laval Normal School, and later served his pupilage with Messrs. Ferdinand Peachy, Forbes, and later, Charles Baillargé. In 1874 he was admitted to practice as a Provincial Land Surveyor, and from that time until 1878 was employed as surveyor and draughtsman in the Crown Lands Office, and also, for a time as draughtsman, in the Department of Public Works of Quebec, working on the plans of the new Parliament Buildings. In 1879 Mr. Gauvin was engaged by the Quebec Street Railway Company, on the building of an extension of their line, and in 1880 he was assistant engineer on one of the divisions of the Newfoundland Railway Survey. In 1881 Mr. Gauvin was appointed teacher of industrial and architectural drawing in the Quebec School of Arts. In 1881 and 1882 he was with the Quebec Central Railway, being in charge of a party, and also fulfilling, for a time, the duties of assistant chief engineer. In 1882 Mr. Gauvin became superintendent of surveys for the Department of Crown Lands for the province of Quebec. In the same year, in association with Senator J. P. B. Casgrain, he founded the Quebec Corporation of Land Surveyors. In 1888 the Hon. Pierre Garneau decided to construct metallic bridges in the province, and Prime Minister Honoré Mercier brought out a Belgian engineer, Mr. Maquet, who constructed with Mr. Gauvin, the Malbaie and Garneau bridges.

At the beginning of the century the Hon. S. N. Parent established the hydraulic service of the province, and Mr. Gauvin was appointed chief engineer of this service, and prepared a scheme for the first hydraulic department on the St. Lawrence at l'Ile du Diable. He made studies for similar schemes for Paugan falls on the Gatineau, for the Manicouagan river, and for the Outardes river.

In 1910 Mr. Gauvin left the provincial government service to become secretary of the National Battlefields Commission under Sir George Garneau.

Mr. Gauvin joined The Institute (then the Canadian Society of Civil Engineers) on January 20th, 1887, as an Associate Member.

Charles John Pigot, A.M.E.I.C.

Members of The Institute will learn with regret of the death of Charles John Pigot, A.M.E.I.C., at Quebec, Que., on March 12th, 1935.

Mr. Pigot was born at Rochester, England, on October 21st, 1854, and was educated at St. Michaels College, Tenbury. The early part of his life was spent coffee planting in Ceylon; coming to Canada in 1889 he was employed until 1894 as leveller and assistant engineer on the construction of the Quebec and Lake St. John Railway, and in the year 1894-1895 he filled the same position on construction and surveys for the Great Northern Railway. He was later resident engineer on the construction of the de Lotbiniere and Megantic Railroad, and subsequently was engaged on the building and operation of the Quebec street railway system and the Quebec, Montmorency and Charlevoix Railroad. In 1911 Mr. Pigot was appointed chief engineer of the Quebec Railway Light and Power Company, and at the time of his retirement two years ago he was consulting engineer for the Quebec Power Company.

Mr. Pigot was a member of The Institute of many years standing, having joined the Canadian Society of Civil Engineers as an Associate Member on March 11th, 1897.

PERSONALS

T. G. Tyrer, A.M.E.I.C., deputy chief surveyor, Surveys Branch, Land Titles Office, Regina, Sask., was recently elected president of the Saskatchewan Land Surveyors Association.

R. M. Herbison, A.M.E.I.C., is at present engaged as hydraulic engineer with Messrs. Glenfield and Kennedy, Limited, Kilmarnock, Scotland. Mr. Herbison was at one time mechanical designer and field engineer in the mechanical department of the Dominion Bridge Company, Lachine.

Eric G. Adams, Jr.E.I.C., has accepted a position as economist on the staff of the assistant to the president of the Canadian Pacific Railway Company, Montreal. Mr. Adams was formerly secretary of the Newsprint Export Manufacturers Association of Canada, at Montreal.

W. L. McFaul, M.E.I.C., city engineer and manager of waterworks of the city of Hamilton, Ontario, was elected chairman of the Canadian section of the American Water Works Association for the year 1935-1936, at the convention held recently in London, Ont.

Louis A. Amos, M.E.I.C., senior partner of the firm of L. A. and P. C. Amos, Montreal, immediate past president of the Province of Quebec Association of Architects, has been elected a Fellow of the Royal Institute of British Architects by that body in recognition of his active efforts in furthering the work and prestige of the Quebec Association during his 1934 term as president.

A. J. C. Paine, A.M.E.I.C., staff architect of the Sun Life Assurance Company of Canada, Montreal, who graduated from McGill University in 1910 with the degree of B.Arch., is the winner of the gymnasia buildings architectural competition sponsored by the Graduates' Society of the University, it has been announced. Mr. Paine has been awarded the first prize of One Thousand Dollars cash, and when the buildings are actually constructed, will be commissioned to carry out the work.

G. W. F. Johnston, A.M.E.I.C., has joined the staff of Watson Jack and Company Ltd., of Montreal, and will be in charge of this company's construction equipment division. Mr. Johnston will also be associated with the work of the Canadian Sheet Piling Company Ltd., a subsidiary of Watson Jack and Company. He graduated from the University of Toronto in 1915 with the degree of B.A.Sc., and since that time has been connected with the construction industry as designing engineer, erection superintendent and sales engineer, and brings a wide experience to his new position.

F. K. Beach, A.M.E.I.C., of the Department of Lands and Mines, Edmonton, Alta., is the present chairman of the Edmonton Branch of The Institute. Mr. Beach was at one time with the Dominion Water Power and Reclamation Service of the Department of the Interior, and in 1927 was transferred to the North West Territories and Yukon Branch of the same Department at Calgary. In 1931 he became attached to the Petroleum and Natural Gas Division, Department of the Interior, at Edmonton, Alta., and has just recently received his present appointment.

G. V. Roney, A.M.E.I.C., has taken over the duties of chief engineer of Farand and Delorme, Limited, Montreal. Mr. Roney, who graduated from Queen's University in 1926 with the degree of B.Sc. was until October of the same year, structural detailer with the Canadian Bridge Company Walkerville, Ont. From that time until May 1927 he was senior draughtsman with the Pennsylvania State Highway Department, and from May to October 1927 was structural detailer with the Pittsburgh-Des Moines Steel Company, at Pittsburgh, Pa. In 1928 Mr. Roney was with F. L. Heughes and Company, Rochester, N.Y., and later, until June 1929, was with the Chesapeake and Ohio Railway Company, Richmond, Va. He has subsequently with the Manitoba Bridge and Iron Works, as checker on structural details, and was transferred to the Dominion Bridge Company, Winnipeg, in the same capacity when these firms amalgamated. In 1934 Mr. Roney joined the staff of the McColl Frontenac Oil Company in Montreal.

Edward Winslow-Spragge, A.M.E.I.C., has been appointed general manager of the Canadian Ingersoll-Rand Company Limited, Montreal. Following graduation from McGill University in 1908, Mr. Winslow-Spragge was for a year with Robert W. Hunt and Company at Sault Ste. Marie and Fort William, Ont. He then joined the staff of the Canadian Ingersoll-Rand Company at Toronto, and shortly after that was transferred to northern Ontario in charge of the Cobalt office. In 1911 he was transferred to the Montreal office. During the war Mr. Winslow-Spragge was engaged on the development of munitions manufacture in Canada, and subsequently became chief inspector and manager of the munitions department of his company. Following the armistice, he was appointed general sales manager, and in 1925 he became assistant general manager. In 1934 he was made first vice-president of the company. Mr. Winslow-Spragge is a member of the Canadian Institute of Mining and Metallurgy.

A. P. Linton, M.E.I.C., has been elected chairman of the Saskatchewan Branch of The Institute for the year 1935-1936. Mr. Linton graduated from the University of Toronto in 1908 with the degree of B.A.Sc. and following graduation was draughtsman with the Dominion Bridge Company until 1911. In 1911-1912 he was with the St. Lawrence Bridge Company working on the design of the Quebec Bridge, and from that time until 1915 was chief bridge engineer with the Department of Highways of Saskatchewan. From 1915 until 1919 Mr. Linton was overseas, serving with the 1st Canadian Pioneers, 9th Battalion, Canadian Railway Troops, in France, and commanded the 1st Bridging Company, Canadian Railway Troops, in Palestine. He was promoted to the rank of Major, was mentioned in despatches, and received the O.B.E. His present rank is Lieutenant-Colonel. Returning to Canada in 1919, he was appointed chief bridge engineer with the Department of Highways, Saskatchewan, which position Lieut.-Colonel Linton has held up to the present time.

W. E. Bonn, M.E.I.C., has been elected chairman of the Toronto Branch of The Institute for the year 1935. Mr. Bonn graduated from the Glasgow and West of Scotland Technical College in 1911, and came to Canada in the same year, being employed until 1913 by the Canadian Northern Railway. In 1913-1914 he was with R. B. Herrin and Company, contractors, on the design of special plant for work on the Toronto harbour development. From 1914 until 1918 Mr. Bonn was assistant resident engineer with the Department of Public Works on the Toronto harbour development and in 1918-1920 he was with James Stewart Inc. (Agents) Emergency Corp., and with the Canadian Stewart Company. During the years 1920-1927 Mr. Bonn was in charge of dredging with the Toronto Harbour Commission, and in 1927-1929 he was chief engineer of Roger Miller and Sons. Since 1929 he has been engineer in charge of the Toronto district for the Canadian Dredging Company Limited. Mr. Bonn is very active in Institute affairs, and was chairman of the Entertainment and Hotel Committee in connection with the Annual Meeting which was held in Toronto in February of this year.

A. Mailhiot, M.E.I.C., professor of mining geology and metallurgy at the Ecole Polytechnique and at the University of Montreal, recently received the honorary degree of Docteur des Sciences Appliquees from the University of Montreal. Dr. Mailhiot has contributed greatly to the knowledge of Canadian geology and mineralogy, having been in charge of many important surveys in the Gaspe, Abitibi and Eastern Townships districts. He has published a number of scientific papers dealing with different phases in these fields, and has delivered numerous lectures before learned bodies throughout Canada. Dr. Mailhiot is a director of the Provincial Mines Laboratory, registrar of the Corporation of Professional Engineers of the Province of Quebec, in the founding of which he took an active part, and a former chairman of the executive of the Canadian Institute of Mining and Metallurgy. In 1910 he graduated from the Ecole Polytechnique and joined the teaching staff of that school as assistant professor of geology and mining. Fifteen years ago Dr. Mailhiot was appointed professor of geology and mineralogy on the faculty of science in the University of Montreal. He has carried on post-graduate work at the Ecole des Mines and at the Museum of Natural History in Paris, and also at the Sorbonne.

S. L. deCarteret, M.E.I.C., has been elected a director, and appointed general manager of the Brompton Pulp and Paper Company Limited. Mr. deCarteret has been associated with the paper industry for twenty-seven years, and for the past eighteen months has been in charge of the woodlands operations of the Brompton Company. He graduated from Yale University with the degree of Ph.B. in civil engineering in 1908, and following graduation he was with the Riordon Paper Company, being engaged on topographic and forest surveys and in charge of office work in connection with the same. In 1910 Mr. deCarteret joined the Brown Corporation, being in charge of the department in connection with topographic and forest surveys, and investigations of water supply and water storage for power purposes. Two years later, with the same company he was engaged on the design and construction of dams, piers, etc., on the Ste. Anne river, Portneuf county, and subsequently on the construction and operation of the loading plant and private sidings at St. Casimir; the operation of the company's private railway and electric plant, Upper St. Maurice river, and the design and construction of various works at Bersimis, Saguenay county. In 1923 he joined the Hammermill Paper Company, and was for some years in charge of the company's properties and operations in the province of Quebec.

ELECTIONS AND TRANSFERS

At the meeting of Council held on April 23rd, 1935, the following elections and transfers were effected:—

Members

CHENEVERT, Joseph Georges, B.A.Sc., C.E., (Ecole Polytechnique), consltg. engr., associate with Arthur Surveyer & Company, Montreal, Que.

EWART, Henry Edward, of 243 First Ave., supt., Royal Canadian Mint, Ottawa, Ont.

KERR, Samuel Logan, B.S., M.E., (Univ. of Penna.), research and test engr., I. P. Morris Divn., Baldwin Southwark Corpn., Philadelphia, Pa.

MEALS, Caspar Dull, (Drexel Institute), wire rope engr., B. Greening Wire Co. Ltd., Hamilton, Ont.

Associate Members

AVERY, Eric, (St. Johns Tech. Sch.), chief engr., Dominion Bridge Co. Ltd., Calgary, Alta.

GODSON, Reginald Gilbert, (R.M.C. and Sch. of Mil. Engrg., Chatham), struct'l. engr., 28 Summerhill Gardens, Toronto, Ont.

LAPLANTE, René, B.A.Sc., C.E., (Ecole Polytechnique), asst. engr., Shawinigan Water & Power Company, Montreal, Que.

WINDSOR, Maurice, M.B.E., (Univ. Coll., London, Eng.), Canadian manager, Armstrong Siddeley Motors Ltd., Ottawa, Ont.

Junior

HUGGINS, Mark William, M.A.Sc., (Univ. of Toronto), engr., E. P. Muntz Ltd., Dundas, Ont.

Transferred from the class of Associate Member to that of Member

HOOVER, Owen Hugo, B.A.Sc., (Univ. of Toronto), engr.-in-charge, Dominion Water Power & Hydrometric Bureau, Dept. of the Interior, Calgary, Alta.

MILNE, Winford Gladstone, (Univ. of Toronto), vice-president and gen. mgr., N. Slater Company, Hamilton, Ont.

PERRY, Philip Carleton, divn. engr., C.N.R., Regina, Sask.

Transferred from the class of Junior to that of Associate Member

BOWMAN, Ronald Fraser Patrick, B.Sc., (Univ. of Alta.), roadmaster, C.P.R., Lethbridge, Alta.

BREAKEY, James, (Assoc., Sheffield Univ.), editorial dept., technical publications, MacLean Publishing Co., Toronto, Ont.

RIDGERS, Arthur Courtney, (R.P.E., B.C., by exam.), designing dftsman., Cons. Mining & Smelting Co. Ltd., Trail, B.C.

Transferred from the class of Student to that of Associate Member

OGILVY, James Angus, B.Sc., (McGill Univ.), 3429 Peel St., Montreal, Que.

RONEY, Gerald Von Suven, B.Sc., (Queen's Univ.), chief engr., Farand & Delorme Ltd., Montreal, Que.

Transferred from the class of Student to that of Junior

BOWLES, William Shedden, B.Sc., (McGill Univ.), estimating, design, etc., Canadian Stebbins Engrg. & Mfg. Co. Ltd., Montreal, Que.

GREENWOOD, Frederick Dwyer, B.Sc., (Queen's Univ.), mech'l. staff, Hollinger Cons. Gold Mines Ltd., Timmins, Ont.

MacDONALD, Arden Morris, B.Sc., (N.S. Tech. Coll.), Londonderry Stn., N.S.

PAMENTER, Archibald Francis, B.Sc., (N.S. Tech. Coll.), lab. asst., Imperial Oil Co. Ltd., Dartmouth, N.S.

Students Admitted

AHEARN, William J., (Queen's Univ.), 538 MacLaren St., Ottawa, Ont.

BIESENTHAL, Clarence G., (Queen's Univ.), 362 Christie St., Pembroke, Ont.

BODWELL, Geoffrey Lionel, (R.M.C.), Royal Military College, Kingston, Ont.

BONNEY, Albert J., (Queen's Univ.), 711 Water St., Peterborough, Ont.

BRICAULT, Fernand, (Ecole Polytechnique), 4312 Delorimier Ave., Montreal, Que.

BROWN, Ernest F., (McGill Univ.), 7219 Alexandra Ave., Montreal, Que.

CARMICHAEL, James Irving, (Queen's Univ.), 134 Cameron St., Fort William, Ont.

CHRISTIAN, John Despard, (R.M.C.), Royal Military College, Kingston, Ont.

COOPER, William Everett, (McGill Univ.), 60 Hall St. E., Moose Jaw, Sask.

DAVIS, Abraham Derek, B.Sc., (Univ. of N.B.), 42 Spring St., Saint John, N.B.

DOUCET, Jean, (Ecole Polytechnique), 10841 Berthelet St., Montreal, Que.

DUMONT, Georges Heliodore, (Ecole Polytechnique), 5707 St. Dominique St., Montreal, Que.

GILDEA, William Frederick Peter, (McGill Univ.), 3647 University St., Montreal, Que.

GUNNING, Merle Percy, (McGill Univ.), 591 Notre Dame Ave. St. Lambert, Que.

HARE, William Lester, (Queen's Univ.), 673 Gilmour St., Ottawa, Ont.

HEBERT, Camille Raymond, (Ecole Polytechnique), 4079 St. Hubert St., Montreal, Que.

HERBERT, Albert Cecil, (Univ. of Alta.), Wilkie, Sask.

HOUGHTON, John Ruse, (McGill Univ.), 730 Upper Belmont Ave., Westmount, Que.

HOWE, Harold Bertram, (Queen's Univ.), West Shefford, Que.

JOHNSTON, William David, (Univ. of Toronto), 583 Vaughan Rd., Toronto, Ont.

LeBEL, Gérard, (Ecole Polytechnique), 3716 Adam St., Montreal, Que.

LEFORT, Jean, (McGill Univ.), 5577 Phillips Ave., Montreal, Que.

LEMIEUX, Gilbert, (Ecole Polytechnique), 195 St. Jean St., Quebec, Que.

MacKAY, Ian Norton, (McGill Univ.), 4375 Montrose Ave., Westmount, Que.

MARSHALL, Lawrence James, (Univ. of Man.), Ashern, Man.

MATHIESON, John Richard, (Univ. of Man.), 642 Walker Ave., Winnipeg, Man.

McKIBBIN, Kenneth Holdsworth, (R.M.C.), Royal Military College, Kingston, Ont.

OXLEY, William Morrow, (R.M.C.), Royal Military College, Kingston, Ont.

PASK, Arthur Henry, (Univ. of Man.), Zenata, Sask.

PATON, Charles Peter, (McGill Univ.), 53 Wolseley Ave., Montreal West, Que.

PETERS, James Horsfield, B.Sc. (Chem.), (Univ. of N.B.), (McGill Univ.), Rothesay, N.B.

RINTOUL, William Vance, (Queen's Univ.), Burk's Falls, Ont.

ROSS, Thomas W., (McGill Univ.), 495 Prince Arthur St., Montreal, Que.

SMITH, Arthur James Edwin, (Univ. of Toronto), 22 Madelaine Ave., Toronto, Ont.

STEVENS, Robert L., (Univ. of Alta.), 9827–85th Ave., Edmonton, Alta.

THOMPSON, Robert, (McGill Univ.), 157–17th Ave., Lachine, Que.

WESTON, Norman O., (Univ. of Alta.), 11038–87th Ave., Edmonton, Alta.

WILKINS, Ronald Edward, (R.M.C.), Royal Military College, Kingston, Ont.

WINN, James, (McGill Univ.), 8289 St. Dominique St., Montreal, Que.

Publications of Other Engineering Societies

From time to time announcements have appeared in The Engineering Journal regarding the exchange arrangements which exist between The Engineering Institute of Canada and the founder engineering societies of the United States, whereby members of The Institute may secure the publications of the American societies at special rates which in most instances are the same as charged to their own members. A list of these publications with the amounts charged is given below, and subscriptions may either be sent direct to New York or through Headquarters of The Institute.

	Rate to E.I.C. Members	*Rate to Non-Members*
American Society of Civil Engineers		
Proceedings, single copies	$ 0.50	$ 1.00
Per year	4.00*	8.00†
Civil Engineering, single copies	.50	.50
Per year	4.00	5.00
(Plus $.75 to cover Canadian postage.)		
Transactions, per year	6.00‡	12.00¶
Year Book	1.00	2.00
(Other publications 50 per cent reduction on catalogue price to E.I.C. members).		

* *If subscription is received before January 1st, otherwise $5.00.*

† *If subscription is received before January 1st, otherwise $10.00.*

‡ *If subscription is received before February 1st, otherwise $8.00.*

¶ *If subscription is received before February 1st, otherwise $16.00.*

	Rate to E.I.C. Members	*Rate to Non-Members*
American Institute of Electrical Engineers		
Electrical Engineering, single copies	$ 0.75	$ 1.50
Per year	6.00*	12.00*
(*Plus postage $1.00.)		
Transactions—annual, bound	6.00*	12.00*
(*Plus postage $1.00.)		
(The single copy price for Electrical Engineering includes postage charge.)		
The American Society of Mechanical Engineers		
Mechanical Engineering, single copies	$ 0.50	$ 0.60
Per year	4.00*	5.00
(*Additional Postage to Canada $.75, Outside United States and Canada, $1.50.)		
Transactions, bound, published annually, about May 15 (price of current volume)	10.00	15.00
(Other publications, same rate to E.I.C. members as to A.S.M.E. members.)		
Journal of Applied Mechanics—Quarterly publications.		
Dates of issue: March, June, Sept. Aug.	4.00	5.00
American Institute of Mining and Metallurgical Engineers		
Mining and Metallurgy, single copies	$ 0.50	$ 0.50
Per year	3.00*	3.00
(*Plus $1.00 for foreign postage.)		
Metals Technology, single copies	1.00	1.00
Per year	7.00*	7.00
(*Plus $.50 for foreign postage.)		
Transactions, per volume	5.00*	7.50
(*Plus $.60 for foreign postage.)		
Technical publications: Supplied at $.01 per page, with a minimum charge of $.25 for single copies, or at a subscription rate per year of	7.00*	7.00
(*Plus $1.00 for foreign postage.)		

RECENT ADDITIONS TO THE LIBRARY

Proceedings, Transactions, etc.

Institution of Civil Engineers:
Proceedings 1933-1934. Part 1, vol. 237.
Institution of Mechanical Engineers:
Proceedings 1934, vol. 127.
American Institute of Consulting Engineers Inc.:
Proceedings of annual meeting 1935.
The Society of Engineers Inc.: Transactions 1934.
Institution of Water Engineers: Transactions 1934, vol. 34.

Radio Engineering, by F. E. Terman. (*McGraw-Hill Book Company.*)
Whitaker's Almanack, 1935.
American Society of Heating and Ventilating Engineers Guide, 1935.

BOOK REVIEWS

Resistance of Materials

By Fred B. Seely, John Wiley and Sons, New York, 1935. 6 by 9¼ inches, 436 pages, diagrams, etc. $3.75. Cloth.

Reviewed by J. N. Finlayson, M.E.I.C.*

The first edition of this book appeared in 1925 and was speedily adopted as a text in many leading universities. The author is professor of theoretical and applied mechanics at the University of Illinois. This second edition contains twenty chapters and three appendices compared with sixteen chapters and five appendices in the former edition, while the number of pages has been reduced from 442 to 436. The book is divided into two parts: Part I, embracing Elementary Topics, and Part II, Special Topics. The principal changes noted in Part I are the addition of review questions throughout the text, making the total number of problems nearly twice that contained in the former edition; the inclusion of a brief discussion on welded joints in chapter 2, and the omitting of chapter 3 on elementary combined stresses, distributing this material to other parts of the book.

In Part II a chapter on limitation of the flexure formula for sections having only one axis of symmetry has been added. The treatment of reinforced concrete beams has been extended and removed from Appendix IV to a chapter of its own in the main part of the book. Chapters on unsymmetrical bending, curved flexural members, and flat plates have likewise been reconstructed from material which was contained in Appendix V of the former edition. New chapters containing material not mentioned in the 1925 edition on thick walled cylinders, and tortional resistance of bars having non-circular cross-sections are added, and the moment-area method of the treatment of beams has been placed in two chapters, one dealing with the deflection of statically determinate beams, the other with statically indeterminate beams. Two chapters on double integration methods are included as formerly in Part I.

Instructors who carry on courses in testing of materials in conjunction with strength of materials may regret that the chapter contained in the former edition dealing with methods of measuring, and significance of mechanical properties of structural materials has been deleted. It is only fair to add, however, that the author has successfully implemented his professed aim in preparing the second edition to give special emphasis to the engineering significance of the subject and not merely to emphasize the mathematical methods of analysis.

*Professor of Civil Engineering, University of Manitoba, Winnipeg, Man.

Introduction to Electric Transients

By E. B. Kurtz and G. F. Corcoran, John Wiley and Sons, New York, 1935. Cloth. 6 by 9¼ inches. 335 pages, plates, figs., diagrams, tables. $4.50.

Reviewed by William Spriggs, Jr.E.I.C.*

This book, which John Wiley and Sons have just issued, is intended, primarily, as a text book for class use. The authors state, in their preface, that a sincere attempt has been made to reach the student and to provide him with the background which is necessary for advanced study in this field. In the usual undergraduate courses, formulae and expressions are developed which are valid only during the periods in which the circuits and machines are in their so-called "steady states." However, the steady state solution of a circuit problem is only one part of the complete solution, because a certain lapse of time is required, before the electrical conditions can adjust themselves to their ultimate steady state mode of variation. It is this time interval that is known as the transient period.

The volume is divided into a section for direct current transients, a section for alternating current transients and a mathematical appendix covering Heaviside's operational calculus, particular differential and algebraic equations and tables of exponential and hyperbolic functions. The method of presentation employed is to consider each type of transient under three distinct headings: physical considerations, mathematical analysis and oscillographic verification. Exercises are provided at the end of every chapter.

A good working knowledge of the elementary calculus is an essential requisite for anyone who wishes to gain something of real value from the book and this knowledge must be expanded as progress is made. Considerable use is made of Heaviside's operational calculus, an operational solution being given alongside the conventional one.

The student's assimilation of the text is helped very materially by the wide use which has been made of actual oscillograms, both to illustrate the text and to provide material for examples and exercises. The clearness of the printing, the excellence of the diagrams and illustrations and the smooth progress from problem to problem, hold the attention and encourage the interest of the reader.

The question of "power" transients has been given a prominent part and the attention of any engineer desiring some general information on transients in circuits containing variable resistance and inductance (such as incandescent lamps, transformers, motors and alternators) is referred to Chapter X on "Variable Circuit Parameters."

The work gives a clear and systematic presentation of the various types of transient problems and can be recommended as an excellent basis for postgraduate study.

*The Shawinigan Engineering Company Limited, Montreal.

BULLETINS

Culverts.—A 4-page folder received gives particulars regarding Ideal corrugated culverts manufactured by the Quebec Culvert Corp. Ltd., St. Hyacinthe, Que.

Caterpillar Equipment.—The Caterpillar Tractor Company, Peoria, Ill., have issued a 32-page booklet describing the company's products, which include tractors, graders, maintenance machines, power units and industrial engines.

Tube Benders.—Bulletin No. 39, containing 8 pages, published by the Parker Appliance Company, Cleveland, Ohio, gives details of the production tube bender and its capabilities.

Pumps.—The Worthington Pump and Machinery Corp., Harrison, N.J., have issued a 4-page leaflet describing the self-priming Worthington centrifugal monobloc pumping units, with capacities of from 50 to 400 gallons per minute, and total head of 25 to 150 feet.

Carbon Monoxide.—A 20-page booklet issued by Mine Safety Appliances Company, Pittsburgh, Pa., stresses the menace of carbon monoxide in industry, and gives information regarding the habits and toxic effects of this poison, and also the equipment developed to detect its presence, protect the individual and resuscitate the victim. Copies of this booklet are available without charge from the company.

Instruments.—A 24-page catalogue received from the Minneapolis-Honeywell Regulator Company Ltd., Toronto, Ont., gives particulars of the company's range of products, including controls of various kinds, protection relays, valves, automatic pilots, motors, flow meters, tachometers, hydrometers, thermometers, pressure gauges, etc.

Speed Reducing Units.—The Dominion Engineering Company, Montreal, have issued a 24-page booklet containing data regarding the company's standard speed reducing gear units, including tables to assist in the selection of suitable units for any purpose.

Special Products.—An 8-page leaflet received illustrates the various products manufactured by the by-products steel division of the Lukens Steel Company, Coatesville, Pa., including such items as plates of 50,000 pounds, 25-inch thickness; fly wheels; base plates; locomotive fire boxes; engine frames; tank cars; fusion welded pressure vessels, etc.

Valves.—Bulletin No. 38, a 60-page publication issued by the Parker Appliance Company, Cleveland, Ohio, covers a typical variety of valves manufactured by the company, together with specifications covering straight globe, angle globe, cross globe, straight flow valves, drain cocks, etc.

Alarm Equipment.—Edwards and Company of Canada Ltd., Montreal, have issued a 16-page booklet containing specifications and price list of the company's alarm bells and buzzers of various kinds, musical chimes, industrial horns and sirens, signalling transformers, fire and emergency stations, etc.

BRANCH NEWS

Border Cities Branch

C. F. Davison, A.M.E.I.C., Secretary-Treasurer.
F. J. Ryder, S.E.I.C., Branch News Editor.

The Wind Sail as Applied to Yachts

At the January meeting of the Branch several of the committee reports were read. Mr. Davison read the financial report; B. Candlish, A.M.E.I.C., spoke for the papers committee, and T. H. Jenkins, A.M.E.I.C., submitted the report for the membership committee.

The guest for the evening, Dr. W. F. Gerhardt, was introduced by Mr. Candlish. Dr. Gerhardt, with Mr. Locke as his assistant, is in charge of the Department of Aeronautics at Wayne University. The subject presented was "The Wind Sail as Applied to Yachts." Dr. Gerhardt gave a short synopsis of sailing from the time our ancestors straddled a log and held a branch aloft going wherever the wind took them, to the present day of international yachting and close sailing into the wind.

There have been several types of air-foils or power sails. The passing wind-mill, the various types of rails used as driving power for boats and Dr. Flintner's rotating cylinder are well known.

The important problems in sailing these days are: (1) the danger and difficulties of the swinging boom; (2) the instability of the vessel; (3) the drag of the hull in the water.

The method of overcoming the first difficulty was to do away with the boom and use the airplane wing in a vertical position as a sail, the ribs of the wing being convex on both sides and the sail (taking the place of the fabric on an airplane wing) covering the wing loosely. In this manner the sail automatically takes a streamline form in which way the wind is striking the sail. The ribs of the wing are attached firmly to the mast. Bearings at the foot of the mast allow the sail to swing when the course of the vessel is changed.

A good deal of experimenting has been attempted in keeping the boat level, the main one being the use of double hull vessels.

In attempting to overcome the drag on the hull, the speaker resorted to hydro-foils to raise the hull out of the water, thus decreasing its resistance.

A hearty vote of thanks was moved by T. Jenkins and extended to Dr. Gerhardt and Mr. Locke by H. J. Coulter, A.M.E.I.C.

Calgary Branch

John Dow, M.E.I.C., Secretary-Treasurer.
H. W. Tooker, A.M.E.I.C., Branch News Editor.

Joint Dinner

To further the establishment of closer relationship between the various branches of engineering in Canada, a joint dinner was held by the Calgary Branch of The Institute, the Association of Professional Engineers of Alberta, and the Canadian Institute of Mining and Metallurgy in the Renfrew club on Saturday evening, February 16th. Approximately eighty were present, and the dinner was presided over by P. Turner Bone, M.E.I.C.

The advantages to be derived by such a gathering of the three associations were stressed by G. P. F. Boese, A.M.E.I.C., chairman of the Calgary Branch.

J. B. de Hart, M.E.I.C., of Lethbridge, representing the Professional Engineers, spoke on the proposed amalgamation of the three associations, and contributed various suggestions as to how this might be accomplished. J. M. Stevenson of Calgary contrasted the methods of engineering advertising with those of other industries and businesses. Dr. J. O. G. Sanderson of Calgary brought the greetings of the Mining and Metallurgical Institute.

Community singing led by W. B. Trotter, A.M.E.I.C., and G. H. Patrick, A.M.E.I.C., was the feature of the evening, and the gathering was also entertained by Ted Forsey's orchestra.

Two motion pictures comprising seven reels in all, entitled "Empires of Steel," showing the construction of the Empire State Building in New York, and "Span Supreme," showing the erection of the George Washington bridge, which spans the Hudson river from 177th to 178th Street, New York (known as Fort Washington), to Pallisades on the New Jersey side (known as Fort Lee), were the features of the programme of the last general meeting of the season of the Calgary Branch, on Thursday, February 28th, 1935, at which well over a hundred members and their friends were present.

By the kindness of the Otis-Fensom Elevator Company, through their local representative Mr. W. W. Pratt, the Branch was privileged to witness these films. Mr. Pratt also gave a short address pointing out the salient features.

This meeting was also chosen for the presenting of the prize to I. Abramson, Jr.E.I.C., the winner of the competition for the younger members. F. N. Rhodes, A.M.E.I.C., one of the adjudicators, made a few remarks on the rules governing the competition.

A hearty vote of thanks was given to Mr. Pratt by the chairman, and G. P. F. Boese, A.M.E.I.C., congratulated Mr. Abramson on his winning the prize.

By the kindness of the ladies, refreshments were served following two violin solos given by Miss Mary Makar, assisted at the piano by Mrs. G. P. F. Boese.

The meeting adjourned at 11 o'clock p.m.

Annual Meeting

The annual meeting of the Calgary Branch of The Institute was held in the Lougheed Building on March 9th, 1935, and took the form of a luncheon meeting at which some twenty-two members were present. Community singing led by G. H. Patrick, A.M.E.I.C., was indulged in.

Following the lunch, S. G. Porter, M.E.I.C., addressed the meeting on phases of the annual meeting held in Toronto, February 7th, 8th and 9th, 1935, stressing chiefly the drought situation in the prairie provinces on which papers were presented. He also gave a short outline of the discussion on the consolidation of engineering organizations throughout Canada, stating that a committee had been appointed with Mr. G. McL. Pitts, A.M.E.I.C., as chairman to report on the subject. To enable the committee to keep in touch with Branch affairs, a branch correspondent, R. S. Trowsdale, A.M.E.I.C., was appointed.

Following Mr. Porter's address, Colonel F. M. Steel, M.E.I.C., Councillor for the Branch, reported on a visit made to Headquarters and congratulated the chairman, G. P. F. Boese, A.M.E.I.C., on the attendance at the Branch meetings. He suggested that contact be maintained with the non-active members to make it as easy as possible for them to return to active membership when they are in a position to do so.

Mr. Porter, on behalf of the members, presented Mr. Dow with a travelling bag in appreciation of his so efficiently performing the duties of secretary-treasurer during his two years of office. In reply Mr. Dow took the opportunity of thanking the members of the Executive for their co-operation, which to a great degree lightened his work.

Reports were read by the convenors of the various committees, which reflected gratifying results, especially the secretary-treasurer's; this showed transactions to the amount of $284.72 and assets totalling $1,030.31 with no liabilities.

On a motion proposed by P. Turner Bone, M.E.I.C., and seconded by G. H. Patrick all reports were adopted.

The result of the ballot in the election of officers was reported by the scrutineers.

Prior to John Haddin, M.E.I.C., the new chairman, taking the chair, Mr. Boese thanked the committees and the Executive for their co-operation, especially the Programme committee. Mr. Boese said that the welfare of the Branch had been well advanced by the timely visit of President F. P. Shearwood, M.E.I.C.

F. N. Rhodes, A.M.E.I.C., suggested a joint meeting with similar organizations in the United States, preferably in Montana or other states near the border. This suggestion was referred to the incoming Executive.

The meeting adjourned at 3.45 o'clock p.m.

Hamilton Branch

A. Love, M.E.I.C., Secretary-Treasurer.
A. B. Dove, Jr.E.I.C., Branch News Editor.

Members of the Branch and guests to the number of four hundred and fifty gathered in the auditorium of the Hamilton Technical Institute on the evening of Tuesday, March 12th, 1935, to hear Mr. D. A. Boyd of the Dominion Bridge Company, Montreal, speak on "Arc Welding."

Mr. Boyd has already addressed several Branches of The Institute and his fame had preceded him to Hamilton, hence the large audience, for in this district the steel industry is of the greatest importance.

The chairman of the Branch, W. Hollingworth, M.E.I.C., occupied the chair and welcomed the visitors who came from outlying points such as Galt, Brantford, Dundas and Grimsby as well as the city of Hamilton. Mr. Boyd was introduced and gave a most instructive talk, in a masterly way showing that he was thoroughly familiar with the subject and was well able to set it out clearly to the audience.

At the close of the address a number of questions were asked and answered. Interesting test pieces and models were also shown and explained. Mr. Paulin proposed a vote of thanks to Mr. Boyd and this was enthusiastically endorsed by the members and friends present.

The following paragraphs give the substance of the lecture delivered by Mr. Boyd who, in addition to being an expert on welding, is also a remarkably able speaker.

Arc Welding

The great heat of the electric arc process was first determined by a Frenchman in 1880. Two years later a Russian developed the first carbon arc process.

The intense heat developed is in the neighbourhood of 5-6,000 degrees C., where under 20-30 volts, and under the influence of heat, air between the electrode and the steel is ionized assisting a flow of current across an apparent void. Without the ionization of the air, the arc would not be continuous and welding would be impossible. Under the influence of this intense heat, both the parent metal and the electrode becomes fluid and the molten electrode is drawn to the article to be welded by virtue of the latter's positive polarity. Without the fluidity of the metal to be welded the electrodes metal would freeze in globules on its surface. Thus the electrode particles actually become a part of the metal to be welded. In this consideration the speaker compared bare and coated electrodes.

Investigation of many weld failures led Mr. Boyd to the conclusion that weld design and not welding practice was responsible for practically all weld failures. Properly designed joints, Mr. Boyd said, were almost 100 per cent efficient. The weld metal should be as close as possible in analysis to the stock to be welded. Over 0.25 per cent carbon, serious difficulty is encountered in arc welding.

Mr. Boyd completed his lecture by showing a great many slides which were indicative of the types of work handled by electric welders. These served to demonstrate the tremendous advances in modern welding and many showed interesting stress distributions in welded joints.

Highlights of European Nights

The annual joint meeting of the Toronto Branch A.I.E.E. and the Hamilton Branch E.I.C. was held in the Westinghouse Auditorium on Friday, April 12th, 1935, when Mr. S. G. Hibben, Director of Applied Lighting of the Westinghouse Lamp Manufacturing Company of Bloomfield, N.J., addressed the meeting on the subject of "Highlights of European Nights." The attendance was two hundred.

Mr. Hibben carried the assembly on a travelogue from New York to the British Isles, and Central Europe with a lecture profusely illustrated with photographs showing various types of lighting—both domestic and public. Such structures of international interest as Big Ben, the Arc de Triomphe, the Rhine castles and Notre Dame were shown in their nocturnal beauty even more pronounced than in daytime. Mr. Hibben went on to show various indirect and direct lighting systems of homes, stores and streets of Europe. In Germany and Holland, highway lighting was of a much more superior type than in Canada. Sodium tube lighting makes travel highways and rural districts safe for high speed, while mercury arc high voltage equipment is particularly applicable to civic lighting.

Light may be produced from three common sources: Chemical, low efficiency methods; high voltage methods; and low voltage ionization processes.

In connection with the first method, the speaker demonstrated that light of short life could be produced by mixing in water a hydrozine with potassium ferrocyanide to produce a "cold" light. Even ice has little effect upon this light, and constant stirring will prolong the life of the light. This method is of little practical use at present, but may be utilized in the future.

The speaker then demonstrated by screen projection the types of failures met in normal incandescent lamps under accelerated conditions. Water vapour—the least trace—caused blackening and possible fire hazard by arcing. Air in the bulb caused blackened condition and rapid deterioration of the filament; the use of a metal like molybdenum was shown to be unsatisfactory due to filament warpage and low life. Poor tungsten, too, failed when tested, by warping and breaking prematurely. All these types of failures brought home to the listeners the fact that incandescent lamp design and control was no easy matter.

In explaining the action of metallic arc principles, the speaker illustrated by sketches of the accepted electronic structure of the elements. When bombarded with electrons, some of the electrons which normally rotated about the nucleiic proton were disturbed from their regular paths by actual collision with the current's electrons and in returning again to their natural paths, the elements' electrons emitted a spark. This gives rise to light. Mr. Hibben then demonstrated the features of various arc type bulbs—the mercury arc, sodium, and the amalgam (cadmium, zinc, etc.,) tubes were actually shown in operation. Their uses were limited due to their lighting characteristics; the sodium light was intensely yellow and turned red, and other dark colours, to black, and lighter shades to a white or grey; the mercury light gave a peculiar greenish tint, while the amalgam light gave a pinkish hue. The latter type is a new development with, as yet, few uses, but the other types are greatly used, especially on the continent. Sodium light is objectionable due to its tendency to show colours as black and white alone, and for this reason is used only in rural lighting, for highways, etc., while the mercury arc vapour lamp is more applicable to downtown sections where foliage and colouring generally is to be preserved.

Mr. Hibben closed by describing some of the operating characteristics of the various types, and was accorded a hearty vote of thanks by the assembly. The interest of the meeting was manifested by the nature of the questions asked when the meeting was thrown open for discussion. The meeting was adjourned after a vote of thanks to Mr. Hibben and officials of the Canadian Westinghouse Company, and refreshment furnished by the latter was thoroughly enjoyed.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

Consolidation

On March 14th, 1935, R. F. Legget, A.M.E.I.C., secretary of the Committee on Consolidation, visited Moncton and was entertained at luncheon by the Executive of the Branch. Mr. Legget spoke briefly on the proposed co-ordination. During the discussion that followed, the opinion was expressed that in New Brunswick no great need for amalgamation had been felt. The Institute branches and the Professional Association were performing their respective educational and legal functions satisfactorily, and furthermore the fees of the Professional Association were very low. At the same time, for the good of The Institute as a whole, Moncton Branch was ready to co-operate with the Committee. The Executive were pleased to learn that it was not proposed to eliminate the branches. Loyalty of the individual member to his branch, in their opinion, was responsible for holding The Institute together during the depression years.

Nickel and Its Uses

"Nickel and Its Uses" was the subject of a very interesting address delivered before the Branch on April 1st by T. H. Dickson, B.Sc., A.M.E.I.C. H. B. Titus, A.M.E.I.C., vice-chairman of the Branch, presided.

Although known to the ancients, it is only within the last fifty years that the metallurgical importance of nickel has been realized. When combined with other metals, notably iron and steel, alloys of great strength and toughness are produced.

Notwithstanding nickel is found in eight other countries, Canada supplies 90 per cent of the world's requirements. This is made possible because of low production costs and a stabilized price.

A vote of thanks to Mr. Dickson was moved by G. E. Smith, A.M.E.I.C., seconded by E. R. Evans, M.E.I.C.

Three motion pictures were then shown. The first, "Power," showed construction and operation of the C.N.R. giant locomotives. "Making Money," the second film, showed the various coinage processes at the Royal Mint at Ottawa. "Forest Fighters of the Skies" was the final picture. The standard motion picture projector recently purchased by the Branch, was used on this occasion and the chairman extended the thanks of the members to H. J. Crudge, A.M.E.I.C., for giving the Branch the benefit of his experience in selecting and negotiating the purchase of the motion picture equipment.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

Junior Section

On March 25th, 1935, two papers were presented before the Section, one by C. R. Whittemore, A.M.E.I.C., metallurgist with the Dominion Bridge Company, Lachine, on "The Metallurgy of Metallic Arc Welding," and one by Gordon Cape, who is also with the Dominion Bridge Company, on "Welding Procedure."

C. J. Pimenoff, S.E.I.C., acted as chairman.

Water Purification

W. S. Lea, M.E.I.C., consulting engineer, of Montreal, on April 4th, 1935, gave a most interesting talk on the history, recent developments and special processes used in water purification.

Professor R. E. Jamieson, M.E.I.C., was in the chair.

Basic Principles in Making Durable Concrete

The above was the subject of an address given by E. Viens, M.E.I.C., director of Testing Laboratories, Department of Public Works, Ottawa, on March 28th, 1935. He defined Portland cement and concrete, gave particulars regarding various mixtures, aggregates and control of water cement rates, and also data on the placing and curing of concrete.

Previous to the lecture a dinner was held at the Windsor Hotel. J. S. Brett, A.M.E.I.C., presided.

Junior Section

On April 8th, 1935, papers were presented on the "Operation of the Kaelin Electric Steam Generator" by H. C. Buller, S.E.I.C., assistant engineer with the Dominion Rubber Company, Montreal, and another on "The Small Maintenance Shop" by Paul Poitras, engineer with the Steel Company of Canada, Montreal.

The first paper covered the reasons for the installation, general theory, testing and operation of an 8,000 kw. unit, and the second paper was a study of layout, equipment and operations in general in the small maintenance plant.

Jules Archambault acted as chairman.

Electric Heating

On April 11th, 1935, Mr. Lee P. Hynes, consulting engineer of New York, gave a paper on "Electric Heating as Applied to Hydraulic Control Gates, Buildings and Industrial Processes." He described many of the recent developments and stated that as any radical change in the thermal efficiency of electric heating could not be expected, improvements must be obtained in the engineering technique for applying and controlling the heat.

A dinner at the Windsor hotel was held previous to the meeting. The chairman was Max V. Sauer, M.E.I.C.

The Smoker

The Montreal Branch smoker was held on April 12th, in the Rose Room of the Windsor hotel, and was attended by nearly three hundred and fifty members and guests.

The arrangements were under the direction of R. H. Findlay, M.E.I.C., and his smoker committee, who provided an excellent series of amateur turns and skits. The music was furnished by the D.B. and D.E.W. Amateur Orchestra with Mr. F. F. Cleal as conductor. F. S. B. Heward, A.M.E.I.C., chairman of the Branch, and Dr. F. A. Gaby, M.E.I.C., president of The Institute, both gave short addresses.

The X-ray in Metallurgy

The various uses of the X-ray in metallurgy were described by Andre Hone, D.Sc., lecturer in metallurgy at the Ecole Polytechnique, Montreal, on April 18th, 1935. His talk was well illustrated with lantern slides.

F. S. B. Heward, A.M.E.I.C., presided.

JUNIOR SECTION—PLANT VISIT

On Monday evening, April 22nd, 1935, some forty members visited the pipe mill of the Steel Company of Canada, on St. Ambroise Street.

A general talk on the manufacture of pipe was given by Mr. Blampied, plant superintendent, after which the party went through the plant. Refreshments were also served through the kindness of the Steel Company.

Niagara Peninsula

P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

This Branch held a joint meeting with the Niagara District Chemical and Industrial Association at St. Catharines on April 11th, 1935, with Mr. A. E. H. Fair as chairman and T. Stanley Glover, A.M.E.I.C., as speaker. About one hundred members and guests were in attendance.

Messrs. E. G. Cameron, A.M.E.I.C., W. R. Manock, A.M.E.I.C., and Paul Buss, A.M.E.I.C., spoke briefly as to the aims of The Institute, the fields of usefulness of the two organizations and of proposed meetings in the future.

Mr. Glover showed some most interesting lantern slides and told of his experiences while employed with the administration of the Crown Colony of Nigeria. This colony, on the west coast of Africa, is about the size of Ontario and is inhabited by some 20,000,000 blacks and 4,000 white people. There are more than one hundred dialects spoken, which makes the administration somewhat difficult. No white man is allowed to own land.

The northern portion, wherein the higher type of black is encountered, is subject to indirect rule with native chieftains acting in the Legislative Assembly, whereas the southern half is administered directly by white officials.

Two thousand miles of 3-foot 6-inch-gauge railway are already built and the ports of Lagos and Harcourt are quite modernized.

Palm kernels and oil are the principal exports but the mineralized portions of the country contain coal, tin ore and some gold. There are possibilities of trade for some of our Canadian products which might be well worth looking into.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

THUNDERSTORMS AND ATMOSPHERIC ELECTRIC EFFECTS

The noon luncheon on March 7th, 1935, was addressed by D. C. Rose, Ph.D., of the National Research Council, on the subject "Thunderstorms and Atmospheric Electric Effects." The address was illustrated with lantern slides.

Past chairman A. K. Hay, A.M.E.I.C., presided and in addition head table guests included: J. L. Busfield, M.E.I.C., of Montreal, Hon. R. B. Hanson, Dr. H. M. Tory, Dr. C. Camsell, M.E.I.C., R. C. Rose, Engr.-Com. A. D. M. Curry, M.E.I.C., Lieut.-Col. W. A. Steel, A.M.E.I.C., Group Captain E. W. Stedman, M.E.I.C., J. Murphy, M.E.I.C., J. T. Johnston, M.E.I.C., R. Meldrum Stewart, M.E.I.C., and E. M. Dennis, A.M.E.I.C. The chairman, in introducing the head table guests, made mention of the fact that Mr. Dennis for a number of years had been a prominent member of the Proceedings committee of the Ottawa branch and was now retiring from this committee membership.

The first part of the address dealt with the electrical state of the atmosphere in normal fine weather. The air of the atmosphere is to a small extent charged with electricity. It contains minute particles which carry positive and negative electrical charges. These are called ions and their existence makes the air a conductor of electricity. However, it is a very poor one being about of ten thousand million times lower conductivity than copper.

The density or amount of ionization increases with height and the fact that there is more positive electricity at higher altitudes results in an electrical field which is constantly driving positive electricity to the earth's surface. A constant current of about 1,000 amperes flows into the earth from the atmosphere. To a large extent, if not entirely, this is compensated for by the fact that during thunderstorms the electric field is reversed and higher currents flow upwards in lightning flashes and discharge off trees and points.

Dr. Rose discussed the meteorological effects leading up to thunderstorms. There are two general types: the first, or heat storm, which is local and occurs in fine weather when there is little or no wind; and the second, which is caused by instability in the atmosphere due to the movements of large bodies of air associated with low pressure centres. The latter, sometimes known as cyclonic storms, move across continents more or less regularly. There are many things not yet completely understood with regard to the process of building up the electrical charge in the thunderstorm, but in some manner the bottom of the cloud becomes negatively charged and the upper parts positive. When the potentials are great enough to break down the air in between, a lightning flash takes place. The majority of these flashes are from cloud to cloud, a small percentage only occurring between cloud and ground.

The speaker presented some interesting information regarding the estimated amount of energy that occurs in lightning flashes. For instance, it has been estimated that there are about seventeen billions of joules in the average lightning flash, which is enough energy to convert about seven tons of water from 0 degree C. into steam. There are estimated to be about one hundred flashes of lightning taking place on the average every second throughout the world, which means a continuous dissipation of about two thousand million horse-power. This again represents only a fraction of the total energy stored up in the atmosphere in storm conditions.

In some countries detailed observations are being obtained on the distribution, not of thunderstorms but of lightning flashes to the ground, with relation to the topographical and other features of the country so that data may be collected which would help in locating transmission lines in positions least likely to be struck. So far the information is insufficient and not very conclusive.

SOME BASIC PRINCIPLES IN MAKING DURABLE CONCRETE

At an evening meeting held on Thursday, March 21st, 1935, in the rooms of the photographic section of the Royal Canadian Air Force, Jackson building, the members of the Ottawa Branch listened to an address by Mr. J. W. Lucas, of the staff of the Testing Laboratories of the Department of Public Works. Mr. Lucas spoke upon "Some Basic Principles in Making Durable Concrete," his address being illustrated with lantern slides. It was prepared in collaboration with E. Viens, M.E.I.C., director of the Testing Laboratories of the Department of Public Works.

In Canada in a single year, as Mr. Lucas explained, as much as $100,000,000 has been spent on concrete, a figure which alone justified every effort to secure a good quality in the product. Inconvenience and cost in repairing or replacing leaking walls, dusty floors and deteriorating structures, are added reasons for warranting the study of methods for producing the very best, most serviceable and most durable kinds of concrete.

The composition of cement, the mixing of the concrete including particulars with regard to aggregates, and the water rates were referred to. The speaker also gave some interesting information with regard to the filling of forms and the curing of concrete.

Following the address, the meeting was thrown open to discussion in which many of those present participated.

PULP AND PAPER

About one hundred and fifty members and their friends attended a noon luncheon at Standish Hall, Hull, P.Q., on Saturday, March 30th, 1935, and afterwards paid a visit to the plant of the E. B. Eddy Co. Ltd. At the luncheon, W. S. Kidd, A.M.E.I.C., production manager for the company, gave an address on "Pulp and Paper" preliminary to the visit of inspection. Luncheon guests at the head table included a number of the officials of the company. Dr. R. W. Boyle, M.E.I.C., chairman, presided.

Mr. Kidd in his address briefly traced the history of paper-making and outlined the various steps in present-day processes, illustrating them with lantern slides.

The speaker stated that men with training in the various branches of engineering, particularly mechanical, electrical, civil, chemical and forestry, deserve much of the credit for making Canada the largest newsprint producing country in the world, and Canadian mills the most efficient.

Until a few years ago the engineers' activity in the industry was confined to the designing and building of paper mills. Gradually, however, they have been taken into the operating organization, so that today they are found in all departments, from the woods to the shipping room, striving continually to make better paper cheaper.

The future of the technically trained man in the paper industry is bright, for he alone is equipped to solve the many problems still to be found in every department.

In the course of the afternoon's inspection trip a train of several cars was provided for transferring the guests from one end of the grounds to the other. The main units of the plant were visited, including the wood room, wood clearing department, sulphite mill, groundwood mill, and the different mills for the manufacture of newsprint and other papers.

SPECIAL MEETING ON CONSOLIDATION

A special meeting of the Branch was held in the R.C.A.F. Rooms, Jackson Building, on the evening of April 9th, 1935, in order to afford the members an opportunity to discuss a resolution of the last annual meeting of The Institute on the possibilities of consolidation of the engineering profession in Canada. At this meeting J. L. Busfield, M.E.I.C., and R. J. Durley, M.E.I.C., the general secretary, both of Montreal, attended.

The matter of possible consolidation was discussed and Dr. R. W. Boyle, M.E.I.C., and A. K. Hay, A.M.E.I.C., were appointed as a committee of two to confer with the members of the Ontario Association of Professional Engineers in the Ottawa district regarding the matter. After the opinions upon the possibility of consolidation had been obtained by this committee, it was to communicate its findings and report back to the general committee of The Institute on Consolidation, under the chairmanship of Gordon M. Pitts, A.M.E.I.C., of Montreal.

Quebec Branch

J. Joyal, A.M.E.I.C., Secretary-Treasurer.

The Isle of Orleans Bridge

At a meeting of the Quebec Branch of The Institute held on April 8th, 1935, P. L. Pratley, M.E.I.C., described the construction of the Isle of Orleans Bridge, and O. Desjardins, A.M.E.I.C., chief engineer of the Department of Public Works, who thanked the speaker, dealt with the cost of the project. H. Cimon, M.E.I.C., chairman of the Branch, presided and introduced the speaker.

Mr. Pratley dealt principally with the superstructure of the central portion, the suspension bridge, and with the anchor piers which were both important and somewhat unique. Slides were shown of studies for other types of span and the advantages of the suspension bridge were outlined. Reference was then made to the problems facing the designing engineer, such as the construction of anchorages in tidal waters, the choice of material, the selection of floor detail, the appearance of the towers, the mathematical determination of the dimensions of the stiffening trusses and so forth. The speaker went on to illustrate the construction of the anchor-piers, and views of the building procedure, and the insertion of the steel anchor-girders were shown. He then dealt with the specification, design and testing of the cables, and reference was made to the process of prestressing to which all cable-strands and hanger-ropes were submitted. The build-up of the main cables which support the roadway floor and also the detail manner in which these cables are anchored into the piers was shown by slides, and Mr. Pratley pointed out several entirely new features. Following this the design and erection of the towers was referred to, and the stringing of temporary walk-ways upon which to lay the main cables. This was followed by views of the methods by which the cables were hauled over, attached to their anchorages and adjusted for correct sag. The assembling of the individual strands, thirty-seven of which formed one cable, was also indicated by the slides and the final process of wrapping the cable with a wire covering which has not yet been undertaken at the side was illustrated by the exhibition of the same process being carried on at Grand'Mere six or seven years ago.

The lifting of the truss sections from the ice was the next feature dealt with, and was followed by references to the concrete-filled steel grid decking also new in this structure.

The construction programme calls for completion this summer, and it is expected that the bridge will be open to traffic by Dominion Day.

Saskatchewan Branch

S. Young, A.M.E.I.C., Secretary-Treasurer.

Eighteenth Annual Meeting

The eighteenth annual meeting of the Saskatchewan Branch of The Institute was held in the Parliament Buildings, Regina, commencing at 8.00 p.m. on Friday evening, March 22nd, 1935. The meeting was preceded by a dinner at 6.30 p.m., the total attendance being fifty. Previous to the dinner the majority of those attending met in contest at curling, 12 rinks taking part.

Professor R. A. Spencer, A.M.E.I.C., of the staff of the University of Saskatchewan, Branch chairman, spoke briefly at dinner on engineering education. The business session was conducted by the vice-chairman A. P. Linton, A.M.E.I.C.

S. J. Swayze, accompanied by R. Pym, contributed two songs which were heartily applauded.

The report of the executive covering its activities during the past year, the report of the auditors, presented by R. W. Allen, A.M.E.I.C., and the report of the Papers and Library committee, presented by S. R. Muirhead, A.M.E.I.C., were adopted.

Mr. Muirhead announced that the next meeting would be in the Hotel Champlain, Regina, on April 8th, 1935, when H. N. MacPherson, A.M.E.I.C., would address the Branch on "The Preservation of Timber." Mr. Muirhead also gave a brief résumé of the contents of the February and March numbers of The Journal.

H. R. MacKenzie, A.M.E.I.C., reported for the committee on unemployment outlining verbally the activities of the committee during the past year.

The report of the Saskatoon Section read by the secretary on behalf of Professor Spencer was adopted. In the discussion consequent to this report attention was drawn to the possibility of including Prince Albert in the Saskatoon Section.

H. R. MacKenzie then informed the meeting of the action recently taken at the annual meeting of the Association of Professional Engineers with respect to the consolidation of the engineering profession throughout Canada, requesting similar action by this Branch of The Institute. Moved by H. R. MacKenzie, seconded by D. A. R. McCannel, M.E.I.C., and carried that, "this Branch of The Engineering Institute of Canada in annual meeting assembled hereby goes on record as being in favour of the consolidation of the engineering profession in Canada."

As a step towards consolidation Mr. McCannel then explained the desirability of having one person as secretary for the association and the Branch, but in order to facilitate the appointment of such a person it would be necessary to amend the Branch by-laws in accordance with the notice of motion sent out with the notice of the annual meeting.

H. R. MacKenzie raised the question of supporting the proposed action of the Association of Professional Engineers towards a meeting of all engineers in the province, probably in October or November of this year; moved by H. R. MacKenzie, seconded by H. C. Ritchie, A.M.E.I.C., and carried that this Branch of The Institute endorse the action of the Association of Professional Engineers recently taken at the annual meeting towards a general meeting of all engineers in the Province.

The speaker of the evening, E. E. Lord, A.M.E.I.C., was then introduced by the chairman, the subject of his address being "River Improvement Work in Manchuria."

Mr. Lord, who for ten years after the close of the Great War was assistant chief engineer on river improvement work at the mouth of the Liao river, confined his remarks to this project. The mouth of the Liao river, long in use for navigation purposes, became subject to heavy silting by reason of a diversion of part of the discharge. The preliminary work consisted of the making of a proper survey by triangulation to embrace a network suited to the taking of soundings.

The improvement work consisted in the first instance of the erection of a wall 36,000 feet in length for the purpose of directing the stream flow and confining it to a limited waterway thus increasing the rate of flow and thereby reducing the tendency to silt. The wall, erected two feet above low water mark, of loose rubble placed from scows, contained in excess of 500,000 cubic yards at a cost of approximately $2.00 per cubic yard. The work, including the driving of piles, was carried on without the use of machinery there being no power equipment, only hand labour—all concrete being hand mixed.

The cost of the work was paid by the Chinese government out of a tax on shipping.

Mr. Lord's address was provocative of considerable discussion after which a hearty vote of thanks was tendered the speaker.

The Preservation of Timber

The Saskatchewan Branch, Engineering Institute of Canada, met in regular session at the Hotel Champlain, Regina, on April 8th, 1935, being preceded by a dinner at 6.30 p.m. at which the attendance was thirty-one.

The chairman, A. P. Linton, M.E.I.C., introduced the speaker of the evening, H. N. MacPherson, A.M.E.I.C., consulting engineer, Vancouver, now specializing in the field of timber preservation, a former highly esteemed member of the Saskatchewan Branch, his subject being "The Preservation of Timber."

Mr. MacPherson, after outlining the various types of deterioration to which timber in use is subjected, gave an historical outline of development of methods of timber preservation followed by descriptions of modern methods of timber treatment, illustrating his subject with two reels of moving pictures.

The address was provocative of interested discussion whereupon a hearty vote of thanks was tendered the speaker.

The scrutineers reported the ballot on by-law amendments and the chairman declared the amendments duly carried, following which the meeting adjourned.

Winnipeg Branch

J. F. Cunningham, A.M.E.I.C., Secretary-Treasurer.
H. L. Briggs, A.M.E.I.C., Branch News Editor.

Items of Interest in Aviation

About sixty engineers were present at the Branch meeting of March 21st, 1935, to hear Mr. J. C. Uhlman, of the Manitoba Government Air Services, present a paper on "Items of Interest in Aviation."

Mr. Uhlman said that any reaction of the public against air transportation was generally based on one or more of three main causes—fear, cost, or lack of comfort. Fear was usually greatly alleviated after taking one air trip. Cost now compares very favourably with that of surface transportation, and is reduced as further advantage is taken of air services. The comfort is now comparable with that of bus transportation, except possibly for noise and 'bumpy' air.

The greatest remaining hazards of civil flying are conditions cutting off visibility and causing ice to form on the wings. Instrument flying is not difficult particularly if beam radio is used, but landing blind is a problem. One system which has been developed to allow this, depends on the detection by the pilot of intersections of a radio beam inclined slightly above the horizontal, with two vertical radio beams, one near the edge of the landing field, and the second two miles distant.

Variable pitch propellers have been a great advance. These are made adjustable at the will of the pilot, or are made automatically adjustable, control being dependent on the amount of thrust on the revolving blade.

Engine weight has been reduced to the place where, in the larger sizes, it amounts to only 1.34 pounds per horsepower, and in the smaller sizes, 1.6 pounds per horsepower.

In regard to the future, Mr. Uhlman pointed out that in 1934 the French had flown the south Atlantic seventeen times, and the Germans thirty-two.

The Manitoba Government Air Service, organized in 1932, had since that date flown the equivalent of six times around the world without a single accident to passengers or personnel.

The vote of thanks to Mr. Uhlman proposed by D. L. McLean, A.M.E.I.C., was heartily endorsed by all present.

Protective Relays

On April 4th, 1935, H. L. Briggs, A.M.E.I.C., relay engineer, Winnipeg Hydro-Electric System, addressed the Branch on the subject "Protective Relays, the Watch Dogs of a Power System."

The speaker emphasized that in spite of the best of operation and maintenance of an electric power system, electrical faults do occur. Among the tables showing causes of faults was the following, showing the summary of four years of operation of 495 miles of 66 kv. isolated neutral transmission circuits.

66,000 Volt Short Circuits

Cause	Number of troubles	Per cent
Lightning	22	29.7
Insulator failures	10	13.5
Large birds	15	20.3
Sleet	8	10.8
Miscellaneous	12	16.2
Unknown	7	9.5
	74	100.0

The function of protective relays was to cause the quick isolation of such faults, thereby limiting the damage at the point of the fault, and limiting the effects on the remainder of the power system. A number of principles of relay operation were described, and several schemes illustrated whereby difficult protection problems on the 66 kv. system of the Hydro were solved.

Where the question of electrical stability between power plants or loads was concerned, the tremendous economic importance of high speed clearance of faults was exemplified. A number of slides showing modern high speed (less than 1/30 second to operate) relays of various types were shown.

The vote of thanks to the speaker was tendered by Dean E. P. Featherstonhaugh, M.E.I.C., after which all present enjoyed cake and coffee.

1935 Annual Meeting of the Canadian Institute of Mining and Metallurgy at Winnipeg

The Engineering Institute of Canada was represented at the annual meeting of the Canadian Institute of Mining and Metallurgy held at Winnipeg on March 12th, 13th and 14th, 1935, by E. V. Caton, M.E.I.C., vice-president of The Institute, and Fred V. Seibert, M.E.I.C., chairman of the Winnipeg Branch, and a large number of the local members of The Institute. Many papers of interest to members of The Institute were delivered.

The announcement of the presentation of the Leonard Medal to D. E. Keeley, McIntyre-Porcupine Mines, Schumacher, Ont., was also made. This medal was awarded by the late Colonel R. W. Leonard, M.E.I.C., past-president of The Institute, for the best paper published in the transactions of either The Engineering Institute of Canada or the Canadian Institute of Mining and Metallurgy, by a member of either organization. The subject of Mr. Keeley's paper was "Guniting at the McIntyre."

Errata

Errata in the discussion on "The English Bay Interceptor, Vancouver," by G. M. Gilbert, A.M.E.I.C., which appeared in the March 1935 issue of The Journal: In the discussion by J. M. Begg, M.E.I.C., instead of "design was based on an estimate of the flow of sewage for the maximum hour of the minimum day" read "the maximum hour of the maximum day" and instead of "in the repair shop" read "in the repair work."

In the review of "An Introduction to Structural Theory and Design" by Sutherland and Bowman, published by John Wiley and Sons, appearing on page 237 of the April issue of The Journal, the phrase appearing in the fifth paragraph as "With the Cross method of moment distribution now available, which greatly simplified the *layout*," should read "With the Cross method of moment distribution now available, which greatly simplified the *labour*."

R. S. Stockton, M.E.I.C., Superintendent, Operation and Maintenance, Western Section, Irrigation System, Canadian Pacific Railway Department of Natural Resoures, Strathmore, Alta., was stated incorrectly on page 231 of the April, 1935, issue of The Journal, to be manager of the Canadian Pacific Railway Experimental Farm at Strathmore.

Annual Meeting, Corporation of Professional Engineers of the Province of Quebec

Dr. A. R. Decary, M.E.I.C., superintendent engineer for the Province of Quebec in the Department of Public Works of Canada, was re-elected president of the Corporation of Professional Engineers of Quebec for the sixteenth time on Wednesday, March 27th, 1935, at the annual meeting of the Corporation held at the Headquarters of The Engineering Institute of Canada, Montreal.

The reports of Council and of the various committees showed great activity within the Corporation.

The report of Council mentions that the Corporation has succeeded in having certain laws amended at the last session of the Quebec Legislature, i.e., the Stationary Enginemen's Act, the Quebec Mining Act, the Quebec Insurance Companies Act respecting adjustment of claims.

The Committee on Affiliation with The Engineering Institute of Canada reported that the Corporation is ready and willing to co-operate immediately with the other provincial engineering organizations in an attempt to develop with The Engineering Institute a suitable and adequate basis of co-ordination of the engineering profession in the Dominion, and that the lines along which such co-ordination should proceed should be generally similar to those which have governed the organization of sister professions in Canada.

The Committee on Publicity recommended that special attention be given to publicity relating to the usefulness and the importance of the engineering profession to the public.

The committee nominated to study the proposed N.R.A. Code for engineers of the United States considered that said code covers the complete field of the practice of engineering in a most comprehensive and practical manner, and suggested that the by-laws and code of ethics of the Corporation be altered along the lines of the N.R.A. code wherever possible.

Immediately after the meeting the Council met and elected the following officers: President, Dr. A. R. Decary, M.E.I.C.; vice-president, Mr. J. M. Robertson, M.E.I.C.; Honorary Secretary-Treasurer, Mr. S. F. Rutherford, A.M.E.I.C. The other members of Council are: Dr. O. O. Lefebvre, M.E.I.C., Colonel C. N. Monsarrat, M.E.I.C., and Messrs. A. B. Normandin, M.E.I.C., Geo. K. McDougall, M.E.I.C., and Hector Cimon, M.E.I.C. Mr. Adhemar Mailhiot, M.E.I.C., was re-elected Registrar of the Corporation.

List of New and Revised British Standard Specifications

(issued during February, 1935)

B.S.S. No.

32—1935. *Steel bars for the Production of Machined Parts for General Engineering Purposes. (Revision.)*
Withdrawal of Grade 3—free cutting steel for repetition work—and inclusion of a Grade 4 for rapid machining steel for repetition work which has superior shock resistance to the former Grade 3.

140—1935. *Liquid Starters and Controllers for the Rotor Circuits of Induction Electric Motors. (Revision.)*
Provides for standard ratings and sizes, general features of design and construction, etc. Includes appendices on estimation of capacity.

232—1935. *Vitreous-Enamelled Steel Reflectors for Electric Lighting. Open Dispersive Type No. 1. (Revision.)*
Deals with vitreous-enamelled steel reflectors for direct general lighting (open dispersive type) which are designated according to the nominal consumption of the gas-filled lamps for which each is suitable.

587—1935. *Motor Starters and Controllers (Excluding Liquid Starters and Controllers and Single-Phase A.C. Models).*
Revised specification, which supersedes the undermentioned, provides for standard ratings and sizes, etc., and includes detailed appendices on terminal markings.
(Superseded B.S.S. Nos.:—
117—1923. Drum Starters; 118—1923. Drum Controllers and Resistances; 123—1923. Face-Plate Controllers and Resistances; 129—1923. Contactor Controllers and Resistances; 141—1923. Switch Starters; 147—1923. Multiple Switch Starters; 155—1923. Contactor Starters; 167—1923. Auto-Transformer Starters; 246—1927. Face-plate Starters (D.C.); 247—1927. Face-plate Rotor Starters.)

588—1935. *Grading of Plywood (Veneered with Oak, Mahogany, Walnut, Teak and other Ornamental Woods).*
This standard forms the second of a series for commercial plywoods and includes definitions, general clauses and four simple grades.

589—1935. *Nomenclature of Softwoods (Including Botanical Species and Sources of Supply).*
Includes over seventy (70) trade names as well as botanical country of origin and synonyms in common use.

The Laws of a Mass of Clay Under Pressure

M. A. Ravenor, M.E.I.C., M. Inst.C.E.

Abstract from Sessional Notice No. 3, February, 1935, of the Institution of Civil Engineers.

Reprinted by Permission

Engineers have been in the habit of referring to the capacity of a soil to carry so many tons per unit area without regard to the corresponding amount of settlement, whereas it is an accepted principle in the testing of engineering materials that stress is accompanied by a corresponding deformation. A knowledge of the behaviour of clay under pressure would permit greater loads to be used. Millions of pounds are expended annually upon the foundations of all kinds of structures, a considerable part of that cost being incurred, of necessity, to allow for the uncertainty of design due to an almost entire lack of knowledge of the subject.

The author has made a prolonged study of the problem of a large mass of clay subjected to the pressure of a finite area; he has conducted a large number of tests on clay, and has been able to reconcile their results with the actual settlement of structures erected in the same clay. The laws which have been deduced from the tests confirm experiments which have been made by other investigators. In particular, the author's law of induration not only fills the gap between Professor Rankine's and Mr. A. L. Bell's[1] formulae, but it gives the intensity of the load in terms of settlement, and, indirectly, in terms of depth and water content. The large divergence from Rankine's formula is shown to be due mainly to compression or induration of the material. In other respects the author confirms the work of Professors Ackerman and Terzaghi, Dr. Faber, and others, which gives added confidence and assists in co-ordinating the stages through which a mass of clay under pressure passes.

It is an accepted principle that the testing of an engineering material should emulate, as closely as possible, the conditions to which it is subjected in use. For this reason it is considered that the most reliable method of testing the resistance of clay is by the slow penetration of a loaded plunger.

Earlier experimenters have, generally speaking, aimed at the discovery of a single law which clay under pressure would obey; no previous investigator appears to have found that clay under test passes through the elastic, ductile and plastic stages, although it should be stated that such an analogy has been suggested, but the author shows that the analogy of clay and such metals as steel, copper, etc., is striking. He attributes his more satisfactory results largely to the development of a method of testing explained in the paper, which measures the reaction of a mass of clay to the pressure of a finite area more accurately than has been possible hitherto.

From the foundation-engineer's viewpoint, clay should be considered as a porous, permeable and compressible mass, composed of fine grains of clay matter which are surrounded by a "lubricant" consisting of water and colloid matter; its physical properties are thus remote from those of the ideal material assumed by Rankine. Mr. Berridge[2] has pointed out that clay has a maximum water-content consistent with the pressure and with its colloid-content. The principal effect of extraneous pressure is to change its physical properties within a limiting zone.

Law of Induration.—When an extensive mass of clay *whose resistance to compression is less than its resistance to motion* is subjected to the pressure of a finite area, the material undergoes physical changes comprising the process of induration, and resulting in a change in water content, compression (closer aggregation of grains), a change in texture, and an increase in strength (cohesion). The direct result of these changes is the development of a compressed area or "bulb" whose effective area increases towards a maximum with increase of pressure. From a large number of tests made by the author and also by other investigators, the relation of load and deformation, during this stage, is found to be represented by the equation:

$$C = \left(\frac{P}{m} + I\right)^6,$$

where C denotes the deformation or settlement of the loaded area in ins.
P " the intensity of the load in lbs. per sq. ft.
I " a constant, representing elastic deformation in ins.
m " a coefficient which depends for its value upon the water-content and extent of the area as described.

The author investigated the process of induration described by an examination and analysis of material after conducting tests which showed the physical changes referred to. Dr. Faber's[3] demonstration of a maximum stress at the outer edge of the loaded area is consistent with the formation of the bulb described, and comparative results are given.

The influence of water-content is dealt with, also the effect of varying load-increment and of different areas experimented upon up to 10 inches diameter and at depths up to 15 feet. For a constant settlement the general equation given above becomes a straight-line law connecting the load and the area, as already shown by Mr. W. S. Housel.[4]

A comparison is made with Rankine's and Bell's formulae. By assuming a constant settlement for a given area, the general equation becomes a linear relation between load and depth, as shown by Mr. Bell's formula, but the location of this straight line in relation to the axes is shown to vary according to the amount of settlement assumed. Rankine's formula may be said to be based on the hydraulic analogy, and it can be shown that the only difference between his formula and Bell's is in the intercept on the load axis. In dealing with a compressible material it will be appreciated that its resistance to compression may be less than its resistance to motion or displacement, and in the case of clay this is always so until the condition of a liquid mud is approached. For an infinite area, however, the resistance of clay to compression cannot be less than that represented by its unit weight multiplied by the depth, as the material will have been compressed by its own superincumbent weight.

The relation of test results to the settlement of structures erected in the same clay is shown; the author considers that it is now possible, by making tests at the site of the proposed works, to determine with reasonable certainty the permissible load corresponding to a given settlement.

Submergible Road Bridge Near Jubbulpore, India

This bridge over the Nerbudda replaces a ferry in the rains and a temporary wooden erection for the rest of the year, and has at last made possible practically uninterrupted road communication between Nagpur and Jubbulpore. Ever since the British occupation of this part of India, this road, 165 miles long, has been of outstanding importance for both the civil and military administrations, and it was macadamized throughout at an early date, every river and stream being bridged, except the Nerbudda. The serious technical difficulties involved in bridging this river prevented the work being undertaken until quite recently. Ultimately, a design for a submergible bridge, a type largely developed in the central provinces, was made, and work was started in February, 1929.

The type of bridge adopted is called submergible because it is definitely designed to be overtopped, without suffering any serious damage, by the occasional very high flood, such as that in 1926, which completely washed away both the adjacent railway bridges, but it will pass all but the highest floods of a normal season. This type is thus more economical than a high-level bridge for rivers subject to such extremely high floods as the Nerbudda, the maximum flood rise of which is 78 feet. Although, being built deliberately to allow the highest of the annual, as well as the exceptional, floods to pass over them, such bridges have to be extremely massive in construction to withstand uplift, overturning and the buffeting from huge logs brought down in flood-time, nevertheless they effect a considerable saving of cost, even over a high-level bridge of much lighter construction, owing to the reduced height of piers, abutments and approach banking. There is the further extremely important advantage that, if the bridge has been correctly designed and properly constructed, it will reappear undamaged, or at worst but slightly damaged, after submergence by any flood, however exceptional, whereas a high-level bridge, if overtopped, is almost certain to be completely destroyed.

The determination of the formation-level, to give the most useful service and yet permit of the greatest economy, is effected by keeping a record over a series of years of the rise and fall of the river at the site selected. These records, when plotted, make it possible to choose a formation-level which will ensure that in a normal year the bridge is only overtopped on some three or four occasions during the monsoon, and for a maximum period at any one occasion of about twenty-four hours only. In this case, the formation-level actually selected was 40 feet above the lowest bed-level of the river.

The bridge consists of eight arches of 46-foot clear span, five at one end and three at the other, and six spans of 98 feet in the central length; including abutments and wings, the overall length is 1,222 feet. The roadway is 21 feet wide, paved with blocks of hard red sandstone, and traffic is protected by a special form of collapsible railing, which can be rapidly let down into slots in the bed of the roadway, so as to avoid damage in a high flood. This paved roadway is level over the central length of the bridge, and has a slope of 1 in 25 at each end to conform with the slope of the approach cutting. The lengths between the level and sloping portions follow carefully calculated vertical curves to ensure fast traffic passing without any jolt.

The piers, except three at the centre, are of stone masonry with a concrete hearting, founded on rock. The three central piers are similar, but are founded on a reinforced-concrete slab 2 feet thick, supported by forty-six reinforced-concrete piles, 14 inches square, driven to an average penetration of 18 inches into rock. All the piers had twelve steel 90-pound rails embedded in them from rock-level (or slab-level in the case of those on pile foundations) up to well into the arches, to the reinforcement of which they were tied, making the whole bridge effectively monolithic in its resistance to buoyancy and overturning.—Mr. A. W. H. Dean in *Engineering.*

The Dominion Bridge Company Limited have completed arrangements with The Wellman Engineering Company of Cleveland giving the Dominion Bridge Company Limited rights for the manufacture and sale of "Williams" buckets in Canada.

Preliminary Notice

of Applications for Admission and for Transfer

April 29th, 1935

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in June, 1935.

R. J. Durley, Secretary.

---

*The professional requirements are as follows.—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

> The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ATTENBOROUGH—ERNEST ARTHUR, of 72 East Lynn Ave., Toronto, Ont., Born at Toronto, July 13th, 1913; Educ., Ontario Matriculation. Evening course, app. mechs. and strength of materials; 1930 to date, tracer, sewer dfting. office, Dept. of Works, City of Toronto.
References: F. J. Hancox, G. Phelps, T. Taylor, A. U. Sanderson, G. G. Powell.

DAVIS—WILLIAM ROE, Jr., of Calgary, Alta., Born at Calgary, June 28th, 1909; Educ., B.Sc. (E.E.), Univ. of Alta., 1934; 1928-30, and at present, asst. engr., Calgary Power Co., Calgary, Alta.
References: G. H. Thompson, H. B. Sherman, H. B. LeBourveau, H. J. MacLeod, J. H. Ross.

EVANS—THOMAS OWEN, of St. Vincent de Paul, Que., Born at Montreal, Jan. 31st, 1905; Educ., B.Sc., McGill Univ., 1927; With Montreal Light, Heat & Power Cons., as follows: Summers 1923-24, and May 1925 to Oct. 1926, at Cedars plant, floorman, asst. operator and operator in transformer house. 1927-29, at Montreal, ap'tice. engr., operating and mtce. substations; cable gang; layout work in distribution dept.; 1930 to date, asst. supt., Back River plant, Montreal Island Power Co., St. Vincent de Paul, Que.
References: R. N. Coke, G. P. Hawley, L. H. Marrotte, M. V. Sauer, J. F. Roberts.

HALLE—CHARLES JULES, of 61 de Repentigny, Quebec, Que., Born at St. Lambert, Que., July 8th, 1901; Educ., 1923-26, Ecole de Génie Civil, Paris. R.P.E., Quebec, 1927; 1927 to date, professor, Quebec Technical School, maths., app. mechs., strength of materials, etc. Also consltg. engr., reinforced concrete structures.
References: A. Frigon, P. Methe, J. H. A. E. Drolet, A. V. Dumas.

HAMILTON—VESEY COURTHOPE, of Exshaw, Alta., Born at Sterling, Ont., Jan. 10th, 1903; Educ., Grad., R.M.C., 1924; 1924-27, timber cruising, surveying, logging, with Price Bros. & Co. Ltd., Chicoutimi, Que.; 1929-30, supt., National Cement Co. Ltd., Montreal; With Canada Cement Co. Ltd., as follows: 1927-28, asst. engr., constrn., Lakefield, Ont., 1929, asst. supt., Exshaw, Alta., 1930-33, supt., Winnipeg, 1933 to date, supt., in charge of plant at Exshaw, Alta.
References: S. Barr, J. A. Creaser, L. F. Grant, F. B. Kilbourn, H. J. McLean, R. S. Trowsdale.

HUDSON—ARTHUR MAGENISS, of Toronto, Ont., Born at Norwich, England, July 11th, 1889; Educ., 1904-07, articled to Duge & Son, Norwich, gen. engrg. work, principally bldgs.; 1908-09, levelman, C.N.R. constrn.; 1909-10, levelman, Algoma Eastern Rly. constrn.; 1910-12, foreman and supt., for Roger Miller & Sons, and 1912-15, administrative engrg. for same company; 1915-17, overseas, Capt., C.E.F.; 1917-19, res. engr. in charge of aerodrome constrn., British War Office; 1920-27, suptg. and administrative engr., principally design and set-up of equipment, Roger Miller & Sons; 1927-33, with Canadian Ingersoll Rand Co., specializing on the application of pneumatic tools for rock-mining and general contract work; 1934 to date, equipment engr., Dept. of Northern Development, Ontario Government, covering equipment and its application to road constrn., also engrg. costs of gen. mtce.

FOR TRANSFER FROM THE CLASS OF JUNIOR

SHUTTLEWORTH—WILBUR IRVIN, of 192 James St., Ottawa, Ont., Born at Ottawa, Oct. 4th, 1901; Educ., Passed Institute's exams. Schedule "B" (1932) and Schedule "C" (1933); 1922-26, instr'man and asst. engr., Geodetic Survey; 1926-27, instr'man., Gatineau Power Co.; 1929 (Apr.-Sept.), res. engr., Foundation Co., at Dalhousie, N.B.; 1929-30, engr. on addition to ground wood mill and hydraulic plant for Jas. MacLaren Co., Buckingham, Que.; 1930-31, engr. at Lucerne in Quebec, on hotel and bldgs., also water main, dam and pumping station; 1931 (Aug.-Dec.), engr. at Masson, for Foundation Co.; 1932 (June-Dec.), engr. for L. G. Ogilvie Co., on a high school in Verdun, Que.; Nov. 1933 to date, instr'man., sewer branch, engrg. dept., City of Ottawa. Giving line and grade for all open cut sewers, checking line and grade in tunnels, also some dfting. (*Jr. 1932.*)

Glare from Motor-Car Headlights

A frequent cause of accident, not only to those most intimately concerned but to other road users, is glare from the headlights of one car dazzling the driver of another coming in the opposite direction. This risk is not removed by extinguishing the headlights of one or both cars and, though many anti-dazzle devices have been proposed, their relative efficiency yet remains to be determined. This arises from the fact that glare is due to a variety of causes; and that any attempt to assess the efficiency of a proposed system by direct trial is greatly hampered by their interplay under practical conditions. It is therefore primarily necessary to make a scientific analysis of these contributory factors.

A report, recently issued by the Department of Scientific and Industrial Research, is intended to provide one way of making such approach. It defines glare as being the reduction in the driver's power to detect objects ahead of him in the roadway and describes a method of estimating its effect on a driver when the oncoming car is fitted with headlights whose light distribution is known. The principal factors, which determine the amount of the reduction are the candle-power of the approaching headlight in the direction of the observing driver's eye, the relative positions of the two cars and the object to be detected, the reflection factors of this object and of the road surface and the speed at which the cars are approaching each other.

The visibility of an object can be stated as the ratio of the brightness difference to the brightness difference threshold. The former quantity is the difference between the brightness of the object, as seen by the driver, and of the road or sky immediately surrounding it. It may be either positive or negative and will be perceptible if it exceeds the smallest perceptible brightness difference or brightness threshold. In absolute magnitude, irrespective of sign, this visibility must have a value considerably greater than unity, possibly as high as five before an object can be picked up by a driver with any degree of certainty. When the headlights of an approaching car appear in the field of view they generally bring about an increase in the brightness threshold, thus reducing the sensitivity of the eye and decreasing the visibility. This increase depends on the value which the brightness threshold assumes when the glare is removed, on the angles which the driver's direction of vision makes with the lines joining his eyes to the glaring headlights and on the illuminations in the plane of the driver's eyes, due to those headlights. Glare is completely specified by the two angles and the two illuminations, while the brightness threshold, for an object surrounded by a given brightness in the presence of a glare specified by these four qualities, has the same value as for an object surrounded by a second or equivalent brightness in the absence of glare.

Now the brightness difference, the field brightness, the eye illuminations and the angles of direction can all be determined when the positions of the two cars and of the object, the reflecting properties of the object and roadway and the light distributions in the headlight beams are known. Thus the visibility of the object, as reduced by glare, can be determined, though as a study of the report will show, a great deal of work is necessary for the attainment of this end.—*Engineering.*

Dr. M. I. Pupin Dead

Dr. Michael Idvorsky Pupin died in New York, N.Y., on March 12th, 1935, at the age of seventy-six. Dr. Pupin was born at Idvor, Banat, Hungary, on October 4th, 1854, and emigrated to New York in 1874 where by working during the daytime and studying at night he was able to enter Columbia University in 1879, obtaining a B.A. degree in 1883 and becoming a naturalized American citizen at the same time. He then returned to Europe, studying physics and mathematics at the Universities of Cambridge and Berlin, and obtaining a Ph.D. degree from the latter in 1889. Returning to America, he joined the staff of Columbia University, as instructor in mathematical physics, being appointed Adjunct Professor of Mechanics in 1892. In 1901 he was made Professor of Electromechanics, and two years later was appointed Director of the Phoenix Research Laboratory. He retained this position and his professorship until 1929, when he retired with the title of Emeritus Professor in Active Residence.

In addition to his invention of the loading coil for long-distance telephone cables he made many contributions to the advancement of scientific knowledge. For instance in 1896, he invented the method of increasing the rapidity of X-ray photography by placing a screen of fluorescent material between the object and the photographic plate. He also discovered secondary X-ray radiations and produced X-ray photographs for use as a guide to surgeons in operations. In 1899 he published his mathematical theory of artificial lines or networks, which has been widely applied since then, and, in 1902, he was granted a patent for tuned electrical circuits, the patent being acquired by the Marconi Company.

Dr. Pupin became president of the American Institute of Electrical Engineers in 1925, and was awarded the Edison Medal in 1920 and the John Fritz Medal in 1932. That the value of his work was recognized during his lifetime may be gathered from the numerous awards he received, both in the United States and in foreign countries.

Canadian Electrical Association Annual Convention

The forty-fifth annual convention of the Canadian Electrical Association Inc. will be held at the Algonquin Hotel, St. Andrews-by-the-Sea, N.B., on June 26th to 28th, 1935.

An interesting and instructive programme is being planned, which will include the regular business sessions, discussion of the various committee reports, and the presentation of several special papers which will be of interest and value to all.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situations Vacant

MECHANICAL ENGINEER, not over 45 years of age, with practical experience in machine shop practice to act as production engineer with large machinery manufacturing company. Location province of Quebec. Give full details of experience and personal qualifications to Box No. 1142-V.

CIVIL SERVICE OF CANADA
List No. 623

The Civil Service Commission announces an open competitive examination for the following position:

23953.—A Chief Operating Officer, Board of Railway Commissioners, at an initial salary of $4,800 per annum, subject to such deduction as may be provided for by legislation.

Duties.—Under the direction of the Board to administer the Operating Department of the Board of Railway Commissioners; to consider and report upon questions of operation, train rules, signals, train services, car supply, fire prevention regulations and safety appliances, including cars and locomotives and stationary and locomotive boilers; to direct the staff engaged upon inspection of safety appliances and railroad operation, and upon investigating all types of accident, personal injury or death in or from moving trains or complaints in respect to railroad services; to consider and report upon applications for abandonment of lines; to hold conferences of railway and employees' representatives on matters referred to the Board or arising out of the Department's work; to make investigations and reports as requested by the Board in any matter of railway operation; ou occasion to conduct personal investigations of accidents or complaints; and to perform other related work as required.

Qualifications Required.—Education equivalent to graduation from a university of recognized standing; at least ten years of experience in the operating department of a railway, at least five years of which shall have been in an administrative capacity or on equivalent regulatory work; thorough knowledge of general railway operation including train rules, signals and methods of fire prevention; familiarity with the mechanism, use and inspection of safety appliances required on railway operating equipment, including cars and locomotives, boilers and appurtenances, air brakes, crossing signals and other safety equipment; demonstrated administrative ability, tact, good judgment. Although no definite age limit has been stated, age may be a determining factor in making a selection.

Applicants must give full particulars concerning their technical training and experience, especially as they bear on the qualifications for and duties of this position. An oral examination may be given, if necessary in the opinion of the Commission.

An eligible list valid for one year may be established.

General Directions

Application forms properly filled in must be filed with the Civil Service Commission, Ottawa, **not later than May 23, 1935.** Application forms may be obtained from the offices of the Employment Service of Canada, from the Postmasters at any City Post Office, from the Secretary of the Civil Service Commission, Ottawa, or from The Engineering Institute of Canada, Montreal.

Candidates must be British subjects, and have resided in Canada for at least five years.

Situations Wanted

PURCHASING AGENT. Graduate mechanical engineer, Canadian, married, age 36, with fourteen years experience in industrial field, including design, construction and operation, eight years of which had to do with the development of specifications and ordering of equipment and materials for plant extensions and maintenance; one year engaged on sale of surplus construction equipment. Full details on request. At present employed. Apply to Box No. 161-W.

SALES ENGINEER, S.E.I.C.; B.SC. C.E., 1930 (Univ. New Bruns.), P.E.N.B. Age 28. Experience includes building inspection, structural detailing, road construction, and chemical operation. Interested in sales work on the sales staff of some manufacturing or wholesale concern. Apply to Box No. 225-W.

REINFORCED CONCRETE ENGINEER, B.SC., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

Situations Wanted

ENGINEER AND ACCOUNTANT, JR.E.I.C., (Capt. Can. Engrs., reserve). Age 35, Canadian. Experienced in mechanical and civil engineering, Diploma; general office, draughting and instrument work; assistant engineer erection Royal York hotel; assistant resident engineer T. & N.O. Ry. const. Desires position in Toronto where combination of technical and business experience will be of value, as have been director and accountant last three years. Apply to Box No. 377-W.

CIVIL ENGINEER, B.A.SC. and C.E.; A.M.E.I.C., JUN. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.SC. Univ of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

Employment Service Bureau

This bureau is maintained by The Engineering Institute of Canada for the benefit of members and organizations employing technically trained men.

An enquiry addressed to 2050 Mansfield Street, Montreal, will bring full information concerning the services offered. Details can also be obtained from Branch secretaries who are located in the larger centres throughout Canada.

Brief announcements of men available and positions vacant will be published without charge in The Engineering Journal and the Bulletin. Replies addressed in care of the required box number will be forwarded to the advertiser without delay.

An additional service also offered those who are unemployed or wish to change their positions, is the opportunity of placing their names and records on file at 2050 Mansfield Street for consideration by employers wishing to employ engineers. This is of great assistance as many employers will not advertise or wish to locate a suitable man on short notice. If desired the information contained in these records can be kept confidential.

Forms for registration purposes may be obtained from The Institute Headquarters of Branch secretaries.

MECHANICAL ENGINEER, B.SC. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

CONSTRUCTION ENGINEER, age 26, unmarried, graduate C.E. Experience includes hydro-electric, railroad, highway, and industrial plant construction, both field and office, including cost accounting, estimating, stores, layout, general engineering and supervision, as well as practical work in mechanical trades. Apply to Box No. 567-W.

MECHANICAL ENGINEER, A.M.E.I.C. Experienced on plant maintenance, steel plant, cement plant and mining plants. Available on short notice. Apply to Box No. 571-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

Situations Wanted

ELECTRICAL ENGINEER, McGill '31, desires permanent position in engineering field. Experience includes draughting, designing and testing of induction motors, radio supervision and test, and some construction. Available immediately. Apply to Box No. 626-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W

ELECTRICAL ENGINEER, B.SC. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial Apply to Box. No 651-W.

ELECTRICAL ENGINEER, Univ. Grad. 1928. Two years Students' apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660 W.

ELECTRICAL AND RADIO ENGINEER, B.SC. '30 Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC., Elec., '29, B.SC., Civil '33. Age 27. JR.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.SC., '27, JR.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.SC., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.SC. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.SC. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box. No 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.SC., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

Situations Wanted

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.Sc. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, JR.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten years diversified electrical and mechanical experience in the industrial field. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box. No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

Situations Wanted

AGENCIES WANTED. Young engineer, B.A.Sc. in C.E., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W

CIVIL ENGINEER, B.A.Sc., JR E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.
