He then visualized new industries, particularly ship building on the 8,300 mile shore line of the Great Lakes which would bring increased prosperity to the people of Canada and United States. He felt that even if the St. Lawrence Seaway was not justified as an economic project, the total cost would be in the neighbourhood of $350,000,000, it was justified as a defense measure as it would enable us to build cruisers, destroyers and all but the largest vessels, thousands of miles inland where the building of them would be less likely interferred with by hostile aircraft.

In the discussion that followed J. L. Lang objected to the building of the Seaway at the present time. He felt that we could bend our endeavours to more timely matters. He felt that all our energies would be required to win the war.

The chairman thanked the speaker on behalf of the branch. On motion of K. G. Ross, the meeting adjourned.

WINNIPEG BRANCH

C. P. Haltalin, M.E.I.C. - *Secretary-Treasurer*
T. A. Lindsay, M.E.I.C. - *Branch News Editor*

The Winnipeg Branch met on Thursday, April 3rd, 1941, in the Theatre of the University of Manitoba, to see two very interesting and unusual coloured movies, contributed through the courtesy of the Department of Mines and Natural Resources, Province of Manitoba.

The first movie, **Base Line Survey,** was prefaced with remarks by Mr. H. E. Beresford, director of Surveys. The film showed operations of the survey party, while running the base line from the principal meridian to a point some 140 miles west.

This survey was made in January, 1940, and the picture gave some idea of the problems involved in maintaining a mobile camp unit hundreds of miles from civilization, in the dead of winter. A Provincial Government Forestry Service plane attended the party, and was used to transport supplies and equipment. A two-way radio set provided communication with the outside world.

In the discussion which followed the showing of the film, Professor G. H. Herriot questioned Mr. Beresford regarding the cost of the completed survey. Mr. Beresford stated that the base line survey in question was performed very economically at a cost of $65.00 per mile.

The Hon. J. S. McDiarmid, Minister of Mines & Natural Resources, gave a running commentary on the second film, **The Summerberry Fur Rehabilitation Project.**

Mr. McDiarmid explained that the Summerberry marshes include a large tract of land lying to the east of the Pas. Many years ago this region was a productive fur bearing territory, but due to the receding water table and continued drought, the shallow lakes and creeks had dried up, and left the marshes devoid of practically all vegetable and animal life. Trappers, who found their only means of subsistence reduced to the vanishing point, were forced to go on relief. In order to alleviate this situation, the Natural Resources Branch made quite an intensive study of the marshes and decided to undertake their restoration. It was found that by diverting the flood waters of the Saskatchewan river into the Summerberry river, the marshes could be flooded, and sufficient water could be retained throughout the summer to make a natural habitat for the muskrat.

A construction programme was launched, control dams were constructed, and canals cut at predetermined locations. During the past few years 140,000 acres of dried-out marsh land has been re-flooded, and as a result there has been an extraordinary increase in the wild life of the area. The abundance of vegetation has provided an ideal home for the muskrat, and the fact that the area has been closed to trappers up until 1940 has given the rats an opportunity to multiply.

The movie showed interesting pictures of the marshes before and after the project was started, illustrated how the area is patrolled and administered, displayed typical trapping operations, and also pictured some of the finer details of skinning and stretching the pelts. In 1940 the first fur harvest was taken from the Summerberry area, and yielded 120,000 pelts, which were sold at public auction for approximately $170,000. In harvesting this muskrat crop, 275 trappers were employed, and these men received the proceeds of the fur sale less the cost of administration and a portion which is set aside to repay the original capital investment.

Mr. McDiarmid claimed that the scheme had been very successful, especially from the point of view of providing a livelihood for the trappers in that district.

Mr. E. V. Caton moved a hearty vote of thanks to Mr. McDiarmid and the staff of the Natural Resources Branch, and the meeting then adjourned for refreshments.

Library Notes

Book notes, Additions to the Library of the Engineering Institute, Reviews of New Books and Publications

ADDITIONS TO THE LIBRARY

TECHNICAL BOOKS

Concrete Products and Cast Stone:

By H. L. Childe, London, Concrete Publications Limited, 1940. 263 pp., 6½ by 9¾ in.

Cracking Art in 1939:

Published by Universal Oil Products Company, Chicago. 617 pp.

Electromagnetic Devices:

By Herbert C. Roters, New York, John Wiley & Sons, Inc., 1941. 561 pp. 6 by 9¼ in., $6.00.

Engineers' Manual of Statistical Methods:

By Leslie E. Simon, New York, John Wiley & Sons, Inc., 1941. 231 pp. 6½ by 9¾ in., $2.75.

Hydraulic Measurements:

By Herbert Addison, New York, John Wiley & Sons, Inc., 1941. 301 pp. 5½ by 8¾ in., $5.00.

Non-Ferrous Production Metallurgy:

By John L. Bray, New York, John Wiley & Sons, Inc., 1941. 430 pp. 6 by 9¼ in., $4.00.

Public Works Engineers' Yearbook, 1941:

Published by American Public Works Association, Chicago, 404 pp. 5½ by 8¾ in.

REPORTS

Bell Telephone System:

Insulating paper in the telephone industry; note on theoretical and observed distributions of repetitive occurrences; diffusion of sulphur in rubber; location of hysteresis phenomena in Rochelle salt crystals; description of the C-5 carrier telephone system; dielectric properties of organic compounds; new broadcast-transmitter circuit design for frequency modulation; neutron studies of order in Fe-Ni Alloys; decade of progress in use of electronic tubes—part 1, communication. Monographs B-1260-B-1268.

Canada Department of Mines and Resources—Mines and Geology Branch:

Investigations in ore dressing and metallurgy, July to December, 1939. Ottawa, 1941.

Canada Department of Mines and Resources—Mines and Geology Branch —Geological Survey—Memoirs:

Palaeozoic geology of the Toronto-Hamilton area, Ontario; Pictou coalfield, Nova Scotia; Jacquet river and Tetagouche river map-areas, New Brunswick; Nelson map-area, east half, British Columbia. Memoirs 224, 225, 227, 228.

Canadian Engineering Standards Association:

Canadian electrical code, part 11—essential requirements and minimum standards covering electrical equipment. Specification No. 1 construction and test and power-operated radio devices. Section B—conductively coupled (transformerless) type. Ottawa, 1941, C22.2 No. 1 (B)-1941. Canadian electrical code, part 2, essential requirements and minimum standards covering electrical equipment, construction and test of armoured cables and armoured cords, No. 51. Canadian electrical code part 2, essential requirements and minimum standards covering electrical equipment, construction and test of service-entrance cables, No. 52.

Illinois State Water Survey—Bulletin:

Water resources in Peoria-Pekin district. Bulletin No. 33, Urbana, Illinois, 1940.

United States Department of the Interior—Bureau of Mines—Bulletin.

Reconnaissance of gold mining districts in the Black Hills, S. Dak.; fire-retardant treatments of liquid-oxygen explosives; quarry accidents in the United States during the calendar year 1938. Bulletin 432, 429, 427.

United States Department of the Interior —Geological Survey Bulletin.

Spirit leveling in Texas, part 2, Panhandle 1896-1939; sub-surface geology and oil and gas resources of Osage County, Oklahoma; structural control of ore deposition in the Uncompahgre district Ouray County, Colo.; quicksilver deposits of the Mayacmas and sulphur bank districts California; chromite deposits of the eastern part of the still-water complex, Stillwater County, Montana; tungsten deposits in the tungsten hills, Inyo County, California; tungsten deposits of the Benton Range, Mono County, California. Bulletins, 883-B; 900-F; 906-E; 922-L; 922-N; 922-Q; 922-S; 925-A.

United States Department of the Interior —Geological Survey Water-Supply: Paper:

Summary of records of surface waters of Washington, 1919-35; surface water supply of the United States 1939, part II, Pacific slope basins in California; surface water supply of the United States, 1939, part 14, Pacific slope basins in Oregon and lower Columbia River basin; water levels and artesian pressure in observation wells in the United States in 1939. Papers, 870, 881, 883, 886.

United States Department of the Interior —Bureau of Mines—Technical Papers:

Coke-oven accidents in the United States; increasing the concentration of sulphur dioxide in the effluent gases from dwight-Lloyd sintering machines treating lead products; thermodynamic properties of gypsum and its dehydration products; production of explosives in the United States; splint coals of the Appalachian region; their occurrence, petrography, and comparison of chemical and physical properties with associated bright coals; carbonizing properties and petrographic composition of lower banner-bed coal from Keen mountain mine, Buchanan county, Va., and the effect of blending this coal with Pittsburgh-bed (warden mine) coal; characteristics of fuel pitches and their explosibility in pulverized form; hydrogenation and liquefaction of coal. Papers, 623, 624, 625, 627, 615, 616, 617, 622.

United States Work Projects Administration—Bibliography of Aeronautics:

Supplement to part 17—diesel aircraft engines, 1940; supplement to part 29—lubricants, 1941.

PROCEEDINGS AND TRANSACTIONS, ETC.

Canadian Institute of Mining and Metallurgy.

Directory section, list of members, 1941.

American Institute of Mining and Metallurgical Engineers, Inc.

Transactions of the Canadian Institute of Mining and Metallurgy and of the Mining Society of Nova Scotia, 1940.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet the books are not in the Institute Library, but inquiries will be welcomed at headquarters, or may be sent direct to the publishers.

Air Raid Precautions Handbook No. 11, CAMOUFLAGE OF LARGE INSTALLATIONS

His Majesty's Stationery Office, London. 15 pp., illus., 6½ x 4 in., paper, (obtainable from British Library of Information, 50 Rockefeller Plaza, New York, $.10).

This pamphlet describes in general terms the measures which may be taken by way of camouflage to render factories and other buildings less distinguishable from the air. Illustrations and color plates are included.

AIRPLANE METAL WORK. Vol. 3:—Airplane Sheet Metal Pattern Development and Template Making.

By A. M. Robson. D. Van Nostrand Co., New York, 1941. 102 pp., illus., diagrs., tables, 9½ x 7 in., paper, $1.25.

Intended both for mechanics actively engaged in the aircraft industry and for prospective mechanics in training, this book is designed to provide a correlation of the fundamentals of general sheet-metal pattern development to the aircraft industry. Resulting from the author's practical experience, it covers basic operations, calculations, actual pattern development and comprehensive lists of tools and shop equipment.

(The) ANODIC OXIDATION OF ALUMINIUM AND ITS ALLOYS

By A. Jenny, translated by W. Lewis. Chemical Publishing Co., New York, 1940. 231 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $6.50.

This monograph deals with the electrolytic and chemical production of protective films on aluminum and its alloys, and with their uses in practice. An introductory study of the relevant electrochemical theory is presented. The original text, as translated from the German, has been supplemented with additional information.

CHEMICAL WARFARE

By C. Wachtel. Chemical Publishing Co., Brooklyn, N.Y., 1941. 312 pp., diagrs., tables, 9 x 5½ in., cloth, $4.00.

This currently important topic is covered in all of its ramifications. The history of the subject, including the men responsible for its development, is briefly presented; the various classifications of gases by composition and physiological effects are given in detail; and statistics and other pertinent material are included. Both the practical military application of the gases and protection against them are considered.

COMPOSITION OF FURNACE ATMOSPHERES RESULTING FROM PARTIAL COMBUSTION OF GASEOUS FUELS

(American Gas Association Testing Laboratories, Bulletin No. 11).

Cleveland, Ohio, 1940. 91 pp., illus., diagrs., charts., tables, 10 x 7 in., paper, $1.25.

Four progress reports and some new data

are summarized in this bulletin which deals specifically with studies of the composition of flue gases resulting from combustion of different types of fuel gases with a deficiency of air. The test equipment and procedure are described, results are discussed, and a practical interpretation of the data is presented.

DESIGN FOR INDUSTRIAL CO-ORDINATION

By R. W. Porter. Harper & Brothers, New York and London, 1941. 249 pp., diagrs., charts, 9½ x 6 in., cloth, $3.00.

This book, the work of a management consultant of long experience, shows how and why the structure of business organization and the elements of co-ordination which make it function efficiently form a technical design within which management must operate for best results. The problems of industrial management are classified, and twenty-one elements of performance are given upon which the author bases the effectiveness of the general pattern. A late chapter indicates ways to measure results.

DESIGN OF MACHINE ELEMENTS

By V. M. Faires. rev. ed. Macmillan Co., New York, 1941. 490 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.00.

PROBLEMS ON THE DESIGN OF MACHINE ELEMENTS

By V. M. Faires and R. M. Wingren. Macmillan Co., New York, 1941. 147 pp., illus., diagrs., charts. tables, 8½ x 6 in., paper, $1.40.

The beginning chapters of this textbook cover briefly the general topics of materials and their properties, stress analysis, tolerances and fatigue. Although the conventional method of grouping the subsequent design material is generally followed, the simpler machine elements have been considered first to allow the subject to be studied concurrently with strength of materials. The new edition has been considerably revised in accordance with recent developments. A companion volume contains nearly 1,200 problems illustrating points made by the text.

DYKE'S AUTOMOBILE AND GASOLINE ENGINE ENCYCLOPEDIA

By A. L. Dyke. 19th ed. Goodheart-Willcox Co., Inc., Chicago, 1941. 1,483 pp., illus., diagrs., charts, tables, 10 x 7 in., cloth, $6.00.

A remarkably comprehensive collection of information on automobiles and internal-combustion engines is presented in this manual for the use of students, repairmen and owners. Topics covered include the principles, description and operation of all mechanical, propulsive and electrical parts of an automobile, maintenance, testing and repair, specifications and definitions. There is new material on aircraft engines and their accessories, automotive Diesels, fluid drive, automatic transmissions and other recent developments. A wealth of illustrations and ninety pages of general and supplementary index increase the utility of the book.

ELECTROMAGNETIC DEVICES

By H. C. Roters. John Wiley & Sons, New York, 1941. 561 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $6.00.

The fundamentals, characteristics and designs of electromagnets are presented for graduate students and practical engineers. The first eight chapters develop the background theory and methods applicable to all types of magnetic circuits and non-rotary electromagnetic devices. In the last six chapters these principles are applied to a variety of problems, first in general terms, then in detailed, numerical solutions. Special attention is paid to magnetic leakage and non-linear relationships.

ELEMENTARY AERODYNAMICS

By D. C. M. Hume. Pitman Publishing Corporation, New York and Chicago, 1941. 136 pp., diagrs., charts, tables, 8½ x 5½ in., cloth, $1.50.

This textbook for beginning students presents the fundamentals of air flow, forces on a wing, control methods, analyses of basic manoeuvres and performance characteristics. There is a set of test questions for review purposes.

FLUID MECHANICS

By G. N. Cox and F. J. Germano. D. Van Nostrand Co., New York, 1941. 274 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.00.

This practical textbook on the behavior of fluids is intended to prepare engineering students for problems encountered in the industrial field, and covers both liquids and gases. The text is divided roughly into five parts: hydrostatics, measurement, transportation and dynamics of fluids, and centrifugal pumps. The necessary basic theoretical treatment is included, and there are many problems from actual practice.

Great Britain, Dept. of Scientific and Industrial Research, BUILDING RESEARCH. WARTIME BUILDING BULLETIN No. 13. THE FIRE PROTECTION OF STRUCTURAL STEELWORK

His Majesty's Stationery Office, London, 1941. 13 pp., diagrs., tables, 11 x 8½ in., paper, (obtainable from British Library of Information, 50 Rockefeller Plaza, New York, $.30).

Amplifying certain points brought out in Bulletin No. 10, this pamphlet shows how to determine the degree of protection required for structural members, and discusses various methods available for treating both old and new structures.

HIGH-SPEED COMPRESSION-IGNITION ENGINE

By C. B. Dicksee. Blackie & Son, London and Glasgow; Interscience Publishers, New York, 1940. 331 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.50.

The principles governing the operation of high-speed compression-ignition engines are dealt with in detail, including discussions of associated problems. The early chapters present the fundamental chemical and thermodynamical theory. There is a particularly large chapter on fuel injection.

THE HIGH-SPEED INTERNAL-COMBUSTION ENGINE

By H. R. Ricardo, revised by H. S. Glyde. Interscience Publishers, New York; Blackie & Son, Ltd., London and Glasgow, 1941. 434 pp., illus., diagrs., charts, tables, 10 x 6½ in., cloth, $7.50.

This comprehensive, authoritative work upon the characteristics and design of high-speed internal-combustion engines has been revised again to conform with current practice. There has been some addition and deletion in the standard material on engine design and fuel behavior, while other parts, the chapter on high-speed Diesels in particular, have been completely rewritten.

HIGHWAY SAFETY AND AUTOMOBILE STYLING

By A. W. Stevens. Christopher Publishing House, Boston, Mass., 1941. 155 pp., diagrs., 8 x 5 in., cloth, $1.75.

The author describes the general conditions of highway travel, points out various factors of importance in causing accidents, and suggests remedies. The emphasis is on the redesign of automobiles to put the driver at the very front of the car, in order to increase visibility. The conclusions are the result of a six-year investigation of the problem.

HISTORY OF MAGIC AND EXPERIMENTAL SCIENCE, Vols. 5 and 6: The Sixteenth Century.

By L. Thorndike. Columbia University Press, New York, 1941. Vol. 5, 695 pp.; Vol. 6, 766 pp., 9 x 5½ in., cloth, $10.00 per set of 2 Vols.

With these two volumes, covering approximately the period from 1500 to 1630, Professor Thorndike completes his monumental study of magic and experimental science during the first sixteen centuries of the Christian era. In his integration of the two fields, in his exposition of the inter-relations of science and society and in the considerable amount of new material presented, the author has produced a valuable work for scholar and historian. A general index to the whole series, occupying some 150 pages, is included in the sixth and last volume.

INSTRUMENTS, Pt. 2 (Aeroplane Maintenance and Operation Series, Vol. 15).

Ed. by E. Molloy and E. W. Knott. Chemical Publishing Co., Brooklyn, N.Y., 1941. 132 pp., illus., diagrs., 9 x 5½ in., cloth, $2.00.

Continuing a series on airplane maintenance and operation, this volume describes the operation, installation and maintenance of the various instruments (indicators, compasses, etc.), manufactured by the Kelvin, Bottomley and Baird Company. There is a long chapter dealing with the Smith automatic Pilot, and a brief description of electrical temperature measuring instruments is given.

MATERIALS OF INDUSTRY

By S. F. Mersereau, with an introduction by A. L. Colston. rev. and enl., McGraw-Hill Book Co., New York and London, 1941. 578 pp., illus., diagrs., maps, tables, 8½ x 5½ in., cloth, $2.00.

This textbook is intended to give students in technical and vocational high schools some knowledge of the main facts of industry, including the distribution and production of raw materials, their general properties, transportation, conversion into commercial products and economic importance. The principal products of forestry, mining and chemical industry are described clearly and simply. Glossaries of terms and brief bibliographies are included.

MODERN PRACTICE IN LEATHER MANUFACTURE

By J. A. Wilson. Reinhold Publishing Corp., 1941. 744 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $9.50.

The object of this comprehensive treatise is to present what is considered the minimum that a tanner should know in order to conduct a modern business successfully. To this end the more important phases of leather manufacture, such as preparing, tanning and finishing procedures, and the structure and properties of leather, are given in detail. Other topics covered include sources of hides and other materials, government regulations, hide damages, purchasing, marketing and other economic factors. The complex chemical reactions in tanning are discussed in non-technical language. Full bibliographies, a glossary of terms and many microphotographs are included.

NON-FERROUS PRODUCTION METALLURGY

By J. L. Bray. John Wiley & Sons, New York, 1941. 430 pp., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.

Intended as a basic college text, this book deals in alphabetical order with the non-ferrous metals. It gives brief information about their history, economics, properties, marketing, uses and ores, and the working essentials of production and refining practice. Space is also given to slags and fluxes, secondary metals and the marketing of bullion, ores and concentrates. Suggested references accompany each chapter.

Pennsylvania State College, Engineering Experiment Station Bulletin No. 54. OXYGEN-BOOSTING OF DIESEL ENGINES FOR TAKE OFF

By P. H. Schweitzer and E. R. Klinge. State College, Pa., 1941. 29 pp., illus., charts, diagrs., tables, 9 x 6 in., paper, $.50.

This pamphlet describes an investigation to determine the effect of feeding oxygen into the intake air of a diesel engine. Results are given, and special reference is made to the use of this procedure in the case of airplane diesels during take-off time when extra power is necessary for a few minutes.

PIT AND QUARRY HANDBOOK with which is consolidated the DIRECTORY of Cement, Gypsum, Lime, Sand, Gravel and Crushed-Stone Plants. 34 ed. 1941.

Complete Service Publishing Co., Chicago, Ill., 1941, 856 pp., illus., diagrs., charts, tables, 11 x 8 in., cloth, $10.00.

Nearly 600 pages of the current edition of this annual are devoted to technical information concerning processes, practices, machinery and materials in the non-metallic mineral industries. There is a directory of cement, gypsum, lime, sand, gravel and crushed-stone plants, arranged both alphabetically and geographically. Condensed machinery catalog, a list of trade associations and technical societies, statistical information, trade names and a buyers' guide are also included.

PREVENTION OF THE FAILURE OF METALS UNDER REPEATED STRESS, a Handbook prepared for the Bureau of Aeronautics, Navy Department.

By the Staff of Batelle Memorial Institute. John Wiley & Sons, New York, 1941. 273 pp. illus., diagrs., charts, tables, 9½ x 6 in., cloth, $2.75.

Believing that lack of knowledge or appreciation of engineering principles among designers and builders of aircraft is responsible for many fatigue failures, this summary has been prepared. It brings together in convenient form the available information concerning the engineering principles involved in the precautions through which fatigue failures may be prevented, as they appear in published literature and the files of the Bureau of Aeronautics and the National Bureau of Standards. There is a good bibliography.

PROCEDURE HANDBOOK FOR AIRCRAFT STRESS ANALYSIS

By W. L. Nye, D. Hamilton and J. P. Eames. Aviation Press, San Francisco, Calif., 1940. 334 pp., illus., diagrs., charts, tables, $4.00.

This textbook was compiled to present as simple a treatment as possible on the subjects of strength of materials and stress analysis as applied to the present-day airplane. It deals with the fundamentals of aircraft stress analysis and presents examples which are currently encountered in conventional airplane design work. Particular attention is given to the solution of beams by polar diagrams, the shell type of structure and the theory of joints.

PSYCHROMETRIC NOTES AND TABLES

By E. Torok. rev. ed. North American Rayon Corporation, 261 Fifth Ave., New York, 1941. 125 pp., charts, tables, 7 x 5 in., lea., $2.50.

This handbook for textile manufacturers, engineers and students presents the necessary information, accompanied by practical examples, for the solution of psychrometric problems. There is also a chapter containing tables of heat-transmission coefficients for building materials.

PUBLIC UTILITY ECONOMICS

By C. W. Thompson and W. R. Smith. McGraw-Hill Book Co., New York and London, 1941. 727 pp., illus., maps, charts, tables, 9½ x 6 in., cloth, $4.50.

Designed as a textbook for advanced students in economics and commerce, this book relates the field of public utilities to the broader area of economics of which it is a part. Thus the book seeks to acquaint the student with the place which public utilities occupy within our economic structure, and with the special problems of price control, service supervision, security regulation, etc.

REFRIGERATION FUNDAMENTALS

By G. Holman. Nickerson & Collins Co., Chicago, Ill., 1940. 175 pp., diagrs., charts, tables, 9½ x 6 in., cloth, $2.00.

Written by an operating engineer for other operating engineers, this outline of refrigeration theory and practice begins with simple discussions about such physical phenomena as temperature, heat, pressure and energy. Basic refrigeration processes are carefully described, and there are helpful practical suggestions on operating technique.

STRUCTURAL DRAFTING

By C. T. Bishop. John Wiley & Sons, New York, 1941. 287 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.50.

This book has been prepared especially to meet the requirements of engineering students and structural draftsmen. It corresponds in scope to the duties of the structural-steel draftsmen in the preparation of detailed working drawings for the members of steel structures. Drawings for concrete and timber structures are also discussed briefly, and billing practice is covered. There are many detailed illustrations, and a glossary of engineering terms is provided.

TECHNOLOGY AND SOCIETY, the Influence of Machines in the United States

By S. M. and L. Rosen, with an introductory chapter by W. F. Ogburn. Macmillan Co., New York, 1941. 474 pp., illus., charts, tables, maps 9 x 5½ in., cloth, $3.00.

The interrelations between technology and the social scheme as they affect present-day life are presented in a simple, balanced manner. In addition to the four main sections, dealing respectively with the technologic base and economic, social and political effects, there is a general introductory chapter and a final summing up. The book is intended particularly for undergraduate students, both in the social sciences and engineering. Suggestions for further reading are included.

TEMPERATURE MEASUREMENT

By R. L. Weber. Edwards Brothers, Inc., Ann Arbor, Michigan, 1941. 171 pp., illus., diagrs., charts, tables, 11 x 8½ in., paper, $2.50.

This book presents the substance of a course offered for juniors by the physics department of the Pennsylvania State College. Part I covers in a concise manner the theoretical basis for all the important methods of temperature measurement. Part II contains a comprehensive group of tested illustrative laboratory experiments. Literature references and review exercises are included.

(The) WORLD AND THE ATOM

By C. Moller and E. Rasmussen, with foreword by N. Bohr. D. Van Nostrand Co., New York, 1940. 199 pp., illus., diagrs., charts, tables, 9 x 5½ in., cloth, $2.75.

The development of modern atomic physics from the end of the last century to 1938 is briefly described for the layman. The major part of the book has been kept as simple as possible, and general physical concepts have been included wherever necessary. The book has been translated and revised from the original Danish, and is the product of the joint work of an experimental physicist and a theoretical physicist.

BIBLIOGRAPHY ON INDUCTION HEAT TREATMENT

The Engineering Societies Library has prepared a list of selected references on the heat treatment of metals by induction heating. Forty papers of importance are listed, selected from domestic and foreign periodicals, dealing with the metallurgical problems involved, the design of heating coils and electrical circuits, and with typical actual installations.

Members of the Founder Societies may obtain copies by sending $1.00 to the Engineering Societies Library, 29 West 39th Street, New York. The price to others is $1.25.

PRELIMINARY NOTICE

of Applications for Admission and for Transfer

May 29th, 1941

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in July, 1941.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A **Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A **Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinstions specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A **Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An **Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

GOROWSKI—CHARLES S., of 1457 Mansfield St., Montreal, Que. Born at Winnipeg, Man., Feb. 26th, 1913. Educ.: B.Sc. (Elec.) Univ. of Manitoba, 1934. May and June 1940, engr., levelling work for W. E. Seely, M.E.I.C.; July to Dec., 1940, engr. on C.N.R. Tunnel, Durite Co. of Quebec; Dec. 1940 to date, engr., Canadian Associated Aircraft Ltd., Montreal.

(*Continued on page 323*)

Employment Service Bureau

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.

SITUATIONS VACANT

GRADUATE MECHANICAL ENGINEER in good health, energetic, to work with large industrial concern in British Guiana. Applications should be sent to Box No. 2328-V.

CONSTRUCTION MAN with experience in heavy construction for either a long or short term contract in British Guiana. Applications should be addressed to Box No. 2330-V.

GRADUATE ENGINEER with at least two years practical experience in a tool room to act as an instructor in the Apprentice School of a large industrial concern. Apply Box No. 2344-V.

REQUIRED a number of experienced concrete detailers, designers and draughtsmen for work on industrial plants and power developments. Apply Box No. 2351-V.

MECHANICAL DESIGNING DRAUGHTSMAN with experience for permanent position with firm engaged in war work. Apply Box No. 2375-V.

ARCHITECTURAL DRAUGHTSMEN required immediately by large industrial concern for their Montreal office. Apply Box No. 2376-V.

SITUATIONS WANTED

GRADUATE ELECTRICAL ENGINEER, University of Toronto, five years experience drafting and design in connection with electrical instruments and small motors. Also experienced in design of small jigs and fixtures and general machine design. Desires permanent position. Apply to Box No. 1486-W.

GRADUATE MECHANICAL ENGINEER, M.E.I.C., 14 years' experience as factory manager in machine tool factory and as consulting industrial engineer in widely diversified metal working trades improving factory and office methods specially cost accounting, desires permanent position. Apply to Box No. 1730-W.

WANTED

Would purchase complete surveying equipment in good condition. Write, giving complete list with catalogue numbers and sale price. State where delivered. Box No. 43-S.

A.I.E.E. SUMMER CONVENTION

With the 1941 Summer Convention of the American Institute of Electrical Engineers only a month away, plans for the meeting are now practically completed and the Royal York Hotel reports that many reservations have already been received.

The programme of inspection trips has been slightly enlarged since it was first drawn up, and a new trip has been arranged for delegates interested in highway lighting to travel out along the Queen Elizabeth Way on the evening of Wednesday, June 18th. This modern four-lane highway is the longest stretch of highway lighting in the world, and the Wednesday evening inspection trip should be a popular one.

Complete details of the technical programme are not yet available, but it may reliably be stated that papers by seven Canadian engineers are to be included in the programme. Three of these Canadian papers come under the heading of "Power Transmission and Distribution." James W. Speight, of the Hydro Electric Power Commission of Ontario, will give a paper on "Conductor Vibration—the Theory of Torsional Dampers," and Gordon B. Tebo, also of the Ontario Hydro, will give one on "Measurements and Control of Conductor Vibration."

Another interesting paper to be heard at a Power Transmission and Distribution session will be one on "The 220,000-Volt System of the Hydro Electric Power Commission of Ontario." This is to be a joint presentation by A. H. Frampton and E. M. Wood.

The Canadian paper to be presented at the Land Transportation Session is that on "Glass-Bulb Mercury-Arc Rectifiers for Traction Service" by Charles E. Woolgar, of the Northern Electric Co. Ltd.

Other Canadian papers which will likely be presented are: "Canadian Broadcasting Systems" by A. Frigon, Canadian Broadcasting Corporation; "Mechanical Simplicity of Air-Blast Circuit Breakers" by H. W. Haberl, Montreal Light, Heat & Power Consolidated; and Otto Jensen I-T-E Circuit Breaker Co.; "A Distribution System for Wartime Plant Expansion" by J. L. McKeever, Canadian General Electric Co. Ltd.

PRELIMINARY NOTICE (*Continued from page 322*)

MONAGHAN—CECIL, of 10726–106th Street, Edmonton, Alta. Born at Edmonton, Feb. 5th, 1916. Educ.: B.Sc. (Elec.) Univ. of Alberta, 1939. 1938 (6 mos). surveyor, City of Edmonton; 1940, Apr. to Dec., jr. engrg. clerk, and 1941, Jan. to date, senior engrg. clerk, City of Edmonton Electric Light & Power Dept. (St. 1939).

References: W. E. Cornish, H. R. Webb. R. M. Hardy.

MYERS—GORDON ALEXANDER, of Clarenville, Nfld. Born at Bay Roberts, Nfld., April 19th, 1915. Educ.: B.E. (Elec.) N.S. Tech. Coll. 1936. 1936 (summer) paving inspr., Milton Hersey Co. Ltd.; 1936 (Sept. to Dec.) second i/c of survey for Highroads Divn., Nfld. Govt.; 1937 (Jan. to July) and Oct. 1939 to Apr. 1940 own radio business, repairs and sales; 1937 (Aug. to Oct.) chemist, and 1938 (May to Oct.) chief chemist, Colas Nfld. Ltd., Clarenville, mfrs. of asphaltic paving emulsions; Nov. 1937 to Apr. 1938, and Nov. 1938 to Apr. 1939, electrician, Nfld. Airport, inst'lln. opera. and mtce.; May 1940 to date acting mgr. and res. engr. Colas Nfld. Ltd. i/c of machinery, mfg. processes and all mtce., and i/c of extension to plant. (St. 1937).

WONG—HENRY GOE, of 1090 Chenneville St., Montreal, Que. Born at Montreal Dec. 27th, 1913. Educ.: B.Eng., McGill Univ., 1935. 1935-39, res. engr., Avon Gold Mines, Ltd., Oldham, N.S.; 1939, field engr. Belmont Constrn. Co. Ltd., Montreal; 1940 dftsmn., Canadian Car Munitions Ltd., St. Paul L'Ermite, Que.; 1940, field engr., Atlas Constrn. Co. Ltd., Montreal; 1941, dftsman., Federal Aircraft Ltd. (St. 1934).

References: A. Olsen, R. A. Young, H. R. Montgomery.

MOTORS

The various types of motors manufactured by Canadian Westinghouse Co. Limited, are illustrated and described in their new 16-page bulletin, H-7048. Construction features, typical specifications, and details covering stator winding and insulation are given.

SPECIAL IRON CASTINGS FOR HEAVY MACHINERY

An 8-page reprint from "Metals and Alloys" which is being distributed by E. Long Limited, Orillia, Ont., gives a pictorial account of the production of special iron castings for heavy machinery, using "Meehanite," a special cast iron made by a proprietary process.

SOUND ABSORBING MATERIAL

An attractive and interesting 12-page brochure has been published by Alexander Murray & Co. Ltd., Montreal, Que., entitled "Quiet Please," this publication features the company's acoustical material "Donnacousti," and contains information on sound, its characteristics, reactions, and methods for its absorption. It contains installation photographs and drawings and specifications. The product is made in Canada.

TRUCK MOUNTING ROTARY PUMPS

Bulletin 1505, published by Viking Pump Co. of Canada, Ltd., Windsor, Ont., gives dimensional specifications, illustrates and describes Viking Truck mounting rotary pumps for fire trucks and street washers.

WATER TEMPERATURE CONTROLS

Powers automatic thermostatic temperature controllers for use in showers and various industrial applications are described and illustrated in a 4-page folder, No. 3017, recently issued by Canadian Powers Regulator Co. Ltd., Toronto, Ont. This folder contains table of list prices, capacities, and shipping weights.

FENCE PRODUCTS

Catalogue, No. 25, is the designation of a new 44-page "General Fence Catalogue," covering the wide range of fence products and fence erection tools made by The Steel Co. of Canada, Ltd., Montreal, Que., and Hamilton, Ont. It is well illustrated and contains much useful information with specifications and many designs for fences for every purpose.

GRIT COLLECTOR AND WASHER

A 4-page folder, No. 1942, published by Link-Belt Limited, Toronto, Ont., describes and illustrates the "Link-Belt Straight-line Grit Collector and Washer" for collecting, washing and removing settled grit from sewage. This grit chamber equipment consists of a conveyor with pitched flights to turn the material over and over, and an inclined washing and dewatering screw into which the collector-conveyor discharges.

ASPHALT

Six new publications of The Asphalt Institute, New York, N.Y., have been made available to officials, engineers, technologists, and the industry. The titles are as follows:—

R.S. No. 6, "The Significance of Various Methods of Test Used on Asphaltic Paving Materials"; R.S. No. 7, "A Direct Method of Determining Thickness of Asphalt Pavement with Reference to Subgrade Support"; C.S. No. 54, "The Washington National Airport and Choice of Surfacing Types for Airports"; C.S. No. 55, "Specification for Asphalt Enamel Protective Coatings for Steel Water Pipe"; C.S. No. 56, "Asphalt for Heavy-Duty Highways"; Pocket Reference Manual for Highway Engineers. A new edition, 256 pages.

PORTABLE ELECTRIC TOOLS

Black & Decker Mfg. Co. Ltd., Toronto, Ont., have issued a 62-page catalogue which describes and illustrates the Company's many portable electric tools, attachments and accessories. Among these are included: drills, hole saws, tool chests, drill stands, screw drivers, nut runners, tappers, saws, hammers, lectroshears, die grinders, bench grinders, portable grinders, clean and shine shop, valve seat grinders, vacuum cleaners, valve refacers, valve lapper, valve shop, heat gun, glue pot, surfacer, sanders, buffers.

RESURFACING FLOORS

Entitled "Busy Factories Need Quick Repairs," a 4-page folder issued by Flexrock Company, Toronto, Ont., features the repairing and resurfacing of industrial and other floors with "Ruggedwear Resurfacer" and the Company's new special type "Grid Tamp" and "Power Float" developed for the rapid resurfacing of large floor areas.

SAFETY SAW

Stanley Works of Canada Ltd., Hamilton, Ont., in a new folder, No. 865, announces the complete line of "Stanley Electric Safety Saws" for builders, maintenance men and shippers. Saws with cutting capacities from 1⅞ ins. to 6 ins. are illustrated, described and priced. Stone saws are also shown.

CAST-IRON PIPE JOINT

Dresser Manufacturing Co. Ltd., Toronto, Ont., have published an 8-page catalogue, No. 413, which thoroughly illustrates and describes the new "Dresser Bellmaster Joint, Style 85," for cast-iron pipe. Includes specifications, tables of sizes and deflection. Features of the joint are—completely enclosed, corrosion-proof, factory assembled, armored gasket and installation time of 2 to 5 minutes.

CUPOLA AIR WEIGHT CONTROL

Bulletin B-268, issued by The Foxboro Co. Ltd., Montreal, Que., illustrates and describes the "Foxboro Air Weight Control" for foundries, by which a measured and uniform weight of air is delivered to the cupola regardless of temperature, barometer or characteristics of the operating equipment. This company is represented in Canada by Peacock Bros. Ltd.

DIAMOND TOOLS

Humorously illustrated, a 23-page booklet published by Canadian Koebel Diamond Tools, Ltd., of Windsor, Ont., describes thoroughly the care and maintenance of diamond tools.

ENGINEERING PROGRESS, 1940

The important part played by the electrical industry in the progress of engineering is described and illustrated under the headings, "Generation and Handling of Power," "Use of Power," "Illumination," "X-ray," "Domestic," "Research," in an interesting 40-page booklet being distributed by Canadian Westinghouse Co. Ltd., of Hamilton, Ont.

CORRECT CASTING DESIGN

An interesting reprint from "Product Engineering" has been distributed by E. Long Limited, of Orillia, Ont., dealing with the application of correct basic principles to the design of castings. This article gives details that promote production and quality.

ELECTRICAL EQUIPMENT

Canadian General Electric Co. Ltd., Toronto, Ont., have published an attractive 36-page brochure entitled "Pioneers of Progress" which outlines the development of the company from its earliest days to the present time and features its contributions to the electrical and mechanical industries of Canada. Each of its five factories are described and the products of these illustrated. Also many photographs are included showing "Electricity at Work in Industry."

ELECTRODES

A 32-page booklet issued by Canadian Liquid Air Co. Ltd., Montreal, Que., entitled "Alflex Electrodes for Every Arc-Welding Purpose," describes and illustrates these electrodes and contains factual data under the following headings:—Qualification of L.A. electrodes; weldability of metals and alloys; choice of mild steel electrodes; and lists of electrodes for mild steel, cast iron, special alloys and hard facing. Other useful information and engineering data are included.

ENGINEERING AND INDUSTRIAL SUPPLIES

A general catalogue of 150 pages, issued by Railway & Power Engineering Corp. Ltd., Toronto, Ont., is profusely illustrated and includes a wide range of equipment and supplies used in the Mining, Transit, Foundry, Electrical and Industrial fields. A few of the many items included are: Stainless and specialty steels, temperature and water controls, trucks, hoists, well boring equipment, pumps, railroad trucks, couplers, seating, lighting, door control engines, refractories, metallurgical alloys, electrical control panels and generator and motor supplies.

FEED WATER REGULATORS

Northern Equipment Co., Erie, Pa., represented in Canada by Peacock Bros. Ltd., have published an 8-page bulletin, No. 431, entitled "Operating Experience at Ruppert Brewery with Copes Flowmatic Regulator." Describes the brewery's modernized boiler plant and features the close boiler water level control being obtained.

GASKET MATERIAL AND SPECIALTIES

"Durabla" compressed, long-fibre homogeneous sheet packing for permanent gaskets; "Durabla" high pressure gauge glass; and "Durabla" pump valve service are described in a folder issued by Canadian Durabla Ltd., Toronto, Ont.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

VOLUME 24 | MONTREAL, JULY 1941 | NUMBER 7

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

A TRANSMISSION LINE FAULT LOCATING SYSTEM

E. W. KNAPP, M.E.I.C.

Assistant Electrical Engineer, The Shawinigan Water & Power Company, Montreal, Que.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, on February 27th, 1941.

One of the most vulnerable parts of a hydro-electric power system is the high voltage transmission line. Nature has endowed certain sections of our country with an abundance of water power. Very frequently, however, the source of power is located some distance from the load centre, which necessitates the use of transmission lines, often of considerable length. Nature is not so kind here, and the transmission engineer must cope with many difficulties caused by the elements such as lightning, wind, snow and sleet, etc. Many improvements have been made in the design and construction of transmission lines but, so far, a fault-proof line has not been built.

This paper relates to a system of locating faults in electrical transmission lines and the primary object of the scheme is to provide a system of a permanently supervisory character, which will operate automatically to record the effects of both transient and permanent faults in electrical transmission lines, whereby the approximate location of such faults may be determined in order to expedite inspection of the line at the fault point and effect repairs if necessary.

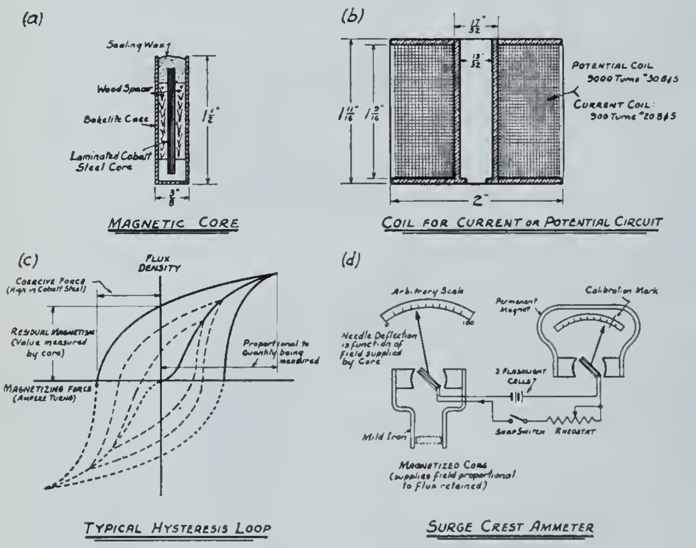

Fig. 1—Magnetic link, spool and ammeter.

The location, inspection and, if necessary, the repair of faults in electrical transmission lines have always been a serious problem for power companies and are becoming increasingly difficult by reason of the increasing lengths of the lines as power developments are located at progressively greater distances from centres of habitation. The transmission lines are frequently of great length, sometimes several hundred miles, and extend for a large part of their lengths through rough and unsettled country where patrolling is difficult and where the absence of exact knowledge greatly delays the finding and repairing of a fault. The faults herein dealt with are of two classes, namely: transient faults, where only minor damage is suffered and the line can be immediately returned to service without repairs being first necessary; and permanent faults, where the damage is such that the line cannot be returned to service until repairs have been made. In the first class may be included the effects of lightning, flashover due to atmospheric conditions, momentary short circuits due to wind driven matter or swinging conductors and the like. In the second class may be included broken conductors, fallen towers, broken poles or insulators and the like. The effects of transient faults, if not repaired, invite permanent faults and it is therefore almost as important to locate, inspect and, if necessary, repair transient faults as it is to locate and repair permanent faults. According to existing methods, the location of transient faults from a supply station is difficult or impossible, as the faults may be evident for only a very few seconds or even only a fraction of a second and the information available as to location usually determines it merely as somewhere within the length of line. Inspection is thus a time-consuming and highly unsatisfactory procedure and quite frequently the fault is never located. Permanent faults are, of course, easily observed but the delay before repairs can be made depends to a considerable extent upon the accuracy with which the location of the fault has been determined and upon promptness in informing repair men.

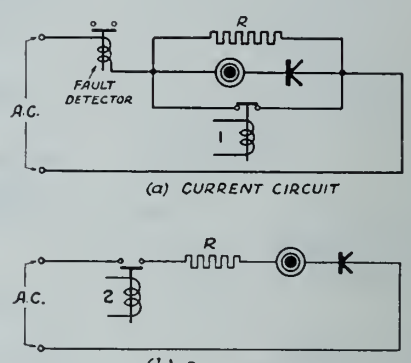

Fig. 2—Current and potential recording elements.

The present scheme consists of a supervisory system adapted to measure and record, at one or more points in the length of the line, variations in current and potential in the line, thereby providing data from which the location of a fault may be calculated with close approach to accuracy. Maintaining always the essentials of recording variation of current and potential, the scheme includes systems varying considerably in detail arrangement according to the line to be supervised and the conditions to be dealt with.

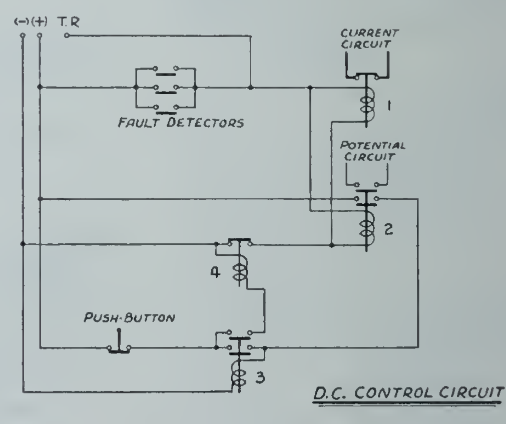

Fig. 3—Control circuits.

The desirability of having some effective means of locating transmission line faults has long been recognized, and many attempts have been made to develop such equipment. At the present time there are several methods of

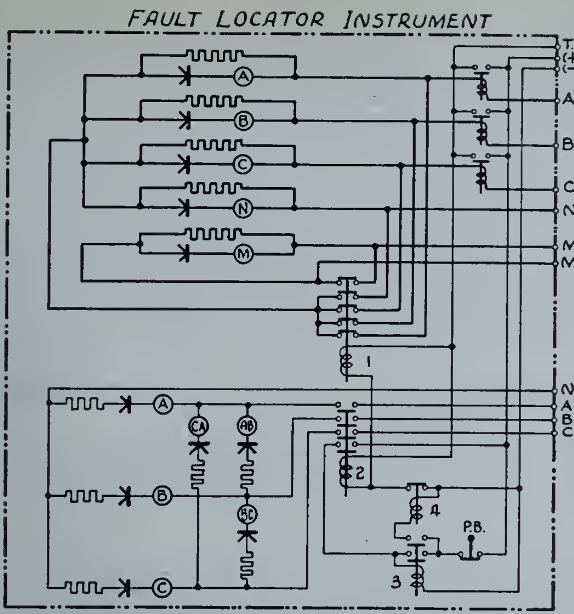

Fig. 4—Five current and six potential recording elements and circuits.

locating transmission line faults but none of these schemes have come into general use, which would seem to indicate that no scheme so far available combines all of the essential requirements. The scheme which has been evolved by the Shawinigan Water & Power Company has been developed primarily as a low cost arrangement, using standard equipment and designed to meet most of the essential requirements. It is not a precision instrument, and has certain limitations, but regardless of these facts, it is believed that it can be made to serve a useful purpose.

Theory and Operation

In general, the scheme consists of a a number of current and potential units. Each unit is composed of a number of turns of wire forming a coil wound on a suitable spool in such a manner that an electric current flowing through this coil produces a magnetic field. The centre of the spool in the present design is hollow and is arranged to hold a small, normally demagnetized, magnetic link. Associated with each coil is a rectifying unit to convert alternating current into direct current and the field thus produced in the coil is unidirectional, permitting the magnetic link to become magnetized. The degree of magnetism imparted to this link is a measure of the current which flows through the coil, and, therefore, a measure of the alternating current or

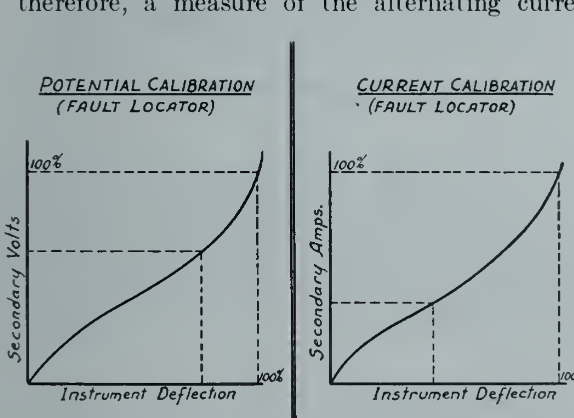

Fig. 5—Fault locator calibration curves.

potential impressed on the circuit, and having magnetized the link, a surge crest ammeter can then be utilized to determine the degree of magnetism. This can then be converted into current or potential by the use of a suitable calibration curve or table. The current and potential units are similar except that in the potential unit the magnetic circuit is provided with a series resistor, whereas the current unit is provided with a shunt resistor. In either case, the magnetic circuits are normally de-energized until the occurrence of a fault, when the magnetic circuits are automatically energized for a few cycles only. This is accomplished by means of a suitable relay arrangement to meet individual requirements and the recording units are blocked from further operation until de-magnetized links can be made available for additional records. In practice, two or more sets of links are provided, so that successive records may be obtained at short intervals by replacing the links as required. The complete instrument would have ten or more potential and current units to record all conbinations of potentials and currents required for fault location on the

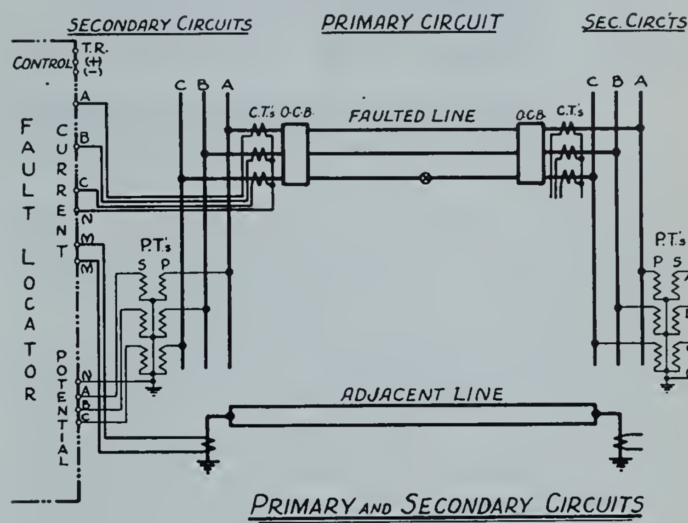

Fig. 6—Connection of fault locator to primary system through instrument transformers.

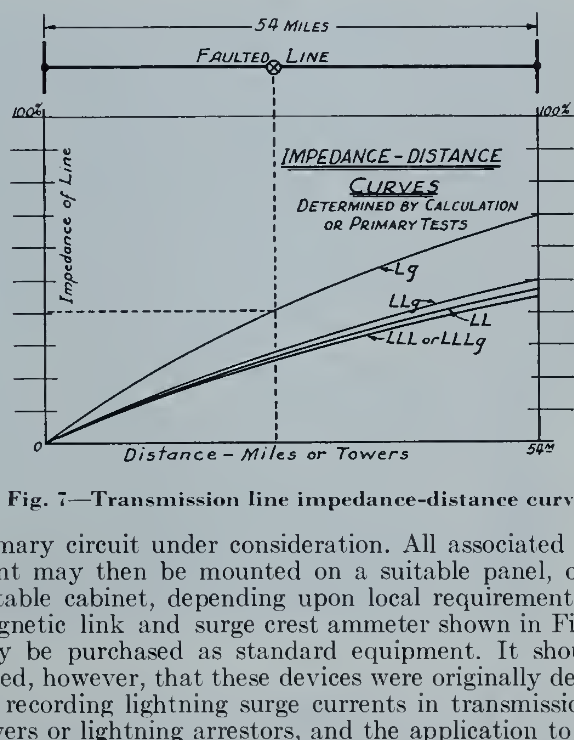

Fig. 7—Transmission line impedance-distance curves.

primary circuit under consideration. All associated equipment may then be mounted on a suitable panel, or in a suitable cabinet, depending upon local requirements. The magnetic link and surge crest ammeter shown in Figure 1 may be purchased as standard equipment. It should be noted, however, that these devices were originally designed for recording lightning surge currents in transmission line towers or lightning arrestors, and the application to transmission line fault location is a new development of the art, not previously undertaken. The surge crest ammeter is in principle a d-c milliammeter with a fixed direct current, using the magnetic link in place of the permanent magnet. In this manner the degree of magnetism is measured instead of the value of direct current.

The current and potential recording circuit, shown in Fig. 2, reveals the essential differences in these two recorders.

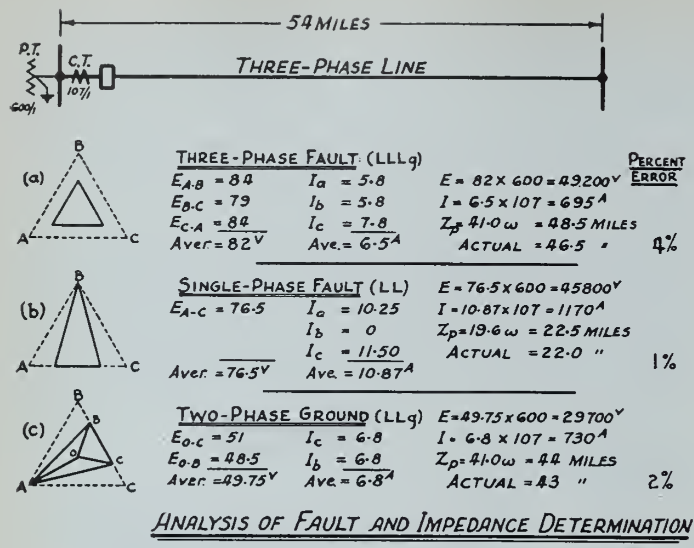

Fig. 8—Sample calculation using simple impedance method.

In both cases a potential is impressed on the recording element, forcing through the coil a pulsating direct current due to the action of the rectifying units. The arrangement of the relay circuits need not necessarily be as shown, but may vary depending upon local requirements.

In practice, the recording elements are energized for a few cycles only, usually from three to six half cycles. Figures 3 and 4 indicate the relation between the control circuit and recording elements. On the occurrence of a fault on the system, the control relays 1 and 2 are energized either from fault detector relays or from protection relays. This permits voltage to be impressed on the recording elements and at the same time energizes relay 3. As the contacts of relay 3 are closed, this relay is locked closed through the push button circuit, causing relay 4 to open the circuit to relays 1 and 2, thus removing the recorders from service and preventing them from being re-energized until the system is reset through operation of the push button. In practice, this would only be done after all the links have been removed and replaced with de-magnetized links.

In the arrangement under discussion, calibration curves showing the relation between surge crest ammeter reading and primary current and voltage are essential. Figure 5 ndicates the type of curve obtained from the available

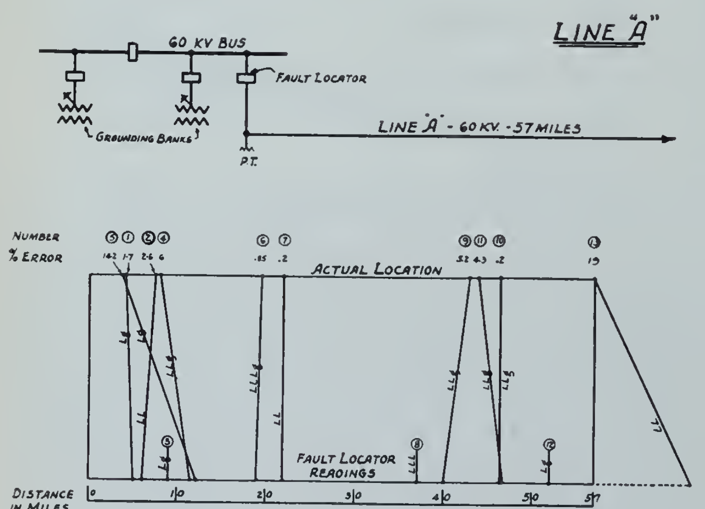

Fig. 9—Experience with original instrument on a radial 60 kv. line.

instruments. Figure 6 shows the method of connecting the fault locator into the primary circuits through instrument transformers. In some cases it might be advisable to install instruments at each end of the transmission line for greater accuracy. A recorder inserted in an adjacent parallel circuit may at times prove useful in case of ground faults. In this case the amount of induced current would be an indication of the length of parallel to point of fault and, therefore, an indication of fault location.

The impedance of a transmission line is dependent upon a number of factors. Most of these factors are constants for any given type of fault and the line impedance can, therefore, be calculated with a fair degree of accuracy. The curves shown in Fig. 7 were actually obtained by primary test on a radial, 60 kv. steel tower line operated from a delta system equipped with small grounding banks. It will be noted that the line impedance is different for each type

Fig. 11—Experience with original instrument on three parallel 60 kv. lines.

of fault such as one, two- or three-phases-to-ground, phase-to-phase, or three-phase. No consideration has been given to power arc resistance or ground resistance in this instance. One method of determining the type of fault and calculating the impedance to the point of fault is illustrated in Fig. 8. Having calculated the impedance and type of fault, the curves of Fig. 7 may then be used to determine fault location.

Experience with Existing Fault Locators

The original instrument was initially installed during 1937 at the sending end of the 60 kv. radial line shown in Fig. 7 but was transferred to the terminal station bus during 1939. Figures 9, 10 and 11 indicate the general experience gained with this instrument during the four years under consideration.

In Fig. 9 is shown the experience on the line previously referred to. The horizontal base line represents the estimated

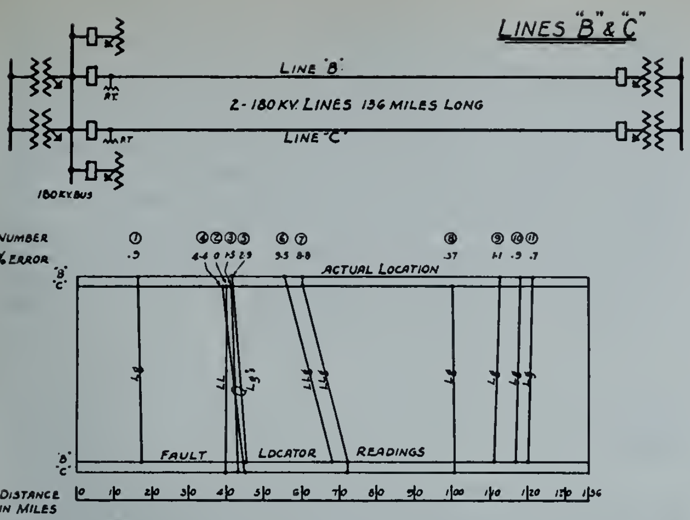

Fig. 12—Experience with two instruments of later design on two parallel 165 kv. lines.

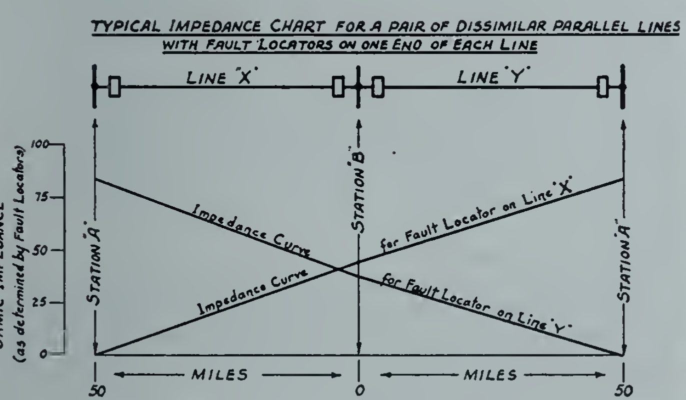
fault location and the upper horizontal line represents the actual location of fault. It will be noted that there were 13 faults during the four year period, ten of which were actually located. In eight cases, the fault location was moderately accurate, but in two cases the estimated distance was quite inaccurate. In the case of fault No. 5, the line conductor broke and fell to the ground. It is not known if the measured impedance was too high due to measuring the arc resistance as the conductor was falling; or if the conductor fell to the ground before the record was taken, thus measuring the earth contact resistance in addition to the impedance of the conductor to the point of fault. In the case of fault No. 13, two conductors were blown together near the far end of the line during blasting. The instantaneous impedance relays could not operate, thereby leaving the short-circuit on the line for approximately 0.8 second. Before the fault locator was energized to complete the record, the arc had been blown out to a considerable length and the effect of arc resistance resulted in an increase of calculated impedance. One solution of this difficulty is to take the record before the arc has time to become extended.

The records obtained in Figs. 10 and 11 were during the period when the single instrument was connected to the 60 kv. bus to record faults on six separate lines. Due to the limited number of recording elements, it was arranged to record bus voltages, ground fault current and a limited number of phase currents. This tended to limit the records to one- and two-phase-to-ground faults only. Many of these single-conductor-to-ground faults were not located, possibly due to the limited fault current and fast clearing time which prevented serious damage to line material. All five of these lines were of steel construction with overhead grounding wires, so that ground fault resistances should have been moderately low.

The next step in this development consisted of installing four more instruments during 1939. Two of these were installed on one end of two parallel 180 kv. lines, 136 miles long and of a solidly grounded star system. A special formula was adapted to this system with fair success as indicated in Fig. 12, although some adjustment may be required in the case of two-conductor-to-ground faults.



TABULATION OF FAULTS

NUMBER OF FAULTS	TYPE OF FAULTS	PER CENT. LOCATED	AVERAGE % ERROR	PER CENT. NOT LOCATED

Fig. 13—Experience with two instruments of later design on two parallel 60 kv. wood pole lines.

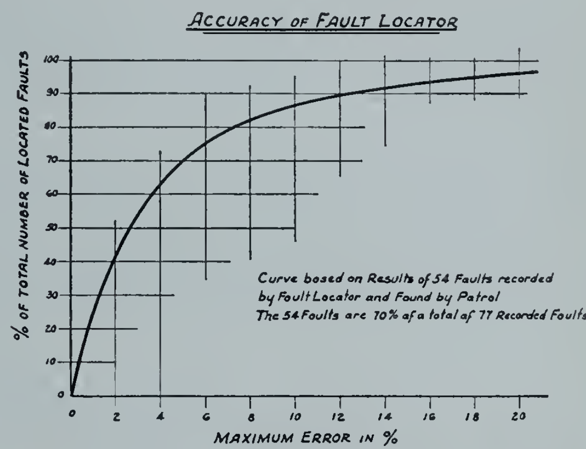

Fig. 14—Percentage error curve of located faults.

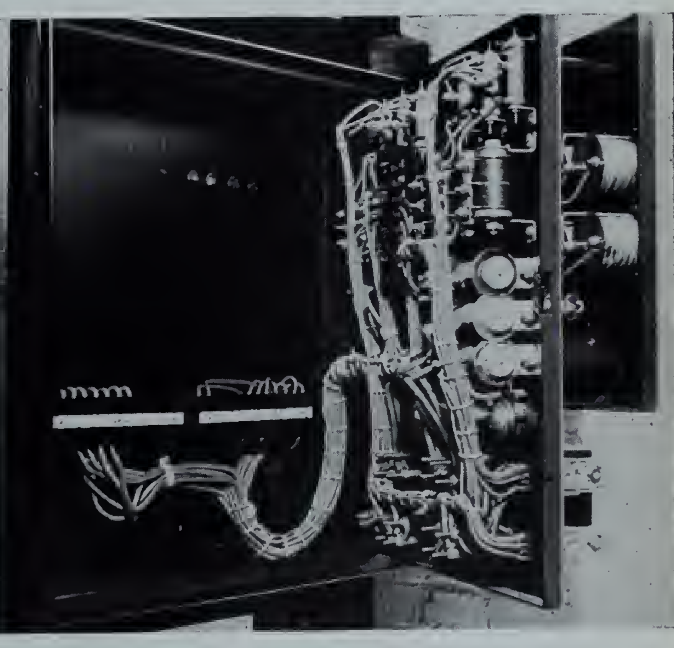

Fig. 15—Instrument of improved design recently placed in service.

Figure 13 indicates the experience with two similar instruments located at Station "A" on two parallel 60 kv. wood pole lines. These lines are not provided with either overhead or buried ground wires, so that one-conductor-to-ground faults would probably be influenced due to high ground resistance. There are, however, a number of distribution stations connected to each line, and the records include flashovers at these stations. In most cases where faults were located, this was done with a fair degree of accuracy.

However, many faults were not located, owing possibly to a number of conditions including limited fault current, fast clearing of faults and flashovers in mid-span.

The photograph shown in Fig. 15 illustrates a recent design of fault locator which has been constructed for general use. Four of these have been installed on four 110 kv. parallel lines, approximately 85 miles long, of a solidly grounded star system. The limited experience with these instruments would appear to indicate that satisfactory results will be obtained. Two additional instruments of this design are now being installed on a single 220 kv. line, approximately 100 miles long, of a solidly grounded star system. This will complete the installation of eleven instruments on various types of transmission lines with operating voltages ranging from 60 to 220 kv. and a total mileage in excess of 1,100 miles.

In conclusion, mention should be made of the co-operation and assistance rendered by the personnel of the Shawinigan Water & Power Company during the development, installation, testing and operation of these fault locators. This applies particularly to Mr. R. B. Reed, who has been closely associated with this work during the past three years. The Canadian General Electric Company have also materially contributed to the success of the general scheme in adapting the initial investigations to the design and construction of the latest instrument.

DISCUSSION

W. B. Brown, Jr.E.I.C.[1]

The author has capably discussed one device, the fault locator, used for locating the approximate point and type of faults on transmission lines. This device, conceived and built under his direction, has, as his records indicated, given satisfactory results for the lines analyzed.

As reference has been made to the part taken by our Company in improving the design, a few comments may be offered to supplement those of the speaker.

It is, as Mr. Knapp has stated, not a precision device, as there are certain factors which affect its application. The accuracy of such a device, and the ease with which results may be interpreted, measure its practical value. A number of such factors are:—

1. The equipment measures and records fault current and potential values which give, by subsequent calculations, total (line and fault) impedance. The factors noted below will introduce errors in the calculation of distance to point of fault:

(*a*) Tower footing resistance.

(*b*) Arc resistance.

(*c*) Resistance of earth return circuit.

Approximate values for these factors must be known except when they are known to be so small as not to affect the desired accuracy.

2. Harmonics. The device measures the peak instantaneous value of the wave, and since we are interested in values at fundamental wave frequency for impedance measurement, the wave shape affects its accuracy. Their relative importance as a source of error decreases with the higher frequencies. A 5 per cent. third harmonic in the voltage wave would produce a maximum error of approximately 3 per cent, while harmonics in the current wave are usually well damped by the inductive reactance of the power circuit. From this it may be seen that while wave form is a potential source of error, it will not materially affect results on the average system.

3. D-C Offset. Fault current frequently contains a d-c component of current; however, on most systems this decays to a small percentage of its original value in three to four cycles even with a 100 per cent offset wave. Since the a-c component only should be used for link magnetization, the current and potential elements should be inserted simultaneously in the circuit after this period.

4. When high-speed breakers and protective relays are used, the circuit may possibly be opened before the d-c component of total fault current has disappeared.

One method to reject this d-c component and use only the a-c component for link magnetization would be the use of a reactor, as well as a resistor, as a shunt for the current elements.

5. Recovery voltage. The potential elements must be removed from the circuit before the breaker contacts part. Since the elements must remain in the circuit for a minimum of 1½ cycles, this becomes a real problem when used on a circuit with high-speed breakers and relays. Electronic valves might prove to be the solution.

6. Auxiliary relay contacts in series with the potential elements connect them to the potential transformers. It is obviously extremely difficult for each contact to part at the same instant; thus, a transient voltage is set up which discharges through the other potential elements. Errors in the voltage reading up to 10 per cent have been noted from this, but can be reduced considerably by providing a shunt path to neutral. In most installations this path is provided by an external line to neutral load.

7. The magnetic link must be seated properly in the slot provided for it in the surge crest ammeter.

8. The surge crest ammeter is a sensitive device and will give different readings for the same magnetic link when at right angle or parallel to the earth's magnetic field. To eliminate this effect it is only necessary to check and reset, if necessary, the zero adjustment for each different position of the surge crest ammeter.

9. Error due to possible current transformer ratio breakdown on heavy through fault current.

When the fault locator is shipped it is calibrated in terms of secondary volts and amperes vs. surge crest ammeter deflection. Therefore, it is necessary to interpret these values in terms of primary volts and amperes by applying the proper instrument transformer ratio under fault condition.

10. Delta-connected current transformers make the interpretation of results more involved; however, it is usually possible to connect the current elements inside the delta connection.

The elimination or reduction of any or all of the above factors, the reduction of burden imposed on the instrument transformers, and improved methods in the calculation of distance to the point of fault from the results obtained, are the immediate objectives on the way to an improved fault locator.

Ralph C. Silver, M.E.I.C.[2]

Mr. Knapp is to be congratulated on the development of an apparatus which should be very useful in locating faults on transmission lines and in checking up, generally, on the magnitudes of currents and voltages on a transmission system under fault conditions.

Having witnessed tests on one of the experimental sets the writer was impressed by the relative simplicity of operation and the accuracy with which ground faults of comparatively high resistance were located.

As the author points out, there is a need for inexpensive equipment which will give even an approximate location of faults on long transmission lines through rough country. Hours, and, in some cases, days have been required to locate faults on such lines and restore service.

Interpretation of the current and voltage readings on single circuits with one or two points of grounding does not

[1] Switchgear Engineering Department, Canadian General Electric Company, Limited, Peterborough, Ont.

[2] Protection Engineer, Gatineau Power Company, Ottawa, Ont.

appear difficult, but on parallel circuits, close enough for the mutual inductance between circuits to be comparable with the self-inductance, and with a number of grounding transformers, it is felt that some difficulty may be experienced. It would be interesting to hear the results of the studies being carried out by Mr. Knapp's associates on this particular phase of the application of the fault locator.

What is the burden of the apparatus on current transformers and potential transformers, and has this had any adverse effect on the operation of the protective relays?

Would it be possible to show the direction of flow of fault current?

H. W. Haberl[3]

The writer cannot offer any constructive criticism or comments on the paper, as regards using the equipment described, in the manner for which it was originally intended; i.e., on long overhead transmission lines or medium-high to high voltage type.

On the power system with which the author is associated, there are many types of lines on which this equipment would be a real advantage. However, on a system operating in a metropolitan district where there are thirty or more low-voltage feeders which radiate from three or four bus sections usually fed by separate transformer banks, various conditions might decrease its accuracy to the point where it might become useless. One question might be—what changes could be made in the equipment so that it would, with reasonable accuracy, measure faults in cable systems on 4,000 and 12,000 volt services? These cable systems are usually in metropolitan districts and in underground duct systems. Our Company, operating such a system, is very interested in an apparatus of the type described in the paper, if it could be suited to our needs.

A. S. Runciman, m.e.i.c.[4]

A few years ago, a fault locator was developed by the Pennsylvania Water & Power Company engineers, which, when connected to a transmission line, would give information indicating the end of the line either "open" or "grounded." This device gave very accurate information in reference to breaks or grounds. Recent inquiry as to the usefulness of such apparatus indicates that any device which requires a considerable time to set up and use, does not give the information quickly enough, except in rare cases.

The fault locator, which has been developed by Mr. Knapp and his associates, is automatic in operation and shows considerable promise. The interpretation of the readings, as yet, requires specially trained men who give our Company operators the information required after a line has been faulted. It has been our experience that, when the instrument's results have been worked out, possibly several hours after the trouble has occurred, the location of the trouble as indicated by the instrument is usually within a mile or two of the actual fault. At times the agreement has been very much closer than this.

We look forward to the time when all of our station operators will be able to interpret the location of the fault within a few minutes. So far, this quick use of the instrument is not general. Our suggestion is that an interpreting machine be developed, into which the magnets can be placed in some definite order, so that by a proper procedure, a meter will be actuated which will indicate the tower number where the trouble occurred. This may seem a far step, but other schemes quite as complicated have been worked out.

P. W. Shill[5]

Mr. Runciman has laid considerable stress on the time that he felt must elapse between the occurrence of a fault and the computation of its position, so that the line crews could get busy on the necessary repairs.

Apparently over ninety per cent of transmission line faults are transient ones. In these cases time is not an important factor, for the line is soon replaced in service and remains so until arrangements can be made to take it out of service for inspection and to repair the damage, if any. But, in the cases of permanent faults—except where the position of the fault is such that the time necessary to compute its position may be longer than that required to notify the patrol and to patrol the line from one end to the position of the fault—there would be a saving in time. The number of cases of *permanent* faults that would take longer to locate with the detector than without it would probably not exceed ten per cent. Thus it seems that the fault detector as it now stands must be worthwhile in at least 99 per cent of all cases of trouble. Further, where no fault detector is in use, in order to locate the position of any fault with a minimum of delay, it is necessary to go to the expense of two patrols being sent out, one from each end of the line, and for them to work inwards along the section where the fault appears to be from the indications on the targets of the relays and from the circuit breakers affected.

It, therefore, seems that from an economic as well as an operating point of view the fault locator must offer very definite advantages in almost all cases of trouble.

No doubt as refinements are made the device will become a much more precise instrument than it appears at present.

There appear to be a few possible sources of error which it might not be too difficult to eliminate or minimize, if this has not already been done. These are:—

1. The rectifier units.
2. The magnetic links.
3. The surge crest ammeter.

It is very doubtful if any two rectifier units have exactly the same degree of perfection of rectification. That is to say, the best rectifiers allow some back-flow of current and they are surely not likely to be all exactly alike in this respect. Therefore, it seems that a circuit would be better if it had as many records as possible made through one rectifier.

The hysteresis loops and therefore the remanences of the several magnetic links in a set are bound to be somewhat different unless accurate tests are made in order to match them closely. If a link can be made to take a composite record of two or more phases or conditions by magnetizing it with a solenoid with more than one winding, and if a sufficient number of such combinations could be arranged, it might be possible to evaluate the errors due to this cause and eliminate them.

It is almost certain that the surge crest ammeter has some appreciable remanence. The effect of this could be reduced by the insertion of a soft iron core magnetized from an a-c source between its pole pieces between each reading of a magnetic link. Further, the surge crest ammeter and its standard comparison ammeter could both be equipped with knife edge pointers and have hand-drawn, accurately calibrated, scales which could be read if necessary with a magnifying glass. Experience has shown that any indicating instruments taken from a production bench and equipped with standard printed scales are seldom any more accurate than one requires for ordinary purposes and it is certain that not many of them are much better than the error allowed by their guaranteed accuracy. It might be more accurate to read the fluxes of the links with some sort of galvanometer with a movement suspended on a fine fibre rather than on the usual type of jewelled bearings.

The author has made it quite clear that the fault locator is not claimed to be a precision instrument. It is evident however that this instrument is a step in the right direction and that as time goes on and further work is done on it, accurately finding the location of a transmission line fault will become little more than a routine operation.

[5] Electrical Designer, Montreal Light, Heat & Power, Consolidated, Montreal, Que.

Donald King, s.e.i.c.[6]

Experience with the fault locator in the field has shown that it is readily handled and that few difficulties are met within its operation.

After a fault has occurred, the operator must remove the links from the instrument and measure the extent of their magnetization with the surge crest ammeter. While doing this, he must take care not to drop the links, or hold them together, in order to avoid altering their magnetization. After recording the surge crest ammeter readings, he demagnetizes the links, making them ready for further service.

The operator transmits the locator readings to the system office, which is on duty twenty-four hours a day. For the fault locators turned over to "Operation," the system office is in a position to determine the location of the fault directly, and quite simply, from the surge crest ammeter readings.

At the present time, when a fault occurs, it takes the station operator about twenty minutes to reach the links, measure their magnetization and give the information to the system office; the personnel of the latter require, roughly, half an hour to calculate the fault location, so that the whereabouts of many faults can be known within an hour of their occurrence.

There are some inherent drawbacks in the operation of the instrument itself. Upon a fault occurring, the instrument locks itself out, preventing its further operation until reset by the push button. Before it is reset and returned to service, the links magnetized by the fault (which has just occurred) must be removed and replaced by "fresh" links. All this takes time, and if a series of faults on the line occur in quick succession, it is likely that only the initial fault will be recorded by the fault locator.

A difficulty along similar lines is met with during periods of extensive line trouble in stations with a large number of lines. A sleet storm, with its numerous line outages, is very likely to keep the station operators so busy with straight switching, that fault locator operation must be neglected temporarily. In this way, valuable information as to the location of faults may be lost.

R. B. Reed[7]

It may be of interest to consider some of the relationships between voltages and currents during transmission line faults on three-phase systems. These relationships are as follows, (see also Fig. 16):

For 3-phase faults:

$E_{12} = Z_\phi\ (I_1 - I_2) \times d$ Equation 1A
$E_{23} = Z_\phi\ (I_2 - I_3) \times d$ Equation 1B
$E_{31} = Z_\phi\ (I_3 - I_1) \times d$ Equation 1C

For phase-to-phase and phase-to-phase-to-ground faults on:

Phases 1 and 2 $E_{12} = Z_\phi\ (I_1 - I_2) \times d$ Equation 2A
Phases 2 and 3 $E_{23} = Z_\phi\ (I_2 - I_3) \times d$ Equation 2B
Phases 3 and 1 $E_{31} = Z_\phi\ (I_3 - I_1) \times d$ Equation 2C

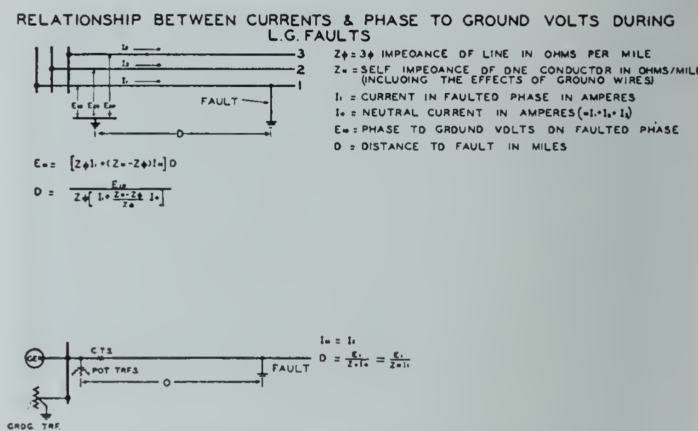
For single-phase-to-ground faults on:

Phase 1 $E_{10} = [Z_\phi I_1 + (Z_n - Z_\phi)\ I_n] \times d$ Equation 3A
Phase 2 $E_{20} = [Z_\phi I_2 + (Z_n - Z_\phi)\ I_n] \times d$ Equation 3B
Phase 3 $E_{30} = [Z_\phi I_3 + (Z_n - Z_\phi)\ I_n] \times d$ Equation 3C

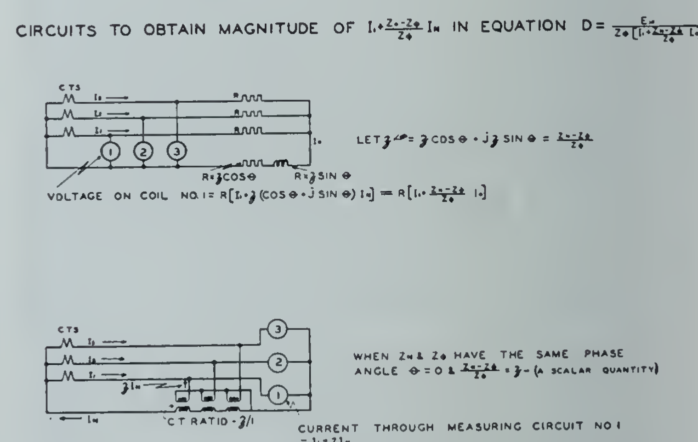
Where Z_ϕ = 3-phase impedance of line in ohms per mile.
Z_n = self impedance of one conductor in ohms per mile, (including effects of overhead ground wires and counterpoise).
I_1, I_2, I_3 = current in phase wires 1, 2, or 3.
$I_n = I_1 + I_2 + I_3$ = neutral current.
E_{12}, E_{23}, E_{31} = voltage between phases 1 and 2, 2 and 3, 3 and 1.
E_{10}, E_{20}, E_{30} = voltage to ground on phases 1, 2, 3.
d = distance to fault in miles.

Let us consider first equations 1 and 2; it will be noted that each of these equations contains a term consisting of the difference between two currents. This term is merely the delta current and is easily obtained on most installations. Thus, if we measure the phase-to-phase voltage and its corresponding delta current it is a simple matter to calculate the distance to any fault involving two or three phases. This calculation is accurate where the phases involved are at the same location on the line, and is substantially independent of any ground impedance or mutual impedance to any other line, under this condition.

Consideration of equations 3 shows, however, that the calculation for single-phase-to-ground faults offers considerable difficulty. This is due to the fact that one term of the equation consists of a vector sum of two currents each multiplied by a different line impedance constant. One method of overcoming this difficulty would be to measure the sum of the phase current and a part of the neutral current directly by the fault locator. This method requires three current coils per line as shown in Fig. 17. In practice, coils Nos. 1, 2 and 3 would be calibrated in amperes. Thus the distance to the fault may be calculated in the same manner as for phase-to-phase faults, except that the hybrid current would be used instead of delta current and phase-to-ground voltage used instead of phase-to-phase voltage. Since, on most lines Z_n and Z_ϕ have approximately the same phase angle, most installations would be satisfied with the arrangement shown in Fig. 19, in which the hybrid current is produced by current transformers in the neutral wire of the secondary circuit.



Figs. 16 and 17—Relation between currents and phase-to-ground volts during L.G. faults.



Figs. 18 and 19—Circuits for calculating phase-to-ground faults.

[6] Assistant Engineer, The Shawinigan Water & Power Company, Montreal, Que.

[7] Assistant Engineer, The Shawinigan Water & Power Company, Montreal, Que.

When using the hybrid circuit, results will be independent of system set-up and will give correct results for cross shorts. However, it is somewhat subject to errors due to ground impedance, and may need, in some cases, adjustment for mutual impedance between parallel lines.

The hybrid circuit is unnecessary for the system arrangement shown in Fig. 17, where all synchronous machines and grounding banks are behind the fault locator. Under this condition $E_{10}=Z_n I_n\ d$. Hence the calculation for distance is quite simple. It requires only one current recording element for all single phase-to-ground faults. It will not be accurate for certain cross shorts but simplifies calculations for mutual impedance between parallel lines and for ground resistance.

In those cases where it is not desirable to apply the hybrid circuit, there are two possible ratios to consider in determining the location of single-phase-to-ground faults. One is the ratio between phase-to-ground volts and neutral current. The other would be the ratio between phase-to-ground volts and phase current. If these ratios be treated as impedance to point of fault, the apparent impedance in ohms per mile of the transmission line will vary with the system set up and location of the fault. These effects may be estimated as follows:

Using the ratio between phase-to-ground volts and neutral current

$$\frac{E}{I}=[Z_n+2/3\,(C_1/C_0-1)\,Z\phi]\times d$$

where C_1 = distribution factor for pos. and neg. sequence currents.

C_0 = distribution factor for zero sequence currents.

Impedance ohms per mile $=Z_n+2/3\ (C_1/C_0-1)Z\phi$

$=Z_n-2/3\ Z\phi$ when $C_1/C_0=0$

$=Z_n$ when $C_1/C_0=1$

(condition of radial line discussed above).

= Infinity when C_1/C_0 = infinity

For the ratio between phase-to-ground volts and phase current,

$$\frac{E}{I}=\frac{[3\ Z_n+\ 2\ (C_1/C_0-1)\ Z\phi]\times d}{2\ C_1/C_0+1}$$

Impedance ohms per mile $=\dfrac{3\ Z_n+2\ (C_1/C_0-1)\ Z\phi}{2\ C_1/C_0+1}$

$=3\ Z_n-2\ Z\phi$ when $C_1/C_0=0$

$=Z_n$ when $C_1/C_0=1$

$=Z\phi$ when C_1/C_0 = infinity

The Author

The points brought out in these discussions deserve special consideration and an attempt will therefore be made to reply as fully as possible.

Tower Footing Resistance

High voltage steel tower lines are usually provided with overhead ground wires, supplemented with special grounding at the tower base and possibly buried counterpoise wires. Where any or all of these grounding facilities are provided, the effect of individual high tower footing resistance would be minimized. In those cases where no special grounding has been provided, tower footing resistance might prove a factor of some importance. This would apply particularly if the soil is of high resistance material, such as rock, or sand and gravel. It is quite possible, however, that this type of line would be more subject to flashovers involving two or more phases, in which case the phase-to-phase records should prove adequate for fault location. Although no difficulty has been experienced on steel tower lines as far as known, some difficulty has been experienced on wood pole lines. The redeeming feature on the wood pole lines, not provided with adequate grounding, is that in most cases, two or more phases are involved. In those cases of single-conductor-to-ground faults, the measured impedance is usually so high that no attempt is made to determine fault location from the records. This latter is especially true where two or more lines are operating in parallel with fault locating equipment on each line. Single-conductor-to-ground faults at the distribution stations are usually of low ground resistance and there have been several cases of quite accurate fault location for flashovers at distribution stations connected to wood pole lines.

Arc Resistance

There are a number of conditions where arc resistance might affect the accuracy of fault location. These include records on low voltage overhead lines, records during periods when the arc has become extended possibly due to high wind and a condition of obtaining a record as a broken or burned-off conductor is involved in an arc while falling to the ground. On relatively low voltage overhead lines, arc voltage may represent a large percentage of the system voltage. In practice, however, it is doubtful if this is a serious factor except on very short high voltage lines, or lines operating at less than possibly 4,000 volts. Fault locating equipment would probably not be applied to short overhead lines of any voltage and particularly lines operating at voltages below 4,000 volts. Moreover, on large capacity low voltage lines, the heavy fault currents would tend to keep the arc resistance per foot of arc to a low value, thereby tending to improve the general situation. In those cases where the arc might become extended, due to wind or other similar action, as might occur on line-end faults, the fault locator might be started from the sensitive protection so as to obtain the record before the arc has had time to become extended. To some extent this might apply to falling conductors but this is by no means certain. A single conductor lying on the ground might prove difficult of location if the soil is of high resistance material or possibly covered with either ice or snow. In general, fault location when applied to a broken conductor lying on the ground would appear to be more of a problem than high resistance tower footings. Fortunately, this type of fault does not occur frequently and a record obtained during the break might prove adequate, as the arc would probably involve two or more phases before reaching ground. In all of the records obtained to date, in only one case has a broken conductor affected the accuracy of fault location.

Resistance of Earth Return Circuit

This is a factor which may affect the accuracy of fault location on one and two conductors to ground. In practice this has not proved a serious factor, but where improved accuracy is required this may be obtained by conducting primary tests on the circuits under consideration. If this is not possible, the initial impedance-distance curves may be corrected as experience has been gained on the respective lines. In addition to the above, the formulae adapted to this application by Mr. R. B. Reed tend to minimize the effects of resistance of earth return circuit.

D-C Offset

A number of experiments have been completed on the possible effectiveness of a by-pass reactor for the current elements. These experiments have been rather gratifying and it is believed that the effect of d-c offset can be largely reduced in this manner. In the meantime a number of these reactors have been constructed and tested on existing instruments with a view to obtaining experience with regard to this problem and these experiments are being continued.

Recovery Voltage

No experience has been obtained on fault location where the clearing times are less than eight cycles and no difficulty has been experienced to date with recovery voltage. However, during 1941 an installation is being completed where the clearing times may be as low as six cycles. It is quite possible that future experience will dictate the necessity of special action regarding this feature and, as Mr. Brown has suggested, "electronic valves might prove to be the solution."

Simultaneous Operation of Auxiliary Relay Contracts

This is a condition which must be given careful consideration. Tests have revealed certain limitations but, in practice, voltage records have been moderately accurate without adopting special circuits. Should future experience indicate that trouble is being caused by this condition, then some action may become necessary.

Errors Due to Rectifier Units, Magnetic Links and the Surge Crest Ammeter

In practice, each element is calibrated as a unit and a given link is always used in the same current or potential element. The same surge crest ammeter is always used at any one station so that once this instrument has been properly adjusted, fairly consistent readings may be obtained. The back-flow of current through the rectifier is usually less than one per cent, so that this difficulty has not been important. The surge crest ammeter has an accuracy within the limits aimed at in the present arrangement. However, it may be necessary to use a different arrangement in the future. One important limitation at present is the range from minimum to maximum reading. This is only about ten to one, which is somewhat less than the preferred range, and may also require attention in the future.

Mr. Shill has suggested an arrangement of the current circuits to improve the accuracy of records. This arrangement might have certain advantages where it is impossible to use delta connected current transformers, or in case of single-conductor-to-ground faults. However, the added burden of the current elements together with the additional complication of fault analysis might tend to neutralize the advantages. No attempt has been made to use a circuit of this nature in the initial installations and it will be necessary to review the situation carefully before attempting to fully balance the advantages against the possible disadvantages.

Current Transformer Ratio Changes

In practice it has been customary to complete phantom load checks on all instruments in place in such a manner as to include all burdens encountered during operation. The calibration curves are then based on primary amperes and volts so that any current transformer ratio change is included in these curves. This represents considerable work, but the improved accuracy of readings appears to justify this method of calibration. In some cases these calibrations have been extended to primary tests, using an oscillograph to record currents and voltages, and from the results of these tests impedance-distance curves are plotted. In general, however, this procedure is not justified as calculated impedance-distance curves, based on phantom load checks, have proved satisfactory. In cases where it is difficult to calculate line constants, due to complications of system arrangement, primary tests would be desirable, although as mentioned previously actual experience should provide check points over a period of time. However, in those cases where either a d-c calculating board or an a-c network analyzer is available to the power company, these facilities could be used to good advantage.

Current and Potential Burdens

Current burdens are moderately low and compare favourably with relay burdens. These are somewhat as follows:—

0.5 to 5	ampere rating	= 65 VA/5 amperes
1.0 to 10	" "	= 13 VA/5 "
2.0 to 20	" "	= 7.5 VA/5 "
3.0 to 30	" "	= 5.0 VA/5 "

As the calibration curves are based on primary current under conditions of normal burden, accuracy of records is safeguarded. Protection relaying is not affected as the fault locator is not connected into the protection circuit until after the relays have operated. If the fault is within the instantaneous zone of protection, the circuit breaker receives a tripping impulse at about the same time as the fault locator. In any case, the instrument is only left in the protection circuits for a few half cycles. Potential burdens are low and should not prove a serious factor.

No attempt has been made to determine the direction of power flow during system faults with the present system. An arrangement of single wave rectifiers in the current and potential circuits might be used to furnish this record, but this might prove to be rather involved and possibly not suitable. However, the problem is worthy of consideration.

Use on 4,000 Volt to 12,000 Volt Underground Cable Systems

No experience has been obtained on underground cable systems to date. It would, however, be quite interesting to have one or more installations on a system of this nature. It is presumed that practically all faults on this type of system are of a permanent nature. A single portable instrument might, therefore, be used for a number of feeders in any one station, by providing a means of connecting into the relay circuits.

On radial feeders, no series difficulty should be experienced, particularly at the higher voltages. However, some difficulty might be experienced at the lower voltages, but even here experience might indicate that arc voltages might be low enough and consistent enough to establish fairly accurate impedance-distance curves for the various types of faults likely to occur in practice. It should not be necessary to make any changes in the fundamental design. although minor changes to the initiating and relay circuits might be necessary.

Time Required for Fault Location Analysis

Tests have been conducted to determine the times for various servicing operations. These are somewhat as follows:—

Time required to change links and reset the instrument—2 minutes.

Time required to take readings and demagnetize one set of links—5 minutes.

Time to transform original surge crest ammeter readings into primary current and voltage and analyze the results—about 15 minutes.

Total time—22 minutes.

This assumes an operation on an instrument which has been properly calibrated and for which there are available adequate calibration curves and impedance-distance formula. Any delay experienced in fault locator analysis is therefore due to conditions not directly associated with the instruments or records. This includes such problems as having a man available to take readings, a series of troubles in rapid succession, pressure of other duties during system troubles and possibly inadequate information on fault locator calibrations.

Some discussion has taken place with regard to additional faults occurring on a given line before magnetized links can be replaced and the instrument reset. This situation may develop, particularly during such conditions as wet snow, high wind, sleet or lightning. In case of transient faults, a number of faults might therefore occur with no corresponding fault location record. The work of taking readings, demagnetizing links, replacing links and resetting the instruments is comparatively simple, and can be done by the relay man, electrical repair man or anyone who has some knowledge of electrical equipment and who has received the necessary instructions. In times of severe storm, arrangements could probably be made to delegate someone, not directly connected with operation, to handle fault locator records. In this manner, more or less complete records could be obtained without interfering with normal operation. The readings could then be analyzed when convenient.

In case of a permanent outage on a transmission line, the record pertaining to the initial fault or faults on the respective line should be available. In case of necessity, it should be possible to close the line on test in order to obtain a specific reading. This record should then be compared with previous records in order to improve the accuracy of analysis.

The suggestion that an interpreting machine be developed has certain merit and an instrument of this nature could probably be devised. However, this type of instrument would be expensive and this might limit its application to important transmission lines operated by the larger power companies. This would appear to defeat the original purpose of the scheme which was to produce a low priced instrument of moderate accuracy which would have a wide application. The market price of the available instrument is such that it compares favourably with a graphic voltmeter or ammeter when equipped with high speed attachments and chronograph elements.

Any individual capable of handling the metering or relaying of a power system should be able to handle the fault locating equipment and fault analysis with the scheme presently developed. It should be kept in mind that this instrument is automatic in operation, can be returned to service after an operation by changing the links and operating a push button and need not interfere either with system operation or the operating staff during system troubles. It would, therefore, appear inadvisable to extend this development too far until more experience has been gained as to future requirements. It is quite possible, however, that if sufficient interest is taken in the present arrangement, additional improvements may be undertaken as the necessity arises.

The author would like to take this opportunity of expressing his appreciation to all those who have taken part in the discussion. Many good points have been given consideration and this has not only been helpful in foreseeing possible difficulties, but the interest shown has been gratifying.

DISCUSSION OF MOMENT DISTRIBUTION AND THE ANALYSIS OF A CONTINUOUS TRUSS OF VARYING DEPTH

Paper by E. R. Jacobsen, M.E.I.C.,[1] published in *The Engineering Journal*, January, 1941

H. J. A. Chambers, m.e.i.c.[2]

In discussing Mr. Jacobsen's paper one can hardly question the advisability of constructing a five-span continuous highway truss of varying depth, although this point might be raised.

Among the numerous means now employed in analyzing stresses in statically indeterminate structures, it is usually found that each designer uses the method of his preference. In this case the author submits that the method here presented involves less work and avoids some uncertainties inherent in other methods of analysis. While this may be apparently the case, in practice it may not actually be so. There are, undoubtedly, some among us who have already applied the Hardy Cross method to the continuous truss problem. Mr. Jacobsen, however, has taken the trouble to tell others about it. That he has found time to do so, under the pressure of war, makes his contribution all the more commendable.

There is perhaps a lack of clarity in the use of the same nomenclature in Formulae (5) and (6) under the heading "Fixed End Moment" as in Formulae (7), (8) and (9) under the heading "Carry Over Factor "*f*". Stresses X and Y in Formulae (5) and (6) are the result of the application of loads P, whereas X in Formulae (7), (8) and (9) is an assumed load, having no relation to load P and inducing stress Y at point b. This should perhaps have been made more clear, possibly by the use of subscripts. Also the statement that the minus sign in Equation (7) results from the fact that a moment applied at the free end of a member, fixed at the other end, produces a moment of opposite sign at the fixed end, while obvious in this instance, presupposes a knowledge of the sense of the moment in all cases. Unfortunately, this knowledge is frequently lacking. It would, perhaps, be better to state that, since the force Y has the opposite sense to the unit load at this point, the sign becomes negative.

There appears to be some doubt in the author's mind of Professor Haertlein's findings as to the general application. One wonders, therefore, at the advisability of using this short cut, since its use may not give approximations any nearer to the truth than the use of the moment distribution method using a uniform moment of inertia.

It would seem that the application of the basic formulae established in the paper should not present any serious difficulties. There is inherent in the design of a structure of this type a considerable amount of calculation. This should be lessened, however, by familiarity with this application of the Hardy Cross method.

The paper makes no reference to any investigations of stresses resulting from pier settlement. It should be kept in mind, of course, that this eventually can occur and, although the spans here are reaching lengths where reasonable settlement would not possibly have a serious effect upon the structure, the determination of the amount of these stresses should always be provided for.

Another factor entering into the stresses in a structure of this type might conceivably be the frictional resistance of the pier members. Normally this factor is neglected. In a five-span continuous truss, however, there are five restraints to movement from temperature effect. The movement is also considerable. It would be interesting to know if Mr. Jacobsen considered this in his analysis.

W. M. Laughlin, m.e.i.c.[3]

The writer wishes to offer his appreciation of Mr. Jacobsen's paper. The application of the Hardy Cross method of moment distribution to the analysis of continuous trusses of varying moments of inertia is unique. The determination of fixed-end moments, stiffnesses and carry-over factors for prismatic or solid-web members of varying moments of inertia has frequently been worked out but this is the first time the writer has seen such an application for trusses. The two laws of moment-area are usually applied to obtain these quantities for solid-web members of varying moment of inertia. In dealing with trusses, it is usual to consider only the chords in determining the moments of inertia, since the bending moments are resisted by the chords. The effect of web members does not add to the rigidity of the truss but rather makes it less rigid by reason of the distortion due to shear.

Referring to Table I of Mr. Jacobsen's paper for the 240 ft. span, neglecting all items for the web system, the writer

[1] Structural Designer, Dominion Bridge Company, Limited, Montreal, Que.

[2] Chief Engineer, Hamilton Bridge Company, Limited, Hamilton, Ont.

[3] Designing Engineer, Dominion Bridge Company, Limited, Toronto, Ont.

calculates the left F.E.M. to be +15708 ft. kips and the right F.E.M. to be —18354 ft. kips which values are within three and five per cent, respectively, of the F.E.M's. used in the determination of the dead load moments for the 240 ft. span. Again, neglecting the web, the carry-over factor from left to right was 0.67, and from right to left 0.582, these values being both nine per cent higher than the values given for these quantities in the paper. Owing to curtailment of Table I for the 200 and 280 ft. spans, it was not possible to make a comparison of the stiffness factors. Also for comparison, the writer used the preliminary chord areas for the 240 ft. span, as determined by Mr. Jacobsen, on the assumption of constant moment of inertia. The moments of inertia were calculated at 20 ft. intervals and the web system was again neglected. This yielded a F.E.M. at the left of +15130 ft. kips and a F.E.M. at the right of −17570 ft. kips, these values being 6.6 and 9 per cent less than the values shown in Table I. The carry-over factors were 0.637 from left to right and 0.553, as against 0.614 and 0.535 shown in the table. The fixed-end moments were calculated by moment-area and checked by column analogy methods.

Mr. Jacobsen has shown us the tremendous saving in calculations resulting from moment distribution in analysis compared with conventional methods. Table III shows clearly the errors in moments over supports resulting from the usual assumption of constant moment of inertia. The application of Professor Haertlein's method, in which the $\frac{L}{A}$ terms for the members may be neglected, is very interesting and for the problem in question gives results in close agreement with the true moments.

It may be assumed that settlement of piers is of secondary importance for this structure. A continuous structure of this type would not be considered without fairly positive assurance that the settlement of piers would be negligible. The effect of any small settlement on any pier may be readily determined. The actual deflection of any point of the structure may be 10 per cent less than the theoretical deflection due to the effect of details in increasing the moment of inertia.

A. E. Macdonald, m.e.i.c.[4]

Mr. Jacobsen's paper is a definite contribution to the literature on the solution of trussed structures with redundant elements. Any method which can be applied to simplify and materially reduce the tedious calculations inherent in the conventional solution of statically indeterminate problems will be welcomed by structural designers. The author's adaptation of Professor Hardy Cross' method of moment distribution is not altogether surprising. More interesting, I think, is his application of the investigations of Professor Albert Haertlein, which tend to show that the lengths of members and more particularly their areas have less effect on the accuracy of analysis than has been supposed, and that the old dilemma of first having to know the area in order to find it may be taken care of, without practical error, by merely omitting the area term from summations.

Temperature must play some part in stressing members of such a long continuous truss, and it may be of some interest to know what effect it would have in this particular design. It is probably assumed that all but one of the reactions are "frictionless" and free to move longitudinally but, even so, a temperature variation of 100 deg. F. (from +70 deg. F. to − 30 deg. F.) would tend to shorten the truss a total of some 9 inches.

Again, it is always assumed that the supports are unyielding, yet this is not always the case and in a continuous truss such as this one any differential settlement of the piers would alter the distribution of the loading and consequently of member stresses.

[4] Professor and Head of the Department of Civil Engineering, University of Manitoba, Winnipeg, Man.

I. F. Morrison, m.e.i.c.[5]

In the process of the determination of the stresses in an indeterminate structure, a stage is reached which involves the solution of a set of simultaneous linear equations in terms of the redundants. In general these equations are of the form

$$\sum a_{ik} X_i = Z_i, \quad \begin{matrix} i & 1 \ldots\ldots\ldots n \\ k & 1 \ldots\ldots\ldots n \end{matrix} \qquad (1)$$

in which the a_{ik} are coefficients dependent only on the size, shape and elastic properties of the structure. The X_i are the redundants which may be chosen arbitrarily and the Z_i are constant terms which arise from various items such as the loading, temperature changes, etc. It is easy to show that the solution of the equations (1) can be obtained in the form of equations (2).

$$X_i = \sum b_{ik} Z_i \qquad (2)$$

in which the b_{ik} are explicit functions of the a_{ik} only. This method possesses the distinct advantage that once the b_{ik} are determined, they are constants for the structure and the changes of loading, and consequent changes in the Z_i enable the immediate and direct determination of the appropriate X_i.

The solution of the set of equations (1) by the usual process proves to be time-consuming, especially to those who are not skilled in the computation of determinants. It is natural, therefore, to expect engineers to seek to avoid the solution of these equations and it was for this purpose that the moment distribution method was developed by Professor Cross. That method, which has become further developed in the decade following 1930, effects the solution of the equations by a process of successive approximation and will always succeed wherever the process is convergent —as it usually is. In the present paper the author has quite successfully extended this process to apply to continuous

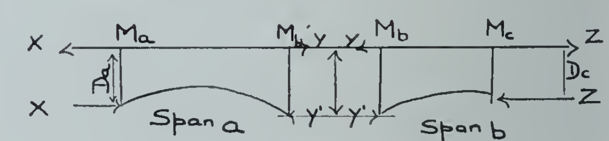


Fig. 5

trusses of variable depth and therefore has made a contribution of considerable value to the development of the method.

In every case, the number of redundants, external and internal, is equal to the degree of indeterminateness of the structure but the choice of the redundants, such as stresses in certain members, reactions, moments at supports, etc., is entirely arbitrary. For continuous structures, of the type under discussion in this paper, it is easy to show that, by choosing as redundants the moments over the supports, equations (1) become a set of three-term linear equations the coefficients of which form a symmetrical matrix. The solution of such equations is not difficult and may readily be reduced to a systematic process in which the calculations of the b_{ik} may be carried out on an ordinary slide-rule and the "difficulty and uncertainty of conventional methods" is not present. Unfortunately this method is not generally known to practising engineers.

The classical example of such a set of three-term equations is the well known three-moment equation of Clapeyron. A similar set of equations can be derived for framed structures such as illustrated in Figure 1 of the paper.

Figure 5 represents two contiguous spans of a continuous truss. Taking as the redundants the moments over the supports, i.e., the M_r the theory of least work gives the equation (3).

[5] Professor of Applied Mechanics, Department of Civil and Municipal Engineering, University of Alberta, Edmonton, Alta.

$$\frac{M_a}{D_a}\sum_a \frac{U_aU_bL}{AE} + \frac{M_b}{D_b}\left(\sum_a \frac{U_b^2L}{AE} + \sum_b \frac{U_b^2L}{AE}\right) + \frac{M_c}{D_c}\sum_b \frac{U_cU_bL}{AE}$$
$$= -\sum_a \frac{S_oU_bL}{AE} - \sum_b \frac{S_oU_bL}{AE} \qquad (3)$$

The notation is essentially the same as in the paper. The S_o and S_o' are the stresses due to the real loads on the trusses taken as simply supported and the same terms may be made to include temperature effects, sinking of supports, etc.

This equation for trusses is the counterpart of the three-moment equation for girders. The coefficients $\frac{1}{D_a}\sum_a \frac{U_aU_bL,}{AE}$ etc are the a_{ik} of equations (1). The working out of their numerical values amounts to essentially the same process as that given in the paper and in fact they are, in a sense, stiffness factors; though not according to the definition laid down in the paper. The systematic solution of the numerical equations is not difficult and will lead to the same results as are obtained by the moment distribution method. No carry-over factors are required.

The equations (3) in the present case include only three unknowns and it is open to question whether the time spent in the direct solution of them would be any more than that involved in the moment distribution process. Moreover, once the b_{ik} have been determined, the

$$Z_i \equiv -\sum_a \frac{S_oU_bL}{AE} - \sum \frac{S_oU_bL}{AE}$$

can readily be computed to consider any number of loadings and this turns out to be especially convenient for influence lines.

In equations (5) and (6) of the paper the E_s have been omitted because if E be assumed constant throughout the structure it may be factored out and cancelled in the equations. It should be pointed out, however, that it is not the modulus of elasticity of the material of which the structure is built but the constant of proportionality of the total stress-stretch curve for each member of the truss that is represented by E in the equations (1) to (4) and it is pertinent to raise the question as to whether this is a constant for the members collectively. Compression tests on full sized built-up steel columns show that the variation is not large and give values which agree quite well with the modulus of elasticity of the material. However, the writer has been able—after only a brief search to be sure—to find nothing in the way of test values on the constant of proportionality for built-up tension members and there is reason to suspect that such information would yield results quite different from those determined by the compression tests. For this reason it is suggested that the E_s for the compression members may be different than those for the built-up tension members and therefore they could not be cancelled from the equations. This difficulty could be overcome, however, by multiplying the terms for tension members by the ratio $\frac{E_c}{E_t}$.

C. W. Deans, m.e.i.c.[6]

The use of the deflections in the energy method of the differential of $V = \sum \frac{S^2L}{2EA}$ where $S = P$ and $S = U_aX + U_bY$ is more accurate also than other schemes[7] where angle changes at joints are calculated and used as elastic weights. Mr. Jacobsen has shown very clearly the advantage of cancelling out the L over A terms for the purposes of preliminary design. The advantage of bringing complicated structural design into the realm of slide-rule operations is quite apparent in the clear way the paper is arranged.

[6] Acting Designing Engineer, Hamilton Bridge Western, Limited, Vancouver, B.C.

[7] "Beam Constants for Continuous Trusses and Beams," George L. Epps, Am. Soc. Civ. Engineers *Transactions*, Vol. 104, 1939, p. 1522.

The method has been applied, for brevity in presentation no doubt, only to a structure on unyielding supports but it is readily applicable to the investigation of the effect of the settling of supports. In this case the fixed-end moments will be found from the following simultaneous equations:

$$\triangle\left(\frac{D_b}{L}\right) = Y\sum \frac{U_b^2L}{EA} - X\sum \frac{U_aU_bL}{EA}$$
$$\triangle\left(\frac{D_a}{L}\right) = X\sum \frac{U_a^2L}{EA} - Y\sum \frac{U_aU_bL}{EA}$$

where $\triangle$ is the relative vertical displacement of the two ends of the span in question.

The calculation of fixed-end moments, carry-over factors and stiffness factors is very well explained. However it is perhaps well to point out that in Equations (10) and (11) the second term on the right is zero for the condition of the far end being free to rotate, as in the 200-ft. span, giving the added advantage of shortening the moment distribution procedure for the end joint and span.

A discussion of fixed-end moments calculation from the point of view of influence lines may be worth while. The use of simultaneous equations for each separate load condition as in Equations (5) and (6) is most useful for full span load conditions, but for the cases of partial span load conditions

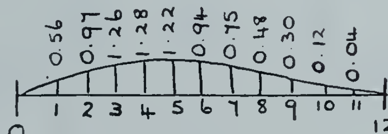

Fig. 6

it is advantageous to construct influence lines for fixed-end moments. The following is a suggested method: Let us consider the 240-ft. span. If $X = 1$ then the horizontal displacement is $\delta_b = \sum \frac{U_aU_bL}{EA}$; the equation for restoring the displacement to zero is $\delta_b' = Y\sum \frac{U_bU}{EA}$ so that for $\delta = \delta_b'$; $Y = \frac{\sum \frac{U_aU_bL}{EA}}{\sum \frac{U_b^2L}{EA}}$ which is similar to the carry-over equations (8) and (9). For this span $Y = \frac{61,403}{115,213} = 0.53$ from Columns 12 and 14 of Table I.

If we now multiply all the stresses of the line "Unit $MU_{12}L_{12}$" in Table V by (0.53) $\left(\frac{38}{33}\right) = 0.61$ with opposite sign and add them to stress values of line "Unit MU_0L_0" we have a set of stresses for the condition of moment at end U_0L_0 with end $U_{12}L_{12}$ fixed against rotation. Draw a Williot diagram with U_{12} and L_{12} fixed and determine the vertical displacements of load points δ_1', δ_2, ... δ_{11} and the horizontal displacement of $U_0 = \delta U_0$. The influence ordinates for X at U_0 are $\frac{\delta_1}{\delta U_0}$, $\frac{\delta_2}{\delta U_0}$ .... $\frac{\delta_{11}}{\delta U_0}$. Figure 6 shows the final form of the influence line for X at U_0, which gives fixed end moments directly.

End moments for partial loadings are determined by adding influence ordinates and multiplying by panel load as is usual in this type of work. The influence line for the far end being free can be taken directly from the Williot diagram for stresses recorded on the lines "MU_0L_0" and "$MU_{12}L_{12}$" in Table V.

In some cases of moment distribution work a great deal of time and space can be saved by balancing largest unbalances at each step in the procedure. Plus and minus additions and double calculations for distribution and carry-over factors can be avoided by using combined carry-over-distribution or COD factors shown in Table VI for the 240-ft. span.

Table VI

	a	b	c	d	e	e′	d′	c′	b′	a′
DF		0.41	0.59	0.50	0.50	0.50	0.50	0.59	0.41	
COF		0	0.61	0.53	0.52	0.52	0.53	0.61	0	
COD		0	0.36	0.26	0.26	0.26	0.26	0.26	0	

DF—Distribution Factor COD—Carry-over Distribution Factor
COF—Carry-over Factor

In this COD method it is best to distribute and carry over largest unbalances in order of size rather than in simultaneous steps across the whole sheet of calculations. After all the carry-over moments (COM) have been recorded, an addition is made and the sums are distributed in one final operation.

The advantage of using the percentage method of considering fixed-end moments is ably demonstrated by Mr. Jacobsen and should be noted. This arrangement with the other short cuts makes the moment distribution method of analyzing beams and trusses of varying depth very efficient and fast without any loss of accuracy.

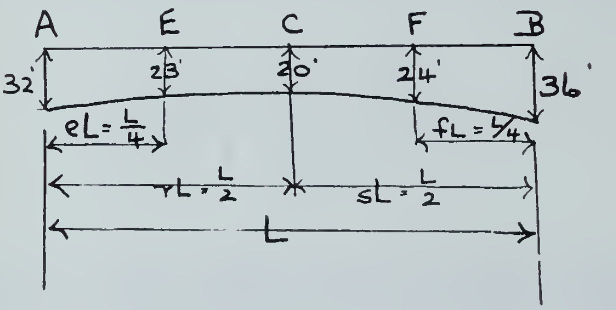

Fig. 7

The excellent arrangement of Table V should be studied. Perhaps it would be clearer if chord stresses and web stresses were kept separate, but that is a matter of choice. It should be pointed out that the method of using a stress diagram for unit reaction is most useful even in single span structures for moving load analysis.

Everything considered we should feel most grateful for the accurate and well explained paper prepared by Mr. Jacobsen, and students and practising engineers will be well advised to go over the paper in minute detail. Multiple span arches on trussed towers and multiple span trusses on trussed towers should be studied by using extensions of the ideas outlined in this paper.

C. M. Goodrich, m.e.i.c.[8]

Mr. Jacobsen's treatment of a continuous truss by moment distribution is a very clean-cut and workmanlike application of that method, using the elastic energy method to find carry-over and stiffness factors. It is a pleasure to see such a paper in the *Journal*, for it contributes to engineering knowledge.

It may be of interest to note the possible usefulness of the formulae developed by Weiskopf and Pickworth in the *Proceedings* of the American Society of Civil Engineers, October 1935. If one assumes the depths of the 240 ft. truss as shown in Fig. 7, and the moments of inertia to vary as the squares of the depths, the appropriate formulae and figures are as follows:—

$I_A = 2.56;\ I_E = 1.32;\ I_C = 1;\ I_F = 1.44;\ I_B = 3.24$ (relative I's)

$$A = \frac{I_A - I_C}{I_C} = 1.56 \qquad B = \frac{I_B - I_C}{I_C} = 2.24$$

$$n = \frac{lg\,\dfrac{I_A - I_E}{AI_E}}{lg\,\dfrac{e}{r}} = 1.11$$

$$m = \frac{lg\,\dfrac{I_B - I_E}{BI_E}}{lg\,\dfrac{f}{s}} = 1.07$$

$$F_1 = r^2\left[\frac{1}{2} - \frac{r}{3} + A\left(\frac{1}{n+2} - \frac{r}{n+3}\right)\right] = s^2\frac{I_A}{I_B}\left[\frac{1}{2} - \frac{s}{3} + B\left(\frac{1}{m+2} - \frac{s}{m+2}\right)\right] = 0.317$$

$$F_2 = r^3\left(\frac{1}{3} + \frac{A}{n+3}\right) + s\frac{I_A}{I_B}\left[1 - s + \frac{s^2}{3} + B\left(\frac{1}{m+1} - \frac{2s}{m+2} + \frac{s^2}{m+3}\right)\right] = 0.553$$

$$F_3 = r\left[1 - r + \frac{r^2}{3} + A\left(\frac{1}{n+1} - \frac{2r}{n+2} + \frac{r^2}{m+3}\right)\right] + s^3\frac{I_A}{I_B}\left(\frac{1}{3} + \frac{B}{m+3}\right) = 0.545$$

$$M_B = \frac{F_1}{F_2}M_A = 0.57\ M_A$$

$$M_A = \frac{F_1}{F_3}\ M_B = 0.58\ M_B$$

For stiffness:

$$K_A = \frac{F_2\,I_A}{4\,(F_2\,F_3 - F_1^2)\,L}$$

$$K_B = \frac{F_3\,I_A}{4\,(F_2\,F_3 - F_1^2)\,L}$$

The relative stiffnesses are as F_2 to F_3, 0.553 to 0.545, or 0.51 to 0.49. As to the actual stiffness, no figures can be made from the relative I's. Of course the design will change the relative I's from the ratio assumed. It will be noted that this treatment gives results roughly comparable in accuracy to the approximate method of Mr. Jacobsen's Table II.

There is another method which seems to possess sufficient accuracy, and an advantage over the Weiskopf and Pickworth method in the possibility of seeing more clearly what one is doing. In a beam of uniform moment of inertia, if we call $\angle B = 1$ the unit stiffness, then by Mohr's first theorem of elastic weights (announced in 1868), that the angle at B = the shear of the $\frac{M}{I}$ area divided by E, $\left(M_B\frac{L}{2}\frac{2}{3} - M_A\frac{L}{2}\frac{L}{3}\right)\frac{1}{EI} = \angle B = 1$. Now $\angle A = 0 = \left(M_B\frac{L}{2}\frac{1}{3} - M_A\frac{L}{2}\frac{2}{3}\right)\frac{1}{EI}$

From the latter $M_A = 1/2\ M_B$. From the former the stiffness $= \frac{M_B}{4EI}$. All this is for a uniform I. But to adapt it to a varying I we have only to plot the $\frac{M_X}{I}$ at various points, run a smooth curve through them, find the centroids of the two moment areas, and proceed as we did with the beam of uniform moment of inertia. This method seems rather attractive, as it cuts out all the $\frac{PUL}{E}$ work.

Whether the fabrication and erection can match the mathematical accuracy of the calculations is a doubtful matter, but fortunately that is of little practical importance, since at the limit of its capacity the structure can redistribute an overload in one part upon other elements with deformations still of the elastic order.

One wonders as to the treatment of the expansion problem as at least a 720-ft. length must be considered, with a

[8] Consulting Engineer, The Canadian Bridge Company, Limited, Walkerville, Ont.

range at the point farthest from the fixed point of say 8 inches. Slabs rounded at top and bottom, and of 30 inches and more in height have been very successfully used to provide a relatively free movement. This would, however, introduce a horizontal component in the case of so large a movement, while rollers would respond rather sluggishly, at least after a period of some years, when rust and dirt have accumulated. Rollers often offer considerable resistance to movement in old bridges, in such cases one hopes that the larger movements will take place when the span is unloaded.

There are alternatives to the design selected, doubtless all carefully considered. One is the so-called Garber system, where points off the piers are chosen to interrupt continuity, as is done in cantilever spans. This largely reduces the problem of expansion, and also renders the structure statically determinate.

A second possible alternative design is the Wichert truss, which is indeed the title of a book written by Dr. D. B. Steinman and published by Van Nostrand in 1932. The arrangement at the piers is as sketched in Fig. 8, where the heavy dots indicate pins. It will be noted that the structure is statically determinate, that any trifling errors

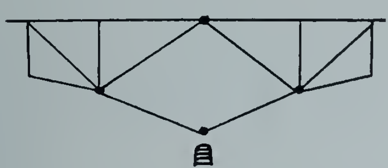

Fig. 8

in fabrication or erection (and settlements of piers as well) is automatically cared for. The problem of adequately caring for expansion remains the same as in Mr. Jacobsen's problem.

The Weiskopf and Pickworth formulae are applied to various uses, of which the above is but one instance, and at least two pamphlets on this subject were published by the American Institute of Steel Construction.

From the aesthetic standpoint, the outline of the 200-ft. span, where the central portion of the bottom cord L4-L6 is horizontal, is better than are the other two spans. The eye here travels more easily along the bottom chord.

Alfred Gordon[9]

The author's inspiration, to find the stiffness ratios, carry-over factors and F.E.M's of each span as ideally fixed, and then, with these constants, use moment distribution, starts an entirely new train of thought.

The great merit lies in having thought of these constants at all, for, by making moment distribution available, they save so much time that just how they are determined may seem a trifle, yet, in the writer's opinion even further saving may be effected by finding them in a somewhat different manner from the equations given.

The writer's suggestion is that the influence-line for the F.E.M's of each span as ideally fixed should be obtained immediately and directly, all the other constants required being found incidentally, as will be shown.

We know that if we take the beam shown in Fig. 9, and rotate the left-hand end, it will deflect as shown by the dotted line, and that this curve is also the influence-line for the moment at the left-hand end due to a unit load crossing the span when it is fixed at both ends, a uniform moment of inertia being assumed.[10]

We know also that this curve may be obtained qualitatively if we load the beam of Fig. 10 with the shaded area, representing the algebraic sum of the parallelogram and

Fig. 9

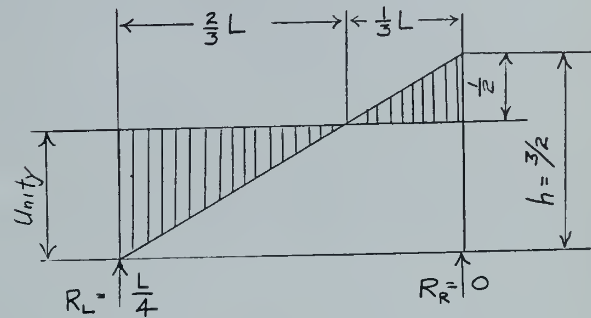

Fig. 10

triangle, and divide the resulting bending-moments by the reaction at the left-hand end.

We observe that the height ($h=3/2$) of the triangle was found by equating the moments of the parrallelogram and triangle about the left-hand end so that the right-hand reaction became zero, the left-hand reaction consequently becoming $L/4$; and we note that in the process of making this adjustment there appeared both the carry-over and stiffness factors for the left-hand end, the former being the ratio of the end moments, $(h-1)$ to 1, and the latter the reciprocal of the left-hand reaction, i.e. of $L/4$.

In short, the beam of Fig. 10 is "conjugate" to the "given" beam of Fig. 9, so that the shears and moments of the former are equal numerically to the slopes and deflections, respectively, of the latter. This conception[11] (a rather useful re-presentation of the method of "elastic weights") is doubtless so well-known that only allusion to it is necessary, and it may be superfluous to remark that for the end spans the "conjugate" beam will be a simple span upon which the load is a triangle of unit height at the restrained end of the actual span.

If the beam has a variable moment of inertia, the only change is a modification of the load applied to the "conjugate" beam, each ordinate or load of the diagram being divided by the appropriate I of the "given" beam. If the beam is unsymmetrical, and restrained at both ends, the same procedure must be followed for each end in turn. *If the "beam" is a framed truss, the loads applied to, and balanced on, the "conjugate" beam, are the same parallelograms and triangles, modified by the "elastic weights" of the various members of the truss.* The "elastic weight" of a truss member is $L/AE\rho^2$, ρ being the perpendicular distance to its moment centre. It is the exact counterpart of ds/I in beam analysis, and is applied as an "elastic load" at the moment centre of the member (except when this is inaccessible, two equivalent loads being then used, as described in various texts).

In a first approximation, at least, the effect of the web-members, as is well-known, may be neglected. This approximation, together with that of omitting all L and A terms, reduced the work of finding the "elastic loads" to calculating merely $1/\rho^2$ ($=G$) for each chord member.

If Y_p and Y_t be the ordinates of the parallelogram and triangle (of assumed unit height at the right-hand end) at any panel-point; G the "elastic weight" of the member having that panel-point for its moment-centre; and x the distance of the panel-point from the left-hand end: then the final elastic weight, W, to be placed at each panel-point is given by (with due regard to signs):

$$W=Y_pG+Y_tGh;\ \text{in which}\ h=\left(\sum Y_pGx\right)\div\left(\sum Y_tGx\right)$$

The bending-moments for these final weights, W, when divided by the sum of the weights, W, supplied as a reaction at the left-hand end, give the desired influence-line for the

[9] Canadian Pacific Railway Company, Montreal, Que.

[10] "Continuous Frames of Reinforced Concrete," Cross and Morgan, p. 79. "Applied Elasticity," Timoshenko, p. 126.

[11] "Deflection of Beams by the Conjugate Beam Method," H. M. Westergaard, *Journal* of the Western Society of Engineers, Vol. 26, No. 11, November, 1921.

moment at the left-hand end. The carry-over factor is $(h-1)$ and the stiffness factor is $1/W$. As a check, $\sum Wx=0$.

This procedure has several advantages:

1. The ideal F.E.M's are obtained for any loads whatsoever by the solving of two "conjugate" beams for each type of unsymmetrical intermediate span, and one for each end span, if they are different, the solutions at the same time giving all other constants required.
2. The calculations are extremely simple, because any units may be used so long as they are consistent, panel-lengths being most convenient, the multipliers becoming 1, 2, 3, etc., up to the number of panel-points, and moments are obtained by successive addition.
3. It is readily checked during development, quite a consideration, as there is usually no check until columns of summations have been made, and equations have been solved.
4. For continuous spans, when the number is so great as five or more and especially if "point loads" have to be taken into account, as they would have to be in a railway bridge, there is much to be said for graphical or semi-graphical methods,[12] which are greatly facilitated by this method of determining the constants; thus: The points of inflection of the influence-lines for the F-E.M's are "fixed points" of the spans, and may be accurately located as the points of zero shear for the "elastic loads" used in finding the influence-lines. The intersections of the line joining the ideal F.E.M's of any one span with the two vertical lines through these "fixed points" locate the "characteristic points." By means of the latter the complete moment diagram for a unit load at any point may be rapidly drawn, and the reactions thereby found. By the method of double influence-lines,[13] once the reaction influence-lines are drawn, all others, whether for moment or shear, may be obtained without any further work except drawing lines across them. This takes full advantage of the simultaneous determination of the F.E.M's, and is, in the writer's opinion, quicker than moment distribution for the particular problem. If, however, only full span loads are considered, this special advantage does not result, though it is still very convenient to have all the F.E.M's at "one fell swoop."

The figures obtained by this procedure, for the example given, were, in part, as follows:

	200 ft. Span	240 ft. Span	
Stiffness Factor	0.367	0.633	
Carry-over	0	0.63	0.57
F.E.M	18,800	15,450	17,320

The lever arms were merely scaled from a small diagram. The length of all chords was taken as one, except that of those next to the peak over the pier, which was taken as ½. All areas were taken as one. Web members were omitted. Despite all these crudities, the results are in substantial agreement with those of the author, so it appears doubly certain that a uniform moment of inertia is just about the one assumption that should not be made even for a first approximation.

A. R. Ketterson, m.e.i.c. [14]

The determination of the maximum stress in the members of a five-span continuous truss bridge by conventional methods, even when each truss is of uniform depth throughout, is a tedious job in itself, but the problem in this case is further complicated by the fact that each truss is of varying depth with the result that the computations to determine the unknown moments over the supports require an exceptional degree of patience and perseverance backed by good judgment to enable the various steps in the procedure to be carried through without error.

To determine the unknowns, practically all of the so-called conventional methods require the solution of successive sets of simultaneous equations, each containing terms which are themselves unknown and require to be estimated by judgment. It is a process of "trial and error" and then try again.

A most interesting section of the paper is that dealing with Professor Haertlein's discovery that, in general, the L over A terms in the virtual-work series could be omitted without appreciably affecting the final results. It is interesting to note that, for the dead load moment over the first support the omission of these terms made no difference and over the second support the difference was found to be only 3 per cent. Having in mind the fact that the calculations which include these terms involve the summation of a large number of small strains produced by the computed (or theoretical) stress in the various members, but that their actual stress under service conditions may vary therefrom as a result of external conditions, such as the effect of connections and of other members, it would seem that an even greater discrepancy could be ignored under such circumstances.

Referring to the fixed end moments, carry-over factors and stiffness ratios as determined from Table I, the writer infers that, starting with the member areas found by assuming a constant moment of inertia for each span it was necessary to set up Table I, or its equivalent, several times before a final solution which was considered sufficiently accurate was reached. It may be a question, therefore, whether the time expended in arriving at this preliminary table would not have seen the designer well on his journey towards the complete solution of the stresses by other methods.

However, by investigating Professor Haertlein's claim when applied to structures like that under discussion—and thus obtaining the material for Table II—the author has not only contributed information on a subject which should be valuable to every designer, but has also demonstrated that, at least for those structures in which the L over A term may be omitted (which would be the majority of ordinary cases), his suggested method is direct and saves much time and drudgery. The writer doubts, however, that the latter remarks would apply if it were always necessary to go through the procedure involved in arriving at the final Table I.

That a still greater saving might be possible by the adoption of some other method is, in any case, beside the point. Methods may often be left to individual preference—what may seem the longest way round may be the shortest way home if the direct route is full of pitfalls. It has been wisely stated that the best methods are those which enable the designer to vizualize the varying distortions of the structure which result from the varying mathematical steps. The suggested method conforms to that requirement. With some of the older conventional procedures the designer is liable to become so steeped in the solution of successive equations that his analytical work does not provide the assistance it otherwise should, when he begins the actual design, which, after all, is the important matter for which the computations are the preliminaries. No doubt there are many structures in which the actual service stress is quite different from the computed stress because of a lack of harmony between the various members which have a common meeting place under the influence of the stiff gussets which form the connections.

In the case of a railway bridge having span lengths the same as in this structure, or somewhat longer, it would be possible, after setting up Tables II and IV, to reduce the subsequent work since it would probably be found unnecessary to adhere strictly to those combinations of span loadings—either full or partial—which according to

[12] "Moments in Restrained and Continuous Beams by the Method of Conjugate Points," Nishkian and Steinman, Paper 1598, Am. Soc. C.E., the discussion as well as the paper. Note that for symmetrical spans Ruppel's Tables are available.

[13] "Movable and Long-Span Bridges," Hool and Kinne, Sec. 4-3 by D. B. Steinman.

[14] Bridge Engineer, Canadian Pacific Railway Company, Montreal, Que.

theory are necessary for the determination of maximums—are, nevertheless, when applied to service conditions, highly improbable combinations in some cases and impracticable in others.

S. D. Lash, M.E.I.C.[15]

More than forty years ago Professor Perry observed that not more than one good engineer in a hundred believes in what is usually called theory. Unless the percentage has greatly increased in the intervening years Mr. Jacobsen must belong to a very select group, for he has given proof not only of his belief in theory, but of his ability to use the tools provided by theory, with considerable adroitness.

It is interesting to read in the *Proceedings* of the Institution of Civil Engineers for 1850 that the Board of Railway Commissioners would not permit the use of a continuous tubular girder of two spans, which had been built for the Manchester, Sheffield and Lincolnshire railway at Torksey. The reason given was that if the spans were considered as simply supported, as had been done by Stephenson in the case of the Brittannia bridge, the allowable working stresses were exceeded. The ban continued for four months during which time the effects of continuity were hotly debated. It was finally established both by actual tests and by mathematical analysis that the stresses were greatly reduced by virtue of the continuity and the bridge was allowed to go into service. Rather surprisingly, there was no mention in the discussion of the possible consequences of settlement of the middle support.

It would seem, however, that bridge engineers have been reluctant to take advantage of the economies made possible by continuity largely owing to doubt about the effects of unequal settlement of supports and also owing to the more difficult calculations that are required. Mr. Jacobsen has indicated methods by which the latter difficulties may be overcome and it would be interesting to know if his studies indicated the probable effects of the former. In recent years there appears to have been a tendency to prefer the Wichert truss to the continuous truss since it is statically determinate and stresses are not induced by sinking of an intermediate support.

On previous occasions continuous trusses have been analysed using Professor Cross' "column analogy" method. Most engineers will prefer the moment distribution method described by Mr. Jacobsen if only for the reason that the significance of the method can be much more easily grasped. There would appear to be no doubt about the general validity of Mr. Jacobsen's approach and there are only a number of minor points to which attention may be directed.

The extension of the Maxwell-Mohr equations to include external couples, in order to determine fixed end moments, appears to be unnecessary. Actually this has not been done, since Equations (1) and (4) are not expressed in terms of angular rotations but in terms of linear displacements resulting from the application of horizontal forces at the ends of the top chord of the truss. It is true of course that in order to balance these forces suitable reactions must be introduced at the supports. However this is always the case whether the loads be horizontal or vertical and such reactions do no work and hence do not enter into the equations.

The use of the symbol U to represent stresses in members resulting from unit loads at deflection points is not in agreement with American Standards Association Standard Z 10a 1932, where u is preferred, and is somewhat confusing to those familiar with British literature in which U is the symbol for strain energy.

Engineers generally should be grateful to Mr. Jacobsen for drawing attention to Professor Haertlein's approximate method for determining stresses in redundant members. Approximate methods for solving redundant structures are of great utility and often prove to be surprisingly accurate. For example studies were made by Professor Baker of the University of Bristol of the distribution of moments in building frames on the assumption that columns were of uniform cross-section throughout their length. A check indicated that errors introduced by this apparently very drastic assumption were not likely to exceed two per cent. It appears probable however that the errors introduced by approximate method will be greatest in circumstances where it is difficult to make a check, viz: when the number of redundancies is large.

W. Chase Thompson, M.E.I.C.[16]

The method has been so clearly described in the text, and so well illustrated by diagrams and tables, that little can be said in criticism, except as follows: In the text, the equations for determining the fixed-end moments have been arranged for an intermediate span, whereas the lettering on the illustrating diagram would indicate an end span. This is slightly confusing, appearing to indicate that fixed-end moments are required at both ends of the end spans as well as for the intermediate spans. Now, although the necessary adaptations of these equations have been made in Tables I and II, it would seem advisable to explain in the text that, for the end spans, fixed-end moments are to be computed for the restrained end only, and to show the arrangement of the equations required for this case, in addition to that already provided for intermediate spans.

Referring to live-load stresses in the web members: To obtain mathematically-correct results for partially loaded spans, it would be necessary to calculate the fixed-end moments for every point of loading on the bridge, which would greatly increase the designer's work; even so, the total labour involved would not exceed that required to design, for point loadings, a continuous plate girder of variable I. But such treatment, although insisted upon by some engineers, seems to be an unnecessary refinement.

The writer has recently been engaged in designing a continuous-truss highway bridge of three spans: 120+240+120 ft. It may be explained that the central span of 240 ft. had been fixed by existing conditions, and that the side spans were made sufficiently long only to prevent uplift at the ends. For the final design of the trusses, the elastic-curve method was used, by which all stresses were obtained, and which may be considered to be substantially correct.

Then, in order to determine the degree of accuracy of the author's method for obtaining stresses in web members due to discontinuity of live load in a given span, the stresses produced by the omitted loads, as computed for a truss of uniform I, were deducted from the substantially-correct stresses, as previously obtained by the elastic-curve method for the controling combination of fully-loaded spans. The live-load stresses in web members, thus derived, were found to be from 0 to 5 per cent too great; but, when combined with the dead-load stress therein, the resulting total stress in the central web members was only 2.5 per cent too great, and in no way affected the section of these members which was determined by the stiffness requirements of the specification rather than by the stress. For all other web members, the total difference in stress did not exceed one per cent, and in no case was any difference in section required. Thus no reasonable objection can be made to the author's method for obtaining such stresses.

For a continuous truss having more than three spans, Mr. Jacobsen's method is particularly advantageous; but, where only two or three spans are involved, the elastic-curve method seems to be more convenient in some respects and to involve less labour. By this method substantially-correct reactions for unit loads at panel points may be readily derived; thus there is no need for fixed-end moments, carry-over factors, stiffness factors or moment distribution; and no additional work is required to obtain the stresses in web members due to broken loading in a span.

The elastic curve is constructed from ordinates obtained

[15] Acting Secretary, National Building Code Project, National Research Council, Ottawa, Ont.

[16] Engineer, Department of Public Works of the Province of Quebec, Quebec.

by a Williot diagram and representing the vertical deflection of every panel point when the truss is supported at both ends only and subjected to a unit load applied at one of the two intermediate supports, both of which are assumed to be removed temporarily. Having determined the elastic curve, a slide rule may be used with sufficient accuracy in calculating the reaction coefficients.

J. C. Trueman[17]

Knowing that the omission of the $\frac{A}{L}$ factor gives a close approximation will save the designer considerable time. Even though the error be much greater than the 3 per cent figure of this particular case, the original unit calculations apply to all subsequent trials so that further trials will not be laborious.

The author's original approach, assuming uniform moment of inertia and solving by the three moment theorem, is not in itself a difficult calculation. The writer has made the same calculations using the Cross method both on the basis of equal stiffness for all spans and on the basis of stiffness varying as to length of span. These different assumptions for stiffness affected the resulting moments very little, suggesting that the error is largely included in the fixed-end moments. The results were about 15 per cent in error, a little less than the author's 20 per cent. The method, to the writer, is simpler. The calculation is not needed for preliminary areas. It gives, however, a rough overall check since it is obvious from the shape of the trusses that the true moments will be greater than those so found. In view of this latter, the writer wondered why the author had not added some arbitrary percentage to the moments before making his first approximation of areas (Table I).

The author found an error of one or two per cent in his approximations for web members (part loading) but does not say whether this is a percentage of the total dead and live or of live load stresses only. The writer is interested in this phase as many highway bridges built in the West have wood decks. These have, of course, a higher proportion of live load stress than in the author's example. The economy of continuity will be less and the error of live load stress in webs more important. It would be interesting to know in this regard the estimated saving in tonnage of this continuous bridge over corresponding simple spans.

The author is to be complimented on the clear presentation and on his confining the paper to the principle and method involved without digressing into detail or variations not necessary for that purpose.

R. M. Hardy, m.e.i.c.[18]

The author has contributed an interesting and valuable piece of technique to the literature of the analysis of indeterminate structures. His approach to the solution of the particular problem discussed is from the engineering and not the mathematician's point of view. For this reason the paper will probably be the better appreciated by its readers.

It is of interest, however, to approach the general problem involved from the mathematicians point of view. From this aspect the technique of handling the computations to determine the redundant moments is essentially a process of solving a set of simultaneous equations by successive approximations. It seems reasonable to suppose, therefore, that the general equations of the conventional analysis for indeterminate structures based on the principle of Maxwell-Mohr could be arranged so that the technique of successive approximations could be applied to them.

Such an attempt has been made by O. T. Voodhigula in a paper scheduled to appear in the December, 1940, *Proceedings* of the A.S.C.E. In accordance with this procedure Mr. Jacobsen's fundamental equations can be generalized as follows:

$$-\sum\frac{PU_aL}{AE} = X\sum\frac{U_a^2L}{AE} + Y\sum\frac{U_aU_bL}{AE} + Z\sum\frac{U_aU_cL}{AE} + \ldots \text{(a)}$$

$$-\sum\frac{PU_bL}{AE} = X\sum\frac{U_aU_bL}{AE} + Y\sum\frac{U_b^2L}{AE} + Z\sum\frac{U_bU_cL}{AE} + \ldots \text{(b)}$$

$$-\sum\frac{PU_cL}{AE} = X\sum\frac{U_aU_cL}{AE} + Y\sum\frac{U_bU_cL}{AE} + Z\sum\frac{U_c^2L}{AE} + \ldots \text{(c)}$$

where in (a), (b) and (c) the terminology is the same as used by Mr. Jacobsen except that the redundants X, Y and Z may be any redundants, reactions, moments, or bar stresses; and U_a, U_b, U_c are the stresses due to the redundants X, Y, Z, respectively, having values of unity.

Equations (a), (b) and (c) may be written:

$$X = -\frac{\sum\frac{PU_aL}{AE}}{\sum\frac{U_a^2L}{AE}} - Y\frac{\sum\frac{U_aU_bL}{AE}}{\sum\frac{U_a^2L}{AE}} - Z\frac{\sum\frac{U_aU_cL}{AE}}{\sum\frac{U_a^2L}{AE}} - \ldots\ldots\ldots \text{(d)}$$

$$Y = -\frac{\sum\frac{PU_bL}{AE}}{\sum\frac{U_b^2L}{AE}} - X\frac{\sum\frac{U_aU_bL}{AE}}{\sum\frac{U_b^2L}{AE}} - Z\frac{\sum\frac{U_bU_cL}{AE}}{\sum\frac{U_b^2L}{AE}} - \ldots\ldots\ldots \text{(e)}$$

$$Z = -\frac{\sum\frac{PU_cL}{AE}}{\sum\frac{U_c^2L}{AE}} - X\frac{\sum\frac{U_aU_cL}{AE}}{\sum\frac{U_c^2L}{AE}} - Y\frac{\sum\frac{U_bU_cL}{AE}}{\sum\frac{U_c^2L}{AE}} - \ldots\ldots\ldots \text{(f)}$$

Consider the terms in (d). The first term is the value of the redundant X when no other redundants are acting. Further in the second term the coefficient Y is the value of the redundant X when the redundant Y is unity, or, it satisfies the definition of a "carry-over factor" for any value of the redundant Y to give the corresponding value of the redundant X. Similarly the coefficient of Z in the third term can be regarded as a "carry-over factor" from Z. The corresponding terms in equations (e) and (f) will, of course, have analogous meanings.

In applying this last group of equations, appropriate redundants would be selected and the first term of each equation computed. These values constitute the first approximation for the values of the redundants. The "carry-over factors" can then be readily figured, and the process of successive approximations applied in essentially the same manner as in the "moment distribution" procedure. It will be noted, however, that the process is simplified to the extent that no "stiffness factors" enter into the analysis. However, on the other hand the summations for the computations of the "carry-over factor" are for the whole frame, not simply for one span as in Mr. Jacobsen's procedure.

Equations (d), (e) and (f) are perfectly general and the redundancies may be either internal or external. In the case of external redundancies either moments or reactions may be selected as the redundants, but most designers would probably select them as reactions. It will also be noted that the simplification of assuming $\frac{L}{AE}$ constant can be introduced if desired.

The Author

The author wishes to express his appreciation for the thoroughness of the discussion and his thanks for the unanimous kindness of the discussers.

Mr. Chambers' commendation for finding time under pressure of war to prepare a paper applies equally well to Mr. Chambers and the others who have found time to digest and discuss the paper. Actually, the paper was conceived and roughly drafted before the pressure became

[17] Designing Engineer, Dominion Bridge Company, Limited, Winnipeg, Man.

[18] Assistant Professor of Civil Engineering, University of Alberta, Edmonton, Alta.

acute. But it did suffer in its final stages and the author has since been unable to give this discussion the consideration it deserves.

Before considering each discussion, it will save time to deal with those points which are common to several.

The first, while not strictly germane to the paper, appears to be pier settlement, mentioned by Messrs. Chambers, Deans, Lash, Laughlin and Macdonald. Obviously, foundation conditions must be taken into account before continuous structures are projected. However, on spans over a hundred feet, pier settlements large enough to cause serious overstress would have to be taken care of for quite other reasons. That is to say, the necessity for jacking and shimming would be apparent long before a structure of such dimensions would feel any structural distress. For instance, on the six-span continuous Ste-Anne-de-la-Pérade bridge (see *Engineering Journal*, April, 1938) a settlement of four inches, which would be objectionable from the point of view of grade, produced overstresses of 22 per cent—well within the elastic limit.

Unfortunately, the author has not found time to work out figures for the case under review. However, the method of the paper lends itself to such a study. Replace any pier by a unit load. Fix adjacent ends. Resulting PU/E tables will give deflections and fixed-end moments which are then distributed to give moments resulting from a pier deflection equal to the deflection found at the removed pier. Note that this deflection is, in terms of our example, the result of simple and fixed-end conditions. Mr. Deans' or Mr. Morrison's mathematical statement of this problem is to be noted.

The concern about expansion members dates from the days when rollers were made too small and were not properly guided to prevent misalignment and jamming. With modern pintle design, large rollers, proper skirting and dust and water protection, there can be little doubt that expansion members will act as they are supposed to with a minimum of resistance.

Criticism of the author's nomenclature and symbols by Messrs. Chambers, Lash and Thomson is justified. Nothing is more annoying in a technical paper than poor or faulty nomenclature and it is to be hoped that the remarks of these discussers will serve as a sufficient warning as regards this deficiency in the text.

The author is very grateful for the independent checks on his figures by Messrs. Goodrich, Gordon, Laughlin and Thomson. Speaking of independent checks such as those advanced by Mr. Goodrich and Mr. Laughlin, they either assume a solid web or neglect the web members. From the point of view of results, these assumptions may be accurate enough, but the author, as is usually the case, was under the necessity of producing a stress-sheet for each figure of which a watchful department was going to demand chapter and verse.

Mr. Chambers is to be commended for entering the discussion with his critical faculties at the alert. It is true that most designers have their own favourite methods. Now, on any particular job, it is always shorter to use the known method than to develop a new one. Unfortunately, there the matter usually rests until the next time.

Mr. Deans' favourable comments are doubly appreciated because of the discerning nature of his discussion. With rare economy and felicity of statement, Mr. Deans has made four distinct additions to the paper. His reference to and appraisal of Mr. George L. Epps' paper is to be noted. His statement of the pier settlement problem is terse and adequate. His calculation of influence lines from the data of the paper is useful. Lastly, he has added a refinement to the art of moment distribution which deserves a fuller treatment and which will repay study.

Mr. Goodrich's two alternate methods are to be welcomed. As a matter of reference, an example of his second method will be found fully worked out in the now famous discussion of Mr. Hardy Cross' pioneer paper in the *Transactions* of A.S.C.E., 1930. The Gerber system has been used by the author but, in this case, problems of details and erection outweighed its other advantages. The Wichert truss introduces complicated details, it makes difficult the simple cantilever erection necessary on high piers and it requires a steeper angle in the end chords over the supports than was deemed desirable. It was the author's good fortune a number of years ago to come under the stimulating influence of Mr. Goodrich who first interested and instructed him in the work of Hardy Cross.

Mr. Alfred Gordon's discussion extends the boundaries of the paper by adapting the useful and too little appreciated "conjugate" beam theory to a framed truss. It is to be regretted that he took so much for granted in suggesting the transition from the beam theory to the truss theory. Mr. Deans' remarks and his reference to Mr. Epps' paper should be taken in conjunction with Mr. Gordon's discussion. In passing, it is the author's feeling that the expression "method of elastic weights" has a misleading air of unreality which does a disservice to the simplicity and straightforwardness of the method itself.

Mr. Hardy has pointed out that the author's approach is from an engineering and not a mathematical point of view. This is a significant and discerning observation. The choice was a very conscious one on the part of the writer. It is therefore salutary that two such excellent appraisals should appear from a strictly mathematical point of view as those of Mr. Hardy and Mr. Morrison. In the author's opinion, Mr. Voodhigula's paper in the December *Proceedings* of the A.S.C.E. did not live up to the expectations engendered by Mr. Hardy's discussion. It seemed to have as its main preoccupation an unwarranted idea of the difficulties of solving a series of simultaneous equations. Like Mr. Morrison, the author has been unable to find any data relating to the difference between constants of proportionality of tension and compression built up members.

Mr. Ketterson's general remarks are both kind and penetrating. He questions the saving in time were it necessary to set up Table I involving lengths and areas rather than to proceed directly to Table II. By actual count, the number of calculations for the conventional solution using the four reactions as redundants was eight times as many as were required to arrive at the same result via Table I. In practice, however, Table II would be set up first and Table I would be used as a final check if deemed necessary.

Mr. Lash does not think it was necessary to extend the Maxwell-Mohr equations to include couples. The author cannot agree, although the point is mainly academic. Rotations are measured by the relative movements of the top and bottom of the end verticals. True, we can assume the base of one end vertical as fixed, but the bottom of the other end vertical must of necessity move from its original position.

The author is grateful for Mr. Chase Thomson's corroboration in the matter of the effect of broken loads on web members. He agrees, further, that the three-span continuous truss falls into a rather special category to which the elastic curve treatment is particularly applicable.

In answer to Mr. Trueman's question, the errors of one to two per cent in web stresses are for total dead plus live load. The ratio of dead to live load was about one to one. The author cannot give figures for a comparable simple span. The point is that the desired arched profile does not lend itself to simple span treatment.

In the main, the discussions speak for themselves and do not need further comment by the author.

CONSTRUCTION NORTH OF 54°

ROBERT F. LEGGET, M.E.I.C.
Assistant Professor of Civil Engineering, University of Toronto, Toronto, Ont.

Summary of an address delivered to the London Branch of the Engineering Institute of Canada, on December 12, 1940.

NOTE—This brief paper is based on observations made during a summer spent in the Mackenzie River basin, supplemented by information kindly supplied by the Consolidated Mining and Smelting Co. of Canada, Ltd., and Imperial Oil Ltd. The paper may be regarded as a supplement to that by Professor J. A. Allan, entitled "Mineral Development North of 54°" and published in *The Engineering Journal* for June, 1940. In order to make this description of construction activity in the Mackenzie basin complete in itself, a general description of the area has been included even though a similar note is to be found in Professor Allan's paper. Photographs kindly supplied by the two companies already mentioned supplement those of the author in serving as illustrations.

Further particulars of the Wellington Lake water power plant will be found in a paper by E. M. Stiles published in the Bulletin of the Canadian Institute of Mining and Metallurgy for August, 1940, on pages 468-480. In the February, 1941, issue of the same journal appears a description by Max W. Ball of the Abasand tar-sand refining project at Fort MacMurray, mentioned briefly at the end of this paper. Since the paper was written, the area with which it deals has attracted public attention because of the decision to build a series of airfields between Edmonton and Alaska. Some of the difficulties to be faced during the construction of these fields will be apparent from the description which follows.

Although recent developments in the vast area of northwestern Canada formed by the Mackenzie River Basin are known to mining engineers, if only because of the much publicised Eldorado radium mine on Great Bear Lake, to civil engineers the region still remains as a large space on maps of the continent and but little more. The distortions of map projections have probably led many to discount the size of the basin. Actually, the Mackenzie is one of the eight major river systems of the world, second only in size, in North America, to the Mississippi. Its catchment area is about 682,000 square miles, the St. Lawrence basin being only 498,000 square miles in comparison. From its source to its deltaic mouth in the Arctic Ocean the Mackenzie is about 2,525 miles long, the Columbia River ranking third in length at 2,200 miles. And Great Slave Lake, with an area of over 12,000 square miles, is the fourth great lake of the continent.

Extending from the 53rd parallel to the Arctic Ocean, the topography of the basin is featured by a central plain flanked by the western extremity of the Laurentian Shield on the east, and by the Rocky Mountains on the west. First explored by Alexander Mackenzie in 1791, in one of the greatest canoe journeys ever made, the region retained its virgin character until well on into the present century. The trapping of fur bearing animals was the only encroachment of man into this vast area of the wilds. Hudson's Bay Company posts along the main waterways were the only permanent settlements. Transport was limited to movements along navigable waterways and to short journeys inland from the river banks.

The coming of the aeroplane effected a radical change, making contact with the outer world regular and speedy, and permitting the study of large areas of otherwise inaccessible country with ease. The first flight into the North from Edmonton was made in March, 1921. In 1922 planes of the Royal Canadian Air Force started aerial survey work. To-day, two well established aerial transport companies operate regular services along the Mackenzie as far as the Arctic from Edmonton, Alberta, and Prince Albert, Saskatchewan. Aerial surveying of the basin is well advanced, especially for those parts adjacent to the main water routes. Strategically located government radio stations enable all planes to maintain constant touch with land throughout the entire area. Airport problems do not exist, for all planes are fitted with pontoons in summer and with skis in winter, using the rivers and innumerable lakes as regular and emergency landing places. Loose ice conditions in the fall and spring, and excessive smoke from forest fires are the only obstacles in the way of all-the-year schedules.

Prospecting, in the pre-cambrian rocks of the Shield, was greatly facilitated by aerial travel. As a result of the increased activity in prospecting, five gold mines are to-day

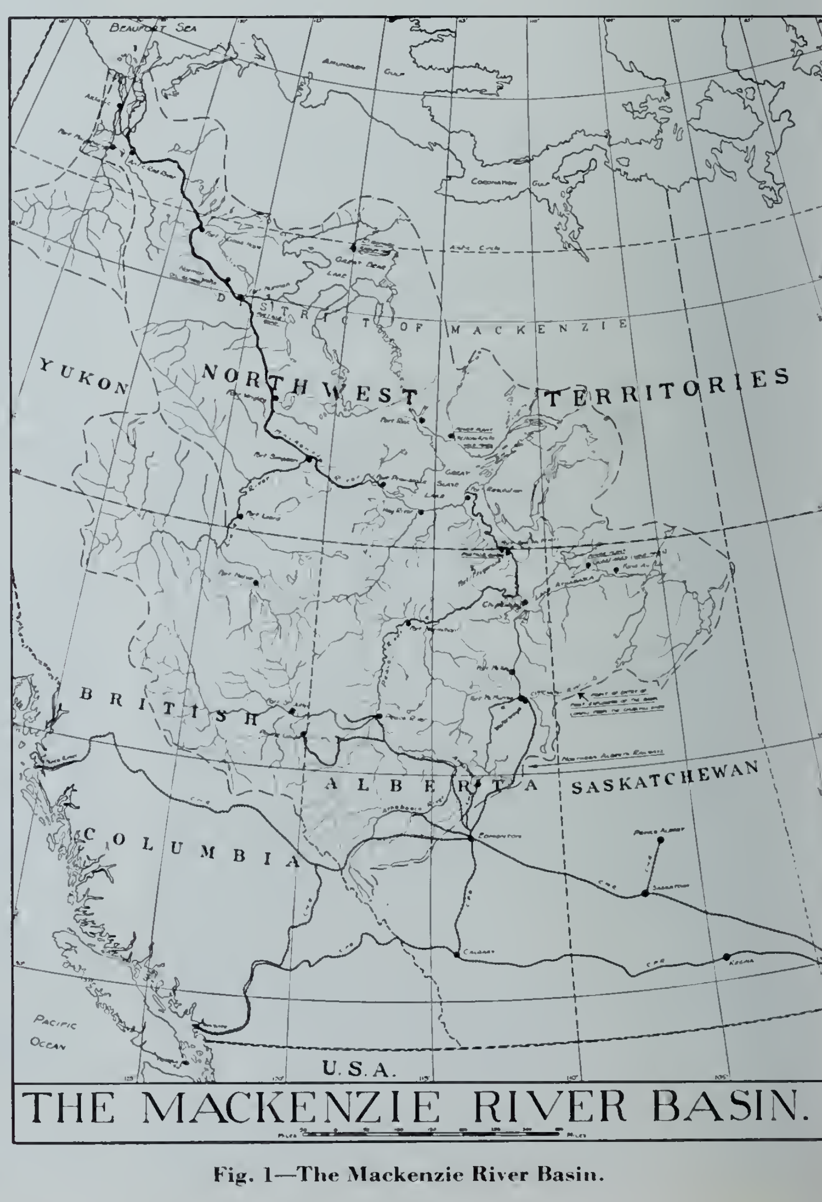

Fig. 1—The Mackenzie River Basin.

operating on the north shores of Lake Athabasca and Great Slave Lake, while on Great Bear Lake is the well known radium mine, now shut down. Other prospects are in course of development. Where previously Fort Smith, "capital" of the Northwest Territories, was the metropolis of the basin with a total population of about 400, to-day Goldfields on Lake Athabasca has a population of about 1,000 and Yellowknife on Great Slave Lake is about the same size, both thriving mining settlements.

The mills associated with the gold mines have a total capacity of 1,700 tons of ore per day; their construction involved the usual structural work encountered with mill buildings. Power supply was originally obtained from Diesel engines, but to-day the Box mine at Goldfields is served by a small water power plant on Wellington Lake, power being delivered to the mine over a 22 mile 60,000 volt transmission line. In view of the nature of the country traversed, rocky and rugged with much muskeg, steel towers were used for the line with the longest spans practicable. In consequence, there are only 107 spans in the whole line. Water for the plant is diverted from Tazin Lake through a 16 ft. by 12 ft. rock tunnel 1,100 ft. long, to Mud Lake. Three open cuts, totaling 77,000 cubic yards of excavation, provide a water channel from Mud Lake to White Lake, the level of which has been raised 15 ft. by a log crib dam 350 ft. long. Serving as the forebay, this lake is tapped by another tunnel, 15 ft. in diameter leading to two 10 ft. woodstave pipes, through a 14 ft. wye piece, and so to the power house. At present a flow of 500 cu. ft. per sec. is used to generate 3,300 h.p. under a 75 ft. head, but all the permanent works have been designed and constructed for an ultimate development of 6,600 h.p. using 1,000 cu. ft. per sec.

Fig. 2—Loading equipment for transport by air to Mud Lake, during the construction of the Wellington Lake Water power development.

Constructed in 1937-38 the plant called for no unusual construction methods but it did necessitate special transportation arrangements. Every conceivable means of transport in the north was employed at some time during the progress of the job, even to dog teams in the winter for hauling lumber over the ice. The greatest difficulties were encountered in connection with the Mud Lake tunnel and open cut excavation. A road was constructed from Lake Athabasca to the power house site, but diligent search failed to reveal any route from there to Mud Lake, either by land or by water, that would provide a road that could be economically constructed in the time available. All equipment and supplies for this section of the work were therefore flown in to the site. Handled in this way, in several large multi-passenger planes, were 300 tons of oil, 250 tons of gasoline, food for 40,000 man-shifts of work, three two-ton trucks, three 360-cu. ft. compressors, eighteen dump ore cars, a four-ton gasoline locomotive, and even a three-quarter yard Diesel shovel, this being the largest size that could be dismantled into parts sufficiently small for transport by air. The cost of this unusual transport job was $48,000, the total transportation cost for the whole project,

Fig. 3—Rock fill dam in process of construction on Bluefish Lake, as part of the Prosperous Lake water power development.

from the railhead at Waterways, being $229,000. Labour costs amounted to $457,000, the complete installation costing in all $1,511,600. This figure should be considered only in relation to the extremely isolated location of the job, and the fact that a good deal of the work had to be carried out in winter.

There has just been completed, to serve the mines in the Yellowknife area, a second water power plant of 4,700 h.p. capacity on Prosperous Lake, the power house of which is located on the Yellowknife River, below the lake. Water storage is obtained in nearby Bluefish Lake, the level of which has been raised 10 ft. by a rockfill crib dam about 500 ft. long, the penstock being supplied through a 900 ft. rock tunnel. Surge tank and penstock are of woodstave construction, the latter being 1,800 ft. long, giving a head of 105 ft. at the power house. Power will be delivered to the mines over a 22 mile transmission line, also constructed with steel towers and unusually long spans. Transportation problems have been relatively easy since all material could be delivered almost to the power house site by water with only one transfer from the regular freighting service on Great Slave Lake. Construction started with the summer opening of navigation in 1940 and was completed early in 1941. Both water power plants are projects of the Consolidated Mining and Smelting Company of Canada Limited, for whom W. G. Jewett is local superintendent.

The precious metal mines are all located in that part of the Mackenzie basin formed by the edge of the Laurentian Shield. To the west, but unconformable with the pre-cambrian rocks of the Shield, are exposures of cretaceous and palaeozoic rocks in which occur coal and oil deposits. One of the coal beds exposed on the banks of the Mackenzie River has been burning slowly ever since it was first seen by Mackenzie in 1791. Although the coal has been little used

Fig. 4—General view of oil refinery at Norman Wells, about 100 miles south of the Arctic Circle.

as yet, the Imperial Oil Company Limited have a small oil refinery located at Norman Wells, about 100 miles south of the Arctic Circle. Their Discovery Well No. 1 was completed in 1921 but lack of a market for the oil delayed further progress. Recent mining operations have provided a small market and led to the building of the refinery in 1939. The new unit has a capacity of 840 barrels of crude oil per day; an aviation gasoline and light Diesel fuel are produced. It operates for about three months of each year, all equipment near the river being hauled up high on the bank before the winter sets in so that it shall be clear of spring flood waters. Flood water level may be more than 50 ft. above normal water level, due to the fact that the river flows northwards and so thaws out first at its source; this unusual feature affects all river-bank development.

Construction of the refinery was interesting in that the ground at the site is frozen to a depth of over 50 feet, thawing out in the short summer season to no more than 18 inches below the surface. Grading operations for construction consisted of "skimming" off this thawed layer, and using it to form a foundation area raised above the general level of the surrounding ground. This raised section of thawed out earth was surrounded by a stone filled trench which prevents surface drainage from entering the soil and so freezing during the winter. As the untouched ground beneath the fill will never thaw, since the sun never reaches it, all frost heaving has been prevented. All equipment for the refinery had to be brought in to the site by water, the heaviest pieces being limited to 10 tons in weight and 10 ft. by 35 ft. in size. The fractionating tower was 35 ft. high and 4 ft. in diameter and so was shipped complete. All large piping was shop fabricated; storage tanks were of bolted construction.

Fig. 5—General view of the water front on the Clearwater River, at Waterways, Alberta. Freight cars on Northern Alberta Railway spur can be seen in centre, discharging into typical river craft below.

It will be appreciated that apart from the surmounting of climatic difficulties such construction as has been carried out in this great area has presented few unusual features. Contrary to usual experience, it is transport rather than building operations that presents the problems. Aerial transport has been mentioned; it provides all mail and light express service, but ordinary freight and heavy equipment have to be brought in by water, during the very short summer season of open navigation, always less than six months. The Northern Alberta Railway provides access to the basin from Edmonton by means of their Peace River lines and that to Waterways on the Clearwater River near its junction with the Athabasca River; the latter is the route used for all but local Peace River shipments. From Waterways to the Arctic Ocean at Aklavik the river route is about 1,600 miles long and in this distance the fall in water level is only 820 feet. Very fortunately 125 feet of this drop occur in a series of big rapids at Fort Smith, N.W.T., and these provide the only serious impediment to navigation in the whole course of this long journey to the sea. Two sixteen-mile portage roads have been built around the rapids on which operate competing fleets of heavy duty trucks and tractors capable of handling practically anything that can be loaded on to river boats from railway cars at Waterways.

The several water transport organizations have each to maintain two fleets of vessels, above and below the Fort Smith rapids respectively. The service thus provided has a special interest in that it is now one of the very few inland water transportation systems in this continent unaffected, as yet, by competition from road or rail. The economic problems are as unusual as the service provided. Practically all freight moves one way only, to the north; all freight for the Northwest Territories has to be portaged sixteen miles; and all freight for the year has to be moved in less than six months—these are some of the problems that complicate operations. In recent years there have always been competing transport services, but most of these have had short periods of existence. One service only has continued unimpaired throughout the years, that provided by the Mackenzie River Transport, a branch of the Hudson's Bay Company which has been operating in the north of Canada since it was incorporated on 2nd. May, 1670. The M. R. T. fleets consist of steam wood-fired stern-wheelers for passenger and special freight traffic, and Diesel tunnel tug boats and barges for its general freight services. On these boats over two thirds of the total freight on the river is handled.

Fig. 6—Steel drums of an electric mine hoist being unloaded at Fort Fitzgerald for portage, by truck to Fort Smith, seventeen miles downstream. Sternwheeler S.S. "Northland Echo" in background.

This note cannot close without brief reference to the tar sand deposits in the vicinity of Waterways and Fort MacMurray, Alberta, the latter settlement usually having its name associated with the deposits. Believed to cover an area of at least 750 square miles, and of great thickness, this vast area of bituminous sand has tempted many to investigate the commercial possibilities of separating the sand from the oil and bitumen. Several small plants have operated with some success and some of the untreated sand has been used for road pavement work in some locations in Alberta, but it has yet to be shown that the separation of the constituents can be put upon an economic basis. One small plant is operating to-day near MacMurray. When commercial success is achieved, the southern end of the Mackenzie River basin may be expected to develop rapidly. Until that time it would appear that human activity in this great area will continue to depend on the vagaries of precious metal mining as the only rival to fur trapping, which, after all these years, still remains the major incursion of man into this last frontier of the Continent.

UNDERPINNING THE HEADQUARTERS BUILDING

The Institute Council appreciates the willing response of the branches to the appeal for funds to meet the unforeseen expenditure on the foundations of the Headquarters' building. The House Committee—under whose direction this necessary repair work was handled—has approved the publication of the following detailed information about the undertaking, as it is felt that members generally should know why and how the money was spent. It is desirable also that the *Journal* should contain a record of a piece of work whose success was important to the Institute, even though it involved no unusual engineering features. The account which follows is based upon a report kindly furnished by Brian R. Perry, Chairman of the House Committee, who investigated the trouble and supervised the work of the contractors. E. V. Gage, representing the contractors, is also another member of the Institute.

Early in the summer of 1940, cracks opened up in the rear wall of the Headquarters building that indicated some foundation settlement. They were not serious enough to be considered dangerous, but the movement soon developed to the point where repairs were essential. In October, the House Committee reported to Council and were authorized to dig test pits to develop the fundamental reason for the cracking before arranging details and drawing definite conclusions for the extent of the repair.

The southwest corner of the wall had settled and the south wall was cracked horizontally near the top. Further, the rear wall opened in a wedge-shaped split with a maximum of 2 in.; this compares with a settlement which was probably about ½ in. at the extreme southwest corner. At the same time plaster partitions inside the auditorium section indicated a minor settlement of one interior column.

The rear portion of the Headquarters building contains a large auditorium section of fireproof design which was built in 1912. The front portion, facing on Mansfield Street, is an old residence built many years earlier and has shown evidence of minor settlement for many years. No details were available as to the type of foundation. Drawings of the auditorium section were available and indicated wood piles, but there were no details as to their arrangement or length.

Fig. 1—Cracked wall in the library on the ground floor.

To investigate the condition, three test pits were opened to expose the underside of the foundations. The first was dug at the southwest corner where trouble had developed; a second was located at the front portion of the south wall, and the third along the north wall. In general, the conditions found were quite uniform although there was some difference in degree. Excavation was carried through about 18 in. of fill and top soil and 3 to 4 ft. of firm yellow clay, at which point blue clay was encountered. These materials are all typical of Montreal conditions. In the test pits on the south side, the blue clay near the top was stiff and firm. On the north side this blue clay, even in the upper layer, was so soft that a man would sink in several inches. Pipes were driven in all test holes, pushed down by hand for about 20 ft. and then driven with a hammer. At a depth of about 25 ft. the sounding pipes brought up on hard pan and boulders. No water was encountered in the pits except a small amount of ground water seeping in from the top soil. Due to shrinkage of the clay from diminution of water content over a period of years, the clay had settled quite evenly away from the bottom of the foundation pads which were about 5 ft. wide. It was interesting to note the surprising uniformity of the settlement in each area. The soil had obviously shrunk so that a clear space existed as far as a flashlight could show details. The irregularities of the underside of the concrete footings were evident in the top surface of the clay. It was also noted that even around the wood piles the soil had settled quite cleanly and uniformly with very little disturbance due to adhering to the piles.

Fig. 2—Southwest corner of auditorium on the second floor, showing damage to plaster partition.

While the settlement was quite uniform in any one area, it varied in amount, being about 5 to 6 in. at the southwest corner; about 3 in. toward the front of this wall and 1½ in. under the north wall. As would be expected this shrinkage varied consistently with the firmness of the upper layers of clay.

Under the walls there were three rows of wood piles at about two foot centres; a surprisingly large number considering that the building is not heavy. The piles were small and badly decayed at the southwest corner. At the second test hole there was also evidence of considerable decay, but not as bad as at the rear. On the north side, where the clay was wet, the piles were quite sound. The conclusions of the committee were that the settlement was obviously due to decay which was associated with the fact that shrinkage had produced an air space and a semi-dry condition conducive to the development of decay under the footings. It seemed evident that the changed moisture condition in the clay was largely due to the very rapid and almost complete run-off of natural precipitation due to the large percentage of the ground covered by buildings and pavement during the past years. Along the south wall it is probable that one or two large trees contribute a great deal to the trouble by drawing moisture from the upper layers of the ground, but it is also possible that the location of the bricked-in ventilating duct laid on the basement floor along the south wall may have had some drying effect.

Fig. 3—Rear wall of building, showing the amount of movement previous to underpinning.

The committee investigated various means of doing the work and recommended to Council that competitive tenders should be received for various portions of the work. The principal decision to be made and obviously the most serious one was the extent to which underpinning should be carried. The very fact of doing work of this kind was certain to upset existing static conditions somewhat; and the provision of permanent support in only a portion of the building was also certain to hasten the relative movement of adjacent portions. It seemed obvious that the fundamental foundation condition was uniform and that eventually there would be trouble throughout the building although the decay had reached the final stage at only one corner. If a partial repair was undertaken the cost would be somewhat higher than the proportion of the building taken care of. Without doubt a second section would not be undertaken before the need became very obvious and the resulting repairs to masonry cracks, plastering and consequent complete re-decoration would cost well over a thousand dollars. Comparing this to the expenditure for a complete job, Council decided to proceed at once with the underpinning of the auditorium section complete, together with the old wall dividing this new building from the old residence. Similar proportional expense for this old building did not appear to be justified and its consideration was eliminated.

In considering repair, partial estimates were made of several arrangements for permanent support. Steel and pipe piles were investigated and also consideration was given to such ideas as lowering the footings and re-capping the existing wood piles after cutting off at a lower level where reasonably permanent moisture appeared to be available. Practically all of these alternative schemes were eliminated after checking comparative costs. It was found that sinking open piers would be the cheapest, quickest, most adaptable and permanent method of repair and would cause less disruption of normal headquarters activities. Sinking these open piers (often miscalled caissons in this district) requires only the simplest of equipment and unskilled labour, the availability of men and material being of primary importance due to war conditions. These piers are 4 ft. 6 in. diameter which is the minimum size in which a man can conveniently work. Their load carrying capacity is far greater than is necessary in this case but the ultimate cost was considerably less than for other methods. Due to the structural arrangement of the building with large windows and frequent points of concentrated load, it was necessary to support at twenty-one points. The aggregate capacity of this support is far in excess of the building load. However, it was found to be more expensive to attempt to introduce beams spanning from point to point than to sink the extra piers required. The only variation from this arrangement occurred at the interior columns which are located in pairs. They are quite close together and it was obviously very convenient to sink a pier mid-way between two columns and then install a steel beam to pick up the symmetrical column load after the lower part of the underpinning had been completed. This also avoided any necessity of shoring the upper floors; which would have been comparatively expensive due to suspended plaster ceilings. The use of piers also eliminated the necessity for needling through exterior walls to provide temporary support and it was also possible to do 80 per cent of the work from outside the building with obvious economy and a great saving of inconvenience to the staff.

The committee called for competitive prices on the basis of this scheme which seemed to them to be the cheapest and was without question definite and reliable. At the same time, they provided generous latitude for the submission of any alternate scheme which would provide safe support and which might be more economical. Prices, based on the plans and specifications and alternative bids, were received on various types of concrete piles jacked into place which varied in cost from $12,000.00 to $18,500.00. It is interesting to note that in the opinion of the committee the conditions developed during actual construction would have made it economically impractical to carry through any of the alternates submitted. In spite of the considerable difference in prices, it was the opinion of the committee that the lowest figure was reasonably safe, if not generous; it was therefore accepted and work started early in January.

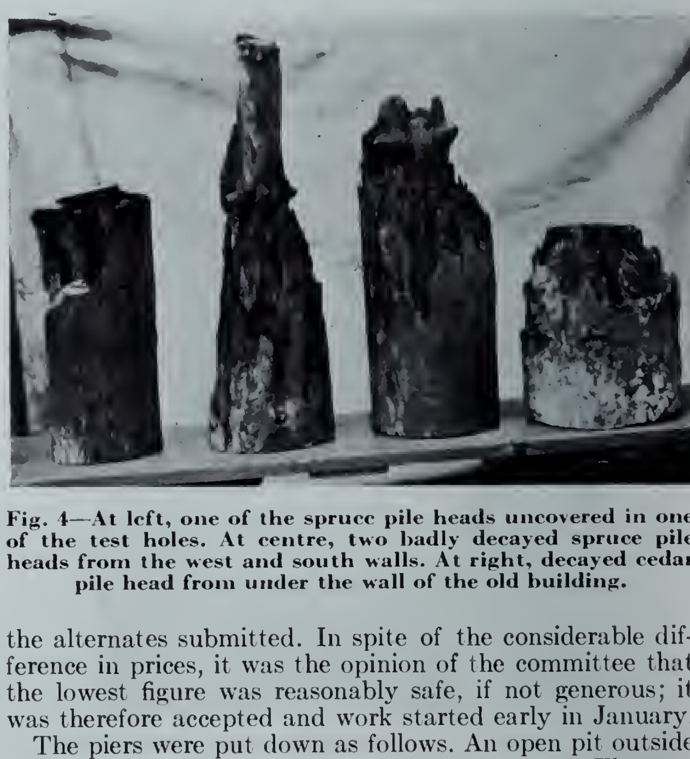

Fig. 4—At left, one of the spruce pile heads uncovered in one of the test holes. At centre, two badly decayed spruce pile heads from the west and south walls. At right, decayed cedar pile head from under the wall of the old building.

The piers were put down as follows. An open pit outside the building was carried 3 ft. below footing level. The projecting portion of the footing pad was broken off and any piles that interfered were cut away. Excavation was then carried on in the restricted size required for the pier. As soon as a depth of 3 to 4 ft. was reached, the excavated hole was trimmed carefully to diameter and 2-in. plank sheeting was placed in short vertical lengths, set in a ring; heavy steel hoops were used to support the sheeting in a true circle and to carry pressure when it developed. If necessary, the rings were held in place by occasional spikes driven into the sheeting. The excavation was carried out progressively to full depth in this manner using small derricks with buckets to remove the material. Even at the lower depths, the clay stood up quite satisfactorily to allow placing the sheeting loose. It was unnecessary at this pit to drive sheeting down into the clay ahead of the open excavation as is often the case where clay is extremely soft and pressure serious. Some pressure developed in all piers due to the plastic nature of the clay. It was possible to carry the pit down about 8 ft. in a shift with one man working at the bottom of the hole and another at the top, hoisting and taking the material away. As soon as satisfactory bearing material was reached and approved the hole was filled with concrete. It is necessary to have the full area of concrete at the bottom to provide bearing; but it is uneconomical and not practical to attempt to build forms and erect small sized shafts to carry the load above. For this reason, a comparatively lean concrete was used carried up on to within six inches of the under side of the footing and allowed to set. After preliminary set and consequent shrinkage was complete, this space was then packed with a dry mix of fine concrete rammed in place by hand using a small heavy tamp.

The depth to which footings were carried was determined by examination after taking the first two or three piers quite deep into the hardpan to make sure that satisfactory material had been reached and was not underlaid by soft layers. The material under the building proved to be soft clay to within about three feet of hardpan. At this point, it changed to a finely divided or pulverized limestone flour. Undoubtedly, there is a considerable clay content mixed with it and in this district it is ordinarily classed as clay, in the building trade. However, it acts in a very different manner from clay, particularly in that it bleeds water when exposed. This difference may involve a serious construction difficulty although in this particular case no trouble developed. It was noticeable that, at this level, water continually trickled into the excavation and it was essential to sheet the excavation although no pressure developed. If left exposed, large chunks of this soil would crack away and fall into the hole instead of squeezing in a plastic manner as in the clay above. The hardpan commenced at a uniform level and formed a very marked stratum. At the top of the hard-pan, the mixture is of ordinary sized gravel embedded in clay. At many points, it was soft due to the constant presence of water carried in the granular material overlying it. Within a few inches, clay in the hardpan became extremely stiff and the boulders increased in size rapidly with depth. These conditions are typical in the Montreal district. Such hardpan is quite satisfactory as bearing material and in many cases is so tough and well cemented that pneumatic spades are required for its removal.

Throughout the excavation, it was necessary to remove the wooden piles. These piles proved to be very small at the tip and most of them reached into the hardpan. The deepest ones driven did not enter the hardpan more than about three feet at which point they were locked between boulders and in many cases were badly broomed. It would appear that the springy nature of the piles and the small tip permitted the heavy driving that apparently was done and which caused some brooming at the pile heads. A few of the piles were found to slope as much as 15 deg., some of them passing out of the caisson excavation entirely and in many holes new piles were encountered as digging proceeded. A great many piles in the west and south walls were badly decayed and as expected those in the southwest corner proved to be the worst. One of these piles was rotted away completely for a height of two feet. Under the old residence wall, it was found that piles also had been used; these were of cedar, and comparatively large, being about 12 to 14 in. diameter. Only six or seven of these piles were removed as they were not closely spaced. In two instances, it was found that short piles had been driven with an additional butt about five feet long driven on top; apparently an old fashioned touch of economy. No splice had been used except that the piles had been cut square. It was interesting to note that the tops of the whole cedar piles were quite badly decayed for a height of about two feet but that these 5-ft. butts were so completely rotted away that they had no structural value.

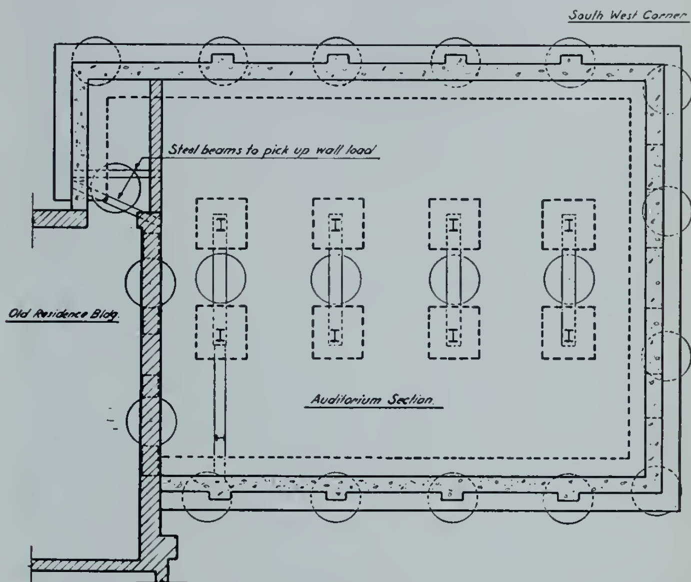

Fig. 5—Plan of the auditorium section showing location of new piers.

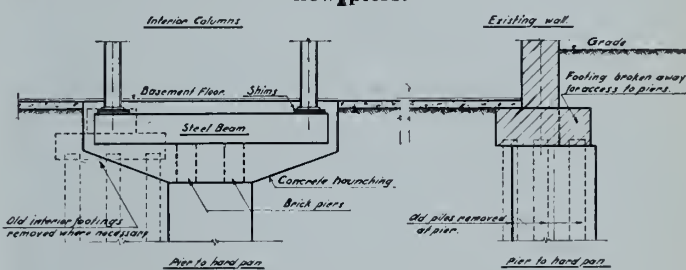

Fig. 6—Sectional view showing the arrangement of the piers between the interior columns.

No serious movement developed during the work. Some attention was paid to this detail and paper stickers were maintained over all cracks. A few of these tore through indicating a very slight movement which could be termed adjustment.

This spring, the brickwork at the southwest corner was cut out and bonded across the main crack and some plaster has been cut away. Complete plaster repairs and re-decoration remain to be done. Obviously it is essential to permit time for adjustment of all strains and movement before carrying out this portion of the repair.

Not the least important part of the work was the clearing out of all books and accumulation of magazines and other fyles from the basement. This room was fitted up as a library years ago and a great mass of papers and records had accumulated which Institute facilities could not utilise. It is interesting to note that at least six tons of scrap paper was sold.

In carrying out these repairs the House Committee was greatly assisted by the co-operation of the general contractors A. F. Byers & Company Limited. The Committee itself was augmented and profited by the advice of Messrs. R. E. Jamieson, J. A. Lalonde, and J. A. McCrory, all of whom were invited to assist because of their wide construction experience. The Committee is pleased to report that the work has been done satisfactorily and none the less happy to report also that the contractors made a satisfactory profit.

BRITISH WORKMANSHIP

From *Trade & Engineering*, (London), April, 1941

"None of Our Aircraft is Missing"

On good days the official communiqués relating to the bombing activities of the R.A.F. frequently conclude with the words "None of our aircraft is missing." It all sounds so simple, as though the aircraft have had an uneventful, unmolested journey; but often the truthfulness of that ending is due to the sterling qualities of the big machines to which our pilots and crews have entrusted their lives, and in part also to the skill and devotion of the ground maintenance crews and the skill and endurance of the flying crews.

The shattered condition in which some of our aircraft have survived terrible batterings by the German anti-aircraft guns and yet succeeded in reaching home is a better tribute to the skill of British workmanship than anything else could be. It is doubtful whether the majority of German aeroplanes would have survived similar rough treatment. Very recently, for instance, a Whitley bomber, while seeking its target at Cologne, was hit by a splinter which penetrated the fuselage. By sheer bad luck the splinter also hit a particularly large flare and blew it up. The consequence can easily be imagined. The whole of the skin and ribs were blown off one side of the fuselage, and on the other side most of the rivets were forced out. There was very little left to hold on the tailplane, but it held; and after they had reached home safely pilot and crew were the first to acknowledge that they owed their safe home-coming to the first-class workmanship.

There are many similar stories. One is of the tail and rudder of a Hampden being shattered by cannon and machine-gun bullets by three Junkers bombers, which attacked at the same time; another, of the fuselage and of a Whitley which were holed by anti-aircraft fire while the British bomber was flying at a height of little more than 2,000 ft.; a third is of a Wellington hit in six places by a severe barrage over Berlin; a fourth, of very serious damage to the port airscrew of another Hampden; and a fifth, of a Hurricane which came back looking more like a colander than a fighter aircraft. And yet, in the words of the official communique, "all our aircraft returned safely."

There is almost no end to the stories demonstrating the toughness of British aircraft. The case is recorded of a Hampden, flying over Hamburg, which received a direct hit in the port wing which ripped open the oil tanks. Yet the port engine, much to the pilot's relief and astonishment, ran "sweetly" all the way home—a distance of more than 400 miles. A Blenheim operating over Rotterdam met exceptionally heavy anti-aircraft fire and the port oil tank was perforated in three places, the lead from the starboard petrol tank was fractured, the elevator main spar was holed, the main spar and fin shot through and a rudder cable cut half through. There were also holes in the tail and fuselage. Yet the buffeted machine not only got home but was back in service within three days.

Another Blenheim actually rose safely again after hitting the sea at almost full speed. After this dangerous encounter with the water the airscrew was badly bent back, the tail wheel was missing, the bomb-hatch cover stove in, and the cowlings and air intakes completely wrecked. Yet once again the machine remained airworthy and made what the pilot afterwards declared to have been a "good" journey home.

This is the sort of thing which is happening every week. Nothing could have been put to a more severe test than British workmanship and materials—and nothing could have emerged from that test with greater credit.

THE ROLE OF THE ENGINEER

From *Civil Engineering and Public Works Review*, May, 1941

Every day that passes brings fresh proof of the important part which the machine is playing in the war effort of the nation. The present struggle is only one of machine against machine and of the men that design and operate them. There is nothing new in this. Down the ages the engineer has ever played his part in warfare as in the more peaceful pursuits. When Alexander the Great attacked the Phoenician town of Tyre, he was only successful after his engineers had constructed a causeway across the strip of water that separated the town from the mainland. It was the engineer and his skill who made the final military assault possible.

The defeat of the Spanish Armada was directly attributable to the superior skill displayed in designing and building the ships used by Drake, Frobisher and the other sea captains of Queen Elizabeth. This skill was no chance thing, but was the outcome of experience gained by the sailors when fighting the enemy along the Spanish Main. The superiority of the English ships can be traced to the careful co-operation of the ship-builders of those days with the men who had to sail in those ships when they were built. It was this co-operation that made it possible to arm Elizabeth's ships more heavily than their Spanish equivalent. This skill played as great a part in the defeat of the Armada as did the courage and the determination of the men who sailed in them. It placed in the hands of the sailors the weapon with which to strike the enemy.

If the part played by the craftsmen in the days of Elizabeth was one of the decisive factors in that epoch making struggle, it is entirely overshadowed by the work of the engineer of to-day. In whatever direction we probe in our endeavours to gain a true picture of the nation's war effort we meet the work of the skilled craftsman and the product of the scientifically trained mind. In the days of Drake the ships stood as the great memorial to the skill of the shipwright. To-day there is no branch of the Army, the Navy or the Air Force that is not dependent on the skill of hands and the genius of science for the implements which it uses.

Since the rise of the Nazi regime to power, the German people have steadily and quietly devoted all their technical skill to the development of the machine for the purposes of war. The scientific mind of the German abandoned its peace-time pursuits and turned to the consideration of every aspect of the creation of an efficient and overwhelmingly powerful mechanised war machine. As physicists, chemists and metallurgists developed their researches, the military engineer translated that scientific knowledge into machines for the Army, the Navy and the Air Force.

The conception of the machine age was fully exploited and the rapid break through last summer bore eloquent testimony to the careful planning and detailed preparations which had been made.

The only counter move to the machine is the machine. The waters of the English Channel checked the advance and enabled this country somewhat belatedly to turn to her workshops and her laboratories. War is no longer a matter of masses of infantry advancing over open country or defending trenches as in the last war. The struggle has been transferred to the designing office and the workshop, for it is there that victory will be decided. It is the skill of our engineers and the craftsmanship of our work-people that has taken up the struggle.

No profession has contributed so much to the growing might of Britain as the engineer, and none is pressing forward with greater eagerness in the fulfilment of his destined part in this struggle. It is a profession that has every reason for pride in its contribution to the national effort, a contribution which will become greater and greater as the days and the months pass by.

THE APPLICATION OF AUTOMOBILE METHODS TO AIRCRAFT PRODUCTION

By Don R. Berlin & Peter F. Rossmann, *Curtiss Aeroplane Division, Curtiss-Wright Corp.*

From *S.A.E. Journal* (New York) June 1941

The international situation has demonstrated that the effectiveness of the airplane is a decisive factor in the outcome of the issues at stake. This potent weapon has directed attention to the urgency for quantity production of aircraft essential to national defense.

With the need for increased production quantities it is natural that there should be serious interest in the application of mass-production technique in the manufacture of aircraft. Consequently, the aircraft industry is urged to utilize the experience and facilities of the world's most outstanding mass-production enterprise, the American automobile industry.

What appears to be reluctance on the part of the aircraft industry to accept automobile production standards is due primarily to the numerical and other differences in what constitutes quantity or mass production and the influence of conditions peculiar to each field. Five hundred cars per day under normal circumstances would not represent unusually high production, whereas up to recently ten airplanes of one type per day would be outstanding. The situation is complicated further by the imperative compliance to rigid weight, performance, reliability, and strength specifications in aircraft manufacture. An empty gasoline tank or a broken gasoline line in an automobile is not a serious hazard; it is an inconvenience; while, in an airplane, a similar failure usually represents an emergency.

Special and single-purpose machine tooling and extensive conveyor systems are economically essential in the manufacture of 100,000 cars wherein certain details of the cost of 1/100 of a cent become important. In aircraft construction the application of such refinements obviously cannot be as extensive. Careful analysis, however, supports the conclusion that much can be gained through the utilization of automobile methods and practices when combined with a liberal application of common sense.

The term mass production is somewhat misleading. The general belief is that it involves only the manufacture of a large number of identical parts, usually by means of special machine tools. Quantity alone does not make mass production, however, mass demand is a reciprocal factor. Therefore, it is necessary to differentiate between large quantity and mass production. A change in the production demand from 100 to 1,000 parts, with certain time limitations, requires more than merely moving the decimal point on a shop order. It may necessitate redesign or re-tooling of the part as dictated by conditions.

Mass production results in uniformity. Although a single craftsman can produce an object of superior quality, it is unlikely—except under the most propitious circumstances—that the same craftsman can duplicate the original results exactly. Nor is it reasonable to expect that artisans of equal skill using average tools can produce identical results unless the operations influenced by individual judgment, tending to cause variations in the final product, can be controlled.

Therefore, mass production may be defined as being the most efficient utilization of the human element. It can be accomplished by observing four requisites. Additional elements could be added; however, the following are listed in sequence rather than in the order of their importance:

(a) Product Engineering;
(b) Tool Engineering;
(c) Cost Analysis and Regulation;
(d) Production Control.

Interchangeability is a desirable product of reduced manufacturing tolerances that automatically eliminates the need for selective fits which represent a definite limitation on output and control. These advantages can be obtained by special machine tooling and processing, but in the automobile industry mass production begins on the drafting board when the design is in an embryonic stage.

This suggests the first consideration in that it has been found advantageous to have design personnel familiar with machining and other factory processes.

It then becomes the problem of determining the extent to which the engineer in the development of a product is constrained to permit tooling methods and manufacturing processes to influence design.

Engineering is basically concerned with the creation or development of a new device or product, or an improvement on one in current use, the design of which is dictated by certain conditions—trend of the art, sales appeal, improved durability, weight and strength requirements—some of which permit no deviation from prescribed specifications.

The project of tooling, on the other hand, is that of utilizing, wherever possible, available standard machine tools, selecting, designing and providing suitable jigs and fixtures, assuring the maintenance of the specified degree of accuracy, and planning the manufacturing operations to obtain the lowest possible production cost.

Unless the product designer is familiar with manufacturing processes and production methods, the impression might be gained that the production tool engineers in their analysis of the design are unnecessarily critical and do not fully appreciate its functional requirements.

Often a slight change in a casting or forging—a modification to simplify basic design or increased tolerances—makes appreciable savings in tool and manufacturing costs. Also, attempts to reduce cost through redesign frequently result in seriously penalizing weight and performance. They are also closely related to serviceability since liberal tolerances, and, in some cases, incomplete interchangeability, might be economical from a production standpoint but the cost of subsequent service because of such conditions might be excessive, and very often the difference between profit and loss. Engine cowling is in this category.

However, the product engineer should not normally be fettered by precedent to the extent that the expression of ingenuity and invention in the design is restrained. Frequently the development and perfection of new and original processes necessitated by engineering design are distinctly advantageous in that competitors are handicapped in duplicating or approximating the new designs if a special process is vital to its fabrication.

In general, the trend in manufacturing processes should tend to permit the engineer more latitude in designs.

Tool engineering is influenced greatly by quantity and the basic design of the part. Properly planned and executed tooling contributes much toward the fulfilment of the mass-production principle, particularly:

(a) Properly planned operation sequences;
(b) Simple foolproof jig-and-fixture design;
(c) Gauging and locating points common to mating parts;
(d) Non-fatiguing work heights and positions;
(e) Reasonable application of time-and-motion studies;
(f) Providing adequate inspection tools.

The advantages and necessity of proper tooling cannot be over-emphasized since the manufacture of interchangeable parts is the indispensable requisite precedent to mass production.

The inspection item, although limited in its application (by quantity requirements), is of more importance than is generally conceded; it is one of the most essential factors in controlling variations in the product. Inspection expedites production, witness for example, the extensive and ingenious automobile inspection tools. Therefore, it is imperative that provisions should be made in the airplane tooling budget for inspection equipment. Good inspection tools inspire greater confidence in inspection results.

The third requisite, accurate "Cost Analysis and Regulation," is more than keeping books to record expenditures. Accurate estimates are necessary for reliable cost predictions, and there is sufficient precedent and cataloging of aircraft manufacturing operation data to be of material assistance in compiling useful cost estimates. Cost regulation is the applied art of intercepting costs before the money is expended. All costs should be challenged and justified; otherwise there can be no confidence in the operation of the expense budget. Time studies may be considered part of the analysis.

The fourth requisite, "Production Control," involves principally scheduling and material handling. The former requires accurate data on equipment and man-power capacities so that an orderly flow of production can be maintained with the minimum of congestion due to holdups, changes, shortages, and so on. This control in automobile manufacture is the nerve centre of production and the clock-like precision with which cars are produced is significant evidence of its effectiveness. Another element of such control that has had practically no recognition in the aircraft industry is the application of economical lot size (the economical cycle) or as it is more generally known the most economical number of parts to make in a set-up. Heretofore, there has been limited opportunity to apply this science in aircraft, but now circumstances are much more favourable to its adaptation.

Material handling can be regarded as part of production control. Its function is more than regulating and moving material through the plant. In fact, an efficient plant layout is planned on the basis of proper routing of material.

Finally, there is the problem of designing the experimental airplane. In the automobile industry there are different influences with regard to sales, customer's desires and requirements, trend of the art, and so on. Furthermore, there is this important difference: the automobile industry flourishes under more advantageous conditions because that type of product can be slanted toward a sales field with every assurance that the experimental model will finally go into active production. In addition, the experimental costs can be amortized over a larger number of units. With aircraft, all experimental projects are likewise considered as production possibilities but this cannot be regarded with the same degree of certainty. Of necessity, progress in this regard has been cautious.

In conclusion, it must be said that the aircraft industry is unique in its development and resourcefulness under the handicap of small quantity production which circumstance has stimulated ingenious methods and techniques adapted to its special requirements. The similarities between the automobile and the aircraft industry are greater than the differences, and the exchange of ideas is a logical development and conducive to progress if the art is not merely utilized but advanced.

HIGH STEAM PRESSURES IN MARINE SERVICE

From *Trade & Engineering*, (London), April, 1941

The employment of higher boiler pressures and temperatures with regenerative feed heating and other expedients has progressively improved the performance of marine steam propelling machinery. The pioneer modern water-tube boiler installations fitted in this country were arranged to work at about 375 lb. pressure, but later installations in the Strathmore, Orion, and similar vessels work at 450 lb. Notable examples fitted abroad include a number of United States tankers with boilers working at 600 lb., and the Yarrow boilers of the Nieuw Amsterdam are arranged for 625 lb., while the German liners Gneisenau and Scharnhorst were fitted with Wagner boilers working at 710 lb.

All these boilers rely upon natural flow for the water circulation, which results from the mixture in the rows of tubes receiving the greater proportion of transmitted heat being less dense than that in the other tubes. This tends to set a limit upon the pressure at which natural circulation can be relied upon to maintain sufficient velocity for the avoidance of over-heating at the high rating of modern installations, and for this reason an alternative line of development with forced circulation boilers working at pressures from 1,900 lb. up to the critical condition of water has been pursued in a number of German liners, including the Uckermark, Potsdam, Pretoria, and Windhuk.

The gain theoretically obtainable from really high pressures is very considerable, and recent research gives promise of even better performances than have hitherto been claimed. High-pressure steam plants under test conditions have frequently shown better results than were expected from calculation, and the difference has been generally attributed to inadequacy of the steam tables on which the predictions were based or to errors of observation on the test. It has, however, been found that the Reynolds number corresponding to the steam conditions has a marked influence on turbine efficiency, so that, with all the other factors equal, a better relative performance is to be expected with high-pressure than with low-pressure steam. At the same time it has to be considered that gains due to improvements in the theoretical cycle with high initial pressures are more readily dissipated through parasitic losses in the nozzles, blading, and spindle glands.

That the thermal performances reported from the German super-pressure liners have been disappointing may be partly due to the latter cause, and it is doubtful whether the complications inherently involved in fitting forced circulation boilers on shipboard can be thermally justified unless the utmost degree of economy offered by their adoption is forthcoming. Consideration of all these factors suggests that steam conditions for marine service may be stabilized at a pressure which, while permitting the employment of natural circulation boilers, is higher than the value so far employed with steam generators of this type but appreciably below those adopted with the German forced circulation boilers.

For this reason special interest attaches to the experimental high-pressure installation which is being fitted in one of the United States Maritime Commission's C 3 class cargo vessels. The main propulsion turbines are of the three-cylinder double-reduction geared type developing a total of 8,000 s.h.p. at a propeller speed of 96 r.p.m., and taking steam at about 1,200 lb. pressure and 740 deg. F. temperature. The two boilers are of a special design of natural circulation three-drum type with air preheater, economizer, and convection superheater. A reheating section fitted in each of them takes the exhaust steam from the high-pressure turbine at about 260 lb. and restores its temperature to about 740 deg. F. before it completed its work in the intermediate and low-pressure cylinders.

Separate oil burners are provided for steam generation and the reheating sections of the boilers. To prevent excessive superheat temperatures during manoeuvring when the reheater is out of action, primary and secondary superheater elements are provided, so located that there is a balance of heat transmission under all conditions of working to maintain a constant outlet steam temperature. Automatic combustion control is provided to maintain a steady steam pressure, and the reheating is regulated by the outlet steam temperature. Manual control is also provided together with safeguards for the reheating section should the flow of steam fall below a predetermined rate. An efficiency of 87 per cent is guaranteed, but it is expected that this figure will be exceeded. All the auxiliaries will be motor-driven with electrical power provided by turbo-generators using steam at 230 lb. which has been reheated to 740 deg. F. and extracted from the intermediate turbine inlet. It is estimated that an oil fuel rate of 0.5 lb. per s.h.p. hour for all purposes will be obtained. An important feature in the design is that as the steam temperature is limited to under 750 deg. F., special alloys are unnecessary and the ordinary materials of construction can be used.

FOG LIGHTS AND FOG FALLACIES

From *Aeronautics* (London), April, 1941

The following is an extract from a paper read before the Institute of the Aeronautical Sciences at Columbia University, New York, by Dr. Sverre Petterssen.

It was commonly believed for some time that light of long wave length (red and infra-red) would penetrate fog more readily than the shorter wave lengths. This supposition was based on the formula developed by Lord Rayleigh for the transmission of light through a suspension of particles of a diameter small compared with the wave length of the light. This formula showed that the scattering coefficient was inversely proportional to the fourth power of the wave length. However, since fog drops are large compared with the wave length of visible and near infra-red light, this formula does not apply. In a typical fog with an average drop radius of 20 microns, the transmission is the same for all wave lengths less than about four microns. The transmission would not become appreciably higher until the wave length was greater than 40 microns. In this far infra-red region water vapour and some of the other atmospheric gases absorb strongly, so that even though the scattering were reduced, the total transmitted energy would probably be smaller. It may, therefore, be concluded that there is no region of the radiant energy spectrum which will penetrate fog better than visible light. This result has been confirmed by direct measurements.

Koschmieder has shown that the visibility or more properly the visual range, is a function only of the scattering coefficient if the observed object is essentially black, is seen against the horizon sky and the sky is uniformly overcast. These conditions are generally satisfied in the case of a fog of considerable depth.

SIX NEW R.A.F. MACHINES

From *Trade & Engineering,* (London), April, 1941

Gradually information is being released about the new types of British aircraft with which the Royal Air Force will conduct its offensive and its defence of Britain in the months ahead. Many of the details of these aircraft, and most of their performance figures, are still secret, but what is no secret is that the authorities are well pleased with the new bombers, while great things are expected from two new fighters.

The existence of the four-engined heavy bomber, the Short Stirling, had already been made public, and two or three weeks ago the existence of the Avro Manchester was made known. It is a twin-engined bomber and according to an American technical journal—these facts cannot be confirmed or denied—the engines are Rolls-Royce Vultures. The Vulture is described as being "two Merlins put together." The same journal says that the Manchester has a speed of 325 miles an hour, a wing span of 90 to 95 feet, and a gross weight of 30,000 lb. This is heavier than the U.S. Army Air Corps' B18 and B23 and much faster than the B18. The Manchester is made by the firm of A. V. Roe, which gave the R.A.F. the excellent training and reconnaissance machine, the Anson. The Anson has achieved such phenomenal success as a fighter—though not intended for that purpose—that the men of the Coastal Command have an expression, "Anson is as Anson does."

The somewhat scanty details about the new range of bombers were added to materially by Sir Archibald Sinclair, Secretary of State for Air, when he introduced the Air Estimates in Parliament on March 11. He revealed that there was in existence a third new bomber, the Halifax. All of these, i.e., the Stirling, the Manchester, and the Halifax, the Minister said, had already proved their worth, and the Stirling had been used against enemy targets. These bombers, he added, were more than twice the size of any earlier type. They were faster and could carry not only a heavier defensive armament, but also three times the weight of bombs for the same distance as their predecessors. The Hampdens, Whitleys, the Wellingtons which, in the past, had constituted the main offensive power of the R.A.F., had undergone many improvements. The latest models were fitted with more powerful engines which gave them increased performance and striking power. Some of them, although the original name remained, were really quite different aircraft from those which flew under the same name last year. Sir Archibald also renewed the assurance given just previously by the Prime Minister that developments would also be continued in the types supplied for coastal reconnaissance and for Army co-operation work.

Then he turned to the fighters. It was known some time ago that the original Spitfires and Hurricanes had been "hotted up" and that the Mark 2 Hurricane and the Mark 3 Spitfire which had come into service were fitted with more powerful engines which had considerably increased their speeds and provided the ability to fight at much greater height, although equipped with heavier armament which increased their fire-power. The Secretary of State was able to reveal that the new Hawker Tornado, with an engine "nearly twice the horse-power of the machines which bore the brunt of the Battle of Britain" and carrying still heavier armament can yet attain speeds in excess of 400 m.p.h. It had previously been stated that the Tornado is a single-seat fighter equipped with a 2,000 h.p. Rolls-Royce Vulture engine.

Then came the first public reference to the existence of the Beaufort Fighter (known as the Beaufighter), which the Secretary of State said is being used for long-range operations and night fighting. He completed the announcement on this formidable range of new aircraft by referring to the twin-engined Whirlwind.

This made a total of six new machines—three bombers (the Stirling, Manchester, and Halifax) and three fighters (the Tornado, Whirlwind, and the Beaufighter)—to be announced this year. They show the speed at which new types have been able to go into production, thanks very largely to the sustained success of the faithful Spitfires and Hurricanes, backed up by the Defiants. The Air Minister summed up by saying:—

"Unless Hitler has up his sleeve a more effective secret weapon than he has yet managed to produce, our technical superiority, with the moral superiority which accompanies it, will certainly be maintained during the year."

Sir Archibald Sinclair also paid a well-deserved tribute to those concerned in the British aircraft industry. The Air Ministry and the R.A.F., he said, recognized their debt to those who, in the crisis of the Battles of France and Britain last year, served the country so well behind the lines. Sometimes it happened that we lost dozens of aircraft in a single battle, but the pilots who baled out nearly always "found fresh mounts waiting for them in the stable." For this strong and timely flow of aircraft into the R.A.F. they must thank, first and foremost, the workman in the factory—the man who gave ungrudgingly of his skill, who worked long hours and seven days a week cheerfully, whose careful and unerring industry never flagged, and who went on working after the sirens had sounded. The victories of the R.A.F. were his victories, too. He included in his tribute the executives, scientists, and designers, who had all "deserved as much as a victorious general." The Ministry of Aircraft Production was devoting its efforts not only to increasing the flow of production but to bringing on as rapidly as possible those new types of bombers and fighters with which we shall engage the enemy this year.

The Minister also referred to a subject which has inevitably given rise to some difficulty—the question of the sterilization of land because of the necessity for constructing many new airfields since the collapse of France deprived us of the use of any airfields on the Continent. He pointed out that more than half of the British Isles is mountain, rock, marsh, or land in other ways unsuitable for aerodromes, which must be level and easily drained. In the flatter parts of the country there are more than 3,700 miles of electric grid to be avoided—and avoided with a wide safety margin—not to mention canals and railways, smoke from industrial areas, balloon barrages, and other obstacles. An aerodrome must also be less than 600 ft. above sea level, otherwise it may be in the clouds for considerable periods; while he pointed out that the development of aircraft tends towards a longer take-off run, so that aerodromes now have to be bigger than before.

Many of the agricultural Members of the House were relieved to have his assurance that the Air Minister was taking no rigid attitude, that he had gone closely into the problem with the Minister of Agriculture, and that, as a result, there would in the future be improved liaison between the Air Ministry and the County War Agricultural Committees.

WARTIME BUILDING

By R. Fitzmaurice, B.Sc.

From *Civil Engineering and Public Works Review*, April, 1941

Wartime building presents peculiarly difficult problems for the designer, since a number of factors unknown in peacetime become of the utmost importance.

The Building Research Board was requested by the Works and Buildings Priority Sub-Committee to take as a first task during the war the solution of problems of building created by the changed position of supplies of building materials. The work carried out as a result is summarized in a series of publications, known as the Wartime Building Bulletins, published by H.M. Stationery Office. The first task undertaken was a study of methods of factory construction suitable for wartime conditions.

Factory Design

At this stage it is appropriate to consider what are the factors to be taken into account in the design of a factory. They are as follows:

1. Suitability for the particular process to be carried out in the factory.
2. Speed and ease of erection, taking into account the conditions of supply of material and labour prevailing at the time.
3. Economy in the use of materials and labour for which demands are heavy in wartime.
4. Ease of concealment from the air.
5. Resistance to damage by air attack.

It will be realized that the wartime factory must be shorn of embellishment, for every single brick and ton of steel must be used to maximum advantage.

Large, clear spaces have their disadvantages in that big spans need more steel than smaller ones and the damage due to the explosion of a bomb may be more widespread.

The whole problem of ease and speed of erection turns on using to the maximum advantage such materials and labour as are available at the time. Thus in a building consisting mainly of structural steel-work it is desirable to find out what range of sections is most readily available at the time required. If reinforced concrete structures are proposed, it may be well worth while to give the contractor some latitude in such matters as the use of precast elements or work poured "in situ." The essential condition for speed in building in wartime is collaboration between all parties concerned and avoidance of too rigid adherence to the original details and specifications. However carefully these details may have been prepared, it is better to adjust a project to the changed conditions than to delay it by insistence on carrying it out exactly in accordance with the original intention.

Building Material

There are various ways of setting out to find the most economic method of covering a given building space. The co-operation of a group of leading structural steelwork designers was enlisted through the kind offices of the British Steelwork Association and the Director of Structures of the Iron and Steel Control.

This group assembled a series of designs of structural steelwork for single storey factories; these were tabulated and reviewed and the less economical rejected. The final selection, for roof spans of 22, 33, 40, 55, 77 and 110 feet, was then again reviewed and the results were made available in Wartime Building Bulletins Nos. 1, 4 and 10. The designs have recently been revised to incorporate the results of experience of actual air attack.

The investigation has shown the importance of the economy which can be got by making use of continuity to keep bending moments to a minimum. Structural continuity also contributes materially to resistance to effects of bomb explosions.

Concrete Construction

To use reinforced concrete construction is an obvious method of economizing in the use of steel. Some typical structures have been designed, suitable for dormitory hutting and temporary hospital accommodation, as well as single storey factories.

Arch structures in reinforced concrete represent a still further move towards economy. The potentialities of reinforced concrete arched construction have been little exploited in Britain, though in France very interesting pro jects have been carried out.

The use of reinforced concrete in wartime is made somewhat more difficult by the need to economize in timber for shuttering. It has been found, however, that by keeping structures simple and repetitive, and by designing in terms of specific, recoverable systems of shuttering, that the waste of timber can be kept very small indeed. This and other aspects of reinforced concrete construction are discussed in Wartime Building Bulletins Nos. 3 and 5.

Generally speaking, great quantities of cement are used in roads, paved areas, runways and solid concrete floors in factories.

Tar macadam can be substituted when necessary for concrete for roadways and paved areas out of doors, and recommended specifications are given in Wartime Building Bulletin No. 9.

Timber in Shuttering

Mention has already been made of the investigations into economy in the use of timber in shuttering and formwork for concrete construction.

The Forest Products Research Laboratory of the Department of Scientific and Industrial Research is preparing data on working stresses to be used in the design of timber structures and these should be available in the near future.

Concealment and Camouflage

Concealment from the air is a very important aspect of wartime construction. As with all other A.R.P. questions, it is an elementary precaution to assume that the worst form of attack may come at some time or other. It is dangerous to assume that there is no possibility of daylight air attack.

One method of approach to the problem of concealment is to disregard it entirely, allowing the building project to take whatever shape it will, then at completion to call in the camouflage expert to disguise the resulting structure. This is the worst possible approach and the camoufleur is presented with a task which may be impossible.

It is strongly recommended that the Civil Defence Camouflage Establishment, Ministry of Home Security, should be consulted at the earliest stage in a wartime building project. Advice is given free of charge.

The following are some of the more important factors to be observed:

(a) Choice of site. Avoid conspicuous landmarks such as the confluence of rivers, important junctions of roads and railways, lakes, etc.

(b) The orientation and arrangement of the buildings on the site should be contrived so as to avoid conspicuous regular patterns. Consideration should be given to the type of building development in the locality which so far as is possible should be simulated.

(c) Saw-tooth and northlight roof lighting should as a general rule be avoided. The deep shadows cast by vertical and steeply pitched glazing are very difficult to conceal.

(d) Where ground has to be excavated the soil may with advantage be banked against the north, east and west sides of the buildings to conceal the shadows cast by the walls. Generally speaking, the buildings should be kept as low as possible in order to minimize the shadows they cast.

(e) Natural features on the site such as clumps of trees, hedges, ditches and streams should be preserved as far as possible and advantage should be taken of them in working out the camouflage scheme.

(f) Building work should be restricted to the minimum possible area of ground. Heavily scarred ground is difficult to conceal and even if ploughed and planted at completion, a considerable time must elapse before the scars recede into the general tone of the landscape.

(g) Great size of individual buildings makes concealment difficult, and factory units should be kept to the smallest size consistent with a satisfactory production layout. A maximum dimension for a unit of 200 ft. in any direction is a desirable limit to aim at.

War Damage

There are three main lines of approach to the problem of minimizing damage by air attack, firstly, by disposing the buildings on the site so that the likelihood of damage by direct hit in any one attack is reduced; secondly, by constructing the buildings so that in the event of a direct hit or near miss by high explosive bombs the resulting damage is reduced to a minimum and production can easily be started again; and, thirdly, by constructing the buildings so that damage by fire resulting from incendiary attack is minimized.

Bombs are dropped in rows or "sticks", so that other things being equal, it is well in laying out a new site to keep in mind the possibility of reducing the chance of a single stick of bombs hitting a number of buildings in line. For instance, arrangements of buildings in curves or crescents on plan is advantageous.

It is a gratifying fact that factory buildings can be made highly resistant to demolition by direct hits or near misses by high explosive bombs. A study of this aspect has been made by Prof. J. F. Baker of the Research and Experiments Department of the Ministry of Home Security, and the advice of this organization is freely available.

The studies of Prof. Baker are particularly complete for single-storey buildings in structural steelwork. The aim should be for such structures to be so designed that any one main member can be cut without causing adjacent members to collapse.

With very little or no additional steel a great many normal roof types are capable of satisfying this condition, but there are other types which are inherently so unstable that injury to one member may lead to progressive collapse extending to the whole of the shop concerned.

The ability of a soundly designed structure to withstand the demolition of a main member without significant deflection of the remainder has been amply proved in recent raids. These principles have been observed in the buildings which are dealt with in Wartime Building Bulletins Nos. 1, 4 and 10, and the revisions which are now just complete.

Briefly the following are the main principles:

1. Trusses and lattices of an unbalanced type should not be arranged so that the removal of a supporting member at one end causes adjacent members to collapse.

2. Beams and built-up girders should be designed to develop full continuity in their lower flanges or chords over staunchion supports, so that in the event of staunchions being removed or damaged the beam or girder can span between adjacent staunchions without collapsing.

3. Roof systems generally should be braced more liberally than would normally be provided for wind action, realizing that damage to a truss or its supports may induce considerable forces which will be transmitted along the line of the purlins.

Fires due to incendiary attack have caused very serious damage. It is suggested that some discrimination needs to be exercised between buildings where the occupancy is such that the fire hazard is important and those where it is negligible.

Where the fire hazard exists, the roof structure may with advantage be made resistant to the small incendiary bomb but, in addition, the building should also be divided up into compartments of moderate extent by adequate fire walls carried right up to the roof with openings closed by fireproof doors (not self-acting). It is suggested when considerable quantities of combustible goods are stored or handled, that a limit of 10,000 sq. ft. of floor area should be the maximum size for any one compartment. In addition all steel work in the building should be encased in concrete or otherwise protected against fire.

From Month to Month

News of the Institute and other Societies, Comments and Correspondence, Elections and Transfers

THE ENGINEERING INSTITUTE OF CANADA IN KINGSTON

On Saturday, June 14th, there was a combination of events in Kingston that will long mark the day in local Institute history. Taking as a central "motif" the presentation of an honorary membership certificate to Dr. R. C. Wallace, Council and the branch arranged a full and interesting programme.

Under the guidance of the president a regional meeting of Council was held during the afternoon in the board room of the gymnasium of Queen's. There was an excellent attendance of officers, councillors and guests. This latter group included past presidents, past councillors, chairmen of three other Ontario branches, and members of the local executive. Another very welcome guest was the president of the Association of Professional Engineers of Ontario.

For the ladies the afternoon programme consisted of a sight-seeing tour and tea. In the evening, dinner was held at the golf club. Details of these features are given in the branch news.

R. C. Wallace, Hon.M.E.I.C.

The Kingston members and their wives may well be proud of the success of their efforts. Every detail was well thought out, and much time and effort was expended in making arrangements so that visitors would fully enjoy their day. The value of such gatherings cannot be over estimated. They assist materially in developing interest and friendship not only in the branch itself but throughout the Institute. The Kingston branch has done an excellent piece of work.

GREETINGS FROM ENGLAND

As mentioned in the June *Journal*, the Institution of Electrical Engineers has done the Engineering Institute of Canada a great favour in presenting in such a handsome manner the Sir John Kennedy Medal to Lieut.-General A. G. L. McNaughton. The illuminated address and the photographs referred to in the correspondence arrived a short time ago, and were presented to Council at the regional meeting held in Kingston in June.

The address is reproduced on an adjacent page, and herewith is a copy of the acknowledgement from Council sent to the Institution at the conclusion of the Kingston meeting:

"James R. Beard, Esq., President,
The Institution of Electrical Engineers,
London, England.

"Dear Mr. Beard:

"The Council of The Engineering Institute of Canada, at a regional meeting held in Kingston, Ontario, on June 14th, received the message from the President, Council and Members of The Institution of Electrical Engineers, and the illuminated address commemorating the presentation of the Sir John Kennedy Medal to Lieut.-General A. G. L. McNaughton, which presentation was so graciously carried out by the Institution of Electrical Engineers on behalf of The Engineering Institute of Canada.

"The Council of the Institute is greatly pleased by the action of the Institution and hastens to express its agreement with the policy of 'close co-operation between engineering institutions in Great Britain and their sister institutions in the overseas countries of our Commonwealth of Nations.' The further development of such co-operation is a part of the programme for the future of this society, and opportunities for such co-operation will be planned for and welcomed at all times.

"May I, Sir, on instructions of Council, convey this message to you and at the same time thank you personally for all that you have done in assisting us to honour this distinguished engineer whose name graces the membership lists of both our organizations.

"Yours sincerely,

(*Signed*) L. Austin Wright,
General Secretary.

Lieutenant-General A. G. L. McNaughton, M.E.I.C., acknowledges the Sir John Kennedy Medal of the Engineering Institute of Canada which has been presented to him by J. R. Beard, President of the Institution of Electrical Engineers, at their meeting held in London, England, on May 8th.

1942 ANNUAL MEETING

Montreal's invitation to hold the next annual and professional meeting in that city was accepted at the 1941 meeting in Hamilton. There was some discussion as to whether or not the programme should be curtailed because of war conditions, but the decision on this point was left with the branch executive. The success of the Hamilton meeting seemed to indicate that there was a place for such functions even during war years.

The Montreal executive has held its first meeting to complete preliminary arrangements. The dates selected are Thursday and Friday, February fifth and sixth, and the location will be the Windsor Hotel. Chairmen of committees have been named, and the work of securing papers is already under way. It is planned to restrict papers and discussions to phases of the engineers' participation in Canada's war effort.

The President, Council and members of

The Institution of Electrical Engineers,

on the occasion of the Ordinary Meeting of The Institution held on Thursday, 8th May, 1941, wish to place on record their appreciation of the invitation received from

The Engineering Institute of Canada

that The Institution should, on their behalf, present to

Lieut.-General A. G. L. McNaughton, C.B., C.M.G., D.S.O.,

the

Sir John Kennedy Medal

awarded to him for "his noteworthy contribution to the science of engineering".

Since some years before the outbreak of the present war this Institution has advocated and fostered closer co-operation between Engineering Institutions in Great Britain and their sister Institutions in the overseas countries of our Commonwealth of Nations; the opportunity to carry out this ceremony on behalf of The Engineering Institute of Canada has therefore been especially welcome at a time when activities towards that co-operation have necessarily had to be curtailed. It adds to the Council's pleasure in arranging this ceremony that General McNaughton has long been an Associate Member of The Institution of Electrical Engineers.

The members present at this meeting extend a hearty welcome to General McNaughton and offer him their warm congratulations, not only on the signal honour in the engineering field conferred on him by the award of the Medal, but on the great distinction which he has achieved in a wider sphere by his appointment as head of the Canadian Forces in Great Britain during the present momentous conflict.

The contribution which is being made by Canadian Engineers to the war effort is recognised to be one of inestimable value in the vital place that is being taken by Canada in the cause of freedom at the side of the Mother Country.

A facsimile copy of this Address is being handed to-day to General McNaughton in commemoration of the occasion of the presentation to him of the Medal.

Witness our hand and Seal at Westminster this Eighth day of May, 1941.

James R. Beard. President.

Johnstone Wright. Past President.

W. K. Brasher. Secretary.

A reproduction of the address prepared by the Institution of Electrical Engineers to commemorate the presentation of the Sir John Kennedy Medal to Lieutenant-General McNaughton.

UNIVERSITY OF TORONTO APPOINTS NEW DEAN

Clarence Richard Young, M.E.I.C., has been appointed Dean of the Faculty of Applied Science in the University of Toronto, in succession to Brigadier-General C. H. Mitchell, M.E.I.C., who has retired. This appointment is a fitting climax to Professor Young's distinguished career as educationalist, author and practising consultant.

The new dean is an honour graduate of the University of Toronto of the class of 1905. He has been on the teaching staff of its engineering school since 1907, when he became lecturer in civil engineering; his professorship dates from 1929, when he succeeded the late Peter Gillespie in the chair of civil engineering.

Dean C. R. Young, M.E.I.C.

His published works include text books and articles in structural engineering subjects and on engineering law. He has been much in request as a consultant on matters concerning the design of structures, and on technical, economic and legal problems of a civil engineering character. In 1937-38 he sat on Mr. Justice Chevrier's three-man Royal Commission on Transportation, dealing with the economics of motor transport in Ontario. The Engineering Alumni Association of the University awarded him their medal in 1939, for outstanding achievement in engineering.

The extent of Professor Young's activities is further shown by his services to The Engineering Institute of Canada of which he is a past councillor and past chairman of the Toronto Branch. He is now chairman of the Institute's Committee on International Relations, and also represents the Institute on the Committee on Professional Training of the Engineers' Council for Professional Development. He has been prominent in the work of the Canadian Engineering Standards Association and in the preparation of the National Building Code.

In view of his wide range of interests it is not surprising to note that during the last war Major Young was Second-in-Command of the Polish Army Camp at Niagara, where over twenty thousand Polish soldiers were trained and sent to France—later to Poland. His services were fittingly recognized by the French and Polish governments.

The Institute membership, which includes so many of Professor Young's friends and former students, will join in wishing the new dean a long and prosperous term of office.

ERRATUM

Attention is called to a serious error made in the June *Journal* in the article "The Justification and Control of the Limit Design Method" by F. P. Shearwood, M.E.I.C. Inadvertently, in laying out the pages, two galleys were interchanged, with the result that the continuity of the paper was badly broken. As there has been a heavy demand for copies (one order from the United States being for 2,000), reprints have been made. Any member who desires a corrected copy may have it upon request without cost. Both to the author and to readers we apologize for this mistake.

WARTIME BUREAU OF TECHNICAL PERSONNEL

A new phase of the Bureau's activity has developed lately. The Department of Labour has placed with the Bureau instructions to proceed with an extension of the plant training scheme for producing skilled and semi-skilled workmen, and with the proposal to put machine shops on a twenty-four hour basis for the manufacture of materials for war contracts. The schools included in the federal government training schemes are well ahead of schedule, but lack of shop facilities has made it difficult to give the candidates sufficient practical experience. The proposal to put partly idle machine shops on a twenty-four hour basis will permit of training a greater number of men, and of producing an increased quantity of war supplies at the same time. Already the pulp and paper industry has produced fine results, and it is expected that the extension of the scheme to other industrial groups will aid materially in producing the much needed and related products of trained mechanics and mechanical merchandise.

The Bureau has already consulted with the mining industry at a largely attended meeting in Ottawa. Out of this conference has come an extension of the activity, setting up an organization to handle the work on behalf of the whole group, and generally developing a plan to utilize the spare machine hours of all mine machine shops.

Steps are now being taken to discuss the proposals with other groups. It is expected that each group will take in other shops that are close to it geographically or industrially so that eventually the scheme will be expanded to cover the country and to permit owners of large and small shops alike to participate in the war effort.

This programme is similar to the "bits and pieces" policy of the old country which has produced such excellent results there. There is no doubt of its practicality—the example of the pulp and paper group proves that. The need for machine tools and for trained mechanics can be met by an intensive development of this proposal.

The Editor of the Engineering Journal,
Montreal, P.Q.

Aircraft Cost Estimating

Dear Sir:

In Mr. Wanek's most interesting paper and Miss MacGill's enlightening discussion thereon, published in the May issue of the *Journal*, it is noted that Mr. Wanek places the emphasis on estimated costs, while Miss MacGill places it on actual shop costs. As the writer has worked in engineering shops in both England and America, though not on aircraft, perhaps he can comment on this difference in viewpoint.

In America all important shops have an elaborate shop costing system, while in England few concerns, even now, have such systems; and until recently the only cost figure usually available was the total expense charged to a completed order. As a result the management of an English firm placed the emphasis on the estimated cost; and if the actual shop costs differed from this it was the shop that was criticized; while in America it is, of course, the opposite. An American manager would consider that an English estimated cost obtained as indicated in Mr. Wanek's paper was merely an approximate figure. But that is not the case. English estimators are highly expert engineers with long practical experience, and their work is really very accurate. The English and the American methods are each based on their respective national industrial aptitudes. The American is based on detailed specialization in the job of costing, and the English on a high degree of craftsmanship in estimating. Both give reasonably accurate results with the type of personnel available.

Respectfully,

(Signed) W. L. Waters, M.E.I.C.

Rainier, Alberta,
June 8th, 1941.

L. Austin Wright, Esq., M.E.I.C., General Secretary,
The Engineering Institute of Canada,
2050 Mansfield Street, Montreal, P.Q.

Dear Mr. Wright:

I would like to take this opportunity to thank you for your letter of congratulation on my winning "The Engineering Institute of Canada Prize" at the University of Alberta for the year 1941.

This high honour encourages me greatly in the belief I have chosen the correct profession.

During the last term I became a Student Member of The Engineering Institute of Canada and found their meetings interesting and educational.

I believe this close association between student and professional engineers helps the student considerably in realizing his future duties as a professional engineer.

I am sure that I am also speaking for my classmates when I say that I am indeed looking forward to becoming a Member of The Engineering Institute of Canada.

Yours sincerely,

(Signed) Ralph N. McManus.

The following letters refer to Council's recent action in granting remission of fees to all members in the combatant zones. Many additional letters have been received but these are typical of them all—*Editor.*

Ruston & Hornsby Ltd.,
London, W.C.2., 6th June, 1941.

L. Austin Wright, Esq., General Secretary,
The Engineering Institute of Canada,
Montreal, Canada.

Dear Sir:

I have your letter of May 3rd re Institute fees of members in the United Kingdom.

I request that you will place before the President and Council this, my sincere appreciation of the very handsome gesture thus made by the governing body of the Institute.

Although you are all exceptionally sympathetic and generously minded in respect of the inconveniences and danger we are putting up with in the old country just now, I would have you know that the spirit of all our people is such that these dangers and hardships seem less than they sound. As a matter of fact you would be amazed how nearly normal we all seem to manage to be in the doing of our job in wartime, which, needless to say, is plenty.

Nobody has any doubt as to the ultimate result, and already we feel we are getting steadfastly towards that superiority of power which will ultimately put the supermaniac out of business.

Speaking for all concerned, we thank you for your excellent sentiment on behalf of your fellow Britishers. Although the monetary aspect of the gesture is not perhaps called for by any privation on this side, it is true that we have difficulty in getting permission to remit money overseas.

One wishes that more Institutions and persons could see their way to be as understanding and brotherly as the Engineering Institute of Canada.

With compliments and kindest regards to you all.

Yours sincerely,

(Signed) T. W. Fairhurst.

Exeter, Devon, England.
June 7th, 1941.

Dear Mr. Wright:

I have only just recently received your very nice letter of May 3rd, remitting annual fees payable to the Engineering Institute of Canada for the duration of the war and until happier days come. Please convey my very best thanks to the Members of the Council and also to yourself for the generous resolution.

The forces of Righteousness must eventually triumph and it is a grand thing to see the way in which all this world wide misery and trouble has knitted together more firmly than ever before the peoples of our great God given Empire in the cause of Justice and Truth.

I remain,

Yours sincerely,

(Signed) F. J. Bellamy.

Dorset, England,
June 1st, 1941.

Dear Mr. Wright:

I wish to acknowledge your letter of May 3rd in which you inform me of the Council's resolution, regarding the remittance of fees to members residing in the United Kingdom; may I express my deep appreciation of their kindness, which act is so typically Canadian. Truly we have many hardships and trials to contend with, but the receipt of your letter brought great encouragement and I am sure the effect of the resolution on all members over here will far exceed anything the Council could have anticipated.

Yours sincerely,

(Signed) P. Reynolds, M.E.I.C.

9 Copplestone Road,
Budleigh Salterton, Devon.,
4th June, 1941.

Dear Sir:

Your letter dated 3rd May with reference to the remission of fees granted to members of the Institute in the United Kingdom, only reached me this morning.

I shall be obliged if you will convey to the Council my thanks and appreciation of the thoughtful kindness they have shown by their action, which forges another link in the ties between the Mother Country and Canada, and I trust that our final victory may not be long delayed.

Yours sincerely,

(*Signed*) H. A. Elgee, M.E.I.C.

56 Beaconsfield Road, London, S.E.3, England,
4th June, 1941.

Dear Mr. Wright:

The friendly gesture of the Council of the Institute in arranging to remit my fees during this trying period, as indicated in your letter of 3rd May, is greatly appreciated. It is not so much the amount of money involved that concerns us on this side, as the difficulties of obtaining Canadian exchange and the desire on our part to avoid using any foreign exchange except for the purpose of prosecuting the war.

You will no doubt be glad to know that I am engaged as a director of a very large works employed exclusively on the manufacture of vital explosives plant and armaments, and in spite of the great numbers of H. E. bombs, oil bombs and incendiaries that the Germans have dropped on our works, we have been able to put out all the fires quickly and clean up and repair all damage with great speed, and our output has not dropped even one per cent, although we can consider ourselves very lucky. Of course, we have all had very narrow shaves at times, and working continuously round the clock, Saturdays and Sundays included, with such heavy air attacks going on from time to time has been a bit trying, but as a member of the Institute having opportunities better than most people of knowing what our vital works on this side are doing, I think we will yet turn out the necessary equipment to enable our fighting forces to win through. Most of us now hardly call ourselves civilians, as those, like myself, who must stick to their jobs nevertheless belong to the Home Guard, in which I hold H.M. Commission.

My lifelong friend, C. G. Du Cane, who was a member of the Institute and was for some years in partnership with me in Vancouver, has, as you will know, passed away. I think it was due to his being out all night in his car on rescue work in the City of London when he was suffering from a very severe cold aggravated by asthma, which brought on pneumonia.

Yours sincerely,

(*Signed*) H. B. Fergusson, M.E.I.C.

Apparently at the time of writing, the author of the following letter had not received notice of Council's decision to remit fees for members in combatant areas. The letter is reproduced as it seems to indicate in a subtle way something of the splendid spirit of the people who are so gallantly and so calmly resisting the worst efforts of the enemy.

—*Editor.*

"The Secretary, Engineering Institute of Canada,
2050 Mansfield Street, Montreal, Canada.

"Dear Sir:

"I wish to advise you that I have taken up a post as Assistant Works Manager with International Alloys Ltd.

"I lost my home some time ago due to enemy action, and have therefore lost the statement of dues—could you let me have a copy of same in order that I may make application to our Government for permission to export the necessary Canadian currency to meet these dues. In the meantime, will you continue please to mail the Journal to me.

"Yours faithfully,

(*Signed*) C. H. Oakes."

The recipients of honorary degrees at the spring convocation of McGill University, held on the campus on May 29th. From left to right: Her Royal Highness the Princess Alice, Doctor of Laws; Right Hon. Malcolm MacDonald, British High Commissioner to Canada, Doctor of Laws; Dorothy Thompson, Doctor of Letters; Dr. Hu Shih, Chinese Ambassador to the United States, Doctor of Letters; Dean C. J. Mackenzie, Acting President of the National Research Council of Canada, and President of the Engineering Institute of Canada, Doctor of Science; and Principal James.

MEETING OF COUNCIL

A regional meeting of the Council of the Institute was held at Queen's University, Kingston, Ontario, on Saturday, June 14th, 1941, at two-thirty o'clock p.m.

Present: President C. J. Mackenzie in the chair; Past-Presidents J. B. Challies (Montreal), T. H. Hogg (Toronto); Vice-Presidents deGaspé Beaubien (Montreal), K. M. Cameron (Ottawa), and McNeely DuBose (Montreal); Councillors W. H. Munro (Ottawa), D. S. Ellis (Kingston), J. H. Fregeau (Three Rivers), C. K. McLeod (Montreal), H. Massue (Montreal); Secretary Emeritus R. J. Durley, and General Secretary L. Austin Wright.

There were also present by invitation: Past-Presidents F. P. Shearwood, G. J. Desbarats, A. Surveyer; Past Vice-Presidents A. H. Harkness, R. L. Dobbin, E. V. Buchanan; Past Councillor L. M. Arkley; Branch Chairmen H. E. Brandon (Toronto), T. A. McElhanney (Ottawa); T. A. McGinnis (Kingston); D. J. Emery (Peterborough), and H. H. Lawson (Kingston); S. Frost, President of the Association of Professional Engineers of Ontario.

Past-President Challies, as Chairman of the Institute's Committee on Professional Interests, reported on the recent negotiations with the Association of Professional Engineers of New Brunswick. He commented on the discussions which had taken place between members of his committee and members of the council of the Association in Saint John in May. Out of these negotiations a revised agreement had been developed and a new draft prepared. He recommended that the agreement be submitted to the Institute's legal authorities before it went out for final approval. Subject to this condition, Mr. Challies recommended that the council approve of the draft, so that the agreement could be submitted to all councillors, to corporate members in the province of New Brunswick, and printed in *The Engineering Journal* in accordance with the terms of By-law No. 78 (old No. 76). Accordingly it was agreed that the draft be approved.

It was noted that the financial statement up to the end of May showed the Institute finances to be in good condition. It was recommended by the committee that the cost of repairs to headquarters, beyond the amounts which were collected by the branches, should be paid this year out of current funds. Mr. Beaubien thought that with the excellent assistance which had been given by the branches, the Institute would have little difficulty in meeting its obligations for the year. Past-President Challies, in moving the approval of the financial report, complimented Mr. Beaubien on his excellent management of this important part of Institute affairs.

The secretary made a general report on the amounts collected by various branches. Discussion followed as to the advisability of council making a further appeal to the branches, but it was decided that all branches were fully informed and would do their best without any further requests.

The finance committee recommended that a sum of $2,500.00 be used to purchase Victory Loan Bonds, this to be taken from cash lying in "special accounts." It was also recommended that a further $2,500.00 be taken from current funds. It was felt that the latter sum might be a large amount to withdraw from the cash available, but that it was a patriotic action and the Institute should make every effort to assist in the endeavour. Mr. Beaubien stated that if at the end of the year it was found that cash was needed, the bonds could be very readily converted. After discussion Council agreed that the purchase should be made.

The general secretary read communications from the Institution of Electrical Engineers describing the ceremony which had been put on by that body to present the Sir John Kennedy Medal to Lieutenant-General A. G. L. McNaughton in London.

A beautiful illuminated address had been prepared to commemorate the ceremony, one copy being given to

General McNaughton and one being sent to the Institute. The secretary read this address and he was instructed to communicate to the Institution Council's appreciation of the manner in which the presentation had been made, and also of the sentiments expressed in the address.

The general secretary reported that some of the branches of the Institute had set up special groups to co-operate with others in their localities in the development of Air Raid Precautions in Canada. He also reported that permission had been received from the Ministry of Home Security to distribute in Canada the various bulletins printed in London by the Ministry. Duplicate sets of all bulletins issued to date had been forwarded to the Institute and the secretary asked council if they would discuss the matter in order to determine to what extent the Institute would participate in this activity. The secretary also reported that some preliminary figures had been obtained on the cost of mimeographing the bulletins, and that he had also been in touch with Dr. Glidden, Federal Director of A.R.P. at Ottawa to discuss with him the possibility of the Institute assisting. Mr. Munro reported on some of the activities in Ottawa, and pointed out that these bulletins might be of assistance to groups such as that established in Ottawa as well as those in other cities.

Mr. McElhanney reported that the Ottawa Branch had recently discussed the question, and that it was thought that the branch might join with other groups in Ottawa to set up a joint committee to deal with at least one phase of Air Raid Precautions, that is, air raid shelters. It had been suggested that the question of community shelters and the improvement of personal property for the same purpose might also be considered. A joint committee had already been formed with the A.R.P. group.

The president stated that he thought the Institute should investigate this matter to see if it could not be of assistance. He thought it might be advisable to suggest to the federal A.R.P. group that the Institute should have a representative on their committee.

Past-President Challies supported the president in his suggestion. He recommended that the Institute take the matter up aggressively, and constructively, and give all the support possible.

The president stated that an attempt was being made in the National Research Council to have some one person familiarize himself with the many bulletins which had been published in Britain so that information appropriate to Canadian conditions could be brought to the attention of interested parties. Some one person should read everything so as to obviate the necessity of many people going through the same material. Finally, it was decided that Mr. Munro be appointed chairman of a committee, with power to add. He was to communicate with the proper authorities at Ottawa to see what could be done by the Institute to assist the federal and local authorities. It was also agreed that Mr. Munro and his committee could make the decisions with regard to the printing of the bulletins.

The general secretary presented a report on the Institute prizes and medals prepared at Council's request by Mr. Durley and himself, making recommendations that would eliminate some of the over-lapping and confusion in the present arrangement.

The report read by Mr. Durley made many suggestions of a constructive nature. The re-distribution which it proposed made it possible for the Institute to offer a reward in each of the principal fields in which the members of the Institute are interested. The report also clarified regulations applying to several of the existing awards. It also recommended certain additional prizes.

The president congratulated Mr. Durley on the recommendations, and suggested that copies be made and sent to all councillors so that a full discussion could take place at a later meeting. It was agreed that this should be done and that all past-presidents should be included in the list of those receiving copies.

A communication was read from Dean Wilson, of the University of Alberta, in which he inquired whether students in engineering physics would be eligible for the Institute undergraduate prizes. It was agreed that such students should be eligible.

Attention was called to the summer meeting of the American Institute of Electrical Engineers to take place in Toronto. The president reported that he had received an invitation to attend, but that he would be absent from Canada at that time on important business. Past-president Hogg was asked to represent the president and to present the meeting with the good wishes of the Institute.

As it is not customary to have meetings of Council in July and August it was left with the president and the general secretary to set a date for the next meeting.

Before adjourning the meeting, the president expressed Council's appreciation of the attendance of Mr. Stanley Frost, president of the Association of Professional Engineers of the Province of Ontario.

The meeting adjourned at 5.15 p.m.

THE QUEBEC SCHOOL OF MINES

The recent inauguration of the Quebec School of Mines marks another milestone in the advance of engineering education in Canada. The establishment of this new school by Laval University, as part of its Faculty of Science, has been made possible by an undertaking on the part of the provincial government to provide a substantial yearly grant.

The Quebec School of Mines

Laval University has been granting degrees since 1852 in Medicine, Law, Theology and Arts, but has only recently extended its activities into the field of engineering. It is the first university in Canada to offer courses in mining and metallurgical engineering and geology to French speaking students. The courses leading to the Bachelor's degree in mining and metallurgical engineering extend over a period of four years. Bachelor's degrees in geology are not granted, but graduates in mining engineering can obtain their Master's degree in geology by taking one year of post-graduate work. Students wishing to take courses in other branches of engineering may, on completion of the first two years at Laval, apply for admission to the third year in other universities. The courses offered at the School are very similar to those offered by other Canadian universities in these branches of learning. The first two years are devoted largely to the fundamental sciences: chemistry, physics and mathematics. Courses are also given in engineering drawing and descriptive geometry. The third and fourth years are devoted to specialization in engineering subjects.

The School of Mines occupies a new five-story building of steel and masonry construction on the outskirts of the city of Quebec. The fifth floor is now largely used by the Canadian Officers Training Corps. The fourth floor is occupied by the department of geology and includes lecture rooms, offices, the geological museum, research laboratories and laboratories for general geology, economic geology, mineralogy and petrography. On the third floor are the library, the amphitheatre, draughting rooms and offices and some of the ore dressing laboratories. The second or ground floor is occupied by the administration offices of the Faculty of Science, the museum of mining and metallurgy, various laboratories and the recreation room. On the first floor are located the strength of materials laboratories, the main ore dressing and metallurgy laboratories and the showers and locker rooms. The heating plant, the transformer and panel rooms, and most of the mechanical engineering laboratories are in the basement.

A corner of the ore dressing laboratory

The equipment in the various laboratories is all of the latest design. The metallurgy laboratories are equipped with an Ajax-Northrup high frequency induction furnace, a Hayes controlled-atmosphere Globar furnace, two electric furnaces for fusion and cupellation and several gas furnaces. There are also assay balances, a Burrell gas analyzer, a Junkers gas calorimeter, an oxygen bomb calorimeter, a gas density balance, potentiometers, various types of pyrometers, a set of rolls, Amsler and Brinell hardness machines, an Amsler impact testing machine and a torsion machine. Equipment for hydrometallurgical tests has been ordered from England and will be installed as soon as received. The metallography laboratories include all the equipment necessary for grinding and polishing, several Leitz microscopes and a Panphot microscope. This equipment is also used for mineralography.

The ore dressing laboratories contain in laboratory and small commercial sizes all the types of equipment used in crushing, grinding, classification, flotation, amalgamation, cyanidation and precipitation. The various pieces of equipment in the advanced section can be operated as a complete mill unit or separately for research purposes.

In the strength of materials laboratory are a 72,000 lb. Amsler universal tensile testing machine, a 200,000 lb. Amsler compression machine with a special beam carriage for flexure tests, a Chatillon crane scale for deflection of beams, extensometers and all the equipment required for concrete, oil and asphalt testing. The mechanical engineering laboratory contains a 50 hp. boiler for boiler trials, a 15 hp. steam engine, a Diesel engine, a fan with wind tunnel for experiments in ventilation, a compressor, a vacuum pump and other equipment. The most important equipment in the hydraulics laboratory includes two centrifugal pumps, a Pelton wheel and two flumes. In the electrical engineering laboratory the main pieces of equipment are a 40 kw. motor generator set which supplies direct current to the various laboratories of the building, a dynamometer set, various types of motors and generators and a mercury-arc rectifier.

The geological laboratories have several microscopes, a Merman specific gravity balance, a Fuess one-circle goniometer, a Baird x-ray unit, a Zeiss Abbe refractometer, a diamond saw and polishing equipment.

The teaching staff has been selected with great care, each member of the faculty being a specialist in his particular field. With its long experience as an institution of higher learning and its well established traditions, Laval University will no doubt do much to maintain the high standards of the engineering profession in Canada.

The following members of The Engineering Institute of Canada are on the teaching staff:

A. O. Dufresne, M.E.I.C., Deputy Minister of Mines of the Province of Quebec; Professor of Mineral Economics.

G. W. Waddington, M.E.I.C., Professor of Mining Engineering.

René Dupuis, M.E.I.C., Assistant General Superintendent, Quebec Power Company; Lecturer on Industrial Relations.

R. F. LeBlanc, S.E.I.C., General Assistant in the Mining Department and Lecturer on Mine Surveying.

Other members of the staff are:

Adrien Pouliot, Dean of the Faculty of Science of Laval.

Gérard Letendre, Director of the Department and Lecturer on Metallurgy.

Maurice Archambault, Chief of the Division of Chemistry and Mineralogy, Bureau of Mines, Quebec; Lecturer on Assaying.

Eugène F. Poncelet, in charge of the Ore Dressing course.

Joseph W. Laverdière, Secretary of the Faculty of Science; Professor of Geology and Paleontology.

Carl Faessler, Geologist for the Provincial Department of Mines; Professor of Mineralogy and Petrography.

J. D. H. Donnay, Lecturer in Crystallography and Mineralogy.

G. M. Schwartz, Professor in Economic Geology and Mineralography.

THE ENGINEERING INSTITUTE OF CANADA PRIZE AWARDS 1941

Eleven prizes known as "The Engineering Institute of Canada Prizes" are offered annually for competition among the registered students in the year prior to the graduating year in the engineering schools and applied science faculties of universities giving a degree course throughout Canada.

Each prize consists of twenty-five dollars in cash, and having in view that one of the objects of the Institute is to facilitate the acquirement and interchange of professional knowledge among its members, it has been the desire of the Institute that the method of award should be determined by the appropriate authority in each school or university so that the prize may be given to the student who, in the year prior to his graduating year, in any department of engineering has proved himself most deserving as disclosed by the examination results of the year in combination with his activities in the students' engineering organization, or in the local branch of a recognized engineering society.

The following are the prize awards for 1941:

Nova Scotia Technical College	Harold Thomas Rose
University of New Brunswick	Alastair D. Cameron
McGill University	John F. Davis, S.E.I.C.
Ecole Polytechnique	Gérard Lefebvre, S.E.I.C.
Queen's University	N. Grandfield
University of Toronto	A. B. Extence
University of Manitoba	John Frederick Pink
University of Saskatchewan	James Charles Buchanan
University of Alberta	Ralph Norman McManus, S.E.I.C.
University of British Columbia	Eric L. Smith
Royal Military College of Canada	No award—regular course discontinued during the war

RECENT GRADUATES IN ENGINEERING

Congratulations are in order to the following Juniors and Students of The Institute who have completed their courses at the various Universities:—

NOVA SCOTIA TECHNICAL COLLEGE

HONOURS

Archibald, Lester Joseph, Halifax, N.S., B.E. (Mi.); Honours in Mining Engineering.

DEGREE OF BACHELOR OF ENGINEERING

MacCallum, Wallace Allison, Amherst, N.S., B.E. (Mech.)
McInnis, John Francis, Inverness, N.S., B.E. (Mech.).
MacKinnon, Archibald Hugh, New Glasgow, N.S., B.E. (Mech.).
Tibbo, Gordon Tucker, Grand Bank, Nfld., B.E. (Mech.).

THE UNIVERSITY OF NEW BRUNSWICK

HONOURS AND MEDALS

Ronalds, Ivan Frederick, Toronto, Ont., B.Sc. (Ci.); Honours in Civil Engineering; Ketchum Silver Medal for the highest standing in civil engineering.

DEGREE OF BACHELOR OF SCIENCE

Brenan, William Murdoch, Saint John, N.B., B.Sc. (Ci.).
Bruce, Gordon Wyndham, Fredericton, N.B., B.Sc. (Ci).
Kennedy, John Frederick, Fredericton, N.B., B.Sc. (Ci.).
Kinghorn, William Wallace, Fredericton, N.B., B.Sc (Ci.).
Lutes, Eric MacPherson, Fredericton, N.B., B.Sc (Ci.).
McKnight, Samuel William, Fredericton, N.B., B.Sc. (Elec.).
McLaughlin, George Frederick Armstrong, Perth, N.B., B.Sc. (Ci.).
Saunders, William Allison Baxter, Calgary, Alta., B.Sc. (Ci.).
Shearer, John Alexander, Fredericton Junction, N.B., B.Sc. (Ci.).
Snodgrass, John Roscoe, Fredericton, N.B., B.Sc. (Ci.).

ÉCOLE POLYTECHNIQUE

DISTINCTIONS ET PRIX

Lessard, Roger, Montréal, Qué., B.Sc.A., I.C., avec grande distinction. Médaille de S. H. Le Lieutenant-Gouverneur de la province, décernée au premier de sa promotion pour toute la durée des études.
Manseau, Marcel, Montréal, Qué., B.Sc.A., I.C.; avec grande distinction. Médaille de L'Association des Anciens Elèves de l'Ecole Polytechnique, attribuée au premier dans les matières de cinquième année d'études.
Monti, Thomas Attilio, Montréal, Qué., B.Sc.A., I.C., avec grande distinction. Médaille de bronze l'Association des Anciens Elèves de l'Ecole Polytechnique, le prix Augustin Frigon ($25.00) offert au premier des cours de Physique et d'Electrotechnique, cours theoriques et travaux de laboratoires.
Lavigueur, Bernard, Montréal, Qué., B.Sc.A., I.C., avec distinction. Médaille d'or de l'Association des Anciens Elèves de l'Ecole Polytechnique, offerte à l'étudiant ayant presenté la meilleure thèse.
Aubry, Gérard, Montréal, Qué., B.Sc.A., I.C., avec distinction. Prix de la Cinquantième Promotion de l'Ecole Polytechnique ($50.00), offert à l'élève qui a présenté la meilleure thèse industrielle.
Melillo, Vincent, Montréal, Qué., B.Sc.A., I.C., avec distinction.
Proulx, Gilbert, Montréal, Qué., B.Sc.A., I.C., avec distinction.
Larose, Gerard, Montréal, Qué., B.Sc., I.C., avec distinction.
Beaupré, Bernard, Montréal, Qué., B.Sc., I.C., avec distinction.

DEGRÉS

Marceau, Séraphin, Montréal, Qué., B.Sc.A., I.C.
Lanouette, Marcel, Montréal, Qué., B.Sc.A., I.C.
Ravary, Robert, Montréal, Qué., B.Sc.A., I.C.
Martel, Pierre, Montréal, Qué., B.Sc.A., I.C.
Joncas, Louis, Montréal, Qué., B.Sc.A., I.C.
Archambault, Jean, Montréal, Qué., B.Sc.A., I.C.
Michaud, Maurice, Montréal, Qué., B.Sc.A., I.C.
Samson, Jean, Montréal, Qué., B.Sc.A., I.C.
Bousquet, Paul, La Providence, Qué., B.Sc.A., I.C.
Lacroix, Jean, Montréal, Qué., B.Sc.A., I.C.
Grothé, André, Montréal, Qué., B.Sc.A., I.C.
Dauphinais, Ernest, Montréal, Qué., B.Sc.A., I.C.

McGILL UNIVERSITY

HONOURS, MEDALS AND PRIZE AWARDS

Brown, William Crocker, St. John's, Nfld., B.Eng. (Elec.); Honours in Electrical Engineering; British Association Medal; Montreal Light, Heat and Power Consolidated First Prize; The Institute of Radio Engineers' Prize.
Godbout, Adolphe Gérard, Montreal, Que., B.Eng. (Ci.); The Robert Forsyth Prize in Theory of Structures and Strength of Materials.
Gordon, John Abraham, Canso, N.S., B.Eng. (Elec.); Montreal Light, Heat and Power Consolidated Second Prize.
Harvie, Thomas Allan, Montreal, Que., B.Eng. (Mech.); Honours in Mechanical Engineering; British Association Medal.

DEGREE OF BACHELOR OF ENGINEERING

Baburek, Christian Stephen, Montreal, Que., B.Eng. (Mech.).
Blanchard, John Rust, Montreal West, Que., B.Eng. (Chem.).
Copping, Edward, Joliette, Que., B.Eng. (Elec.).
Cumming, John William, New Glasgow, N.S., B.Eng. (Ci.).
Dubé, Jean Thomas, Montreal, Que., B.Eng. (Mech.).
Harley, Gordon Glen, Montreal, Que., B.Eng. (Mi.).
Hayman, William Morris, Montreal, Que., B.Eng. (Mech.).
Hibbard, Ashley Gardner, Sherbrooke, Que., B.Eng. (Ci.).
Hodgson, Ronald High, Montreal, Que., B.Eng. (Mech.).
Jones, Edward Lewis, Calgary, Alta., B.Eng. (Chem.).
Kane, Redmond John, Westmount, Que., B.Eng. (Ci.).
Kelly, James Oswald, Montreal, Que., B.Eng. (Chem.).
Keyfitz, Irving Mortimer, Montreal, Que., B.Eng. (Mech.).
Mackay, William Ronald, Montreal, Que., B.Eng. (Elec.).
Morse, Clifford Eric, Montreal, Que., B.Eng. (Elec.).
Pue-Gilchrist, Alfred Condé, Sydney, N.S., B.Eng. (Mech.).
Russell, Gordon Douglas, Montreal, Que., B.Eng. (Chem.).
Simpkins, Arthur Chalkley, Sunny Brae, N.B., B.Eng. (Mech.).
Stopps, Frank Sidney, Cochrane, Ont., B.Eng. (Mech.).
Webster, Geddes Murray, Yarmouth, N.S., B.Eng. (Mi.).
Williams, Donald Drysdale, Montreal, Que., B.Eng. (Mech.).
Wright, Austin Meade, Westmount, Que., B.Eng. (Elec.).

QUEEN'S UNIVERSITY

HONOURS, MEDALS, SCHOLARSHIP AND PRIZES

Courtright, James Milton, Ottawa, Ont., B.Sc. (Ci.); Honours in Civil Engineering.
Curtis, John Knowlton, Kingston, Ont., B.Sc. (Ci.); Honours in Civil Engineering.
Eddy, Robert Cheyne, Bathurst, N.B., B.Sc. (Chem.); Honours in Chemical Engineering; Post-Graduate Scholarship in Chemical Engineering.
Kennedy, Russell Jordan, Dunrobin, Ont., B.Sc. (Ci.); Honours in Civil Engineering; Departmental Medal.
Van Damme, Joseph, Arvida, Que., B.Sc. (Mech.); Honours in Mechanical Engineering; Departmental Medal.

DEGREE OF BACHELOR OF SCIENCE

Brown, Graham Edward, Ottawa, Ont., B.Sc. (Chem.).
Carlson, Arthur John, Fort Frances, Ont., B.Sc. (Ci.).
Chandler, Ralph Wright, Kingston, Ont., B.Sc. (Ci.).
Collins, Kenneth Fawcett, Niagara Falls, Ont., B.Sc. (Chem.).
Cunningham, Robert Auld, Ottawa, Ont., B.Sc. (Ci.).
Cuthbertson, Robert Shedden, Cardinal, Ont., B.Sc. (Mech.).
Demers, Charles Eugène, Québec, Que., B.Sc. (Ci.).
Dickie, Harold Guthrie, Fort William, Ont., B.Sc. (Mech.).
Dowd, Elbert Watson, Ottawa, Ont., B.Sc. (Ci.).
Guy, Ross Thomas, Oshawa, Ont., B.Sc. (Mech.).
Hamilton, Harry Irwin, Sault Ste. Marie, Ont., B.Sc. (Mech.).
Kempton, Douglas Robert, Brockville, Ont., B.Sc. (Ci.).
Mitchell, John Douglas, Moose Jaw, Sask., B.Sc. (Mi.).
McCorkindale, Donald Harvey, Indian Head, Sask., B.Sc. (Ci.).
McDowell, Creighton Joseph Mackintosh, Windsor, Ont., B.Sc. (Mech.).
Pearce, Eldridge Burton, Fort Erie, West, Ont., B.Sc. (Mech.).
Phemister, William Ian, Niagara Falls, Ont., B.Sc. (Mech.).
Pierce, John Gourley, Peterborough, Ont., B.Sc. (Ci.).
Remus, Frank Richard, Oshawa, Ont., B.Sc. (Mech.).
Rigsby, David L., Chatham, Ont., B.Sc. (Mech.).
Sanders, Robert Lewis, Cornwall, Ont., B.Sc. (Mech.).
Savory, John Alfred, Hamilton, Ont., B.Sc. (Mech.).
Stone, John Gordon, Ottawa, Ont., B.Sc. (Ci.).
Thompson, George Wilbert, Niagara Falls, Ont., B.Sc. (Chem.).
Tkacz, William, Fort William, Ont., B.Sc. (Mech.).
Trout, Ross Gregory, Estevan, Sask., B.Sc. (Mech.).

UNIVERSITY OF MANITOBA

DEGREE OF BACHELOR OF SCIENCE

Boone, William Edward Roy, Indian Head, Sask., B.Sc. (Elec.).
Borrowman, Ralph Willson, Winnipeg, Man., B.Sc. (Ci.).
Browne, Jack Wilkinson, Winnipeg, Man., B.Sc. (Elec.).
Gauthier, Raymond Claude, St. Boniface, Man., B.Sc. (Ci.).
Gavlas, Edward Henry, Winnipeg, Man., B.Sc. (Elec.).
Heppner, Selwyn Alexander, Winnipeg, Man., B.Sc. (Elec.).
Hopps, John Alexander, Tuxedo, Man., B.Sc. (Elec.).
Horsburgh, John Graham, Winnipeg, Man., B.Sc. (Ci.).
Kippen, James Alexander, Winnipeg, Man., B.Sc. (Ci.).
Knights, Kenneth Ronald, Winnipeg, Man., B.Sc. (Elec.).
Koropatnick, Peter, Winnipeg, Man., B.Sc. (Ci.).
Kummen, Harold Thorvald, Winnipeg, Man., B.Sc. (Elec.).
Lamb, Thomas, Winnipeg, B.Sc. (Ci.).
Mackinnon, William Donald, Winnipeg, Man., B.Sc. (Ci.).
Olafson, Harold Sigmur, Winnipeg, Man., B.Sc. (Elec.).
Paget, Kenneth Kane, Winnipeg, Man., B.Sc. (Ci.).
Pauch, John Emil, Winnipeg, Man., B.Sc. (Elec.).
Sokoloski, Steve, Winnipeg, Man., B.Sc. (Elec.).
Steinman, Morris Irvin, Winnipeg, Man., B.Sc. (Ci.).
Vance, Fenton Russell, Winnipeg, Man., B.Sc. (Elec.).
Yee, Thomas Marion, Winnipeg, Man., B.Sc. (Elec.).
Young, Hume Blake, Winnipeg, Man., B.Sc. (Ci.).

UNIVERSITY OF TORONTO

HONOURS

Dinsmore, Clarence Sherman, Clarksburg, Ont., B.A.Sc. (Eng. Physics); Honours in Engineering Physics.
Etkin, Bernard, Toronto, Ont., B.A.Sc. (Eng. Physics); Honours in Engineering Physics.
Phripp, Clarence Frank, Toronto, Ont., B.A.Sc. (Ci.); Honours in Civil Engineering.
Smith, Harold Pennell, Newtonbrook, Ont., B.A.Sc. (Elec.); Honours in Electrical Engineering.

DEGREE OF BACHELOR OF APPLIED SCIENCE

Ames, John Wilkes, Toronto, Ont., B.A.Sc. (Ci.).
Merritt, Robert James, Toronto, Ont., B.A.Sc. (Met.).
Near, James Dailey, St. Catharines, Ont., B.A.Sc. (Ci.) Degree of Master of Applied Science.
Ramore, William David, Port Arthur, Ont., B.A.Sc. (Ci.).
Waller, Milford John, Montreal, Que., B.A.Sc. (Elec.).
White, Walter Edmund, Toronto, Ont., M.A.C.

UNIVERSITY OF SASKATCHEWAN

HONOURS

Mantle, John Bertram, Saskatoon, Sask., B.Sc. (Mech.); Great Distinction in Mechanical Engineering.

DEGREE OF BACHELOR OF SCIENCE

Armbruster, Erhart, Saskatoon, Sask., B.Sc. (Ci.).
Ball, Walter Harvey, Maidstone, Sask., B.Sc. (Ci.).
Crook, Donald Gordon, Regina, Sask., B.Sc. (Ci.).
Dawson, George Ernest, Medicine Hat, Alta., B.Sc. (Mech.).
Dougall, Allan Thomas, Saskatoon, Sask., B.Sc. (Mech.).
Dwyer, Francis Richard, Macoun, Sask., B.Sc. (Mech.).
Edwards, John Bevan, Saskatoon, Sask., B.Sc. (Mech.).
English, William John, Saskatoon, Sask., B.Sc. (Mech.).
Fraser, Frederick Walter, Calgary, Alta., B.Sc. (Ci.).
Genge, John Pope, Gliddon, Sask., B.Sc. (Mech.).
Malloff, William, Yorkton, Sask., B.Sc. (Mech.).
Mann, Gordon Charles, Tessier, Sask., B.Sc. (Mech.).
Mercer, George, Saskatoon, Sask., B.Sc. (Ci.).
Milavsky, David Saul, Saskatoon, Sask., B.Sc. (Ci.).
Miller, John Leonard, Saskatoon, Sask., B.Sc. (Ci.).
Minty, Gordon Robert, Eldersley, Sask., B.Sc. (Mech.).
Mitchell, John Hugh, Regina, Sask., B.Sc. (Mech.).
Noble, William Lawrence, Saskatoon, Sask. B.Sc. (Ci.)
Powers, John Louis, Artland, Sask., B.Sc. (Mech.).
Sturdy, Ferris Durnin, Saskatoon, Sask., B.Sc. (Mech.)
Sweeney, John Bartholomew, Saskatoon, Sask., B.Sc. (Chem.)
Symons, Lloyd George, Jansen, Sask., B.Sc. (Mech.).
Todd, Henry, Biggar, Sask., B.Sc. (Ceramic).
Walker, Roger Hugh, Grandview, Man., B.Sc. (Ci.).

UNIVERSITY OF ALBERTA

HONOURS AND PRIZE AWARDS

Stollery, Charles Alexander, Edmonton, Alta., B.Sc. (Ci.); High Distinction with First Class General Standing in Civil Engineering; First Class General Standing in Applied Science; Association of Professional Engineers of Alberta Prize in Civil Engineering.

DEGREE OF BACHELOR OF SCIENCE

Dewis, Marshall Woodworth, Canmore, Alta., B.Sc. (Elec.).
Ehly, Lucas Joseph, Edmonton, Alta., B.Sc.
Hargrave, John Huxley, Walsh, Alta., B.Sc. (Ci.).
McKernan, Earl Wesley, Edmonton, Alta., B.Sc. (Elec.).

ELECTIONS AND TRANSFERS

At the meeting of Council held on June 14th, 1941, the following elections and transfers were effected:

Members

Carroll, Cyril James Gibson, B.Arch. (Univ. of Toronto), Flight-Lieutenant, R.C.A.F., Ottawa.

Dixon, Noel (Mansfield Tech. College, England), office engr., H. F. McLean Limited, Valleyfield, Que.

Gray, Nesbit (Dalziel Technical School), dsgr. and supervisor of constrn., Shawinigan Water & Power Co., Three Rivers, Que.

Lajoie, Gerard, B.Sc.A. (Ecole Polytechnique), i/c constrn. of Intercepting Sewer, Quebec City, for Arthur Surveyer & Co.

Leipoldt, Ewald Van Niekerk (Charlottenburg Tech., Berlin), elctl. engr., Shawinigan Engineering Co., Montreal.

Mitchell, William Geddes, B.A. (Trinity College, Univ. of Dublin), chief dftsman., Canadian Bridge Co., Walkerville, Ont.

Morissette, Joseph Simeon Antonio, B.Sc.A. (Ecole Polytechnique), dist. engr., Department of Roads, Quebec.

McLeish, William Andrew Edward, elecl. supt., Belgo Divn., Consolidated Paper Corp., Shawinigan Falls, Que.

Nixon, William Herbert, B.A.Sc. (Univ. of Toronto), night supt., Foundation Co. of Canada, Arvida, Que.

Pinto, Enrico Arthur (London Univ.), engr., United Kingdom Technical Mission in Canada, Montreal.

***Reynolds,** John Alfred, Aircraft Inspector, Trenton Air Station, R.C.A.F.

Ryley, Alfred St. Clair, B.Sc. (McGill Univ.), vice-pres. and dist. mgr., Truscon Steel Co. Ltd., Montreal.

Affiliate

Holland, Alwin, res. engr. Watson Lake Aerodrome, Civil Aviation Divn., Dept. of Transport, Watson Lake, Yukon Territory.
Schenck, William Edwin, partner, The Pfeffer Co., Stratford, Ont.

Junior

Arpin, Jean Victor, B.Sc.A. (Ecole Polytechnique), prod. engr., Canadian Car Munitions Ltd., Montreal.

***Linke,** Richard Herman (Univ. of Alta.), instrumentman, City of Edmonton.

Lucyk, John Wasyl, B.Sc. (Univ. of Manitoba), demonstrator, University of Manitoba, Winnipeg.

Swift, Lionel D., B.Eng. (McGill Univ.), operation dept., Shawinigan Water & Power Co., St. Roch, P.O. Quebec, Que.

Transferred from the class of Student to that of Member

Arnason, Einar, B.Sc. (Univ. of Man.), Capt., 2nd in command, 1st Canadian Corps, Field Park Coy, R.C.E. (Overseas).

Berenstein, Leslie, B.Sc. (McGill Univ.), vice-pres., and structl. engr., Louis Pickard & Co. Inc., Montreal.

Dow, Gordon Young, B.Sc. (Univ. of N.B.), Capt., O.C. 1st Brighton Fortress, R.C.E., Saint John, N.B., M.D. No. 7.

Dunlop, Duthie MacIntosh, E.E. (1933), C.E. (1934), (Univ. of Man.), Roadmaster, C.P.R., Reston, Man.

Hare, Charles Mackay, B.Sc. (McGill Univ.), surveyor & dftsmn., Noranda Mines Ltd.

Heavysege, Bruce Reid, B.Eng. (McGill Univ.), inspr., Canadian Underwriters Assoc., Montreal.

Muir, Clarke Bower (B.Sc.), (N.S. Tech. Coll.), genl. foreman and asst. engr., i/c Wire Dept., Canadian General Electric Co., Peterborough, Ont.

Transferred from the class of Affiliate to that of Junior

***Pollock,** Allan, McIntyre Porcupine Mines, Schumacher, Ontario.

Transferred from the class of Student to that of Junior

Corbett, Bruce Sherwood, M.A.Sc. (Univ. of Toronto), Pilot Officer, R.C.A.F., Montreal.

Diggle, William Marvin, B.Sc. (Univ. of Sask.), dftsmn., Canadian Bridge Co., Walkerville, Ont.

Piette, Guillaume, B.Sc.A. (Ecole Polytechnique), soil engr., Quebec Highway Dept., Quebec, P.Q.

Thibault, Joseph George, B.Sc. (Univ. of Sask.), engrg. apprtee., Southern Canada Power Co., Montreal.

Admitted as Students

Cumming, John William (McGill Univ.), jr. dsgr. & dftsmn., Aluminum Co. of Canada, Montreal.

Dawson, George E. (Univ. of Sask.), attending A.I.D. School, Toronto.

Macdonald, Ian Malcolm (N.S. Tech. Sch.), 267 South St., Halifax.

Thompson, George Wilbert, B.Sc. (Queen's Univ.), chemist, Welland Chemical Works, Niagara Falls, Ont.

Tetrault, Robert (McGill Univ.), 1587 MacGregor St., Montreal.

*Has passed the Institute's examinations.

COMING MEETINGS

Fourth Pan-American Highway Congress—Mexico City, September 15-24.

National Industrial Advertisers Association—Annual Conference, September 17-19, Royal York Hotel, Toronto, Ont.

Canadian Good Roads Association—Twenty-sixth Annual Convention—early in October, Niagara Falls, Ont.

Personals

News of the Personal Activities of members of the Institute, and visitors to Headquarters

John McLeish, M.E.I.C., director of the Mines and Geology Branch of the Department of Mines and Resources, has retired, after completing forty-five years in the service of the Dominion Government. The good wishes of his chiefs and colleagues were conveyed to him by the Minister, the Hon. T. A. Crerar, at a recent gathering of the departmental staff. In doing so, the Minister referred particularly to the effective part taken by Mr. McLeish in the work of developing the mining industry—now so important a factor in Canada's war effort. During Mr. McLeish's twenty-year period of responsible office as director, the Mines Branch has become widely known for the work of its ore dressing, metallurgical and fuel testing laboratories and for the technological assistance rendered to industry and engineering.

A graduate of the University of Toronto Mr. McLeish entered the Civil Service in 1896, rising until in 1936 on the amalgamation of the Mines, Interior, Immigration and Indian Affairs departments to form the new Department of Mines and Resources, he was selected as the first director of its Mines and Geology Branch.

John McLeish, M.E.I.C.

During his government service, Mr. McLeish held many special appointments among which may be mentioned his membership of a commission on the Iron Industry of Canada (1914), the vice-chairmanship of the Dominion Fuel Board (1922), and membership of the Turner Valley Gas Conservation Board (1932). He has served on various Associate Committees of the National Research Council, including that recently formed to deal with the metallic magnesium question.

His services to the professional and scientific bodies to which he belonged included the chairmanship of the Ottawa Branch of the Institute for four years; for two years he was president of the Ottawa Branch of the Royal Astronomical Society of Canada. He has always given freely of his time and energy in promoting the welfare and advancing the legitimate interests of his fellow members of the technical and scientific services of Canada. His many friends hope that in his leisure he may long be able to continue such public spirited activities.

Lt. Colonel H. G. Thompson, M.E.I.C., has been promoted to colonel and appointed chief ordnance mechanical engineer at the Department of National Defence, Ottawa. He returned recently from England where he commanded No. 2 Army Field Workshop, R.C.O.C. In his new work, Colonel Thompson is to have available to him, through consultation, the expert advice and experience of Colonel N. C. Sherman, M.E.I.C., Commandant of the R.C.O.C. Training Centre at Kingston, Ont.

H. G. Angell, M.E.I.C., has resigned from the engineering staff of the Aluminum Company of Canada Limited to take up official duties with the British Admiralty at Bermuda. He had returned last year from Portsmouth, England, where he had been employed with the Admiralty for the past few years.

C. H. McL. Burns, M.E.I.C., formerly manager of the Welland plants of Canada Foundries and Forgings Limited recently joined the Ordnance Division of the Otis-Fensom Elevator Company at Hamilton and is at the present time on temporary loan to the Wartime Merchant Shipping Limited, Montreal.

(Courtesy Canadian Newspaper Service)
James Ruddick, M.E.I.C.

James Ruddick, M.E.I.C., has recently been appointed consulting engineer to the Royal Canadian Air Force. Born in England, he was educated at Durham College of Science and served his apprenticeship with the firm of Selby, Bigge and Company, Newcastle-on-Tyne, and with Messrs. Clarke, Chapman & Company, at Gateshead. After several years of electrical construction experience in England he came to Canada in 1907 and joined the Shawinigan Water & Power Company where he was responsible for construction work. From 1909 to 1912 he was employed by E. A. Wallberg of Cobalt, Ont., as construction engineer, and later as general superintendent of operation. In 1912 he became chief construction engineer with the Dominion Coal Company at Glace Bay. From 1915 to 1924 he was manager and engineer with the Laurentian Power Company. In 1924 he engaged in private practice, and has since specialized as a consultant in general engineering.

R. H. Findlater, M.E.I.C., is now located at Joplin, Mo., where he is employed with the Inspection Board of the United Kingdom and Canada as British Inspection representative at the plant of the Atlas Powder Company.

R. C. McMordie, M.E.I.C., has obtained his degree of Civil Engineer from the University of Toronto this spring. He is on the staff of the Hydro-Electric Power Commission of Ontario at Toronto.

Joachim Fortin, M.E.I.C., is now employed as an engineer in the Agricultural Engineering Department of the Province of Quebec, at Quebec.

Augustin Frigon, M.E.I.C.

F. H. Kester, M.E.I.C.

McNeely DuBose, M.E.I.C.

Augustin Frigon, M.E.I.C., assistant general manager of the Canadian Broadcasting Corporation, has recently been entrusted with new responsibilities by the Board of Governors of the Canadian Broadcasting Corporation. Hereafter, he will be in charge of the financial administration of the Commercial and of the Engineering Divisions and will supervise generally the programmes of the French network. He will also be responsible for the entire staff of the Corporation, numbering 620, except for the programme producing staff remaining under the general manager who is still looking after the national network, public relations, policy matters and official relations generally. According to the revised by-laws of the Corporation, Dr. Frigon is now reporting directly to the Board of Governors of the Canadian Broadcasting Corporation and to its Executive Committee. His headquarters will be in Ottawa.

F. H. Kester, M.E.I.C., has resigned from the position of general manager of the Canadian Bridge Company Limited, Walkerville, Ont., and has been asked to remain with the organization as consultant. He has been with the firm since 1907 when he joined as a draughtsman, becoming successively assistant engineer from 1912 to 1919, contracting engineer from 1919 to 1927, vice-president and director from 1927 to 1937 when he was elected president of the company. Until his recent resignation he combined with his office of president that of general manager.

McNeely DuBose, M.E.I.C., has been elected president of the Canadian Electrical Association at the annual meeting held at the Seigniory Club, Lucerne, Que., last month. Mr. DuBose who is a vice-president of the Institute, is the general manager of Saguenay Power Company Limited.

J. R. Hango, M.E.I.C., has been appointed general superintendent of Saguenay Transmission Company Limited at Arvida, Que. He was previously superintendent of distribution of Saguenay Power Company Limited.

S. W. Hall, M.E.I.C., is now employed as senior assistant engineer, Works and Buildings Branch, Naval Service, Ottawa. Since his graduation from the University of Toronto in 1938 he had been with the Building Department of the City of Toronto.

W. M. Reynolds, M.E.I.C., has accepted a position with the Hydro-Electric Power Commission of Ontario at Ferland, Ont. He previously carried a consulting practice at Sault Ste. Marie, Ont.

J. H. Ingham, M.E.I.C., has joined the staff of Walter Kidde Company of Canada at Montreal. A graduate of McGill University in 1935 he had been with the Dominion Bridge Company ever since as a mechanical designer and estimator.

G. H. Kimpton, M.E.I.C., has left the Oxygen Company of Canada, Montreal, to join the Royal Canadian Air Force in the aeronautical engineering division. He is at present stationed in Montreal. He was graduated in chemical engineering from McGill University in 1935.

C. K. McDonald, M.E.I.C., is at present on the staff of Wartime Merchant Shipping Limited, Montreal, on loan from the Shawinigan Water & Power Company.

J. P. Leroux, Jr.E.I.C., is now employed as resident engineer at Mont-Joli Airport, Mont-Joli, Que. He was graduated from the Ecole Polytechnique in 1939, and was employed with the Department of Public Works of Canada at Montreal until last year when he transferred to the Civil Aviation Branch of the Department of Transport.

Flight-Lieutenant R. C. C. Brown, Jr.E.I.C., is now officer commanding No. 3 Repair Depot, R.C.A.F., at Vancouver, B.C.

G. K. Narsted, Jr.E.I.C., has joined the engineering staff of Sorel Steel Industries Limited. He was graduated in mechanical engineering from McGill University in 1940, and worked for several months with the Canadian Bridge Company Limited at Walkerville, Ont. Lately he had been employed with the Eaton, Wilcox Company Limited at Windsor, Ont.

Paul E. Rose, Jr.E.I.C., who is on the staff of the Canadian General Electric Company, has recently been transferred from Toronto to Montreal. He was graduated from the Ecole Polytechnique in 1937, and upon his graduation joined the company as an apprentice in the test course.

A. E. Chard, Jr.E.I.C., has received a commission as pilot officer in the armaments branch of the R.C.A.F., and is stationed at Belleville, Ont. He was graduated in mechanical engineering from the University of British Columbia in 1935. In 1937 and 1938 he was employed with the British Columbia Pulp and Paper Company at Port Alice, B.C. Lately he had been on the staff of Spruce Falls Pulp and Paper Company at Kapuskasing, Ont.

Lorne B. Whiteway, Jr.E.I.C., who has been resident engineer with the Prince Edward Island Department of Public Works and Highways for the past three years, has accepted an appointment with the R.C.A.F. Works and Buildings, as assistant engineer at No. 4 Repair Depot, Scoudouc, N.B.

L. J. Ehly, S.E.I.C., who was graduated from the University of Alberta in chemical engineering this spring is now employed with the Royalite Oil Company at Turner Valley, Alta.

J. Angelo Roncarelli, S.E.I.C., is now overseas where he is attached to the Royal Montreal Regiment in charge of transport. Captain Roncarelli was graduated in mechanical engineering from McGill University in 1938. He joined the Royal Canadian Ordnance Corps at the outbreak of war as a sub-lieutenant, and was soon promoted and sent to England where he took a special course in ordnance at the Royal Academy of Military Science.

J. C. Loiselle, S.E.I.C., has returned to the staff of Canadian International Paper Company at Gatineau, Que. He was graduated in civil engineering from McGill University in 1937. Upon his graduation he joined the Canadian International Paper Company at Gatineau. From 1938 to 1940 he worked with Baulne & Leonard, consulting engineers, Montreal. For the past year he had been with Truscon Steel Company of Canada at Montreal.

Gérard Brosseau, S.E.I.C., has been appointed by the Aeronautical Inspection Directorate as inspector at the plant of Federal Aircraft Limited, Montreal, upon his return from Toronto where he followed a four months' course. Previous to his joining the Department of National Defence he was with Canadian Car & Foundry Company Limited in Montreal.

Murray D. Stewart, S.E.I.C., has resigned from the staff of Messrs. Babcock, Wilcox and Goldie-McCulloch Limited, to accept a commission as lieutenant in the Royal Canadian Ordnance Corps, and is now located at Toronto.

Marcel Papineau, S.E.I.C., has joined the R.C.A.F. as a pilot officer in the aeronautical engineering branch, and is located at Montreal. He was graduated from the Ecole Polytechnique in 1940, and was on the staff of Noranda Mines Limited at Noranda, Que., for the past year.

J. E. Pauch, S.E.I.C., has joined the engineering staff of R.C.A. Victor Company at Montreal.

VISITORS TO HEADQUARTERS

H. N. Goodspeed, S.E.I.C., International Nickel Company, Sudbury, Ont., on May 30th.

Lieut. J. R. Carson, S.E.I.C., H.Q. 3rd Canadian Division Engineers, Debert, N.S., on June 2nd.

S. Hogg, M.E.I.C., St. John Drydock and Shipbuilding Co. Limited, Saint John, N.B., on June 4th.

C. J. Oliver, M.E.I.C., Assistant Superintendent, Electrical Distribution, Rio de Janeiro Tramway Co. Limited, Rio de Janeiro, Brazil, on June 4th.

A. E. Hopper, M.E.I.C., Ottawa, Ont., on June 6th.

G. N. Houston, M.E.I.C., Olds, Alta., on June 7th.

B. E. Surveyer, AFFIL. E.I.C., Aluminum Company of Canada Limited, Arvida, Que., on June 9th.

P. M. Schear, S.E.I.C., Buchans Mining Company Limited, Buchans, Nfld., on June 10th.

E. L. Ball, Jr.E.I.C., Field Engineer, Foundation Company of Canada Limited, Arvida, Que., on June 11th.

D. A. Evans, M.E.I.C., Resident Manager, Powell River Paper Co. Limited, Powell River, B.C., on June 17th.

W. G. Reekie, M.E.I.C., Resident Engineer, Quebec North Shore Paper Co. Limited, Baie Comeau, Que., on June 19th.

N. Klodniski, S.E.I.C., International Nickel Co. of Canada Limited, Sudbury, Ont., on June 20th.

R. D. McKay, M.E.I.C., Sanitary Engineer, Dept. of Public Health, Halifax, N.S., on June 21st.

Obituary

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Theodore Kipp, M.E.I.C., died at Winnipeg, on May 30th after a lengthy illness. He was born in Germany in 1880 and came to the United States with his parents at the age of one year. He was educated at Bradley Polytechnic Institute, Peoria, Ill. From 1897 to 1903 he served an apprenticeship in flour and cereal mills at the same time taking home courses and private instruction in mechanical engineering. In 1904 to 1905 he was mill superintendent with Woolner Distilling Company, Peoria, and in 1906 he became assistant manager and engineer with Independent Cereal and Milling Company. During the years 1907 and 1908 he was engaged in contracting and consulting engineering in the firm of Kipp-Lackey Company at Peoria. He came to Canada in 1909 as mill superintendent with Tillson Company Limited, at Tillsonburg, Ont. From 1910 to 1914 he was manager of the cereal department at Robin Hood Mills Limited, at Moose Jaw, Sask. From 1914 to 1918, he was engaged in consulting and sales engineering under his own name in Winnipeg, Man. In 1918 he was appointed general superintendent and engineer of Ogilvie Flour Mills Company Limited, at Winnipeg. He later returned to consulting engineering and contracting and organized the firm of Kipp-Kelly Limited, at Winnipeg. He was also a partner in the firm of Sullivan, Kipp and Chace Limited, of Winnipeg. During the last war he was consultant to the British Food Board for whom he designed and built a number of cereal mills in England and Ireland. At the time of his death he was director of several firms.

Mr. Kipp joined the Institute as a Member in 1918.

CANADIAN PETROLEUM PRODUCTION

Canada's crude petroleum production in 1940 amounted to 8,717,345 barrels compared with 7,826,301 barrels in 1939, reports the Department of Mines and Resources.

About 97 per cent of the total Canadian output came from the Turner Valley field, southwest of Calgary, Alberta, where at the close of the year 131 wells were producing crude oil and 24 others were being drilled. Thirty-five crude oil wells were completed in 1940 in Turner Valley. Small amounts of crude oil were also produced in other localities in Alberta, namely, in Red Coulee, Wainwright, Vermilion, Del Bonita, Dina, Lloydminster, and Moose Dome. Alberta's total production of petroleum in 1940 aggregated 8,493,000 barrels as compared with 7,576,932 barrels in the preceding year.

Ontario, New Brunswick, and the Northwest Territories also produced crude petroleum in 1940. The Ontario output, totalling 186,000 barrels, came from Petrolia, Oil Springs, Bothwell, and the townships of Dawn, Warwick, West Dover, and Mosa. The Stoney Creek field, southwest of Moncton, New Brunswick, produced 21,161 barrels, and the wells near Norman, about fifty miles west of Great Bear Lake in the Northwest Territories, yielded 17,184 barrels.

Tests were completed at a number of prospective producing localities in Alberta during the year, namely, at the Blood Indian Reserve, Brazeau, Lloydminster, Steveville, and Vermilion, and drilling or preliminary operations were in progress in several other areas including Black Diamond, Clearwater, Grease Creek, Mill Creek, Moose Dome, Pincher Creek, Pouce Coupé, Sheppard Creek, Spring Coulee, Taber, Twin River, and Willow Creek. Tests were also conducted in Saskatchewan at Bishopric, Kamsack, Lloydminster, and Little Pines; in British Columbia at Commotion Creek; in Ontario near Collingwood and on Manitoulin Island, and in Quebec near York River in the Gaspé Peninsula.

News of the Branches

Activities of the Twenty-five Branches of the Institute and abstracts of papers presented

HAMILTON BRANCH

A. R. Hannaford, M.E.I.C. - *Secretary-Treasurer*
W. E. Brown, Jr.E.I.C. - - *Branch News Editor*

On the evening of May 9th, Dr. H. B. Speakman addressed the regular branch meeting on **Alcohol from Wheat.** The speaker was introduced by Vice-Chairman S. Shupe. Dr. Speakman outlined briefly the historical background and the serious character of the present situation in regard to stocks of wheat in western Canada. Reference was made to the use of alcohol in motor fuels in European countries, and the attempts recently made to show its possibilities, both technically and economically in the United States. Working under the auspices of the Associated Boards of Trade, a committee of chemists and engineers has recently looked into the possibilities of "Power Alcohol" from a Canadian viewpoint.

Dr. Speakman outlined the findings of this committee and discussed the merits of the proposal both as a relief from an emergency and also as a part of a long-term policy for Canada. The necessity for continued research and economic study along other lines was emphasized.

The lecture brought forward many questions from a very deeply interested audience of 36. After the lecture, members and visitors retired for coffee and cake and a friendly chat with the speaker of the evening. Before the address the audience enjoyed the showing of the Engineering Institute film of the events leading up to and the failure of the Tacoma Bridge.

KINGSTON BRANCH

J. B. Baty, M.E.I.C. - *Secretary-Treasurer*

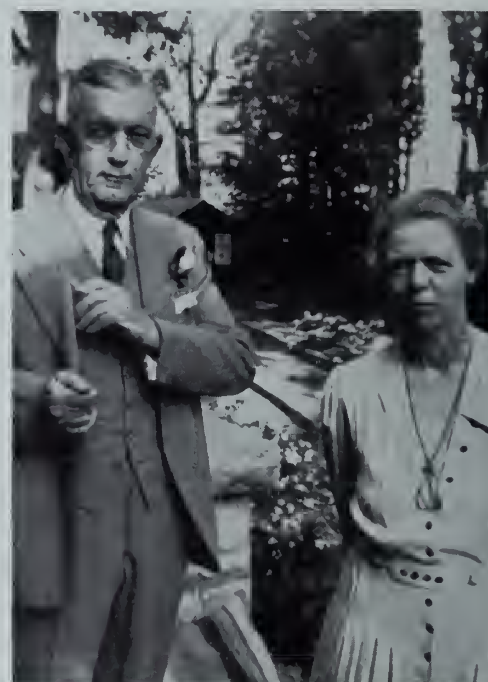
The Kingston Branch of the Engineering Institute felt that such an event as the election of Principal Wallace of Queen's University to honorary membership in the Institute should be acknowledged in some special way. A dinner, given to the principal by the branch was decided upon, with the hope that the Council would mark the occasion by meeting in Kingston. These invitations were willingly accepted, and the date was set for Saturday, June 14.

A report of the Council meeting held in the Board room of the Gymnasium at Queen's University will be found elsewhere in this issue.

During the afternoon the visiting ladies were taken for a drive, to see the sights of Kingston and the surrounding country. They then gathered at the home of the branch chairman, where Mrs. McGinnis entertained them at tea, and where they were later joined by the members of council, just released from their official duties. The hospitable reception and the beautiful gardens and lawns were enjoyed in a perfect summer afternoon.

The dinner took place in the evening at the Cataraqui Golf Club, where over one hundred members and guests sat down about eight o'clock. The chairman of the branch presided.

At the close of the dinner Mr. McGinnis welcomed the guests, and then asked Past President Dr. A. Surveyer of Montreal to speak about the new honorary member. Dr. Surveyer's presentation of Dr. Wallace was delightful. He told of the principal's early education in Scotland and Germany, his coming to Canada as a young man some thirty years ago, the way in which he entered into the life



Tea host and hostess—Mr. and Mrs. T. A. McGinnis

Past President Surveyer introduces Principal Wallace, Left to right: Dr. Wallace, Chairman T. A. McGinnis, Mrs. Wallace, and President Mackenzie. The vice-principal of Queen's, Dr. W. E. McNeill, is in the foreground.

A birds-eye view of the dinner at the golf club.

Past President Hogg and Vice-President DuBose seem to be combining business with pleasure.

After the council meeting the gentlemen joined the ladies for tea. Left to right: Vice-President K. M. Cameron, Past President F. P. Shearwood, Past Councillor Colonel LeRoy Grant and Councillor D. S. Ellis.

of the West of that time, both as a university teacher and as an administrator. He then spoke of his later work as principal at the University of Alberta, and at Queen's. He concluded by citing Dr. Wallace as one eminently deserving of the honour which the Institute had conferred upon him.

The president of the Institute then, with a few words of appreciation handed to Dr. Wallace the parchment certificate of his honorary membership in the Institute.

Principal Wallace in reply expressed his gratitude, and pride in the honour which had been done him. With dry Scottish humour he recalled various experiences in the early days in the West when he was in closer contact with engineering works than he had been in later times. In closing he pointed out the serious task now lying ahead of the engineering profession, not only in the prosecution of the war but in the great work of reconstruction afterwards.

Meanwhile the chairman had been looking over the assembly, noting the presence of five past presidents, he promptly called for a few words from those who had not already spoken. Messrs. Shearwood, Desbarats, Challies and Hogg rose in turn and gracefully expressed their congratulations to Dr. Wallace and also to the Institute. One of our Montreal members, Professor McBride, of McGill University, now president of the Canadian Institute of Mining and Metallurgy also conveyed his felicitations to the new honorary member. Dean Clark of the Faculty of Applied Science at Queen's, one of the senior honorary members spoke briefly.

Although the fact was perhaps not generally realized, the occasion was really President Mackenzie's first official visit to the branch. He marked the event by a happy speech which was not only diverting, but also contained serious touches meriting careful consideration. After briefly discussing Institute affairs he touched upon the idea so generally held, that engineers should plunge into public life, and pointed out that the qualities which make a man a good engineer did not necessarily fit him for public life. Later he dealt with the need for the development of an entirely new point of view by the peoples of the earth if peaceful relationships among them are to be maintained, an event which will require great sacrifices and the abandonment of many historical traditions.

After this very successful dinner, the tables were removed and the room cleared for dancing. Bridge tables were set up, and everyone had an opportunity to chat and discuss questions of the hour.

Since the success of such affairs depends so largely upon those attending, the members of the Kingston Branch feel very grateful to those who came from the other branches and from headquarters and who were such welcome guests.

The out-of-town guests included: President and Mrs. C. J. Mackenzie, Ottawa; Dr. A. Surveyer; Mr. and Mrs. F. P. Shearwood; Dr. J. B. Challies and Miss Challies; Mr. C. K. McLeod; Mr. and Mrs. L. Austin Wright; E. J. Carlyle; deGaspé Beaubien; R. J. Durley; Huet Massue; Mr. and Mrs. McNeely DuBose; Professor W. G. McBride, all of Montreal; J. H. Fregeau, of Three Rivers. Mr. and Mrs. T. A. McElhanney, Mr. and Mrs. W. H. Munro, Mr. and Mrs. G. J. Desbarats, of Ottawa. Mr. R. L. Dobbin, Mr. D. J. Emery and Mr. Ball, of Peterborough. Dr. and Mrs. A. H. Harkness, Mr. and Mrs. H. E. Brandon, Dr. and Mrs. T. H. Hogg, Mr. and Mrs. S. R. Frost, all of Toronto. Mr. and Mrs. E. V. Buchanan, of London.

LAKEHEAD BRANCH

H. M. Olsson, m.e.i.c. - *Secretary-Treasurer*
W. C. Byers, Jr.e.i.c. - *Branch News Editor*

A dinner meeting was held on April 23rd at the Royal Edward Hotel in Fort William, commencing at 6.30 p.m.

The chairman, H. G. O'Leary, presided at the meeting which was attended by 30 members and guests.

Mr. E. J. Davies introduced the speaker of the evening, Mr. R. R. Holmes of the Thunder Bay Paper Company, who spoke on **The Treatment of Boiler Feedwater.**

There are four results that should be obtained in treating any feedwater: (1) Heating and evaporating surfaces of the boiler have to be kept free from scale; (2) Boiler metal must be protected against corrosion; (3) The carry-over of liquids or solids must be avoided in the steam leaving the boiler; (4) Embrittlement of the boiler metal must be prevented.

Lake Superior water has a hardness of 2.5 to 3.0 grains per gal. and can be safely used for average fire-tube boilers with a rating of from 1,000 to 5,000 lb. per hr. used for heating and hoisting operations. If a boiler evaporating 40,000 lb. per hr. with 25 per cent make-up, used water with 3.0 grains per gal., then the scale would precipitate at the rate of about 3,000 lb. per year with a drop in efficiency of 7.5 per cent. Besides lowering efficiency, the presence of scale in high rating boilers may cause over-heating and rupture of the tubes.

The best and most costly method of preventing scale formation is by the use of an evaporator, which is only used in large central power stations.

Water softeners are more widely used, the simplest being the zeolite softener, which is a continuous and completely automatic operation. The lime soda softener while not as simple as the zeolite softener, probably gives better results. The lime soda softener has the advantage over the zeolite softener by removing most of the compounds forming the hardness rather than passing them on as soluble sodium compounds.

Corrosion in boilers is usually caused by dissolved oxygen in the feedwater, although, other causes may be dissolved carbon dioxide or acid condition in the feedwater. The greater proportion of the oxygen and the carbon dioxide is easily removed by the use of a deaerator. In the deaerator the water is boiled under a vacuum and recondensed; the oxygen and carbon dioxide being removed by evacuating equipment.

When water is slightly acidic, a great deal of trouble is experienced with corrosion and pitting, especially in economizer tubes. The ideal pH for feedwater is from 8.0 to 8.5. If the pH is below 7.5 serious corrosion can be expected.

Corrosion due to electrolytic action can be prevented by suspending zinc plates in the boiler and making an electrical contact with the boiler shell.

Boiler plate embrittlement is a term commonly applied to intercrystalline cracks which develop in the presence of high concentrations of caustic. Three conditions are necessary for the occurrence of caustic embrittlement: (1) The boiler water must have high alkalinity; (2) There must be a crack in the boiler plate or seam where the caustic solution can become concentrated; (3) The boiler plate must also be stressed beyond the yield point.

In the past year or two the linings which are used to absorb oxygen in the feedwater have been gaining favour in the treatment for embrittlement. In almost all cases of embrittlement part of the trouble has been due to poor workmanship or defective material. No cases of embrittlement have been reported in forged steel, welded, or internally caulked rivetted boiler drums. All failures have occurred in boilers of rivetted construction which were externally caulked or both externally and internally caulked.

Lake Superior water shows an analysis as follows: Hardness 2.6; total alkalinity 3.0; chloride 0.35; other contents are practically negligible. The hardness present is almost all calcium bicarbonate. Very little sulphate hardness is present in this water and thus the lime soda softener is the best type of softener and will precipitate the bicarbonate out of the water. The zeolite softener will merely exchange the calcium bicarbonate for sodium bicarbonate and when this material reaches the boiler it increases the alkalinity. Most of the corrosion, in feed lines, caus d by waters in the Lakehead district, can be prevented fairly effectively by the use of a deaerator, which will remove most of the dissolved oxygen and carbon dioxide.

Mr. S. E. Flook gave a vote of thanks to the speaker and his motion was seconded by Mr. R. B. Chandler.

LONDON BRANCH

H. G. Stead, Jr.E.I.C. - - *Secretary-Treasurer*
A. L. Furanna, S.E.I.C. - *Branch News Editor*

The branch held its first supper meeting outside of London on May 21st, 1941, at the Gettas Restaurant in St. Thomas. This meeting was the result of an invitation extended to the branch by Mr. W. C. Miller on behalf of the St. Thomas members. The programme consisted of dinner and the showing of the Engineering Institute's movie of the failure of the Tacoma Narrows Bridge.

After dinner, Mayor P. Laing of St. Thomas was introduced by the chairman, R. W. Garrett. He welcomed the members and guests of the Institute and expressed the hope that the London Branch would accept his invitation to return to St. Thomas for other meetings. Mr. J. A. Vance then gave a short report on the Maritime Regional Council Meeting which he attended recently in St. Johns, New Brunswick. Mr. Vance also said he was very much impressed by what he saw in the east coast of Canada at war.

Before Mr. T. L. McManamna started to show the film, Mr. H. F. Bennett gave the meeting many details concerning the structure of the bridge. This bridge was built at an estimated construction cost of $6,400,000.00. It consisted of a suspended structure having a total length of 5,000 ft., divided into a centre span of 2,800 ft. and two side spans of 1,100 ft. each. The roadway was 26 ft. wide for two-lane traffic and flanked on both sides by a 4 ft. 9 in. sidewalk. This was the most slender suspension bridge ever built. The minimum vertical clearance for navigation was 196 ft. The two main towers were 425 ft. high and built to feature the newest advance in suspension bridge designs. They were "flexible," that is although the towers were rigidly anchored in concrete at the bottom, the top could move as much as 5 ft. either way in the direction of the longitudinal axis of the bridge. The two main cables supporting the span were 14¼ in. in diameter, consisting of 6,300 parallel wires and having a total length of 5,772 ft. each. The life of the structure was only a little more than four months. It was dedicated on July 1, 1940, and collapsed on November 7, 1940.

The opening scenes of the reel showed the bridge in its characteristic undulating motion with a frequency of 36 cycles per minute and a moderate amplitude. This was the condition before 10.00 a.m. on that fateful morning of November 7th. Traffic was still crossing the bridge. Suddenly the frequency of the motion increased and for the first time the two main cables became out of phase by 90 degrees. That is, when one side of the span was at the peak of its vertical motion the other side was at its minimum. During this period the oscillating motion, at times, seemed to exceed that of gravity and the amplitude at the extreme edge of the sidewalk was in excess of 28 ft. vertical with a complete cycle occurring in four seconds. This violent twisting motion continued until just after 11.00 a.m. when the centre span collapsed in a 42-mile-an-hour wind.

The film also showed pictures of the testing model on which a number of tests had just been completed. From the series of resultant proposals rendered, it is believed that, had time permitted, this catastrophy would have been averted.

Judging by the enthusiastic discussions which followed this film it is little wonder that the Institute is anxious to have it shown at all its branches.

MONCTON BRANCH

V. C. Blackett, M.E.I.C. - *Secretary-Treasurer*

The annual meeting of the branch was held on May 30th. F. O. Condon, chairman of the branch, presided. The annual report, showing the activities of the branch for the past season, and the financial statement, were presented. On motion, it was decided that the branch shall buy a hundred-dollar Victory bond, during the coming War Loan Campaign. The chairman announced that as a result of nominations made at the previous meeting, branch officers for 1941-42 would be as follows: Chairman, F. O. Condon; Vice-Chairman, H. J. Crudge; Secretary-Treasurer, V. C. Blackett; Executive Committee, B. E. Bayne, G. L. Dickson, T. H. Dickson, R. H. Emmerson, E. R. Evans, E. B. Martin; Ex-Officio, H. W. McKiel, G. E. Smith.

MONTREAL BRANCH

L. A. Duchastel, M.E.I.C. - *Secretary-Treasurer*

On April 28th, L'Association des Anciens Elèves de L'Ecole Polytechnique de Montréal invited the members of the Institute to hear Mr. N. W. McLeod deliver a paper entitled **The Place of Soil Technology in Modern Highway and Airport Construction.** The meeting was held in the new auditorium of L'Ecole Polytechnique and the paper dealt with soil classification, fundamentals of soil grading, principles of sub-grade and base course construction, characteristics of wearing surfaces, importance of adequate laboratory control. The paper was illustrated with practical demonstrations and lantern slides.

On June 12th the Canadian Vickers Limited were hosts to members of the branch who were given an opportunity of seeing ships and aeroplanes in various stages of construction. The interest shown was demonstrated by the fact that over 300 members attended this visit and were given the opportunity of inspecting engine and boiler construction and other industrial work.

THE WORK OF THE ENGINEERS' COUNCIL FOR PROFESSIONAL DEVELOPMENT

Discussions at New York by E.C.P.D. Committee on Professional Training

Continuing its exploration of all promising means of smoothing the transition of the young engineering graduate from the supervised and rather closely directed life of his college years to the confident and successful practice of engineering, the Committee on Professional Training of the Engineers' Council for Professional Development met at New York on May 29. Mr. S. D. Kirkpatrick, Vice-President of the American Institute of Chemical Engineers, was in the chair, supported by Mr. O. B. Schier, Chairman of the Junior Committee on Professional Training. The Engineering Institute of Canada, which, since October, 1940, has been one of the bodies participating in the E.C.P.D., was represented on the committee by Professor C. R. Young, of the University of Toronto.

While an official report of the proceedings to the Executive Committee of E.C.P.D. is still in preparation and is not at present available, information concerning certain matters of fact placed before the Committee on Professional Training has been made available to *The Engineering Journal.*

Most of the discussion turned on matters brought out by Mr. George W. Dyson in an admirable review of the answers to a questionnaire sent out in the autumn of 1940 relative to student guidance, relations with young engineers and policy and organization. While most of the replies particularly concerned questions of student guidance, some of them threw helpful light on the relations of the engineering societies to young engineers.

Junior Groups in the Societies

Although junior groups of the various engineering societies have not always proved to be successful, they have in certain cases been found to be definitely advantageous.

This is likely to be so where the section or branch of the society has a large pool of young members from which to draw, as, for example, the Metropolitan (New York) section of the American Society of Mechanical Engineers. One of the most valuable activities of this body has been the organization of study groups to prepare for examinations in connection with professional licensing.

Chemical engineers in Metropolitan New York and in the Philadelphia-Wilmington area have organized junior groups that are apparently functioning successfully. In the latter area a number of informative plant inspection trips have been held, usually on Saturday mornings.

In areas where the junior membership of the individual societies does not warrant a separate organization, successful groups have in some instances been organized under the auspices of a local engineering society. In this connection the work of the Providence Engineering Society and the Engineers' Club of St. Louis has been noteworthy. The Providence group undertakes to stress personal contacts and self expression rather than technical advancement.

Discussion groups are held to be of particular value to the junior engineer, since they not only give him an opportunity to express himself under particularly favourable circumstances, but also subject him to the "give and take process" prevalent in such meetings.

Engineering schools in certain cities are offering courses of evening study, accredited by the E.C.P.D., leading to a degree. In certain cases where sufficient enrolment for complete degree programmes cannot be obtained, courses in specialized fields have been organized by the students themselves. In New York City, for example, member societies of the E.C.P.D. sponsor review courses particularly designed to assist young engineers preparing for their professional engineer's licence.

Some opinion was expressed at the meeting that since the problems of junior engineers are much the same as those of their more mature professional brethren, no good purpose is served by segregating them in a distinct group. It was contended that the best results are obtained when a genuine spirit of comradeship exists between all age groups. The big problem is to "break the ice" between the older and the younger members and in doing this the initiative must come from the older members. A sure way of making the young engineer at home amongst his elders is to give him something to do. Several of the societites participating in the E.C.P.D. make it a point to include a junior member or two on every committee. In this way they serve an unofficial but nevertheless effective apprenticeship in the work of managing professional societies.

ANNUAL MEETING OF CANADIAN INSTITUTE OF STEEL CONSTRUCTION

C. S. Kane, Dominion Bridge Company, Limited, Montreal, was elected to the presidency when the Canadian Institute of Steel Construction held its annual meeting in Montreal last month. Luncheon was taken at the Mount Stephen Club with 55 attending. Assistant Steel Controller D. S. Wood spoke informally. Mr. Kane succeeds G. P. Wilbur of Dominion Bridge Company Limited, Toronto.

C. S. Kane, M.E.I.C.

Vice-presidents are G. G. Henderson of Canadian Bridge Company, Limited, Walkerville, for the Central Division, and C. W. Marshall, Dominion Structural Steel, Limited, Montreal, for the Eastern Division.

The executive committee is divided into three groups representing respectively the Central, Eastern divisions and the Mills. For the Central Division, representatives are G. P. Wilbur, Dominion Bridge Company, Limited, Toronto; F. P. Flett, Truscon Steel Company of Canada, Limited, Toronto; Thomas Boyce, Disher Steel Construction Company, Limited, Toronto; and R. E. Nicholson, Algoma Steel Corporation, Limited, Toronto. For the Eastern Division the representatives are J. E. Bertrand, Canadian Structural Steel Works Company, Limited, Montreal; G. V. Roney, Farand and Delorme, Limited, Montreal; and H. W. Welsh, MacKinnon Steel Corporation, Limited, Sherbrooke. Representing the mills are H. J.

Leitch, Algoma Steel Corporation, Limited, Montreal; Huntly Gordon, Dominion Foundries and Steel Limited, Hamilton; A. H. Pepper, Dominion Steel and Coal Corporation, Limited, Montreal; and E. M. Seale, Canadian Tube and Steel Products, Limited, Montreal.

PULP AND PAPER MILLS TRAIN EMPLOYEES FOR WAR WORK

To relieve the present shortage of skilled machinists and to speed production of war supplies, training-schools have been created in the pulp and paper mills throughout Canada under the direction of a special committee of the Canadian Pulp and Paper Association. Pulp and paper mills have already supplied a large number of skilled workers to war industries and the current educational plan seeks to build up a reserve of trained men to fill the places of those who have been released or loaned for war work.

The educational plan, far-reaching and of major importance, is the result of co-ordinated efforts on the part of the pulp and paper industry in Canada. The schools provide a relatively short but balanced training in practical shop work, and to date applications to take the courses have exceeded the number of men that can be handled. The scheme calls for individual selection of men and individual training; the work of both student and mentor is given voluntarily.

In each of the companies which have adopted the plan, men and staff are getting on with the job with real enthusiasm and progress. It has been welcomed by the men at the plants, with the result that hundreds of workers are now taking a short practical course in machine shop work.

Because time is limited and in order that this training plan may be of the utmost usefulness to Canada, the training period has been limited to twelve months as a maximum. Actually, since the training is on an individual basis many men make substantial progress in less than the twelve-month period. There is no doubt that men who satisfactorily complete any of the given courses will be able to take their places in industry and rapidly acquire the balance of manual skill necessary to assume positions of responsibility in their chosen trades.

The plan consists of two parts: home study courses to provide theoretical training, and practical machine shop instruction conducted simultaneously with the home study to develop required manual skill. The plan also offers an opportunity to provide the necessary theoretical training more quickly and at an appreciably lower cost than could be arranged under any other circumstances.

Since the pulp and paper industry's training plan makes a definite contribution to Canada's war effort, progress is being closely watched by Government officials in Ottawa who heartily endorse this practical method of speeding up production of supplies and materials for war purposes.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet the books are not in the Institute Library, but inquiries will be welcomed at headquarters, or may be sent direct to the publishers.

ACOUSTICS

By A. Wood. Interscience Publishers, New York, 1941. 588 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $6.00.

Both the theoretical and practical phases of the subject are considered in this comprehensive and detailed work. Following the chapters on wave motion, diffraction, vibrations and other elements of classical theory much space is devoted to modern topics, such as ultrasonic waves and sound recording and reproduction. There are many illustrative graphs and pictures.

Air Raid Precautions Handbook No. 5, STRUCTURAL DEFENCE, 1st ed.

Issued by the Home Office, Air Raid Precautions Dept. London, His Majesty's Stationery Office, 1939. 58 pp., diagrs., charts, tables, 13 x 8 in., paper, 2s. (obtainable from British Library of Information, 620 Fifth Ave., New York, 60c.).

Fundamental principles and data derived from research and experiment are presented in this handbook. In the first two chapters the theoretical and practical effects of explosive bombs are considered in some detail. The subsequent chapters deal with the requirements and principles of design of structures to resist such attacks, both for the construction of new buildings and the adaptation of existing ones.

ANTIAIRCRAFT DEFENSE

Military Service Publishing Co., Harrisburg, Pa., 1940. 603 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, $2.00.

The main function of this volume is to present a study of antiaircraft artillery from the .30-caliber machine gun to the 105-mm. gun, together with all the accessories that make up the antiaircraft regiment. The comprehensive treatment of the subject includes also formations and manoeuvres, tactics of units, field fortifications and defense against chemical warfare. Appended are a glossary of terms, condensed drill tables for units and a list of War Department publications, from which much of the material has been taken.

CORRECTING OIL BURNER DEFICIENCIES, with Special Application to Pressure Atomizing Oil Burners

By Z. Kogan. Zuce Kogan Consulting Service, Chicago, Ill., 1941. 152 pp., illus., diagrs., charts, tables, 9½ x 6½ in., cloth, $5.00.

The variation in efficiency between test runs and general operation in oil-burning power plants is considered by the author, a consulting engineer, to be due to dependence on certain traditional concepts which no longer apply. Under the following headings: mixing of oil and air, furnace heating zone, fineness of atomization and burner applications, he presents new concepts and techniques for correcting oil-burner deficiencies, particularly in pressure burners.

(An) ENGINEERS' MANUAL OF STATISTICAL METHODS

By L. E. Simon. John Wiley & Sons, New York, 1941. 231 pp., illus., diagrs., charts, tables, 10 x 6½ in., cloth, $2.75.

This book is a summary of certain working parts of the sciences of probability, statistics and logic, and is designed to assist the practical man in industrial or engineering work. Since the book is written primarily for use in an ordnance school for instruction in statistical techniques, the illustrative examples are generally taken from standard procedures or research at arsenals and proving grounds. The principles are, however, applicable to other inspection or quality control problems.

FLIGHT, First Principles

By B. Wright, J. J. Smiley and R. Martin. 283 pp.

FLIGHT, Construction and Maintenance

By B. Wright, W. E. Dyer and R. Martin. 259 pp.

American Technical Society, Chicago, Ill., 1941. Illus., diagrs., charts, tables, 9½ x 6 in., cloth, $2.50 each.

These two volumes present in a simple, practical manner the fundamentals of aviation and airplane manufacture. The book on first principles covers aerodynamics, soaring theory and parachutes, and contains an illustrated glossary. The second volume deals with blueprint reading, airplane materials, construction methods, repair work and propeller practice. A series of quiz questions with answers appears at the end of each book.

A GOOD MECHANIC SELDOM GETS HURT

By H. R. Graman. American Technical Society, Chicago, 1941. 94 pp., illus., 7 x 5 in., paper, 50c.

The object of this collection of safety rules is to give the beginning craftsman an idea of what to look out for when working in a machine shop. For simplicity the safety precautions for each machine have been grouped together. A set of review questions on safety in the machine shop appears at the end.

Great Britain. Dept. of Scientific and Industrial Research. Methods for the Detection of Toxic Gases in Industry, Leaflet No. 12, ORGANIC HALOGEN COMPOUNDS

London, His Majesty's Stationery Office, 1940. 6 pp., tables, 9½ x 6 in., paper, (obtainable from British Library of Information, 620 Fifth Ave., New York, 5c.).

The poisonous effects of the more important organic halogen compounds are indicated and precise directions given for a simple method for their detection. As in the case of tests given in previous leaflets, the object is not an extreme degree of accuracy but a rapid indication of the relative safety of the atmosphere.

Great Britain. Dept. of Scientific and Industrial Research, BUILDING RESEARCH

Wartime Building Bulletin No. 14. CENTERLESS ARCH DESIGNS

His Majesty's Stationery Office, London, 1941. 15 pp., illus., diagrs., charts, tables, 11 x 8½ in., paper (obtainable from British Library of Information, 620 Fifth Ave., New York, 30c.).

Continuing the material on centerless arch work described in Bull. No. 6, the present bulletin gives several designs for segmental arch structures and notes and curves for the design of other segmental arch rings. For illustration, the application of the system to a factory scheme is discussed.

IMPERIAL INSTITUTE, ANNUAL REPORT 1939

London, South Kensington. 90 pp., illus., 10 x 6 in., paper (obtainable from British Library of Information, 620 Fifth Ave., New York, not for sale, limited distribution, apply).

The investigation carried out by the various scientific departments are summarized, and other activities of the Institute, such as exhibitions and library work, are described. Pertinent information is also given concerning the personnel of the Institute and its relations with other organizations.

Industrial Relations Digests

IV. JOB CLASSIFICATION AND EVALUATION

V. POLICIES IN THE ADJUSTMENT OF WAGE RATES

VI. BASIC TRAINING POLICIES

Princeton University, Industrial Relations Section, Princeton, N.J., 1941. 8 pp. each, tables, 10 x 7 in., paper, 20c. each.

The three pamphlets listed above continue a series of digests prepared for use in companies facing rapid expansion because of defense orders. They are based on information received currently from a large number of representative companies.

INSULATION OF ELECTRICAL APPARATUS

By D. F. Miner. McGraw-Hill Book Co., New York and London, 1941. 452 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $3.00.

This key to insulation problems for the designer and user of electrical apparatus presents a well-rounded correlation of theory and design. It discusses present knowledge of dielectric behaviour, describes the problems encountered in insulating the major forms of electric power equipment and how they are solved, and shows what tests are of value in determining the performance of insulation. A condensed directory of plastics is appended.

INTERNATIONAL ACETYLENE ASSOCIATION, 40th Annual Convention Official Proceedings held at Milwaukee, Wisconsin, April 10-12, 1940

Publ. by International Acetylene Association, New York, 1941. 284 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, apply.

A complete record of the sessions of the 1940 convention is presented in this volume. In addition to the reports of various committees, the membership list and other information about the association, the text of some fifteen technical papers on brazing, welding and cutting is included. There is a subject index to the papers.

LAND ECONOMICS

By R. T. Ely and G. S. Wehrwein. Macmillan Co., New York, 1940. 512 pp., illus., diagrs., charts, tables, maps, 9½ x 6 in., cloth, $4.00.

In the first five chapters the various aspects of land utilization, both natural and by design, are discussed generally. The remainder of the book treats of the specific uses, for human benefits, to which land areas are devoted; of the problems which arise and of ways in which these uses may be most efficient. There is a final chapter on conservation, aad a large bibliography is appended.

MACHINE TRADES BLUEPRINT READING

By R. W. Ihne and W. E. Streeter. American Technical Society, Chicago, 1941. 138 pp., blueprints, diagrs., charts, tables, 11 x 9 in., paper, $2.00.

The first part of this book, which includes a glossary of shop terms, has been designed to teach all the basic information necessary to interpret a print. The rest of the book is composed of actual production blueprints, each of which is accompanied by a question sheet intended to bring out the important points embodied in the drawing.

MARINE'S HANDBOOK

By Major L. A. Brown. 7 ed. United States Naval Institute, Annapolis, Md., 1940. 242 pp., illus., diagrs., charts, tables, 9½ x 6 in., paper, 75c.

Comprehensive coverage of the requisite basic information for enlisted men is provided in question and answer form in this Marine Corps manual. All subjects are gone into in detail, with many descriptive and explanatory illustrations. The purpose of the handbook is to enable noncommissioned officers and men, particularly of the Reserve, to achieve certain standards of performance.

METHODS OF STUDY OF SEDIMENTS

By W. H. Twenhofel and S. A. Tyler. McGraw-Hill Book Co., New York and London, 1941. 183 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $2.00.

The authors present a brief, non-mathematical, yet complete treatment of methods of study of sediments. Standard methods of sampling for various types of sediments are described, methods of analyses are given, and various forms of graphical representation of the characteristics of sediments and sedimentary rocks are shown. Coal and oil shales receive particular attention, and further references accompany each chapter.

PRELIMINARY NOTICE

of Applications for Admission and for Transfer

June 14th, 1941

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described at the next meeting.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science or engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ALTON—JACK, of Windsor, Ont. Born at Bexhill-on-Sea, Sussex, England, March 3rd, 1903. Educ.: Woolwich Polytechnic, London, 1918-20; New Zealand Univ. Eng. College, 1924-25; Regent St. Polytechnic, London, 1927-37; A. M. Institution of Structural Engrs., London, England. 1918-20, jr. dftsman., Royal Arsenal, Woolwich; 1920-21, asst. dsgr., Trussed Concrete Steel Co., London; 1922-27, dftsman and estmtr., G. Fraser & Sons, Ltd., Auckland, N.Z.; 1927-29, dftsmn., Ledward & Beckett, London; 1929-33, dftsmn. Marconi Wireless Tel. Co., London; 1933-38, asst. dsgr., Installn. designs divn., Marconi Wireless Tel. Co., London; 1938-39, dftsmn., and 1939 to date dsgning. engr., Canadian Bridge Co. Ltd., Walkerville, Ont.

Employment Service Bureau

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.

SITUATIONS VACANT

CONSTRUCTION SUPERVISOR with experience in heavy construction for either long or short term contract in British Guiana. Applications should be addressed to Box No. 2330-V.

GRADUATE ENGINEER with at least two years practical experience in a tool room to act as an instructor in the Apprentice School of a large industrial concern. Apply Box No. 2344-V.

MECHANICAL DESIGNING DRAUGHTSMAN with experience for permanent position with firm engaged in war work. Apply Box No. 2375-V.

ARCHITECTURAL DRAUGHTSMEN required immediately by large industrial concern for their Montreal office. Apply Box No. 2376-V.

FIELD ENGINEER, aggressive, capable, preferably one with a university degree in chemical engineering and who has some knowledge of boiler plant operation to sell and service boiler feed water treatment chemicals. Candidate must possess personality conducive to good salesmanship having good educational and family background. Remuneration will be $1,500.00 a year and travelling expenses when away from Headquarters. Write fully education, experience and present occupation, giving references. Personal interview will be arranged only by written application to Box No. 2394-V.

HIGH GRADE ARCHITECT urgently required for work in Montreal on industrial plant project. Apply Box No. 2399-V.

JUNIOR CHEMICAL AND METALLURGICAL ENGINEER for plant installation and operation work. Apply Box No. 2400-V.

STRUCTURAL OR GENERAL DRAUGHTSMAN for plant extension work. Apply Box No. 2401-V.

JUNIOR MECHANICAL GRADUATE with about one to five years experience for work in South America. Apply Box No. 2402-V.

MUNICIPAL ENGINEER, conversant with road construction, paving, construction and maintenance of sewers and water services, for a town in Ontario. Salary from $2,400 to $3,000 per year according to experience and qualifications. Send applications with full particulars to Box No. 2403-V.

SITUATIONS WANTED

GRADUATE ELECTRICAL ENGINEER, University of Toronto, five years experience drafting and design in connection with electrical instruments and small motors. Also experienced in design of small jigs and fixtures and general machine design. Desires permanent position. Apply to Box No. 1486-W.

GRADUATE MECHANICAL ENGINEER, M.E.I.C., 14 years' experience as factory manager in machine tool factory and as consulting industrial engineer in widely diversified metal working trades improving factory and office methods specially cost accounting, desires permanent position. Apply to Box No. 1730-W.

GRADUATE CIVIL ENGINEER, M.E.I.C., 15 years engineering on this continent and five years overseas. Experienced in design and construction of dams, hydro-electric and industrial plants. Field engineer for construction on dams and transmission lines, considerable experience in concrete work. Desires position preferably as field engineer or construction superintendent. Apply Box No. 1527-W.

ELECTRICAL ENGINEER, Age 32 with the following experience—Eight years field work in general construction, supervision, estimating and ordering materials. At present employed in general construction but wants to enter the electrical field. Apply Box No. 1992-W.

MECHANICAL ENGINEER, JR.E.I.C., and member of the American Society for Metals. Since graduation (Toronto '33) has specialized in the metallurgy, processing, and heat treatment of steel, aluminum and aluminum alloys. Also five years successful sales experience and is thoroughly familiar with materials specifications of all types. Now thirty years of age, available at once, and can furnish the best of references. Desires permanent position. Apply Box No. 2365-W.

LIBRARY NOTES

(*Continued from page 375*)

THE MOTOR SHIP REFERENCE BOOK for 1941

Compiled by the Staff of "The Motor Ship" Temple Press, Ltd., London, E.C.1, 1941. 324 pp., illus., diagrs., charts, tables, 8½ x 5½ in., cloth, 7s. 6d. net, or 8s. post free.

This annual publication on Diesel motor ships presents technical information on oil engines in general and on specific types, and contains an alphabetical list of all vessels completed to December, 1939, with a partial list for 1940. Lloyd's rules for the construction and survey of motor ship machinery are included, and there is a list of builders of marine Diesel engines in all countries.

PLANT-PRODUCTION DIRECTORY

Vol. 1, No. 1. First edition, 1941. Industrial Directories, Chicago, Ill., 578 pp., illus., 12½ x 11 in., cloth, $10.00.

The major part of this new industrial directory is devoted to an alphabetical listing of industrial products with the manufacturers of them. Other information given includes sources of supply for industrial chemicals, a large section of mathematical tables and mechanical data, a trade name index and a complete alphabetical list of manufacturers with addresses only.

PRACTICAL ELECTRICAL WIRING, Residential, Farm, and Industrial

By H. P. Richter. 2 ed. McGraw-Hill Book Co., New York and London, 1941. 521 pp., illus., diagrs., charts, tables, 8½ x 5½ in., cloth, $3.00.

Practical methods of electrical wiring are explained in plain language for the man who does it. All kinds of light and power wiring for home, farm and factory are described, and the basic theoretical principles are clearly presented. This second edition, including the appended tables of data, has been based on and revised in accordance with the new 1940 National Electrical Code.

PUBLIC WORKS ENGINEERS' YEARBOOK, 1941

American Public Works Association, Chicago, 1941. 424 pp., illus., diagrs., charts, tables, 9 x 5½ in., cloth, $3.50.

The papers presented at the 1940 Public Works Congress and the Western Regional Conference are included in the current volume of this yearbook. They are broadly grouped under the following headings: public works administration; city and regional planning; streets and highways; traffic control; and sewerage and sewage disposal. Other important material and the business proceedings of the American Public Works Association are also included.

RAILWAY FUEL AND TRAVELLING ENGINEERS' ASSOCIATION

Fourth Annual Proceedings, Hotel Sherman, Chicago, Ill., Oct. 22nd to 25th, 1940. Railway Fuel and Travelling Engineers' Association, Chicago, Ill., 1941. 339 pp., illus., charts, tables, 9 x 6 in., lea., $3.00.

The full text of the committee reports and special papers presented is included in this publication of the detailed proceedings of the Association's annual meeting. The membership list, constitution and by-laws appear at the end of the volume.

SOIL MECHANICS

By D. P. Krynine. McGraw-Hill Book Co., New York and London, 1941. 451 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $5.00.

This book presents the principles used in the design, construction and maintenance of foundations of structures and structures made of earth material. Engineering applications of these principles are discussed; field and laboratory soil investigations are described; and the settlement of structures, its causes, prevention and damage are considered. The physical properties of soil materials are studied, and many important conceptions and principles, such as idealized earth masses and continuity of strains, are fully dealt with. Problems and references accompany each chapter.

STUDENT AND EMPLOYEE SAFETY IN COLLEGES AND UNIVERSITIES

National Safety Council, Chicago, Ill., 1941. 82 pp., illus., maps, charts, tables, 9 x 6 in., paper, $1.00.

This pamphlet points out some of the hazards involved in college shops and buildings, in athletics and in campus traffic. Suggestions are given for preventive measures to eliminate accidents which are the result of unsafe environmental conditions or unsafe human behaviour.

TABLES OF SINE, COSINE AND EXPONENTIAL INTEGRALS

Vol. 2, prepared by the Federal Works Agency, Work Projects Administration for the City of New York, conducted under the sponsorship and for sale by the National Bureau of Standards, Washington, D.C., 1940. 225 pp., tables, 11 x 8 in., cloth, $2.00, advance payment required.

The functions indicated are tabulated in this volume over the range between 0 and 10 at intervals of 0.001. Differences have been listed for purposes of interpolation, although for the range from 0 to 2, Vol. I should be consulted for greater accuracy in this respect. Several supplementary tables and various reference lists are included.

(The) TELEPHONE IN A CHANGING WORLD

By M. M. Dilts. Longmans, Green & Co., New York and Toronto, 1941. 219 pp., illus., diagrs., woodcuts, maps, 8½ x 5½ in., cloth, $2.50.

The telephone as a "great American institution" is the theme of this book. Historical and anecdotal information is presented upon the development of the telephone, operator service, directories, by-products and radiotelephony. The increasing effect of the telephone upon many phases of everyday life is emphasized.

TEXTBOOK OF GEOLOGY, Pt. 2, Historical Geology

By C. Schuchert and C. O. Dunbar, 4 ed., largely rewritten. John Wiley & Sons, New York, 1941. 544 pp., illus., diagrs., charts, maps, tables, 9 x 6 in., cloth, $4.00.

As in previous editions, the history of the geologic changes on the earth is presented chronologically. A prologue of several chapters presents basic conceptions for interpreting geological records, and the whole subject is treated in a simple manner for the beginning student. In order to take account of new facts the subject matter has been considerably revised.

Industrial News

Industrial development — new products — changes in personnel — special events — trade literature

FILE CLEANERS

S. A. Felton & Son Co. (Canadian Div.), Hamilton, Ont., have published a data sheet which illustrates four well-tried designs of "Felton's" file cleaners with specifications and prices in each case.

GROUND CONNECTORS

Canadian Line Materials, Ltd., Toronto, Ont., are distributing Bulletin Form No. 6018, issued by the Burndy Engineering Company, Inc., New York, N.Y., which illustrates fourteen types of "Burndy Ground Connectors."

Five methods of grounding are shown diagrammatically.

HYDRAULIC SCRAPERS

Form No. A-113-639, a 16-page booklet, issued by La Plant-Choate Mfg. Co. Inc., Cedar Rapids, Iowa, gives complete details of the hydraulic controls and other features of hydraulic "Carrimor" scrapers ranging in size from 2.9 to 8.2 cu. yds.

INDUSTRIAL INSULATION

Fiberglas Canada Ltd., Oshawa, Ont., have published a 16-page booklet which deals with the use of Fiberglas insulating products for various industrial uses. An illustrated, descriptive page is devoted to each of the following types of the product: moulded and blanket type for pipe insulation; insulating block for high temperature application; permanent form insulation in bats and panels, and with metal facings; metal mesh blankets to insulate boilers, tanks, cylinders, ducts, etc.; insulation cement, finishing cement, and O-C Mastic for monolithic protection and finish of tanks, ovens and pipes, etc.; duct insulation for concealed or exposed work; insulating wool for marine work and general purpose insulation; sewn blankets for many industrial applications. A section of brief specifications is also included.

INTERIOR AND EXTERIOR PAINTS

"Norface" paint for interior and exterior use on residences, factories, hospitals, public buildings, etc., is described in a four-page folder issued by Northern Paint & Varnish Co. Ltd., Owen Sound, Ont. Contains details of the properties of these paints, how to use them and the advantages. Also samples of colours.

JOINT SEALING COMPOUND

Bulletin No. 208-F, published by Quigley Co. of Canada, Ltd., Lachine, Que., features "Q-SEAL," a plastic expansion joint sealing compound for threaded, flange, gasket, and metal-to-metal joints in pipe lines and equipment carrying high pressure steam, oils, gasoline, tar, creosote, acids, ammonia, brine, and other commodities.

METAL AND WIRE FORMING MACHINE

The A. H. Nilson Machine Co., Bridgeport, Conn., are distributing a four-page bulletin, No. 75A, entitled "Nilson Presents the New Automatic Metal and Wire Forming Machine" which describes the various features of this machine with specifications covering four different models. Contains photographic illustrations and a cross-sectional drawing.

NICKEL ALLOY STEEL CASTINGS IN INDUSTRY

In a booklet of 28 pages and cover published by The International Nickel Co. of Canada, Ltd., Toronto, Ont., the use of nickel alloy steel castings in industry is shown by many illustrations of typical applications for railroads, oil production and refining, power plants, mining and milling, excavating and dredging, steel rolling and forging, construction projects, and miscellaneous equipment. Data on compositions, properties, etc., are also included.

CONDENSERS AND COOLERS

Worthington-Carbondale shell-type condensers and coolers are featured in a 12-page bulletin, No. C-1100—B-13, published by the Carbondale Div., of Worthington Pump & Machinery Corp., Harrison, N.J. This bulletin is well illustrated with equipment and installation photographs. The descriptive matter deals with multi-pass, small multi-pass and vertical coolers and condensers, with special reference to non-priming brine coolers, ice tank coolers and the Worthington-Carbondale "Spiro-Flo" vertical condensers.

CONVECTORS

A four-page folder of the Chatham Malleable & Steel Products, Ltd., Chatham, Ont., describes and illustrates the "Chatco Heat Speed" convectors, which are available in many types and enclosures, four of which are illustrated in the folder. These convectors are adaptable to any room where radiators are used. A sectional illustration shows the construction features.

CONVEYOR AND ELEVATOR BELTING

Dunlop Tire & Rubber Goods Co., Ltd., Toronto, Ont., have published a 62-page book entitled "Rubber Belting Data-Conveyor and Elevator." A compilation of information intended for the users of conveyor and elevator belting, combining the results of technical research and practical field experience, this manual provides a ready reference in determining the proper belt for various types of service commonly encountered. The book should prove invaluable as practically every detail of interest to users of this type of belting is clearly dealt with.

"DUNLOP SERVES THE EMPIRE"

Under the above title the Dunlop Tire & Rubber Goods Co. Ltd., of Toronto, Ont., has produced a pictorial review of the application of this product to the many and varied activities of the fighting forces and industries engaged in the production of munitions of war. Interesting illustrations taken on land, on sea, and in the air, graphically emphasize the importance of this product. The booklet contains 12 pages.

PROTECTIVE PAINT

Northern Paint & Varnish Co. Ltd., Owen Sound, Ont., have issued a four-page folder which provides full details describing Nor-Cote No. 400, an abrasion resisting, skid-proof, protective paint for steel, wood or cement. Contains also information covering the Company's anti-corrosive, acid-resisting and pure metalead paints.

RUST PREVENTATIVE

A folder featuring "Carter's Rust Preventative" for the prevention of rust and corrosion of metal surfaces, both interior and exterior, has been published by Canadian Cork Co. Ltd. of Montreal, Que. Recommended by the makers for industrial plants, ice plants, cold storage plants, dairies, packing houses, etc.

SQUARE AND HEXAGON HOLE DRILLS

"Watts" method of drilling square, hexagon and octagon holes is illustrated and described in a folder recently released by Watts Bros. Tool Works, of Wilmerding, Pa. Any engine or turret lathe, drill press or hand screw machine provides the power while the "Watts" angular drills and full floating chucks do the work.

UNIT HEATERS

Entitled "Chatco Heat Speed" Unit Heaters, a four-page folder issued by Chatham Malleable and Steel Products, Ltd., of Chatham, Ont., contains a complete description of the horizontal and vertical projection type heaters which are available with both steam and hot water. A sectional drawing describes the principal features of the heater and a number of sketches illustrate typical installations.

VOLTAGE REGULATORS

Ferranti Electric Ltd., Toronto, Ont., are distributing a four-page folder in which the company discusses war time voltage problems and describes three general types of Ferranti automatic step-voltage regulators which are available either as single- or three-phase units in any voltage up to 115,000.

WELDED STEEL BASE PLATES

Booklet No. 1882, published by Link Belt Limited, Toronto, Ont., covers the company's line of welded steel base plates for adjusting pillow blocks and common flat boxes for shaft alignment. Type "A," for horizontal adjustment only, and type "B," for both horizontal and vertical adjustment, are tabulated for mounting pillow blocks of shaft sizes up to eight inches. Dimensions and weights are given.

OIL TESTING INSTRUMENTS

A 32-page catalogue, No. 699E, issued by C. J. Tagliabue Mfg. Co., of Brooklyn, N.Y., contains complete illustrated descriptions with specifications covering the Company's oil testing instruments for petroleum products, including "Tag" A.S.T.M. penetrometers, and enclosed scale penetrometers, hydrometers for general laboratory use, and various other oil testing instruments and apparatus including calorimeters, viscosimeters, etc.

COLD HEADED DIE STEEL

Jessop Steel Co., Washington, Pa., are distributing an eight-page bulletin No. 141, which describes the Company's "new process" steel for cold-header dies and punchers, which is a clean, non-porous steel developed especially to meet the severe service conditions encountered when cold-heading bolts, screws, rivets, nails, buttons, and other small metal objects. Contains complete information on the heat treatment of this steel.

CARRIER CURRENT TELEPHONY

W. W. RAPSEY, S.E.I.C.
Canadian General Electric Company, Limited, Toronto

Paper presented before the Peterborough Branch of The Engineering Institute of Canada on November 2nd, 1939

This article is intended to be an introduction to carrier telephone methods, and a general description of the systems now in use. Carrier telephony is really wired wireless, whereby a number of separate telephone messages are transmitted simultaneously on a single electrical circuit by employing a separate alternating current, called a carrier current, for each of the separate messages. This carrier current, is modulated, that is, it is made to vary in accordance with the variations of current representing the telephone message. At the receiving end, the current variations representing the signals are reproduced from the carriers by suitable detectors or demodulators. As in radio, the different carriers must differ sufficiently in frequency so that they may be separated from each other at the terminals by the use of proper electrical circuits.

When a voice frequency is made to modulate a carrier wave, there result what are known as the upper and lower sidebands, groups of frequencies lying one on either side of

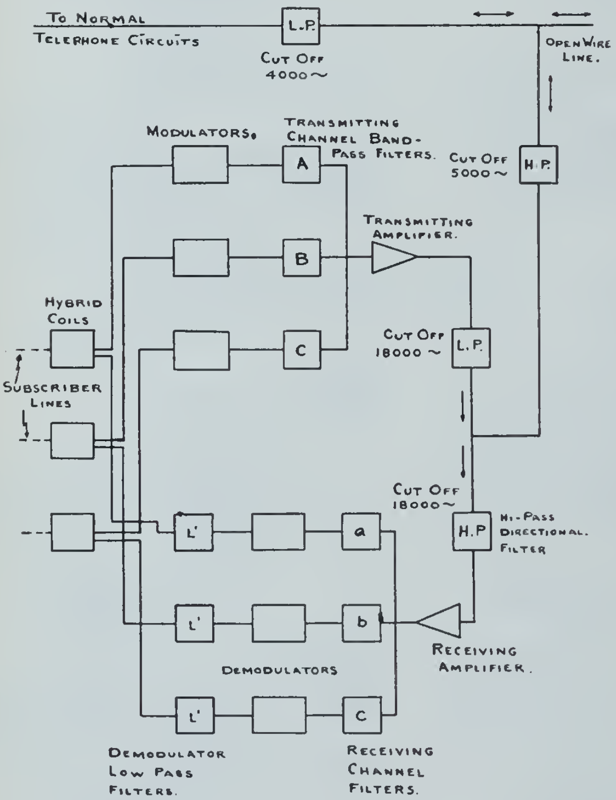

Fig. 1—Eastern terminal of a type C carrier system.

the carrier, which carry the intelligible speech. In most modern carrier systems, only one of these sidebands is transmitted, both the carrier and the other sideband being removed. This effectively halves the space required on the frequency scale for each carrier conversation, and thus increases the number of circuits possible over a given pair of lines.

The Bell Telephone Type C carrier system will now be described as illustrating the main features to be found in all open-wire carrier applications except the new broad band system which will be described later. The type C system provides three carrier channels above the voice frequency channel, and transmits a top frequency of about thirty kilocycles. This was considered to be the highest frequency that ordinary open-wire lines could transmit without too great attenuation. For each channel, the carrier is suppressed and only a single sideband transmitted. The necessary voice band width was set at about 3000 cycles, which requires a carrier frequency separation of 4000 cycles, because the band-pass filters used have not perfectly sharp cut-off characteristics. Different frequencies are used for transmission in the two directions over each channel, the upper sidebands of carrier frequencies at 6000, 10,000 and 14,000 cycles being used for transmission from east to west, while the lower sidebands of carriers at 22,000, 26,000 and 30,000 cycles are used for the west to east conversations. Thus filter selectivity may be used at the repeater stations and the terminals to separate the two groups of frequencies used for opposite directions of transmission.

The diagram in Fig. 1 shows the basic arrangement of apparatus at one terminal of a line carrying an ordinary voice frequency channel plus the three-channel Type C carrier system. This is seen to be an eastern terminal for the lower group of frequencies is used for transmitting.

The currents used in carrier transmission are prevented from reaching the subscribers' lines by means of a low-pass filter included in the normal telephone line which has cut-off just above the voice range. Similarly a high-pass filter in the line connected to the carrier apparatus prevents the absorption of the normal telephone currents by this apparatus. Then directional filters are employed to separate the east and west bound groups of frequency bands, and in addition, band-pass filters are required to separate the individual channels in each group.

Following a subscriber's line to the outgoing toll office, the line is here divided into an outgoing and an incoming circuit. Since the frequencies at this point are all in the voice range however, the separation of incoming and outgoing conversations is secured by the common hybrid coil system shown in Fig. 2. Instead of terminating the sending and receiving branches in a transmitter and receiver respectively, they terminate in what are, in effect, conjugate branches of an alternating current bridge. If the impedance of the artificial line exactly simulates the impedance of the voice frequency line, any electromotive force applied between the points a and b does not cause any current to flow in the branch c-d of the carrier current circuit. Thus there is zero coupling between the input and output circuits of the carrier system, and hence persistent oscillation, i.e., singing, cannot be set up.

From the hybrid coil, each outgoing circuit passes to a modulator employing suppressed carrier. The two sidebands pass on to a band-pass filter which rejects the unwanted sideband. A similar process is undergone by the other two channels. The three bands selected for transmission which come from the three transmitting band-pass filters designated A, B and C, are then united in a single circuit and amplified to the level desired for transmission over the line. From the amplifier they go out through the low-pass directional filter on to the transmission line. The function of this low-pass filter is to prevent the transmitting circuits from absorbing energy from the line which should go to the receiving circuits, and is designed to largely attenuate everything above the lower or east-west group of carrier channels.

In the case of transmission from the western terminal of the line, a similar modulation and selection of frequencies takes place, but here the outgoing conversations are transmitted by the upper frequency channels and enter the line through a high-pass directional filter. These conversations arriving at the east terminal cannot pass into the transmitting circuits because they are blocked by the low-pass filter. They therefore pass through the high-pass directional filter in the receiving branch and then through the receiving amplifier. Leaving the amplifier, the three bands are separated by a group of receiving band-pass filters a, b, c, and then each is passed to a demodulator. The demodulator low-pass filters are necessary to eliminate undesirable high frequency products present in the demodulator output. Thus only the voice currents are passed on to their res-

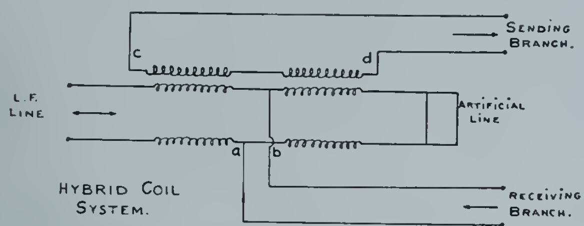

Fig. 2—Common hybrid coil system.

pective telephone stations through the hybrid coils and subscribers' lines. This traces a complete signal path over the carrier system, from subscriber to subscriber.

Because a vacuum tube is a one-way device, allowing energy to flow through it in one direction only, a very similar scheme of directional filtering must be employed at each repeater to guide the east and west-bound groups into separate amplifiers. At the end of the repeater the two groups of channels are combined.

It is obvious that many more circuits could be obtained on a single pair of conductors if the carrier frequency range could be widened. Three different methods of achieving this enhanced frequency range have been developed, and they are all classed as broad-band systems.

The first is applied to open wire transmission lines, which with their large gauge and wide spacing, are favourable to

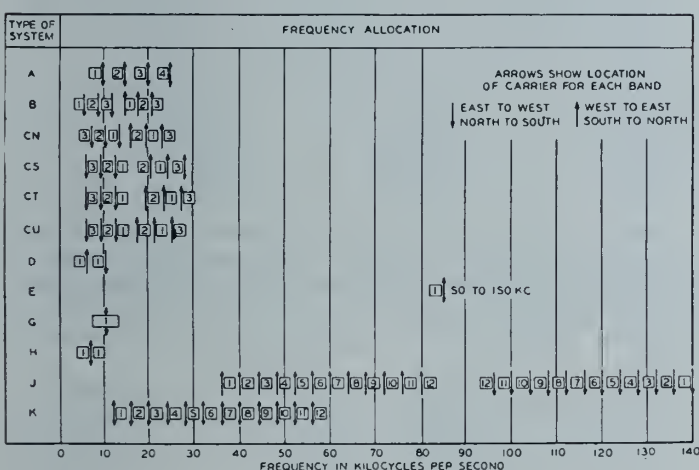

Fig. 3—Frequency allotments for the Bell Telephone's carrier systems.

high frequency transmission. However, this exposed type of structure is difficult to keep free from unwanted currents induced by nearby telephone circuits, by power lines, lightning or other outside disturbances. The limiting factor in using high frequencies on open wire lines has generally been induction or crosstalk between nearby circuits, and until recently 30,000 cycles, the top frequency of the Type C system, represented about the upper limit.

Crosstalk on open wire lines is reduced by applying transposition systems which, at high frequencies, must be made very frequently and precisely. The wires of a pair are crossed over at predetermined intervals so that the induced potentials and currents tend to balance out. There have been important developments in the art of transposition designing during the last few years; also the spacing between the two wires of a pair is being reduced from 12 inches down to 6 or 8 inches so that there is a greater distance between adjacent pairs, and less direct pick-up by each pair. These improvements make it possible to raise the frequencies transmitted to about 140 kilocycles.

The new service, known as the Type J, provides twelve two-way telephone circuits in a frequency band between 36 and 140 kilocycles. There are 24 carriers in all, the lower 12 of which carry the west to east conversations, and the upper 12 carrying those in the opposite direction. This system may be operated on the same pair with a Type C system. With a J system, a C system, and a voice circuit, a total of sixteen telephone circuits may be obtained from one pair of wires.

The chart in Fig. 3 shows the frequency allotment for

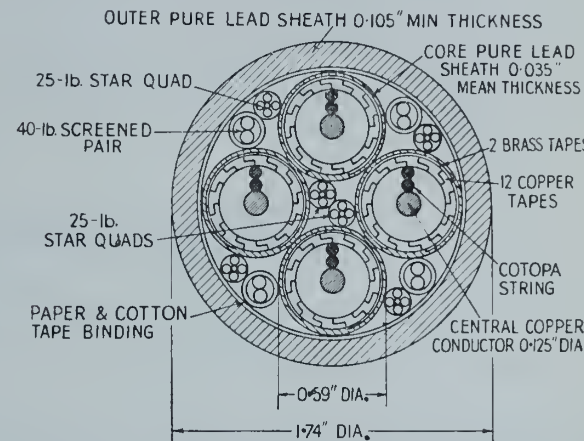

Fig. 4—Cross-section of a coaxial cable made of four coaxial cores, twelve pairs of 25 lb. star-quad and four pairs of 40 lb. screened

the Bell Telephone's carrier systems. Of particular interest are the Type C and Type J systems for use on open wire lines, which have already been described.

The Type K system has been developed for unloaded cables, and provides twelve telephone channels on each pair, using frequencies from 12,000 to 60,000 cycles. The band below twelve kilocycles is not used except for pilot and control circuits. Above that frequency, the attenuation of the unloaded cable pair rises at a steady rate with frequency, and equalization of the loss is made easier.

The fine-gauge, paper-insulated pairs in existing cables do not make inherently good high frequency conductors, as their attenuation is too high, and repeaters are necessary too often. This is offset to some extent by the shielding effect of the lead sheath, which largely excludes external disturbances, and thus permits greater amplification at repeater points than can be used with open wire circuits. Even so, repeaters will be required at much more frequent intervals than for the open wire line, for a corresponding frequency of transmission.

Different pairs are used for transmission in the two directions, making four wires in all. One reason for this is that repeaters are needed so often that the directional filters which would be necessary at each repeater point to separate the opposite directions of transmission on a single pair, would unduly increase the costs. The same frequencies are used for both directions of transmission however, so that shielding is essential between the oppositely-directed transmission paths, and this is obtained by using different cables for the two directions of transmission.

The logical extension of the principle of multi-channel carrier working leads to the replacement of the separate cables for the two directions of transmission by two pairs of conductors designed to carry, as carrier channels, all the circuits required. Each pair consists of a specially designed concentric system of conductors known as the coaxial cable, and this is the third broad-band system. It is the most intriguing of all, as it has been used to give 400 circuits using a frequency range up to two million cycles, on only two pairs of conductors. The coaxial conductor combines something of the favourable low attenuation characteristic of the open wire lines with the interference-free characteristic of shielded cable circuits.

The outside tube of the coaxial unit is a good metallic shield at high frequencies. If currents are induced from external fields such as power circuits, static or lightning, they tend to confine themselves to the outside surface of the tube because of skin effect. In fact the shielding is of such a high order that crosstalk and interference from outside sources or between coaxial pairs is negligible.

Carrier telephony has also been used to provide telephone communication over high voltage transmission lines to save the cost of stringing extra telephone lines below power lines. However, the problems arising from this application are due to the power circuits themselves and the fundamental technique is the same as has been described.

Until the broad-band carrier systems were introduced, the carrier telephone system found its chief application on open wire lines. Because of the high cost of terminal apparatus it was economical only for use over relatively long distances, where it was economical to spend much money on the terminal apparatus, in order to save on the cost of lines. It was often used only to provide increased facilities until such time as a trunk cable was required, or where it was not physically possible to provide additional wires over a given toll line or cable route.

The broad-band systems recently developed use much greater frequency ranges than had been practicable in the past, and hence many more channels per conductor pair.

It now appears that a large part of the growth in the future will be provided by carrier methods: the cable and open wire systems particularly where these lines already exist, the coaxial system where new structures are needed, and in particular, on the heavy traffic routes.

However, considerable complicated equipment is still required, and for the immediate future, these various systems will probably be provided only on the longer routes.

WORLD'S SUPPLY OF ALUMINUM

M. N. HAY, M.E.I.C.

Works Manager, The Aluminum Company of Canada, Limited, Kingston, Ont.

Paper presented before the Kingston Branch of The Engineering Institute of Canada, on January 30th, 1941

Metallic aluminum was first isolated in 1825 by the Danish chemist, Oersted, when he obtained a few globules of "the metal of clay" by a chemical method. Its commercial production was commenced in 1856 by Deville in France, by a slow and expensive method, the product costing about $90.00 a pound. One of the earliest commercial uses in a sizable quantity was the protective cap on the Statue of Liberty in New York harbour. It is interesting to note that Napoleon III subsidized the industry at its birth, thinking it might be useful for warlike purposes.

The process for recovering aluminum in use to-day, which inaugurated the industry's rather spectacular rise, was discovered in 1886 simultaneously by Charles M. Hall in the United States and Paul L. Heroult in France, each working independently. They laid down the essentials for the electrolysis of alumina, namely the use of fused cryolite capable of taking alumina into solution and then decomposing this solution electrolytically to release the metal. It was the invention, between 1870 and 1880, of the electric dynamo that made available the large amount of power necessary for the successful operation of this invention.

Because of these huge power requirements it is, therefore, natural to look for the development of the aluminum industry in those countries having potential sources of electric power such as Switzerland, France, Norway, the United States and Canada, where hydro-electric power is available, and Germany with her coalfields.

For a clear understanding of the economics of aluminum production in the various producing countries, and the importance of aluminum as compared with other leading industrial non-ferrous metals, it is essential to realize the phenomenal expansion of production as shown by yearly world output figures.

At first the output was very low. It is reported that in 1885 only a little over 15 tons were produced, but even this for such a new industry was quite an achievement. However, the rise was quite rapid and by the period of World War No. 1 annual production had increased to over 167,000 tons. After 1918 there was a slump followed by a rise, until in the boom years around 1929 an output of almost double the 1917 production was reached. During the depression which followed, production was on the decline, but rose again from 1934 to 1939 when a new high of over 800,000 tons was reached. With the present expansion all over the world for war requirements, 1940 and the next few years will prove the peak production years in the history of the industry.

Copper, lead, zinc and aluminum are the four leading non-ferrous metals. Their production, considered on a weight basis, of course, features the heavier metals, but when considered on a volume basis, copper, zinc and aluminum were practically equal in 1938. In that year the amounts by volume and weight were as follows:

Copper..........	288,000 cu. yds.	2,165,585 short tons
Zinc..........	284,000 "	1,710,000 "
Aluminum........	276,000 "	624,000 "
Lead............	193,000 "	1,829,741 "
Nickel...........	14,000 "	105,000 "

Aluminum can be rolled, extruded, drawn, forged, pressed, spun and powdered or cast into sand, permanent mould or pressure die castings. With this range of properties and possible variety of products, it is no wonder that aluminum has come to hold such an important place in the industrial world.

Of the three essentials for the production of aluminum one, as already pointed out, is abundant electrical energy; the others are ample supplies of bauxite and coal. As will be shown later, good transportation for raw materials is also an important factor.

It is interesting to note that the principal items required to make one ton of aluminum are as follows:

25,000 kwh. of electrical energy,
4 tons of bauxite,
4 tons of coal,
1/3 ton of soda,
3/4 ton of carbon electrodes,
Small amounts of cryolite and fluoride salts.

Bauxite, the principal commercial ore of aluminum, derived its name from Les Baux, a little town in southern France where the ore was first discovered in 1821. Since then bauxite has been found in many localities throughout the world, chiefly in tropical or semi-tropical countries. In bauxite the aluminum is present as an oxide associated with varying amounts of impurities—iron, silicon and titanium oxides—free and combined water. Iron oxide, being red, colours the ore, and depending on the amount of iron present, ores from different localities vary from white, grey and pink to light brown and dark red.

Following is a list of the principal countries producing bauxite, with their outputs for 1938:

	Short Tons
France	750,685
Hungary	594,000
Surinam (Dutch Guiana)	414,920
British Guiana	420,640
Italy	396,920
United States	347,500
Yugoslavia	436,000
U.S.S.R.	275,000
Dutch East Indies	269,500
Greece	197,875
Misc.—Malay States, India, Brazil, Roumania, Germany	78,060
World Total	4,181,100

The initial processing of the bauxite ore is a chemical treatment in which, by the Bayer process, the ore is treated in a hot soda solution under pressure which separates the alumina (white, aluminum oxide) from the insoluble impurities commonly called red mud. It is in this part of the process that coal is required to provide the heat and steam pressure necessary to speed up the chemical reaction. The alumina, thus separated, is dried and then charged into electric furnaces where it dissolves in the molten cryolite bath. The passage of an electric current through the bath reduces the aluminum oxide to metallic aluminum and oxygen. The metal, being heavier than the molten cryolite, sinks to the bottom of the furnace while the oxygen reacts with the carbon electrodes, forming carbon dioxide, and passes off as a gas. At periodic intervals the electric furnaces are tapped and the metal cast into pigs which are ready for remelting and alloying in the fabricating plants.

Only a few of the principal bauxite producing countries have the necessary coal and electric power for converting the bauxite into aluminum and even in this limited group, insufficient bauxite of the right grade, transportation problems between mines and power plants, or a lack of adequate electric power, all hinder the economical production of aluminum. There is, consequently, a very large international trade in bauxite.

Following is a list of the principal aluminum producing countries of the world in order of their assumed 1940 capacities.

	1938 (Short tons)	Assumed 1940 Capacities (Short Tons)
Germany	177,500	286,500
U.S.A.	143,200	220,000 (300,000—1942)
Canada	72,750	173,000
Russia	48,300	66,200
France	50,000	66,200
Italy	28,450	44,100
Norway	18,730	34,150
United Kingdom	25,700	33,100
Japan	18,730	30,000
Switzerland	29,750	27,550
Misc.—Hungary, Austria, Sweden, Yugoslavia, Spain	14,370	12,100

The yearly output figures of any one country do not necessarily give a true picture of the economics of the aluminum industry in that country. This is particularly true in the case of Germany, which at the present time leads the world in tonnage output despite the fact that it does not have available limitless supplies of the necessary raw materials. Considering the tremendous increase in aircraft production in Germany, it is obvious that the Nazis have, regardless of cost, attempted to make themselves self-sufficient and have largely subsidized the industry in order to feed their vast war machine. It is interesting to note that since 1932, Germany's aluminum production has shown an almost tenfold increase to the output of 1939 and this represents almost one quarter of the total world production. Italy, Russia, Japan and even Norway and Switzerland have developed aluminum industries against economic barriers, although Norway and Switzerland have some justification inasmuch as those countries possess natural hydro-electric facilities.

The ideal aluminum reduction plant would be one situated beside abundant bauxite deposits, adjacent to coal mines and with limitless cheap electric power readily available. The transportation of these raw materials, therefore, would not be a problem. Such an ideal location has not as yet been discovered although France most nearly approaches this condition.

In considering the economics of the aluminum industry, so many factors must be taken into consideration that definite rating of each country as to its suitability becomes almost impossible. In the following table an attempt has been made, nevertheless, to group the important world producers and the three essential raw materials—power, bauxite and coal, together with transportation—and to rate each country in relation to the others, A representing excellent, B, good; C, average; D, fair, and E. poor. This classification is only a personal opinion, because for example for transportation alone, we would require very exacting comparative cost figures, depreciation of rail and boat facilities, an intimate knowledge of such conditions as port, storage and loading investments and the cost of labour in the various countries; all matters which have a direct bearing on the economics of producing metal regardless of the quality and abundance of the raw materials. Obviously, therefore, such a grading as has been made on this list can serve only as a rough guide, since all the many facts relating to the subject are not available.

	Power	Bauxite	Coal	Transport and Other Facilities
Canada	A	E	A	B
U.S.A.	B	B	A	C
Germany	B	D	A	C
Russia	C	D	C	E
France	B	A	A	A
Italy	D	C	E	B
Norway	A	E	E	C
United Kingdom	D	E	A	B
Japan	E	E	C	C
Switzerland	A	E	E	D

Power

Hydro-electric power in the industrial east of Canada needs no explanation. Northern Ontario and Quebec abound with waterways—potential sources of great power developments. Likewise, Norway, Switzerland have hydro-electric power in abundance. The United States is not so fortunate in that there is cheap power available only in New York State, the Southeast and the far West. France has good power developments but as most of these are built at the foot of deep valleys, utilizing high water heads but small volumes, the power plants have been limited in size. Expansion can only take place by building more of these small power units, a very undesirable and uneconomical condition for large scale production. Russia has large power units, the most famous of which is the Dnieprostroi development, but the difficulty with the power developments in Russia, a fact which also holds for many of the best developments in Norway and Switzerland, is that they do not have a water accumulation in lakes back of the power plant to ensure a uniform volume of power throughout the entire year. As a result many of the Russian plants for part of the year are actually short of power, whereas in Canada, with the great chain of lakes and rivers in the north and the abundant snowfall, storage basins are kept at practically a constant level throughout the entire year. Power in Italy and Japan is very costly but being subsidized by the government, cost is a minor consideration. The situation in Germany is different because practically all of their electric power is produced from coal. Thus it is not surprising to find that the German reduction plants have nearly all been built in districts where brown coalfields exist and under these conditions power is made almost as cheap as in the average hydro-electric plant.

Bauxite

Of the important producing countries, France is the only one which has within her own borders abundant supplies of good grade bauxite. In the United States good deposits exist in Arkansas, Alabama and Georgia, but these will by no means provide sufficient ore for the large American industry, and most of the bauxite used at present by the States is imported from Dutch Guiana.

Germany, Russia and Italy have some deposits but they are mostly of an inferior grade. Germany and Italy depend largely on imports from the Balkan countries.

All other producing countries are without deposits of their own and are wholly dependent on imports.

Canada has to bring ore from distant British Guiana, but the quality of this ore is probably the best in the world. Transportation facilities by boat direct from the mines to the smelter are ideal, thus offsetting to a considerable degree the fact that we do not have any bauxite in our own country.

Coal

Canada, United States, Germany, France and the United Kingdom all have an abundant supply of coal. Russia and Japan both have limited deposits, while Italy, Norway and Switzerland are largely dependent on imports.

Transportation

Transportation—including necessary facilities for the handling of ore or raw materials—is a factor which cannot be rated with any certainty. Undoubtedly, France, with coal, bauxite, and power plants practically on the same property, has no transportation problem. Canada, Italy and the United Kingdom, importing as they do by sea, are in a more favourable situation than are most of the other countries. Norway and Japan, for instance, must haul by boat and then transport by rail considerable distances inland, greatly adding to the cost of transportation. The United States, while possessing a very efficient inland transportation system, has of necessity to make long haulages by rail as well as by boat in order to bring together all these raw materials from so many scattered sources of supply. In Gremany they have a real problem, for practically all their ore has to come from the Balkan states by rail or river barge. Much of this traffic is on the Danube river, but because of the narrows at the Iron Gates, the boats and barges are small and shipping small tonnage is costly.

From this very cursory and generalized survey of the aluminum industry it is apparent that Canada should rightly hold a foremost place among world producers. True, there have been difficulties to overcome. At the mines in British Guiana there have been housing and sanitation problems as well as the difficulties of operating in tropical countries far from sources of supplies and equipment repairs. Our long winters in northern Quebec necessitate accelerated imports during the navigation season to provide stocks of raw material for the winter months. This, in turn, has required huge storage sheds and exceptionally large dock facilities to accommodate these supplies. Few people realize that the aluminum industry in Canada has developed and operates in Arvida the largest aluminum plant in the world, supplied by power from Isle Maligne, its own power house, which is the third largest power-house in the world—560,000 hp.—exceeded only by the American Boulder Dam and the Russian Dnieprostroi developments. Port Alfred, the fourth largest port in Canada, also was built for the aluminum industry's immense boat traffic.

By perseverance and hard work this important industry has been built up in Canada—an undertaking now more than ever vital to the nation and to the British Empire, for Canada's entire output is going into aircraft and other essential war equipment.

THE SOLUTION OF SIMULTANEOUS LINEAR EQUATIONS IN STRUCTURAL ANALYSIS

I. F. MORRISON, M.E.I.C.
Professor of Applied Mechanics, University of Alberta, Edmonton, Alta.

The chief difficulty in the application of the three-moment equation lies in the ready solution of the algebraic equations which result from it. This equation, in its most general form, leads, when written out in detail, to a set of n three-term simultaneous linear equations containing the moments at the supports as unknowns. These equations have a special character and advantage can be taken of it to effect a systematic process for the solution of them.[1]

The form of these equations is:

$$A_{r,r-1}\, M_{r-1} + A_{r,r}\, M_r + A_{r,r+1}\, M_{r+1} = Z \qquad (1)$$

where r runs from 1 to n, there being $n+2$ supports numbered from 0 to $n+1$.

The $a_{r,r}$, which are the numerical coefficients, are quite independent of the Z_r. The former depend on the elastic properties of the structure, including the spans and moments of inertia, while, in addition, the latter include the loading, settlement of supports, etc. Moreover, the $a_{r,r}$ form a symmetrical matrix and also in simple cases $a_{1,0} = a_{n,n+1} = 0$. We shall make use of this special character of the equation.

It is a simple matter to show, by means of the theory of linear transformation, that such a set of equations may be solved in the form

$$M_r = \sum_{i=1}^{i=n} b_{r,i}\, Z_i \quad , i \text{ running from } 1 \text{ to } n \qquad (2)$$

in which the $b_{r,i}$ are functions of the $a_{r,r}$ and are not affected by the Z_r. They also, therefore, form a symmetrical matrix, i.e. $b_{r,i} = b_{i,r}$.

If equations (2) be substituted in equations (1), the result is

$$a_{r,r-1} \sum_{i=1}^{i=n} b_{r-1,i}\, Z_i + a_{r,r} \sum_{i=1}^{i=n} b_{r,i}\, Z_i + a_{r,r+1} \sum_{i=1}^{i=n} b_{r+1,i}\, Z_i = Z_r \qquad (3)$$

If the summations be written out and the terms collected according to the Z_i, one finds:

$$\begin{aligned} &(a_{r,r-1}\, b_{r-1,1} + a_{r,r}\, b_{r,1} + a_{r,r+1}\, b_{r+1,1})\, Z_1 \\ &+ \ldots\ldots\ldots\ldots\ldots\ldots \\ &+ (a_{r,r-1}\, b_{r-1,k} + a_{r,r}\, b_{r,k} + a_{r,r+1}\, b_{r+1,k})\, Z_k \\ &+ \ldots\ldots\ldots\ldots\ldots\ldots \\ &+ (a_{r,r-1}\, b_{r-1,n} + a_{r,r}\, b_{r,n} + a_{r,r+1}\, b_{,+1,n})\, Z_n = Z_r \qquad (3a) \end{aligned}$$

This equation would be satisfied if all the coefficients of the

[1] The occurrence of such systems of equations in structural analysis is not confined to the three-moment equation.

Z's were zero, except the coefficient of Z_r, and this coefficient were unity.

Then,

$$a_{r,r-1}\, b_{r-1,k} + a_{r,r}\, b_{r,k} + a_{r,r+1}\, b_{r+1,k} = 0 \qquad (4)$$

would be true for all values of k except the one value $k=r$, for which case:

$$a_{r,r-1}\, b_{r-1,r} + a_{r,r}\, b_{r,r} + a_{r,r+1}\, b_{r+1,r} = 1 \qquad (5)$$

Now let

$$b_{r,k} = c_r\, b_{r+1,k} \qquad (6)$$

Then

$$b_{r-1,k} = c_{r-1}\, b_{r,k} \qquad (6a)$$

Substituting equations (6) and (6a) in equation (4), one gets

$$b_{r,k} = -\frac{a_{r,r+1}\, b_{r\ 1,k}}{a_{r,r} + a_{r,r-1}\, c_{r-1}} \qquad (7)$$

so that

$$c_r = -\frac{a_{r,r+1}}{a_{r,r} + a_{r,r-1}\, c_{r-1}} \qquad (7a)$$

In a similar manner, let

$$b_{r,k} = c'_r\, b_{r-1,k} \qquad (8)$$

then

$$b_{r+1,k} = c'_{r+1}\, b_{r,k} \qquad (8a)$$

and

$$b_{r,k} = -\frac{a_{r,r-1}\, b_{r-1,k}}{a_{r,r} + a_{r,r+1}\, c'_{r+1}} \qquad (9)$$

so that

$$c'_r = -\frac{a_{r,r-1}}{a_{r,r} + a_{r,r+1}\, c'_{r+1}} \qquad (9a)$$

Also, substituting equations (6a) and (8a) in equation (5) and putting $k=r$, one gets:

$$b_{r,r} = \frac{1}{a_{r,r-1}\, c_{r-1} + a_{r,r} + a_{r,r+1}\, c'_{r+1}} \qquad (10)$$

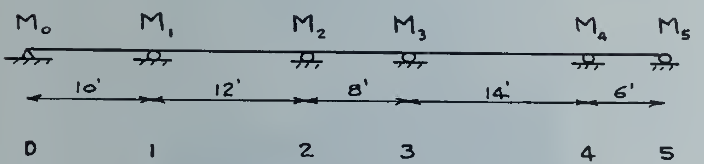

Fig. 1

It is, of course, obvious that difficulty will be encountered should the denominator of equations (7a), (9a) and (10) respectively turn out to be zero. In this case, however, it can be shown that the equations (1) are not compatible. The computation may usually be carried out on a slide-rule except in those cases in which the denominators are nearly zero. In such case more significant figures will have to be employed, making the use of a calculating machine or logarithms necessary.

Now where $a_{1,0} = a_{n,n\ 1} = 0$, starting with these values the c_r and the c'_r may be progressively computed from

TABLE I.

r	$a_{r,r-1}$	$a_{r,r}$	$a_{r,r+1}$	c_r	c'_r	z_r
1	0	44	12	—.273	0	—2,728
2	12	40	8	—.218	—.313	—2,240
3	8	44	14	—.331	—.205	—3,256
4	14	40	0	0	—.350	—2,960

equations (7a) and (9a). The $b_{r,r}$ may then be determined from equation (10) and finally from them all of the $b_{r,k}$ can be formed from equations (6) and (8).

These values, when placed in equations (2) give the M_r which is the ultimate object of the process. The work should be carried out in tabular form but in order to save space the form of the tables will not be given.

In order to display the process as one of systematic computation, the following simple example has been chosen as an illustration. A continuous girder, having a constant moment of inertia of its cross-section carries a uniform load of 4,000 lb. per linear foot over six supports as shown in Fig. 1.

The three-moment equation is for this case.

$$L_a\ M_a + 2\ M_m\ (L_a + L_b) + M_b L_b = -\tfrac{1}{4} L_a^3 w_a - \tfrac{1}{4} L_b^3 w_b.$$

By inspection all of the a_r can be written down and all of the Z_r can be readily computed. Obviously $n=4$, and the various numerical values have been entered in Table I. The Z_r are in foot-kips.

Next the c_r and c'_r are computed.

For example:

$$c_1 = -\frac{12}{44} = -.273$$

$$c_2 = -\frac{8}{40 - .273 \times 12} = -.218$$

Table II is next filled in. To do this start at the lower right hand corner and compute:

$$b_{4,4} = \frac{1000}{-14 \times .331 + 40} = +28.28$$

TABLE II.

k \ r	1	2	3	4
1	+24.8	—7.77	+1.59	—0.557
2	—7.77	+28.5	—5.83	+2.04
3	+1.59	—5.83	+26.8	—9.37
4	—0.557	+2.04	—9.37	+28.3

TABLE III.

Z_r	M_1 +	M_1 —	M_2 +	M_2 —	M_3 +	M_3 —	M_4 +	M_4 —
—2,728		67,700	21,200			4,340	1,520	
—2,240	17,400			63,800	13,100			4,570
—3,256		5,180	19,000			87,200	30,500	
—2,960	1,650			6,040	27,700			83,900
	—53,830		—29,640		—50,740		—56,450	

by equation (10). Here 1000 has been used instead of unity in equation (10) for convenience. This will make all of the $b_{r,k}$ 1000 times too large. Since, however, the Z_r are in foot-kips, when they are multiplied by the b_{rk} the result will be in foot-pounds as shown in Table III.

Starting with $b_{4,4}$ the remaining $b_{r,k}$ are computed upwa:d by successive multiplication by the c_r. Next $b_{3,3}$ is computed from equation (10) and the other $b_{r,k}$ upwards from it by multiplying by the c_r and downwards from it by using the c'_r. Since $b_{r,k} = b_{k,r}$ the computations can be checked at each step.

The solution of the equations is completed by filling in the Table III which contains the products $Z_r b_{r,k}$ and needs no further comment.

Thus, we have

$M_1 = -54,830$ foot-pounds
$M_2 = -29,640$
$M_3 = -50,740$
$M_4 = -56,450$

which will be found to satisfy the original equations.

There is an additional advantage in this procedure because when the loading is changed only the Z_r become altered. The $b_{r,k}$ remain the same. Thus, for different loadings only the Table III need be repeated. This fact also makes the method very useful for the computation of influence lines.

AIR TRAFFIC CONTROL

EWAN D. BOYD

Officer in Charge of Air Traffic Control, Kenyon Field, Lethbridge, Alta.

Paper presented before the Lethbridge Branch of the Engineering Institute of Canada, on November 6th, 1940

The main purpose of air traffic control is, as the name will indicate, essentially to reduce the risk of collision in the air, or on the airport, and to speed up the safe dispatch of aircraft as much as possible.

The necessity for air traffic control probably better emphasises the tremendous progress which aviation has made than does any other individual development. Although most control towers have been installed in Canada because of the congested conditions which would result when the Empire Air Training Scheme is operating at capacity, traffic control has been found necessary at most of the main airline terminals in the United States because of commercial traffic alone. A similar condition may very well follow in Canada. In fact, Vancouver found its volume of civilian flying sufficient to justify the expense of installing a control tower as a civic project over four years ago. It seems very probable that the increase in traffic will make the operation of air traffic control centres essential even after the war.

Classes of Air Traffic

There are two classes of air traffic: these are terminal traffic and airways traffic. Terminal traffic is composed of aircraft flying within a 25-mile radius of the terminal airport, while airways traffic is considered to be all aircraft flying along or across the designated civil airways which connect the various air terminals. These civil airways, incidentally, are defined as "A flight path twenty-five miles in width and extending twenty-five miles beyond the terminals, along which have been established the necessary ground facilities."

Light Gun Control

Let us first explain the procedures used in controlling terminal or airport traffic, first by visual means and secondly by radio means. All aircraft not equipped with radio are handled with a signal light gun. Figure 1 shows the light gun used in the Lethbridge control tower. This gun consists principally of a small 50 candlepower bulb mounted in front of a highly polished reflector which concentrates the light rays into a parallel-ray beam. With this arrangement the light, in spite of its low candlepower, is visible for a distance of ten miles in daylight. A red and a green lens are mounted with suitable controls so that they may be quickly swung between the bulb and the reflector. It is thus possible to give a green, red, or white signal at will. Since the rays are concentrated into a small spot which does not increase in diameter with distance, only the aircraft towards which the gun is pointed can see the signal. A suitable set of cross hair sights are mounted on top of the gun enabling the operator to aim the light accurately on the aircraft concerned.

The movement of a non-radio-equipped aircraft arriving from Calgary, for example, landing, and later departing for Vancouver, is as follows: On arriving over Lethbridge Airport, the pilot will circle the airport control tower to the left at 500 to 1000 ft. above ground level. (Altimeter reading 3500 to 4000 ft. above sea level). If the runway favoured by the wind is being used at the moment, he will receive an intermittent red light from the tower. He will then climb to at least 1000 ft. and continue to circle the field until he receives a steady green light from the tower—the signal that it is all clear to land. It is the pilot's responsibility to watch the tower from time to time during his approach to make sure that his landing clearance is not cancelled by a further intermittent red light before he actually completes his landing. After landing the aircraft comes to a stop and does not move until after receiving an intermittent green, which indicates that it is all clear to taxi. During taxying, the pilot must keep a lookout for other aircraft and an eye on the tower for further signals. During this time he may receive an intermittent red ordering him to stop, or an intermittent white indicating that he is to pull clear of the hard surfaced runway, and hold his position. If the tower operator wishes the aircraft to pull clear of the paved runway and taxi on the grass, he will send out a series of intermittent white and green flashes with the traffic gun. The outgoing aircraft will taxi out to a point opposite the tower and hold until given taxi clearance. When he reaches the take-off point the pilot will face across wind away from the tower until he is ready for take-off clearance. When ready, he will swing around in the direction of take-off or slightly facing the tower and will receive take-off clearance as soon as the runway is clear. He should not park on the end of the runway while testing his engines before take-off, but well to one side so that incoming aircraft will not have to land over him. After

Fig. 1—Light gun used for controlling airport traffic

taking off, the outgoing aircraft will receive no further light signals from the tower, but will merely comply with the rules of the air as outlined in Civil Air Regulations. In passing it might be well to mention that the aircraft acknowledges all signals by rocking its wings in the air and by moving its rudder and ailerons when on the ground. Aircraft equipped with a radio receiver only also acknowledge tower radio signals in this manner.

Traffic Control by Radio Communication

All airport control towers are equipped with a radio voice transmitter operating on a frequency of 278 kilocycles, for the control of aircraft equipped with radio. Any aircraft equipped with a receiver which can be tuned to the radio range band—200 to 400 kcs.—will receive control instructions from the tower regardless of whether they are fitted with a transmitter or not.

Radio control is far superior to light gun control in that it is possible to give specific information to the pilot regarding the wind condition, pertinent traffic and any other information which may be considered useful. The pilot may, if he has a radio transmitter, ask for and receive any information which he desires. This is useful, for example, to pilots going into a strange airport, who are doubtful about some field condition or other point. A definite routine is used in handling incoming and outgoing aircraft equipped with two-way radio.

Approximately 25 miles out, an incoming aircraft will call the airport control tower on his normal transmitting frequency (or one of his frequencies if he has on all the commonly used frequencies), the aircraft's call will be received on that receiver which is tuned to the frequency in question. After the tower has acknowledged the call, the aircraft will report its position, altitude, and estimated time of arrival at the airport. The tower will repeat this information as a check, and then give the runway being used by traffic, altimeter setting, and the essential traffic, if any. This will be acknowledged by the aircraft.

Taking Trans-Canada Airlines Trip 3, westbound from Regina, as an example, the radio patter will go something like this:

"Trans-Canada Trip 3—Lethbridge Tower."

"Lethbridge Tower—Trans-Canada 3, go ahead."

"Trans-Canada 3—Lethbridge Tower, by Taber at five eight, at six thousand, estimate the field at zero nine, beginning descent from six thousand at five nine."

"Lethbridge Tower—Trans-Canada 3, by Taber at five eight, at six thousand, estimate the field at zero nine, beginning descent from six thousand at five nine—wind south west variable, twenty to twenty-five, favouring the northeast-southwest runway—altimeter setting twenty-nine, eighty-seven—two, nine, eight, seven—your traffic is a formation of five Air Force Ansons, departed Lethbridge at fifty-six—five six—for Regina, cruising at five thousand. There are several Moths flying locally."

"Trans-Canada Trip 3." (Note that during conditions of poor radio reception the aircraft would repeat back the above information in his acknowledgment as a further check).

A second inbound check is given approximately five minutes out. This is similar to the first except that more details concerning landing conditions and local traffic are given at this time. It also gives the traffic control officer a further check on the position and speed of the aircraft and permits him to handle his local traffic accordingly.

Air Landing Clearance

This is the third and last routine communication in the air. It is carried out just prior to starting the landing approach. An example of this is as follows:

"Trans-Canada 3—Lethbridge Tower, landing clearance."

"Lethbridge Tower—Trans Canada 3—wind unchanged, two Moths holding clear of the runway on the south side—you are clear to land, wheels down."

"Trans-Canada 3, wheels down."

The comment "wheels down" is given at the request of some operating companies as an extra reminder to the pilot to lower his undercarriage before landing. Belly landings are expensive!

As the aircraft comes to the end of its landing run, the tower will give it taxi clearance; or this may be first requested by the pilot. Specific taxi instructions regarding runways or taxi strips to be used may also be given at this time. Such as: "Pull off to the north side of the runway and hold your position, there is an Air Force Hudson approaching behind you;" or "Taxi back by way of the east-west runway."

The control of outgoing aircraft when radio equipped follows much the same procedure as non-radio-equipped aircraft. That is in regard to the clearances required and given. It is of course, much more specific, as previously mentioned. After the aircraft has taken off and is about five miles from the airport, he will give a position report and request clearance from the tower to the radio range, to his operating company, or to the Air Force station to which he wishes to listen. Normally all outbound aircraft which have filed a flight plan specifying a definite cruising altitude at which they intend to fly (an instrument flight plan) must give a report over definite pre-arranged locations as the flight progresses. They will also be given traffic information and instructions. For this reason, they are required to keep a constant watch on some definite frequency, such as that allotted to their own company, or to the radio range station closest to them. All itinerant aircraft will receive their traffic information from the radio range station to which they are tuned.

Airways Traffic Control

Once the pilot has obtained a clearance from the airport traffic control tower, and is making a flight along a civil airway, he comes under the jurisdiction of airways control. The system of airways control used in Canada at present is being patterned after the procedure laid down by the Civil Aeronautics Board of the United States, but since it is still in the process of development, it naturally is not yet functioning with the same efficiency as the older American service. Rapid progress is being made, however.

It is only in the last few months that any airway control has been considered necessary in Canada, although a circular was issued by the Civil Aviation Division of the Department of Transport in July, 1938, outlining approved practices. This will presumably be followed when all control

Fig. 2—Control tower at Kenyon Field, Lethbridge, Alberta.

towers are completed and in operation. This circular (O/44/38) will be discussed to give an idea of the approved system.

Contact Flight Rules

All flights along a designated civil airway can be completed in one of two ways: either by contact flight rules (known as CFR), or by instrument flight rules.

An aircraft flying by contact flight rules carries out all essential navigation by visual reference to the ground. In order to complete such a flight the pilot must at all times have at least the minimum ceiling and visibility conditions laid down by the Government (Controller of Civil Aviation —O 63/40). If the minimums drop below the allowable limits the pilot must land at the first possible opportunity. He must, under no circumstances, attempt to climb through the overcast. No radio equipment, special blind flying instruments, or instrument flight training is required to complete a flight under contact flight rules.

Instrument Flight Rules

The airways control centres are concerned chiefly with flights made under instrument flight conditions, since, during contact flight conditions, the visibility is sufficient to make the risk of collision on airways negligible. For this reason a pilot need not specify at what altitude he intends to fly when operating under contact flight rules. This, of course, does not apply to an instrument flight. The conditions laid down for making a flight under instrument flight rules not only specify that the aircraft must be equipped with two-way radio, special instruments, and qualified personnel, but a flight plan containing all essential information as regards route, altitude, proposed departure time, speed, estimated time of arrival, etc., must be submitted to the traffic control officer, at the nearest station, for approval before departure. The pilot is also responsible to notify the airways control of his progress along the route by means of his company radio, or through the nearest radio range station. They will relay the message to airways control by interphone or teletype. He must obtain permission before changing his flight level or any other item in his flight plan. Airways control will keep all other aircraft notified through available radio facilities.

On arrival over the terminal airport during instrument conditions the aircraft will if necessary be given an altitude and course to maintain until the air below him and the approach to the field is clear. He will then be given his "approach clearance" which permits him to descend through the overcast, or make "let down" as it is termed. As soon as he can see the ground, that is he is "contact," the pilot makes a landing under the direction of the air-control tower. The next machine which has been holding above him is then permitted to start its "let down."

Sometimes at a busy airport there may be several machines stacked up at thousand-foot intervals waiting for the machines below them to let down and land. The instructions for holding an aircraft prior to an instrument let down given by the airways control are generally worded roughly as follows:

"Hold on south leg of Lethbridge range between station and point five minutes south until further advised."

The subject of airways and airport traffic control is far too large to discuss from every angle in this paper. However, the above outline will give a general idea of how aircraft are prevented from flying into each other even in weather conditions that make it impossible for the pilot to see further than his own wing tips. The fact that there has never been a collision of aircraft operating under civil airways control on this continent is an indication of the efficiency of the system evolved.

The pilots also appreciate the fact there is always someone watching out for them on the ground and giving them useful information when they require it. This applies just as much to the small radio-equipped light aeroplane as it does to the biggest airliner.

Future Outlook

At the rate that aviation is expanding, on the civilian side as well as the military, many traffic problems at airports and their immediate vicinity may develop in the not so distant future. Many interesting methods are likely to be devised to solve this problem. Some of these are likely to be:

(a) The dissipation of the traffic over a larger area. There is plenty of air for everybody to fly if everybody does not try to use the same spot at the same time. Many factors will help in the dissipation of the traffic. Some of these will be more airports and airways, more extensive use of seaplanes and amphibian aircraft; more extensive use of autogyros, helicopters and other types which do not require large airports; the further segregation of types—airliners to use one airport; smaller, slower types to use another.

(b) Changes in the design of aircraft, to give a greater speed range, more manoeuvrability, more fool-proof handling qualities, and a better field of vision.

(c) Improvements in the design of both aircraft and ground station radio equipment. Ultra high frequency apparatus has already gone a long way towards fully reliable reception even in conditions of severe electric disturbances.

(d) The more universal use of radio in aircraft. The time will come when a non-radio-equipped aircraft will be looked upon in the same light as we now look upon an automobile without an electric starter. This will make for faster handling and less confusion.

Future Traffic During Instrument Conditions

Terminal traffic has already become number one airline operating problem at one or two of the large metropolitan airports in the United States, although it is likely to be some little time before such a condition arises in Canada.

To quote from an article by Capt. Fred Smith, of Canadian Colonial Airlines in October's *Aero Digest.*

"Only in polite company do pilots and flight superintendents call it "Terminal Air Traffic." To them it constitutes the greatest single source of fatigue encountered in the year's work. In the airlines' pocketbooks it has caused a sizable loss of revenue, since it has necessitated cancellation of short-haul schedules during perfectly flyable weather due to probable unreasonably long delays over destination airports... Recently, because of increased schedules, it has become usual during the rush hours, for upwards of a dozen airplanes to become stacked up over the airport's (New York's La Guardia Field) environs waiting for a chance to use the single radio range... One evening last spring there were 22 planes waiting to use it. Since, on peak traffic occasion approximately 300 planes per day operate into and out of this one airport (and these usually bunch between noon and eight o'clock in the evening), it can be readily realized the immensity of the problem presented. The runway may not be used for take-off when a plane is approaching or making its landing. A double number three runway, one for take-off, one for landing, would be an immediate relief, but not a solution to the problem."

There are many means that may be employed to reduce this problem of congested traffic over a terminal airport during instrument conditions. Some of these are being acted on at the present and will be put into effect shortly.

(a) Double runways. One for take-offs and one for landings. This will enable more movements to be made per hour.

(b) Instrument landing equipment. This would speed up "let down" procedures and would eliminate the necessity of second attempts at "let downs" with the resultant waste of time. This is being installed in ten centres in the United States this year with another fifteen to follow shortly. It is to be hoped that Canada will get similar equipment as it would be worthwhile for the completion of more trips which would otherwise have to be cancelled for low ceiling and visibility even if it were not needed immediately as an aid in the terminal traffic problem.

(c) Alternate airports. At least two airports equipped with blind landing facilities for every metropolitan centre.

(d) Bigger aircraft. Greater cargo per movement, thus reducing the number of movements necessary to handle a given volume of cargo.

(e) There has also been some development work on an infra-red ray apparatus which, when perfected, will enable a pilot to see through clouds. This naturally will be a tremendous advantage to flying of all types and will practically eliminate the necessity for rigid control that exists to-day during instrument conditions.

FUNDAMENTALS OF PROFESSIONAL EDUCATION*

ELLIOTT D. SMITH

Master of Saybrook College and Chairman of the Department of Economics, Yale University, New Haven, Conn., U.S.A.

An address delivered at the Sixth Annual Meeting of the Allegheny Section of the Society for the Promotion of Engineering Education, Pittsburgh, Penn., on October 25th, 1940

I have been asked to speak on the fundamentals of professional education. It is difficult to speak on fundamentals without being superficial. It is so easy to use stock phrases. It is so easy to say that the task of professional education is to equip a man with something to profess and to give him the ability to use well that which he professes. It is so easy also, to add that to make him truly professional his education must cultivate his mind, and further, because of the ethical tone of all professions, it must train him to use his professional powers for the well-being of society. It is so easy to do this that it is tempting to do it and no more. But when one has finished these "Good words, and well pronounced," one has said nothing that anyone can disagree with, and nothing of effective importance.

One way of making more concrete these general statements, is to examine the world in which the professional student of to-day must practice his profession. This is a very different world from that in which Bacon could truthfully say, "Knowledge in itself is power." For since the time of Bacon the world has undergone a deluge of objective knowledge, great in mass, and great and growing greater in its rate of accumulation. That objective knowledge has changed the character of all professional work and hence of all professional education.

Although scientific knowledge has gone on and on expanding, and in expanding has increased our control over nature, all of the mysteries of life are as great to-day as they were in the time of Bacon. For the meaning of life and death and personality have not been made easier to understand by all that has been learned about the universe of the stars and the universe within the atom.

The expansion of science instead of creating bases for faith, has removed the old moorings to which we tied our faiths and our sense of values. Hardly more than a generation ago those moorings were so secure and the port in which our faiths and sense of values rested was so sheltered that the great mass of people never ventured out into the open sea of fundamental inquiry. But that security has gone. As a result, philosophers have had to become scientific and the great scientists, in their effort to ease the distress of soul that their discoveries have caused, have often become philosophical. And common men, as a Harvard student said in his graduation poem, when they think about values and about what makes life worthwhile and significant,

"...weary-eyed with too much light,
Cry from their dream-forsaken vales of pain,
'Give us our gods, give us our gods again ' "**

As science has advanced, engineering has applied it to life. Through doing this engineering has changed from the roots our way of life and of work and even of war. In the process, social institutions and values that were stable have become insecure. Great to-day is the violence and great the confusion of tongues as to what is good and what is ahead in government, industry, and society.

This means that if our professional training is to equip a man for useful professional attainment it must equip him to go out into insecurity and to face perplexity unabashed. In such a world knowledge is abundant but no longer power in itself. We cannot successfully prepare a man for professional life by merely providing him with information and techniques ready for use. Instead, we must equip him to go back to fundamentals and to be able to work out from origins both values and practices, and in that sense be original. To provide capacity for such fundamental originality is the basic task of all professional education.

Its attainment is made difficult by the fact that the human mind, like the human body, tends to calcify around any material that stays static within its organism. If we give a student precise information and answers and let these lie inert in his mind, they are likely to calcify and produce a crustacean thinker—a man whose thinking is enclosed in a shell of fixed ideas and formulas. Such a mind, like all crustaceans, is exceptionally capable of shielding itself from exposure to the pain of changing reality; but like all crustaceans it is also peculiarly incapable of adapting itself to fundamental change or of controlling changing reality. Worse still, if instead of giving a student that inert knowledge through his own discovery, we give it to him as of our authority, we have created a type of mind similar to the hermit crab, with somebody else's shell that it drags around, a ponderous mass impeding thinking; into which, whenever reality becomes disagreeable or threatening, it can retreat and say, "There are the accepted answers."

If on the other hand, calcification creates a central spine, as it does in the vertebrate, it gives power and adaptability. I believe this is as true of mental as of anatomical organisms. Hence, if we are to give our students this sturdy adaptive power of thought, we should allow calcification of thought only in regard to basic principles as to which we can say, "These are so fundamental that you can safely let them become the solid spine of your thinking." This is not as simple as at first appears, for the problem is by no means merely one of teaching the student science, or even plenty of it. For if we make the scientific core too much an end in itself we are likely to produce a mental skeleton whose inelastic muscular vestiges are dried against its bones.

You will notice on the football field, that the sturdy graceful men who play, not merely have backbones, but that their backbones are extraordinary in their adaptive flexibility. When one of them tackles or throws a pass, his spinal posture must be right for the task or it won't succeed. So, although in the process of professional education we must create solidity at the spine, this basic spine if it is to be good must be produced by a process of growth and exercise which makes it flexible and which develops around it strong muscles of thought.

Professional education must provide an understanding of science. But professional education must go further and provide at *the same time* exercise in the use of science to solve practical problems of technology. Then the growth of spine and muscle will be concurrent and each adapted to the other. If we attempt to teach either in isolation—if we do not make science useful as we teach it, or if we teach technology as the mere learning and manipulation of formulas and techniques instead of the application of fundamental science to concrete problems—we will have made it difficult for science and technology to play their proper parts thereafter in powerful vertebrate thinking.

This applies particularly to teaching the so-called technical tools. To try to teach them separately as things in themselves is to render them unsuited to creative use. If a man is a good craftsman, he can always acquire and learn to use any special tool that he needs. If he is a really good craftsman, he will grind the tool he buys to fit his particular job. Often he will make his own special tool. Intellectual tools are similar. In this age of printing they are widely available and the purchase price is small. If we teach the man the art of acquiring them from the printed word, and

*Reproduced by special arrangement with the Society for the Promotion of Engineering Education.

**Hermann Hagedorn, in "A Troop of the Guard."

the art of using them, and the art of remodeling them, we have given him something more valuable and more adaptable to the future than any quantitative fullness of his technical tool chest. Besides we may then find that the few tools which we have given him in the process of developing these arts are finer than if the provision of the tools and not of the arts had been our aim. Thus, in this as in other respects, it is a fundamental of professional engineering education that it make its aim the development of capacity for basic originality in the use of science and technology, not the provision of the greatest quantity of surface technological proficiencies.

In this respect, as in all others, what a student learns depends upon what he does and two things are outstanding in determining a student's activity. One is the character and the quality of mind of the teacher. If the teacher is a man of full habit and if he is a man of basic originality, his way of thought, his way of conversation with his students, his way of dealing with them, will unconsciously instill itself into them. Give me great persons and great thinkers as teachers before all else.

The other primary factor in determining what a student does and learns is how his attainments are measured. Ask almost any student who is willing to be frank with you what causes him to work at particular things and in particular ways in his daily work, and the answer generally will be—"What 'scores', in the exercises and examinations." For these coming events cast influential shadows before.

There is a type of examination that reminds me of a form of fishing practiced by peasants in Japan. These humble men make their living by training cormorants, large diving birds, to fish for them. The fisherman places a ring around the cormorant's neck, large enough to permit the bird to breathe, but not large enough to let it swallow a fish. He rows out into the fish pond. The cormorant dives for the fish. When it gets back to the boat the fisherman pulls up the ring and out comes the fish. But the cormorant, though he has been through the exercise of fishing, has gained no nourishment.

All too many examinations are similar to this. The only difference is that we stock our intellectual fish ponds with our own types of fish, and when in the examination we pull the ring we take pride that the fish which comes forth comes without scar or modification caused by its sojourn in the student's mental gullet. Under such conditions students who reproduce their mental fish exactly as they received them in the text or lecture stand high. And yet the digestive juices of such students never reach what they have fished out so as to modify it or to give them sustenance from it.

If we are going to teach capacity for true originality, our tests and class work must face our students from time to time with genuine perplexity. This alone gives opportunity to learn true discipline of mind. If a student looks at a problem and doesn't know the answer, he is not truly faced with perplexity if he knows the formula or the method by which, with a few substitutions, he can get the answer. Instead of facing him with perplexity that is merely facing him with "capitalistic certainty"—an investment in a "sure thing," the return on which must be postponed until the known manipulations provide the answer.

True perplexity occurs when the student doesn't know any ready-to-use formula or means of solution and has to take thought as to how to devise one—when he has to return to fundamental principles in order to work between formulas or beyond them. With such true perplexity, even after he gets the answer, he is not sure that it is right because, having created the formulas or measures all along the way, he cannot be sure that better ones might not have been found. But if he has worked out his process of solution from the core, he will have learned the beginning of the art of fundamental originality. Out of his perplexity will come power and confidence that can survive in the perplexity of the world into which he later must go.

Now this means that we cannot teach a student to think under his own steam, to use President Doherty's term—we cannot teach him to use creative originality, if we regiment him. Yet if we permit undisciplined educational self-indulgence, we are in danger of producing a jellyfish mind without a spine at all—scientific, technical, or otherwise. To solve this conflict discipline must be raised above the level of regimentation. And to do this it is necessary to have wide enough gaps between tests and between assignments to permit large enough problems or tasks to involve the use of creative power and not merely the manipulation of technical minutiae. Furthermore, for the word "exercise" we should seek to be able honestly to substitute the words "experiment" and "original problem." That I fear can be done in only a few institutions. It is so easy to teach the laboratory or the technical manual of arms, and so hard to give opportunity to learn strategy Yet, the lifting of discipline above regimentation is truly a fundamental of good professional education.

The extensiveness of objective knowledge has faced professional education with another difficulty. In nearly all fields the mass of scientific and technological data and practice is so great that when teachers look at it they can hardly escape from gasping, "How can we teach all this in the time available ? Years ago when people didn't know so much, to teach was easy. But now we need more hours of class work and more hours of study than it is possible to get. We must hurry, hurry, hurry, just to teach engineering students all they need to know." They are right in this. If anyone suggests that an engineering school which aims to teach students all they need to know, should also take the time to teach students to think for themselves, the answer is clear. It cannot. It is not possible to teach an engineering undergraduate all he needs to know in his profession and at the same time train him fully how to use that knowledge. If we are going to do the one, we cannot do the other.

But that does not mean that engineering education is condemned to the level of merely imparting engineering information and techniques. The dilemma arises from a non-structural conception of wisdom and power. In teaching a new science or technology, to borrow a simile from Dean Winternitz of Yale, there is a small circle of knowledge, in which the core and periphery are one, and on this account it is easy to teach all there is to know. As the science or technology matures the area of knowledge expands. But the amount of time for instruction remains the same and it becomes impossible to cover the entire circle of knowledge without being utterly superficial. Hence the teaching of each course tends to take the central area for granted. It tends to assume that fundamentals were covered once for all in some elementary course, and tends to concentrate itself upon a band of advanced knowledge around the circumference of the subject. As time goes on and the science and technique expand, the band at the periphery which there is time to teach inevitably grows narrower and narrower and its contact with the core of basic principle more and more remote.

As a consequence the teaching of mature techniques tends toward technical tenuity. The knowledge may be taught with clarity and order. Its surface relationships may be clearly shown. But while such teaching may provide an understanding as perfect as a map, the understanding tends to be as superficial as a map. It develops no thought structure in the student reaching into the central core. The student learning equation after equation, formula after formula, has little time to think, "How did that formula get that way ? How should it be adapted to this situation by going back to deeper levels for reconstruction ?"

Yet teachers who seek to teach the ever-increasing mass of technical knowledge in a more solid way find themselves in the position of the ancient Chinese when they were trying to carry bigger and bigger loads over sand with solid wheels. They had to have bigger and bigger wheels until the wheels got so big they couldn't draw them. Then somebody invented the hub and spoke, and that not only cut the weight way down but strengthened the wheel.

The spoked wheel of knowledge is likewise better in every way and the connection of the periphery with the core is much more clearly defined. Thus the very mass of technical knowledge should urge us to teach well, not badly. For while it is true that it is hopeless to try to teach a student all he ought to know, it is equally true that it is undesirable to do so. What is important to teach a student is how to discover and use what he needs to know when he is faced in later life with concrete problems, and how to learn from his experience. He should be taught those spokes that he needs to get from the hub of basic science to the rim of concrete experience; and having them and the art of using them he can meet the problems of life as they come and learn the lessons of life as they go. Taught in this way, he will start out equipped to *become* a professional man, instead of leaving college well encased in frames of reference and formulas which will tend to shelter him from further learning. He will not be completely informed but he will have acquired the elements of the art of learning from experience that will enable him gradually to move ahead of the routine of his field and reach professional stature.

In this age, such instruction is peculiarly important. For due to engineering invention, students when they graduate enter an institutional world where it is difficult to get free from regimentation. In large companies the young graduate must usually fit into institutional routines, and this means in most instances that only routine problems will reach him for years. Hence unless young engineers have been equipped with a sturdy capacity for basic originality before they get into industrial institutions, it is difficult indeed for them to survive the inevitable institutional treadmills and to rise above routine competency to professional skill.

The pressure for time to teach the mass of technical proficiencies has not only tended to overcrowd with surface instruction the hours of technical study, but it has also tended to squeeze out of the curriculum all else, including those things that equip a man to stand on his own feet among men and in his community. Yet a merely technical man, no matter how proficient, is a fragile and vulnerable person in the world to-day.

Some of you, I know, have seen Barrie's play, "The Admirable Crichton." In it a British lord, who handled himself with great distinction within the narrow boundaries of his own social group, was shipwrecked on a desert island. There he had to come in contact with realities other than those to which his social status had hitherto exposed him. In a little while he became a slave of his butler, who was better equipped to meet the cruder necessities of island life.

Technical graduates *if narrowly taught* run the risks of the lord in that play. When such technicians leave the sheltering environment of their laboratories or drafting rooms, they are in danger of finding that their personalities have been over-narrowed by an exclusively technical education. When they progress to a level in their careers where leadership calls for power to deal with men, or when they encounter the social problems so largely caused by the progress of their own technology, they are likely to find that they lack competency.

Such competency is not something that can be easily acquired after professional education is over. When my son hurt his knee and was in bed for a period of time, I was astonished at how much attention the doctors gave to insuring that the injured leg was exercised, "because," they said, "if the leg isn't exercised it will atrophy and will not grow as it should, and once it gets behind the rest of his body in growth, there will be no way we can restore it to proper length." In the same way during the period of professional growth exclusive emphasis on technology may cause other parts of the personality to atrophy possibly beyond repair.

What is essential in this respect is the development of the student as a cultivated and competent engineer and citizen —as one who adds to strictly technical powers a capacity to take his place professionally as a leader of men and as a wholesome member of his community. Just to give him courses in English literature, English composition, economics or industrial relations, even if we can provide time in the curriculum without overcrowding it, does not necessarily do this. Usually the student patiently submits to such courses and then sloughs them off. A few students may carry them through life as appendages. In their vertebral development, however, although the vestiges of these courses may remain as living tissue, they remain tumors unassimilated in the organism. Or to use President Doherty's concept of education as a tree with many stems, they are like mistletoe, sometimes attractive parasites, but neither a part of the trunk nor one of the limbs of the student's professional development.

This is most likely to occur when the social sciences and the humanities are not taught as an integral part of the student's professional education. Hence a final fundamental of professional education is that its broadening elements should be integral, not external—that students should be developed in human and social power, not by "side courses," but by ways of study that interpenetrate their technical professional development. And, as other speakers on this program will demonstrate, this can be done and done with true benefit to sound technical education.

The task of professional education, then, is fundamentally to develop power to learn and to solve, not to provide fullness of information and of technical tools. It is a problem, not of informing, but of providing development through disciplined activity that is raised above regimentation. It involves the selection of significant subject matter through which to give this disciplined exercise—and in this respect the use of subject matter relating to man and to society is important. But far more important than subject matter is the character of the teacher and of his teaching.

Good teaching can combine discipline with fundamental originality. It can face the student with a genuine perplexity that causes him to escape from stereotypes and to break through routine to fundamental thought. It can cause methods as well as data to cease to be inert; to become flesh and dwell within the student; to be material which he uses and remolds under a vigorous, trained and flexible style that is truly his own. It can make his professional style so fundamental that it strengthens his power in every field, not merely in that of his university study. It can give him confidence to meet the perplexities of this world unabashed as a citizen as well as an engineer. In a word, professional education, by its teachers and by its teaching, should develop capacity for fundamental originality in learning from experience and in meeting the problems that life brings. How fully this can be done by engineering education has been richly shown by great engineering teachers and great engineers.

OUR CITIES—THEIR ROLE IN THE NATIONAL ECONOMY

GEORGE S. MOONEY
Joint Director, Montreal Industries and Economic Bureau, Montreal, Que.

Paper presented before the Montreal Branch of The Engineering Institute of Canada on January 16th, 1941

Of all our national resources—natural and manmade—the most important, and the one in terms of which all the others have to be judged, is human life. The safety, welfare and happiness of the men, women, and children who compose the Canadian people constitute the only justification of government. They are the end for which all our resources—land, water, minerals, forests, animals, technology, institutions and laws—are merely instruments.

The manner of life of our people, the problems they face, and the hopes and desires they cherish for improvement in their existence and the advance of their civilization should be the supreme concern of government.

Even since Confederation, three quarters of a century ago,—one man's lifetime—the mode of life, the problems and the aims of our people have undergone many significant changes. Of these, probably none is more important than the transition from a crude and simple handicraft economy to an advanced type of modern industrialism, and from a rural to a predominantly urban mode of living.

Urban Canada in 1867

When the Dominion of Canada embarked upon its career as a confederation of provinces within the British Commonwealth, the cities of Vancouver, Calgary, Edmonton, Regina, Saskatoon, Verdun, Sydney, Fort William, Moose Jaw, and a host of others were either idle prairie plains or undeveloped farm lands. The City of Winnipeg was an outpost of the Hudson's Bay Company (Fort Garry), with a population of 241, and Moncton was a hamlet of some 600 souls. There were only three cities with a population of over 50,000; Montreal having 130,833, Quebec 59,699, and Toronto 59,000. Uniform currency had not yet been established and the trans-continental railroad was still but an idle dream.

Municipal services were few and comparatively inexpensive. It was the day of wooden sidewalks and dirt roads, of oil-lit street lamps and volunteer fire brigades. Sewage and water systems were crude or undeveloped, and garbage was burnt in the back yards. Secondary schools were still in the future, while primary schools were concerned largely with the simple teaching of the three R's. Civic libraries, municipal hospitals and supervised playgrounds were non-existent.

The limited services which municipalities rendered were almost wholly related to the servicing of land and buildings. As such, they were of tangible benefit to the land owner. Custom had it that every good citizen owned his own home, no matter how humble it might be.

Further, the ownership of property was the principal evidence of wealth. Investment in business enterprises, either direct or through the medium of the stock exchange, was of a limited nature and confined to but a fraction of the population. Moreover, urban land values were experiencing a boom period. Land and property was a "safe" investment, because taxes and building costs were low enough to permit a fair return, with the added prospect that the real estate buyer could expect, in those expanding days, to find his property materially increasing in value.

The 74 years that have elapsed since Confederation have witnessed a transformation in the urban scene.

During this period, thousands of new towns and cities have emerged. In 1867, Canada was an overwhelmingly rural domain. By 1891, out of every thousand persons in the community, 682 were resident in rural communities; 318 in urban centres. By 1921, the population was approximately evenly divided between rural and urban, there being 505 in rural and 495 in urban communities out of every 1000. But by 1931, urban Canada had leaped forward, 463 being rural and 537 being urban out of each 1000 population. In the decade 1921-31, urban communities had absorbed nearly 77 per cent of the total increase in population, with the result that the urban population by 1931, had exceeded the rural by 667,330. In the decade since 1931, the trek to the cities has continued without interruption and probably at an accelerated pace. The industrial boom which is accompanying the war period will undoubtedly bring about great and probably permanent shifts in population, a good deal of which will be from the rural areas to urban centres.

This shift of the population to urban areas carries with it a fundamental change in the occupational structure of the nation, as is evidenced by the fact that in 1891, 51.2 per cent of Canadian workers were gainfully employed in agriculture, while in 1931, the percentage had fallen to 34. This suggests that in less than half a century, to be exact 40 years, our country has profoundly altered its mode of life during which it has been transformed from a rural frontier settlement into a full-fledged urban industrial society.

This development is not peculiar to Canada, for it characterizes the development of the United States and is also symptomatic of other countries of the world, especially those of western Europe that have been touched by the machine technology, and consequently have undergone similar changes. But while the old world grew by degrees over a period of many centuries from a town economy into its present urban cast, Canada started as a wilderness on the outskirts of civilization and took the leap from primitive primary pursuits associated with its land, forests and streams, and in the matter of a few decades, has blossomed into a mature urban industrial economy.

The figures on the extent and rapidity of urbanization in Canada, dramatic as they are, fail to convey the full significance of what the rise of cities has done to our civilization. The crowding of an increasing number and proportion of our people into relatively restricted areas has meant for them a revolution both in the way of living and in the ways of making a living, and has in turn been reflected in the changed character of our national life. Part of this change is conditioned by the fact that ever larger aggregates of population and ever widening areas are being brought within the orbit of a central dominant city. The recent experience of the five leading cities of the Dominion will exemplify this trend. Between 1921 and 1931, Canada's population grew 18 per cent whereas that of Greater Vancouver increased by 50 per cent, Greater Montreal by 39 per cent, the Hamilton area by 36 per cent, Greater Toronto by 31 per cent and Greater Winnipeg by 28 per cent. By 1931, these five urban areas embraced over 23 per cent of the Dominion total. More than ten per cent of the total population of the Dominion is now concentrated in the Montreal metropolitan area, an area of approximately 50 square miles.

Causes of Urban Development

steam

The growth of cities since about the beginning of the 19th century is primarily attributable to the scientific discoveries and mechanical inventions which facilitated the development of power-driven machinery. Of these revolutionizing innovations none was probably more fundamental than the application of steam as a source of power for industry and transportation to supplement and replace the previously available sources of power, especially water. Prior to the steam era, few cities exceeded 100,000 and it is doubtful whether any city, even such renowned centres as Rome, Peking or Nanking, ever exceeded one million in population. Not until the great economic and social changes that we identify as the Industrial Revolution had been set in motion did the modern great city become possible. The emergence of the great city, however, itself in turn became a major force in revolutionizing man's existence.

Steam not only made possible a vast increase in man's potential means of subsistence and, consequently, in his numbers, but, indirectly, by releasing a rapidly increasing proportion of the population from the actual tilling of the soil, it became an overwhelming force in the cityward migration and played a major role in determining the internal structure of the city and of the economic organization of which it became the nucleus. In the pre-steam era, because of the crude, inefficient, and expensive means of transportation which man had at his disposal, the provisioning of large cities was difficult, as was the supplying of raw materials and the distribution of finished products over a wide area. Consequently most manufacturing was local.

Apart from the military necessity of concentrating the largest number of inhabitants and structures within the smallest possible walled area, the city before the age of steam had no need for marked concentration into a "downtown" or central—business district, which is a distinguishing mark of the modern city. Steam has operated as a concentrative force through its direct use as power. Since steam is most cheaply produced in large quantities and must be used close to where it is produced, from which point the power it generates can be extended only over limited distances by means of shafting, belts and pulleys, it fostered the concentration of manufacturing processes and large units of production. But since it could not be used economically for local transportation, its use as power in manufacturing tended also to concentrate managerial and wholesale distributing activities and, above all, population near the factory. Moreover, the great economies in long-distance transportation, which steam made possible, further accentuated the concentration of industry and population into large urban centres, which because of their favourable situation from the standpoint of production and markets, continued to attract ever more industries, commerce, and population. The large, densely built up and rapidly growing city with a single centre where transportation lines and hence traffic converge, derives its principal structural features in large measure from the centripetal influence of steam.

ELECTRIC POWER AND THE GASOLINE ENGINE

All the while that steam was moulding the pattern of urbanization, two other forces were converging upon the scene. Whereas steam has had a concentrative effect, electricity and the internal combustion engine, which became available after the pattern of most Canadian cities had already become fixed, have tended to have precisely the opposite effect. The dispersive influence of electricity is due to the fact that it can be transmitted economically even now over distances up to about 300 miles, and that it can be used as power with almost equal efficiency in large or small units. It also has decided advantages over steam for rapid local transportation. It has at least the potentiality of exercising a centrifugal influence upon cities as contrasted with the centripetal force exerted by steam. Up to the present, however, electricity through its use as power for the fast electric elevator and for urban and suburban transit, has mainly accentuated concentration as in the skyscraper and in the overdeveloped, congested, central business district.

In addition to its use as power, electricity, as distinguished from steam, has a quality which has to be reckoned with as a reconstructive element in urban life, the urban structure and our entire social order, namely its use in communication. This use in the form of the telegraph, the telephone, and the radio has only recently been felt and appreciated. It gives promise of having at least as great an influence in reshaping our cities and our civilization during the twentieth century as steam did during the nineteenth.

If to the influences of electricity we add the flexibility, the speed and the individualization of transportation effected by the internal combustion engine as embodied in the automobile and the airplane, we may say that these new technological devices are likely to alter the structure of the urban community and national life profoundly, whether or not we consciously use them as instruments to improve our mode of living.

One further factor which should not be lost sight of in understanding how the 19th and 20th century city civilization came to be, is the contribution of modern methods of sanitation. Life for large masses of people removed from and yet closely dependent upon a constant supply of water, food, fuel, and raw materials is in itself conditioned by a high degree of technological development and the perfection of administrative organization. But the task of conquering the hazards of life among a vast congested population, such as inhabits a great city, in the face of disease, can be appreciated better if we consider that before the advent of modern sanitation the deaths in cities of the western world regularly exceeded the births by a considerable margin. If, in addition, we recall that the population of the western countries was frequently afflicted by epidemics that swept away a large portion of their inhabitants and that this is still in a measure true of backward countries, we can realize the significance of modern sanitation for urban existence. The ample provision of pure water, the perfection of centralized sewerage and waste disposal systems, the insurance of a safe food supply, including dairy products, and the prevention and control of contagious diseases are the chief measures that for more than a century have made it possible for western cities to maintain population by lowering the death rate.

Having considered the principal preconditions for urbanization, we may now turn to examine some of the factors that are shaping this process to-day. In doing so, we shall discern certain trends that may considerably influence the city of to-morrow.

As we have previously indicated, the outstanding factor in the urbanization of Canada is the speed with which it has progressed and is still progressing. Within a single generation Canada has been transformed from a primarily rural to a primarily urban domain.

In 1867, Canadians were best characterized as a rural people; and their pursuits were associated with the primary industries. In 1941, Canadians are best characterized as urban dwellers with little prospect of any major shift countrywards.

Cities as Centres of Industry

But the city is not merely the characteristic place of residence, it is also the workshop of the nation. It is in the cities where the major portion of our industrial plants are located, and these, in turn are for the most part highly concentrated in relatively few centres.

In recent years, certain shifts in industrial location have occurred. This may indicate a trend likely to have increasing significance. The long run effect may have the result of reshaping the pattern of our industrial urban civilization.

So far, this movement has been largely confined to certain small scale industries which have tended to locate in peripheral areas contiguous to large cities. Large scale industry with large capital investments in huge and complex plants, and requiring concentrated pools of labour, has shown little or no tendency to follow. This so-called "decentralization of industry" has been a spreading out into the suburban and adjoining territories of large cities, rather than a movement from the city to the country. It is a phenomenon which characterizes every large city on the continent; and although it has given grounds for local concern, its long time economic effect is likely to be more beneficial than harmful. It should have the effect of creating a better economic balance between the large city and its surrounding countryside and in other ways establish a more functional relationship between the urban and rural population.

Industries locating or re-locating in the suburban and satellite zones of great cities have done so to gain competitive advantages derivable from such factors as lessened transport time and cost, freedom from the restraints of "big city" control, cheaper labour costs and decreased labour turn-over, and lower land values and taxes. These advantages to the industry are frequently ephemeral and sometimes are offset by the disadvantages accruing to the community itself. Moreover, the gains of the peripheral area are sometimes a loss to the central city, especially if they are politically separated, because the central city may continue to render certain public services incident to the industry without receiving proportionate tax revenue.

While there are sound economic reasons for the location of certain types of industries in the peripheral areas of metropolitan centres, or in one industrial area as against another, too frequently the decision to locate is based upon other than economic grounds. In the past, publicity campaigns, special grants and subsidies, including sometimes free sites and free plants, credits, and exemption from or special consideration in respect to taxation, have been employed to attract industries and to lead them to ignore more advantageous locations elsewhere. Such inducements as these have been offered by cities and, especially, small towns without even a guarantee from industry to maintain minimum labour standards, in the attempt to gain advantages by artificial means which they do not possess by nature. Unless communities can be persuaded to pursue sounder principles of industrial planning, large sums will be wasted on the private and community plant in the attempt to expand or strengthen the physical base of the community beyond reasonable and economic justification. This will, in the long run, saddle these communities with debt and an unbalanced and unstable industrial structure. Community industrial unbalancing operates in a vicious cycle. The weak industries of the community constantly become weaker and this, in turn, discourages new industry which might otherwise locate there.

In recent years, the use by communities of such incentives to industries as credits, tax exemption and free land has declined, although the depression for a time revived the practice. On the whole, it does not appear that such attempts to attract industries have been very successful. Of late, more attention has been given to the problem of industrial articulation. There seems to be less of a tendency on the part of both communities and industries to accept surface indications as satisfactory reasons for locations. Only scientifically sound, long-range planning can lead toward a more economical and stable national pattern of industry and prevent and mitigate the evils of substandard, mushroom community structures based upon short-sighted and potentially socially disastrous perspectives.

Cities as Commercial and Service Centres

The rapid growth of cities, particularly the larger metropolitan areas, is traceable in part to the increasing concentration within them of commercial and service activities. As industrial production has grown in volume and diversification so have the related commercial and service functions associated with its development. There are probably just as many so-called white-collar jobs in the large city, as there are jobs in industry. In the very large metropolitan cities such as New York and Chicago, clerical and other white-collar employment exceeds that of industrial labour. This is a further shift in occupational emphasis and is bound to have an influence on the pattern of urban growth, design and development. With industry and business entering more and more into mass production and mass distribution techniques, there will be a relatively larger need for persons engaged in managerial, service and clerical functions. The range of occupations, of incomes, and consequently of standards of living tends to increase with the size of the city, so that the city becomes both a product and a cause of the division of labour.

Types of Cities

Similarly, individual cities themselves acquire a specialized role in the national economy. They become differentiated partly by such characteristics as access to suitable resources, transportation facilities and labour supply. In addition to these natural and technological factors, cities in the course of time become distinguishable from one another also because of the initiative and foresight of aggressive business leaders and of the advantages derived from an auspicious start, which are cumulatively enhanced by tradition and reputation so that certain cities acquire a prestige and renown for the production of certain goods. Such factors will in the course of time shape the industrial contour of the community. Furthermore, certain industries can exist advantageously only when others upon which they depend are already established. Some cities, therefore, developed a highly specialized economic base, while others, offering more general locational advantages, attract a variety of industries and thus become more balanced economic entities.

The functional differentiation of cities, moreover, proceeds not merely on the basis of industrial specialization but is conditioned also by the commercial, governmental and social roles which cities assume. Thus we have developed some cities in Canada whose economic base rests primarily upon the extraction of natural resources from the immediate or nearby sites. Mining cities, oil cities, fishing cities and lumber cities are familiar examples of specialized urban communities. Others derive their specialized industrial character from the presence of less localized advantages. The selection of one Canadian city as a site for a steel producing centre proved eminently satisfactory despite the absence of either coal or iron ore in the immediate territory, because of the economical accessibility of the raw materials for steel manufacture derived from its position intermediate between coal fields and ore fields, combined with proximity to a good market and a source of labour and power. Again, one western city has arisen primarily on an economic basis as a transportation focus and transshipment centre, just as others have centred around a port. Still other cities are predominently commercial, others are educational centres, governmental centres or resorts. Moreover, cities that were once expanding and prosperous communities have changed their primary function in the course of time; or declined either because of the exhaustion of nearby resources, the development elsewhere of a new industry which made a prior one obsolete, the perfection of transportation facilities, changes in the rate structure, or the rise of a rival city with special advantages. Many communities have become chronically substandard as a consequence of such changes which have deprived them of their economic base.

What has been said so far by no means exhausts the factors which have contributed towards the significant role which our cities play in the national economy. But neither the time nor the occasion permits a complete picture of the forces which have been at work in the building up of our modern city civilization. The factors mentioned have been chosen merely as a background from which to approach the other aspect of this paper, which has to do with a consideration of some of the problems which the too-rapid growth of our cities have created.

Let us therefore sketch the typical features of the environment in which the modern city-dweller lives, and from which he has acquired his distinctive traits of personality and behaviour. Much as the rural and the urban ways of life may tend to approximate each other, the rural landscape and the urban landscape, from whatever angle they may be viewed, are visibly distinct. The view one gets of the cities depends of course upon the position of the observer. No city of any size can be envisaged as a whole, except from some distance of elevation, and while the topography, the size, and type of city will make a marked difference in the impression it creates, the average urban panorama has a number of general points of uniformity.

The City Viewed from the Air

If the observer views it from an aeroplane, the typical Canadian city will appear as a sprawling mass of structures of varying size, shape and construction, criss-crossed by a checkerboard street pattern which here and there assumes irregularities. The cells, or blocks, into which the city is divided seem to lack any organic grouping into units. The general impression to be derived from the arrangement is that of unimaginative, stereotyped, mechanical monotony. Only rarely will one find even a partially organic pattern throughout. Upon closer inspection it will appear that portions of the area are devoid of structures, and consist of green open spaces, or parks. Other vacant space will turn out to be public squares, railroad yards, or merely unutilized land areas of varying shapes and sizes. The observer will note that the rectangles or other shapes that make up the horizontal pattern of the city are generally built up around the edges and are a hollow in the middle, indicating that the structures line up along the streets.

More intensive examination of the city of medium or large size will show that the city is more densely built up at the core where, even if it is only a few square miles in area, one or more tall structures will loom up grotesquely, marking the location of the central business district. If the city is large the number of these sky-scrapers will be correspondingly multiplied, and they will re-appear irregularly at places somewhat distant from the city centre, indicating the location of sub-centres. The central business district will flatten out abruptly toward the edges, where the city's light manufacturing and warehouse areas may be recognized, interspersed by ramshackle structures constituting the blighted areas and slums. Adjacent to this belt are to be found the tenants' and working-men's homes, and beyond are the more densely-built apartment-house sections, tapering off rather unsymmetrically, and stretching finger-like along the main traffic streets into areas of single homes, with small gardens and open spaces. Along these radials that follow the main transportation lines, and, like a web between them, will cluster other less intensively built-up settlements. The city will thus approximate a circular, or semi-circular pattern, at the edges of which tentacles will protrude, tending to stretch the circle into a star-shaped outline. The symmetry of the total configuration is sometimes warped by water-fronts, rivers, elevations and depressions in the topography, and by the proximity of other cities.

Beyond the built-up parts of the city, there are to be found great open spaces, on which the occasional structures reveal the location of truck farms, nurseries and gardens, country clubs, and abandoned or unsuccessful subdivisions, marked by pavements and sidewalks and other improvements, but showing no, or only a few, scattered buildings. At the most favourable sites, partly obscured by woods, nestle imposing mansions, with large fenced-in grounds, resembling the feudal estates of the European countryside. At intervals along the railroad lines and through-highways, often as uninterrupted extensions of the city proper, more densely-settled areas are distributed. These are the suburbs and satellite towns. Some of these immature cities will be clearly recognizable as industrial sites, and others, but for the abundance of yards and trees and absence of building concentration, might be mistaken for residential sections of the city itself.

A Lateral View of the City

Another perspective of the outlines of the Canadian city, its profile, may be obtained by viewing it from a distance. This vertical, cross-sectional view makes the intense development of the centre seem even more grotesque, and reveals how really precipitous is the drop from the towering peaks of the sky-scrapers, which mark the business centre, to the encircling belt of much lower, often obsolescent and decaying building. The taller the sky-scrapers at the centre, the more abrupt, it seems, is the decline to the building height of the surrounding area. Apparently in a small city, a single sky-scraper can, so to speak, suck up all or most of the demand for office space, and create a vacuum of blight all around. The more imposing the sky-scrapers at the centre, the wider is the area over which they exert a blighting and depressing influence. This is reflected in actual physical deterioration, in accelerated obsolescence, vacant building sites, and in decaying commercial areas and residential slums.

The Inner View of the City

Quite another set of pictures of the urban scene is revealed to the observer, who views it from the inside, whether he is a traveller, getting a glimpse of it as he enters it by boat, railroad or automobile, or views its structures from the streets. Most American and Canadian cities have a façade which often turns out to be a false front. They are adorned at the centre as if for public display. But behind this front are hidden the shambles, the slums, and the scenes of decay, filth and disorder. To the visitor, especially if he is accustomed to wide expanses of fields, meadows and woods, the stone, brick, concrete, steel and glass out of which the physical city is built, must appear as very unnatural. In the heart of the city, huge boxlike buildings rise abruptly on both sides of the street, forming canyons that shut out light and air. Buildings of assorted design, size and structure are huddled together, wall on wall, without following any perceivable pattern of arrangement, except that outlined by the narrow strips of land that are the streets. The smoke, the grime and the din, the maddening tempo of movement of men, and vehicles, the surge of crowds, especially when the city centre fills and empties in the course of the daily pendular movement of its people—all these appear to the uninitiated as a fantastic, meaningless, and buzzing confusion. Aside from the scenes that meet the eye on the surface, there is the city underground, its sewers, water mains, light, gas and telephone lines; its basements, tunnels and subways.

Land Use Pattern

It is in the centre of the city that most of the white-collar inhabitants work. Here are the government administrative buildings, the offices of commercial and industrial firms, and of the professional and technical services; the department stores and specialty shops; the transient hotels and restaurants and theatres. In fact, here centre all those activities that transcend the neighbourhood and function for the city and its region as a whole. Here, land values are high, and real estate is sold by the square foot at fantastic prices.

Beyond the city centre are wholesale houses and warehouses, railroad yards, freight and passenger terminals, junk yards, and light manufacturing establishments, interspersed with dilapidated residences, roominghouses and tenements. This area, which contains the slums, is the forgotten section of most of our cities. Inquiry will disclose that much of the land of the area is in the hands of absentee owners, who hold it for speculative reasons, hoping that as the city grows the business district will expand, and that their land will be at a premium. Consequently, land values are inflated, but rents, in comparison, are low. Buildings are crowded and in disrepair, and sanitary facilities are inadequate or utterly lacking. The people who must live in them are deprived of the minimum requisites of healthful and decent housing.

At its periphery this area merges with the zone of workingmen's homes which, though they command relatively low rent, are in one degree of better repair than the slums. This area in turn shades into the middle-class apartment-house area, with its own local business centre. The residents of this section of the city have a higher level of income, pay higher rent, and command better facilities than those nearer the centre. The last zone of the city proper is the single family residence area, where land normally is considerably cheaper, and where consequently more spacious individual family dwellings, with garages, yards, small gardens and larger open spaces can be bought or rented. Beyond this area is the suburban zone with scattered estates, golf courses, residential communities and industrial areas, interspersed with truck gardens, farm lands, and embryonic residential subdivisions.

As the city grows, it empties its population at the centre, and these successive zones of land utilization are progressively pushed outward. In this way, one zone eats its way into the next, and in the process of conversion from one type of land use to another, considerable junking takes place. Thus the city has an internal structure and a typical cycle of growth which are significantly conditioned by the existing rights of ownership and speculation in land, and by the competitive economic regime of our society.

This, then, is the broad nature of the physical pattern of the typical Canadian city. The statement was made at the beginning of this paper that the most important factor in our national life is not our national resources, nor our man-made physical environment. The important thing, and the one in terms of which all others have to be judged, is human life. They are the end for which all these resources are merely instruments. Let us again repeat that the manner of life of our people, the problems they face, and the hopes and desires they cherish for the improvement in their existence, and the advance of their civilization, should be our single and supreme concern. Let us for a moment, therefore, and in conclusion take a look at the kind of persons, their types and characteristics, which our city civilization seems to have produced.

The mobility of the city dweller, the range, the superficiality, the anonymity, and the segmental character of his contact, account in part for his freedom from tradition, and for the rationality of his outlook. In the competition of the city, the status of a man is determined more by what he can do, or what he owns, than by his blood, or ancesters. The city man typically moves in and is a transitory part of a multitude of social groups, and is not permanently attached to anyone of them. His loyalties are thus more fickle, and he is inclined to greater tolerance, which he sorely needs in order to live among fellow-citizens who are so different from himself in heritage, interest, belief and character. Moreover, the city man is typically out for himself; he is a member of a large, rather than small, group, and associated with others for the pursuit of a common interest rather than because of sentimental ties. His relations with his fellow men, therefore, tend to be formal, rather than intimate, and he is inclined to use other men as instruments to gain his own end, rather than to regard them as ends in themselves. This may aid in accounting for what may appear to the country man as an abnormal and mercenary type of human relationship in the city.

Cities have traditionally been regarded as the home of inventions, and revolutions. They secularize the sacred beliefs, practices and institutions. They democratize knowledge, fashions and tastes, and consequently generate wants and stimulate unrest. The urban mode of life tends to create solitary souls, to uproot the individual from his customs, to confront him with a social void, and to weaken traditional restraints on personal conduct. This may aid in understanding both the achievement and the disorder characteristic of cities. The grandeur of the city is capable of stirring men's souls, and rousing their imagination. It is not merely the magnificent size of the structures, the hum of the traffic, the display of cultural wealth, side by side with the most abject poverty and degradation, but it is also the imposing demonstration of human ingenuity, the sense of personal emancipation, amidst a many-sided cultural life that stirs the city man to thought and action and gives urban existence a zest. In modern civilization, it is the city that becomes the scene where the ultimate struggle between contending forces is waged and decided.

Personal existence and social solidarity in the urban community appear to hang by a slender thread. The tenuous relations between men, based for the most part upon a pecuniary bond, make urban existence seem very fragile and capable of being disturbed by a multitude of forces over which the individual has little or no control. This may lead some to evince the most fruitful ingenuity and heroic courage, while it overpowers others with a paralyzing sense of individual helplessness and despair. The oscillation of the city man between the most extreme individual and the most concerted type of collective action with his fellow men arises out of the conflicting forces that impinge upon him. But it is precisely because of the tenuous basis of his existence that the city man is inclined to have a sense of his own interdependence with others, to have a cosmopolitan outlook, and to unite with others near and far in the pursuit of similar if not common ends.

The city dweller is not happy in his habitat. Many of them, having failed to find a satisfactory life in the city, often generate a nostalgic longing for more natural ways of living and seek a refuge in the country. Because the city has become indispensable to civilized existence, but at the same time subjects man to so many frustrations of his deepest longings, the notion of an ideal mode of life lying somewhere between these two extremes, has been a force ever since the cities have been in existence. In recent times this ideal has expressed itself in varying moods. They embody an effort to find a balance between agriculture and industry, between the open, natural landscape and the congestion of the city. Model suburbs, garden cities, greenbelts, and suburban homesteads represent different variations of this movement, and the promoters of large-scale decentralization of industry have also found argument for their programme in the attempt to combine the advantages of urban and rural life in the same community.

If conscious social effort may be assumed to play a significant role in shaping the conditions under which man lives, then the present crisis is really an opportunity calling for a prompt examination of the alternative modes of life that we might follow, or at least move in the direction of, in the post-war years. If rural life, or living in communities of small size is either wholly or in certain respects more desirable than living in small or large cities, the evidence to that effect is yet still a matter of opinion. It may well be that the future of our civilization will in large measure depend, not upon man's ability to escape from the city, but upon his ability to master and use the forces that move and control it. It is doubtful whether, without the city, we can hope to enjoy the plane of living that contemporary civilization so far has made possible. The central problem of national life in regard to cities is a problem of creating those conditions that are required to make cities livable for human beings in a machine age.

NEW U.S. MEDIUM TANK M3

By Lieut.-Col. J. K. Christmas, Ordnance Department, U.S.

Abstracted from *Army Ordnance* (Washington) July-August, 1941

Prior to the outbreak of the war in Europe, the Ordnance Department had developed a medium tank (M2) of approximately eighteen tons' weight and had delivered a small number of these to the Infantry at Fort Benning, Ga., which was then charged with the operation of such tanks. An improved type of medium tank M2, known as the M2A1 was then developed. This type had a little heavier armor and weighed approximately twenty tons. A number of tanks of this type were manufactured by Rock Island Arsenal; some of these are now in the hands of troops, others are still under manufacture.

Early in 1939, a project was originated by the Ordnance Department to mount in the medium tank M2 a 75-mm. howitzer in addition to the turret-mounted high-velocity 37-mm. gun and caliber .30 machine guns used in the medium tanks of the M2 series. The object of mounting the 75-mm. howitzer was to add to the tank a weapon capable of firing high-explosive shell, shrapnel, and smoke shell, in order that the medium tank might furnish direct light artillery support for tank and other mechanized units and in order that the medium tanks might take full advantage of the many outstanding qualities of light artillery fire, not only against personnel but against many classes of unarmored material targets.

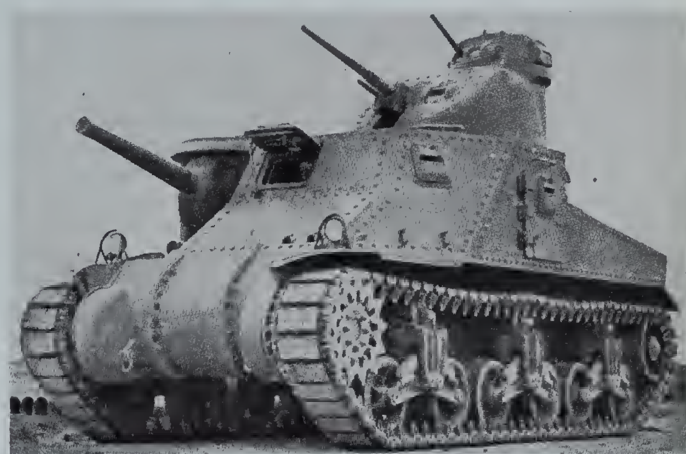
This project was completed in the winter of 1939 at Aberdeen Proving Ground, Md. The tests, both at the proving ground and by the Infantry Board at Fort Benning, were so successful that recommendations were submitted by the proving ground in the early part of 1940 that all medium tanks to be manufactured or completed thereafter should be fitted with a 75-mm. weapon, mounted for fire generally to the front, in addition to the 37-mm. high-velocity armor-piercing gun mounted in the turret for all-around fire. This project was not immediately acted upon. However, when the Congress in the spring and summer of 1940 made available funds for the manufacture of a large additional quantity of medium tanks, and when the lessons of the war in Europe were more and more being brought to our attention, the importance of this project soon was realized together with the great importance of tanks generally. Valuable information and advice were obtained particularly from Great Britain, birthplace of the tank in 1915. It was decided to apply the principle of mounting a cannon of 75-mm. caliber to any new medium tanks to be manufactured.

In the summer of 1940, the War Department reorganized our mechanized cavalry and our infantry tank units into an Armored Force, with the result that the tactics and equipment requirements of our mechanized units were placed in somewhat different hands and some new desired tactical characteristics were added to the armored fighting vehicles to be used by the Armored Force. The fighting tank had somewhat belatedly come of age and at last had been recognized in the military family!

The design of the medium tank M3 was started in September, 1940, and completed the first day of March, 1941. Experienced tank drafting personnel were lent to Aberdeen Proving Ground from Rock Island Arsenal for this redesign.

In the design and development of the medium tank M3 at Aberdeen, the following procedure was, in general, employed. General layouts first were made of the major components and assemblies involved. These layouts then were roughly reduced to full-scale wooden models, which usually led to some revision of the design in the interest of better functioning, strength, or convenience in use. As a result of study of the preliminary wooden mock-ups, the layouts were revised and a more careful and more detailed full-scale wooden mock-up or model again made, this time for greater attention to details.

From the revised layouts, detailed working drawings were made, and from these drawings full-scale actual metal components were manufactured, just as required in the production tank, and were fully tested to determine that they were satisfactory in every way. When this test had been made, the detailed working drawings were given a final check and issued to the various manufacturers. In order to expedite the work, the manufacturers, (that is, the prime contractors who were to manufacture the medium tank)



The medium tank M3 mounts a 75mm cannon, a 37mm gun, and two machine guns

were furnished preliminary prints so that they might plan their shops, order the necessary machine tools and materials, and in general set up their manufacturing facilities.

During the process of development, the various prime tank manufacturers, as well as the manufacturers of the principal components commercial units and accessories, had engineers almost constantly at the proving ground. This practice had the advantage of acquainting the manufacturers with what they were required to make and of acquainting the Ordnance Department with the very latest in manufacturing processes, in engineering development, and in commercial components available for incorporation in the new tank. The advice of experts was thus obtained on the hundreds of special engineering problems involved in the manufacture of this tank.

It should be understood that the design of an armored fighting vehicle, such as the medium tank M3, can in no case be called the work of one man, or even of a few men. Like the airplane or the naval vessel, the fighting tank incorporates within itself a very large proportion of the best technical advancements available in science and industry. Our automotive, steel, rubber, and electrical industries all have contributed to its development. Valuable assistance also was obtained from those activities of the Ordnance Department concerned with fire-control instruments and cannon. Close co-operation was maintained with the Signal Corps with respect to radio equipment and with the Armored Force which is to use the tank for the serious business of defending America. Co-operation with the latter was carried on particularly through a resident representative of the Armored Force at Aberdeen.

Some idea of the work involved in developing and designing this new medium tank may be gathered from the fact that a tank in its entirety contains approximately 25,000 separate parts, covered by nearly 6,000 drawings. Some of these drawings are of commercial origin as in the case of the instruments, engine, generator, and batteries. Owing to the number of contractors, subcontractors, and agencies of the Ordnance Department involved in the manufacture of this tank, it was necessary to distribute from Aberdeen Proving Ground between October, 1940, and March, 1941, some 75,000 prints, as well as thousands of letters and specifications concerning design and manufacture. Formal and close co-operation among all concerned was further maintained by frequent meetings of our Tank Committee, usually at Aberdeen. At these meetings, the drawings and model components were explained and discussed fully and frankly. On this committee were represented the office of the Chief of Ordnance, Aberdeen Proving Ground, the tank manufacturers, the principal subcontractors, and the Ordnance districts responsible for inspection.

The pilot medium tank M3 was built as follows: Rock Island Arsenal manufactured what may be referred to as the chassis; that is, the tank less the turret assembly. The cannon was manufactured at Watervliet Arsenal, the sights at Frankford Arsenal, the turret assembly at Aberdeen Proving Ground. The pilot was completed in March and was formally demonstrated in manoeuvres and firing before the Chief of Ordnance, officials from his office, from the Office of Production Management, and representatives of the tank manufacturers and subcontractors at Aberdeen Proving Ground on April 4, 1941.

A few weeks later, the American Locomotive Company, the Baldwin Locomotive Company, and the Chrysler Corporation each formally delivered to the Chief of Ordnance or his representatives the first production models of the medium tank, M3, thereby initiating the quantity production of this important vehicle which is the backbone of our Armored Force. It may be fairly said here that while this tank incorporates to the fullest extent the latest lessons learned from the war in Europe, it is fully an American concept and an American accomplishment. It is a relatively high-speed, manoeuvreable tank with great fire power, fitting the American policy of aggressive mobile warfare. It represents, I believe, the best integrated experience, ability, and intelligence of American industry and the American Army. By dint of hard, high-pressure, expedited work, this tank was designed and developed in a remarkably short time and put into production in a total period well under a year—and some six months earlier than estimated. This redesign was justified both because our limited funds during the years of peace had not allowed us to develop ideas which we knew should be in a tank and also because the war in Europe had brought out new ideas and had greatly reinforced the ideas of mechanization. No time was lost in getting tanks into production; for the tank manufacturers in the interim were getting their plants ready.

THE TRAINING OF THE ENGINEER

From *Civil Engineering and Public Works Review* (London), June, 1941.

Members of the engineering profession will feel considerable satisfaction at the action taken by the Council of the Institution of Civil Engineers of Great Britain in their momentous step towards the introduction of a long overdue reform in the curriculum of the engineering student.

The absence of a course of lectures on the economics of engineering, on organization and management, and on the relations of aesthetic considerations to engineering design and construction has been a constant source of weakness in the training of our young engineers.

By some strange mental apathy or by an inability of the teaching profession to realize their significance, these all-important considerations have been left in the past for the young engineer to acquire by experience. Not infrequently, economic experience has been gained at the expense of the public, and the lack of an appreciation of aesthetic principles has left behind testimonials to an inability to appreciate what is pleasing to the discerning eye.

As a commencement, the Council of the Institution has approached the Vice-Chancellor of Cambridge University with an offer to finance for a period of five years a lectureship on the subjects envisaged, in the hope that they would in due course form part of the engineering curriculum of the Mechanical Science Tripos.

The proposal put forward by the Institution has been cordially welcomed in principle by the Senate of the University and it is proposed that a beginning should be made in the next academical year. It is suggested that the scheme should be initiated by inviting a number of eminent engineers and others to visit the University to give either single lectures or short courses on subjects coming within the terms of the proposal.

To the layman it has long been a mystery how the teaching of engineering could be divorced from all consideration of the financial aspect of the profession. In spite of the closest possible association of the economic with the technical aspects, little emphasis has up till now been laid upon it, and few professions have thought it of importance to devote any part of their curriculum to the preparation of the student in what will be a dominating feature of their lives.

Many engineers, when commencing their careers, have regretted their lack of knowledge of the economic aspects of their work. In most instances the technical aspect of the engineering task to be accomplished is dominated by economic considerations. Most men who have risen to eminence in the profession have done so, not only by virtue of their technical knowledge and skill, but by their ability to co-ordinate the application of that knowledge and skill with the financial and ecomonic factors dominating the work on hand.

An example of engineering work that is pleasing to the eye and lends dignity to its surroundings remains as a lasting memorial to the skill and the taste of the men who conceived and carried out the work.

When we look back at the past, we must at times feel surprised that the results achieved have been as successful as they have. That this is so is undoubtedly due to the high general technical standard the profession demands of its members.

It is easy enough for an engineer to carry out constructional work when money is of no object. How often is such a condition encountered, and even if encountered, how far is such a state of affairs desirable ? Every engineer should be mentally equipped on entering his professional life to grapple with the economic and aesthetic aspects of his work.

The principles of organization and management should be as much an integral part of the training as any technical engineering subject in the present curriculum. In its broad sense these subjects may be taken as but part of the economic principles involved in engineering work.

The general public will in due course have reason to thank the Institution for the splendid step they have taken and the wisdom they have displayed in recognizing the importance of aesthetics as applied to their profession.

That the first proposal should come from the civil engineers themselves and not from the teaching profession, is of importance, as it bears witness to the progressive spirit that has seen in the future the necessity of keeping the profession in touch with the changing attitude of the public and the determination of the profession that its members shall take their full part in the steady improvement of the appreciation of the close relation of the technical, the economic and the aesthetic.

LORD REITH'S ADDRESS TO THE INSTITUTION OF CIVIL ENGINEERS

From *Journal of The Institution of Civil Engineers* (London), June 1941

A luncheon was held by The Institution at Grosvenor House, Park Lane, on Wednesday, 30th April, when 227 members and guests were present. Sir Leopold Savile, K.C.B., president, was in the chair.

Lord Reith of Stonehaven, P.C., G.C.V.O., G.B.E., D.C.L., LL.D., M.Inst.C.E., Minister of Works and Buildings, proposed the toast of "The Institution of Civil Engineers." He said: Having spoken last year, and not being set on talking at the best of times, although gratified by your invitation, I should have asked the president to excuse me had it not been for the creation of a Ministry of Works, of such interest and concern to you (and to the sister profession of architecture), and that one of your members was the first minister. He ought to have something to say to his own Institution about what has been done, about what is being done, about what is planned, and which, God and other departments being willing, will or may be done. I was informed yesterday that the Ministry of Works did not advertise itself enough; that few people knew how much had been done and planned in the six months since its creation, and, for the matter of that, by the Office of Works since war started. Even in time of war, even in these times of test and trial, it seems that acts do not always speak for themselves, and that ministers—Mr. George Hicks and I—ought to have been talking more than we have done, either about these acts or in place of them. Sermons in stones or books in structural steel are not enough.

A new ministry is not always popular, especially when its creation involves or should involve the transfer of authorities and responsibilities from elsewhere; but at least it can be used as a scapegoat of convenient and astonishing capacity.

I will tell you a thing or two it does. In addition to looking after Duck Island, in St. Jame's Park, it is responsible for the provision, maintenance, and repair of 14,000 Government buildings throughout the country. It is itself carrying out an immense building programme, factories of all sorts, storage, landing grounds, hostels, training establishments camps, depots—more than one million pounds of work a week. It has an office staff of 9,000, half of them technical, and a field force of 12,000. But do not imagine that this is some gargantuan department about to seize the work of individual engineers and architects. I believe in individuals, and we intend to make full use of them.

One of its achievements has been the substitution for the old priority system, with all its inconsistencies, of a system of allocation in terms of labour to departments. The amount of work permitted is limited to the capacity of the building industry. It sounds simple; but it has taken months to get it through. Whereas building proposals had reached a peak far in excess of what the industry could meet, we have secured, after vast discussion and negotiation, a reduction to the real capacity of the country, namely, about £350 millions a year. The allocation system will be in operation to-morrow; and all hopefully expect that once it is running there will be a far more efficient building effort. The more urgent construction works will be so manned as to ensure their speedy completion. This has involved much investigation—the more difficult because of the absence of statistics—but when departments produced their complete programmes some of us were, I think, surprised to find what they had in hand. Returns have been obtained from builders, contractors, and local authorities, showing the number of employees and the categories of employment and work. But these figures will be seriously incomplete until many local authorities take a more responsible view than they do to-day of their position as large employers of building labour. After three months, less than half have provided the information required: but we shall not stop until we have full and regular statistical control; we are engineers and builders, preferring to move in this field by sight and not by faith.

The Ministry has also established effective control over many building materials, in particular cement and bricks, a cause of much tribulation in the past. In its charter it was invited to institute research into such questions as the adoption of substitutes for building materials, modifications of design and specifications, standardization of design and of all materials for war economy, and to ensure that the results of past and future research are used. All this is done in close collaboration with the Building Research Station; but a Ministry of Works covers a still wider field and there is a great deal of scientific engineering research, in large-scale field experiments and the collation of information from all over the world, which it is now setting out to deal with. In standardization, the policy is to eliminate everything but the minimum necessary for war effort: that may affront the feelings of many engineers and architects; but this is no time to play for safety, nor even to study susceptibilities.

Unnecessary building, unnecessary demolition and clearance, and extravagant reconstruction are being controlled; and licences for building by private interests are now compulsory (and not easily obtainable) for £100 to be spent on any building within twelve months; it may be still further reduced, as nothing that is not contributory to the war should be permitted.

A new department was established in the Ministry two months ago to help in the rapid repair of damaged houses, services, and factories. It is organized on the basis of Emergency Works Officers at all the important target towns, supervised by Assistant Directors in charge of large grouped areas. There are engineers and architects and contractors, all working together, and from accounts they seem to be carrying out their duties with remarkable, though unadvertised, success.

I will not prolong the tale. But there are two other matters I want to mention: the first because we are aiming at such a combination of all sections and interests of the civil engineering and building industries as will not only notably increase the war effort but also make a radical and permanent improvement in their structure and operation. Discussions were initiated by my Ministry, with the co-operation of the Ministry of Labour, with representatives of the civil engineering and building industries many weeks ago with the view of securing by their better direction, a more satisfactory building output and a more efficient machine more in keeping with the serious and urgent needs of the day and better fitted to meet the post-war problems.

On the other matter: a good deal has already been said in public about the planning and reconstruction responsibilities vested in me, to advise on the machinery, constitutional and administrative, necessary for the planning and reconstruction of town and country after the war. This subject also is controversial. Do not let any one think that what I or anybody else may be doing about the machinery for planning detracts from the war effort. I said in another place that the idea of a planned and ordered reconstruction is surely an incentive to and an encouragement of war effort: and surely engineers, of all people, so careful in planning their own works should welcome planning in this larger sphere. They should, in fact, be among those who, insisting on a proper design of whatever they are about to build, must welcome a design for living not only in planned and ordered communities of concrete and bricks and timber and stone and steel, but also of highways and byways; of farms where farms should be, and flowers and grass and trees where they should be; and of industrial communities where they should be; (and definitely not where they should not be). There must be co-ordination between living and working and moving and playing, with amenities, natural and otherwise, of civilized life instead of the haphazard, confused disorder and inconvenience of our lives, or the monstrous and obscene mutilations of the countryside.

One word to engineers from my own experience in the profession. The Institution has done well to initiate and finance a course of instruction at Cambridge University under the distinguished professor of engineering there, in order that the engineer may be something more than an engineer—which, in fact, he too rarely is—and that he may have some idea of the general problems of management and of the broader issues involved in engineering works and in business generally.

On the moral issues of war and peace we in this country are on unassailable ground, and we know that there is no compromise possible. We know, too, that we have opportunities of immense service to mankind and to the world. We may be fighting for self-preservation with no bridge of escape, and desiring none, but beyond self-survival there is this opportunity of something far bigger than ourselves, in the conquest of evil and in the establishment of a better order here and throughout the world, for a better order here will depend on a better order everywhere. Put quite simply, I conceive that we are engaged in a struggle for the standard of living, economic and cultural, throughout the world. This is not a purely materialistic end; it includes and transcends the materialistic. A rise in the standard of living, if economic alone, would at best be static, and what was gained would soon be lost. Of at least equal importance is a rise in, and the permanent establishment of, the moral and spiritual standards of living, all now in the balance; and this for all peoples in all countries. And it will be for us to see that, when peace falls like a benediction on the world, it bestows for all time and for all people security and happiness, and freedom from fear and want.

Your chairman has made an announcement about Greece. In what I have said about the establishment of moral and spiritual values I see — and I think we all see — in Greece the faith for which the Empire fights, and for which we look beyond war, as an engineer looks beyond this day to the completion of the job, to the passage of traffic over his mighty bridge, to the first flow of water over the spillway of his dam. Life and war are all engineering achievements after a kind. If there were more of the engineer's outlook, his factor of safety, his factor of efficiency, his planned organization, there would be fewer disasters and difficulties in both life and war. But difficulties and disasters there must be, and bridges have been known to collapse more than once; you all know one bridge that I am talking about. Do let us see these Mediterranean happenings, particularly in Greece, in their right perspective, as an engineer surely would. There are setbacks to be encountered on every job, however carefully planned; but it is an essential of engineering, having counted the cost, to take the risk. Here in Greece was an obvious and admitted risk, but every dictate of honour and moral obligation proclaimed that the risk must be taken; and it was taken, nobly and bravely. If to us, gentlemen, as engineers, this is a week when the progress report is not quite so satisfactory as it might be, we are used to that, and we look to the end of the job.

I give you the good health of your Institution. May it flourish and continue to command the respect of the community, as in times past.

AIR BRAKES

From *Aeronautics* (London), May, 1941

Brakes for aircraft are almost becoming a perennial subject. Years ago they were seldom heard of, for the machines of those days had a comparatively high drag which acted as a reasonably good brake without extra assistance; in fact if the engine was shut off when they were flying at their best speed the effect on the occupants resembled the effect of pushing hard on the brake pedal of a modern motor-car. But nowadays things are very different. The modern aeroplane has had most of the old drag-making accessories removed, the wing area has been reduced, everything possible has been faired over, and even the radiator has been induced to give a small thrust instead of a large drag, and the same thing is true of exhaust manifolds.

The result is that the modern aeroplane is not only much faster than its ancestors, but when it has gained this extra speed it is extremely reluctant to lose it, hence the modern cry for brakes. I think everyone will agree that all fast vehicles should have efficient brakes; fast passenger trains are fitted with a device which applies a brake to every wheel; many modern motor-cars have an arrangement which enables the engine to assist the driver in applying brakes so that the power may be increased. Even ships can reduce their speed quickly—in the sailing days by putting a sail aback, and in modern times by reversing propellers.

The fact is that the power of reducing speed quickly is as much a part of the capability of manoeuvering as the capability of steering; in fact, manoeuvrability in its highest degree can only be attained when accelerating, reducing speed, turning, and in the special case of the aeroplane climbing and descending, are all under the control of the steersman. The fact that wheel brakes are fitted to all modern aeroplanes is rather outside the scope of this argument, except to show that the modern aeroplane designer realizes the importance of quick speed reduction on the ground but does not think it so necessary in the air.

For an example, let us assume that a fast fighter has dived on to the tail of a hostile bomber, and has straightened out at a speed of 450 miles an hour, while the bomber is proceeding at 250. Then, in order to stay behind the tail the fighter has to reduce his speed by 200 miles an hour, and he ought to be able to do this quickly or he will shoot in front of the bomber. In order to simplify the calculations let us suppose that the average L/D of the fighter over this range of speeds is eight. Under these conditions the drag of the fighter will be one-eighth of its weight and the deceleration will be about four feet per second. As 200 miles an hour is about 293 foot-seconds, the time taken to reduce speed from 450 to 250 miles an hour will be 293/4, or about 73 seconds.

During this period the bomber will have travelled about 5.1 miles and the fighter, whose average speed while decelerating may be taken as the mean between 450 and 250, or 450 plus 250/2, would be travelling at 350 miles an hour, so that during the 73 seconds it would cover about 7.1 miles, or about two miles more than the bomber. So that the fighter pilot must arrange that his dive finishes some two miles behind his opponent, or out of effective shooting distance. If he does not do this he will run past his antagonist and may be shot up by the latter's side-mounted guns without being able to reply.

We have now to consider what form these brakes are to take. The first that I remember being fitted to a service aeroplane were fitted to the Sopwith One-and-a-Half Strutter during the last war. This machine was in its day the best two-seat fighter ever produced. The brake consisted of arranging that the trailing portion of the lower wing near the fuselage could turn about its central axis. I think that this movable portion extended some two feet on each side of the fuselage. This scheme worked quite well, but was liable to vibrate severely at high speeds and, for this reason, I do not think it suitable for modern fighters.

Another scheme, suggested by Mr. W. E. Hick in a recent article in this journal, consisted in using a central flap across the bottom of the fuselage, in line with the wing flaps. A rough calculation suggests that about two square feet of area in this position would be sufficient to give adequate braking, and the arrangement should work very well in practice.

But there are some other schemes which should be considered. It might, for instance, be possible to lower the undercarriage either completely or partially. This would give a considerable amount of braking at high speeds, which are the only ones we are interested in, but the amount of the brake effect would of course depend on the design of the particular under carriage. Extending the chassis in this way would give a nose-diving moment the effect of which would have to be carefully considered, but probably the chief objection to the scheme is that a chassis cannot be extended and retracted very quickly, and speed is always of importance where manoeuvrability is concerned.

Small flaps projecting at right angles to the wings near the trailing edges have been used on several types of aircraft, but this arrangement is certain to increase the wing lift, which is not altogether desirable, and can be expected to produce a nose-diving moment.

The scheme I personally would prefer would be to use the propeller as a brake. It would not be difficult to arrange to turn the blades of a variable pitch propeller to a position in which no thrust existed when the engine was running statically on the ground. We might call this "zero pitch". The effect would be that the blades would act like flat plates at right angles to the wind, and the fact that they would be revolving slowly under engine power would not be of importance.

But I am afraid we should want another lever to operate this arrangement; but in this it would be in the same position as all the others. I would be extremely reluctant to add even one more lever to those the pilot already has to look after, but I am afraid it is unavoidable. Another working part must have another control. Now the lever I suggest should be completely separate from the others and should, when operated, move the propeller to "zero pitch" and at the same time throttle the engine down to the ticking-over position.

The operation of doing this and of putting things back to normal could be done very quickly. If found desirable, a small amount of negative pitch could be arranged; by modifying this a negative thrust or additional drag of any amount required could be easily produced but if this were done the engine throttle must be opened somewhat to ensure that the airscrew does not stop turning. Twin-engined aircraft could be dealt with in the same way by arranging that both airscrews could be set to "zero pitch" and that both engines could be throttled down simultaneously.

This would involve a little care in the design of the gear so as to ensure synchronization but there should not be any great difficulty about it. When required, such an arrangement would be very useful for rapid pulling up on the ground, especially if negative thrust was used. When airscrews are used as brakes when on the gound, any amount of braking force can be applied without any risk of nosing over.

AERODROME SPACE

From *Aeronautics* (London), May, 1941

Two things gather in importance as the size of the Royal Air Force increases: the provision of additional aerodromes and the fuller use of existing aerodromes. They are problems of space and of traffic control. At the La Guardia airport of New York a range control system has been proposed in order to increase the amount of traffic that can be handled there in bad weather every twenty-four hours. Even so the four-minute interval seems to be the smallest contemplated.

For the operation of large bomber forces such as the Royal Air Force will shortly dispose, traffic control systems which enable aircraft to take off and to land in all weathers, by day and by night, at short intervals of time are essential. In this work the knowledge and experience of those who, in peace time, controlled the traffic at our civil airports will be of value.

Meanwhile the search for new aerodrome sites must go on and methods must be studied whereby aircraft can operate from a small space. The military aerodrome of to-day neutralizes between 20 and 25 square miles of country. Devices—and there are such— which might drastically reduce this area must be urgently developed. The technique of the runway, with cross-wind taking-off and landing runs, must be studied. Assisted take-off might be another way of reducing the length of these runs.

In the past the higher command of the Royal Air Force has been, perhaps, too content to assume that there would always be plenty of space in this small island and that no matter how large and how numerous were our bombers, there would always be long and clear runways from which they could operate in all weathers.

In Great Britain, aircraft will soon be packed tighter than ever. The methods of traffic control must be advanced to enable them to work efficiently at high densities so that the full power of our growing Royal Air Force can be exerted against the enemy.

AIR CONDITIONING OF RAILWAY COACHES

By F. Roedler, *Zeitschrift des VDI*, January, 1941

Abstracted from *The Engineers' Digest* (London, Eng.)

The difficulty of air-conditioning in railway coaches is the limited space of from one cubic metre per head in 3rd class coaches to 2.6 cubic metres in 1st class coaches. The problem of maintaining a uniform temperature in the coach is easier to solve than the ventilation question. Open windows lead to draught and considerably increases the air resistance of the train. Special arrangements taking the form of suction and pressure ventilator are therefore indispensable.

To compare the efficiency of the air-conditioning a Kata-theremometer has been developed. The measured "dry Kata number" gives the cooling effect of the atmosphere. The actual value depends on the temperature and also on the flow of air. The ratio of air temperature T and Kata number A gives the correlation between Kata number and the comfort of the passenger. It is termed "comfort index" and Table I gives information regarding this characteristic.

"D" class cars fabricated in steel, built in 1929-30, employing low pressure circulation heating with automatic regulation for each compartment were investigated. When the windows, flaps, and roof ventilators were closed the comfort index was between 3.3 and 5.2 and the temperature was constant. The relative humidity averaged 60 per cent, and was, therefore, pleasant.

The effect of ventilation on the atmosphere in a motor coach was investigated. With no ventilation the comfort index was 5.0; this could be reduced to 4.3 by the use of suitable fans, and to 3.9 by using natural draught. To ensure the necessity for artificial air-conditioning only on hot summer days, special callottes taking the shape of perforated spherical openings were fitted into the roof.

Aeration of the seats is only bearable at room temperature from 20 deg. C. upwards, at lower temperatures the perforated callotte was fitted with a pair of flaps. It appears that at about 20 deg. C. a critical temperature exists to which is correlated an airspeed of 0.3 metres per second.

TABLE I

		Stationary Air	Velocity of Airflow in m/sec.			
			0.1	1.2	0.4	0.6
Upperlimit of comfort (warm)	t_L	22.0	22.6	23.75	25.3	26.2
	A	4.0	4.5	4.8	5.1	5.3
	$B=t_L/A$	5.5	5.0	5.0	5.0	5.0
Max. Comfort	t_L	18.8	19.0	19.5	21.0	22.0
	A	5.0	5.7	6.4	7.0	7.3
	$B=t_L/A$	3.75	3.35	3.0	3.0	3.0
Lower Limit of comfort (cold)	t_L	15.9	16.0	16.3	17.4	18.4

	$B=t_L/A$	2.65	2.4	2.15	2.0	2.0

From Month to Month

News of the Institute and other Societies, Comments and Correspondence, Elections and Transfers

VISITORS TO CANADA

The great industrial development that has come with the war has brought to Canada many engineers from other countries. Perhaps the greatest number has come from England although many have come from the United States and Europe. This infiltration of members of the profession should be a fine thing for Canadian engineers. It permits of a better knowledge and understanding of the people and the works of all groups, and should result in a widening of the outlook of all concerned.

Engineers from the Old Country have come here with important missions. They have brought with them a knowledge of things which were yet new in this country; things which Canadians proposed to learn so that in time they might become experts and take over some of the burden that rested on the United Kingdom. Others have come to inspect intricate merchandise made to the order of the British Government. Still others have come on a variety of missions; some to stay for only a few days or weeks, and others to settle down in our midst.

The Polish government has a fine appreciation of the value of its technically trained manpower, and so, when the over-running of Poland seemed inevitable, instructions were given that hundreds of these engineers be sent out of the country. They are now in many parts of Europe, with the largest proportion in England. With Canada's great development, and with the accompanying shortage of highly specialized personnel in several fields, it has been found that some relief can be brought to the situation by utilizing the special skill of these people.

Poland had become highly industrialized. Her success in many lines, such as precision instruments, optical goods, machinery, synthetic rubber and so on, was fast bringing her to the top of the European field. The men who accomplished these things have escaped from the country, and some are now in Canada, lending their expert knowledge to our aircraft industry, to our hydro-electric development, and to our munitions programme.

Poland has always featured its engineers. During the life of the last republic, two of their presidents were engineers, namely: Narutowicz and Moscicki. To some extent this will explain the great industrial development. Perhaps the Polish example might be copied to advantage in other countries.

Canadian engineers will welcome all these experts who have come to our assistance, and will help make their stay pleasant. These relationships should do much to improve our outlook both now and after the war, for they will give us contacts which we would not have had otherwise.

Elsewhere in this Journal is a letter from a newly formed Polish association whose objective is to assist these engineers in the many problems they have to face after their nightmare experiences at home, and the loss of all their goods and chattels, and in most instances the severance of all family ties. They are alone in Canada; they are without funds, but they possess courage, stamina, and the desire to work towards the ultimate defeat of Nazism and their return to their homeland. Their loyalty and their skill is guaranteed by the Polish government, to whom they are all well known.

There are many strangers in our midst from many countries—fellow members of a great calling. Much good can be done for the profession if the opportunities to know and understand our distinguished visitors are seized and fully developed.

THE COST OF BECOMING AN ENGINEER

The Engineering Alumni of the University of Toronto through its Junior Panel and in co-operation with the Engineering Society of the "School" has done some investigating into the fields of costs of engineering education. These are not total costs as the university itself might see them but actual costs to the student. In each case the figure includes an amount of $290.00 to cover tuition, deposits and societies.

For those whose home is Toronto the figures are:

a. Without fraternity.................$550.00 per year
b. With fraternity.....................$635.00 per year

For students from outside Toronto, these figures are given:

a. In boarding house..................$775.00 per year
b. In university residence..............$800.00 per year
c. In fraternity........................$925.00 per year

These costs do not include transportation to and from Toronto.

These figures were developed from the returns of questionnaires submitted to the students of all years. Approximately half the students replied—sixty per cent being in Toronto and the balance from outside.

Excluding tuition the breakdown is as follows:

Food and Shelter	Home in Toronto	Home Outside Toronto
At home	......	......
Boarding-house	......	$225.00
Residence	......	255.00
Fraternity	......	300.00
Incidentals	23.50	29.25
Transportation in City	27.00	15.00
School socials	12.60	12.60
Outside socials	58.20	58.20
Incidental socials	42.90	42.90
Fraternity fees	77.00	77.00
School equipment	40.00	40.00
Clothing	65.00	65.00

This is very pertinent information. Congratulations are due to those responsible for the compilation. It is interesting to note that it is proposed to carry out a more detailed investigation next year.

OF SPECIAL INTEREST

Although at first selected simply as a suitable article for the Abstract Section, a rereading of the address of Lord Reith of Stonehaven, Minister of Works and Buildings in His Majesty's Government, on the occasion of a meeting of the Institution of Civil Engineers, indicates that special attention should be called to it so that no reader may miss it.

Lord Reith discloses some new regulations for the control of buildings and materials, but more than this he talks of a better future wherein the engineer, with others, may give and receive amenities of life which have been denied in the past.

Of this future he says, "There must be co-ordination between living and working and moving and playing, with amenities, natural and otherwise, of civilized life, instead of the haphazard, confused disorder and inconvenience of our lives, or the monstrous and obscene mutiliations of the countryside." . . . "On the moral issues of war and peace we in this country are on unassailable ground, and we know that there is no compromise possible. We know, too, that we have opportunities of immense service to mankind and to the world. We may be fighting for self-preservation with no bridge of escape, and desiring none, but beyond self-survival there is this opportunity of something far bigger than ourselves, in the conquest of evil and in the establishment of a better order here and throughout the world, for a better order here will depend on a better order everywhere."

Time given to reading this short address will be time well spent. See page 401.

WARTIME BUREAU OF TECHNICAL PERSONNEL

The forty thousand questionnaires addressed to those people who said on their national registration that they were engineers, chemists or architects, have been mailed. Additional questionnaires are going—and in many instances have gone—to others whose names were not on the list supplied by the Bureau of Statistics, but who belong to provincial professional associations, technical institutes or similar organizations. A thorough check is being made against all membership lists, to make certain that no one is overlooked.

Forms are being returned daily in great quantities. Sometimes at least a thousand have come in in one mail. At the time of writing 18,000 have come back, with the daily stream hardly showing any abatement.

As was at first suspected many persons recorded their calling incorrectly at the time of registration. It is a revelation to see what some people think constitutes engineering. The returns show that mechanics, electricians, plumbers, boiler attendants, locomotive drivers, firemen, tinsmiths, garage mechanics, repairmen, service men, machine operators, gardeners, janitors, elevator men and dozens of others think their qualifications are correctly described by the word engineer.

The Bureau is receiving many inquiries from war industries and the armed services and is supplying the records of suitable men. It is quite evident that the supply of qualified persons free to accept new positions is small. However, it should be possible to fill many of the present openings when the Bureau records are complete. At least this will show who and where are all the persons with the proper qualifications, and will indicate the degree of their availability. From such basic information it will be possible to appraise conditions properly, and to make whatever arrangements may be necessary to meet the constantly changing situation.

The plant training activities of the Bureau have expanded still farther. Besides the mining industry, the proposals for training have been outlined to a public utilities group representing the electric, gas and power companies; and to the petroleum industry. These groups have attended meetings in Ottawa under the chairmanship of the Director of the Bureau, where they have been addressed by the Deputy Minister of Labour, the Director General of Munitions, the Director of Ship Construction and others. In each instance organizations were estbalished to carry out the proposed expansion of the machine shop work-day so that more men could be trained and more materials prepared for war purposes. Plans for the training of a number of enlisted men in skilled mechanical operations for the army, all within the facilities of industry are being considered.

Meetings have been held in Ottawa, Toronto and Montreal to co-ordinate the efforts of all the agencies interested in these developments. They are many sided and far reaching, and have as their objective the complete co-operation and co-ordination of many power and plant facilities for every phase of industrial training in relationship to the war effort.

CORRESPONDENCE

Oorgaum, South India
June 27th, 1941.

THE GENERAL SECRETARY,
ENGINEERING INSTITUTE OF CANADA,
2050 MANSFIELD ST., MONTREAL, P.Q., CANADA.

Dear Sir:

Under the stress of war conditions your letter of January 20th has just come to hand. I note that the Council has been pleased to award the Leonard Medal for the year 1939-1940 for my paper entitled "Points of View on the Rockburst Problem" published in the C.I.M. & M. Bulletin for August 1939.

I can assure you that recognition of ones humble efforts by the E.I.C. is in addition to encouragement, a distinction

R. G. K. Morrison.

which one cannot fail to appreciate. I am very grateful to the Leonard Medal Committee for their good opinion of the paper, and regret my inability to receive the medal personally at either of the annual meetings referred to in your letter. For your convenience if the medal has not already been forwarded to me at this address I would be glad if it could be sent to my wife.

I enclose a picture as requested but presume the announcement has already been dealt with in your Journal, and the need for it has passed.

Yours sincerely,

(*Signed*) R. G. K. MORRISON

ASSOCIATION OF POLISH ENGINEERS IN CANADA

Ottawa, 28, 6, 41.
66, Delaware Ave.

THE ENGINEERING INSTITUTE OF CANADA,
2050 MANSFIELD St.,
MONTREAL, QUEBEC.

Dear Sirs:

We beg to inform you that owing to the arrival in Canada during the last few months of about 40 Polish technicians and the expectation of the influx of farther parties of them, we formed the "Association of Polish Engineers in Canada."

The aims of our association are: to represent its members before the Canadian authorities, to verify credentials, to obtain employment for them, financial support to members in case of need, to provide a social life among the members of the association, to maintain contact with technical associations in Canada and so on.

The Council of the association consists of Messrs. J. Korwin Gosiewski, president; M. Kurman, W. Jakimiuk, J. Meier and Z. Karczewski.

The Secretary of the association is Mr. R. J. Herget. The office of the association is located at 66 Delaware Ave., in Ottawa.

The majority of the members are graduate engineers with experience in Polish and continental war industry and they are willing to give all their knowledge and energy for work in Canadian war industry for our common cause.

We hope that our young organization will be accepted by you with benevolence and that we shall be always in close co-operation with your association.

Yours very truly,

ASSOCIATION OF POLISH ENGINEERS IN CANADA

(*Signed*) J. KORWIN GOSIEWSKI, *President.*
M. KURMAN, *Councillor.*
R. HERGET, *Secretary.*

AULAC, N.B.,
JULY 15TH, 1941.

THE SECRETARY,
THE ENGINEERING INSTITUTE OF CANADA,
MONTREAL.

We have here at the Fort Beausejour Museum all the data pertaining to the ship railway or as it was sometimes called The Chignecto Marine Railway promoted by H. G. C. Ketchum, 1882-92, for the purpose of transporting sailing ships from the head of the Bay of Fundy to the entrance of Northumberland Strait at Baie Verte.

The only thing missing from the collection is the working model, a wooden structure some eight or ten feet long and three or four feet wide by which a miniature ship is transported from one dock to the other.

The model was shown at an exhibition in Saint John, N.B., but there is now no trace of it in the building.

There is a record of Mr. Ketchum having described his railway to the members of your Institute in 1892. He had his model with him, and it is with the hope that some happy fate caused him to leave it in your care and that it can again become an exhibition piece in a public place near the spot where his Fort Lawrence dock was located that I am writing.

The gambling fraternity would dub my letter a million to one shot but the prize sought is worth the effort.

If it would be possible at this late date to find trace of this historic relic I would pass the information along to Dr. J. C. Webster, Shediac, N.B., who is responsible for our Museum with its fine collection and he would proceed to find a final resting place for it.

Yours sincerely,

(*Signed*) A. W. BULMER.

Personals

News of the Personal Activities of members of the Institute, and visitors to Headquarters

R. A. C. Henry, M.E.I.C., vice-president of the Montreal Light Heat and Power Consolidated, has been appointed chairman of the Canadian Section, Joint Economics Committee of the United States and Canada. He has been at Ottawa since the first months of the war acting as executive assistant to the Minister of Transport, and later as economics advisor to the Department of Munitions and Supply.

R. E. Jamieson, M.E.I.C.

R. E. Jamieson, M.E.I.C., has been named director general of a new Army Engineering Design Branch of the Department of Munitions and Supply at Ottawa. He will head a special inter-departmental advisory committee on army engineering design. Mr. Jamieson, who is professor of civil engineering and chairman of that department at McGill University, has obtained a leave of absence to assume his new duties at Ottawa. He is a past president and member of Council of the Corporation of Professional Engineers of Quebec, and a member of the executive of the Canadian Engineering Standards Association. He has also served on many of the various committees of the Institute.

The new Army Engineering Design branch will involve the transfer from the Department of National Defence to the Department of Munitions and Supply of all work, duties and responsibilities attendant upon army engineering design, and the transfer from the staff of the Defence Department to that of the Munitions and Supply Department of several officers and employees presently engaged in army engineering design.

Wing Commander A. J. S. Taunton, D.S.O., M.E.I.C., is now chief works officer, No. 2 Training Command, R.C.A.F., with headquarters at Winnipeg. Previously he was district engineer at Winnipeg for the Department of Munitions and Supply.

Captain A. B. Dove, M.E.I.C., is now officer commanding, 3rd Field Park Company, Royal Canadian Engineers. Before the outbreak of war he was chemical engineer with the Steel Company of Canada in Montreal.

W. E. Denley, M.E.I.C., maintenance engineer, Department of Highways and Transportation, Saskatchewan, is the officer commanding the 9th Field Company, Royal Canadian Engineers, now being organized at Dundurn Military Camp, Sask. His rank is that of Major.

M. J. Spratt, M.E.I.C., chief engineer, Saskatchewan Co-operative Elevator Company, is a lieutenant serving with the 9th Field Company, Royal Canadian Engineers, now in training at Dundurn.

D. C. Beam, M.E.I.C., is now on the staff of Wartime Housing Limited, Toronto. Since his graduation from the University of Toronto in 1928 he has been with the building Department of the City of Toronto, where he has been given a leave of absence.

Albert Holland, M.E.I.C., has a war appointment in the Dover area, England, as a civilian garrison engineer. He acts as personal assistant to the Deputy Commander, Royal Engineers, Dover.

G. W. E. Nicholson, M.E.I.C., is now resident manager with Union Bag and Paper Corporation, Savannah, Georgia. He was previously production manager with Southern Kraft Corporation, at Panama City, Florida.

H. M. Lewis, M.E.I.C., has resigned as mechanical superintendent at Pacific Mills Limited, Ocean Falls, B.C., to become manager of the new South Shore Yard of the Burrard Drydock Company Limited at Vancouver, B.C.

T. R. Durley, M.E.I.C., who was lately resident inspector in Montreal for the Associated Factory Mutual Fire Companies, has been transferred to the manufacturers Mutual Fire Insurance Company of Providence, R.I. He will be located in the Canadian office of the Company at Toronto.

W. F. Campbell, M.E.I.C., has joined the staff of the Aluminum Company of Canada Limited, at Arvida, Que. He was previously road superintendent and county engineer for the county of Haldimand, Ont.

E. A. Beman, M.E.I.C., has joined the staff of Pandora Limited at Cadillac, Que. Lately he had been connected with Wood Cadillac Mines, at Kewagama, Que.

F. H. Peters, M.E.I.C.

F. H. Peters, M.E.I.C., surveyor-general of Canada was elected to honorary membership at the first meeting of the National Congress on Surveying and Mapping held in Washington, D.C., last June.

J. V. Ludgate, M.E.I.C., who was district engineer of Municipal roads of the Department of Highways of Ontario at North Bay, has been transferred to the same position at Stratford, Ont.

J. B. Burke, M.E.I.C., who is on the staff of Alberta Government Telephones has recently been transferred from Lethbridge to Edmonton.

E. J. Bolger, M.E.I.C., is now on the staff of McLennan Gold Mines Limited at Geraldton, Ont. He was previously connected with Futterer and Reid, mining engineers, Toronto.

Captain R. C. Lane, Jr.E.I.C., is now in the 6th Armoured Regiment (1st Hussars) at Camp Borden, Ont. Previous to his enlistment he was on the staff of International Harvester Company at Toronto.

James Oliver, Jr.E.I.C., has joined the staff of Defence Industries Limited and he is, at present, located in the maintenance department of the Winnipeg plant. A graduate of the University of Alberta in 1937 he has since been engaged on several construction projects.

J. W. Lucyk, Jr.E.I.C., is now employed as a draughtsman with the Hamilton Bridge Company Limited at Hamilton, Ont. Previously he was a demonstrator in the department of electrical engineering at the University of Manitoba.

E. R. Hyman, Jr.E.I.C., has joined the R.C.N.V.R. as a lieutenant and is now located at Halifax, N.S. Previous to his enlistment he was on the staff of Trinidad Leaseholds, Limited, in Trinidad, B.W.I.

R. L. Strong, S.E.I.C., has joined the staff of the Associated Factory Mutual Fire Companies at Boston, Mass., where he expects to receive a special training. He is a graduate in engineering of the University of Toronto, and a bachelor of science in business administration from the Massachusetts Institute of Technology. For the past seven years he had been on the staff of Canadian Industries Limited at Montreal.

Leslie Wiebe, S.E.I.C., is at present employed as assistant engineer with Sutton-Horsley Company Limited at Toronto. He has been with this firm in several capacities since his graduation from the University of Saskatchewan in 1940.

D. D. Reynolds, S.E.I.C., is now working in the division engineer's office of Canadian National Railways at Regina, Sask.

H. Goodfellow, S.E.I.C., Climax, Sask., is now serving with the Royal Canadian Engineers overseas. His rank is that of lieutenant.

W. M. Newby, S.E.I.C., has secured a position on the staff of Canadian General Electric Company at Peterborough, Ont. He was graduated from Queen's University in 1940.

C. H. Vatcher, S.E.I.C., who was with Canadian National Carbon Company Limited at Vancouver, B.C., has been transferred to the Toronto office of the company. Mr. Vatcher is a graduate of the University of Toronto in the class of 1939.

I. M. McLaughlin, S.E.I.C., has joined the staff of Defence Industries Limited at Valleyfield, Que. He was graduated in mechanical engineering this spring from Nova Scotia Technical College.

VISITORS TO HEADQUARTERS

D. W. Houston, M.E.I.C., Superintendent, Street Railway Department, City of Regina, Sask., on June 7th.

P. H. Morgan, M.E.I.C., Mackenzie, British Guiana, on June 18th.

W. H. Blake, M.E.I.C., District Engineer, R.C.E., M.D. No. 7, Department of National Defence, Saint John; N.B., on June 30th.

E. M. Izard, M.E.I.C., Works Manager, Yarrows Limited, Victoria, B.C., on July 4th.

W. F. Purves, S.E.I.C., Schick Shaver Limited, Stamford, Conn., on July 7th.

J. H. Wilson, M.E.I.C., Electrical Superintendent, Quebec North Shore Paper Company, Baie Comeau, Que., on July 15th.

C. H. S. Venart, M.E.I.C., Nobel, Ont., on July 16th.

G. F. St-Jacques, M.E.I.C., Engineer, Public Service Board, Quebec, Que., on July 16th.

Professor J. A. Van den Broek, University of Michigan, Ann Arbor, Mich., on July 16th.

W. H. Sparks, Jr.E.I.C., P/O, R.C.A.F., Victoria, B.C., on July 18th.

L. P. Cousineau, M.E.I.C., Quebec Streams Commission, Cadillac, Que., on July 18th.

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Francis Porter Adams, M.E.I.C., died at his home at Brantford, Ont., on June 26th, 1941, after a short illness. He was born at Brantford on March 27th, 1877, and received his preliminary education at the local Collegiate Institute, and his engineering training at the School of Practical Science at Toronto. In the early days of his career he was engaged in railroad construction on the Brantford and Woodstock railroad. From 1902 to 1905 he was employed with the Ontario Peat Company designing and installing machinery at the Wainfleet plant. In the years 1907 to 1908 he worked as assistant engineer for the Grand Valley Railway Company of Brantford. In March, 1908, he became assistant

F. P. Adams, M.E.I.C.

city engineer of Brantford. During the first great war he was in France with the 10th Battalion, Canadian Railway Troops, and he returned to Canada in 1919 with the rank of Major. In 1920 he became city engineer of Brantford, a position which he retained until his death, along with that of manager of waterworks.

Among the several works which he left may be mentioned the five bridges which he designed and constructed at Brantford. Mr. Adams was among those men of vision who conceived the project of the Shand Dam and the contiguous improvements to the Grand Valley. Fortunately he lived to see those early dreams and discussions well under way.

He was a member of the Grand Valley Group of the Association of Professional Engineers of Ontario and with his fellow members did much to cement the natural ties with the Hamilton Branch of the Institute. He will always be remembered by the members of the branch for his quiet kindness to all.

Mr. Adams joined the Institute as an Associate Member in 1910.

Archibald Sinclair Cook, M.E.I.C., died on June 9th, 1941, at Clarkson, Ont. He was born at Penobsquis, N.B., on November 20th, 1873, and entered the engineering profession in 1899 as one of the field engineers in charge of the construction of various parts of the Dominion Iron and Steel Company's plant at Sydney, N.S. In 1902 he engaged in railroad construction. From 1904 to 1907 he was resident engineer with Dominion Power and Transmission Company of Hamilton, Ont., on power developments near St. Catharines, Ont. In 1911 he was appointed inspecting engineer of the Transcontinental Railway Commissioners at Ottawa, Ont. From 1922 to 1938, when he retired, he was with the Canadian National Telegraphs at Toronto.

Mr. Cook joined the Institute as a Student in 1902. He was transferred to Associate Member in 1906 and he became a Member in 1912.

John Hamilton Gray, M.E.I.C., died in the hospital at Victoria, B.C., on July 1st, 1941. He was born at St. John, N.B., on December 25th, 1853, the son of the Honourable J. H. Gray one of the fathers of Confederation. He served his apprenticeship as a surveyor in Ontario under Bolton McGrath, D.L.S. In 1871 he became engaged in the Canadian Pacific Railway surveys in Ontario. From 1873 to 1880 he did the same work in British Columbia. From 1880 to 1884 he was assistant engineer on the construction of the railway in the Fraser Canyons. From 1884 to 1887 he did location and construction work for the Esquimalt and Nanaimo Railway. During the years 1888 and 1889 he did exploration work on the Vancouver Island for the British Columbia Government. From 1889 to 1891 he was inspector of dyking works on the Fraser River, and from 1891 to 1893 he was location and construction engineer for the government on the Shuswap and Okanagan Railway. He was chief engineer on the construction of the Victoria and Sydney Railway from 1893 to 1895. From 1895 to 1901 he was chief engineer of maintenance and operation with the Kaslo and Kootenay Railway. In 1902 he engaged in private practice in Victoria, B.C. He had retired a number of years ago, and had lived at Albert Head on Victoria Island.

Mr. Gray joined the Institute in 1906 as a Member. He had been made a Life Member in 1934.

Wilmot Earl Harry, M.E.I.C., died at his home in Winnipeg, Man., on June 11th, 1941. He was born at Savanna, Ill., U.S.A., on September 26th, 1885, and was educated at the local high school. In 1904 he started as an instrumentman with the Chicago, Burlington and Quincy Railway and remained in railroad construction in the United States until 1910, when he came to work for the City at Medicine Hat, Alta. From 1911 to 1913 he worked as assistant engineer with the Canadian Northern Railway. From 1915 to 1919 he was overseas as an officer in the Royal Engineers, and in 1919 he went to Russia with the British Military Railway Mission. He returned to Winnipeg in 1920 and became connected with the Peter Lyall Construction Company of Montreal. A few years later he was in the States and for some time was connected with the New York Central Railway. He returned to Winnipeg in 1930, and in 1934 he worked for the Department of National Defence at Nakina, Ont. He returned to Winnipeg in 1937.

Mr. Harry joined the Institute as an Associate Member in 1920.

Joseph Arthur Lamoureux, M.E.I.C., died in Montreal on May 19th, 1941. He was born at Bedford, Que., on July 7th, 1873, and received his education at the Ecole Polytechnique at Montreal where he was graduated in 1898. Upon graduation he became engaged on the construction of the East Richelieu Valley Railway, and in the years 1899 and 1900 he did surveying work for the Montreal, Ottawa and Georgian Bay Canal Company. In 1900 he joined the Department of Public Works of Canada at Ottawa, and remained in the government service until his retirement in 1937, when he came to Montreal. During his numerous years of service he was connected with most of the important projects carried out by the Department of Public Works.

Mr. Lamoureux joined the Institute as an Associate member in 1909.

Patrick Philip, M.E.I.C., died at Montreal on July 14th, 1941. He was born at Londonderry, Ireland, on December 4th, 1882. He received his preliminary education at the Royal High School, Edinburgh, and his technical training at the Londonderry Technical Institute. After a few years practice in Ireland he came to Canada in 1907, and until 1910 was engaged on location and construction work with the Grand Trunk Railway. From 1910 to 1917 he was assistant to the city engineer of Vancouver, B.C. In 1917 he joined the Department of Public Works, Kamloops, B.C., as district engineer, and from 1919 to 1921 he was district

Patrick Philip, M.E.I.C.

engineer at Vancouver. In 1921 he was appointed Public Works engineer at Victoria. In 1935 he came to Montreal with the Canada Creosoting Company.

Mr. Philip joined the Institute as an Associate member in 1917 and he became a Member in 1922.

Robert Ramsay, M.E.I.C., died at his home in Montreal on July 11th. He was born at Glasgow, Scotland, on October 3rd, 1888. He received his preliminary education at Annan Academy, and obtained his technical training at Newbie Technical Classes and at West of Scotland Technical College, Glasgow. In 1910 and 1911 he worked as a draughtsman on the design of cargo vessels machinery with Messrs. D. & W. Henderson, Glasgow. From 1911 to 1913 he was engaged in the design of machinery for torpedo boat destroyers with Messrs. Yarrow & Company, Glasgow, and from 1913 to 1916 he designed machinery for light cruisers with Messrs. Vickers Limited, Barrow-in-Furness. He came to Canada in 1916 as chief draughtsman and assistant to the general manager of Canadian Vickers of Montreal. In 1923 he was appointed assistant chief engineer, and later became manager of the industrial department. In 1937 he became associated with Lambert, German & Milne, naval architects, Montreal. At the time of his death he was consulting engineer with Wartime Merchant Shipping Limited.

Mr. Ramsay joined the Institute as an Associate Member in 1924.

J. H. Ings, M.E.I.C. - - *Secretary-Treasurer*
C. G. Cline, M.E.I.C. - *Branch News Editor*

The annual meeting of the Niagara Peninsula Branch was held in the General Brock Hotel, Niagara Falls, on June 26 with an attendance of fifty. Mr. A. L. McPhail presided, in the absence of the chairman, Mr. C. H. McL. Burns. The retiring secretary, Mr. G. Griffiths, introduced the newly-elected members of the Branch executive and the new secretary, Mr. J. H. Ings.

The guest speaker, Mr. E. L. Durkee, C.E., resident engineer for the Bethlehem Steel Co. at Niagara Falls, N.Y., was introduced by Councillor W. R. Manock. Mr. Durkee spoke on **Erection of Steel Superstructure of the Rainbow Bridge.** His talk was illustrated by a model of the erection layout and by three reels of motion pictures. The new bridge is being erected for the Niagara Falls Bridge Commission. The consulting engineers are Waddell & Hardesty of New York City and the Edward P. Lupfer Corporation of Buffalo. The arch ribs were fabricated by the Bethlehem Steel Company at Pottstown, Pa., the spandrel girders by the Hamilton Bridge Company and the rest of the steel by the Canadian Bridge Company at Walkerville, Ont. The bridge is of the fixed arch type with a span of 950 ft. centre to centre of supports, which is 150 ft. longer than the Henry Hudson bridge at New York. The whole load is carried by the two circular arch ribs which are spaced at 56-ft. centres and rise 150 ft. The bridge will have a reinforced-concrete deck carrying two 22-ft. roadways, separated by a 4-ft. central mall, and one 10-ft. sidewalk on the upstream side facing the falls. The steelwork supporting the deck from the arch ribs will be merely dead load and has not been designed as trusses to stiffen the arches. The fixed arch design was selected as being stiffer for the same depth of rib. Each end of each arch is anchored at the skewbacks by 32 anchor bolts set 23 ft. in concrete imbedded in the solid rock. In erection, three panels, containing 25 per cent of the weight of the ribs, were supported by cantilvering on these bolts. The rest of the weight was carried by 1$\frac{9}{16}$-in. cables from the tops of towers erected temporarily on the end of each concrete approach. The box-type ribs are 12 ft. deep with cover plates from 1$\frac{1}{8}$ to 2$\frac{1}{2}$ in. thick and are stiffened by internal plates set three feet apart and by angles. The ribs were divided into sections weighing between 50 and 75 tons each. These were lowered from the approach by an 85-ton stiff-leg derrick, moved up the arch on a material truck with 8-ft. gauge, and lifted into place by a 55-ton derrick travelling on the arch ribs. As the arches were built out from shore, the supporting cables were moved from one panel point to another, nearly 75 per cent of the erection time being devoted to rigging, erection of falsework, etc. At the centre, the arches were supported temporarily on bolted brackets and shims, the opening being varied by hydraulic jacks. The opening was measured accurately under the desired stress condition and was closed finally by 11-in. steel "keystone" pieces, specially milled to fit. The supporting cables and towers have been removed and by July 10th the steelwork will be finished. Forming will be started at once and concreting will start about August 1st.

After a lengthy question period, the vote of thanks, moved by Mr. M. B. Atkinson, was heartily approved by the audience.

SAGUENAY BRANCH

T. A. Taylor, Jr.E.I.C. - - *Secretary-Treasurer*
B. E. Surveyer, Affil.E.I.C. - *Branch News Editor*

The 1941 Annual Meeting of the Saguenay Branch of the Engineering Institute of Canada was held at Arvida, July 4th, 1941.

At 2.15 p.m., about 25 of the members assembled at the quarters of the 12th Anti-Aircraft Battery stationed in Arvida, where a most interesting tour of inspection took place under the guidance of Major I. B. MacCullum, O.C. the Anti-Aircraft Unit. Judging by the numerous questions asked, it was evident that this tour of inspection was of keen interest to all those participating.

Following the visit to the battery, a handful of the members braved the hazards of the Arvida Golf Club without endangering "Old Man Par" except on one or two holes.

At 7.00 p.m. about 45 members gathered at the Grill Room of the Saguenay Inn for dinner and the annual meeting.

The chairman, Mr. J. W. Ward, in his most able manner proposed a toast to the King, following which he established a precedent for the Saguenay Branch by proposing a toast to the president of the United States, which was heartily responded to by all members. Following the toasts, the members sat down to dinner.

At the conclusion of an enjoyable dinner the chairman introduced the guest speaker for the evening.

Professor R. F. Legget of the University of Toronto, who is in Arvida for the summer in connection with the Shipshaw power development, was the first speaker. He expressed his pleasure in being present at the meeting and conveyed the good wishes of the Toronto Branch Executive of which he is a member. Professor Legget gave a very interesting resumé of the work in progress at the Shipshaw, outlining the geological formation of this section of the Saguenay valley. He invited all members interested to see several samples of well preserved birch and balsam found in the excavation work which he has in his possession and which he estimates to be several tens of thousands years old.

Professor Legget also remarked at the splendid co-operation of the various divisions of engineering in the Saguenay Branch of the Institute, as compared to the larger centres where other organizations tended to segregate the various divisions into their own groups. Unfortunately Professor Legget was obliged to catch the train and had to cut his talk short, but the members are hoping to have the opportunity of a complete paper from him before his work is completed here.

The next speaker, Mr. McNeely DuBose, a familiar figure in the activities of the Saguenay Branch having been an active participant for 15 years, expressed his thanks and pleasure at being present, and also conveyed greetings from the Council at Montreal.

Mr. DuBose outlined the highlights of the Shipshaw development and announced the construction of a powerhouse with a capacity of approximately 1,000,000 horsepower, of which orders had been placed for 500,000 hp. In conjunction with the Shipshaw he also announced the construction of a large storage dam on the Peribonka River to provide additional water for the winter months.

The speaker next mentioned several steps being taken by the Saguenay Power Company to obtain additional power for the Saguenay district one of which was the installation of a 110,000-volt cable across the city of Montreal to transmit off-peak power from the Beauharnois system to the Shawinigan system.

Following Mr. DuBose's interesting talk was a highly informative lecture by Major I. B. MacCullum. He expressed his thanks at being invited to attend the meeting, and also his thanks to the Aluminum Company of Canada for the splendid assistance and co-operation he received as well as the fine accomodations for the battery which he described as equal to anything in Canada.

He described the equipment, and its development since the last war, used by modern Anti-Aircraft Batteries. This included the calibre of various guns, their makes, and their effectiveness. In conjunction with this he mentioned the British made 40 mm. gun as being very superior to anything built to-day.

Included in his remarks were several very interesting facts about the work of A.A. Batteries in France and especially at Dunkerque.

At the conclusion of his talk, Major MacCullum was bombarded by numerous questions by the members which he answered in a most satisfactory manner.

Before turning over the chair to the incoming executive, Mr. Ward moved a vote of thanks to the Protestant School Board of Arvida for their generosity in allowing the Branch to hold its meetings in the school during the past year. He thanked the members of the executive for their support in the past year and then introduced the new chairman, N. F. McCaghey.

Mr. McCaghey expressed his pleasure at being chosen chairman for the second time and then declared the meeting adjourned.

VANCOUVER BRANCH

T. V. Berry, M.E.I.C. - - *Secretary-Treasurer*
Archie Peebles, M.E.I.C. - - *Branch News Editor*

The final meeting on the programme of the Vancouver Branch for this season was held on Wednesday, May 21, in the Georgia Hotel. The speaker was a branch member, Mr. W. N. Kelly, and his subject was **Woodenwalls and Ironclads.** Mr. Kelly has spent his lifetime with ships and shipping, and his intimate knowledge of the historical side of his subject, combined with broad experience, provided a most interesting address.

The speaker opened by paying high tribute to the shipbuilding genius of Noah who, according to the specifications handed down to us in the scriptures, designed and constructed a vessel which ranks with many modern ships in size and tonnage. Its exact proportions are not conclusively known owing to the various interpretations and units of measurement applied in relation to our own.

Other historical references to shipbuilding were made, including the exploits of the ancient Greeks, Phoenicians, Vikings and other races who developed the art of ship construction to a high degree. These early ships used oars or sails, and made voyages over long distances in search of trade or conquest. Some of the early ships built in England were also described, to show that the sturdiness of their construction and the quality of materials used is not often matched at the present time. Beams and ribs were of oak, with copper fastenings, and sometimes the hull would be two feet in thickness. This was especially true in the case of ships of the navy.

In describing the size of ships, Mr. Kelly pointed out that three separate measurements are used. The gross tonnage is the total internal volume of the ship in tons of 200 cu. ft. The registered tonnage is the total internal volume, less deductions for space occupied by machinery, etc. The deadweight tonnage is the displacement in tons of 35 cu. ft.

The invention of gunpowder brought about a change in ship construction to resist the new-found weapons. The old woodenwalls gave place to ironclads when iron plates were used above the waterline on the outside of the timber construction used at that time. In some cases iron plates five inches thick were placed on 22-inch oak walls to resist the battering of cannon fired broadside at close range.

The next big advance was the invention of steam propulsion which began early in the 19th century. The early paddle wheel steamers used steam pressures of 26 to 30 lb. per sq. in. A number of early steamships of historical interest were described such as the *Charlotte Dundas*, the *Fulton*, and the *Comet*. The *Fulton* was built in New York and the others in Scotland, shortly after 1800. In 1865 the Admiralty adopted Ruthven's method of propulsion with screw propellers.

Other advances which have marked the building and use of ships were the compound engine using triple expansion, increased boiler pressures, water tube boilers, and the Parson's Turbine. The turbine brought about a very rapid increase in horsepower as indicated by the fact that in 50 years the horsepower of reciprocating engines increased from 5,000 to 40,000, while in five years the power of turbines increased from 9,000 to 70,000. Torpedo boats and destroyers were an application of the steam turbine. Oil fuel also contributed to rapid growth in speed and power.

Much was contributed to marine architecture by scientific studies of the behaviour of ships at sea; a work which has been carried on largely by the navy departments of various countries. In 1900 the first submarines were built for Great Britain, others having been built a short time previously for the United States and France. The address concluded with a brief description of the corvettes and other vessels being built at the present time.

A great many questions were asked and answered, and many personal experiences were recalled by Mr. Kelly and members of the audience. The meeting was a fitting conclusion to a very successful series which the Vancouver Branch has enjoyed during the winter. In the absence of the chairman, Dean Finlayson, Mr. W. O. Scott, vice-chairman, presided and a hearty vote of thanks was tendered by Mr. W. H. Powell.

News of Other Societies

Items of interest regarding activities of other engineering societies or associations

CANADIAN ELECTRICAL ASSOCIATION

The following officers were elected at the fifty-first convention of the Canadian Electrical Association held at the Seigniory Club, Que., from June 25-27. President: McNeely DuBose, M.E.I.C., General Manager, Saguenay Power Company, W. C. Mainwaring, B.C. Electric Railway Co. Ltd.; R. A. C. Henry, M.E.I.C., Beauharnois Light, Heat & Power Co.; and T. A. Brown, M.E.I.C, Gatineau Power Co,; will be the three vice-presidents for the coming year. B. C. Fairchild was re-elected secretary for the eleventh year and J. B. McCabe, Montreal Light, Heat & Power Cons., was re-elected treasurer. The new executive committee is as follows: A. C. Brittain, Gatineau Power Company, Ottawa, Ont.; A. L. Brown, Northern Electric Co. Ltd., Montreal, Que.; E. V. Caton, M.E.I.C., Winnipeg Electric Company, Winnipeg, Man.; R. N. Coke, M.E.I.C., Montreal Light, Heat & Power Cons., Montreal, Que.; H. A. Cooch, M.E.I.C., Canadian Westinghouse Co. Ltd., Hamilton, Ont,; J. H. Fregeau, M.E.I.C., Shawinigan Water & Power Co., Three Rivers, Que.; J. B. Hayes, M.E.I.C., N. S. Light & Power Co. Ltd., Halifax, N.S.; B. M. Hill, M.E.I.C., Canadian Utilities Ltd., Calgary, Alta.; Chas. Johnstone, Southern Canada Power Co. Ltd., Montreal, Que.; Geo. Kirlin, Canada Wire & Cable Co. Ltd., Montreal, Que.; F. Krug, Montreal Engineering Co. Ltd., Montreal, Que.; G. W. Lawrence, Sangamo Company Limited, Toronto, Ont.; I M. MacLean, Canadian General Electric Co. Ltd., Toronto, Ont.; A. S. McCordick, Moloney Electric Co. of Canada Ltd., Toronto, Ont.; R. A. Merritt, Winnipeg Electric Company, Winnipeg, Man.; W. H. Munro, M.E.I.C., Ottawa Light, Heat & Power Co. Ltd., Ottawa, Ont.; C. R. Reid, M.E.I.C., Shawinigan Water & Power Co., Montreal, Que.; A. Vilstrup, B. C. Electric Railway Co. Ltd., Vancouver, B.C.

CONVENTION OF A.W.W.A.

Canadian Section

Nearly 1,500 persons attended the sixty-first annual convention of the American Waterworks Association in the Royal York Hotel, Toronto, June 22nd-26th. This total comprises a Canadian registration of 382.

In view of the parent association holding its convention in Toronto, the Canadian section confined its activities to a luncheon held on the first day of the convention and a business meeting.

At this meeting, presided over by the retiring chairman, G. H. Strickland, the annual reports were presented. The officers for the new year were elected, and a number of presentations and awards were made. In his report the secretary-treasurer announced an increase in the membership of the section and a change of the status of the membership in western Canada which permits members in that part of the country to hold joint membership in another nearby section, thus affording closer contact with the affairs of the Association.

Memorial awards were presented by the chairman in the names of the late James A. MacMillan of Charlottetown, and Frederick E. Field of Montreal. The first medal was accepted by M. L. Gordon, town engineer of Truro, N.S., and the second by C. J. Desbaillets, M.E.I.C., chief engineer of water supply, Montreal, for delivery to the respective families.

The newly elected officers for the current year are as follows: Chairman, William Storrie, M.E.I.C., Gore & Storrie, Consulting Engineers, Toronto; Trustees: A. L. McPhail, Waterworks Superintendent, St. Catharines, Ont., J. W. Peart, Manager of Public Utilities, St. Thomas, Ont. The other officers of the Canadian Section elected previously are: Past-Chairman, G. H. Strickland; Section Representative of A.W.W.A. Board of Directors, J. Clark Keith, M.E.I.C.; Trustees: T. M. S. Kingston, M.E.I.C., C. C. Folger, M.E.I.C., W. E. Robertson and O. H. Scott.

ROAD BUILDERS WILL CONSIDER POST-WAR WORK

Plans for the launching of a national road building programme after the war, which should provide employment for 200,000 wage earners for a period of three years, will be one of the features to be discussed at the Twenty-sixth Annual Convention of the Canadian Good Roads Association. It is announced by the president, Honorable T. D. Bouchard, Minister of Roads, Province of Quebec, that the Convention will be held at the General Brock Hotel, Niagara Falls, on October 7th, 8th and 9th, and will be attended by ministers of highways and public works, their deputies and engineers, from every province in the Dominion.

The provincial ministers and their engineers have, following last year's convention, already started on a survey of what work can be undertaken in their respective provinces. It has been realized that the preparation of plans, working out of engineering details and acquisition of rights-of-way must be started well in advance of actual roadwork, and factual data relating to highway conditions will be submitted to the Convention for consideration.

The Executive of the Canadian Good Roads Association accepted an invitation from Hon. T. B. McQuesten, Minister of Highways for Ontario, to meet at the hub of Ontario's splendid highway system and plans are now being laid for a three-day programme that will deal specially with war-time matters, current needs for highway improvement to withstand heavy mechanized transportation, as well as with post-war rehabilitation.

The invitations now issuing point out that the provision of adequate highways, and bridge structures, are the basic needs of North America defence plans, for without them the rapid transportation of heavy mechanized forces and the expeditious movement of raw materials and munitions will be impossible.

"Skilled roadmen must be retained for road works," says Hon. T. D. Bouchard, in his invitation to the Convention. "To allow roads to deteriorate in the face of heavy increased demands for military requirements, transportation of munitions and for general commercial purposes, would lower national efficiency to a degree which no apparent financial saving can justify. New standards of construction may have to be determined and provision made for parallel and feeder roads for the transportation of farm and industrial products to commercial centres. Linking up and improving access roads with main routes must be considered, and it is the concensus of opinion among government officials that no time should be lost in studying the necessary improvements, and co-ordinating them into a comprehensive plan which will be of vital importance to the whole country.

ELEMENTARY AERODYNAMICS

By Group Captain D. C. M. Hume

Reviewed by SQN. LD. C. W. CROSSLAND, M.E.I.C.*

Group Captain Hume has succeeded, in this slender textbook, in setting out a clear and accurate statement of the elementary principles of aerodynamics, without attempting to go into involved mathematical processes to demonstrate the proof of these principles. For an elementary book, it breathes a refreshing air of precision and accuracy, frequently lacking in such works.

The book opens with a discussion of the air and its properties and definitions of aeronautic terms. Newton's laws of motion are re-stated in terms of air forces and the laws of fluid pressure are given with reference to air. Measurement of air pressure is explained by reference to the equation:

$$P = \frac{1}{2} \rho V^2$$

and here, unfortunately, an opportunity is missed for a useful explanation of dimensional theory and the unit of mass, the slug. This unit will be unfamiliar to many students. The subject of measuring air pressure leads naturally to a brief description of the various types of wind tunnels, but the only wind tunnel balance described is the original National Physical Laboratory type, now little used. It is stated that wind tunnel tests show that the reaction on a body in an air stream is given by the equation:

$$R = \frac{1}{2} C\rho SV^2$$

Here, again, a page could profitably have been devoted to a proof of this equation by dimensional analysis.

Lift and drag, and the development of the aerofoil section from a flat plate are briefly explained, with some notes on the effect of camber.

Chapter II gives an account of streamline and turbulent air flow, the origin of drag and the stall. A discussion of lift and drag coefficients and their variation with angle of incidence follows in Chapter III, with a reference to L/D curves. The balance of the forces of flight, lift, weight, drag and thrust is also explained. The balance of forces in climb is rather confused, particularly Fig. 22, which omits thrust from the force diagram and shows the flight path as coincident with the thrust line, a condition which is scarcely likely to occur in practice. An alternative conception of climb is offered in which conditions are described which can actually occur only in accelerated flight. The chapter closes with the determination of landing speed.

Chapter IV discusses lift forces more fully, and describes chord distribution, span distribution, induced drag and wing interference in biplanes. The circulation theory of lift is briefly dealt with. Chapter V explains centre of pressure movement and the means by which trim is maintained in flight. Chapter VI defines the three axes of motion and deals with the means of control of rotation of the aircraft about these axes, that is to say, the ailerons, elevators and rudder. The definition of mass balance applies to static balances; the term mass balance usually being reserved for dynamic balance, whose function is to damp out vibration of the control surface, caused by eddies. The action of frise ailerons and differential ailerons, in balancing yawing couples in turning, is also described.

Chapter VII is devoted to static stability; dynamic stability is mentioned, but this subject is one which can hardly be dealt with adequately in a non-mathematical treatment. The explanation of auto-rotation omits any reference to yawing couples and might convey the impression that an aeroplane is capable of performing a pure autorotation continuously.

The action of dihedral in restoring lateral trim in a sideslip is over-simplified by considering only the side-slip velocity. Dihedral simply provides a geometric increase of incidence on the low wing, with a corresponding decrease on the high wing, in side-slip.

The climb, glide, roll, turn and spin are discussed in a further chapter on Manoeuvres. The last two are very clearly explained. Chapter IX, on propulsion, refers to the momentum and vortex theories of airscrews and develops the blade element theory in some detail. Airscrew pitch and efficiency are defined, and mention is made of variable pitch airscrews, gearing and balance.

A final chapter on performance illustrates the calculation of horse-power required and hp. available, the construction of the performance chart, and determination from it of top speed, best climbing speed, rate of climb and ceiling. The current passion for quiz programmes is reflected in the series of questions appended to the book.

On the whole, the book is an excellent introduction to aerodynamics, in spite of a few weak points, and maintains a much higher standard of accuracy than is usually found in its class. It deserves to be popular among student pilots, engineers, and mechanics, as it is interesting and readable, and covers the subject remarkably well, with little mathematical assistance.

* Commanding Officer, No. 17 (Technical) Detachment, Halifax, N.S.

REPORT ON BUILDINGS DAMAGED BY AIR RAIDS, AND NOTES RELATIVE TO RECONSTRUCTION

Institution of Structural Engineers, LONDON, 1941

7pp., 5½ x 8½ inches sixpence

Reviewed by S. R. BANKS. M.E.I.C.*

During the past twenty years the Institution of Structural Engineers has prepared and published reports dealing with a variety of engineering matters. The subject of air-raid precautions received attention some time prior to the beginning of the war; and the present report, based on experience gained during the severe raids of last year, is an equally timely contribution to the war services of the engineer.

It is unfortunate that rigorous censorship, in forbidding reference to specific instances, has robbed the report of much of its value, but nevertheless some of the generalized conclusions are of interest.

In the first place, the reporting committee was greatly impressed by the variety of problems that arise in the survey of damaged structures. It is pointed out the services of competent and broadly experienced engineers are required, and that considerable skill is needed to make sound decisions regarding repairs and replacements.

Secondly, it has been clearly established that modern framed buildings (of reinforced concrete or protected steelwork) have exhibited great powers of resilience and endurance under attacks both explosive and incendiary, while brick-and-timber buildings have proved to be extremely vulnerable.

Thirdly, the use of strong beam-and-column connections and the provision of frequent bracing-systems have been demonstrated to be of distinct value in localizing the effects of bombing. Also, as might have been expected, structures with a liberal factor of safety in their original design have withstood attack much better than have those where that margin was reduced to a minimum.

* General Engineering Department, Aluminum Company of Canada Limited.

ADDITIONS TO THE LIBRARY

Fire tests of wood- and metal-framed partitions, report BMS71.

United States Work Projects Administration—Bibliography of Aeronautics

Supplement to part 4—dynamics of the airplanes; supplement to part 21, blind flight automatic pilot ice formation; supplement to part 48—parachutes; part 49—rocket propulsion; part 50—stratospheric flight.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet the books are not in the Institute Library, but inquiries will be welcomed at Headquarters, or may be sent direct to the publishers.

AIR AND GAS COMPRESSION

By T. T. Gill. John Wiley & Sons, New York, 1941. 181 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.00.

This new textbook discusses the properties of gas in regard to compressibility, critical data and specific heats, as applied to the solution of the problem of air and gas compression. Illustrative problems with solutions accompany each chapter, and a set of practical alignment charts for various calculations is appended.

AIR RAID PRECAUTIONS, in Ten Parts,

reprinted by permission of the Controller of His Britannic Majesty's Stationery Office, First American edition, Chemical Publishing Co., Brooklyn, N.Y.. 1941. diagrs., charts, tables, 9 x 5½ in., cloth, $3.00.

In the ten separately paged sections of this manual are brought together and amplified the materials published previously in the A.R.P. handbook and memorandum series. Topics discussed include the organization of the air raid wardens' service, communications systems, rescue parties and clearance and decontamination work; structural defense and window protection; gas detection and identification; training procedures and the inspection, care and repair of equipment.

AIRCRAFT INSTRUMENTS, Their Theory, Function and Use.

By O. E. Patton. D. Van Nostrand Co., New York, 1941. 220 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $2.75.

Intended both as a textbook for the student and a practical manual for the aviator or mechanic, this book presents a clear, concise discussion of the various flight, navigation and engine instruments. Design and construction are described in such a way that the nature, principle, functioning and purpose of any instrument can be readily understood. Many photographs and diagrams supplement the text.

AIRCRAFT PROPELLERS, Basic Training Manual

By C. M. Harlacher, prepared and edited by H. E. Boughman. Aero Publishers, 120 North Central Ave., Glendale, Calif., 1941. 119 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $2.85.

Intended as a basic training manual, this book presents in question and answer form the fundamentals of propeller theory, construction and maintenance. The Civil Aeronautics Administration regulations are covered, and considerable space is given to detailed descriptions of certain modern adjustable propellers.

(THE) BOULDER CANYON PROJECT, Historical and Economic Aspects.

By P. L. Kleinsorge with a foreword by E. Jones. Stanford University Press, Stanford University, Calif., 1941. 330 pp., illus., diagrs., maps, tables, 9½ x 6 in., cloth, $3.50.

The whole system of related works comprising the Boulder Canyon Project (not merely the Hoover Dam construction and its resulting reservoir area) is discussed. The history of the project is reviewed, and the economic significance of this great flood control, irrigation, power and water supply system is explained in detail. Geological and engineering aspects of the various dams, canals and aqueducts are also considered. The book is well documented.

(The) CHEMISTRY OF POWDER AND EXPLOSIVES, Vol. 1

By T. L. Davis. John Wiley & Sons, New York; Chapman & Hall, London, 1941. 216 pp., illus., diagrs., tables, 9 x 5½ in., cloth, $2.75.

Intended as a text for fourth-year and graduate students, this book has been written to inform chemists concerning the modes of behavior of explosive substances and the phenomena, both chemical and physical, which they exhibit. The use of explosives in ammunition and blasting is treated only so far as is necessary to make certain points clear. This first of a two-volume set covers properties of explosives and deals particularly with black powder, pyrotechnics and aromatic nitro compounds. Other explosives will be considered in the second volumes.

CIVIL AND DEFENSE, a Treatise on the Protection of the Civil Population against Air Attach

By A. M. Prentiss. Whittlesey House (McGraw-Hill Book Co.), New York and London, 1941. 334 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $2.75.

The various means and methods of air attack are described, with the effects produced by each and indications of the scope and character of the threat to civil population. Other topics discussed include protection against high explosives, incendiaries and gases, the organization of warning and warden services, and the construction of shelters. The final chapter discusses the probable influence of civil air defense on the national life and future city development.

DANA'S MANUAL OF MINERALOGY. revised by C. S. Hurlbut, 15th ed,

John Wiley & Sons, New York, 1941. 480 pp., illus., diagrs., charts tables, 9 x 6 in., cloth, $4.00.

This is the fifth major revision of this standard work, now nearly 100 years old. As before, it is designed to meet the needs of the student of mineralogy, the mining engineer, the geologist and the amateur mineralogist. In addition to alterations and additions for the purpose of bringing the material up to date, certain changes have been made to render the book more serviceable as a text for a course in elementary mineralogy.

DRILLING AND PRODUCTION PRACTICE 1939. 675 pp., $3.50.

DRILLING AND PRODUCTION PRACTICE 1940. 263 pp., $2.50

American Petroleum Institute, Division of Production, Central Committee on Drilling and Production Practice, New York., illus., diagrs., charts, tables, 11 x 8 in., cloth.

The American Petroleum Institute annually publishes these collections of papers on drilling and production practice selected from those presented at its meetings. The papers are divided into four groups: drilling practice, production practice, materials and miscellaneous. A bibliography of district-meeting papers, following the main text, contains abstracts and references as to where complete papers have appeared.

FIELD GEOLOGY

By F. H. Lahee. 4 ed. rev. and enl. McGraw-Hill Book Co., New York and London, 1941. 853 pp., illus., diagrs., charts, tables, 7½ x 5 in., lea., $5.00.

Intended both as a textbook for students and a manual for geologists and engineers, this book treats the subject of geology from a field viewpoint and assumes an elementary knowledge of general geology. The first twelve chapters are concerned with the recognition and interpretation of geologic stuctures and topographic forms as they are observed. The succeeding eleven chapters deal with geological surveying, computations, the preparation of reports, geophysical methods and the nature, construction and interpretation of geologic and topographic maps. There is a bibliography.

FLUORESCENT LIGHT and Its Applications

By H. C. Dake and J. De Ment. Chemical Publishing Co., Brooklyn, N.Y., 1941. 256 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $3.00.

The types and theory of luminescence are explained, and the methods of examination of fluorescent substances are described. Separate chapters are included upon the sources of ultraviolet radiations and on fluorescent and radioactive minerals, and some fifty-five pages are devoted to the uses of ultraviolet light in many fields. There is a large, broadly classified bibilography.

FOUNDATIONS OF BRIDGES AND BUILDINGS

By H. S. Jacoby and R. P. Davis. 3 ed. McGraw-Hill Book Co., New York and London, 1941. 535 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $5.00.

Completely revised and reset, this text covers the many recent developments in the field of foundation engineering. The more important phenomena in the field of soil mechanics are covered; there is new material on piling, cofferdams and caissons, grouting, and the obstruction of water flow by bridge piers; and a new chapter has been added on land foundations in open excavation including water control.

IMPERIAL INSTITUTE, ANNUAL REPORT, 1940,

London, South Kensington 60 pp., illus., tables, 10 x 6 in., paper, (obtainable from British Library of Information, 620 Fifth Ave., New York, not for sale, limited distribution only).

The many activities of the Institute are indicated by the brief reports of various committees which appear in this publication. In addition to the scientific research and exhibits thus described, the pamphlet contains the personnel of the governing groups and staff of the Institute, lists of publications and a list of co-operating organizations.

INDUSTRIAL FABRICS, a Handbook for Engineers, Purchasing Agents and Salesmen

By G. B. Haven. 3 ed. Wellington Sears Co., 65 Worth St., New York, 1941. 789 pp., illus., diagrs., charts, tables, 8 x 5 in., fabrikoid, $2.00.

All phases of the cotton fabric industry are covered in this handbook for engineers, purchasing agents and textile students. In addition to the considerable amount of information on the raw material, manufacturing processes and properties of fabrics, much space is devoted to specifications and test methods. There are many illustrations and tables, and the bibilography has been expanded.

INDUSTRIAL RELATIONS DIGESTS

VII. SELECTION AND TRAINING OF FOREMEN, 8 pp.

VIII. UPGRADING OF PRODUCTION WORKERS, 7 pp.

Princeton University, New Jersey, Industrial Relations Section, May, 1941. 10 x 7 in., paper, $.20 each.

The above titles represent two further subjects covered in a series of digests of current practice prepared for use in companies facing rapid expansion owing to defense orders. These digests are based on material received currently from a large number of representative companies.

INTERIOR ELECTRIC WIRING AND ESTIMATING

By A. Uhl, A. L. Nelson and C. H. Dunlap. 3 ed. American Technical Society. Chicago, 1941. 354 pp., illus., diagrs., charts, tables, 8½ x 5½ in., cloth, $2.50.

The methods, equipment and materials for all kinds of interior wiring, from small jobs to apartment and factory buildings, are described in detail. The final chapter covers estimating procedure for electrical work, including both materials and labor costs. Eight blueprints giving the architectural drawings for a small house accompany the book. New material has been added and the whole book has been revised in accordance with the 1940 National Electrical Code.

(An) INTRODUCTION TO PHYSICAL GEOLOGY

By W. J. Miller, 4th ed. D. Van Nostrand Co., New York, 1941. 465 pp., illus., diagrs., charts, maps, tables, 9½ x 6 in., cloth, $3.25.

Intended as an elementary text, no formal knowledge of chemistry or physics is necessary for an understanding of the contents of this book. It covers the composition, structure, unusual attributes and processes of formation and alteration of the earth's crust. The considerable revision of the new edition is particularly evident in the statistical material in the brief discussion of economic geology.

MANUAL OF ENGINEERING DRAWING for Students and Draftsmen

By T. E. French. 6 ed. Rev. and enl., McGraw-Hill Book Co., New York and London, 1941. 622 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $3.00.

The new edition of this comprehensive, standard textbook has undergone considerable revision. The page size has been enlarged to allow an increase in the size and number of illustrations; many problems have been changed and added; and in addition to revision of existing chapters new ones have been included on aircraft drawing, jig and fixture drawing and welding drawing. The material conforms to the standards of the American Standards Association, and there is a useful bibliography of allied subjects.

OUTLINE OF AIR TRANSPORT PRACTICE

By A. E. Blomquist. Pitman Publishing Corp., New York and Chicago, 1941. 402 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.50.

The activities of the various departments within an airline organization are outlined, with discussion of the necessary correlation between departments. The general principles of management, operation and sales that are fundamental to any type of transportation are here applied to air transport. Descriptions and analyses of practice are limited to scheduled operations in the United States. There is a bibliography.

PARTIAL DIFFERENTIAL EQUATIONS

By F. H. Miller. John Wiley & Sons, New York, 1941. 259 pp., tables, diagrs., 9½ x 6 in., cloth, $3.00.

The first two chapters of this elementary text are devoted to a review of ordinary differential equation methods, while Chapter III is designed to show the various ways in which partial differential equations come into being. The remaining chapters, with the exception of VI, which briefly discusses Fourier series, deal with methods of solving different classes of partial differential equations and with geometric and physical problems solvable by the processes explained.

PRACTICAL AIR CONDITIONING

By A. J. Rummel and L. O. Vogelsang. John Wiley & Sons, New York, 1941. 282 pp., illus., diagrs., charts, tables, 9 x 5½ in., cloth, $2.75.

Material originally used for lecture courses for dealers, salesmen, operators and service men has been expanded to form this elementary text book. It covers essential fundamentals and definitions; the properties of air; requirements for human comfort; all types of equipment, including automatic controls; proper methods of operation and complete maintenance and servicing methods and schedules.

PRACTICAL SHELL DEVELOPING FOR STEEL SHIPBUILDERS

By A. F. Tulin. 2 ed. Simmons-Boardman Publishing Corp., New York, 1941. 158 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $3.00.

This manual for loftsmen, shipfitters, hull draftsmen and others who deal with steel ship construction explains the development and laying-out of the shell of a vessel. Consideration is mainly given to the points of mold-loft procedure beyond the minor fundamentals, which are assumed as familiar.

PRINCIPLES OF INTERCHANGEABLE MANUFACTURING

By E. Buckingham. 2 ed. Industrial Press, New York, 1941. 258 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $3.00.

This treatise on the basic principles involved in successful interchangeable manufacturing practice has been reprinted from the earlier edition with minor changes in two chapters. It covers design, tolerances, drawings, manufacturing equipment, gaging and inspection.

(The) RADIO ENGINEERING HANDBOOK

By K. Henney. 3 ed. McGraw-Hill Book Co., New York and London, 1941. 945 pp., diagrs., charts, tables, 7 x 4½ in., lea., $5.00.

The chief revision in this comprehensive working manual of the radio sciences has been made in the sections on television, high-frequency technique, loud-speakers and acoustics, detection and modulation, facsimile, and aircraft radio. As in former editions, considerable fundamental data is provided for the designer and operator, with the emphasis on practice rather than on theory. There are many references to supplementary material both in the form of footnotes and section bibliographies.

RADIO-FREQUENCY MEASUREMENTS by BRIDGE and RESONANCE METHODS

By L. Hartshorn. John Wiley & Sons, New York, 1941. 265 pp., diagrs., charts, tables, 9 x 5½ in., cloth, $4.50.

A systematic account of the basic principles and general working ideas of radio-frequency measurements by bridge and resonance methods is presented for the practicing technician. The various types of apparatus are discussed fully, and special attention is given to screening, earth connections, the physical nature of the quantities measured, and sources of error.

REGULATION OF PIPE LINES AS COMMON CARRIERS

By W. Beard. Columbia University Press, New York, 1941. 184 pp., tables, maps, 9 x 5½ in., cloth, $2.00.

A systematic, comprehensive study of federal and state regulation of pipe lines as common carriers. The coördination of pipe lines with other forms of transportation is dealt with, and the author closes the book with a summary of the existing information and certain conclusions which may be drawn therefrom.

RELAXATION METHODS IN ENGINEERING SCIENCE, a Treatise on Approximate Computation

By R. V. Southwell. Clarendon Press, Oxford, England; Oxford University Press, *New York, 1940. 252 pp., diagrs., charts, tables, 9½ x 6 in., cloth, $5.00.*

In this book, a new approach to engineering and physical computations is described, a method which is termed "systematic relaxation of constraints." The greater part of this treatise relates to problems confronted in the theory of elasticity: stress-calculations for frameworks and continuous beams, estimation of critical loads, etc. However, the method is shown to have wider application, and such problems as the adjustment of errors in surveying and the determination of currents and potentials in electrical networks also receive detailed consideration.

REPORTS ON PROGRESS IN PHYSICS, Vol. 7, 1940,

Edited by J. H. Awbery; published by The Physical Society, 1 Lowther Gardens, Exhibition Road, London, S.W.7, 1941. 362 pp., illus., diagrs., charts, tables, 10 x 7 in., cloth, $4.75.

Continuing the series of reports issued by The Physical Society, the present volume deals with advances in physical science up to the end of 1940. In accordance with the trend of the last few volumes, this issue contains for the most part comprehensive articles upon relatively specific types in a variety of physical fields. The only large topic receiving a general review is "sound". Each article is the work of a specialist, and large bibliographies are included in most cases.

RUBBER AND ITS USE

By H. L. Fisher. Chemical Publishing Co., Brooklyn, N.Y., 1941. 128 pp., illus., diagrs., charts, tables, 9 x 5½ in., cloth, $2.25.

The constitution, properties and history of naturally occurring rubber are discussed, with information upon where it comes from, how it is obtained and how it is manufactured into various commercial articles. Recent developments in synthetic rubber are also covered. There is a list of reference works for supplemental reading containing brief descriptive notes.

SAE HANDBOOK, 1941 Edition.

Society of Automotive Engineers, New York. 830 pp., illus., diagrs., charts, tables, 8½ x 5½ in., cloth, $5.00 to non-members, $2.50 to members.

All the current standards and recommended practices of the Society of Automotive Engineers concerning automobile and aircraft materials and parts, tests and codes, production equipment, nomenclature and definitions are contained in this annually revised handbook. The numerous changes include new and revised standards, corrections and cancellations. There is also a partial list of American standards of interest to the automotive industry.

TRANSFORMERS

By E. E. Wild. Blackie & Son, London and Glasgow; Chemical Publishing Co., Brooklyn, N.Y., 1940. 132 pp., diagrs., charts, tables, 9 x 6 in., fabrikoid, $2.50.

One of a series of small volumes dealing with particular sections of electrical engineering. This book presents a concise account of the theory, design and operation of transformer types. The book contains a considerable number of worked and unworked examples.

TELEMETERING AND SUPERVISORY CONTROL

A report "Telemetering, Supervisory Control, and Associated Circuits," has just been published by the American Institute of Electrical Engineers.

Corrected to December 1940, this report summarizes a wealth of information concerning the electric telemetering and supervisory-control systems currently in use or commercially available in the United States, and includes a detailed discussion of the interconnecting circuits suitable for such purposes.

Telemetering and supervisory control equipment, although electrical developments and widely used in the electric power industry, are finding their greatest potential field of application in non-electrical industries. In water, oil, gas, and other industries this equipment is playing a vital and economically important role in such operations as the remote metering, indication, or control of the levels, pressures, temperatures, flows, etc., of liquids, gases, etc. Supervisory equipment is particularly adaptable to the remote control and monitoring of any device that may be electrically operated. In addition to control features, remote indications of the positions or conditions of practically any device—such as switch positions, governor settings, gate or valve openings, bearing or winding temperatures, synchronization, etc., may be obtained. Arrangements for the telemetering of various quantities may be incorporated in control systems.

In recognition of this ever-widening field of application for telemetering equipment, the report has been prepared in such form and terminology as to make it readily useful to engineers in any branch of industry likely to be concerned with problems of remote measurement and control. Extensive tabulations giving comparative data are designed to enable a prospective or existing user of telemetering or supervisory-control equipment quickly to determine the type of apparatus best suited to his requirements.

All known commercial sources of telemetering and supervisory-control apparatus in the United States have been canvassed, and every effort made to present a complete picture of the instruments and systems available for the purpose. Material for this special publication was prepared by a joint sub-committee of the AIEE committee on automatic stations and the AIEE committee on instruments and measurements. The work is based upon a report compiled by an AIEE subcommittee in 1932, although the coverage has been extended and of course the information has been brought down to date.

The special publication "Telemetering, Supervisory Control, and Associated Circuits" is a 28-page 8½ x 11-inch pamphlet attractively printed on durable paper. Copies may be secured from AIEE headquarters, 33 West 39th Street, New York, N.Y.; price is 40 cents per copy to members (80 cents to non members) subject to a 20 per cent discount for quantities of 10 or more mailed at one time to one address. Remittances, payable in New York exchange, should accompany orders.

BIBLIOGRAPHY OF RELAY LITERATURE PUBLISHED

A "Bibliography of Relay Literature, 1927-1939," has just been published by the American Institute of Electrical Engineers. This special publication was sponsored by the AIEE committee on protective devices and was prepared by a working group of the relay subcommittee. This subcommittee reviewed available indexes and from these compiled this list of significant articles dealing with protective relaying and also with closely related subjects, including all such material published in AIEE *Transactions* or *Electrical Engineering* from January 1927 to December, 1939, and most of that in the principal technical publications of the world from January, 1932 to December 1939.

The 450 odd annotated reference items are divided into the following subject sections, and in each section entries are consecutively numbered and listed alphabetically by years: Line Protection (Distance, Pilot Wire and Carrier; Current, Ground Faults, General), Bus Protection, Apparatus Protection, Distribution and Network Protection, Service Restoration, General and Miscellaneous Relaying, Testing and Analyzing, System Stability, Methods of Calculation, and Instrument Transformers and Other Auxiliary Devices.

The "Bibliography of Relay Literature, 1927-1939" is a 16-page, 8½ by 11-inch pamphlet, attractively printed on substantial paper; it is available at AIEE headquarters, 33 West 39th Street, New York, N.Y., at 25 cents per copy to members of the Institute (50 cents per copy to non-members); price is subject to 20 per cent discount in either instance for quantities of 10 or more to one address at one time. Remittances, payable in New York exchange, should accompany orders.

PRELIMINARY NOTICE

of Applications for Admission and for Transfer

July 25th, 1941

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described at the next meeting.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science or engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

DUNCAN—JOHN MARTIN, of 153 Graham St. So., Hamilton, Ont. Born at Brampton, Ont., Oct. 18th, 1909; Educ.: B.A.Sc., Univ. of Toronto, 1935; 1935-37, gen. work, producing tubes for receiving sets, and 1937-38, supervisor of two units producing various types of tubes—respons. for mech. operation of equipment, etc., Radio Valve Co. of Canada; 1939-40, supervised filling of cylinders for the transportation of dissolved acetylene, also gen. work in oxygen plant at Montreal, and at present, plant manager, oxygen producing plant, Canadian Liquid Air Co. Ltd., Hamilton, Ont.

References: A. R. Hannaford, N. H. A. Eager, F. W. Paulin, A. W. Sinnamon, W. L. McFaul.

ESTABROOK—JAMES PIERCE, of Riverbend, Que. Born at Wallaceburg, Ont., July 31st, 1916; Educ.: B.Sc. (Chem.), Queen's Univ., 1939; 1939 to date, junior chemist, Price Bros. & Co. Ltd., Riverbend, Que.

References: N. F. McCaghey, S. J. Fisher, J. Frisch, K. A. Brebner, A. Jackson.

ESTABROOKS—DONALD STEEVES, of Riverbend, Que. Born at Woodstock, N.B., July 21st, 1912; Educ.: B.Eng. (C.E.), N.S. Tech. Coll., 1938; 1932-35, oiler, SS. Fort St. George; 1935-38 (summers), deputy land surveyer, asst. office engr. and instr'man., on Geol. Surveys of Canada, instr'man. on highway constrn.; 1938-39, inspr. on constrn. for C. A. Fowler, M.E.I.C.; 1939-40, i/c of magnetometer party doing geophysical exploration work in oil fields, Socony-Vaccum Oil Co., Venezuela; At present, records engr., Riverbend paper mill, for Price Bros. & Co. Ltd.

Employment Service Bureau

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.

SITUATIONS VACANT

GRADUATE ENGINEER with at least two years practical experience in a tool room to act as an instructor in the Apprentice School of a large industrial concern. Apply Box No. 2344-V.

MECHANICAL DESIGNING DRAUGHTSMAN with experience for permanent position with firm engaged in war work. Apply Box No. 2375-V.

ARCHITECTURAL DRAUGHTSMEN required immediately by large industrial concern for their Montreal office. Apply Box No. 2376-V.

FIELD ENGINEER, aggressive, capable, preferably one with a university degree in chemical engineering and who has some knowledge of boiler plant operation to sell and service boiler feed water treatment chemicals. Candidate must possess personality conducive to good salesmanship having good educational and family background. Remuneration will be $1,500.00 a year and travelling expenses when away from Headquarters. Write fully education, experience and present occupation, giving references. Personal interview will be arranged only by written application to Box No. 2394-V.

JUNIOR CHEMICAL AND METALLURGICAL ENGINEER for plant installation and operation work. Apply Box No. 2400-V.

STRUCTURAL OR GENERAL DRAUGHTSMAN for plant extension work. Apply Box No. 2401-V.

JUNIOR MECHANICAL GRADUATE with about one to five years experience for work in South America. Apply Box No. 2402-V.

MUNICIPAL ENGINEER, conversant with road construction, paving, construction and maintenance of sewers and water services, for a town in Ontario. Salary from $2,400 to $3,000 per year according to experience and qualifications. Send applications with full particulars to Box No. 2403-V.

CIVIL SERVICE OF CANADA

Engineering Division of the Penitentiary Branch of the Department of Justice at a salary of $2,220 per annum. Although only a temporary appointment can be made at present to this position, this examination will qualify for a permanent appointment. In the case of permanent appointment the initial salary of $2,220 may be increased upon recommendation for meritorious service and increased usefulness at the rate of $120 per annum until a maximum of $2,700 has been reached.

Duties: To assist in designing and to prepare plans and estimates of mechanical equipment, power plant, heating and ventilation systems and electric wiring installations; and to perform other related work as required.

Qualifications Required: Education equivalent to high school graduation; either graduation in mechanical engineering from a school of applied science of recognized standing with three years of experience in mechanical engineering work, one year of which shall have been in a position of professional responsibility; or, five years of mechanical engineering experience, one year of which shall have been in a position of professional responsibility; knowledge of building construction and power plant design.

While no definite age limit has been set for this competition, age may be a determining factor in making a selection. Appointment, however, will be subject to the provisions of Order-in-Council P.C. 4759 of June 27, 1941.

Nature of examination: A rating on education and experience will be given from the sworn statements, supporting documents and other evidence submitted by applicants on and with their application forms. Candidates are requested to furnish full particulars concerning their technical training and experience especially as they bear on the qualifications for and the duties of this position. An oral examination may be given if necessary in the opinion of the Commission. No examination fee is required.

An eligible list valid for a period of one year may be established.

Time Limit: Application forms properly filled in must be filed with the Civil Service Commission, Ottawa, NOT LATER THAN August 30, 1941.

Application forms are obtainable at all City Post Offices, the Post Offices in the larger towns, the offices of the Employment Service of Canada, or from the Civil Service Commission, Ottawa, Canada.

SITUATIONS WANTED

ELECTRICAL ENGINEER, B.SC. in electrical engineering, age 43, married, available on two weeks notice. Fifteen years experience in electrical work. Including electrical installations of all kinds in hydro-electric plants and sub-stations. Maintenance and operation of hydro-electric plants. Electrical maintenance and installations in pulp and paper mill. Considerable experience on relays and meters. At present employed, but desires change. Apply Box No. 636-W.

GRADUATE ELECTRICAL ENGINEER, University of Toronto, five years experience drafting and design in connection with electrical instruments and small motors. Also experienced in design of small jigs and fixtures and general machine design. Desires permanent position. Apply to Box No. 1486-W.

GRADUATE CIVIL ENGINEER, M.E.I.C., 15 years engineering on this continent and five years overseas. Experienced in design and construction of dams, hydro-electric and industrial plants. Field engineer for construction on dams and transmission lines, considerable experience in concrete work. Desires position preferably as field engineer or construction superintendent. Apply Box No. 1527-W.

ELECTRICAL ENGINEER, Age 32 with the following experience—Eight years field work in general construction, supervision, estimating and ordering materials. At present employed in general construction but wants to enter the electrical field. Apply Box No. 1992-W.

MECHANICAL ENGINEER, JR.E.I.C., and member of the American Society for Metals. Since graduation (Toronto '33) has specialized in the metallurgy, processing, and heat treatment of steel, aluminum and aluminum alloys. Also five years successful sales experience and is thoroughly familiar with materials specifications of all types. Now thirty years of age, available at once, and can furnish the best of references. Desires permanent position. Apply Box No. 2365-W.

GOLD OUTPUT INCREASING IN NORTHWEST TERRITORIES

New gold is being produced in increasing quantities in the Northwest Territories, reports the Department of Mines and Resources. Preliminary figures place the output for the first half of 1941 at 31,001 ounces as compared with 24,799 ounces in the first six months of 1940, an increase of 6,202 ounces.

Four mines are now producing—the Con, Negus, and Rycon in the Yellowknife area, and the Slave Lake Gold Mines property on Outpost Island.

In response to the war-time demand for gold, the capacity of the mill at the Con mine is being increased from 100 to 350 tons daily. Development work is going ahead at other properties, which are expected to enter production shortly. Ptarmigan Mines Limited is installing a 100-ton per day mill, Thompson Lundmark Gold Mines Limited is putting in a 150-ton mill, and a 25-ton mill is being installed at the Giant Yellowknife Gold Mines Limited property.

Industrial News

Industrial development — new products — changes in personnel — special events — trade literature

AUTOMATIC CONTROLS AND RECORDING INSTRUMENTS

Catalogue No. 7, 48 pp. issued by Minneapolis-Honeywell Regulator Co. Ltd., Toronto, Ont., provides in condensed form, catalogue data, specifications, and illustrations of the Minneapolis-Honeywell line of controls and instruments with a section devoted to the Company's "Brown Industrial Instruments."

STOKERS

Detroit Stoker Co. of Canada Ltd., Windsor, Ont., have issued a catalogue, No. 840, of 32 pages and cover under the title "Detroit RotoStoker" which is thoroughly illustrated with sectional drawings, unit photographs, installation views and blue print reproductions, and describes the principle of the "RotoStoker" and emphasizes its main features. Operating charts, comments from users and details of installed capacities are also included.

FANS, BLOWERS AND EXHAUSTERS

A 6-page folder, Form CB-2629, entitled "When Heat Gets 'Em Down Comfort Cooling with Fresh Air Builds 'Em Up!" published by Canadian General Electric Co. Ltd., gives an illustrated description featuring the application to modern industry of various types of Canadian Sirocco fans, blowers, exhausters and ventilators, distributed by Canadian General Electric Co. Ltd.

FEED WATER CHEMISTRY

The fundamental reactions involved in water softening are given in a 12-page booklet No. 3006 recently issued by Cochrane Corp., Philadelphia, Pa. A section deals with the "Ionic Analysis" and with "Equivalents per Million," which methods of interpreting water analysis are coming into more general use, according to the Company. Formulae and molecular and equivalent weights of substances frequently appearing in the chemistry of water softening are also included.

METALLIZING

"The History, Purpose and Practice of Metallizing (Metal Spraying)" is the title of a 52-page book recently issued by the Metallizing Co. of America Inc., Chicago, Ill. As its title indicates, this book is a comprehensive treatment of the subject of metal spraying and after reviewing the history, purpose and practice, and indicating in concise forms with illustrations the equipment required to carry on the work of metallizing, the book offers well illustrated descriptions of the application of this process to a wide variety of industrial works.

LABORATORY FILTER

Sparkler Manufacturing Co., Chicago, Ill., have issued a folder describing and illustrating the Sparkler horizontal plate laboratory filter which, the manufacturers state, is a compact, practical unit that can do any laboratory filtering job without extensive preparations or experiments. Available in iron, aluminum, bronze, Monel and stainless steel, the Sparkler unit is designed to handle viscous materials as well as aqueous solutions with any type of filter aid.

MONEL STORAGE HEATERS

An 8-page bulletin No. 40M, entitled "Whitlock-Darling Type K Monel Storage Heaters" has been issued by Darling Brothers Ltd., Montreal, Que. These heaters are of the steam actuated type and consist of a Monel storage shell in which is installed a removable, copper tube, heating section. The bulletin contains sectional drawings of construction and installation details and a table of "Hot Water Fixture Capacities for Various Types of Buildings," as well as specifications and detailed descriptions of the horizontal and vertical heaters.

SINGLE-PHASE WATTHOUR METERS

Bulletin No. 49, issued by Ferranti Electrical Ltd., Toronto, Ont., contains 64 pages of detailed instructions for the use of the following types of single-phase alternating current watthour meters: FR, FRA, FRS, FCc, FDb, FD and C, and the type "C" polyphase watthour meters. The booklet includes full details regarding testing and servicing of new and used meters with illustrated instructions covering adjustments. The Ferranti meter test board is also illustrated and fully described and a considerable amount of other useful reference information is included.

SMALL GASOLINE ENGINES AND PUMPS

D. R. Clarke Engine Co. Ltd., Toronto, Ont., have published an 8-page booklet entitled "Clarke Engine Products," which features the following products: 1¼ h.p. utility gasoline engine, weighing 19 lbs.; centrifugal, primeless, self-draining water pump, weighing 30 lbs., with a 4000 to 5000 gals. per hr. capacity; air compressor and paint spray unit weighing 37 lbs.; 1¼ marine utility inboard type engine, weighing 25 lbs.; and electric generating units from 6 to 110 volts up to 400 watts.

STEAM SAMPLE DEGASIFIER

Publication No. 3020 of the Cochrane Corporation, Philadelphia, Pa., entitled "Cochrane Steam Sample Degasifier," describes this device for condensing a steam sample, separating non-condensible gases for analysis, and degasifying the condensed sample for conductivity tests for determination of carryover.

TRANSMISSION MOTORIZING UNIT FOR MACHINE TOOLS

Dominion Auto-Drive, Ltd., Walkerville, Ont., gives, in a 2-page leaflet, general details and specifications of the "Auto-Drive," and individual transmission motorized unit for machine tools, intended primarily to modernize valuable machinery and eliminate overhead line shafts.

WELDING MACHINES & SUPPLIES

G. D. Peters & Co. of Canada Ltd., Montreal, Que., have issued a comprehensive 128-page catalogue, No. 80, which contains detailed descriptions and illustrations covering complete equipment for the modern arc and gas welding shop.

W. W. Brumby

APPOINTED ASSISTANT PLANT ENGINEER

The English Electric Company of Canada Limited have announced the appointment of W. W. Brumby as Assistant Plant Engineer. Mr. Brumby is a graduate from Technical College and Auckland University in New Zealand, also the City and Guilds of London Institute. He was for several years with the National Electric and Engineering Company of New Zealand, and a number of years with the Auckland Electric Power Board at Auckland. In 1929 he joined the staff of Canadian General Electric Company Limited.

His first job at St. Catharines will be the laying out of the new test department in the company's current plant extension.

APPOINTED TRANSFORMER ENGINEER

M. B. Mallett, who has been appointed Transformer Engineer in the Engineering Dept. of The English Electric Company of Canada Ltd., received a degree in electrical engineering from the Rensselaer Polytechnic Institute in 1924, and, following the completion of the General Electric Test Course at their Pittsfield works, he was with the Pittsfield Transformer Engineering Dept. until joining the "English Electric" staff in March of this year.

His particular specialty will be larger size power transformers, and it is interesting to note that he designed the first 55,000 kv.a. 287 kv. power transformer units for the Boulder Dam development.

M. B. Mallett

NOTES ON THE ANALYSIS AND DESIGN OF RECTANGULAR REINFORCED CONCRETE SLABS SUPPORTED ON FOUR SIDES

S. D. LASH, PH.D., M.E.I.C.
Acting Secretary, National Building Code Project, National Research Council, Ottawa, Ont.

SUMMARY—In the first part of the paper the mathematical analysis of rectangular plates is considered and values of bending moments and shearing forces for various conditions of edge restraint are given. Considerable use has been made of the results obtained by Westergaard, Inglis, Lévy, Timoshenko, and others, and these are compared with the results given by some of the more widely used empirical formulas. In the second part of the paper the above analysis is used to determine moment coefficients for reinforced concrete slabs supported on four edges and reinforced in two directions. Consideration is given to the moments resulting from various arrangements of loads upon a group of panels; and approximate coefficients of maximum moments are derived. These coefficients are then modified to make allowance for plastic flow. It is shown that these modified coefficients are closely represented by linear equations in terms of the ratio of length to breadth of slab. In addition, the intensity of loading on the supporting beams is considered and it is shown that for practical purposes this may be assumed to be uniformly distributed. The recommended design coefficients are included in Part 3 of the National Building Code.

The National Building Code is a model building code, for use by Canadian municipalities, prepared under the joint sponsorship of the National Research Council and the Department of Finance of Canada.

PART I—MATHEMATICAL INVESTIGATIONS OF STRESSES IN RECTANGULAR PLATES

(a) INTRODUCTION

The majority of reinforced concrete slabs, apart from flat slabs, are designed in the same way as beams. It is assumed that they are supported along two opposite edges only, and the effects of curvature at right angles to the direction of the span are not considered. In practice, however, many slabs are supported along four edges and it is obvious that in such circumstances a slab will assume a saucer-shaped deformation and that any load placed on it will be transferred to all of the supporting beams. From the early days of reinforced concrete construction attempts have been made to estimate the manner in which the load will be divided in the two principal directions of bending and many empirical formulas have been proposed. The problem is one in which mathematicians have long been interested and in the first part of this paper it is proposed to present briefly some of the more important results obtained by mathematical analysis. (For a comprehensive treatise on this subject the reader is referred to the recently published book by Timoshenko on the "Theory of Plates and Shells."*)

Problems connected with the bending and vibration of thin plates subject to transverse loads have been considered by mathematicians since the time when Euler investigated the modes of vibration of a bell in 1766. The general equation is due to Lagrange (1811) and the solution for a rectangular plate freely supported at its edges, as generally presented, is due to Poisson (1828) and Kirchoff (1850). A complete solution of the more complex problem of a rectangular plate clamped at its edges was published by Love in 1928; approximate solutions of considerable accuracy were made by Hencky in 1913 and by Inglis in 1925.

In an outstanding paper by Westergaard and Slater[2] the various mathematical results were discussed and simple empirical formulas proposed to represent them.

Reference should also be made to the "elastic web method" due to Marcus (1925); this is an approximate method of solution in which the plate is represented by a net of elastic wires loaded at their points of intersection. (A description in English of the Marcus method has been given by Wise[1].)

The mathematical approach to the problem has been made possible by dividing plates into three main types: thin plates such as membranes in which the deflections may be large but bending stresses are small; thin plates in which the deflections are small and bending stresses are large; and thick plates in which deflections are small but in which the deformation due to shear cannot, in general, be neglected. The first case is analogous to the bending of thin rods, the second to the approximate theory of the bending of beams, and the third to the more rigorous analysis of beams by the method of St-Venant. For engineering purposes beams and slabs are considered to belong to the second class, i.e., deflections are considered small and the influence of shear upon bending stress is neglected. In the case of plates or slabs Love[1] describes the results as "the approximate solution for a thin plate in which deflections are assumed to be small." Westergaard[2] refers to such a plate as "a moderately thick plate."

Prescott[3] emphasizes that the limits of application of the usual theory of bending of plates are more serious than are the limitations of the analogous theories for beams. In each case it is assumed that there is a neutral plane which is not stretched or shortened and the slope is small at all points. It is not possible, however, to bend a thin isotropic plate without deforming some part of the middle surface whereas the neutral axis of a beam may remain unstretched whatever the curvature. With the above rather important reservation, the assumptions involved in applying the usual theory of plates to reinforced concrete slabs are the same as those implied in applying the theory of simple bending to reinforced concrete beams. It is not necessary to discuss these here except perhaps to point out that their validity is being increasingly questioned. There are many who maintain that stress analysis, based upon the assumption of elastic conditions, does not give an accurate indication of the ultimate load carrying capacity of reinforced concrete beams or columns (see, for example, the paper by Hajnal-Konyi and ensuing discussion in *Concrete and Construction Engineering*, January to October, 1937). The objections to elastic analysis of beams apply also in the case of slabs, but to a greater extent, since "plate action" depends upon the existence of torsional moments, without which the slab will tend to behave as a membrane, or as if it were com-

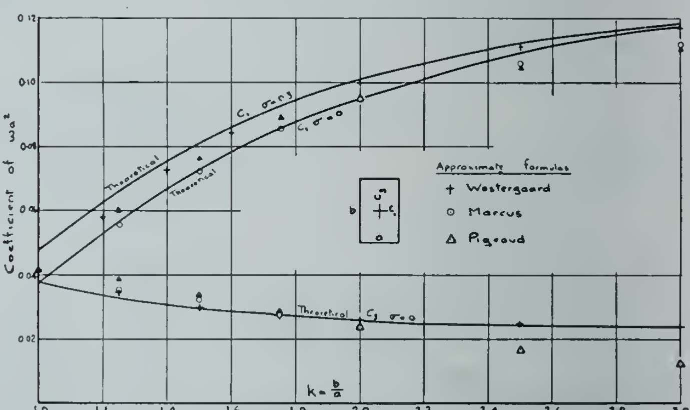

Fig. 1—Rectangular plate freely supported at its edges. Coefficients of maximum bending moments.

*Timoshenko's most valuable monograph had not been published when the manuscript of this paper was written.

posed of a number of independent strips. Gehler[4] states that this is the case when the concrete in a slab has cracked, a theory which is said to have received support from the results of numerous tests carried out for the German Reinforced Concrete Committee from 1915 to 1926 at Stuttgart and from 1927 to 1930 at Dresden. Assuming, however, that the design of beams is based upon the theory of simple bending, it appears reasonable that the design of slabs should be based upon the approximate theory for thin plates. Some modification of the results may be made to make allowance for the redistribution of bending moments due to plastic flow of the concrete.

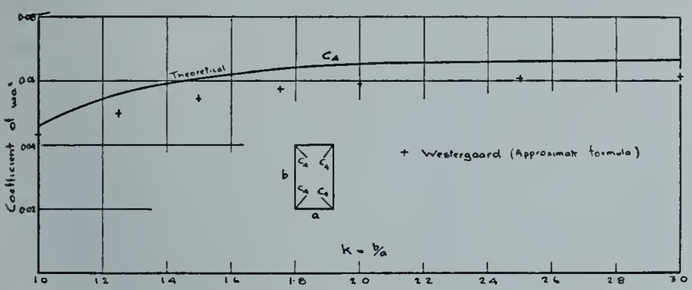

Fig. 2—Rectangular plate freely supported at its edges. Coefficients of maximum torsional moments.

(b) GENERAL EQUATIONS FOR THIN PLATES

Notation

- a Length of side parallel to OX (usually the short side)
- b Length of side parallel to OY (usually the long side)
- $k = \frac{b}{a}$
- w Load per square unit
- W Total load $= wab$
- V_a Shear per unit length along side a
- V_b Shear per unit length along side b
- $m = \frac{a}{b}$
- M_x Bending moment per unit length in a direction perpendicular to OX
- M_y Bending moment per unit length in a direction perpendicular to OY
- M_{xy} Torsional moment
- σ Poisson's ratio
- $E' = \frac{E}{1-\sigma^2}$
- t Thickness
- z Deflection
- q Ratio of live load to dead load

The relation between load and deflection is given by the following equation due to Lagrange.

$$w = \frac{Et^3}{12\,(1-\sigma^2)} \triangle^4 z$$

$$= \frac{E't^3}{12} \triangle^4 z \quad \text{- - - - - - - - - - - - -} \quad (1)$$

where $\triangle^2$ is the operator $\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$

[This is analogous to the equation for simple bending

$$w = El \;\frac{d^4y}{dx^4}\Big]$$

From equation (1) the following equations for bending moments may be deduced:

$$M_x = -E't\left(\frac{\partial^2 z}{\partial x^2} + \sigma\frac{\partial^2 z}{\partial y^2}\right) \quad \text{- - - - - - - - - -} \quad (2)$$

$$M_y = -E't\left(\frac{\partial^2 z}{\partial y^2} + \sigma\frac{\partial^2 z}{\partial x^2}\right) \quad \text{- - - - - - - - - -} \quad (3)$$

In addition, any element will be subjected to torsional moments represented by:

$$M_{xy} = \frac{E\,t}{1+\sigma}\frac{\partial^2 z}{\partial x \partial y} \quad \text{- - - - - - - - - - - -} \quad (4)$$

The shearing forces along the boundaries of the plate will be given by:

$$V_a = -E'\frac{\partial}{\partial y}\triangle^2 z \quad \text{- - - - - - - - - - - -} \quad (5)$$

$$V_b = -E'\frac{\partial}{\partial x}\triangle^2 z \quad \text{- - - - - - - - - - - -} \quad (6)$$

(c) BOUNDARY CONDITIONS

The equations given above apply to any thin plate but only in the simplest cases can they be solved when the correct boundary conditions are substituted. The boundary conditions comprise three geometrical conditions corresponding to the three co-ordinate axes, together with three stress conditions corresponding to bending moment, torsional moment and shear. It can be shown, however, that it is not possible arbitrarily to specify all three stress conditions. For example, in the case of a rectangular plate freely supported on all edges, if the bending moments and the deflection at the edges are assumed to be zero then it can be shown that there must be either torsional moments applied at the edges, or concentrated downward reactions applied at the corners. Much discussion has centred around this problem; for a general consideration of it reference should be made to Love (Fourth Ed. p. 458) and interesting comments on the particular case of a rectangular plate have been made by Pigeaud[5].

Rectangular Plate Freely Supported at its Edges

(a) BENDING MOMENTS

The deflection of a rectangular plate carrying a uniform load and freely supported at its edges is given by the equation:

$$z = \frac{16\;a^4b^4w}{\pi^6\;E\;I}\sum_{m=1,3,etc.}^{\infty}\;\sum_{n=1,3,etc.}^{\infty}\frac{\sin\frac{m\pi x}{a}\;\sin\frac{n\pi y}{b}}{(m^2a^2+n^2b^2)^2} \quad (7)$$

from which the bending moments M_x and M_y may be determined using equations (2) and (3). Considering first

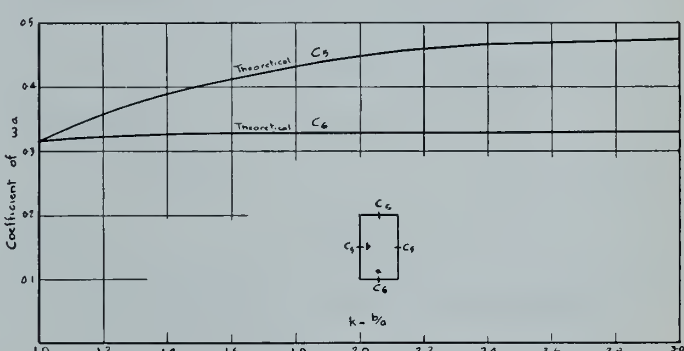

Fig. 3—Rectangular plate freely supported at its edges. Coefficients of shearing forces at the edges of the plate.

the moments in the shorter span. With the notation adopted and assuming "b" to be greater than "a" this will be M_y and can be written in the form

$$M_y = C_1\,wa^2 \quad \text{- - - - - - - - - - - - - -} \quad (8)$$

Figure 1 shows the relation between C_1 and $k = \frac{b}{a}$ for values of k varying from one to three. Two theoretical curves are shown corresponding to values of Poisson's ratio (σ) of 0.3 and zero. Most experiments on reinforced concrete slabs have tended to give results nearer to the lower curve than the upper, and consequently most practical design methods are based upon the assumption that σ is equal to zero.

This also has the advantage of simplifying the theoretical computations which are apt to be long and tedious.

Results obtained from a number of approximate formulas are also shown in Fig. 1. Very many such formulas have been proposed and used, those shown being amongst the most widely accepted. The approximate equation by Marcus appears in the German Regulations for Reinforced Concrete.

The formulas are as follows:

(a) Westergaard,

$$C_1 = \frac{k^3}{8(2+k^3)} \quad \text{- - - - - - - - - - - -} \quad (9)$$

(b) Marcus,

$$C_1 = \left(1 - \frac{5\,k^2}{6\,(1+k^4)}\right) \frac{k^4}{8\,(1+k^4)} \quad \text{- - - - - - -} \quad (10)$$

(c) Pigeaud,

$$C_1 = \frac{k^4}{8\,(k^4+k^2+1)} \quad \text{- - - - - - - - - - -} \quad (11)$$

Coefficients of the maximum moment in the longer span are also shown in Fig. 1. This moment may be written:

$$M_x = C_2\, w\, b^2 \quad \text{- - - - - - - - - - - - -} \quad (12)$$

but from practical considerations it is more convenient to express it in the form:

$$M_x = C_3\, w\, a^2 \quad \text{- - - - - - - - - - - - - -} \quad (13)$$

in which case:

$$C_3 = k^2 C_2 \quad \text{- - - - - - - - - - - - - - -} \quad (14)$$

It has been pointed out by Westergaard and others that the maximum moment in the long span does not occur at the centre except when the plate is nearly square. This makes it difficult to determine the maximum values. The figures plotted in Fig. 1 are due to Westergaard and are based on the assumption that σ is equal to zero. For comparison with the curve, points determined from the following formulas are shown:

(a) Westergaard,

$$C_3 = \frac{k^2+1}{48\,k^2} \quad \text{- - - - - - - - - - - - - -} \quad (15)$$

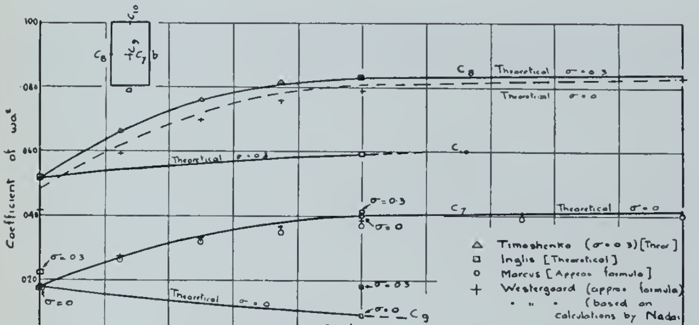

Fig. 4—Rectangular plate fixed at its edges. Coefficients of maximum positive and negative bending moments.

(b) Marcus,

$$C_3 = \left(1 - \frac{5\,k^2}{6\,(1+k^4)}\right) \frac{k^2}{8\,(1+k^4)} \quad \text{- - - - -} \quad (16)$$

(c) Pigeaud,

$$C_3 = \frac{k^2}{8\,(k^4+k^2+1)} \quad \text{- - - - - - - - - -} \quad (17)$$

Torsional moments are unimportant in isotropic plates but must be considered in reinforced concrete slabs. The maximum torsional moment occurs at the corner and is directed perpendicular to the line bisecting the angle between the edges, i.e., at 45 deg. to XY. Figure 2 shows the relation between this moment and k where M_{xy} is expressed in the form:

$$M_{xy} = C_4\, w\, a^2 \quad \text{- - - - - - - - - - - - -} \quad (18)$$

Poisson's ratio is assumed to be zero. Figure 2 also shows points obtained from Westergaard's formula:

$$C_4 = \frac{k^3}{8\,(2k^3+1)} \quad \text{- - - - - - - - - - - -} \quad (19)$$

(b) SHEARING FORCES AT THE EDGE OF THE PLATE

Shearing forces are usually unimportant in reinforced concrete slabs, but since they are equal to the reactions exerted by the beams their distribution is of interest in determining the maximum bending moments in the latter.

An examination of equations (5) and (6) shows that the shearing forces must be zero at the corners increasing to a maximum at mid-span of the supporting beams. Investigation of $\frac{\partial V_a}{\partial y}$ and $\frac{\partial V_b}{\partial y}$ shows that the shear curve has an infinite slope at the corners. Thus the load distribution is similar in general shape to a semi-ellipse. The semi-minor axis of this pseudo-ellipse (i.e., the maximum load on each span) may be determined by approximate methods. Accurate values, however, may be found from equations (5) and (6) and it appears to be unnecessary to use approximations. In Fig. 3 the maximum shear per unit of length for a simply supported span is shown in terms of the load on the shorter span:

$$V_b = C_5\, w\, a \quad \text{- - - - - - - - - - - - - -} \quad (20)$$

$$V_a = C_6\, w\, a \quad \text{- - - - - - - - - - - - - -} \quad (21)$$

It will be noticed that the maximum shear occurs on the longer edge and that C_6 and the loading on the shorter edge is nearly constant throughout the range considered.

Rectangular Plate Fixed at its Edges

(a) BENDING MOMENTS

A valuable addition to the literature on rectangular plates was made by Inglis who in 1925 published an elegant solution of the problem of a rectangular plate clamped at its edges [(7)]. In this method the condition of complete edge restraint was approached by successive approximations but since complete restraint was never reached the method cannot strictly be called an exact solution. Even with a first approximation, however, the errors were shown to be small; with a second approximation they may be considered negligible. Inglis investigated the square plate, and the rectangular plate in which k is equal to two.

A more extensive range of values has been given by Timoshenko [(8)]. Both Inglis and Timoshenko assumed Poisson's ratio to be 0.3. Figure 4 shows curves of the maximum positive and negative moments. The latter occurs at the middle of the longer edge. The moments are expressed by the equations:

For $x=a/2,\ y=b/2,\ M_y = C_7\, w\, a^2$ - - - - - (22)

For $x=0,\ y=b/2,\ M_y = -C_8\, w\, a^2$ - - - - - (23)

Where values of M_x and M_y at any particular point are known for $\sigma = 0.3$ the values corresponding to $\sigma = 0$ may be determined from the equation:

$$M'_x = \frac{M_x - \sigma M_y}{1-\sigma^2} \quad \text{- - - - - - - - - - -} \quad (24)$$

From the values of M_x and M_y given by Inglis it can be shown that C_8 is not appreciably altered by the value chosen for σ. C_7 is reduced somewhat if $\sigma = 0$, particularly in the case of a square plate. Two points calculated from Inglis' figures are shown in Fig. 4, and for comparison with them a curve of values given by Westergaard is indicated by a dotted line. The latter are based on results given by Nadai. Hencky, by an approximate method cited by Love (Fourth Ed. p. 494), obtained values in fair agreement with those of Timoshenko and Inglis. In Fig. 4 coefficients derived from the following approximate formulas are shown:

Westergaard

$$C_7 = \frac{k^4}{8\,(3k^4+4)} \quad \text{- - - - - - - - - - - -} \quad (25)$$

$$C_8 = \frac{k^4}{12\,(k^4+1)} \quad \text{- - - - - - - - - - - - - (26)}$$

Marcus

$$C_7 = \left(1-\frac{5}{18}\,\frac{k^2}{(1+k^4)}\right)\,\frac{k^4}{24\,(1+k^4)} \quad \text{- - - - (27)}$$

Two other curves are shown in Fig. 4. These refer to the moments in the direction of the longer span and are and expressed in terms of $w\,a^2$ using coefficients C_9 and C_{10}.

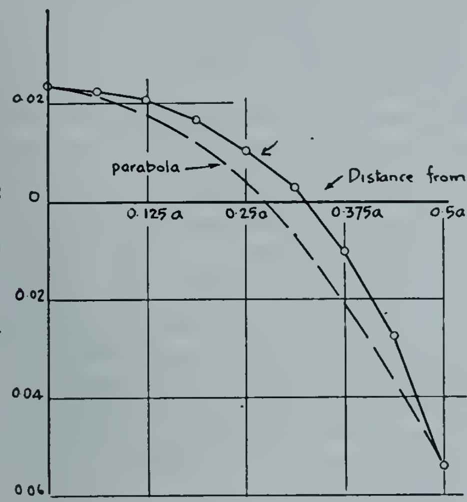

Fig. 5(a)—Square plate fixed at its edges. Distribution of bending moments along centre lines.

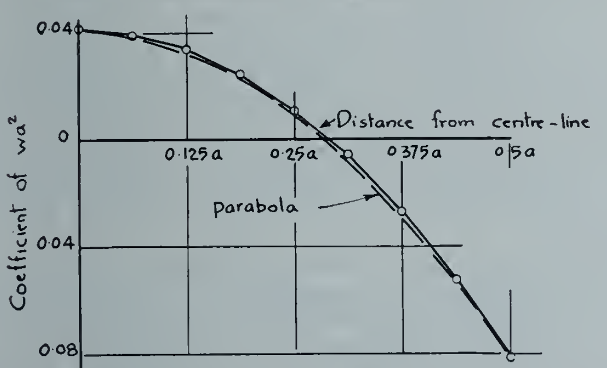

Fig. 5(b)—Rectangular plate (K=2) fixed at its edges. Distribution of bending moments along the centre line of the short span.

For $x=a/2,\ y=b/2 \qquad M_x=C_9\,w\,a^2$ - - - - (28)

For $x=a/2,\ y=0 \qquad M_x=-C_{10}\,w\,a^2$ - - - (29)

It should be noted that in all cases the coefficients change very slowly for values of k greater than two.

From figures given by Inglis it is possible to examine the distribution of moment along the centre line of the plate. For the long span, as in the case of the simply supported plate, the maximum positive moment does not occur at the centre except for nearly square plates. When k is equal to two the moment at the quarter point is 13.5 per cent greater than the mid-span moment. In the case of the short span the curve showing the distribution of moment has the general shape of a parabola though, as is shown in Fig. 5, there is an appreciable difference from a true parabola when the plate is square.

(b) SHEARING FORCES AT THE EDGES OF THE PLATE

Pigeaud implies that shearing forces for a plate with fixed edges are similar to those for a simply supported plate (Résistance des Matériaux, p. 918). Inglis, however, has determined the distribution and the results do not support this view. Figures 6a and 6b show the distribution of pressure along the edges of a square plate and a rectangular plate respectively. In the case of a square plate and for the short side of a rectangular plate the load curve is more nearly parabolic than elliptical in general shape. Graphical integration of the load curve in the case of a square plate shows the maximum bending moment in the beam to be $0.168\ W'a$, W' being the total load on the beam $(W'=\frac{wa^2}{4})$. This compares with $0.1435\ W'a$ assuming an elliptical distribution of load and $0.1667\ W'a$ assuming a triangular distribution with a maximum value of $0.5\ wa$. In the case of the rectangular plate ($k=2$), the maximum moment determined by graphical integration is $0.225\ wa^3$. Using Pigeaud's coefficient of the maximum load and assuming an elliptical distribution, the maximum moment is $0.204\ wa^3$ and assuming a trapezoidal distribution of load with a maximum of $0.5\ wa$ the maximum moment is $0.229\ wa^3$.

Rectangular Plate Fixed at Some Edges and Freely Supported at the Others

If it is assumed that any edge of a rectangular plate may be either freely supported or fixed, and if k is always greater than unity, there are nine possible conditions of restraint for symmetrical loading. These are shown diagrammatically in Fig. 7 and for brevity will be referred to by the numbers given in the figure. Cases 1 and 6 have already been considered. Cases where the restraints are unsymmetrical on opposite sides are not easily treated mathematically. The case where two parallel sides are fixed and two are freely supported (3a and 3b) was considered by Lévy[9], and Westergaard has computed bending moments by a method based upon Lévy's analysis. These results are presented in Figs. 8 and 9. It is assumed that σ is equal to zero and curves are given for the coefficients in the following equations:

Case 3a (Long sides fixed)

For $x=a/2,\ y=b/2 \quad M_y=C_{11}\,w\,a^2$ - - - - (30)

For $x=0,\ y=b/2 \quad M_y=-C_{12}\,w\,a^2$ - - - - (31)

For $x=a/2 \quad M_{x\,(max.)}=C_{13}\,w\,a^2$ - - - (32)

As in the case of the freely supported slab the maximum moment in the long span does not occur at mid-span. Values of coefficients calculated from approximate formulas by Marcus and Westergaard are also shown. The formulas are as follows:

Marcus

$$C_{11} = \left(1-\frac{25}{18}\,\frac{k^2}{(1+5k^4)}\right)\,\frac{5k^4}{24\,(1+5k^4)} \quad \text{- - - (33)}$$

$$C_{13} = \left(1-\frac{5}{6}\,\frac{k^2}{(1+5k^4)}\right)\,\frac{k^2}{8\,(1+5k^4)} \quad \text{- - - (34)}$$

Westergaard

$$C_{11} = \frac{k^4}{24\,(k^4+0.4)} \quad \text{- - - - - - - - - - - (35)}$$

$$C_{12} = \frac{k^4}{12\,(k^4+0.2)} \quad \text{- - - - - - - - - - - (36)}$$

$$C_{13} = \frac{k^2+0.3}{80k^2} \quad \text{- - - - - - - - - - - - (37)}$$

Case 3b (Short sides fixed)

For $x=a/2,\ y=b/2 \quad M_y=C_{14}\,w\,a^2$ - - - - (38)

For $x=a/2 \quad M_{x(max.)}=C_{15}\,w\,a^2$

For $x=a/2,\ y=0 \quad M_x=-C_{16}\,w\,a^2$- - - - (39)

Part II—Derivation of Design Rules for a Group of Approximately Equal Rectangular Slabs Carrying Uniform Loads

INTRODUCTION

When a rectangular slab forms part of a structure, and there are other slabs of approximately the same size continuous at one or more of its edges, an infinite number of combinations of conditions of restraint may occur. In order to arrive at practical rules for design it is necessary to establish a comparatively small number of arbitrary conditions which may be considered to represent practical conditions without serious errors. In the case of one-way slabs the following moment coefficients are widely used:

Positive moment at or near mid span,	
End spans....................	.100
Interior spans...................	.083
Negative moment at first interior support,	
Two spans....................	.125
More than two spans...........	.100
Negative moment at other interior supports............................	.083

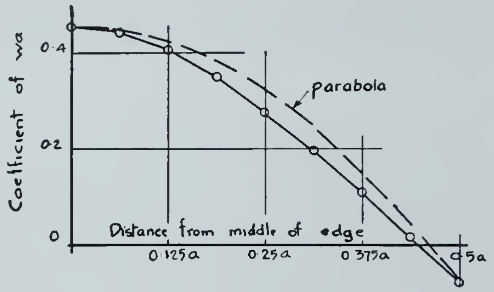

Fig. 6(a)—Square plate fixed at its edges. Distribution of pressure along the edges.

The above coefficients are given in C.E.S.A. Specification A23-1929, Concrete and Reinforced Concrete, and apply to slabs "built to act integrally with beams and girders or other slightly restraining supports." The A.C.I. building regulations for reinforced concrete give similar coefficients except that for slabs having a span of less than 10 feet the coefficient of negative moment at the first interior support may be assumed to be 0.100 in the case of two spans and 0.083 for more than two spans. An attempt will be made to derive practical formulas analogous to the above for use with two-way slabs.

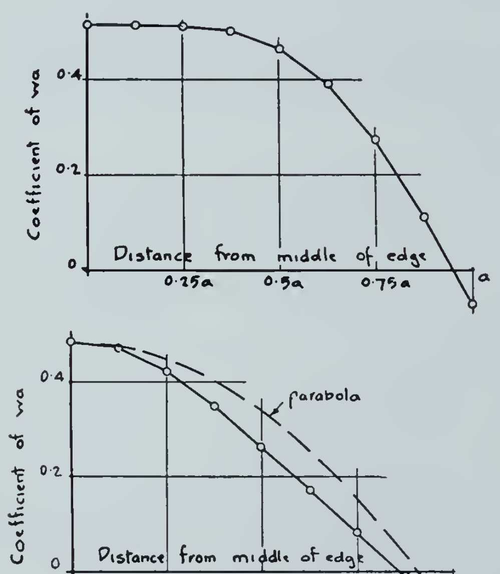

Fig. 6(b)—Rectangular plate (k=2) fixed at its edges. Distribution of pressure along the edges.

Maximum Positive Moment in the Shorter Span

A comparison of the values of C_{11} and C_7 (Figs. 4 and 8) will show that the positive moment at mid-span is not influenced very greatly by the degree of restraint at the short edge of the slab, provided that k is not greater than about 1.5. If slabs are constructed monolithically with the supporting beam, it appears to be reasonable to assume that a fairly high degree of restraint will be present in all cases. This will be particularly true in the case of an interior panel where the short edges will be restrained both by the beams to which they are attached and by the slabs forming against the panels. It is proposed, therefore, to assume that the restraint on the short edges will always correspond to 75 per cent fixity when considering the values of positive moments. This assumption may introduce small errors on the wrong side in the case of a single row of panels and small errors on the right side in the case of a full panel located in an interior row but it appears that, in either case, the errors will be very small. The simplification made possible by this assumption is very great—the positive moment in a slab will not depend upon the location of the slab with respect to parallel rows, i.e., the moment in a corner panel will be assumed to be the same as that in an exterior panel not at a corner.

It is necessary next to consider the conditions of restraint that may exist on the long side of the slab. These, of course, will have considerably more influence upon the values of the positive moments. At an exterior edge it appears reasonable to assume that the degree of restraint will never be less than that corresponding to 25 per cent fixity. This is probably a very conservative figure. At an edge having another slab connected to it any condition of restraint may occur as a result of different combinations of loading. Considering only one row of panels the maximum positive moment at mid-span will occur when the span under consideration and alternate spans on either side carry live load. Löser[10] has shown that the maximum positive moment may conveniently be determined by superimposing the following loading conditions:

(1) Dead load plus half live load on all spans.

(2) Half the live load applied alternately upwards and downwards on successive spans.

For the first loading, moment coefficients will correspond to fixed-end conditions for an infinite number of spans and approximate values may be chosen for any specified number of spans. For the second case, the moments will be those for simply supported conditions. Thus, any long edge of the slab may therefore be considered as simply supported, 25 per cent fixed, or completely fixed, depending upon the loading.

The problem therefore is to find moment coefficients for all the possible cases of restraint. There are six cases and these are shown diagrammatically in Fig. 10 as cases (a) to (f). (Two other cases (g) and (h) are also shown in Fig. 10; these will be referred to when considering negative moments). Moment coefficients can be determined by approximation from the theoretical values already given. These moment coefficients will be designated as C_a^+, C_b^+, etc. for cases (a), (b), etc. Values of these constants have been computed using the following approximate equations:

$$C_a^+ = 0.25\, C_1 + 0.75\, C_{14} \qquad (40)$$

$$C_b^+ = 0.25\, C_{11} + 0.75\, C_7 \qquad (41)$$

C_c^+ No mathematical expression has been given for this. It is believed, however, that very close results can be obtained in the following manner making use of two approximate equations given by Marcus.*

$$C_c^+ = 0.75\, C_M' + 0.25\, C_M'' \qquad (42)$$

$$\text{where } C_M' = \left\{1 - \frac{15}{32}\,\frac{k^2}{(k^4+2)}\right\} \frac{k^4}{k^4+2}\,\frac{9}{128}$$

$$\text{and } C_M'' = \left\{1 - \frac{75}{32}\,\frac{k^2}{(2+5k^4)}\right\} \frac{5k^4}{2+5k^4}\,\frac{9}{128}$$

$$C_d^+ = .75\, C_a^+ + .25\, C_c^+ \qquad (43)$$

$$C_e^+ = .75\, C_a^+ + .25\, C_b^+ \qquad (44)$$

$$C_f^+ = .75\, C_c^+ + .25\, C_b^+ \qquad (45)$$

Applying Löser's method to two spans, for both spans loaded the moment coefficient will be C_f^+, and if half the live load is acting downwards on one span and upwards on the other the moment coefficient will be C_d^+. If q be the

*Reference could also have been made to Timoshenko "Theory of Plates and Shells," pages 211-212.

ratio of live load to dead load, the coefficient of maximum positive moment, C_{17}, will be given by

$$(1+q)\, w\, C_{17} = C_f^+\, (1 + 0.5q)\, w + C_d^+\, (0.5q)\, w$$

$$C_{17} = \frac{C_f^+\, (1 + 0.5q) + 0.5q\, C_d^+}{1+q} \quad - - - \quad (46)$$

Löser's method cannot be applied directly to determine the maximum positive moment in the end panel of a row containing more than two panels. When all panels are loaded the slope of the slab will not be zero at the first interior support and thus the positive moment will be somewhat greater than it was in the case of two spans only. In the case of a continuous beam the coefficient of the maximum positive moment in the first span is .0702 for two spans and .80 for five spans. A reasonable increase in the

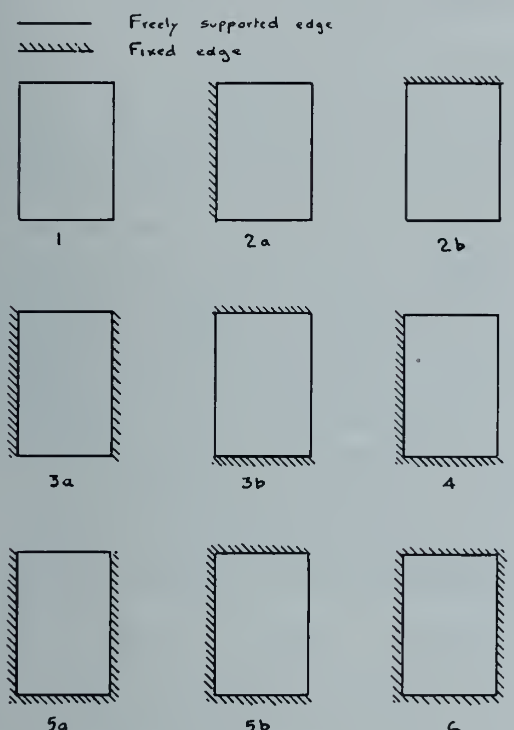

Fig. 7—Rectangular plate. Condition of edge restraint.

case of a slab would appear to be about 10 per cent. If this assumption is made the coefficient of maximum positive moment in the end span of a series of more than two spans will be given by

$$C_{18} = \frac{1.1\, C_f^+\, (1+0.5q) + 0.5q\, C_d^+}{1+q} \quad - - - - - - \quad (47)$$

The maximum positive moment in interior spans can be determined when considering a span forming one of an infinite series. Since the actual number of panels in a row is likely to be comparatively small, errors will be introduced by applying results derived for an infinite number of spans. These errors will only be appreciable in spans near the end of a row where the positive moment will be somewhat less than that given for an infinite series. The errors are, however, on the right side and are not considered to be significant. Applying Löser's method to determine the coefficients of maximum positive moment gives the following equation:

$$C_{19} = \frac{C_b^+\, (1 + 0.5q) + 0.5q\, C_a^+}{1+q} \quad - - - - - - - \quad (48)$$

Maximum Positive Moment in Direction of Longer Span

By the use of equations similar to equations (42) to (48) coefficients of maximum positive moments in the direction of the longer span have been computed. The long edges have been assumed to be 75 per cent fixed in each case.

The results show that positive moments in the long span are but little affected by variations in the restraint of the short edges. This being the case it does not appear to be necessary to consider the effect of differing arrangements of live load upon a group of panels. For practical purposes it will be assumed that the coefficient C_a^+ (long span) will apply in all cases. This coefficient will be designated as C_{20} since the symbol C_a^+ has been used to indicate a particular condition of restraint.

Maximum Negative Moments in the Direction of the Shorter Span

A comparison of C_8 and C_{12} in Figs. 4 and 8 respectively shows that negative moments at the longer support are influenced to an appreciable extent by the degree of restraint provided for the shorter edges of the slab, particularly when k is greater than about 1.7. In considering negative moments in the direction of the shorter span, i.e., at right angles to the longer span, it therefore appears to be necessary to consider not only the effects of varying the restraint along the long edges but also the effect of varying the restraint along the short edges. As in the case of positive moments, it will be assumed that at a continuous edge 75 per cent restraint will be present and at a non-continuous edge 25 per cent. It will also be assumed that maximum negative moments occur when all spans in the row under consideration are loaded. In approximately equal spans the errors involved in this assumption are very small. Making the above assumptions there will be four cases to be considered.

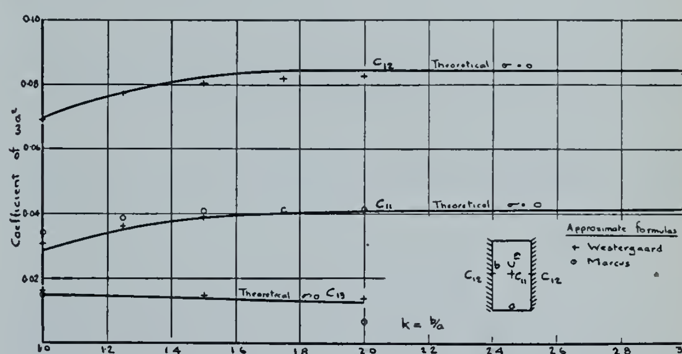

Fig. 8—Rectangular plate having its long edges fixed and its short edges freely supported. Coefficients of maximum positive and negative bending moments.

(1) The first interior support in an exterior row.
(2) Interior supports other than the first in an exterior row.
(3) The first interior support in an interior row.
(4) Supports other than the first interior support in an interior row.

The case of a single row of panels, being comparatively unimportant, has not been considered.

These degrees of restraint correspond to the conditions indicated in Fig. 10 for cases (g), (h), (f), and (b), respectively.

The moment coefficients corresponding to these cases may be determined in the following manner:

Case (b) $C_b^- = 0.75\, C_8 + 0.25\, C_{12}$ - - - - - - - - (49)
Case (f) $C_f^- = 1.375\, C_b^-$ - - - - - - - - - - - - (50)
Case (g) $C_g^- = 1.375\, C_h^-$ - - - - - - - - - - - - (51)
Case (h) $C_h^- = 0.75\, C_M''' + 0.25\, C_{12}$ - - - - - - - (52)

where C_M''' is determined by the Marcus approximation

$$C_M''' = \frac{k^4}{6\,(1+2k^4)}$$

It was stated above that conditions of restraint in an end panel could be represented by cases (f) or (g). These cases, however, only apply strictly to two panels since when there are more than two continuous spans it is necessary to make corrections owing to the fact that the slope of the slab will not be zero at the first interior support. In the case of a continuous beam the coefficient of the moment at the first interior support is about 20 per cent less for five spans than for two. A comparison of the values of C_{17} and C_{18} indicates that, for positive moments, there are only small differences between the values obtained for two spans and for the end span of a row of more than two spans. In the case of negative moments it does not appear to be worth while considering the two cases separately. Since it is somewhat doubtful if the uncommon case of only two panels should be made the governing factor in determining moment coefficients for end spans in general, it is proposed to reduce the appropriate coefficients, viz., C_h^- and C_f^-, by

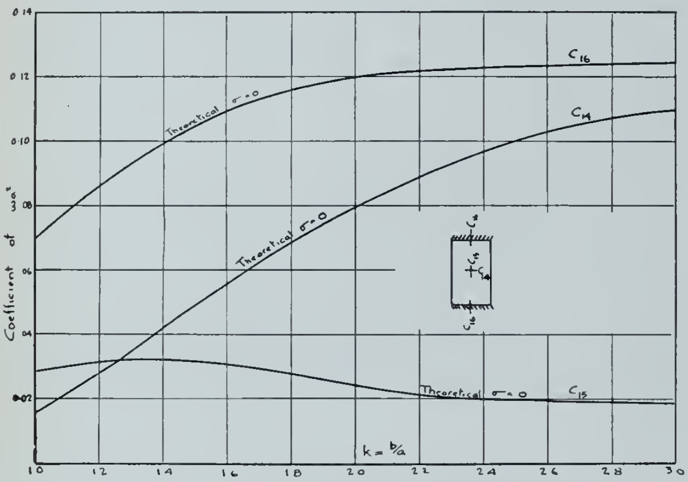

Fig. 9—Rectangular plate having its long edges fixed and its short edges freely supported. Coefficients of maximum positive and negative bending moments.

15 per cent and to assume that the figures so obtained will apply to the first interior support no matter how many panels may be in the row.

Maximum Negative Moments in the Direction of the Longer Span

By a method similar to that used for determining coefficients of negative moments in the shorter span the coefficients of moments in the direction of the longer span have been calculated.

Moment Coefficients for Use in Design

The moment coefficients derived in the preceding paragraphs could be used without further transformation as a basis for the design of slabs. It will be found that the coefficients of negative moments are in general considerably greater than the coefficients for positive moments. There appears to be good reason for believing that this difference will be reduced by the effect of plastic flow or creep. Thus, experiments on continuous frames have shown that, as a consequence of plastic flow, a redistribution of moment occurs. This takes the form of a decrease of moment at the supports together with an increase at mid-span. The German and British regulations take account of this by permitting a reduction of 15 per cent in the maximum negative moment provided this amount is added to the maximum positive moment. In the case of continuous slabs Westergaard[11] has pointed out that the effect of plastic flow will be as follows: The distribution of negative moment along the supports will tend to become more uniform with a consequent reduction of the maximum moment; the negative moment will decrease and the positive moment at mid-span will tend to increase; the positive moment in the short span will tend to decrease and the positive moment in the long span to increase. These conclusions may be accepted as correct but it is difficult to assess the relative importance of the various effects without a considerable amount of experimental evidence.

Most tests have been carried out in a comparatively short time so that in interpreting the results it is difficult to estimate the effects of plastic flow at all accurately. Conditions during a brief time loading test are not the same as those occurring when the load is sustained for a long period of time. Tests in which loading is sustained for a year or more do not appear to have been carried out on two-way slabs and in the absence of such data, design formulas must be based upon assumptions that may or may not be correct.

The following method appears to be reasonable in principle and it is believed that it will always lead to structures with an adequate factor of safety.

It will be assumed that the transference of moment from the supports to mid-span resulting from plastic flow will be such as to lessen the numerical difference between the maximum negative moments and the maximum positive moments to one-half of its calculated value. This will result in the following positive moment coefficient:

Positive moment coefficient assumed in design = calculated positive moment coefficient
+0.25 (calculated negative moment coefficient − calculated positive moment coefficient)
= 0.75 (calculated positive moment coefficient) + 0.25 (calculated negative moment coefficient) - - - - (53)

In cases where the negative moment along the two supporting edges differs, the greater value will be assumed in using equation (53).

In the case of the negative moments it will be assumed that there will be a further reduction due to transference of moment from the middle of the sides to the ends. A reduction of 15 per cent of the calculated moment is proposed for this. The following negative moment will result:

Negative moment coefficient assumed in design = 0.85 (calculated negative moment coefficient)
− 0.25 (calculated negative moment coefficient − calculated positive moment coefficient)
= 0.60 (calculated negative moment coefficient) + 0.25 (calculated positive moment coefficient) - - - - (54)

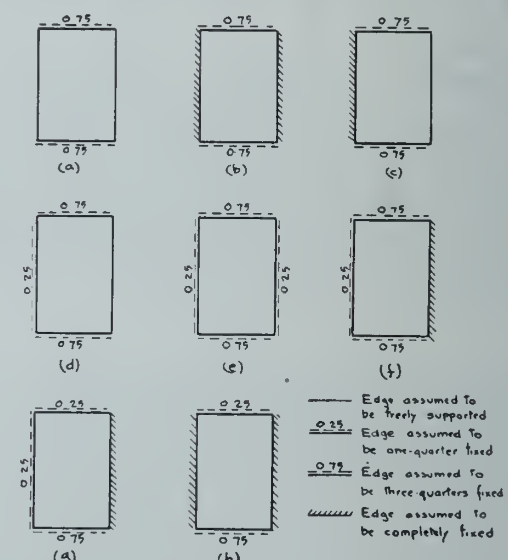

Fig. 10—Rectangular slab. Conditions of restraint.

The coefficient of moments derived in the preceding section (C_{17}—C_{26}) have been modified by the use of equations (53) and (54) and the resulting coefficients are given in Table I and are shown graphically in Figs. 11 and 12.

In Figs. 11 and 12 the coefficients have been plotted against the reciprocal of k, (m), and it will be seen that they can be conveniently represented for practical purposes by linear equations. In some cases the proposed lines follow the calculated coefficients quite closely but in other cases the agreement is not so close. In general, the proposed lines are in close agreement with the derived coefficients for square and nearly square slabs but some consideration

TABLE I

Summary of Calculated Values of Moment Coefficients

Coefficient	Span	k = Long Span / Short Span						
		1.0	1.25	1.5	1.75	2	2.5	3
Positive Moments—								
Two spans, $q=4$	Short	.035	.050	.061	.069	.075	.082	.085
End span of more than two, $q=4$	Short	.031	.045	.055	.064	.070	.077	.080
End span of two or more	Long	.033	.035	.037	.037	.037	.037	.037
Interior span, $q=4$	Short	.029	.041	.051	.059	.064	.069	.073
Interior span	Long	.030	.030	.031	.032	.031	.031	.030
Negative Moments—								
First interior support—								
Exterior row	Short	.046	.058	.066	.071	.074	.077	.079
Interior row	Short	.043	.055	.064	.070	.073	.077	.079
First interior support—								
Exterior row	Long	.046	.053	.059	.061	.063		
Interior row	Long	.044	.049	.052	.054	.054		
Supports other than first interior support—								
Exterior row	Short	.039	.050	.057	.061	.064	.066	.067
Interior row	Short	.037	.047	.055	.060	.063	.065	.067
Supports other than first interior support—								
Exterior row	Long	.040	.046	.051	.053	.054		
Interior row	Long	.038	.043	.046	.047	.047		

has been given to the conventional coefficients for one-way slabs and in most instances moment coefficients in the short span approach the usual coefficients for one-way slabs when k is approximately equal to three ($m=0.33$). From a practical standpoint it has not been considered worth while distinguishing between positive moments in two spans and in the end span of more than two spans of a row of more than two spans, and also between negative moments in exterior and interior rows. It is believed that coefficients obtained from the proposed formulas will have an adequate margin of safety, that they will be found simple to use, and that in the case of square or nearly square panels they are as small as can be justified on the assumption of elastic behaviour.

In addition to the coefficients given in Figs. 11 and 12 it is necessary to propose values for positive moments in an isolated span and for negative moments at exterior edges in general. For an isolated panel the moment coefficients could, of course, be derived from Figs. 1 or 4, providing that some estimate of the degree of restraint at the edges would be made. Such a method, however, might lead to moment coefficients appreciably less than those prescribed for the end panel of a row of two or more.

TABLE II

Coefficients of Maximum Bending Moments in Rectangular Slabs Reinforced in Two Directions

	Coefficient of $w'a^2$	
	Short Span	Long Span
Positive Moments		
(a) Near the centre of single spans	$0.13-0.09m$	0.04
(b) Near the centre of the end span of two or more spans	$0.115-0.08m$	0.035
(c) Near the centre of interior spans	$0.095-0.065m$	0.03
Negative Moments		
(a) At the exterior supports of a slab	$0.05-0.03m$	0.02
(b) At the interior support of two spans and at the first interior support of more than two spans	$0.13-0.085m$	$0.085-0.04m$
(c) At interior supports other than the first	$0.103-0.066m$	$0.077-0.04m$

Symbols have the following meanings:

w' = load per square unit

a = shorter span

$m = \frac{\text{shorter span}}{\text{longer span}}$

In order to avoid this apparent anomaly, the prescribed moment coefficient for positive moment in the short span of an isolated span has been taken as 1.13 times the values prescribed for the end span of a row. This gives a coefficient of $0.13-.09m$. It has been assumed that the coefficient of moment in the long span remains constant at 0.4 irrespective of the value of m. For negative moment at an exterior edge a coefficient of 0.02 is proposed for a square panel, increasing for short spans up to 0.04 for k equal to 3. This upper limit corresponds approximately to the value of 1/24 commonly used when designing one-way slabs. The value for square slabs corresponds to about 38 per cent fixity and it will be remembered that when deriving coefficients at interior supports the fixity at an exterior edge was assumed to be 25 per cent. Thus, the proposed coefficient should contain an adequate margin of safety.

The proposed design coefficients are collected together in Table II.

Intensity of Loading on Supporting Beams

It was shown in the preceding portion of this paper, that the distribution of shear at the edge of a rectangular plate is such as to produce a distribution of pressure along the supports which may be represented approximately by an ellipse if the edges are freely supported, and by a parabola if they are clamped. It was further shown that in the latter case the maximum bending moment in the beam may be closely estimated by assuming a trapezoidal distribution of load. Table III summarizes the coefficients of moment previously derived:

TABLE III

Maximum Bending Moments in the Supporting Beams

Assumed Distribution of Load	Maximum Bending Moment in Side OB	
	$k=1$	$k=2$
Elliptical—freely supported	$.036wb^3$	$.025wb^3$
Trapezoidal—clamped	$.042wb^3$	$.029wb^3$

If no redistribution of moment due to flow occurred, the maximum moment in the beam would presumably be within the above limits for various conditions of restraint. The effects of transference of moment in the slab and deflection in the beam will be to equalize the pressure along all the supporting edges. The German regulations recognize this and state that "the supporting pressures exerted by uniformly loaded rectangular two-way slabs that are supported by beams or walls may be assumed to be uniformly distributed." Making this assumption, the unit load on the beams will be $\frac{wa}{2}\frac{(k)}{(1+k)}$ and the maximum bending moment will be $\frac{wb}{16\,(1+k)}$ and $\frac{wa}{16}\frac{(k)}{(1+k)}$ in the long and the short sides respectively. The maximum moment in the long side will then be $.031\ wb^3$ and $.021\ wb^3$ for $k=1$ and $k=2$ respectively. A comparison of these figures with those given in Table III leads to the conclusion that the assumption of uniform pressure is a convenient way of making allowance for deflection and plastic flow. This method has the further advantage of making it possible to design the supporting

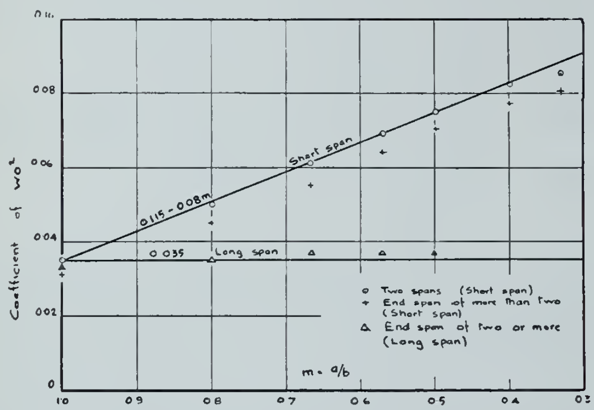

Fig. 11(a)—Continuous rectangular slabs. Coefficients of maximum positive moments in the end span of two or more spans.

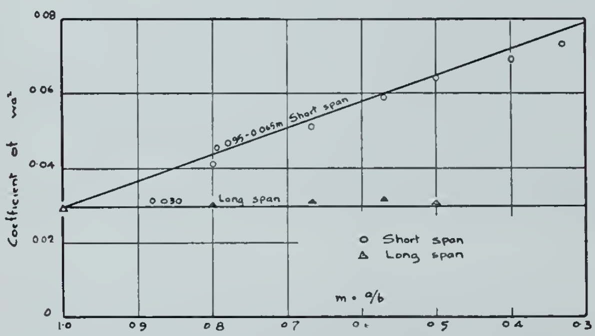

Fig. 11(b)—Continuous rectangular slabs, Coefficients of maximum positive moments in interior spans.

beams as continuous beams making use of the moment coefficients commonly used for uniform loadings. The only disadvantage is that there will be a discontinuity in the loading to be assumed, if a slab, in which k is equal to three for example, is designed as a one-way slab rather than a two-way slab. This may be avoided with a slight loss of economy by assuming that the loading expressed as a coefficient of wa varies uniformly from 0.25 to 0.5 as k varies from one to three. The coefficient will thus be given by the formula:

$$C_{27} = \frac{1+k}{8}$$

$$= \frac{m+1}{8m} \qquad (55)$$

It is suggested therefore that the following rule could be safely adopted:

The pressure exerted by uniformly loaded rectangular two-way slabs on the supporting beams or walls may be assumed to be uniformly distributed and equal in intensity to $\frac{1+k}{8}(wa)$ or $\frac{m+1}{8m}(wa)$.

THE HELEN MINE AND BENEFICIATING PLANT

GEO. G. W. MacLEOD, M.E.I.C.
Manager of the Mines Department, Algoma Ore Properties, Limited, Sault Ste. Marie, Ontario

Paper presented before the Toronto Branch of the Engineering Institute of Canada, on February 20th, 1941

SUMMARY—The history of iron mining in Canada as well as early mining at the Helen Mine serves as an introduction to the description of the mining and sintering operation of the new Helen Mine. The operation of the Magpie Mine is referred to as having a direct effect on the present Helen operation. A description is given of one of the largest and highest speed belt conveyor systems in Canada located at Michipicoten Harbour where vessels are loaded with the mine's product.

Iron mining in Canada goes back to early in the eighteenth century. The first mining took place at Three Rivers and at Radnor Forges in Quebec. Iron at these points was mined almost continuously for one hundred and fifty years.

The earliest iron mining in Ontario is recorded at Normandale in Norfolk County in 1813. Records show New Brunswick and Nova Scotia mining iron in 1848 and 1849, respectively, although it probably started much earlier.

The total recorded iron mined in Canada since 1886, is 7,110,000 tons. Of this, Ontario produced 5,128,000 tons and Nova Scotia 1,279,817. These two provinces were the only ones to figure prominently in iron production. 1913 was the last year Nova Scotia recorded any shipments. It will thus be seen that Ontario has made the main contribution to Canada's iron mining industry in producing 72% of the total.

The Algoma Steel Corporation, since 1899 has been the mainstay of Ontario's production and up to the close of navigation for 1940, has been responsible for nearly 4,500,000 tons or 88 per cent of Ontario's total.

The Helen Mine was discovered in 1898 during the gold rush near Wawa Lake. It was immediately acquired by Mr. Clergue who was at that time building power and paper plants at Sault Ste. Marie. The construction of the steel works at the Sault followed as a direct result of the discovery of the Helen. This is another example, many times repeated in Canadian history, where mineral discoveries have resulted in the establishment of thriving towns and cities. Without the steel plant with its 4,500 employees, the Sault would still, in all probability, be a small village.

The original discovery consisted of a hill of solid hematite ore, rising above the shore of a small lake. The hill was about 100 feet high and at its base, 1,000 feet in length by 700 feet in width.

The property was located eleven and a half miles from Michipicoten Harbour, on the north shore of Lake Superior. Loading docks at the harbour were immediately constructed and a railway built to connect with the mine. This was the start of the Algoma Central Railway Company.

Mining was commenced in 1899 and the first ore was shipped in 1900. The mine was operated until 1918 when the hematite became exhausted at a depth, below the lake level, of 800 feet.

In 1910 it became evident that the life of the Helen was definitely limited and an extensive search was commenced for new iron deposits. A discovery of what appeared to be a magnetite deposit was made about 14 miles north of the Helen and this property was acquired by the Steel Corporation. Diamond drilling soon revealed that the new deposit was not magnetite but siderite, an iron carbonate containing about 35 per cent iron. There were several places where this kind of ore was being used direct in blast furnaces, where cheap fuel was available and the furnaces were near the mine. But for the Algoma Steel to use this class of ore direct, was out of the question. Therefore, experiments were started to improve the grade of the ore before shipping.

It was found that by roasting, the siderite gave off CO and CO_2 gases and was converted to an oxide. In this process the ore was reduced in weight by one third. Thus by treating three tons of ore containing 35 per cent iron, two tons resulted, grading 50 per cent iron. In addition to raising the iron content, it was necessary to burn out most of the 2 per cent sulphur which the Helen ore contained.

The experiments were slow and expensive but a succesful process was gradually evolved; a commercial plant was then erected at the property, now known as the Magpie Mine.

The roasting was done in rotary kilns, similar to those used in the manufacture of cement. They were six in number, each 125 feet long and 8 feet in diameter, lined with firebrick. They sloped to the discharge end at ½ inch to the foot and made one revolution in two minutes. Powdered coal was blown in at the discharge end and 2,800 pounds of siderite and 300 pounds of pulverized coal were required to produce one ton of finished iron. It took four hours for the ore to travel through the kiln and each kiln had a capacity of 110 tons of finished ore per day. The maximum temperature was 1,100 deg. C. The raw ore was crushed to about 3½ inches and the finished material retained pretty much the same structure as the raw ore.

The sulphur in the finished ore was high, averaging about 0.2 per cent, but this did not interfere with marketing the ore, due to its other good characteristics which were no moisture, good structure, 3 per cent manganese, low phosphorus and sufficient lime to make the ore self-fluxing.

Over 1,000,000 tons of finished ore were produced at the Magpie. In 1921, however, ore prices dropped, and due to the cost of treatment, the Magpie could no longer compete with other iron producers so that operations ceased.

Fig. 1—Helen open pit at top of hill and aerial tram loading plant and bin.

It has been proved, however, that an excellent blast furnace product could be made out of siderite.

In 1910 and 1911 it was found that the ore body in the Helen hematite mine diminished in size as greater depths were reached. It was noticed that on three sides, east, west and south, as the hematite ended, the material along the contacts was siderite. Diamond drill holes were put down from underground and a large body of siderite was located, both below the hematite and to the east. It was estimated that this siderite would extend eastward to the edge of a steep hill, 400 feet in height, a distance of 800 feet. It seems almost unbelievable that it was not recognized, that in this hill itself, fully exposed on its western slope, and in many places on the crest, existed the main siderite deposit, now the new Helen Mine. Figure 1 shows this exposure as it existed at that time.

In the latter part of 1911 the first exploration of the ore in this hill commenced and in 1912 and 1913 it was trenched and diamond drilled. An ore body nearly 200 feet in width, 3,000 feet in length and at least 2,200 feet in depth was indicated, estimated to contain one hundred million tons.

No further work was done in the development of this deposit until 1917, when a tunnel was driven into the ore, 300 feet below the top of the hill. In 1918 this work was suspended.

With the experience at the Magpie Mine in view, it was not considered that this ore could be mined and treated in competition with Lake Superior open pit ores.

In 1937, the Ontario Government passed an act giving a bounty of two cents a unit on iron ore produced in the province. This act immediately produced results. Sir James Dunn, now president of the Algoma Steel Corporation, decided to place this huge, but low grade, ore deposit in production. Even with the bounty, it required courage to make this decision. The required expenditure was large and the field a new one. There were no plants treating this class of ore and it was recognized at the outset that the costly and inefficient process used at the Magpie would not be practicable.

The deposit, however, had many things in its favour. It was already connected by the Algoma Central Railway to Michipicoten Harbour, a distance of twelve miles, and to the Sault, 180 miles to the south. The power lines of the Great Lakes Power Company were only a few miles distant.

The upper 400 feet of the ore body could be mined cheaply, largely by open pit; the size of the deposit itself, together with the fact that it stood almost vertical, indicated low mining costs.

The ore body was carefully sampled on a large scale and tests were commenced at various plants to determine the best equipment to use. Mr. C. D. Kaeding was given charge of the entire project and he and his staff, together with the Steel Company's engineers, carried out the tests.

Two main systems of sintering were in use, one an intermittent process and the other continuous. Both systems worked satisfactorily and a decision was finally made to use the continuous or Dwight-Lloyd machine.

At the mine, a tunnel, eight feet by twelve feet, 400 feet long was driven into the ore body 270 feet below the crest of the hill. At the end of this tunnel a raise was put up, coming out on the western slope of the hill 150 feet above the tunnel. At this elevation the quarry floor was established. This would give a maximum quarry face 120 feet high.

At the foot of this raise and close to the south side of the ore body, a crusher chamber was cut and a Traylor Bulldog jaw crusher, 48 inches by 60 inches, was installed. This crusher is fed by a large Ross feeder. The grizzly at the mouth of the raise has 34 inch openings.

Fig. 2—Helen open pit showing ore from face being loaded into trailers.

Drilling in the pit is done with a Bucyrus-Armstrong blast hole drill. Nine-inch holes are drilled, spaced about 25 feet apart. The burden on the holes is also about 25 feet. The holes are drilled 6 feet below grade. One of the most important parts of the whole operation is the loading of the holes. Before loading, the face is carefully surveyed and a knowledge is obtained of the amount of work each hole is expected to do. The whole face, 200 feet in width is shot at one time. From 25 to 35 cases of powder are used in each hole. It is most important that the bottom part of the face breaks out well. Therefore from four to five cases of 60 per cent Forcite are used in this bottom section. This is followed by seven cases of 40 per cent Forcite. Above this, there are three feet of stemming, then two cases of 40 per cent Forcite. This alternate stemming and two cases of Forcite continues about half way up the hole, above which the Forcite is replaced by 60 per cent ammonia powder. The holes are loaded to within 17 to 20 feet of the collar. The powder all comes in 12½ pound bags. The holes are fired by Prima Cord blasting fuse. This fuse is run all the way down each hole and the fuse from all holes, are connected to a trunk line on the surface. It is not necessary to use any detonating caps on this fuse in the holes. One detonator on the fuse on surface fires the whole charge. By

Fig. 3—Side view of sintering plant.

using this fuse the hole is detonated instantaneously from top to bottom as the fuse has a speed of over 20,000 feet a second. From 60,000 to 75,000 tons are broken with each blast, about three weeks production. Two to three rock drills are kept on secondary blasting work to reduce the larger pieces to 34-inch size. As a whole, the fragmentation is very good from the primary blasting. It has, however, taken considerable study and experiment by the mine staff to reach this end.

The broken ore is loaded from the face by a 2½ yard Marion electric shovel into 11-yard Athey quarry trailers, as shown in Fig. 2. These trailers are hauled by a D-7 Caterpillar tractor and taken to the mouth of the raise. The trailers are dumped by oil pressure, directly from the cab of the tractor and the whole operation is quick and efficient.

The ore is passed down the raise to the primary crusher below. It is crushed to 4½-inch size, and conveyed along the tunnel and conveyor gallery to a loading plant equipped with a 500-ton steel ore bin. (See Fig. 1.).

The topography in the vicinity of the mine is very rugged and no site for the sintering plant was available near by. This plant was, therefore, built on a gravel plain, 2½ miles distant. From the 500-ton loading bin mentioned above, the ore is conveyed to the sintering plant by an aerial tramway, having a capacity of 120 tons an hour. The ore on reaching the plant site is discharged into a 1,000-ton steel terminal bin. In all cases ore is referred to in gross tons of 2,240 pounds.

The tests on Helen siderite had been as complete as possible, considering the relatively small scale on which they were made. The new plant (shown in Fig. 3) was designed largely on the experience gained in the experimental work and the investigation of plants working on other types of iron ore. The standard set by the Company for the finished ore involved bringing the iron content to 51.50 per cent and reducing the sulphur to 0.05 per cent.

The sinter had to have good physical structure and be as free as possible from fines.

The ore from the terminal bin is drawn by a Ross feeder on to a conveyor belt. This belt delivers the ore to a surge bin at the top of the crushing and screening plant. Four feeder belts take the ore from the surge bin to the double deck Tyler screens (4 by 8 ft.) where three products are made, plus 1⅛ in., minus 1⅛ in. and plus ¼ in. and minus ¼ in. The latter size is the required product for the sintering machines. The first size is delivered to a 5½-ft. Symons cone crusher, set at ¾ in. and driven by a 150 hp. slip ring motor. The second size is delivered to a set of Traylor heavy duty rolls (72 by 18 in.) driven by two-150 hp. slip ring motors. The third or finished size, minus ¼ in., goes direct to the fine ore charge bins. The undersize from the crusher and rolls is returned to the main belt feeding the ore from the terminal bin to the surge bin. This puts the crude ore in closed circuit with the crushing plant. The circulating load is about 200 per cent and the crushing capacity in terms of all minus ¼ in. product, is 200 tons per hour.

Fig. 4—Front view of sintering plant.

The charge bins are eight in number, each 16 feet in diameter and 40 feet high. Four of these are for the crushed raw ore, two for coke and two for fine sinter.

Coke is used for fuel in the sintering operation and must be crushed and dried. It is necessary to crush the coke at least as fine as the ore in order to obtain a uniform mix. As the sinter comes off the machines, part of it has not been fully sintered and part breaks into pieces 1 in. or less in size. All sinter under one inch is screened out. This material is further screened, all over ½ in. in size goes to one sinter bin and is shipped with the rest of the finished ore. That part under ½ in. goes to the second sinter bin and is later mixed with the raw ore going to the machines.

In all sintering tests it was very evident that this fine sinter, mixed with the raw ore, was important for successful operation. The fine sinter is made up of porous pieces which are not affected by further heat. It, therefore, tends to keep the whole charge uniformly open. Of the whole charge, 20 per cent should be returned fines. Without these fines, the air circulation is not uniform and channelling results.

The returned fines and raw ore are drawn by belt conveyors from their respective bins and fed, in the calculated proportion, to a cross belt. This mixture is then conveyed to three hoppers, one above each sintering machine.

Originally the coke was also added to the cross belt but due to the variation in the sulphur content of the ore, this practice was discontinued.

For average ore containing 2½ to 3 per cent sulphur, about 3 per cent coke was added. However, sulphur itself is a fuel and when the sulphur content rises above this amount it is necessary to cut down the amount of coke. The coke, therefore, is now conveyed directly to coke hoppers, also located above the sintering machines, and in this way the coke feed can be closely controlled.

The charge, both ore and coke, is fed from the hoppers into a pug mill, one mill for each machine, where water is added to aid in nodulizing the charge. From the pug mills, the ore is fed through a swinging spout on to the sintering machines. These sintering machines are of the Dwight-Lloyd type 60 by 77 ft., each served by a 105 in. fan, directly connected to a 500 hp. slip ring motor. There is a dust collector for each machine and a conduit to a 125 ft. stack. The machines are located in parallel on a floor 37½ ft. above the ground level. Figure 4 is a front view of the sintering plant.

The raw ore is fed on to the machines in a bed 15 in. in depth. It then passes under the igniters which are of the oil burning, semi-reverberatory type. As the ore is conveyed down the machines, the fire is gradually drawn down through the charge, by the volume of air sucked through the fans. Vacuum boxes are located under the grates of the machine along its whole length. The ore travels at a rate of four feet per minute and each machine has a capacity of 800 tons of sinter per day.

The sinter cakes drop off the front end of the machine on to heavy grizzly bars set 10 in. apart. Below these bars there is another grizzly with 1 in. spaces. The oversize from both of these grizzlies goes by gravity to the loading bins, from which the ore is loaded directly into railway cars. This loading is controlled by air operated gates. The undersize from the 1 in. grizzly goes to the sinter bins mentioned earlier in this paper. Figure 4 shows the front of the sintering plant with the loading bins.

The ore in these bins is usually quite hot and is sprayed with water. Water sprays are also directed at the inside of the railway cars. This spraying avoids the warping of the steel plates in the bin and railway cars. To prevent dust there should be about 0.7 per cent moisture in the ore as it is shipped.

The Algoma Central Railway handle the ore from the sintering plant to Michipicoten Harbour, a distance of eight miles. Twin hopper, centre-dump gondola cars, 58-tons capacity, are used. (See Fig. 4.)

Fig. 5—Algoma Central Railway trestle with receiving hopper below at Michipicoten harbour.

At the harbour itself, a new plant for loading vessels had to be constructed by the railway company. The old ore dock used twenty years earlier for the old Helen Mine, had been dismantled.

As the Helen Mine was the only customer in sight, it was obvious that the cost of a steel and concrete pocket dock would be prohibitive. Boats, however, demand quick loading and several types of loading facilities were investigated.

It was finally decided to use a belt conveyor system, and it was necessary to load vessels at a rate comparable to the American pocket docks. This meant a single belt with a capacity of at least 1,500 gross tons per hour.

The plan decided on, included loading vessels at the face of an existing coal dock. The coal bridge would be run to the south end of the dock, thus allowing free use of the entire frontage for loading iron ore.

A reinforced concrete tunnel was constructed just north of the coal dock floor and at the same elevation. This tunnel, 250 feet in length, is 10 feet wide by 7 feet in height. Hatches, three feet square, were made in the top of the tunnel at 10 foot intervals, making 24 in all. A basin to hold 14,000 gross tons of ore was created over the tunnel by building up the sides with gravel and facing the top of this fill with railway ties, the effect being to create a large hopper, the bottom of which would be the top of the tunnel.

The railway track came to this loading area at an elevation of 45 ft. above the top of the tunnel and a steel trestle was built out over the entire length of the tunnel. A space between the rails was left open to allow the ore to be dumped from the bottom of the cars. (See Fig. 5).

A 48 in. belt conveyor was installed in the tunnel. This belt is loaded by means of a single loading hopper which travels from hatch to hatch. As this hopper comes under a hatch, it engages the hatch gate which is then opened to any

Fig. 6—Algoma Central Railway gantry transferring ore from dock belt to ship.

desired area by the operator. The loading hopper and the gate are electrically operated. Baffles in the loading hopper allow a uniform feed and flow on to the belt in the direction of belt travel, thus preventing any undue belt wear at this point.

The ore is conveyed on the tunnel belt to a transfer point 37 ft. beyond the tunnel mouth. It is then transferred to a cross belt, also 48 in. in width, which carries it a distance of 150 ft. to the face of the coal dock. This transfer belt is on an incline of 8 degrees. The ore is weighed on this cross belt by a set of Fairbanks conveyor scales.

The ore from the cross belt is then transferred to another 48 in. belt which travels along the face of the dock for a distance of 470 feet as shown in Fig. 6.

A travelling gantry moves on tracks up and down the face of the dock and the ore is transferred by means of a tripper on to the gantry. The tripper travels with the gantry and both are electrically operated.

The gantry, itself, simply consists of an incline belt conveyor mounted on a movable structure. The ore is conveyed to a chute directly over the centre of the ship's hatch, through which it is fed into the vessels's hold. When the required amount is fed into any individual hatch, the gantry, together with the tripper, then moves to the next hatch. During this move the ore feed is shut off at the tunnel. The average time consumed in moving from one hatch to another is about two minutes.

The whole belt system is controlled from the operator's cabin on the gantry. The belts operate with time relay switches. The gantry belt starts first, followed in 15 seconds by the dock belt, which in turn is followed, at the same time intervals, by the cross belt and the tunnel belt. The belts are stopped in the reverse order.

The belts are all the same size but travel at different rates of speed. The slowest speed is used in the tunnel and each succeeding belt runs a little faster with the highest speed obtained with the gantry belt. The tunnel belt travels 580 ft. per minute and the gantry belt 610 ft. per minute.

This system eliminates the possibility of an excess of ore piling up at any point along the system. The tunnel belt can be instantly stopped by the loading operator in the tunnel, should occasion arise, but no other belt can be stopped unless the one immediately behind it has ceased operation. As 12 cubic feet of ore per second is handled on the belts, the reason for such precautions becomes obvious. The tunnel, cross and gantry belts are each driven by 75 hp. motors. The belt along the face of the dock is driven by two 75 hp. motors. The gantry is moved along its track by a 15 hp. motor and the boom carrying the belt over the vessel's hatch is raised and lowered by a 7½ hp. motor. The loading hopper in the tunnel is operated by a 3 hp. motor. The air in the tunnel is kept clear by an exhaust fan driven by a 25 hp. motor.

All of the belts are flood-lighted as loading is done both by day and night.

At the close of navigation for 1940, 471,000 tons had been loaded through these facilities. The whole system has operated very smoothly and efficiently. It has been demonstrated that the belts, when in operation, can handle 2,400 gross tons per hour or 19 cubic feet per second. Including all delays, an average boat can be loaded in five hours and during the season of navigation, 200 days, this installation can handle from one to one and a half million gross tons of ore.

The Helen or Algoma sinter as it is called, is a highly desirable iron ore and goes into the markets of both Canada and the United States. It has good structure and has sufficient lime to make it self fluxing. Sulphur is practically eliminated. Phosphorus is low and the sinter contains 3 per cent manganese.

How well the sinter came up to the standards set before the plant was constructed, is shown by the average analysis of the whole 1940 production:

Fe 52.90%; P 0.024%; SiO_2 7.7%; Mn 2.99%;
Alumina 1.86%; CaO 3.45%; MgO 7.78%; S 0.040%.

This result reflects great credit on Mr. Kaeding and his associates who designed the plant and on Mr. Kidder and his staff who carry on the operation and who successfully overcame the many difficulties that arise in developing any new process of this kind.

TREATMENT OF BOILER FEEDWATER BY CARBONACEOUS ZEOLITE SOFTENER

NICHOLAS FODOR

Engineer, Toronto, Ontario

SUMMARY—This paper describes the introduction into Canada of carbonaceous zeolite water softening which works on the combination of hydrogen and sodium cycle. It also gives the results of the first year's operation.

In 1939, the Goodyear Tire and Rubber Company of Canada, New Toronto, installed a new high pressure boiler and turbine. Great care was given to the selection of the water softener equipment. The high speed turbine required entirely clean steam, free from carry-over. The boiler manufacturer permitted only 1,300 ppm.* total solids in the boiler water for a guaranteed carry-over of not more than 1 ppm. This involved excessive blow-down unless the total solid content of the raw water could be reduced to a fairly low value. Furthermore the decision to use a closed tubular feedwater heater and desuperheaters permitted only a very low hardness in the feedwater. The water softener had to produce makeup water of such quality that the boiler would be entirely free from scale, corrosion and embrittlement. Of course, it was desired to operate the equipment at the lowest possible cost and with the maximum amount of safety.

In this plant the water softener has to supply makeup water for a boiler with 90,000 lb. per hr. continuous output, at a pressure of 665 lb. per sq. in. and a temperature of 650 deg. F. The maximum makeup water requirement is 50,000 lb. per hr. The water, drawn from Lake Ontario and pumped first into a large concrete cistern in the plant, is of a fairly uniform quality, except that in springtime, freshets bring a comparatively high amount of suspended matter. An average analysis is given in Table I.

TABLE I

Average Analysis of Raw Lake Ontario Water

		*ppm.**	*epm.***
Hydroxide	(O H).	0.0	0.00
Carbonate	(CO_3).	0.0	0.00
Bicarbonate	(H CO_3).	119.0	1.95

Total hardness as Ca CO_3.		100.0	. . . .
Calcium hardness	(Ca CO_3).	79.0	. . . .
Magnesium hardness	(Ca CO_3).	21.0	. . . .
pH.		7.6	. . . .

To soften this water only the hot-lime-soda and the carbonaceous zeolite softener were given consideration. The straight zeolite softener, working only on the sodium cycle, was not considered because this merely exchanges the calcium and magnesium ion for sodium, without reducing the total solids content of the water. It was estimated that with the hot-lime-soda softener the hardness in the effluent would be 17 ppm. as Ca CO_3 and the total solids about 145 ppm. Furthermore 0.80 lb. quicklime and 0.45 lb. soda ash would be necessary for 1,000 gallons*** of raw water.

The carbonaceous zeolite softener was stated to give 2-3 ppm. hardness as Ca CO_3 in the effluent and a total solid of 100 ppm., while using 0.88 lb. sulphuric acid and 2.05 lb. sodium chloride per 1,000 gals. of raw water.

*ppm. = parts per million. **epm. = equivalent per million.
***All gallons mentioned are U.S. gallons. To change to 10^6 lb. multiply by 120.

The condition required to be maintained in the boiler water was set at 1,300 ppm. total solids, 86 ppm. trisodium phosphate, 160 ppm. sodium hydroxide and proportionately 706 ppm. sodium sulphate. From the above mentioned data the carbonaceous zeolite softener seemed to be the most economical and was finally chosen. The possibility of keeping the tubular heaters indefinitely free of scale was another reason for this selection.

OPERATING PRINCIPLES AND DESCRIPTION OF THE CARBONACEOUS ZEOLITE SOFTENER

The softener consists of two elements, one working on the sodium cycle with common salt regeneration, and the other working on the hydrogen cycle with sulphuric acid regeneration. The chemical equations of these cycles are the following:—

Sodium cycle

I. SOFTENING

1.) $\begin{matrix}(Ca)\\(Mg)\end{matrix}\ (HCO_3)_2 + (Na_2Z) \rightarrow \begin{matrix}(Ca)\\(Mg)\end{matrix}\ Z + 2\ Na\ H\ CO_3$

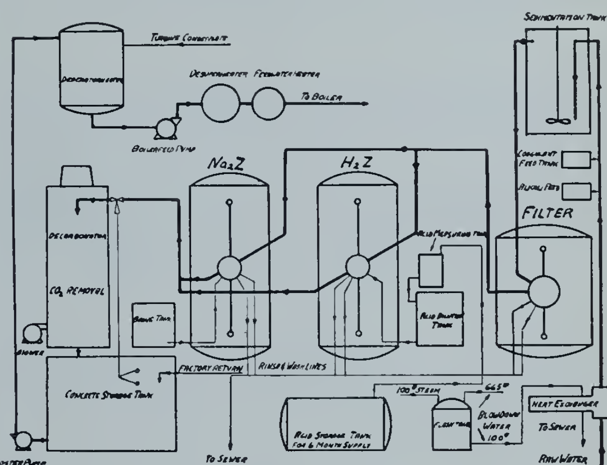

Fig. 1.

1a.) $(Na_2)\ (HCO_3)_2 + (Na_2Z) \rightarrow (Na_2)\ Z + Na_2\ (HCO_3)_2$
No reaction.

2.) $\begin{matrix}(Ca)\\(Mg)\end{matrix}\ (SO_4) + (Na_2Z) \rightarrow \begin{matrix}(Ca)\\(Mg)\end{matrix}\ Z + Na_2\ SO_4$

2a.) $(Na_2)\ (SO_4) + (Na_2Z) \rightarrow (Na_2)\ Z + Na_2\ SO_4$
No reaction.

3.) $\begin{matrix}(Ca)_2\\(Mg)_2\end{matrix}\ (Cl) + (Na_2)Z \rightarrow \begin{matrix}(Ca)\\(Mg)\end{matrix}\ Z + 2\ Na\ Cl$

3a.) $2\ Na\ Cl + (Na_2)Z \rightarrow Na_2\ Z + 2\ Na\ Cl$
No reaction.

II. REGENERATION

4.) $\begin{matrix}(Ca)\\(Mg)\end{matrix}\ Z + 2\,Na\,Cl \rightarrow Na_2\ Z + \begin{matrix}(Ca)\\(Mg)\end{matrix}Cl$

Hydrogen Cycle

I. SOFTENING

5.) $\begin{matrix}(Ca)\\(Mg)\\(Na_2)\end{matrix}\ (HCO_3)_2 + H_2\ Z \rightarrow \begin{matrix}(Ca)\\(Mg)\\(Na_2)\end{matrix}\ Z + 2\ H_2\ CO_3$

6.) $\begin{matrix}(Ca)\\(Mg)\\(Na_2)\end{matrix}\ (SO_4) + H_2Z \rightarrow \begin{matrix}(Ca)\\(Mg)\\(Na_2)\end{matrix} + H_2\ SO_4$

7.) $\begin{matrix}(Ca)\\(Mg)\,Cl_2\\(Na_2)\end{matrix} + H_2Z \rightarrow \begin{matrix}(Ca)\\(Mg)\\(Na_2)\end{matrix} Z + 2\,HCl$

II. Regeneration

8.) $\begin{matrix}(Ca)\\(Mg)\,Z\\(Na_2)\end{matrix} + H_2\,SO_4 \rightarrow H_2\,Z + \begin{matrix}(Ca)\\(Mg)\,SO_4\\(Na_2)\end{matrix}$

The sodium cycle converts all the Ca and Mg salts into the corresponding Na salts following equations 1, 2 and 3. The hydrogen cycle, following equation 5, converts all the bicarbonates into carbonic acid which easily breaks down to water and carbon dioxide following the equation $H_2\,CO_3 = H_2\,O + CO_2$. The sulphates and chlorides will be changed to sulphuric acid and hydrochloric acid respectively following equations 6 and 7.

The effluent of both cycles is mixed, giving the following chemical reactions:—

From 1, 1a and 5:

9.) $2\,Na\,HCO_3 + 2\,H_2\,CO_3 = Na_2\,CO_3 + H_2\,CO_3 + 2\,H_2O + 2\,CO_2 = Na_2\,CO_3 + H_2O + CO_2 = 2\,H_2O + 2\,CO_2.$

From 2, 2a, 6 and 9:

10.) $Na_2\,SO_4 + H_2\,SO_4 + Na_2\,CO_3 = Na_2\,SO_4 + Na_2\,SO_4 + H_2\,CO_3 = 2\,Na_2\,SO_4 + H_2\,O + CO_2.$

From 3, 3a, 7 and 9:

11.) $2Na\,Cl + 2HCl + Na_2\,CO_3 = 2Na\,Cl + H_2\,CO_3 = 2Na\,Cl + H_2\,O + CO_2.$

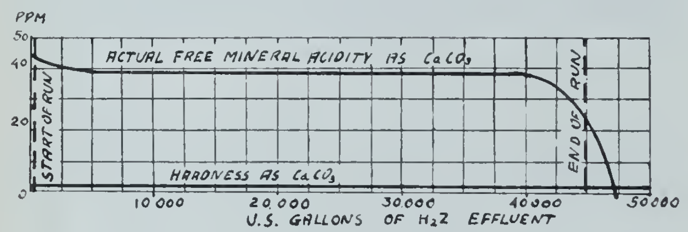

Fig. 2.

All the CO_2 can be easily removed by a mechanical blower. The net result in the effluent from 9, 10 and 11 is: $Na_2\,CO_3 + Na_2\,SO_4 + Na\,Cl$.

The $Na_2\,CO_3$ from 9 is used to neutralize the $H_2\,SO_4$ and HCl in 8 and 9, so that by changing the amount of $Na_2\,CO_3$ any desired $Na_2\,CO_3$ can be obtained in the effluent; if necessary, the effluent can be rendered neutral.

The arrangement of the apparatus and the working principle of the softener is shown diagrammatically in Fig. 1.

It is believed that a zeolite bed does not work effectively with water of higher turbidity than 10 ppm. Although the Lake Ontario water very seldom contains so much turbidity, precautions have been taken to prevent plugging of the zeolite beds from this cause.

The Lake Ontario water, which is stored in the large cistern in the yard of the plant, passes through a heat exchanger which utilizes the heat of the blow-down water. Then it enters the sedimentation tank, which is located overhead to provide the necessary continuous head above the softener and to make overloading of the softening beds impossible. In front of the sedimentation tank are located two cast iron chemical feed tanks. In case of excessive turbidity aluminum sulphate can be fed from one of the cast iron tanks for good flocculation. It was estimated that about 2 grains per gal. feeding would be necessary. Should the pH value become too low, soda ash or some other alkaline could be fed from the second tank to maintain a pH value of 6.5 to 6.8 for best coagulation.

After the water has been properly agitated and coagulated in the sedimentation tank, it passes to an anthrafilt pressure filter. This filter is backwashed at every regeneration of the softener or when the pressure drop becomes excessive. This drop in pressure has never occurred while the sedimentation tank is working properly.

The softener itself consists of two vertical shells placed close together. The water coming from the filter is divided into two parts. One part goes to one of the shells, the hydrogen softener, which is regenerated by sulphuric acid. This shell and all the effluent piping, including some of the valves, are rubber lined. Nearby are the concentrated acid measuring tank and the dilution tank. Both are lead lined. The rest of the water passes to the second shell, the sodium softener, which is regenerated by common salt. Near this a brine preparation tank is provided.

In the shells are the softening beds. The carbonaceous zeolite is a finely screened bituminous coal treated with strong acids, made entirely acid-resisting. The exchange capacity on the sodium cycle has been found to be 6,000 grains per cu. ft. hardness removal, and on the hydrogen cycle about 14,000 grains per cu. ft. cation removal.

The effluent of both softeners is mixed in a simple tee and is discharged through a pilot water-operated diaphragm valve into a wooden spray type decarbonator, where the air-counterflow mechanically expels the carbon dioxide which is formed in the hydrogen softener.

From the decarbonator the soft, slightly alkaline water discharges by gravity into a hotwell where it is mixed with the condensate return of the factory. The water level in the hotwell is kept constant by a float box which actuates a solenoid valve which in turn closes and opens the pilot water line of the main valve ahead of the decarbonator and this starts and stops the softener.

The water is then lifted by a booster pump to a deaerator of the atomizer type from which it is drawn by boiler feed pump.

The addition of sodium hexametaphosphate and sodium sulphite takes care of the least traces of residual hardness and oxygen. This reagent is fed by a variable stroke feed pump straight into the steam drum.

Operation Results

Figures 2, 3 and 4 illustrate a normal run of the softener. The $H_2\,Z$ softener, as indicated in Fig. 2, starts the run at 45 ppm. mineral acidity which is equal to the theoretical which could be formed by having the chloride and sulphate content according to the average water analysis. This drops after about 5,000 gals. of water pass through the softener, and during the bulk of the run remains about 88 per cent of the theoretical mineral acidity. At the end of the run, when the softener becomes exhausted, the acidity starts to drop and finally it goes over to alkalinity. The hardness of the effluent still remains low. The reason for this is that the bed has a tendency to be regenerated by the sodium ion of the raw water, and this sodium ion placed on the bed counteracts the hydrogen ion exchange to a certain degree in forming the mineral acidity. The same sodium ion collected on the bed during the run in exchange of the hydrogen ion makes it possible for the bed, even after the hydrogen ion is all exchanged, to remove all the Ca and Mg of the water and simply work as a $Na_2\,Z$ softener until entirely exhausted In practice, the softener is taken out of service and regenerated as soon as the acidity drops, as this would upset the alkalinity balance of the whole set-up.

The $Na_2\,Z$ softener, as indicated in Fig. 3, starts the run as soon as the hardness is sufficiently low. The curve of the alkalinity to methyl orange indicates that the regeneration of the bed with the Na ion of the raw water also exists in this cycle. The drop of alkalinity at the end shows that the bed, having exhausted the Na of the regeneration fluid, takes up the Na of the raw water. The relatively high Cl content at the start of the run is noticeable, but this is not considered serious when extended over the whole of the run.

It is of interest to note that the hardness removal is decidedly better on the H_2Z than on the Na_2Z cycle.

Figure 4 shows the results. It is evident that the higher alkalinity and the congruent higher acidity of the two cycles are of advantage in forming an even alkalinity of the blended effluent.

According to experience, Lake Ontario water does not change very much regarding dissolved solids. The water only becomes turbid in spring and at that time the pretreatment already described may be necessary. The

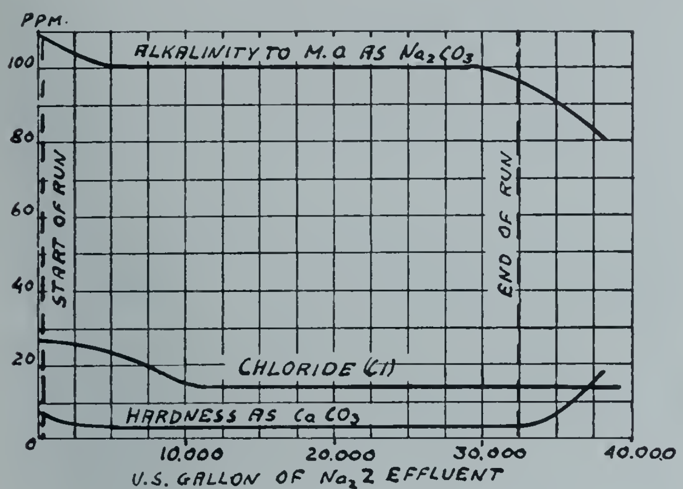

Fig. 3.

stability of the water makes it possible to use almost the same blending proportion throughout the year. If necessary the proportions can easily be computed by the formula:

$$\text{Percentage of } H_2Z \text{ effluent} = 100\ \frac{\text{Alk. inf.—Alk. blended}}{\text{Alk. inf.—Acidity}}$$

Alk. inf. = Alkalinity to methyl orange in influent water

Alk. blended = Alkalinity to methyl orange in blended water

Acidity = Free mineral acidity actually measured on the H_2Z cycle.

In practice the titration of the effluent for methyl orange alkalinity directs the blending.

In the present case it is a practice for the boiler water alkalinity and concentration to be regulated by the amount of blow-down. The blending of the make-up water makes it possible for the ratio between sodium carbonate alkalinity and sodium sulphate to be maintained according to the A.S.M.E. ratio without feeding sodium sulphate. The danger of caustic embrittlement is low, owing to the welded design of the boiler drums and the character of the raw water.

According to the figures, one softener run produces about 45,000 gals. on the H_2Z and 32,000 gals. on the Na_2Z cycle. The daily consumption varies between 80,000 and 92,000 gals. This means that the softener should be regenerated approximately every 20 hours. This operation takes two hours and is made by well-trained shift-engineers. The first step is the back-washing of the softener. During the run there is a downward flow, but during the backwashing the flow direction is reversed, the upward flow then loosens all the particles of the bed and removes the collected dirt. The rate of flow at backwashing is 4 gals. per sq. ft. per min., which is determined by the danger of raising the bed and washing the zeolite out of the tank. The duration of the backwashing is 5 to 10 minutes.

After backwashing, the softener is regenerated by introducing the acid (or salt, as the case may be) to the beds. The concentrated sulphuric acid is diluted to 10 per cent by weight in a lead-lined dilution tank. It then passes to the bed through an eductor where a further dilution to one per cent takes place. The brine is prepared in a similar manner in a tank and is an approximately saturated solution = (26 per cent). It is drawn from this tank through a sand filter to the bed through an eductor where a further dilution to 4 per cent takes place. The regeneration is made at a flow of 2 gals. per sq. ft. per min. and takes 45 minutes on the H_2Z cycle and 28 minutes on the Na_2Z cycle. During that time the bed is completely immersed in the regenerating liquid.

After regeneration is finished, the calcium, magnesium and sodium, the excessive acid, as well as all the sulphates, the excessive brine and all the chlorides are rinsed out of the beds at a flow of 5 gals. per sq. ft. per min. The rinsing takes 25-30 minutes on the H_2Z cycle and 45-50 minutes on the Na_2Z cycle.

The softener is completely regenerated in two hours. During this time the make-up water is taken from a concrete storage tank which has ample storage capacity for 3½ hours' supply. The filter which is near the softener is usually backwashed at the same time. The softener is then put into operation again. At present it works at a flow of 5 gals. per sq. ft. per min.

The softening capacity is apparently greater if the beds are working intermittently. Therefore, the softener runs at a rate of about 6,000 gals. per hour for ten minutes, then the high water level in the storage well stops it and the following low water level starts it up again. Over the week-end the standing time is increased and also the softening capacity.

During the run the softener does not need any special attention. The shift-engineer makes only one complete check on the water during the shift. The end of the run is indicated by large hands on the meters and by an alarm light.

The softener performs three functions during the run. As illustrated in the above figures, it reduces the hardness from 100 to 3 ppm. in terms of Ca CO_3. This assures an entirely scale-free boiler feedwater which also does not produce any deposits in the high temperature tubular heaters at 330 deg. F. It also reduces the alkalinity of the raw water from 100 to 17 ppm. in terms of Na_2CO_3. This assures a very low CO_2 content in the steam, which is of great importance in case of dry steam to prevent the condensate being too low in pH value. The softener also reduces the total solid content of the treated water from 180 to 100 ppm. which makes a low blow-down possible effects considerable saving.

The pH value of the raw water is 7.6. That of the H_2Z softener is around 3.0, and the Na_2Z softener is around 8.0. The blended effluent after the decarbonator is usually 7.0-7.2. The softened water and condensate mixture have a

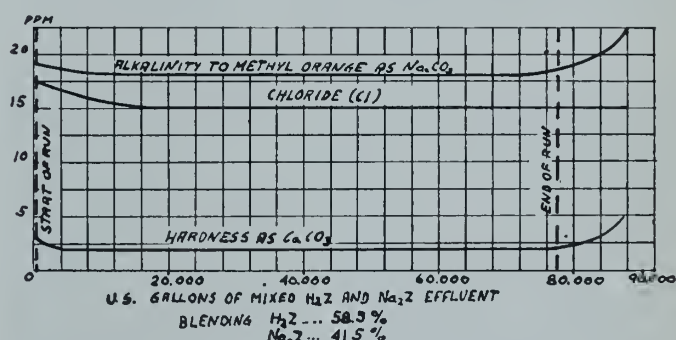

Fig. 4.

pH of 6.8-6.9. Then the water enters the deaerator heater which has an excellent pH raising effect, having an average feedwater of pH = 8.2 to 8.3 at a methyl orange alkalinity of 10-12 ppm. as Na_2CO_3 and an O_2 content of less than .03 cc. per litre.

It should be mentioned that there is no removal of silica in this water conditioning. The silica content of the raw water is low, and all analyses of the deposits taken at frequent boiler inspections show no appreciable silica accumulation. The reason for this is that the very low calcium content of the softened water combines more readily with

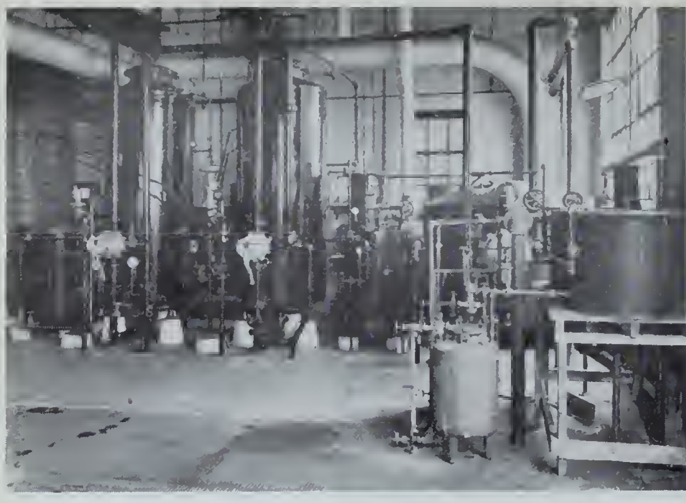

Fig. 5—A view of the carbonaceous zeolite water softening equipment at the Goodyear plant, New Toronto.

the continuously maintained 50 ppm. of PO_4 in the boiler salines than with the silica. The small silica content in the deposits is largely combined with magnesium or iron which are substances generally used to remove silica in flocculent form.

The water softening helps keep the boiler and all parts connected with the feed water in the best condition. This was checked quite frequently in the first year, and it can be stated that the boiler and all the heaters were found to be in first class condition. No corrosion, no scale and no tube losses occurred. Further, there was no shutdown or hindrance on account of failure of the water softening.

The only difficulties encountered were of mechanical character, and were mainly on the H_2Z softener. The softener itself and also a part of the valves are rubber lined. This seems to give full protection by saving wear of the parts. The automatic valves, made of copper alloys, suffered from the acid water, and will be replaced by better acid-resisting materials.

It was found that the feed water had higher hardness than the softened water and condensate. The reason was that the storage tank was of concrete and particles dissolved due to the high temperature of the condensate. It is proposed to apply rubber lining to the concrete storage tank, which would be of great benefit and unique in this line.

Cost of Treatment

During the run from which the above figures have been taken, 34,000 gals. Na_2Z and 46,000 gals. H_2Z softened effluent were supplied to the boiler. For this amount of water the regeneration needed 70 lb. of concentrated sulphuric acid H_2SO_4 and 120 lb. of sodium chloride Na Cl. At the same time the raw water hardness was 6.8 grain per gal. as $CaCO_3$. The price of Na Cl is $0.55 per 100 lb. and of the H_2SO_4 $0.92 per 100 lb. f.o.b. plant. The cost of these reagents was therefore 70 x 0.92 = 64.5c. and 120 x 0.55 = 66c. or a total of 130.5c. for 80,000 gals. The wash-water requirement was 7,350 gals. per regeneration. The plant costs are 2.65c. per 1,000 gals. Thus the cost of wash-water was 7.35 x 2.65 = 19.5c. per regeneration. Therefore, the total cost was 130.5 + 19.5 = 150c. per 80,000 gals. or 1.87c. per 1,000 gals. This is an average monthly figure.

The true comparison of costs requires that all the other costs involved should be taken into consideration, and also the loss in the blow-down water.

On the average the softener described reduces the total solids to 110 ppm., which requires a blow-down of 9 per cent of make-up for 1,300 ppm. total solids.

This blowdown makes the softening costs finally up to 2.08c. per 1,000 gals.

In the present case there is no need, as above explained, for sodium sulphate feeding.

For the final treatment the plant uses sodium hexametaphosphate Na PO_3 to carry an excess of 50 ppm. PO_4 in the boiler salines. At a phosphate price of 18.6c. per lb. this actually means 0.85c. per 1,000 gals. including the loss in blowdown, making a total of 2.08 + 0.85 = 2.93c. per 1,000 gals.

The chemical costs of a hot-lime-soda softener of the usual design for 17 ppm. hardness in the effluent and at a price of 0.6c. per lb. for quicklime and 2c. per lb. for soda-ash, may be estimated at 1.38 per 1,000 gals.

The hot-lime-soda softener requires sodium sulphate feeding, at the rate of 0.53 lb. per 1,000 gals. @ 2.75c. per lb. = 1.46c. per 1,000 gals. The phosphate required for the final treatment may be estimated at 0.154 lb. per 1,000 gals. @ 18.6c. per lb. = 2.86c. per 1,000 gals., making the total of chemical costs amount to 1.38 + 1.46 + 2.86 = 5.70c. The blowdown can be estimated at 14.5 per cent and that gives a final amount of 6.52c. per 1,000 gals.

It should be noted that the costs of the zeolite treatment are taken from the actual monthly average costs, and they are above the amount theoretically required, but below the costs guaranteed by the manufacturer.

This proves the economy of the system adopted, but it must be remembered that each case needs special consideration. In the present case the first costs of the two systems were close to each other. With greater hardness at the same flowrate, the cost would change in favour of the hot-lime-soda softener. The operation costs in case of turbid water also increase considerably. (This item has been neglected here because the plant needs treatment for turbidity only for two months per year). The above figures indicate that the lime treatment is very cheap for temporary hardness removal. The present tendency in the case of larger units is to use a cold lime softener in an improved form, combined with zeolite or sodium and hydrogen zeolite.

Recently there has been a further remarkable improvement in zeolite water softeners. By adding a further unit regenerated with caustic soda or soda ash an effluent can be obtained which is almost equivalent to distilled water.

It can be stated that in this case the carbonaceous zeolite water softener equipment fulfilled the expectations in all chemical and economical lines.

The decision on the choice of equipment was made by Mr. C. R. Smith, Mechanical Engineer, New Toronto, and Mr. J. C. Hergert, Steam Engineer of the Goodyear Plant, Akron, Ohio. The water softener was built by the Canadian Allis Chalmers, the Canadian representative of the Cochrane Corporation, Philadelphia, Pa. The water conditioning is under the supervision of Hall Laboratories, Pittsburgh, Pa.

CO-ORDINATION OF INDUSTRY WITH ENGINEERING COLLEGES*

WALTHER MATHESIUS
Vice-President, United States Steel Corporation of Delaware, U.S.A.

An address delivered at the Sixth Annual Meeting of the Allegheny Section of the Society for the Promotion of Engineering Education, Pittsburgh, Penn., on October 26th, 1940

The opportunity to appear before this group of distinguished educators is an honour for which I am grateful, and I appreciate this chance to present to you some of my views on engineering education and its relation to industry. It has been my good fortune and pleasure over the years to meet some of you individually and in groups such as this and I have always gained from these gatherings a better appreciation of your aims and a stronger desire to assist in the pursuit of our common objective as far as my ability permits me to do so. I trust you will not object when I ask you to receive my statements as representing only an individual viewpoint, rather than that of industry, and to accept my remarks as the observations of one who during his years of service in the operating phases of the steel business has always tried to keep alive his curiosity and interest in the world at large and particularly in the relationships which do and should exist between his field and engineering colleges.

This interest, if I may suggest, is not merely academic with me, since the training of younger and better executives is an urgent requirement of modern industrial enterprise; and besides I have two sons to whom a solution of this problem is of prime importance. Renewed discussion becomes timely due to the growing needs of industry for qualified graduate engineers, and due to the constantly increasing load of manifold responsibilities facing them in the service of industry.

As I view the title of my assignment: "Co-ordination of Industry with Engineering Colleges," I am frank to admit that my definition of co-ordination may not necessarily be the most precise. As I conceive it, it presupposes the existence of one or more problems of common concern and this, in turn, leads to the finding that such co-ordination logically implies mutual aims and interests. Certainly, industry owes much of its progress to the technological advances which have resulted from the skill of your engineering graduates to apply in practice the scientific facts and the knowledge which you taught them, and industry is happy to acknowledge this debt. Since engineering colleges, on the other hand, exist largely because of the demand for their graduate students by industry, they should currently be conversant with industry's requirements and be prepared to meet them.

It is not my intention to discuss any specific technical or engineering course, or its adequacy for fulfilling the expectations of a particular industrial field, but rather to consider college education in a broader sense which assumes a scope substantially wider than the exact curriculum or science itself. My viewpoint is concerned with the need for more adequate training of students at engineering colleges in the basic fundamentals of knowledge and logic, so that in later years they may advance creditably from a strictly engineering activity to administrative and executive positions with a maximum of advantage and continued benefit from the teachings of their college years. I find, in my own practical experience, that the effect of premature specialization in studies for a particular field often clings to the individual in business life and tends, in numerous cases, severely to limit his scope of usefulness and his advance to positions of greater importance in industry. Because engineering courses deal with exact sciences and problems, it might be assumed that the very nature of his early training in these subjects would tend to imbue the individual with unfailing logic and result in the training of men with marked analytical powers. It has been my experience, nevertheless, that quite frequently the contrary trend exists. While these technical graduates can solve specifically assigned and difficult engineering problems, their trained engineering mind tends to focus narrowly upon their task in its designing, construction or production phases and it fails to grasp the importance of essential economic, sociological and other fundamental relationships. Yet, it is frequently more important, in industry, that the needs for an improvement and its consequences, if made, be carefully and intelligently analyzed in their commercial, social and economic aspects rather than that the mechanics of the proposal be designed to the highest degree of perfection and precision. The latter task is as a rule quite capably handled by our graduate engineers, but apparently the former requirement is not so readily recognized by them. That this is due to a lack of inherent ability on the part of those engaged in the engineering profession is not conceivable since the fundamentals involved are certainly no more difficult to comprehend than the intricacies of many specific engineering problems.

It is obvious that engineers must be effective technologists, but it is also necessary that this profession, in order that it may render creditable services to the interests of the nation, be able to recognize and analyze correctly the many varied and complex economic, commercial or human problems which beset the majority of industrial developments today. The serious threats to their very existence, experienced by many branches of industry during the lean years of the recent past, have demonstrated forcibly and convincingly that it is not enough to drive for cost reductions and improved production methods, but that systematic attention must of necessity be given to public and industrial relations, to personnel administration and to research in these directions as well as in strictly engineering matters. Since all of these subjects must be considered as rightfully belonging within the sphere of technological influence, it is with good logic that the steel industry is now taking a more earnest interest in the activities of our colleges and in its mutual relationship and responsibilities with them, of which I should like to outline briefly, what appear to me as two important phases.

Firstly, I submit that one of the primary objectives of our engineering schools is the training of the growing generations to meet the future requirements of operation and management in industrial enterprise. Industry is, in a sense, an important customer for one of the college's principal products—a healthy crop of competent young engineers emerging annually from the undergraduate courses. Obviously it is desirable that there should be agreement between the colleges as producers and the industries as the consumers concerning the specifications for this output, just as they form a proper basis for dealing in the more commercial commodities of everyday business. My contention is that industry's co-operation could go far in aiding the college faculty as well as its students, if it would frankly state its conception of the essential qualifications for engineering graduates, and better still, if it would develop this conception by means of a thorough and continuous analysis of experience with its college trained personnel. While I

* Reproduced by special arrangement with the Society for the Promotion of Engineering Education.

am in no way authorized and perhaps only partly qualified to speak on behalf of the steel industry, I should like to present to you—as a personal good-will token—my own idea of a specification for engineers of college grade. It is my conviction that the essential objective of a higher education in engineering should certainly not be the graduation of specialists, but rather the building of good citizens, equipped with fundamental knowledge, and trained in logic. Completing his college studies should not become the end of, but rather the foundation for the young engineer's education for life, so that he will step out into the world able and eager to broaden his scope or, if he should desire later on to do so, to concentrate on a narrower field, in which he might then become a specialist and expert by choice and experience and not because of educational limitations.

I should like to urge my colleagues in the steel industry and my friends on the college faculties that they add their own statements of experience and recommendation to mine, in support or in rebuttal; and I suggest that these statements be submitted for the consideration of those who must plan and direct the curricula for our future engineers and managers. I am confident that co-operation of this kind will be welcome and helpful to industry, the colleges and the students.

It is obvious that under an educational programme such as I have attempted to describe, our technical colleges could not be expected to supply from its graduating classes to industry engineers so completely and so thoroughly prepared as to fit them at once for responsible positions which usually require not only experience and skill but a substantial amount of further study whereby to develop proficiency in one or more specific fields. This is of course primarily a task which the young engineer must undertake on his own responsibility and for which he will be well prepared if he has learned during his college years, as he should have, the faculty of study. However, in fairness to him as well as in its own interests, industry must assume the obligation to provide adequate opportunity for such further development and study. I regret having to admit that in my opinion the steel industry has as yet made little progress beyond the bare realization of this fact. Too often are the college graduates who join our forces assigned to narrowly confined specific jobs from which they find it difficult to extricate themselves except by resigning and looking for a better chance elsewhere. Too generally is this post-graduate training of engineers in industry left to chance and far too few are the instances where systematic training programmes and intelligent personnel management are actively and effectively applied.

It seems, firstly, that help is required to convince industrial managers that there is need for action on their part, not only as a matter of fair dealing, but definitely in the interest of assuring to their own enterprises intelligent and effective operators and managers for the future. And, secondly, I believe that industry, confused by apparent conflicts of interests and belabored by various pressure groups, needs fair and competent advice concerning the soundness of the principles and the propriety of methods in its personnel management procedures.

I venture the suggestion that you, the members of our college faculties, should be eminently qualified by reason of your impartial standing and your experience in education, to give such counsel to industry. Keeping in touch with the graduates of your schools, collecting, analyzing and reporting on their experiences, their progress and their recommendations for better ways of learning and doing more, you can, I believe, make a major contribution to the welfare of our industrial life, which should improve effectiveness in management and production and promote harmony in industry's ranks on the basis of just rewards to those sharing in its tasks with their hands, their heads and their savings.

And now I should like to point your attention to a second field of relationship between the technical colleges and industry. They can and will find more and more common ground upon which to work as partners for the sole purpose of gaining knowledge and of applying it to the conversion of natural resources into goods and services.

The logical contribution of the universities to this phase of co-operative endeavour comes of course from their facilities and talent for fundamental research—from their opportunities for post-graduate training and for specialized technological courses. The industry's share in this picture, as I see it, appears on the background of a broad long range policy, which directs the conduct of the business in the interest of the common good and subordinates to this requirement the desire for immediate and selfish gains. This policy does not lose sight, however, of the necessity for profits, whereby to assure continuance of the enterprise and to provide for improvements as well as for support to still further search for greater knowledge.

Undoubtedly there are industrial concerns which because of their scope or their position in a given field should undertake fundamental research work in their own laboratories and with their own staff, and some of these have done so creditably and with notable results. This does not, however, in my opinion, alter the fact that the greater share of the responsibility for searching out basic truth impartially and scientifically must always be assumed by our learned institutions.

But even under this arrangement, industry cannot permit itself to become a silent partner and to relinquish the active pursuit of this never-ending search to the universities. Industry must always provide through its own facilities and personnel, for the essential continuity to link fundamental research to applied technology and this in turn to practical operations and results. Theory and practice are thus joining hands more securely in the steel industry, which is learning to appreciate the value of scientific approach to production problems and the necessity for adopting, in place of the old trial and error routes, modern means for the impartial and precise determination of the relationship between cause and effect. In the steel industry, as elsewhere, not only management, but particularly the rank and file is at times apt to discount the experiences of the past and take the present for granted, as rightfully theirs. However, even among those who toil with their hands the recognition is dawning today that the future of their livelihood is linked definitely to that of the industry and that the welfare of the latter cannot be made permanent by dictates of law or by restrictive agreements on output, employment and development. They are making a major contribution to harmony and effective performance in the steel industry by conceding and supporting the value of scientific knowledge in partnership with training and experience. For overall success this co-ordination is essential as much as courageous, competent and conscientious management leadership. Together, they give us, in my opinion, a far better assurance for the future of our economy than could be realized under any other social order, no matter how glowing its promises might be for the pot of gold at the end of the rainbow.

These mutual interests and mutual responsibilities place definite obligations at the doors of industry and colleges and neither have been remiss in their attempts to fulfill their commitments. Nevertheless, I do not believe that the greatest degree of success in co-ordination can be realized for the common good until a strenuous effort is made by both sides to understand fully these mutual relationships in the service of educational as well as technologic advancement and to agree on the manner in which these objectives will be obtained. It is my personal opinion that industry can go somewhat further than it has up to the present time in developing ways and means for effective co-operation with engineering colleges. I suggest that in addition to the various avenues now utilized to this end, representatives of industry might more frequently visit the educational centers to acquaint themselves at first hand with the problems which you face and also to convey to the students as well as the college faculty their conceptions of the needs and prospects in industry. For example, I believe that many executives and others in responsible industrial positions would be willing to give of their time as far as they can, to meet with the students and the faculties for informal talks on specific engineering subjects as well as on the broader aspects of industry's requirements from educational colleges. I suggest further that, in addition to this type of contact, arrangements be made for similarly informal meetings concerned with other phases of world affairs and our national life. This would, in my opinion, be a rational means of directing the student's attention to other essential elements of present-day civilization, which may be remotely beyond the scope of his engineering courses, but which he should learn to understand so as to broaden his grasp of humanity and his appreciation for the wonders of our universe.

And in conclusion, might not the desired co-ordination be more readily consummated through efforts made conversely also by the members of the college faculties, to call more frequently at industrial centers and in the workshops, there to take the initiative of inquiry and of discussions on the problems of both sides with men in industry and in public life ? From such excursions into the whirl of productive and competitive activity you would bring home not only facts and figures, but often evidence of lacking knowledge, of bias and confusion, challenging your powers of impartial observation and scientific analysis. You would find there encouragement for your efforts in research, in teaching, in your written or spoken contributions to the scientific literature and technical wisdom.

Leaving this suggestion for your consideration may I express the hope that continued frank discussion may stimulate thought and action, aiming for continued development rather than for sudden changes to serve a passing need or to meet a present emergency. Only through sustained interest and effort can the coordination of industry with engineering colleges become complete and lasting, and that is for both an essential requirement of preparedness for distinguished service to our country and to mankind. Your S.P.E.E. can and will have an important share in this endeavour.

DISCUSSION

Robert F. Mehl*

I find it very pleasant,—very pleasant indeed,—to discuss this paper by Dr. Mathesius. Six years ago, when we reorganized our curriculum in metallurgical engineering, we discussed the problem with many prominent industrialists, of whom Dr. Mathesius was one of the most helpful. His experience both in metallurgical education and in industry has been such that his advice has always been welcome and his opinions always well-formed and reasonable.

I doubt that there is anyone in engineering education more concerned with co-ordination with industry than the professor of metallurgical engineering. Such cooperation in metallurgy is somewhat more difficult than in other branches of engineering, arising, I believe, from the fact that the profession of metallurgical engineering is not so well defined as, for example, that of chemical engineering or that of electrical engineering. The metallurgical engineer must scatter his attention over so very many different processes and products, and he must be familiar with so many types of engineering and science that it is not easy to formulate *simple* programs of metallurgical education.

The profession of metallurgy itself is in a period of rapid change. The industrial metallurgist may be a man who started in life as a mill boy or he may be one who has attended a university and obtained a doctorate; he is called upon at once to operate mills, to exercise his judgment upon some highly specialized technical and scientific problems, and even to handle labor problems. He is to-day varied in type, and he must handle a wide variety of problems. But in the past decade or so industry has been calling for huge numbers of well-trained metallurgical engineers, and placing them in positions which previously were filled by men of no training but of much practical experience. In such a changing and complex scene, it is inevitable that the problem of metallurgical education should not be an easy one; surely in such a position, it is of the greatest importance that the industrialist and the educator co-operate in such a way as to contribute the maximum good to the profession.

I very much like, therefore, Dr. Mathesius' suggestion of mutual discussions among educators and industrialists. I organized a discussion group on metallurgical education in the American Institute of Mining and Metallurgical Engineers two years ago. It was only moderately successful. I think it showed chiefly that the problem is one which requires careful thought and not one to be solved off-hand. My chief difficulty was that the industrialist was not so much concerned in discussing the content of metallurgical curricula, which he was quite willing to leave to the educator, as he was in discussing the miserable English graduates of technical schools display, which though certainly important was somewhat beside the point. By and large, however, these men agreed with Dr. Mathesius that it is the first function of the educator to present to his students the *fundamentals* of science and engineering, leaving the very, very many details of industrial processes to be learned by later experience in the industry. Not all industrialists feel this, for many think graduates should be more thoroughly acquainted with practical engineering as they graduate. We have found some difficulty in pointing out that the processes in industry are so very numerous that there simply isn't time enough in school to train men even in the important ones, and in pointing out to them also that in a very few years the details of many of these will have changed. Here, I think, is a situation which cries for the type of discussion which Dr. Mathesius recommends so strongly. It has been our experience that when educators and industrialists *fully* discuss these problems, they invariably agree that engineering training should and must be restricted almost exclusively to fundamentals.

I think that misunderstanding occasionally arises by individuals confusing the several duties of the professor. In a school such as ours, the professor has three chief duties: first, to train engineers in a four-year curriculum in such a way that they will be of maximum service to industry second, to train graduate students so as to make them competent to assist industry in research and development; and third and last, to carry on research. These several duties have, as you can see, different objectives and should not be confused. It is not difficult to organize a department in which all three duties may be adequately met. I think it would be easy to agree that the primary duty of the university professor in research is to do research in fundamentals. While industries do some fundamental research, isn't it clear that the university professor should contribute not primarily to practical research and development but to fundamental research and development ? As an example (so that these words should not be wholly empty) the industrially important processes of the carburizing of steels is one which depends on the rate of absorption of carbon *by* steel and on the rate of diffusion of carbon *in* steel. This industrial process has never been adequately handled from an engineering point of view, chiefly because the factors which influence rates of diffusion of carbon in steels have not been studied. The university can then set for itself the task of

*Professor and Head of the Department of Metallurgical Engineering, Carnegie Institute of Technology, Pittsburg, Penn.

studying these fundamental rates, from which in time engineering knowledge may ensue and the industry benefit.

If we admit, then, that the professor should do this type of research, let it be *thoroughly understood* that his activities in this direction do *in no way* preclude his success in training the undergraduate for practical work. As to the responsibilities of the professor in cooperation with industry, should he enjoy such sympathetic understanding from industry, let him then see to it that he welcomes every contact he can make with industry, and let him recognize that his fundamental research is justified only as it will in time be of service to industry.

I may conclude this discussion by suggesting a type of co-operation which I think would be of great value to the engineering school and *especially* to industry. It is obvious that the atmosphere of the engineering college is not that of industry. Every educator must make an effort to acquaint his students with the industrial scene by frequent inspection trips and by frequent lectures by outside engineers. This isn't enough. For years we have wanted to make some arrangements that would permit our undergraduate engineers to spend two or three summers working in mills, but we haven't yet been able to work out such a plan. Only a few students are able to make such arrangements themselves. If such a program could be formally organized, I think it would be as fine a contribution to metallurgical education as anything that has been done in many years. I should not wish this upon Dr. Mathesius as a task, but I should hope that the co-operation between industry and the engineering college for which we both devoutly wish will develop to a degree that a program of this sort may be recognized as desirable and be begun.

DISCUSSION OF COLUMNS SUBJECT TO UNIFORMLY DISTRIBUTED TRANSVERSE LOADS

Paper by Professor J. A. Van den Broek[1], published in *The Engineering Journal*, March, 1941

S. D. Lash, M.E.I.C.[2]

Professor Van den Broek's paper is a very welcome addition to the literature on the design of columns subject to transverse loads.

It is worth while pointing out perhaps, that the assumption that the elastic curve of the column may be closely represented by a sine or cosine curve is not new. It should, I believe, be credited to Professor Perry and dates from 1892[3]. A description of this method has been presented more recently in "The Analysis of Engineering Structures" by A. J. S. Pippard and J. F. Baker, from which the following has been taken using Professor Van den Broek's notation:

Assuming $y = -\triangle \sin\frac{\pi x}{l}$ - - - - - - - - - - - (1)

$M = -EI\frac{d^2y}{dx^2} = Qy + M'$, (where M' is the moment due to the lateral loads acting alone) (2)

$$-EI\ \frac{\pi^2}{l^2}\sin\frac{\pi x}{l} = Qy + M'$$

$$P_{cr}y = Qy + M' \text{ where } P_{cr} = \frac{EI\pi^2}{l^2}$$

$$y = \frac{M'}{P_{cr} - Q}$$

Substituting in (2), $M = \frac{P_{cr}}{P_{cr} - Q}\ M'$ - - - - - - - (3)

Let f_1 be the limiting stress, then $f_1 = \frac{Mc}{I} + \frac{Q}{A}$

$$= \frac{P_{cr}M'c}{(P_{cr} - Q)\ I} + \frac{Q}{A}$$

Substituting, $M' = \frac{kwl^2}{8}$

$$f_1 = \frac{1.23\ kwEc}{P_{cr} - Q} + \frac{Q}{A}$$

$Q = \frac{1}{2}\left[f_1A + P_{cr} - \sqrt{(f_1A - P_{cr})^2 + 4.92\ kwEcA}\right]$ - (4)

The above calculation makes use only of the fundamental relation between curvature and moment and appears considerably simpler than introducing work or energy methods. There does not appear to be any approximation involved, but rather curiously, equation (4) is the same as Professor Van den Broek's formula IV (a). (There is a typographical error in the paper as printed in the March *Journal:* the sign before the square root in formula IV (a) should be minus instead of plus). This result is somewhat surprising since formula IV (a) was arrived at by assuming the elastic curve to be a fourth degree parabola rather than a sine curve. However the difference between the two equations is slight.

It should perhaps be pointed out that the Perry column formula for axially loaded struts without transverse loads, is derived in a somewhat similar way, the imperfections in material, workmanship, etc., being represented by a hypothetical initial curvature of the strut or column, such curvative being represented by a sine or cosine curve.

I. F. Morrison, M.E.I.C.[4]

The treatment of the theory of combined compression and bending as applied to beam-columns by the author is indeed novel and interesting.

The basis on which the analysis rests depends on two fundamental assumptions, namely that the material is elastic and that its stress-strain relationship follows Hooke's law. Both are necessary for the validity of Formula I and the one does not imply the other, for there are materials which, though they possess linear stress-strain relationship, are not elastic and vice versa. In Formula I the integral term is the expression for the internal work done by the auxiliary load, F, in conjunction with the strain caused by the actual loading. Its validity rests on the assumption of Hooke's Law. The left-hand term is the external work done by the auxiliary load, and the validity of the process of equating the two terms rests on the assumption of elasticity of the material as well as of the system as a whole. Thus, it is not only the elastic limit which should be chosen as the controlling stress but also the proportional limit and these, except by assumption, may not have the same numerical value. The assumption that they are the same must, therefore, be added to those assumptions above. In its abstract form, the stress-strain curve for the material is often taken as straight, up to a certain value of the unit stress, which, for those materials, such as mild steel, which possess a well defined yield point, is taken as equal to the yield value and which otherwise must be arbitrarily assumed. It would seem better, therefore to change the meaning of f_1 in the

paper to indicate the yield point instead of the elastic limit stress. Materials which do not follow Hooke's law acquire a well defined yield point after the first application of loading but suffer a permanent strain in the process.

The paper deals with a special case of transverse loading and does not deal with members not initially straight, nor does it deal with eccentrically applied axial loads. Both of these items are of considerable importance in practical design and the paper might well be extended to include them. It is easily shown that both "the initial imperfection," as Southwell calls it, and the application of a couple at each end are equivalent to a suitably chosen transverse loading and, therefore, may be so treated in the theory. However, although the end couples could be dealt with by a change in the load factor k, the initial imperfection required a variable transverse loading. This could be included in the theory by adding $\sum w_n \sin \frac{n\pi x}{l}$ for the kw term. Practically, the first term of the series would likely be found sufficient.

The term P_{cr} in Formula II is apt to be, at first sight, misleading, for it is the critical load for the column based on the assumption that I, the moment of inertia of the constant cross-section about an axis perpendicular to the plane of the loading, is a minimum. This is often not the case, so that the minimum critical load may be much less and may limit the carrying capacity of the number as a column. In addition, the member may be unstable as a beam under transverse loading due to insufficient torsional rigidity.

Southwell gives for the bending moment including the thrust-effect,

$$M = Q\ (A \sin nx + C \cos nx) - \frac{kw}{n^2}$$

in which kw is the intensity of loading and $n^2 = \frac{Q}{EI}$. A and C are constants of integration to be determined by the end conditions.

For a uniform load, i.e. constant kw and pinned ends $M_{max} = \frac{kw}{n^2}\ (\sec \tfrac{1}{2}\ nl - 1)$, and the maximum compressive stress due to combined thrust and bending is $f = \frac{Q}{A} + \frac{kw\ Ec}{Q}\ (\sec \tfrac{1}{2}\ nl - 1)$ - - - - - - - - - - - - (5)

This equation cannot be solved for Q and, although $(\sec \tfrac{1}{2}\ nl - 1)$ can be expanded into a series, this series is convergent only when $(\tfrac{1}{2}\ nl)^2 < \frac{\pi^2}{4}$. When $(\tfrac{1}{2}\ nl)^2 = \frac{\pi^2}{4}$, $Q = \frac{\pi^2\ E\ I}{l^2}$ so that at the critical load the series is no longer convergent and in fact it is so slowly convergent for values of Q near the critical load as to be of no practical value.

In order then to have a unit stress, f_1, produced due to the combined effect of a thrust, Q, and a uniform transverse load, kw, these values must be related by means of the equation (5).

If, as in Table I, one takes as an example l = 25 in. Q = 22,866 lb. for a 1 in. round rod, with $E = 30 \times 10^6$ p. s. i.[6] Then f amounts to 40,035 p. s. i. which is quite close.

The differential equation for the beam-column with a uniformly distributed load is: $E\ I \frac{dy^2}{dx^2} = -\ Q\left(y + \frac{kwlx}{2Q} - \frac{kwx^2}{2Q}\right)$.

This is easily solved and gives:

$$\triangle = + \frac{k\ w}{Qn^2}\ (\sec \tfrac{1}{2}\ nl - 1) - \frac{kwl^2}{8Q} \quad - - - - - - - \quad (6)$$

The numerical value for $\triangle$ from equation (a) is: $\triangle$ = .0458 in. and from equation (6) $\triangle$ = .0460 in.

By these results it is shown that the theory in the paper checks quite well with the classical theory.

C. M. Goodrich, M.E.I.C.[7]

Professor Van den Broek's column formula makes a strong appeal to the writer, partly because of the clean-cut basic analysis, partly because of its treatment of coincident transverse loading.

The ratio at the quarter point between the fourth degree parabola and the sine curve is .711 to .707, with equal centre deflections.

When $k = 0$, one sees a very characteristic straight line to an Euler curve at $L/r = 80$, approximately, as in Figs. 3 to 7 in the paper. In a paper by Mr. Pritchard in the *Transactions* of the American Society of Civil Engineers, Vol. 89, one finds on Page 1238 a table of tests of columns by the U.S. Bureau of Standards, and below it the note "Omitting these three from consideration the U.L.P. (useful limit point) of columns with $L/r = 85$ is smaller than for columns with $L/r = 50$ by less than one per cent." On Page 1246 a table of column tests of lap-welded tubing by the Watertown arsenal gives for spherical ends, $L/r = 47$, 31,700 lb. per sq. in.; $L/r = 72$, 33,300 lb. per sq. in.; for pin ends, $L/r = 47$, 32,300 lb. per sq. in.; $L/r = 72$, 30,300 lb. per sq. in.; for flat ends, $L/r = 50$, 29,500 lb. per sq. in.; $L/r = 75$, 30,500 lb. per sq. in.; $L/r = 100$, 28,700 lb. per sq. in.

In the same table the tests for built pin-ended columns of I-beams with covers and four angles 4 by 3 by 3/8 show the average for $L/r = 50$ as 30,000 lb. per sq. in., for $L/r = 75$ as 29,300 lb. per sq. in., for $L/r = 100$ as 30,700 lb. per sq. in.

It would be interesting to compare still further tables; the writer has merely taken the first such tables that came to hand. As far as they go they appear to confirm the character of the boundary line as given in the paper.

One hopes that the author will add still further light in this twilight zone of column analysis.

E. C. Hartmann[8]

Some of the readers of Professor Van den Broek's interesting and valuable paper will no doubt wish that the method of column design which he has outlined were available in a form suitable for use with conventional allowable working stresses instead of being limited to the case of ultimate loads or "limit" loads. Other readers will wish that the formulas were expressed in more general terms so that the effects of eccentricities, crookedness, and non-uniformly distributed side loads could be handled. For such readers, attention is called to the writer's discussion of a paper by Mr. D. H. Young, "Rational Design of Steel Columns." This discussion, which covers practically the same subject that Professor Van den Broek has covered, but from a somewhat different viewpoint, was first published in the August, 1935, *Proceedings* of the American Society of Civil Engineers and is also available in the 1936 *Transactions* of the same society.

In his discussion of Mr. Young's paper, the writer has derived a formula (Equation 108) for the allowable working stress in any beam-column. This formula, when rewritten in the nomenclature used in Professor Van den Broek's paper with an additional term n representing nominal factor of safety, is as follows:

$$f_w = \frac{f_1}{n} - \frac{Q}{nA}\ \frac{\left(\frac{f_1}{n} - \frac{Q}{nA}\right)}{\frac{P_{cr}}{nA}}$$

in which f_w = the allowable combined direct and bending stress in the extreme fibres of the beam-column, lb. per sq. in.

$\frac{f_1}{n}$ = the allowable extreme fibre stress on the member if it were a beam only, lb. per sq. in.

[6] The use of $E = 40 \times 10^6$ p. s. i. in Table II is obviously a typographical mistake.

[7] Consulting Engineer, The Canadian Bridge Company, Limited, Walkerville, Ont.

$\frac{Q}{n}$ = the working column load for which the member is being designed, lb.

$\frac{P_{cr}}{n}$ = Euler load divided by the same factor of safety used in arriving at $\frac{f_I}{n}$, lb.

A = cross sectional area of member, sq. in.

The formula above appears more complicated than it really is, because the factor of safety n would ordinarily appear only once as an explicit factor.

The writer's formula is best applied in design by cut and try methods. Given the column load and the beam load which a member must safely carry simultaneously, and the allowable stress for the material in bending, a trial member is selected and the proper quantities entered in the above formula to obtain the allowable combined stress. If the resulting allowable combined stress exceeds the combined stress calculated in the conventional manner neglecting the deflection of the member, the member is safe. If the resulting allowable combined stress is less than the calculated, the member does not have the desired factor of safety and stronger members should be investigated until a safe one is found. An example of the application of this method is given in the writer's discussion of Young's paper previously mentioned.

Multiplying through the above formula by n, the factor of safety, one obtains:

$$nf_w = f_I - Q\frac{(f_I - \frac{Q}{A})}{\frac{P_{cr}}{A}}$$

In this form the formula is suitable for use with ultimate loads instead of working loads, the term nf_w on the left representing the permissable combined stress on the extreme fibre of the beam-column when the member is just ready to fail. For a member of the type shown in Fig. 1 of Professor Van den Broek's paper, just ready to fail, the formula may be rewritten as follows:

$$\frac{Q}{A} + \frac{kwl^2c}{8I} = f_I - Q\frac{(f_I - \frac{Q}{A})}{\frac{P_{cr}}{A}}$$

This formula, solved by cut and try methods, gives results identical to those obtained from Professor Van den Broek's formula II. This is not surprising in view of the similarity of the two derivations. This similarity is evident from the fact that Equation 102 of the writer's discussion of Young's paper is identical with Professor Van den Broek's equation (c).

As Professor Van den Broek has ably pointed out, certain constants in the formulas to be used with beam-columns depend upon the configuration of the member in its deflected position. Professor Van den Broek's solutions cover two configurations, the sine curve and the fourth degree parabola; and the writer's formula is derived for the sine curve only. Such formulas are quite accurate when applied to beam-columns with axial end loads and uniformly distributed side loads, but they are not so accurate when applied to eccentrically applied end loads and concentrated side loads, because with these loading conditions the configuration of the column may depart considerably from the sine curve or the fourth degree parabola. The formulas will be found satisfactory, however, for almost all combined loading conditions met with in ordinary design.

The writer's formula, in somewhat modified form, is included in the 1938 and 1940 editions of "Structural Aluminum Handbook"[9] under the heading, "Combined Bending and Direct Compression," on page 57. Included in this section is an additional formula of the same general type derived by the writer's colleague, Mr. H. N. Hill, which permits the analysis of beam-columns to be extended to members which become unstable in the direction perpendicular to the plane of the applied bending moment. This phase of the problem has also been investigated by Dr. Bruce G. Johnson in a paper, "The Lateral Buckling of the I-Section Column with Eccentric End Loads in the Plane of the Web," presented before the National Applied Mechanics Meeting, American Society of Mechanical Engineers, Philadelphia, June 21, 1941.

THE AUTHOR

The discussion of my paper on "Columns Subject to Uniformly Distributed Transverse Loads" is very much appreciated indeed. The major points made by the reviewers appear to fall into two classes. Mr. Goodrich and Professor Morrison would like to see the method of analysis illustrated in my paper applied to other column problems, while Mr. Lash and Mr. Hartmann question the newness of either method or formulae.

There is, indeed, "nothing new under the sun." Yet, it is the method of approach and the distinctiveness of the analysis stressed in the title and in the synopsis which I regard as the most significant part of the paper. Mr. Hartmann states: "This formula (his formula), solved by the cut and try methods, gives results identical to those obtained from Professor Van den Broek's Formula II." Mr. Lash states: ". . . but rather curiously, Equation (4) (Mr. Lash's equation) is the same as Professor Van den Broek's Formula IVa." I believe both gentlemen to be in error. Instead of their formulae being the same as either of mine, Mr. Hartmann's formula is identical to Mr. Lash's which is derived from Pippard and Baker, which in turn, was first developed by Perry.

Mr. Lash's formula seems to contain a slide rule error. His figure 4.92 is derived from $\frac{\pi^2}{2}$ and should therefore have been 4.9348. When Mr. Lash identifies his formula with my formula IVa he fails to note an important difference. His formula contains the term, P_{cr} whereas mine has the expression $9.836EI/l^2$. For practical results an accuracy of four or even three significant figures is not warranted. I will concede, then, that Mr. Lash's formula constitutes a third formula, that all three are but approximate formulae and that for practical results, one may choose any one of them. The following table illustrates the differences in the results obtained by the three formulae:

			Formula IIa	*Formula IVa*	*Mr. Lash's Formula*
For 1″ round bar	$\frac{l}{r} = 100$	$k = 10$	20272	20282	20339
	$\frac{l}{r} = 200$	$k = 10$	4576	4593	4609
For 12″ x 3″ x 25 lb. channel	$\frac{l}{r} = 60$	$k = 10$	253580	254300	254370
For 5¾″ x 9½″ x 40 lb. subway column	$\frac{l}{r} = 60$	$k = 10$	395470	396830	397220

I further concede that, instead of introducing energy methods, I might have limited myself to the use of the differential equation of curvature and obtained identical results. This, however, seems to be strictly a matter of taste and does not warrant further discussion.

If it is conceded that Lash's, Hartmann's and Pippard and Baker's formulae are approximations, the question as to the magnitude of the error remains. The presumption is that they check the results of their formulae with those obtained by means of the exact theory, or what Professor Morrison calls the classic theory. They follow the procedure which Professor Morrison applied to my formulae. In this then lies the essential distinction between my method of analysis and that of Lash's or Hartmann's. I could not call my method either exact or classic, but I feel I am entitled to call it thoroughly rational. Note that in my paper I did not go to any exact or classic theory to obtain a check for my formulae. Had I done so I would have defeated my principal purpose. The most important part of any theory lies in its assumptions or postulates. Therefore, I regard my figure 2, which presents proof of the near identity of the sine curve and the 4th degree parabola, as the most important part of my development. This near identity, in my opinion, makes my treatment complete in itself.

Regarding the application of the method of analysis, illustrated by my paper, to other column problems, which Professor Morrison and Mr. Goodrich request, let us consider the case of the eccentrically loaded column.

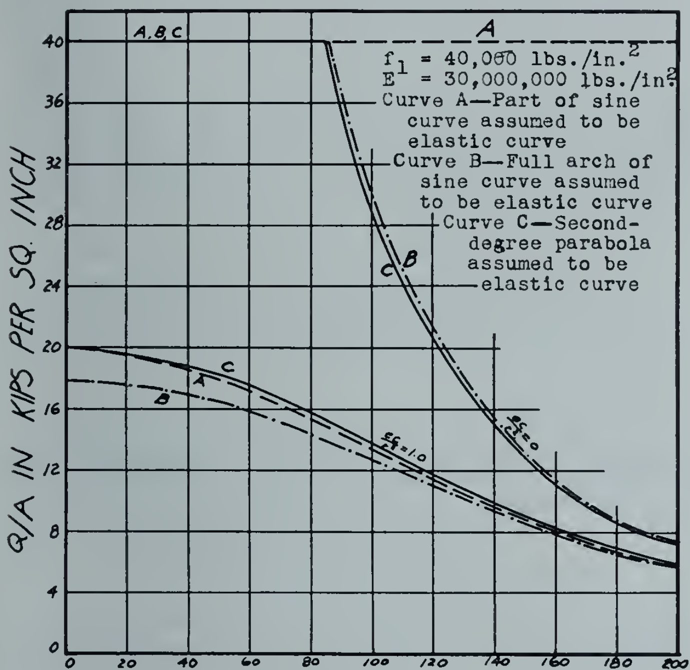

Fig. 9—Comparison of different column formulae for eccentric loading.

The elastic curve of an eccentrically loaded column is an intercept of a sine curve. In the second edition of my book, Elastic Energy Theory[10] which is to appear January 1, 1942, may be found the development of a strength formula for eccentrically loaded columns by the method here under discussion. The resulting formula is the familiar secant formula:

$$f_1=\frac{Q}{A}\left(1+\frac{ce}{r^2}\sec\frac{l}{2}\sqrt{\frac{Q}{EI}}\right) \qquad \text{Formula A}$$

[10] Elastic Energy Theory, by J. A. Van den Broek, John Wiley and Sons, 1942.

Since the elastic curve assumed is the correct elastic curve we arrive at the so-called exact formula.

For the limiting case, in which the eccentricity, e, approaches zero as a limit, the elastic curve of the eccentrically loaded column approaches the sine curve as a limit. For the limiting case, in which the eccentricity, e, approaches infinity as a limit, the elastic curve of the eccentrically loaded column approaches the arc of a circle as a limit.

The strength formula for eccentrically loaded columns, predicated on the assumption that the elastic curve is a complete arch of a sine curve, is:

$$\frac{Q}{A}=\frac{1}{2}\left[f_1+\frac{\pi^2E}{\left(\frac{l}{r}\right)^2}\left(1+\frac{\pi^2}{8}\frac{ec}{r^2}\right)-\sqrt{\left\{f_1+\frac{\pi^2E}{\left(\frac{l}{r}\right)^2}\left(1+\frac{\pi^2}{8}\frac{ec}{r^2}\right)\right\}^2-4f_1\frac{\pi^2E}{\left(\frac{l}{r}\right)^2}}\,\right] \qquad \text{Formula B}$$

Figure 9 shows Formulae A and B plotted for the values of $\frac{ec}{r^2}=0$ and $\frac{ec}{r^2}=1$. In my opinion, Fig. 9 is not necessary to demonstrate the inaccuracy of Formula B. Figure 2 of the original paper is enough to convince me that Formula B will give values which are seriously in error. In the analysis of the beam column the two limiting curves, the sine curve and the 4th degree parabola, are so nearly identical as to be almost indistinguishable as shown in Fig. 2. In this instance, however, the two limiting curves, the sine curve and the circle, show the greatest possible divergence.

While Formula B is obviously unsatisfactory, this does not mean that the method of analysis used in its derivation may not give quite satisfactory results. All we need to do is to choose a compromise curve, which, for values encountered in engineering practice, will give satisfactory results. The second degree parabola is such a compromise curve. This curve, when used in the manner illustrated in the original paper, results in a strength formula for an eccentrically loaded column which appears quite satisfactory. The resulting formula is:

$$\frac{Q}{A}=\frac{1}{2}\left[f_1+\frac{9.6E}{\left(\frac{l}{r}\right)^2}\left(1+\frac{ce}{r^2}\right)-\sqrt{\left\{f_1+\frac{9.6E}{\left(\frac{l}{r}\right)^2}\left(1+\frac{ce}{r^2}\right)\right\}^2-\frac{38.4f_1E}{\left(\frac{l}{r}\right)^2}}\,\right] \qquad \text{Formula C}$$

The mathematical development for this formula may be found in my book[10]. This book also shows curves for a greater range of values of $\frac{ec}{r^2}$, and shows that in all cases Formula C gives results very close to those of Formula A.

The advantage of Formula C over A lies in the fact that it permits of direct solution. Formula A, being a trigonometric formula, can only be solved by cut and try method.

THE ENGINEERS' COUNCIL FOR PROFESSIONAL DEVELOPMENT

A Condensation of the Report to the Boards of Constituent Bodies presented by Dr. R. E. Doherty, Chairman, March 1941.

I. E.C.P.D. Should Look Ahead

The engineering profession is now facing the challenge of the unstable new world it has helped to create. In trying to meet the obligation this implies, two deficiencies appear: lack of capacity for joint action, and defects in the character and extent of the engineer's preparation for his profession. Concerted thought must be given to the correction of these conditions.

While recognizing this responsibility in the accomplishment of national stability, most engineers do not realize that the profession is not yet prepared for its share in the task. There are definite ways in which the E.C.P.D. should contribute to this end, but its constituent groups need clearer understanding and more general conviction as to E.C.P.D.'s purposes and potential usefulness.

It is urgent that the constituent organizations take a greater democratic hand in the affairs of the body they set up eight years ago. To do this, they must understand better than they do now, just what the E.C.P.D. is. Some people think it is merely an accrediting agency for engineering curricula; others fear it may try to usurp some powers of the constituent societies; some do not know or care what it is all about; so there should be an educational campaign by the several engineering groups to acquaint their members with the purposes and work of the Council.

The E.C.P.D. is what its charter says it is. This charter is a great document of engineering statesmanship that clearly points the democratic way toward the further development of the solidarity and prestige of the profession. It says: "The E.C.P.D. is a conference of engineering bodies organized to enhance the professional status of the engineer through the co-operative support of those national organizations directly representing the professional, technical, educational and legislative phases of an engineer's life." To this end it aims to "co-ordinate and promote efforts and aspirations directed toward higher professional standards of education and practice, greater solidarity of the profession, and greater effectiveness in dealing with technical, social, and economic problems.

The E.C.P.D. has been successful as an accrediting agency, in this case performing a task which could be carried out in a few years. But most of its other projects are of a kind that cannot become effective so promptly, although in the long run they may be even more important to the profession than accrediting.

Last October, the Engineering Institute of Canada was welcomed as a constituent member of the E.C.P.D. This affords a liaison with Canadian engineers which will aid the development of common interests in both countries. The Council has already benefited by the presence of its new members.

The constituent bodies have shown that they can co-operate—for example they have formed the E.C.P.D.—but in some cases their co-operation has been limited. Engineers must not stand by in indifferent isolation; the solidarity of the profession is necessary if they are to take effective part in preserving a democratic future for this country.

Constructive co-operation is at the heart of democratic life. In a democracy, if the political, industrial and professional groups are not organically related to the whole, a basis for national stability does not exist. This is the primary reason why the groups of the engineering profession should cultivate the capacity for co-operation.

As regards professional training, upon which the professional status of engineers depends, there must be better selection of students, more appropriate collegiate training, greater incentive and opportunity for post-graduate education, and fuller recognition of professional achievement. All this professional development certainly requires co-operative effort. The purposes involved are precisely those of the E.C.P.D.

Under present conditions, the E.C.P.D. is the only body which, because it has direct representation of the engineer's professional, technical, educational, and legislative interests, can deal effectively with the broad problem of professional development. It is, however, an advisory service organization, responsible to its constituent bodies, and must confine itself to matters strictly within the scope of its charter. But if co-operative progress is to be made by the engineering organizations, the Council is now the only central medium available.

II. Membership and Activities of E.C.P.D.

It will be noted that the Council has functions of advice and recommendation only, and does not administer any project unless it is definitely approved by a majority of the constituent groups.

The constituent bodies include the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Institute of Chemical Engineers, the Society for the Promotion of Engineering Education, the National Council of State Boards of Engineering Examiners, and the Engineering Institute of Canada.

The work of the Council is indicated by the activities of its five principal committees. Brief reports of their work follow:

1. Student Selection and Guidance

The Committee has organized groups of engineers to meet highschool boys and others who make enquiries as to the study of engineering. Some 8,000 boys attended such meetings last year. Various committees and local sections of national societies, and local and state engineering societies have aided. In general, the public schools have welcomed such guidance to prospective students which gives information regarding the mental, physical and personal requirements for success in an engineering career, and the many phases of engineering work. Higher standards of admission to engineering schools are being urged, looking to the selection of better engineering talent.

A pamphlet, "Engineering as a Career," has been prepared for publication.

2. Engineering Schools

A list of 542 undergraduate engineering curricula in 125 institutions has been prepared. One hundred and sixty-four curricula were inspected but not accredited. This work continues.

The basis for accrediting has been a sound educational programme. The committee's visits and the friendly advice given when requested, have, in many cases, resulted in marked improvement.

An analysis of the data gathered by the committee has been published and distributed to the officers and libraries of the various institutions.

3. Professional Training

To advance after graduation, the young engineer must do more than acquire proficiency in his immediate job. He must gain knowledge and experience through further study and through contacts with fellow engineers. The function of the E.C.P.D. Committee on Professional Training is to aid junior engineers in this critical phase of their development. Working with local sections of constituent societies, many junior engineering groups have been organized. Suggested reading lists, extension courses, lectures, discussions, and inspection trips are arranged or encouraged by this committee.

4. PROFESSIONAL RECOGNITION

This committee is concerned with "methods whereby those engineers who have not suitable standards may receive corresponding professional recognition." The E.C.P.D. has set up, as a "suitable standard," certain minimum qualifications—including education as well as capability developed in practice—which afford a basis for common requirements for society membership and legal registration.

So far the many societies devoted to technical advance have not been able to achieve professional solidarity. Legal registration by state engineering boards in seven-eighths of the states has created a new grouping on the basis of competency. But though the 70,000 registered engineers about equal the total membership of the older societies, a majority of each group does not belong to the other.

The committee urges that the societies seriously consider whether their "profession can adequately meet its obligation . . . as an aggregation of individual groups, loosely linked by numerous common agencies." It is hoped that study of engineering as a profession and of professional ethics by student groups can be organized and will lead the ten thousand engineering graduates of each year to distinguish engineering as a profession, from engineering as a technical occupation.

The committee is working to develop a more general understanding of what constitutes professional status, and to help all engineering students to appreciate professional standards and conduct.

5. PRINCIPLES OF PROFESSIONAL ETHICS

This committee was originally sponsored by the American Engineering Council (now discontinued), and was taken over and enlarged by the E.C.P.D. Existing codes of engineering ethics had been studied, and although progress, by correspondence, has necessarily been slow, a draft report is now being prepared, outlining a code of ethics for guidance in the engineering profession.

The object of this study is to stimulate ethical thinking among engineers and to inform them as to what their societies expect of them as regards professional conduct. If such a report, when approved by the E.C.P.D., eventually receives general adoption by engineering societies, a very definite contribution to the solidarity of the profession will have been made.

It is believed that the foregoing brief review of the activities of the E.C.P.D. justifies the hope that the Council will serve engineers increasingly in the cause of professional devlopment.

Abstracts of Current Literature

Abstracts of articles appearing in the current technical periodicals

WOMEN IN ENGINEERING

From *Trade & Engineering*, (London), July, 1941

In a foreword to the first number of a monthly Engineering Bulletin issued by the Ministry of Labour, Mr. Bevin states that the industry must be prepared to take on more recruits, particularly women, for training in the works. In the next few months 750,000 recruits will be wanted in the factories. As most of these will be women it is of interest to note that the employment of women on certain engineering processes, particularly on capstans, milling and milling machines, and on inspection and light assembly work is already very common. In a number of engineering works, however, female labour is employed over a much wider field than this, and, to an ever increasing extent, on precision work connected with aircraft and aircraft engines, shells and fuses, milling gun parts, and optical grinding and polishing to extremely fine limits. The elimination of breakages in various operations is said to be due to the women's more delicate touch. Female labour in engineering is, of course, no new thing, but a war-time development in one area is the successful employment of women as works managers, while one large firm of general engineers employs several hundreds on non-repetitive work.

Meanwhile, the registration of the women of 20 and 21 has brought to light the fact that very few are without occupation. Household work is accepted by the Ministry of Labour as an essential occupation, and the Ministry has rules for ascertaining the degree of necessity in the household occupation. Nevertheless, large numbers of women are required and must be found. Many will be made available by the concentration of industry, and for the rest there will have to be transference on a great scale from less essential to more essential work. The registration of young women was expected to disclose a large reserve of labour. It has not done so, and the policy of the Ministry, therefore, is the transference of young unmarried women from less essential employments. Already the panels are busy arranging transfers beginning in the industries to be concentrated and disregarding, for the present, those that are in the Schedule of Reserved Occupations, as well as the women in undertakings engaged to three-quarters of their capacity on Government work. With regard to the unemployment returns, which for May showed a total of 369,000, it is again pointed out that the unemployment of to-day is mainly that which occurs in the change-over from one job to another.

PENCILS FOR TEMPERATURE MEASUREMENT

An abstract from *schrift des Vereins Deutscher Ingenieure* (*VDI*), 1941, No. 2.

The Engineers' Digest (London) June 1941.

There exist materials which change colour when heated and revert to their original appearance after cooling. These materials have been used among others, by the firm Faber, to produce thermo-chromo pencils for eight temperatures between 120 and 600 deg. C.

The attendant has only to make a stroke with one of these pencils on the body, the temperature of which has to be ascertained, and to observe the moment when the colour changes.

Colour of the pencil when cold	*Temperature, at which colour changes*	*New Colour*
Light-green pencil	120°C.	Blue
Green pencil	150°C.	Violet
Blue pencil	200°C.	Black
Bottle green pencil	300°C.	Brown
Brown stroke of above pencil	350°C.	Red
Rose pencil	450°C.	Black
Light-yellow pencil	510°C.	Orange
Dark-blue pencil	600°C.	White

INVISIBLE LIGHT FOR PROTECTION AGAINST SABOTAGE

From *Aero Digest*, (New York), August, 1941

Numerous means of protection may be employed in setting up a "defense programme" against the would-be saboteur. While these means depend upon the requirements peculiar to the individual establishment there are two problems that are common to all establishments faced with sabotage hazards—to keep outsiders from getting entrance, and to prevent unauthorized persons (including unauthorized employees) from gaining access to restricted areas within the premises.

To achieve these objectives, many concerns are using the A.D.T. Invisible Ray Alarm, one of the electric protection services of the American District Telegraph Company. This system projects a beam of invisible light across the area to be protected, and interruption of the beam by any person or vehicle passing through its path automatically actuates an alarm system.

While the invisible ray is a comparatively recent development in burglary protection, it is by no means untried. It has proved its effectiveness in many mercantile, commercial and industrial establishments for more than five years. Yet, it is only within the past year or so, following installation of the apparatus in various defense plants, government establishments, etc., that officials realized how suited this system is for the protection of premises exposed to sabotage hazards. In many cases, where physical barriers would be impracticable, or where long distances or large areas would make adequate patrol protection by guard forces extremely costly, the invisible ray has proved an effective means of providing the necessary protection.

The invisible ray operates on photo-electric principles similar to those employed in the various electric eye devices used for opening doors, counting objects or persons, etc., but with a far greater range of operating values. The system consists of a light source, a photoelectric receiver, and a control unit.

The light source unit consists of one or more incandescent lamps of a power sufficient to project a beam of modulated light across the desired distance, and a filter glass which blocks all light waves in the visible range, allowing only the invisible infra-red rays to pass.

This beam of invisible light is directed toward the receiver unit, containing a photocell which responds to the modulated radiations from the light source, causing a change in current flow in the receiver unit which, by means of vacuum tubes, is amplified to a value sufficient to operate an alarm relay mechanism. When the beam is interrupted by a solid object of sufficient size, such as a person, vehicle, etc., the current flow in the photocell is momentarily broken. This results in actuating the alarm system.

Connected with the receiver is the control unit, which contains the alarm relay and other mechanism for initiating such protective action as may be desired as the result of an alarm. The system can be so connected that interruption of the beam will automatically result in one or any combination of various protective actions, such as notifying the local guard headquarters, or the police, or the A.D.T. central station; turning on lights inside the premises, or floodlights and searchlights in the yards; stopping the operation of automatic machinery; sounding sirens or gongs, or closing gates, doors, firestops, etc.

Among the many applications for which the invisible ray has been found particularly effective is boundary protection in conjunction with fences. Here the beam usually is projected inside the parallel to the fence, in such a manner that an intruder who might gain entrance by scaling or cutting through the fence would pass through the beam as soon as he got inside. This interruption of the beam would automatically transmit an alarm signal to the local guard headquarters, the police of the central station, as well as performing such other protective functions for which provisions have been made.

For such outdoor protection, light sources are provided which project beams that are unaffected by rain, snow, fog or other weather conditions, and which are effective for distances up to 1,000 ft., or further. For the protection of areas, indoors or out, such as yards, storage spaces, etc., to which access might be gained from several directions, a number of beams may be used to cover the protected area; or, the beam from a single light source, by means of reflectors, may be made to form a network of invisible light rays, zigzag fashion, over the protected area.

Since the invisible ray does not require the erection of physical barriers to impede normal activities, it often is the only feasible means of protection for loading platforms, railroad sidings, storage areas, open water fronts, etc. All that is necessary when it is desired to restrict access is to "turn on" the protection.

The same applies to any other areas, inside or out, which it is desired to protect from intrusion. Many defense plants are employing this method of protection to safeguard approaches to tool cribs, storage rooms for valuable metals, explosives, and rooms where confidential or valuable documents are kept. Or, in a shop, a vital machine, or group of machines, may be ringed with invisible rays so that no one can approach undetected.

Probably the most outstanding example of the adaptability of the system is the installation which, for several years has been protecting the Foreign Trade Zone (Free Port) on Staten Island, N.Y. Here the light source is on a float, keeping it always at the same level above the water regardless of tides. Special equipment projects this light for a distance of 3,000 ft. across the water, from pier to pier, and provides an intangible but effective barrier against smugglers—protection which could not be provided in any other way.

Such beams operate with equal effectiveness day and night. Operation of the system is not affected by sunlight, or by other extraneous lights such as flood lights, headlights of passing cars, etc. The photoelectric receiver is responsive only to light waves modulated to the specific frequency of the radiation projected by the light source. Thus, the system cannot be made ineffective by interposing a flashlight or any other light between the light source and the receiver. Neither will cutting of wires, or otherwise tampering with the equipment help those attempting to defeat the system; such action is just as effective in transmitting an alarm signal as actual interruption of the beam.

BRITISH AIRCRAFT INDUSTRY

Detecting Raiders our "Secret Weapon"

From *Trade & Engineering* (London) July, 1941

Undoubtedly one of the best kept secrets of the war has been the method by which enemy aircraft are detected, often when they are still miles from our shores. Most people knew that the Royal Observer Corps, Fighter Command, and the other defences had some scientific aid. Quite a number of people had made intelligent guesses as to what the device was, and a more select few were "in the know," but, generally speaking, the device was not only born in secret but has passed through adolescence and come to maturity without the general public having an inkling of its character and working.

It is now possible to give some limited particulars of the device, which is generally known as radiolocation. It is by no means a new science but rather an adaptation to war purposes of a discovery known to the whole of the civilized world. Briefly, radiolocation is a system of sending out ether waves which cannot be affected by fog, cloud, or darkness. They can extend many miles beyond our shores. Any solid substance, such as an aeroplane or ship, which is in the path of the waves sends back a "reflection" to the detecting station and thus reveals its presence. Since the outbreak of war these ether waves have been keeping, and continue to keep, a 24-hour watch throughout the year. They obviate the necessity for Fighter Command to maintain standing patrols of fighter aircraft, thus releasing both men and machines for the task of engaging any raiders discovered by this scientific means.

The Germans are believed to be experimenting along the same lines, but there is as yet nothing in the results they have achieved against our bombers to suggest that they have made any marked degree of progress.

Radiolocation was known in its primary form some years ago, and as long ago as March, 1935, the earliest experiments were conducted in this country to apply the knowledge to war use. In its origin the idea was the conception of one man—Mr. R. A. Watson Watt, Scientific Adviser on Telecommunications to the Chief of the Air Staff—who had the vision to see the possibilities inherent in certain electrical phenomena. The initial experiments were carried out in an ancient lorry on a little-used country road not far from Daventry. As a result of those experiments a team of scientists and a number of Service officers also interested in the problem collected together and worked for many months to bring radiolocation to its initial form, and this was achieved towards the middle of 1939.

It had taken four years of continuous and often trying experiments to work the device up to the standard it had attained at the outbreak of war. The threat of war in the summer and autumn of 1938 no doubt speeded progress even then, so that by the time war came the system, in a partially developed state, was in operation. The result of operations since the outbreak of war has demonstrated very clearly the vital nature of the achievement, and since that date scientists, engineers, and technical manufacturers have been combining to produce the best possible equipment for the detection of enemy aircraft. The Battle of Britain was undoubtedly won by the R.A.F. Fighter Command partly because of the help it received from radiolocation. The development of the system has been continuous and rapid. That single lorry on the road near Daventry has now grown into a vast organization covering the whole country, and it serves not only the R.A.F. and the Royal Observer Corps but the Royal Navy and the Army. Instead of the two or three civilians and a few officers there is now working on radiolocation a staff numbering thousands in the three Services.

As the scope of the system has been developed there has obviously been a need for more and more technicians The three Services have been thoroughly combed and the Central Register has brought to light many more men and women with some knowledge of radio, but still the numbers are inadequate. Therefore an Empire-wide appeal has just been made for recruits with some degree of technical knowledge. Air Chief Marshal Sir Philip Joubert de la Ferté, now A.O.C.-in-C., Coastal Command, but formerly in charge of this work, stated when the appeal was launched that the immediate requirement of the R.A.F., Royal Navy, and Army was 10,000 men and women, but that eventually the R.A.F. would need 8,000 men and 3,000 women; the Army about the same number, and the Navy about 2,000 men and 300 women. Already extensive use is being made of women, both as scientific officers and operators.

RAILWAY REPAIR AFTER AIR RAIDS

From *Civil Engineering and Public Works Review* (London), June, 1941.

The following are examples of speedy repair work which are mentioned in a little pamphlet recently published by the railway companies.

As a result of an air raid, the crown of an arch in a shallow tunnel allowed earth to penetrate on to the tracks. Unfortunately, the soil continued to fall through until a hole showed at ground level above. A mechanical excavator was taken to the site, and 2,000 cubic yards of earth removed above the tunnel; a new arch was built; the earth was then moved from inside the tunnel, when the line was reopened for traffic.

When a heavy calibre bomb struck an electric conductor rail on a viaduct, it glanced off, penetrated into the ground below, where it exploded, demolishing part of the viaduct. Two tracks on an adjoining viaduct remained intact. To enable services to be operated, a large high tension cable diversion was made, the installation of a temporary crossover 200 ft. long was built, and automatic signalling over two miles of track was reversed, resulting in the train services being restored the next day. Meanwhile, the remains of the arches were demolished with the aid of a locomotive and wire cables. A special train equipped with a large electric compressor, was worked to the site and the demolition of the brickwork by ten heavy pneumatic hammers was put in hand.

The whole of the brick debris was broken up and removed by lorries, excavation being undertaken to find a new solid bottom. The worst of the crater was dug out and the remaining weak ground was rafted over with steel rails and concrete. A trestle bridge of two spans was then constructed on the concrete raft, incorporated in the design of this bridge being a timber thrust member to take the end thrust of the remaining arches of the viaduct. Rolled steel joists with cross sleepers resting on them were provided for the rails. Hundreds of thousands of passengers have since passed safely over this place with only a slight check in speed to their trains.

During another air raid a high explosive bomb penetrated the booking hall of a busy station, exploding on the track over the station subway. The blast from the bomb in the confined space was very severe. Rails, timbers and girders over the subway were damaged and portions of the platforms destroyed, whilst all the brick and tile constructions on the platforms were demolished together with various kiosks. Numbers of cables under the platform nosing were also put out of action. Two ballast trains were at once rushed to the site, the loading of the material and the track repairs were carried out by gangs sent by lorries, with the result that the station was reopened and both lines were operating with temporary signalling the same day, less than eight hours after the incident occurred.

FRENCH CARGO LINERS

From *Trade and Engineering*, (London), July, 1941

According to information recently received; the three high-speed cargo liners of a new type ordered by the French Government some time before the war broke out have been delivered. Much interest was taken in this contract at the time it was placed, since the ships were specified to have a speed of 17 knots, which is higher than that of any other vessels in the French mercantile fleet. Moreover, although they were constructed to the order of the French Government, it was intended that two of them should be operated by the C.G.T. and the other by a well-known French shipping company.

The three vessels, the Indochinois, Malgache, and Caledonien, are sister ships apart from certain modifications in refrigerated capacity made in view of the different services on which it was intended they should be engaged. They are of 9,000 tons deadweight capacity, with a length of 459.8 ft., a beam of 60 ft., and a loaded draught of 26.4 ft. A 10-cylinder Sulzer-type engine of 7,000 b.h.p. is installed; it runs at 125 r.m.p. and has an overload capacity of about 15 per cent. The cylinders have a diameter of 720mm. and the piston stroke is 1,250mm.

It is difficult to ascertain to what extent mercantile shipbuilding is proceeding in France at the present time, but it was recently recorded that at any rate for a period after the German occupation the industry was very poorly occupied. It would be particularly interesting to know whether the 22-knot passenger liner Marechal Pétain (an 18,000-ton triple-screw Diesel-engined vessel with 22,000 s.h.p. machinery), which was ordered before war broke out for the Messageries Maritimes, is likely to be completed. The fact that she has only recently been named seems to indicate that construction has not been wholly held up until the conclusion of the war.

Fig. 1—Tanks crossing open ground.

BRITISH INFANTRY TANKS

From *"Engineering"* (LONDON), JULY, 1941

Some particulars have now been revealed of the latest type of British infantry tank, formerly known as the Mark 111, but now officially designated as the "Valentine." Figures 1 and 2 show views of the Valentine type, which weighs 16 tons and is manned by a crew of three. Infantry tanks in general are more heavily protected, but less speedy, than the "cruiser" tanks used by the mechanised cavalry regiments, but it is stated that the Valentine has a road speed in excess of 15 miles an hour, and, for the weight of guns and armour which it carries, has proved to be faster than was expected. Its manoeuvrability and cross-country riding qualities are of a high order. The turret mounts a Besa gun, at the side of which is a 2-pounder, stated to be capable of penetrating the armour of any German tank that the British forces have yet encountered.

Reference to the illustrations of the Valentine will show that the method of driving and guiding the track is by a double row of teeth; an arrangement which would appear to have superior advantages when traversing soft ground or the slope of a hill, and to offer the probability of smoother progress over rough ground such as that illustrated in Fig. 1. Tanks, like warships, must represent a compromise, and the dominant factors can seldom be the same in different armies.

DISCREPANCIES IN WAGES

From *Trade & Engineering*, (LONDON), JULY, 1941

A problem that arose in the War of 1914-18 is again proving troublesome. Factories engaged on Government work are paying much higher wages than other employers in the same area can afford, with the result that farmers and others are being denuded of their labour. If there were a properly constituted authority to settle these matters, and it were decided that a ploughman was indispensable for making munitions and far more valuable at that work than at farming, nobody would complain, but it has not yet been authoritatively decided whether the munition worker or the agriculturist is the more important to the country, the services of both being urgently needed. Nor has it been shown that ploughmen are better adapted to munition making than labour that is not essential to the land. It is very difficult to believe that a skilled farmhand could be better employed than in producing food—there cannot be many modern counterparts of Cincinnatus—but that his services should be at the command of the highest bidder irrespective of other considerations is entirely wrong. It is very unfortunate that nothing is done to stop this "beggar my neighbour" policy, which is directly due to want of co-ordination.

MODEL EXPERIMENTS ON THE GEBEL AULIA DAM

By Hasan Zaky, Ph.D., B.Sc., M.Inst. C.E.

From *Journal of The Institution of Civil Engineers* (LONDON), JUNE, 1941

The Gebel Aulia dam is one of a series of large storage reservoirs built on the Nile for augmenting its low-season supply in order to cope with the crop demands and allow for a better development of the Nile valley.

Before its actual construction the Egyptian Government wisely decided to submit the proposed plans to model-tests with the object of investigating the whole design thoroughly, eliminating all undesirable features in the structure, and calibrating the sluices for better control.

An extensive series of experiments were carried out for this purpose at the Delta Barrage laboratory. These proved to be highly satisfactory and of great practical value. In many aspects, the final design that was approved and executed was the outcome of these tests.

The models used were seven in number, and the scales

Fig. 2—Front view of Valentine tank.

ranged from two per cent to full size. The tests can be classified into three categories:

1. Preliminary experiments for investigating the initial proposals.
2. A general study of the modified and final plans.
3. A precise series for the purpose of calibrating the sluices.

The first series, which could be considered as purely exploratory, were conducted on a 1/50 scale model comprising two sluices. The study proved beneficial, as it revealed the desirability of some alterations, including an increase in the number of sluices, lowering the sill-level, and fixing the length of the apron.

A second and more extensive series of experiments were then conducted for the purpose of testing the nature of currents, the grouping of bays, and the best shape of training-walls; and for further study of the character of flow near the downstream lock-wall and the fish-ladder. Two 1/50 scale models comprising more than one bay were used for this study. The tests clearly demonstrated the suitability and effectiveness of the original position of the downstream lock guide-wall, and enabled the consulting engineers to devise two important modifications in their original plan connected with the training-walls and the fish-ladder.

The inquiry then proceeded on entirely different lines. Experiments were undertaken for the purpose of precisely calibrating the sluices. This involved the use of four different models. Considering the diversity in the scales used, and the difficulty of proper simulation of the actual position of the upstream and downstream gauges on the different models, the results exhibited close agreement. The experiments aimed at determining accurately the co-efficient of discharge for drowned conditions, and establishing clearly the limits for such conditions.

The three small models, namely, 1/25 scale, 1/10 scale, and ⅓ scale, were used for testing gate openings exceeding 1.0 metre for various upstream levels. The largest model (full size) was especially constructed for the study of gate openings of less than 0.50 metre with low upstream levels.

The total number of experiments carried out on these models amounted to about twelve hundred.

Table I gives the mean coefficients of discharge for drowned conditions: it shows the close agreement of the results obtained from the three models, the coefficient of discharge C being derived from the following equation:

$$Q = CA\sqrt{H}$$

where Q denotes the discharge, in cubic metres per second per sluice, A the area of the opening, in square metres, and H the difference, in metres between upstream and downstream levels.

TABLE I

	Opening: metres			
Model scale	1.00	2.00	3.00	3.50
	Coefficient of discharge C			
1/25	3.07	3.14	3.32	3.62
1/10	3.02	3.15	3.55	3.81
⅓	3.05	3.18	3.50	3.69
Mean coefficient of discharge C	3.04	3.16	3.47	3.70

The tendencies observed earlier in tests made at the Aswan and Sennar dams were confirmed by this investigation; namely, that the coefficient of discharge increases with the gate opening, and that the coefficient is a function of the ratio $\frac{\text{gate opening}}{\text{height of opening}}$. Finally, suitable formulas were derived for the discharge of submerged small gate openings.

The above-mentioned tests served as a useful and reliable base for the correct estimation of the discharge passing through the dam—a matter of vital importance for drawing up the preliminary programme of its filling and emptying. Moreover, the tests helped in settling many points connected with the proper functioning of the reservoir.

In general, the Gebel Aulia dam is the first major structure in Egypt which has been the subject of a detailed technical study through different stages of its construction by the aid of models on various scales, a procedure which proved quite satisfactory, as it resulted in a great saving of time, labour, and money.

SALVAGE OPERATIONS ON AIRPLANE EMBEDDED IN ICE

From *Aero Digest*, (NEW YORK), AUGUST, 1941

Landing at Lake Athabasca in the northwest part of Saskatchewan last winter, a Bellanca aircruiser belonging to Mackenzie Air Service started to taxi in over the ice when it passed over a weak spot on the surface about a half mile from shore. The ice gave way, and, as the plane's skis dropped through abruptly while the turning propeller chopped out huge chunks of snow and ice, the fuselage and wings slid through the opening, then held as the wing tips and tail surfaces contacted the lake's solid covering.

The plane was on a flight last December 11 between Fort Smith and Goldfields. Pilot D. Page McPhee had set down on the ice about two miles from shore, making a normal landing on the Mackenzie developed skis which use the landing wheel tires for shock absorbers. The taxi into shore was also normal, until a triangular crack opened in the ice about a half-mile out and the plane dropped in. The pilot and the crew jumped out of the cabin and, using the wing top as an escape to solid ice, brought out the mail and express bags.

Coming back the next day to have a look at the plane they found it had sunk farther into the ice. It was apparent that if the crack opened much wider it would take a combination of summer weather and a deep sea diver for salvage. Conditions at that time were such that it was doubted that the ice was strong enough to support the weight of additional salvaging equipment, so the work of raising the airplane had to be postponed for about five weeks until the ice was able to hold up the weight imposed on it.

Any attempt to pull the plane out at that time would have yanked off the tail and left the rest to sink. There was nothing to do but wait for colder weather to freeze the lake solid and to hope that no sudden wind storm would drive the plane on under the ice.

Salvage crews went to work under the direction of Mackenzie's service engineer, George Taylor, and despite fears that the airplane was beyond repair, they succeeded in reclaiming and fixing it so that it is now back in regular service.

Taylor first ordered out a crew of men to chop wood. He wanted firewood enough to make a fir-sized forest fire. All during the waiting period he kept men busy chopping wood. Other crews were put to work building rough wooden sheds and placing them on rollers. These sheds were to act as a combination hangar and heat treat department. Planes from the home base at Edmonton brought ice axes and other tools to be used in the de-icing process.

Gasoline was drained from the tanks in the top wing section, both to remove the danger of fire and also to lessen the weight pressing the plane into the ice. Taylor and his men literally burned the plane out of the ice. Wings and fuselage were practically filled with ice. Exceptional care was required to avoid damaging the wings while they were being raised, an inch or two at a time, since the accumulation of ice had created a tremendous load on them. Fires were built in the immediate area and were kept burning throughout the day and night while the ice was thawed out of the wings. This operation took about seven days, and when the wings were salvaged and thawed out, they were transported to a permanent camp about a mile from the lake.

Some of the fabric on the fuselage had to be cut away to facilitate salvage operations, but this was subsequently replaced on the job. Sufficient heat again had to be applied about the fuselage to keep the water from freezing in the tubing and thus cracking it. After the tubing was drained, the engine was thoroughly dried out over a wood fire and then the fuselage, with the engine, still on its mount, was transported to the camp. Since the Cyclone had been submerged while running, water had been pulled into the carburetor, supercharger, cylinders and other internal areas.

Mechanics put new spark plugs in the engine, but used the same ignition harness and magnetos. They heated up the engine oil and poured it in, turned over the engine and the Cyclone started almost instantaneously.

Examination, meanwhile, revealed no major damage to the airplane; the propellor, however, had suffered some damage, but the company's propeller repair man put it back in shape at the camp. After superficial repairs, the airplane was flown back to the main shops at Edmonton on April 2, and, after complete overhaul, went back into service none the worse for its month and four days in the solid ice.

CALL FOR FORESIGHT

The Engineering Journal's support has been asked in the "save gasoline" campaign which is now being conducted vigourously across Canada. This request comes from the Canadian Publishers War Finance Publicity Committee, and perhaps no better way can be found to carry out the request than to present herewith an abridgement of the communication which was addressed to the editor. It is a pleasure to do so.

"Canadians are not forced to fall back on blind faith to convince themselves that the battling people in the British Isles are working feverishly to prepare for an offensive operation in Europe. Our newspapers have been publishing dispatches which bristle with evidence that doughty Britishers are getting ready to strike back. But when the blow will be struck, none in Canada knows.

"If the inner War Council did decide on a major operation, it could not 'telegraph its punch.' No one over there is in a position to send a message to Canada—'We are about to attack. We must have every drop of gasoline and oil you can rush across to us now.'

"But surely we in Canada have enough intelligence and imagination to foresee that a sudden favourable opportunity may present itself to the armies in Great Britain anytime within the next few weeks. And that same intelligence and imagination should dictate the sharpest curtailment in the use of motor fuel for motor cars without a day's delay.

"It would be a pity if the stamina of Canadian citizenry were to be judged by the spectacle of a few thousand motor car drivers in Ontario, for example, who knew that gasoline had to be saved for the decisive battles overseas, and knowing it, deliberately travelled thousands of miles for the long week-end holiday.

"It would be too harsh perhaps to say that all of these motorists deliberately thumbed their noses at the Empire's war effort. The answer might be that they have not yet been sufficiently impressed by the seriousness of the situation. And if that is the answer, then the press of Canada has not yet reached the point where the appeal for conservation can be eased off.

"Most editors and publishers are working under a handicap in their effort to conduct the appeal for gasoline and oil conservation. Newspapers and periodicals are being forced by circumstances to work alone. There are as yet no local committees, no local authorities with whom editors may co-operate in convincing motor car drivers that the need for conservation is real and in persuading them that the co-operation of everyone is vital.

"It may be that this situation will eventually be righted, but in the meantime the press holds the fort alone. The amount of motor fuel to be saved during the next two or three weeks at least will depend on the degree of effort made by the press."

GOOD READING

It is natural that Canadians should be great readers of periodicals coming from the United States; unfortunately facilities do not seem to be available to make us equally aware of the merits of similar publications prepared in England.

In view of the fact that to-day the world's interest is centred on the Old Country, this is certainly a time to study the literature of that country. To engineers in particular this is important. Marked advances in methods and equipment, both civil and military, are coming so fast that to be out of touch with them is almost to be out of touch with progress.

There are many journals published in London that might add greatly to the sum of engineering knowledge in this country. Some of them are the organs of engineering societies, and others are commercial ventures of considerable magnitude. The outward style or "format" in general is different from that used in America, and to us may appear unnecessarily awkward, but the contents leave little to criticize. The material is excellent, and without exception is a definite contribution to the literature of engineering. The style differs from American practice, being very simple and direct, with little or no attention paid to type or layout. The editorials are of general interest, and usually touch more on matters of national or economic importance than on engineering topics.

One publication that appeals to a very wide field is *The Times Trade and Engineering*—a monthly review of industrial progress issued by the same publishers as the great newspaper *The Times*. This mammoth periodical seems to cover the field of national and international news under a variety of headings such as: Condition Abroad, Engineering and Shipbuilding, Aircraft Industry, Transport, Finance and Industry, Trade Within the Empire, Parliament and Trade, Official Regulations and so on. The cheap, rude or smart comments or jibes that too often are used in the popular business magazines published on this side of the water are absent—no attempt is made to report everything in monosyllablic or tabloid form.

If any Canadian engineer wants to read news or editorials that tell about the trend of developments in Europe, the economic situation in the United Kingdom and the Empire, industrial and political progress, as well as matters of engineering interest, let him read *Trade and Engineering*. No engineer could do this regularly without acquiring a breadth of knowledge of world affairs that would widen the boundaries of his interests and make him a better citizen.

CORRESPONDENCE

The following letter comes from a member who wishes his name omitted.

VANCOUVER, B.C.,
August 20th, 1941.

TO THE EDITOR,
THE ENGINEERING JOURNAL,
MONTREAL, QUEBEC.

Dear Sir,

I note with regret, from the Obituaries in the August *Journal* the passing of John Hamilton Gray, at the age of eighty-seven, almost eighty-eight.

Your notice states that he had retired a number of years ago. As late as 1938 Mr. Gray was, to my knowledge, still in actual practise in a small way but what is more remarkable is the fact that, in 1930, at the age of more than seventy-seven, Mr. Gray undertook surveys in northern British Columbia for a route for the then projected Alaska Highway, which involved several weeks arduous travel in the northern hinterland with pack horses over entirely uninhabited country; he also made his own plans, and his draughtsmanship for a man of that age was remarkable. He was one of those men of unflagging energy who never seem to grow old, but merely fade away.

Many of us also learn with regret the untimely passing of Pat Philip, as stated in your obituary column in the same issue. I do not feel that your notice does full justice to the late Mr. Philip. In 1921 he was appointed to the position of Public Works Engineer for the Provincial Government which position was later altered to Chief Engineer; he also became Deputy Minister of Public Works, and it was during his time that the Fraser Canyon Highway was re-built between Yale and Lytton and the Thompson Canyon Highway between Lytton and Spencer Bridge, being opened in 1926 and 1928 respectively, thus providing the first motor highway from the coast to the interior of B.C. without having to travel through the United States.

Mr. Philip was President of the Association of Professional Engineers for B.C. He was, I believe, councillor for the Victoria Branch of the E.I.C. and possibly your records may show that he was a vice-president. He was a very kindly man and well known throughout the Province of British Columbia.

Editor's Note—We are grateful to the author of the above letter for his interesting remarks. The obituaries that are published in the *Journal* are based on the information contained in the files at Headquarters and any additional information supplied by branches is always very helpful.

The records show that Mr. Philip was chairman of the Victoria Branch in 1922, and member of the executive in 1923, 1924 and 1925. He was the author of the following papers published in the *Journal:* "Consideration in the design and construction of highways," September, 1924; "Cariboo Road," July, 1928; "Highways and highway transportation in British Columbia," September, 1934.

KENYA AND UGANDA RAILWAYS AND HARBOURS

NAIROBI, KENYA COLONY,
JUNE 12TH, 1941

L. Austin Wright, General Secretary,
The Engineering Institute of Canada,
Montreal, P.Q.

Dear Mr. Wright,

I am very grateful to you for your letter of the 24th February which reached me recently.

We in East Africa have, of course, been closely connected with the war effort from this area, but the success of the Army based on East Africa has been so rapid and so complete that it looks now as if we would be less directly concerned. However, this area will always remain a base for certain units and no doubt too the advent of prisoners of war and evacuees will very much increase the transport problems of the country.

The Kenya and Uganda Railways and Harbours Administration has been fairly hard pressed to meet all demands that have been made upon it by the Army, but I am glad to say that in all cases we have fulfilled the requirements of the military authorities, satisfactorily and without accident. The results of the year's working are reflected in my Annual Report for 1940, of which a copy has already been sent to you. This will show that, while we have benefited from the war conditions that have existed, we have returned considerable sums to the military authorities in the form of rebates for traffic carried.

I am afraid that I am not able to give you information regarding the engineering efforts of the Army in Abyssinia, partly because I am not directly concerned with the Army and partly also because the censor would not pass any information of military interest or value. However, I can say that the engineering activities of the Army in repairing roads, bridges, building huts, camps, etc., have been on an immense scale and during the actual campaign the road work, provision of water supplies, bridging and other such items have been carried out with extreme speed and success, in fact, it is not too much to say that the successful conclusion of the campaign was due to the excellent engineering organization in a very large measure. Many of the skilled engineers came from South Africa, including road making companies, works companies, railway construction and operating companies.

So far as we ourselves were concerned, apart from purely transport matters, we have been very busily employed in building depots, sidings, railway yards, store sheds, etc., and in our workshops very extensive repair work and manufacture of military articles have been carried out.

I hope this will give you some idea of our activities, but, for reasons which I have already indicated to you, I cannot amplify them any further at the present time.

As a Canadian, I, of course, watch for all reports of the war effort in Canada and am glad to know that one and all, from one end to the other are doing everything they can to ensure the eventual success of our cause.

Your *Journal* arrives regularly and is read with much interest, not only by me personally, but also by my engineering staff.

I wish the Institute all possible good luck during the coming years and I feel sure that all your members will be giving a good account of themselves in the general war effort.

Yours sincerely,

(*Signed*) BRIG.-GEN. SIR GODFREY D. RHODES

WARTIME BUREAU OF TECHNICAL PERSONNEL

Monthly Bulletin

If any technically trained persons have not received the questionnaire from the Bureau by now, it would be appreciated if they would so advise the office at Ottawa. All the names secured from the national registration and from the following organizations have now been canvassed—eight provincial Professional Associations, the Engineering Institute of Canada, the Canadian Institute of Mining and Metallurgy, the Canadian Institute of Chemistry, the Royal Architectural Institute of Canada.

Approximately forty-five thousand forms have now been circulated. Naturally, there has been some duplication, although great care has been taken to avoid it. With so many membership lists included in the scheme, it is evident that hundreds of names will appear more than once. All lists have been checked against each other, but caustic comments from a handful of disturbed persons indicate that the work was not perfect. Just why anyone should be so disturbed at receiving more than one form, is a little difficult to understand, particularly in view of the statement in the covering letter to the effect that such a thing might occur.

The comments have been both interesting and amusing, and run all the way from superlative praise to withering complaint. Some persons who by their own words have indicated that their war work to date has consisted solely of filling out three or four forms, complain bitterly of the inconvenience to which they have been put by such requests. Fortunately ninety-nine per cent of the returns are encouraging. Many persons have expressed with some enthusiasm their appreciation of the huge task undertaken by a small group of engineers and chemists who are working day and night without even the elusive "dollar a year" remuneration in the hope of assisting the entire profession to amplify its contribution to the war effort.

The momentum of the work is steadily increasing. More requests for men are arriving than ever before. More men are being placed than ever before and with the fuller records now available, it is expected that the vacancies in war industry, and in government activity, will more and more be filled from the Bureau.

The emphasis is still on mechanical engineers in a variety of specialized fields. Lately, the demand for "civils" has increased both in industry and in the active service forces. In this latter group, the need for men of junior office qualifications is very great. One single request is for seventy-five to a hundred men for overseas service. Another request which came by trans-atlantic telephone is for twelve civil engineers and draughtsmen for urgent work overseas in civilian capacity.

The experience of the Bureau to date indicates clearly the great need of organization and co-operation. There is much overlapping of effort to secure technical help. There are many gaps in the systems presently used to meet the needs. There is lack of workable legislation or regulations to meet the new conditions, and it begins to look as if some comprehensive and inclusive scheme would have to be devised for national application if any high degree of efficiency is to be attained in this important field. All those persons and organizations which are now so diligently applying themselves to some particular section of the problem would welcome such a proposal.

The Universities and the Students

Among the groups most disturbed by war developments have been the universities. Almost without exception, the engineering faculties have been depleted seriously, and now a new term is faced with increased obligations and decreased facilities. The Bureau has received many requests for teaching personnel, without being able to meet the situation with any degree of satisfaction.

One point has been gained in that universities have been acknowledged to be in the same category as "essential industries," as far as protection to the present staff is concerned. This will not fill the holes already made, but it will assist in preventing any further and disastrous extension of the deprivation already experienced.

From the information available at present to the Bureau, it appears as if students should be encouraged to enter those courses at university which make a definite and direct contribution to the war. For instance, engineers are needed well beyond the available supply. More and more young men of university age are joining the combatant forces, and, therefore, it is desirable that of those who do go on to university, a high percentage should follow engineering.

Of the courses themselves, the past and present indications are that mechanical is the most useful field of specialization. The others follow in this order—electrical, civil, metallurgical, chemical and mining. A sudden change in international conditions might easily upset this order, but for the present these are the definite indications. The information is circulated in the hope that it may be useful to the universities themselves and to prospective as well as present students.

Personals

News of the Personal Activities of members of the Institute, and visitors to Headquarters

Colonel W. M. Miller, M.E.I.C., Chief Signal Officer, British Troops in Egypt, has been made a Commander of the Order of the British Empire as a result of the operations in Egypt. The appointment was actually made a few months ago, but it was only last month that the good news reached the Institute. Col. Miller, who was born in Montreal, and educated at the Royal Military College, Kingston, was at one time Senior Engineer Officer of Military District No. 1.

F. B. Kilbourn, M.E.I.C., vice-president and assistant general manager of Canada Cement Company, Montreal, is the new steel controller, appointed recently by the Minister of Munitions and Supply. He has been with the Company since 1906, being appointed general superintendent in 1919.

N. F. McCaghey, M.E.I.C., has been elected as chairman of the Saguenay Branch of the Institute. It is his second election to this office as he acted as chairman of the same branch in 1933. He is with Price Brothers & Company, Limited, at Riverbend, Que., having joined this company upon his return from overseas in 1919.

Robert F. Ogilvy, M.E.I.C., is now employed with the Aluminum Company of Canada, Limited, and is located at St. Thomas, Virgin Islands of the United States. Graduated from McGill University in the class of 1925, he has since been engaged on several large construction projects. Lately he has been connected with the General Engineering Company Limited, of Toronto.

Recent changes have been made at the City Hall of Montreal which affect some of our members as follows:

J. G. Caron, M.E.I.C., has been appointed member of the new Board of Revision. He had been assistant director of public works for the past year, and previously, he had been for eight years, superintendent of the technical division of the Public Works Department. He has had about twenty-five years of service at the City Hall.

C. J. LeBlanc, M.E.I.C., has been appointed engineer attached to the office of the Director of Public Works. A graduate of the Ecole Polytechnique of the class of 1910, he has been with the city since 1912. His previous position was that of assistant director of public works.

H. A. Gibeau, M.E.I.C., has been appointed assistant director of public works. He was graduated in civil engineering from Rensselaer Polytehnic Institute. He has been with the city for several years having occupied the position of assistant chief engineer.

A. T. Hurter, M.E.I.C., has been transferred from the engineering department of Defence Industries Limited, where he acted as project engineer, to the Bouchard Works at Ste. Therese, Que., where he is in charge of production.

Geo. R. MacLeod, M.E.I.C., has received an appointment on the engineering staff of No. 3 Air Training Command, Royal Canadian Air Force, in Montreal. He had retired a few years ago from the service of the City of Montreal, where he had occupied, for several years, the position of assistant chief engineer. He is a past vice-president of the Institute and has served on many committees.

Walter L. Rice, M.E.I.C., formerly of Toronto, has accepted a position as senior assistant engineer with the Works and Buildings Branch, No. 3 Air Training Command, Royal Canadian Air Force, Montreal.

Léon A. Fraikin, M.E.I.C., went overseas last month in command of the second detachment of Belgian soldiers to go to England from their Canadian training centre at Joliette, Que. He had returned to Canada last summer after having served as a first lieutenant with the First Royal Belgium Regiment of Artillery during the campaign of Belgium.

He was graduated in civil engineering from the University of Ghent, Belgium, in 1929, and in 1931 received the degree of Master of Science from the Massachusetts Institute of Technology. From 1931 to 1935 he was employed as designing and field engineer with the Franki Compressed Pile Company Limited, in Belgium and Norway. From 1935 to 1937 he acted as consulting engineer to Messrs. Braithwaite, Burn & Jessop Construction Company at Calcutta, India. In 1937-1938 he was assistant to the chief engineer on the Mohammed Ali Barrages contract at Cairo, Egypt, for Macdonald, Gibbs and Company (Engineers), London, England. In 1938, he was appointed vice-president and general manager of the Franki Compressed Pile Company of Canada Limited at Montreal, a position which he occupied at the time of his enlistment.

Augustus Griffin, M.E.I.C.

N. F. McCaghey, M.E.I.C.

A. T. Hurter, M.E.I.C.

Augustus Griffin, M.E.I.C., has been appointed assistant manager of the Department of Natural Resources of the Canadian Pacific Railway Company, with headquarters at Calgary, Alta. He will continue his duties as chief engineer of the department, but will relinquish his functions as superintendent of the operation and maintenance of the Company's Western Section Irrigation Project.

Mr. Griffin has been in the service of the Company since 1918. He was born in Visalia, California. In 1906 he was graduated from the University of California with the degree of B.Sc. in civil engineering, specializing in irrigation. From 1906 to 1918 he supervised a number of irrigation projects in California, and in the latter year came to Canada as superintendent of operation and maintenance of the Canadian Pacific Railway's Eastern Section Irrigation Project at Brooks, Alta., where he remained until 1935. In 1932 he succeeded the late Mr. A. S. Dawson as chief engineer of the Department of Natural Resources. In 1935 his headquarters were moved to Strathmore, Alta., where he supervised the operation of the Company's Western Section Irrigation Project. He is a recognized authority on irrigation, both in Canada and the United States, and for two years he was chairman of the Irrigation Division of the American Society of Civil Engineers.

The Department of Natural Resources has under its jurisdiction the administration of the Company's lands, townsites, irrigation works, petroleum, gas and coal rights, and timber properties, and covers in a general way the natural resources of the Company in western Canada.

E. N. Ridley, M.E.I.C., canal superintendent of the Department of Natural Resources of the Canadian Pacific Railway Company, has been appointed superintendent of operation and maintenance, Western Section Irrigation Project, with headquarters at Strathmore, Alta.

Mr. Ridley was born at Belleville, Ont., and received his early education at the Collegiate Institute of Ottawa. After serving his apprenticeship with Henry A. F. MacLeod, consulting engineer, Ottawa, he entered the service of the Canadian Pacific Railway Company in 1902 as an instrument man. In 1907 he became an assistant engineer in the Department of Natural Resources of the Company and in 1914 he was made canal superintendent.

H. W. Lea, M.E.I.C., has joined the staff of the Wartime Bureau of Technical Personnel at Ottawa. His company, Canadian Telephones and Supplies, Limited, has given him six months leave of absence to render this service to the Government. Mr. Lea, who is a graduate of McGill University is district manager of his company in Montreal.

J. E. Dion, M.E.I.C., has joined the staff of Wartime Merchant Shipping Limited, at Montreal. For the past five years he had been plant superintendent of the Laurentian Laboratories Limited, Montreal. Previously he had been for several years with Montreal Engineering Company. He is a graduate in mechanical engineering of McGill University, in the class of 1926.

A. M. Bain, M.E.I.C., structural engineer with Dominion Bridge Company, Limited, Montreal, has been loaned to the Department of Munitions and Supply, and is acting as a technical assistant to Professor R. E. Jamieson, M.E.I.C., director general of the Army Engineering Design Branch.

E. L. Miles, M.E.I.C., is now acting as supervising engineer with the Royal Canadian Air Force at the Mont Joli Airport, Que.

H. M. Martin, Jr., M.E.I.C., has been transferred from the Sault Ste. Marie to the Toronto works of the Dominion Tar and Chemical Company, Limited. He was graduated in chemical engineering from McGill University in 1937.

Lawrence O. Cooper, M.E.I.C., has been promoted to Flight Lieutenant in the Royal Canadian Air Force, and he is now stationed at Ottawa.

Edward H. Beck, M.E.I.C., is now on the staff of E. G. M. Cape and Company, and is located at Botwood, Newfoundland. He was previously connected with the construction of the new National Research Council laboratories at Ottawa.

C. K. Hurst, M.E.I.C., has left the staff of the Water Works Department of the City of Edmonton, to accept a position on the hydraulic staff of the Canals Branch of the Department of Transport, Ottawa, Ont.

C. F. Davison, M.E.I.C., has been appointed resident engineer with Defence Industries Limited, Bouchard Works, Ste. Thérèse, Que. He was previously connected with Canadian Industries Limited at Windsor, Ont.

John L. Jomini, Jr.E.I.C., is now overseas with the 14th Canadian Field Regiment, R.C.A. He was previously connected with Consolidated Paper Corporation at Grand' Mère, Que.

C. G. Kauth, Jr.E.I.C., has been transferred from Toronto to the Montreal works of the Dominion Oxygen Company, Limited. He was graduated from Queens University in 1934, and has been with the company since 1935.

A. L. Denton, Jr.E.I.C., has joined the Royal Canadian Air Force and is stationed at Brandon, Man. He was previously employed with the Lamaque Mining Company, Limited, at Bourlamaque, Que.

J. R. Rettie, Jr.E.I.C., has recently been appointed district engineer of the Manitoba Department of Mines and Natural Resources at The Pas, Man. He was previously employed with the department at Winnipeg.

W. H. Sparks, jr.e.i.c., has joined the Royal Canadian Air Force and has been commissioned as a Pilot Officer. He is stationed at Montreal. Previously he was hydraulic engineer with the Water Rights Branch, Department of Lands, Victoria, B.C.

Lieutenant R. E. Kirkpatrick, s.e.i.c., has been recalled from overseas and is attached to the Inspection Board of the United Kingdom in Canada, at Ottawa.

A. T. Dougall, s.e.i.c., has joined the Royal Canadian Navy Volunteer Reserve. He was graduated in mechanical engineering from the University of Saskatchewan this spring.

Jean Flahault, Jr., s.e.i.c., is now employed with the Aluminum Company of Canada, Limited at Arvida, Que. Early in 1940 he had gone overseas to join the French Army. After going through the Battle of France in the spring of 1940, he was taken prisoner by the Germans, but later managed to escape. After a hazardous trip through occupied and unoccupied France and northern Africa, he finally succeeded in returning to Canada a few months ago.

Mr. Flahault is a graduate of the Ecole Polytechnique, of the class of 1938. He did some post graduate work in metallurgy at the Carnegie Institute of Technology at Pittsburgh, Pa.

W. F. Jarrett, s.e.i.c., who has been on the staff of the Saguenay Power Company at Arvida, Que., since last spring has been transferred recently to the Aluminum Company of Canada, Limited at Montreal.

Jean Lefort, s.e.i.c., has joined the staff of Stevenson and Kellogg, Limited, Management Engineers, Montreal. He was graduated in civil engineering from McGill University in 1936, and in 1939 he obtained the degree of Bachelor of Civil Law from the same University. Lately he had been connected with the Aluminum Company of Canada, Limited, Arvida, Que.

A. M. Swan, s.e.i.c., has been transferred from the Toronto office to the Apparatus Sales Department of the Canadian General Electric Company, Limited, at Hamilton, Ont.

Jules Mercier, s.e.i.c., has been transferred from the Test Department of Canadian General Electric Company, Limited, Peterborough, to the Meter Engineering Department as assistant engineer.

G. W. Moule, s.e.i.c., has been transferred to the Winnipeg plant of Defence Industries Limited. Since his graduation from the University of Manitoba in 1937, he had been with Canadian Industries Limited at Montreal.

Bertram Taylor, s.e.i.c., has received the degree of Bachelor of Science in Geological Engineering at the University of Saskatchewan this spring. He is now located at Siscoe, Que.

VISITORS TO HEADQUARTERS

J. M. Mercier, s.e.i.c., Canadian General Electric Company, Limited, Peterborough, Ont., on July 23rd.

H. C. Seely, m.e.i.c., Plant Engineer, East Malartic Mines Limited, Norrie, Que., on July 25th.

H. W. Furlong, m.e.i.c., Stone & Webster Engineering Corporation, Boston, Mass., on July 25th.

W. H. Malone, m.e.i.c., Smooth Rock Falls, Ont., on July 29th.

E. A. Allcut, m.e.i.c., Professor of Mechanical Engineering, University of Toronto, Toronto, Ont., on August 6th.

J. J. Freeland, m.e.i.c., Canadian International Paper Company, Limited, Temiskaming, Que., on August 7th.

A. L. Denton, jr.e.i.c., Lamaque Mining Company, Limited, Bourlamaque, Que., on August 12th.

C. R. Young, m.e.i.c., Dean of Engineering, University of Toronto, Toronto, Ont., on August 15th.

J. G. W. Campbell, m.e.i.c., Eastern Air Command, Headquarters, R.C.A.F., Halifax, N.S., on August 15th.

S. Hogg, m.e.i.c., St. John Dry Dock & Shipbuilding Company, Limited, St. John, N.B., on August 15th.

F. C. Read, s.e.i.c., Spruce Falls Power & Paper Company, Kapuskasing, Ont., on August 16th.

H. B. Stuart, m.e.i.c., Consulting Engineer, Toronto, Ont., on August 18th.

Donald Ross, m.e.i.c., The Foundation Company of Canada, Limited, Mont Laurier, Que., on August 18th.

Eugene Vinet, m.e.i.c., New York City, N.Y., on August 20th.

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Charles Hamilton Mitchell, m.e.i.c. Not long ago, at a funeral service in St. Paul's Church, Toronto, many leaders in university, professional and industrial circles, assembled to pay respect and express sorrow at the death of Charles Hamilton Mitchell, engineer, soldier and Dean Emeritus of the Faculty of Applied Science and Engineering in the University of Toronto.

The President of the University conducted the service. Dr. Cody spoke of the life, character and achievements of one whom he termed "a great Canadian, a public servant, and a true Christian soldier". Members of the Engineering Institute of Canada will desire to associate themselves with this sincere tribute to the memory of a Past President of the Institute, whose professional career as a practising engineer was followed by equally distinguished active service as a soldier, and then by twenty years at the head of the engineering faculty of a great university.

Charles Hamilton Mitchell, M.E.I.C.

General Mitchell was a "son of the manse," for he was born in a Methodist parsonage at Petrolia, Ontario. He graduated at the University of Toronto in 1894, taking the professional degree of C.E. in 1898.

His engineering practice, commenced shortly after graduation, was largely in hydraulic and hydro-electric power work. He was retained as consulting engineer in the design and construction of power plants in many parts of Canada, and for some years was consulting engineer to the Water Power Branch, Department of the Interior, Ottawa, on water power investigations and conservation in Western Canada. In 1920 he was a member of a Royal Commission to report on radial railways in Ontario, and acted as arbitrator as to power shortage at Niagara and the setting of power rates. In 1924 he was appointed by the Dominion Government to the Joint Board of Engineers (Canadian and from the United States) to study and report upon the St. Lawrence waterway project for navigation and power.

General Mitchell's military career dates from 1899 when he joined the Militia Service. At the outbreak of war in 1914 he was Divisional Intelligence Officer on the General Staff, 2nd Division, Toronto; after proceeding overseas, he won marked distinction in the Intelligence Branch of the General Staff in France, Belgium and Italy. In 1918 he was promoted Brigadier-General and served in 1919 at the War Office, London. During his five years' overseas service he was mentioned in despatches seven times, and received many honours, including the D.S.O. (1916), C.M.G. (1917), C.B. (1918); he was also awarded decorations by the French, Belgian and Italian governments.

Joining the Engineering Institute of Canada as a Student in 1894, he became Associate Member in 1898 and Member in 1902. His interest in Institute and professional affairs is shown by his services as member of Council during 1908-1909, as Vice-President from 1920-1923, and as President for the year 1929. In 1922-1923 he was President of the Association of Professional Engineers of Ontario. He was a Member of the Institution of Civil Engineers (London), of the American Society of Civil Engineers, and of many societies interested in professional, civic and national welfare.

At the time of his death, he was a director of Consumers' Gas Company of Toronto, the United States Fidelity and Guaranty Company of Canada, and the Canada Steamship Limited.

General Mitchell's connection with University administration began when he was elected to the Senate of Toronto University in 1901 to represent the graduates in Engineering. He served on the Board of Governors of the University from 1913 to 1919, and in July of that year was appointed Dean of the Faculty of Engineering. On his retirement from that post in March of this year, he was given a dinner by the alumni, at which he had the satisfaction of hearing what his twenty-one years as Dean had meant to his students and colleagues.

Always proud of his profession, he lost no opportunity of impressing upon the students and young engineers with whom he came in contact, the important place held by the engineer in the economic scheme of today. He was a loveable man with a great sense of humour and a genius for making friends. His devotion to duty was shown by the fact that since the fateful days of September, 1939, he had been doing special war work for the Department of National Defence. His last public appearance was on June 22nd when he took the salute of the University C.O.T.C. upon its return from camp. His death on August 26th, in his seventieth year, takes from us a figure whose remarkable personality and wise counsel will long be missed.

Walter Robert Benny, Jr.E.I.C., was accidentally drowned on June 8, 1941, at Black Bird River near Noslo Siding, about seventeen miles east of Schreiber, Ont., while examining the waterway structure at this point. He was born at White River, Ont., on January 3rd, 1909, the son of W. W. Benny, M.E.I.C., Division Engineer of the Canadian Pacific Railway Company, now retired and residing at Ottawa. Walter R. Benny received his early education at the Public Schools of Ottawa and at Glebe Collegiate Institute. Later he attended McGill University where he was graduated in 1932 with the degree of Bachelor of Engineering. During his University course, between sessions and for some time following graduation he was engaged on surveys as chainman and instrumentman with the Dominion Geological Survey Department, the Construction and Maintenance of Way Departments of the Canadian Pacific Railway Company, the Shawinigan Water & Power Company on transmission line location, the Temiskaming and Northern Ontario Railway extension to Moosonee, the construction of airports with Canada Airways and with the Ontario Department of Northern Development.

In October, 1935, he received a permanent appointment as transitman with the operating department of the Canadian Pacific Railway Company at Smiths Falls, Ont. In August, 1938, he was appointed assistant engineer in the office of

Walter Robert Benny, Jr.E.I.C.

the engineer of maintenance of way at Toronto, and in August, 1939, he was appointed division engineer of the Schreiber Division, at Schreiber, Ont., a position which he held at the time of his tragic death.

Mr. Benny joined the Institute as a Student in 1928, and he was transferred to Junior in 1936. At the time of his death he was a member of the executive of the Lakehead Branch.

William Lewis Reford Stewart, M.E.I.C., died suddenly in the hospital at Montreal on July 13th, 1941. He was born at Toronto on October 6th, 1900. He received his early education in the Toronto public schools and later attended St. Clement's College in Toronto and the Royal Military College at Kingston, where he was graduated in 1920. Upon graduation he went with Lockwood, Greene & Company, Industrial Engineers, as assistant to the resident engineer on various factory construction work. In 1921 and 1922 he worked as assistant resident engineer with Morrow & Beatty, Limited, Contracting Engineers, on the construction of the Twin Falls power development of the Abitibi Power and Paper Company. In 1923 he was engineer on building construction work for Robert Reford Steamship Company. In 1924 he came to Montreal as engineer with the Newton-Dakin Construction Company Limited, and was employed on the Metis Lakes storage dams contract. The following year he went to Sherbrooke, Que., as manager of the local office for the same firm. In 1927 he organized the Stewart Construction Company Limited, which progressed steadily under his able leadership. At the time of his death he was still managing director of the firm. Among the works which were successfully carried out by his company, under his direction, are the most important of the industrial, commercial, and educational buildings in the Eastern Townships. Lately his firm had carried out important defence work in the Maritime provinces.

Mr. Stewart joined the Institute as a Student in 1920, and he was transferred to Associate Member in 1928.

News of the Branches

Activities of the Twenty-five Branches of the Institute and abstracts of papers presented

LAKEHEAD BRANCH

H. M. Olsson, M.E.I.C. - - *Secretary-Treasurer*
W. C. Byers, Jr.E.I.C. - - *Branch News Editor*

The Lakehead Branch held their annual dinner meeting on May 21st in the Port Arthur Golf and Country Club, which was attended by forty-nine members and guests.

The chairman, Mr. H. G. O'Leary, presided at the meeting and presented his annual report. He stated that he had appreciated serving as Chairman and thanked all the committees and executive for their splendid work and co-operation which had made it possible to have the most successful year to date, and hoped that the incoming chairman and executive would have an even better year.

The nominating committee presented the following slate of officers for 1941-42: Chairman, B. A. Culpeper; Vice-Chairman, Miss E. M. G. MacGill; Executive, E. J. Davies, J. I. Carmichael, S. E. Flook, S. T. McCavour, R. B. Chandler, W. H. Small, W. R. Benny, C. D. Mackintosh; Ex-Officio, H. G. O'Leary; Secretary, W. C. Byers.

The outgoing chairman, Mr. H. G. O'Leary, welcomed the incoming officers and handed over the chairmanship to Mr. B. A. Culpeper, who expressed his appreciation for being appointed chairman.

The financial report showed a favourable credit balance and the various committees were given a vote of thanks.

The members and guests were then entertained with a game of "Bingo" and a "Quiz" Contest.

OTTAWA BRANCH

R. K. Odell, M.E.I.C. - *Secretary-Treasurer*

On invitation of Lieut.-Col. J. P. Richards, Officer Commanding the Royal Canadian Engineering Centre at the Petewawa Military Camp, a party consisting of members of the Ottawa Branch of The Engineering Institute and their ladies visited the camp on Sunday, August 17th.

It was one of the most successful events staged by the branch in a long time. The combination of perfect weather, a well prepared and interesting programme, hospitality and congeniality, made up a day that will be outstanding in Institute history. As would be expected in a military camp, every detail had been thought of and all arrangements were carried out with delightful precision. It was a real pleasure for civil engineers to see something of the work of military engineers.

A group of officers who accompanied the party. Second from left is Lieut.-Col. J. P. Richards.

After a buffet lunch at the Officers' Mess, the men of the party visited the bridging site on the Petewawa river, travelling from headquarters by way of the Dominion Forest Experiment Station at Corry Lake.

A most interesting demonstration was given by the engineers of the bridging of streams for infantry and heavy equipment; the bridging of a ravine for the passage of motor transport; the method of construction and operation of collapsible boats; and the carrying out of other engineering operations. On return to the camp a visit was paid to the trade-shops and the field works stores where a variety of engineering equipment was demonstrated. An opportunity was also afforded of seeing large field guns used by the artillery training centre.

Some of the party watching a demonstration of pontoon bridge building.

Ladies of the party visited the library, reading and writing rooms, recreation room, and the men's mess kitchen. In the evening, a regular meal, as provided for the men of the training centre, was served in the men's mess room—and a very satisfactory meal it was too! At the conclusion of this feature, the chairman of the branch expressed to Colonel Richards the thanks of the group for his hospitality and excellent arrangements. Colonel Richards modestly gave the credit to his staff, and invited the guests to visit the camp again.

Members of the Institute test out the "Kapok" assault bridge which has just been launched.

The method of bridging a ravine with steel box beams by the cantilever method is explained.

The beams in place after the demonstration.

The Engineering Institute of Canada, through its various branches throughout the Dominion, is assisting in obtaining trained engineers for military and civil work in connection with the war effort, in air raid precaution work, and in other ways. The visit to the Petewawa Engineering Centre afforded an opportunity for members of the Institute to obtain some first hand knowledge of engineering problems connected with modern warfare.

The party was headed by T. A. McElhanney, chairman of the branch, and K. M. Cameron, vice-president of the Institute from eastern Ontario. Unfortunately, at the last moment, President and Mrs. Mackenzie had to cancel the arrangements they had made to be with the party.

SAGUENAY BRANCH

D. S. Estabrooks - *Secretary-Treasurer*
J. P. Estabrook - *Branch News Editor*

On Friday, August 22nd, a meeting of the Branch was held in the Arvida School.

About 120 members and friends were present to hear an illustrated lecture on **Sub-surface Engineering.**

Chairman N. F. McCaghey, presided and introduced the speaker, Professor R. F. Legget of the University of Toronto, who is connected with the Shipshaw power development for the summer.

Professor Legget expressed his pleasure at having been chosen as speaker for two consecutive meetings. He began his talk by illustrating and explaining various formations of rock, some of which aid and others hinder the engineer in underground construction. Consequently, before undertaking any large construction where a solid foundation is required, it is necessary to find out what is under the ground.

He then illustrated how test drilling, coupled with the knowledge of geologists, was one of the best ways to get a cross section of the conditions to be encountered.

Professor Legget spoke for a short time on tunneling operations and described a unique way of excavating the material from the tunnel, which consisted of grinding up the removal material into a fine powder, after which it could be mixed with water and pumped to the surface.

Illustrations were given of several dams where huge quantities of silt and other fine materials had to be removed so as to get down to solid rock. At the Grand Coulee dam, the material to be excavated was so liquid that it kept running in as fast as it could be removed. The ingenious engineers installed a refrigeration system, after which excavation proceeded satisfactorily.

Another very interesting point was that of a bridge in India, one end of which had been repeatedly carried away by landslides. This obstacle was overcome by building a cantilever-type bridge and connecting it to the hazardous shore by means of a timber trestle. When an avalanche now occurs the wooden trestle is carried away without injuring the main portion of the bridge and can be easily replaced in a few hours.

Reference was also made to the new Shipshaw development where test drilling is now being carried out and where, among other things, old beds of the Saguenay River are found.

A vote of thanks was extended to Professor Legget at the conclusion of the meeting by Mr. S. J. Fisher and the hearty-hand-clap as well as the unusually large attendance attested the interest his talk had aroused.

THE NEED FOR FUEL

Consumption of gasoline and oil in Canada helps to win the war only where it serves war industry, and other industries that in turn support the war effort, army vehicles, training planes and naval craft.

If Canadians were wholly intent in their ambition to leave nothing undone that should be done to insure a Victory against Hitler, most of the balance of motor fuel stocks in Canada would be put at the disposal of the fighting forces overseas. If Canadians really understood just how precious motor fuel will be in the scheme of operations soon to be launched by the British Empire forces, they could not possibly use up gasoline and oil for pleasure purposes without great pangs of conscience.

In the British Isles, where motor car drivers are so close to military operations that they can see the urgent necessity for guarding the motor fuel supply, private motoring has become almost non-existent. On this continent we need only use a little more native intelligence to enable us to see the picture more as our compatriots across the seas do. Then Canada's gasoline consumption will really drop sharply.

Employment Service Bureau

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.

SITUATIONS VACANT

EXPERIENCED MECHANICAL DESIGNING DRAUGHTSMAN for general mechanical work and industrial piping. Apply Box No. 2375-V.

EXPERIENCED ARCHITECTURAL DRAUGHTSMEN required by large industrial concern for their Montreal office. Apply Box No. 2376-V.

JUNIOR CHEMICAL OR METALLURGICAL ENGINEER for work in plant installation and operation. Required immediately. Apply Box No. 2400-V.

STRUCTURAL AND CONCRETE DRAUGHTSMEN for industrial plant design. Apply Box No. 2401-V.

JUNIOR MECHANICAL DRAUGHTSMAN with one to five years experience for work in South America. Apply Box No. 2402-V.

TIME AND MOTION STUDY: Opportunity for man who can prove his ability in setting of wage incentive standards, methods analysis, and plant layout. Give experience in detail. Address reply to Box No. 2439-V.

JUNIOR RESEARCH METALLURGIST required immediately, with one to five years experience. Apply Box No. 2440-V.

MECHANICAL GRADUATE ENGINEER, with machine shop experience, required for work in South America on important war contract. Apply Box No. 2441-V.

SITUATIONS WANTED

ELECTRICAL ENGINEER, B.Sc. in electrical engineering, age 43, married, available on two weeks notice. Fifteen years experience in electrical work. Including electrical installations of all kinds in hydro-electric plants and sub-stations. Maintenance and operation of hydro-electric plants. Electrical maintenance and installations in pulp and paper mill. Considerable experience on relays and meters. At present employed, but desires change. Apply Box No. 636-W.

GRADUATE ELECTRICAL ENGINEER, University of Toronto, five years experience drafting and design in connection with electrical instruments and small motors. Also experienced in design of small jigs and fixtures and general machine design. Desires permanent position. Apply to Box No. 1486-W.

GRADUATE CIVIL ENGINEER, M.E.I.C., 15 years engineering on this continent and five years overseas. Experienced in design and construction of dams, hydro-electric and industrial plants. Field engineer for construction on dams and transmission lines, considerable experience in concrete work. Desires position preferably as field engineer or construction superintendent. Apply Box No. 1527-W.

ELECTRICAL ENGINEER, Age 32 with the following experience—Eight years field work in general construction, supervision, estimating and ordering materials. At present employed in general construction but wants to enter the electrical field. Apply Box No. 1992-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, married. Two years city engineer, five years experience in highway work, including surveying, location, construction, estimating and inspection. Apply Box No. 2409-W.

Library Notes

Book notes, Additions to the Library of the Engineering Institute, Reviews of New Books and Publications

ADDITIONS TO THE LIBRARY

TECHNICAL BOOKS

Elementary Aerodynamics:

By D. C. M. Hume, Toronto, Isaac Pitman & Sons, 1941. 136 pp., 5½ x 8½ in., $1.50.

Engineering Descriptive Geometry and Drawing:

By. F. W. Bartlett and T. W. Johnson, New York, John Wiley & Sons, Inc., 1941. 572 pp., 6 x 9¼ in., $4.00.

Surge Phenomena, Seven Years' Research for the Central Electricity Board, 1933-1940:

London, British Electrical and Allied Industries Research Association, 1941. 426 pp., 8¾ x 11½ in., £2 10s.

REPORTS

Canada Department of Mines and Resources, Mines and Geology Branch, Geological Survey, Memoirs:

Pictou Coalfield, Nova Scotia; Palaeozoic Geology of the Brantford area, Ontario. Memoirs, 225, 226.

Canadian Engineering Standards Association, Specifications:

Standard specification for lead service pipe, waste pipe, traps, bends and accessories, B67-1941; Construction and test of flexible cords and fixture wires (including heater cords), C22.2-No. 49-1941.

Defence of Canada Regulations:

Defence of Canada regulations, Ottawa, 1941.

Hydro-Electric Power Commission of Ontario:

Thirty-third Annual report, 1940. Toronto, 1941.

United States Department of Commerce —Building Materials:

Structural properties of "Mu-Steel" prefabricated sheet-steel constructions for walls, partitions, floors, and roofs BMS67, Asphalt-prepared roll roofings and shingles, BMS70; Structural properties of "Precision-Built, Jr." prefabricated wood-frame wall construction, BMS72.

United States Department of the Interior Geological Survey Bulletins:

Spirit leveling in Texas, part 3, West-central, Texas, 1896-1938; Geology of the Upper Tetling river district Alaska; Spirit leveling in Michigan, 1896-1938; Manganese carbonate in the Batesville district Arkansas; Quicksilver deposits in San Luis Obispo county and south-western Monterey county, California; Geology and mineral resources of the Randolph quadrangle, Utah-Wyoming; Geophysical abstracts 102, July-September 1940; Mineral industry of Alaska in 1939; Tungsten resources of the Blue Wing district Lemhi County, Idaho; Some quicksilver prospects in adjacent parts of Nevada, California and Oregon. Nos. 883-C; 917-B; 919; 912-A; 922-R; 923; 925-C; 926-A; 931-A; 931-B.

United States Department of the Interior, Bureau of Mines, Bulletins:

Coal-mine accidents in the United States, 1938; Quarry accidents in the United States, 1939; Bulletins 437 and 438.

United States Department of the Interior, Bureau of Mines, Miners' Circular:

Barricading as a life-saving measure in connection with mine fires and explosions. Circular 42.

United States Department of the Interior, Bureau of Mines, Technical Papers:

Carbonizing properties and petrographic composition of upper freeport coal from Morgantown district, Monongalia county, W.Va., and of lower freeport coal from eastern Indiana county near Cambria county, Pa., Technical paper 621.

United States Department of the Interior, Geological Survey, Professional Paper:

Geology of the Kettleman hills oil field California, No. 195.

United States Department of the Interior, Geological Survey Water-Supply Papers:

Surface water supply of the United States 1939, part 2, South Atlantic slope and eastern gulf of Mexico basins; Part 4, St. Lawrence river basin; Part 6, Missouri river basin; Part 7, Lower Mississippi river basin; Part 8, Western Gulf of Mexico basins. Papers 872, 874, 876, 877 878.

PRELIMINARY NOTICE

of Applications for Admission and for Transfer

August 29th, 1941

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described at the October meeting.

L. Austin Wright General Secretary.

*The professional requirements are as follows:—

A Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science or engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BARNES—HENRY JAMES, of London, Ont. Born at Windsor, Ont., Feb. 23rd, 1912; Educ.: 1932-33, extension dept. (arch'ture), Univ. of Southern California; at present studying I.C.S. course in civil engrg.; 1929-30 ap'tice dftsman., Watt & Blackwell; 1932-33, rodman, dting., O. Roy Kelly, Los Angeles; 1933-34, dftsman., Standard Oil California; 1936, store front design, Hobbs Glass Co., London, and Bennett Glass Co., Windsor, Ont.; 1936-37, dftsman., J. R. Boyd, Windsor, Ont.; 1939-40, barracks design and foreman of works, and from Nov., 1940, to date, engr. dftsman. for D.E.O., Mil. Dist. No. 1, London, Ont.

References: W. M. Veitch, H. L. Hayman, E. B. Allan, S. Shupe, F. C. Ball.

KLINE—JOSEPH DOUGLAS, of 107 St. Joseph St., Dorval, Que. Born at Halifax, N.S., Nov. 23rd, 1917; Educ.: B.Eng. (Civil), N.S. Tech. Coll., 1940; 1938-39 (summers), gravel and asphalt inspr., truck boss, Standard Paving Maritime Ltd.; May, 1940, to date, dftsman., Defence Industries Ltd., Montreal, Que.

Industrial News

Industrial development — new products — changes in personnel — special events — trade literature

CHAIN SAWS

Reed-Prentice (B.C.) Ltd., Vancouver. B.C., have featured in a four-page folder the "Timberhog" chain saws. The folder contains illustrations, descriptions and specifications of the gasoline, electric, and air driven saws. Several actual photographs are also included.

ELEVATING TABLE TRUCKS

The "Lyon" line of material handling equipment featuring trucks with hydraulic elevating tables is thoroughly illustrated and described in a six-page folder by the Lyon Iron Works, Greene, N.Y. Details of standard equipment and application are included together with specifications.

ELECTRICAL CONTROLS FOR CHEMICAL FEEDERS

"Cochrane Electrical Controls for Proportional Chemical Feeders for Water Conditioning Equipments" is the title of a 6-page publication, No. 3015, issued by Cochrane Corp., Philadelphia, Pa. It features a number of control panels upon which the Cochrane Flow Meters are mounted along with other controls such as time-cycle relays, program-controllers, pH controllers, etc., with brief descriptions of the service performed.

TRUCK BODIES

A 4-page folder, issued by The Wilson Motor Bodies Ltd., Toronto, Ont., entitled "Galion Allsteel Hydraulic Hoists and Bodies," illustrates various "Galion" allsteel body types equipped with "Galion" hydraulic hoists.

HIGH CARBON—HIGH CHROME DIE STEEL

An 8-page bulletin No. 341, entitled "Jessop 3C High Carbon—High Chrome Die Steel" is being distributed by Jessop Steel Co. Ltd., Toronto, Ont. This is an oil hardening alloy steel possessing extreme resistance to wear, nondeforming qualities and improved machinability, for use where long runs per grind of die are desirable. In addition to outlining its uses, details of its qualities are given under the headings "Forging, Annealing, Hardening and Tempering."

INSULATING PAD FOR DISTRIBUTION CABLE SPLICING

A 4-page bulletin No. 6017, which is a reprint of an article from "Electrical World," March 8th, 1941, entitled "New Form of Insulation Simplifies Splicing," by C. P. Xenis and F. B. Thomson, of Consolidated Edison Company, New York, Inc., is being distributed by Canadian Line Materials Ltd., Toronto, Ont. Describes this new form of insulation manufactured by Burndy Engineering Co. Inc., New York, N.Y., and distributed by Canadian Line Materials Limited, Toronto, Ont. This is a new form of multi-layer rubber insulation called the "insulating pad" which is a unitary piece of insulation composed of three distinct layers of rubber each subjected to different degrees of curing during manufacture. The reprint contains a complete description with illustrations showing the composition of the "pad" and step-by-step procedure for applying a pad to a straight joint.

UNIT AIR CONDITIONER

With descriptive matter, specifications, drawings and illustrations, a leaflet, No. C-1100-S23A issued by the Carbondale Div. of Worthington Pump & Machinery Corp., Harrison, N.J., describes what the Company terms "A Complete Air Conditioner System in one Package," which, it is stated, provides air conditioning in its most economical and perfect form for the store, office, shop or any other limited space. These combined units are completely factory built, tested and made ready to install before shipment.

ROTARY PUMPS

Worthington Pump & Machinery Corp., Harrison, N.J., have issued a 12-page bulletin, W-483-B1, which contains descriptive data, specifications, tables of sizes and ratings and lists of applications covering seven types of rotary pumps with double-helical gears. Photographic illustrations and sectional drawings are included.

SMOKE CONTROL EQUIPMENT

Under the title "Rehtron Electric-Eye Smoke Control Robot," the Rehtron Corporation, Chicago, Ill., have issued a 4-page bulletin which contains illustrated descriptions of two models of this equipment which continuously indicates the density of smoke in breeching or stack, signals fireman when density exceeds predetermined limit and automatically controls the supply of steam and air for over-fire injection.

TOOL STEEL

Devoted to the description of "Jessop Rapid Finishing Tool Steel," a semi-high speed, tungsten-bearing tool steel especially suitable for rapid finishing cuts where a smooth, accurate surface is desired, a 4-page bulletin, No. 541 has been issued by Jessop Steel Co. Ltd., Toronto, Ont.

AUTOMATIC VOLTAGE REGULATORS

Ferranti Electric Limited, Mount Dennis, Toronto, 9, Ont., has issued a bulletin, No. 397, which, in addition to numerous illustrations, contains a lot of valuable information on the subject of voltage regulation. It features Ferranti Step-Voltage Regulators and deals with the value of "good voltage" from a revenue standpoint, and outlines a number of voltage problems that arise.

BULK CONVEYOR SYSTEM

Book, No. 1975, published by Link-Belt Limited, Toronto, describes, with numerous illustrations, the "Link-Belt Bulk-Flo Conveyors," a distinctly new power-operated conveyor system for the positive and continuous conveying of flowable granular, crushed, ground or pulverized material of a non-corrosive, non-abrasive nature. Construction features, typical arrangements, list of typical materials conveyed, tables of sizes, capacities and dimensions and installation photographs are included.

FLOW METERS

Cochrane Corporation, Philadelphia, Pa., has issued a new 52-page handbook on Flow Meters. Originating as a catalogue, "Flow Meters by Cochrane" has developed into a handbook of instrument application to steam, water, air, gas, and viscous, volatile and corrosive fluid measurement. Important operating details are given on ten different types of instruments. Construction features of the friction-free electric flow meter and the high-torque mechanical flow meters are explained. The importance of flow records in the efficient operation of boiler and turbine rooms and various process departments is stressed. Control applications, dual range recorders, detached instruments and summation meters are also featured.

LIST OF CURRENT PUBLICATIONS

"Current Publications for Production Men, Designing Engineers, Metallurgists," issued by The International Nickel Company of Canada Limited, Toronto, is an up-to-date list of the Company's publications on ferrous nickle alloys and nickel brasses, and bronzes, arranged for easy reference, with descriptive notes of the contents of each publication. A reply paid mailing sheet is attached to check any publications desired.

FOR USERS OF PIPE MILL PRODUCTS

Canadian Tube and Steel Products, Limited, Montreal, Que., Page-Hersey Tubes, Limited, Toronto, Ont., and The Steel Company of Canada Limited, Montreal, Que., jointly have issued a pamphlet emphasizing the importance of conserving non-ferrous metals to meet essential war requirements and requesting the co-operation of users of pipe mill products by making certain that "galvanized pipe" is used only where it is absolutely essential.

TREE EMULSION

"Braco" Tree Emulsion is featured in a folder published by Brantford Roofing Co. Ltd., Brantford, Ont. This emulsion is a waterproof surgical dressing for trees when pruning and grafting. Discusses the structure of trees, reasons and methods of pruning, and treatment of tree wounds.

PATCHING CONCRETE FLOORS

Seven steps in the process of patching concrete floors by the use of "Braco" Floor Mastic N-13-F are described in a folder of Brantford Roofing Co. Ltd., Brantford, Ont. The description includes preparing and priming the surface, preparing and mixing the Mastic mixture, placing the Mastic, troweling and finishing.

POWER ASSEMBLY TOOLS

Black & Decker Mfg. Co. Ltd., Toronto, Ont., has published a 56-page handbook entitled "Black & Decker Data Book on Power Assembly Tools, Portable Electric Screw Drivers, Nut Runners and Tappers." Thoroughly illustrated with large size reproductions of the various tools, descriptive and dimensional drawings, and action photographs, this handbook contains complete descriptive information, specifications and other useful technical and tabular data of value to the users of these tools.

VARIABLE VOLTAGE PLANER DRIVE

Bulletin H-7050, of Canadian Westinghouse Co. Ltd., Hamilton, Ont., describes in detail the company's variable voltage planer drive. Sections deal with the principle of the drive; the resulting increase in production due to its use; features of design, and the economics of this type of planer drive. Ample illustrations are included.

THE FORGEABILITY OF METALS

OWEN W. ELLIS, M.E.I.C.
Director, Department of Engineering and Metallurgy, Ontario Research Foundation, Toronto, Ont.

Paper presented before a joint meeting of the Niagara Peninsula Branch of the Engineering Institute of Canada and the Ontario Chapter of the American Society for Metals, at St. Catharines, Ont., on May 16th, 1941.

SUMMARY—**A recapitulation of experimental work on forgeability of metals with reference to properties of materials, technique required and results obtained in die-forging and in free-forging. The author refers to methods necessary for the forging of light alloys as well as steel and copper, and concludes with an example in detail of an eccentric cam produced in steel and in aluminum alloy of medium forgeability with an estimate of comparative cost of manufacture.**

In the author's opinion, the words "forgeability" and "malleability" are synonymous. Malleability has been defined as "the property which permits a metal to be hammered or pressed into shape without cracking." In this definition the word "forgeability" could be substituted for the word "malleability." However, there might be some justification for the argument that malleability connotes hammering or pressing at room temperature or temperatures not far removed from room temperature, while forgeability connotes hammering or pressing at elevated temperatures—temperatures above dull red heat.

The subject of forgeability or malleability has interested the author for a number of years, during which time he has conducted numerous experiments, the results of which have been published in a series of papers. The first of these appeared in 1924. It dealt with the effects of the critical points in iron and steel upon their forgeability and showed clearly that these points had an important influence in this connection.

Earlier work along these lines was done by Robin, a French scientist, who, in 1910, presented a thesis to the Iron and Steel Institute on "The Resistance of Steels to Crushing," This appeared in the *Carnegie Scholarship Memoirs* for that year. Robin conducted tests on a number of alloys, both ferrous and non-ferrous, at temperatures which ranged from −300 deg. F. to 2010 deg. F. From the results of these tests he was able to estimate the energy required to reduce "normal" cylinders (cylinders whose

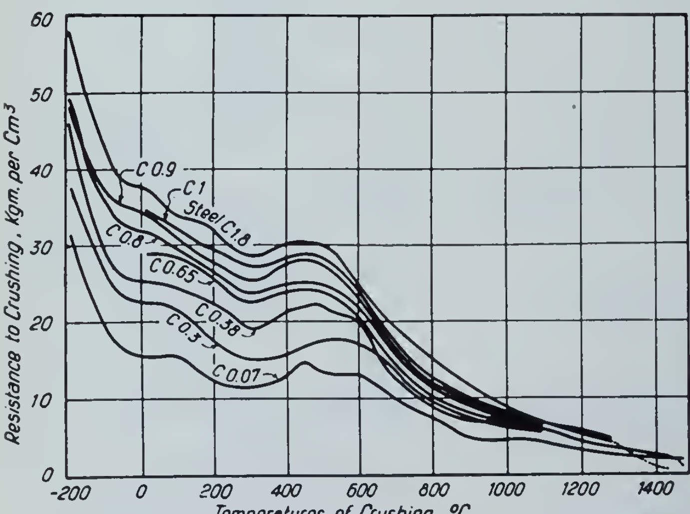

Fig. 1—Resistance of carbon steels to crushing.

heights and diameters are equal) of these alloys by 20 per cent of their initial height. He plotted curves showing the relationship between temperature and resistance to crushing, of which those shown in Fig. 1 are representative. These refer to a series of straight carbon steels and bring out clearly the well-known fact that the higher the carbon content of a steel the greater is its resistance to crushing or, in other words, the less is its forgeability, other things being equal.

In his experiments the author has used a small drop hammer, the tup of which weighs about 113 lb. Various methods of heating the samples have been employed, according to the place where the tests have been conducted and the temperatures to which the samples have been heated. Small changes in the weight of the tup can be produced by means of small lead weights.

The height of drop of the tup can be varied at will. The tup is allowed to fall freely, once it has been raised to the desired height for a given experiment. Every precaution is taken to ensure the free fall of the tup and care is exercised at all times to forge the test samples as quickly as possible after their removal from the furnace.

The essential features of the test are shown in Fig. 2. Herein is shown a normal sample in place on the anvil with the hammer descending. The height h_1, of the sample is known. After forging, the height, h_2, of the sample is measured. The difference, $h_1 - h_2$, divided by h_1 and multiplied by 100, is referred to as the *percentage reduction in height* of the sample and is the value generally reported as the result of such tests as these.

The results of a long series of tests on a straight carbon steel containing 0.4 per cent of carbon are shown in Fig. 3. Here are six curves relating energy of blow to percentage reduction in height of a number of normal half-inch samples.

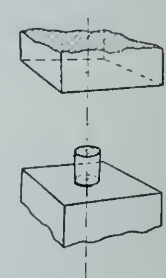

Fig. 2—Diagram of conditions of single-blow drop test.

If, in this case, we consider the energy required to cause a 55 per cent reduction in height of a normal half-inch sample of this steel, it will be seen that this decreases, as the temperature is raised, from about 470 ft.-lb. at 847 deg. C. (1558 deg. F.) to about 370 ft.-lb. at 927 deg. C. (1710 deg. F.) and then to about 310 ft.-lb. at 1010 deg. C. (1850 deg. F.).

For a blow of given energy the percentage reduction in height of a normal sample of this SAE 1040 steel increases *more or less* uniformly with increase in temperature. For example, with a blow of 400 ft.-lb. at the following temperatures the following approximate reductions in height were obtained with this steel:—

Temperature deg. C.	*Reduction per cent.*
584	31
674	37
754	44
847	52
927	58
1010	62

Percentage reduction in height does not increase *quite* uniformly with temperature, as would be discovered if the above results were plotted, since the critical points have an

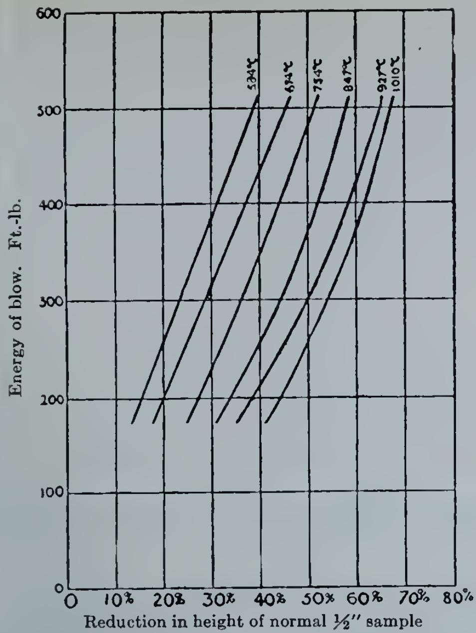

Fig. 3—Relation between reduction of height and energy of blow at different temperatures (0.4% C. steel)

important effect upon the properties of steel. This will be shown in some of the later illustrations. The influence of the A3 point on practically pure iron is particularly marked, as is demonstrated in Fig. 4, which shows the forgeability-temperature relationship of pure iron over the range 900-950 deg. C. (1652-1742 deg. F.), within which lies the A3 point, shown to be in the vicinity of 915 deg. C. (1679 deg. F.) in this particular series of tests. It will be seen that pure iron is actually more resistant to plastic deformation at temperatures just above the A3 point than at the A3 point itself. In fact, it does not become as forgeable as it is at the A3 point until it has been heated at least another 45 deg. C. (81 deg. F.) higher.

Groups of curves, like those in Fig. 3 have certain important characteristics which may now be referred to. For all practical purposes these curves can all be represented by equations of the simple form

$$E = bD^n$$

where E represents the energy in foot-pounds required to produce a percentage reduction in height D of a sample. What is rather more surprising is that the constants b and

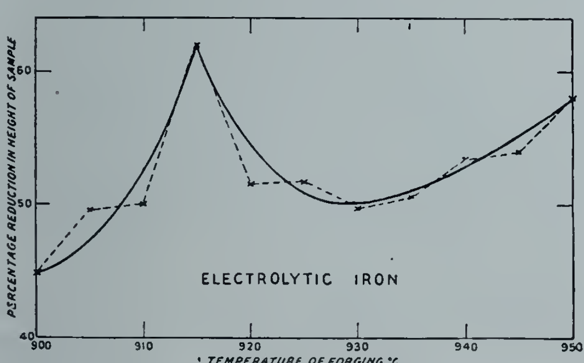

Fig. 4—Relation between forgeability and temperature for electrolytic iron.

n in this equation are related one to the other, in the case of *normal half-inch samples*, by the simple formula

$$n = 1.56 - 0.47 \log b$$

so that the equation

$$E = bD^{1.56 - 0.47 \log b}$$

gives the energy required to produce any percentage reduction of a sample if we know the energy needed to produce any one percentage deformation, say, of 30 per cent.

This equation applies not only to steel, but also to copper, nickel, lead and probably aluminum. And furthermore, it can be used in connection with samples of shapes other than normal cylinders; shapes, for example, such as cones or frusta.

Main, an English metallurgist, when discussing the paper in which the author first brought forward this equation, pointed out that it could be re-written in the form

$$3.32 - \log E = a\ (2.13 - \log D)$$

where

$$a = 1.56 — 0.47 \log b$$

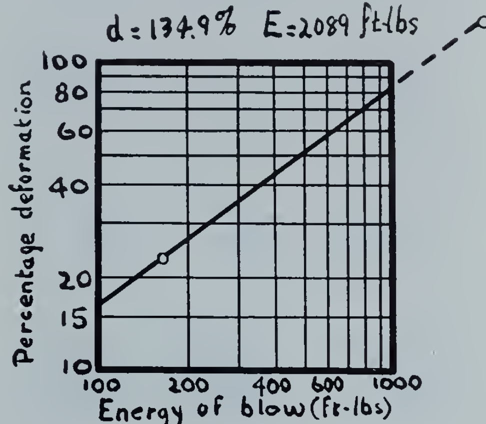

Fig. 5—Fundamental diagram of energy and percentage deformation for half-inch samples.

Now, it can readily be seen that, when $\log D = 2.13$, the right hand side of the new equation becomes zero, so that

$$3.32 - \log E = 0$$

$$\text{or} \quad \log E = 3.32$$

Hence, when $\log D = 2.13$ or $D = 134.9$ per cent, $\log E = 3.32$ or $E = 2089$ ft.-lb.

It is manifestly impossible to reduce the height of a sample, no matter what its form, by 134.9 per cent, so that the conditions described above are imaginary only. But, given this information, such a graph can be drawn as that in Fig. 5, which is one of the innumerable straight lines which could be drawn through the point corresponding to $D = 134.9$ per cent and $E = 2089$ ft.-lb. In this figure percentage reduction is plotted on logarithm paper against energy of blow. Suppose now that a few experiments on a single-blow drop test machine have proved that a blow of 170 ft.-lb. will produce a percentage deformation of 23 in a normal half-inch sample of steel of known volume at 1850 deg. F., all that is necessary to find out the energy required

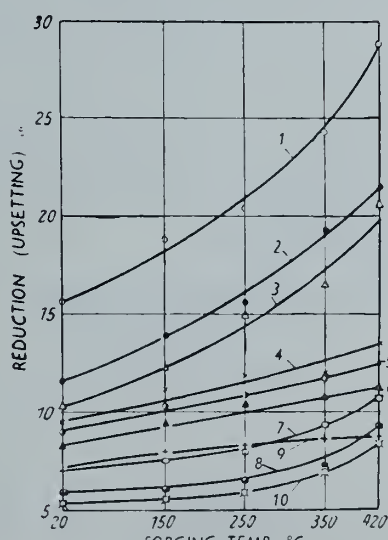

Fig. 6—Forgeability of representative aluminum alloys at different temperatures.

to produce other percentage deformations in samples of the same material having the same size and shape and formed at the same temperature is to join the point in Fig. 5 corresponding to $E=170$ and $D=23$ to the point corresponding to $E=2089$ and $D=134.9$ by a straight line and the points on the straight line so obtained will provide all

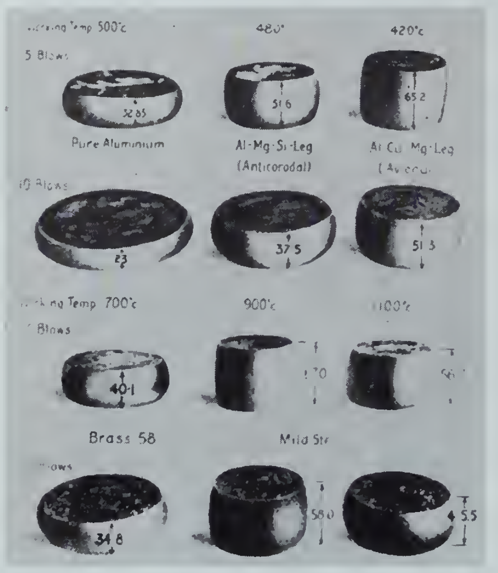

Fig. 7—Representative specimens subjected to plastic deformation.

the desired information. For example, to produce a percentage deformation of 70 per cent a blow of 800 ft.-lb. would be required, and so on. As already pointed out, these equations apply to normal ½-inch samples only, by which are meant cylinders, cones or frusta, ½ inch high and having a volume equal to that of a normal half-inch cylinder. It is possible that the formula applies as well to other shapes of height and volume equal to normal half-inch cylinders, but the author has not checked this point.

There is a well-known law known as Tresca's theorem which states that the amount of energy required to produce analogous changes of shape in geometrically similar bodies is proportional to the volumes or weights of the bodies concerned. Now what may be called the fundamental diagram (Fig. 5) for normal half-inch samples can be usefully employed in estimating the energy required to deform smaller or larger samples. How does this work ? Suppose it is desired to know roughly how much energy would be needed to reduce a normal *three*-inch cylinder of steel by 70 per cent of its height in a single blow at a temperature of 1850 deg. F. We have already found by experiment that 170 ft.-lb. of energy will reduce the height of a normal half-inch cylinder of this steel by 23 per cent and, using the fundamental graph, have discovered that 800 ft.-lb. are needed to reduce a normal half-inch cylinder of the same steel by 70 per cent at the same temperature. According to Tresca's theorem the energy required to reduce a normal three-inch cylinder of the same steel at the same temperature would be

$$\frac{800 \text{ x volume of 3-inch cylinder}}{\text{volume of } 1/2\text{-inch cylinder}}$$

$$= \frac{800 \text{ x } \frac{\pi (3)^2}{4} \text{ x } 3}{\frac{\pi (1/2)^2}{4} \text{ x } 1/2}$$

$$= \frac{800 \text{ x } (3)^3}{(1/2)^3}$$

$$= 800 \text{ x } 9 \text{ x } 8$$

$$= 57{,}600 \text{ ft.-lb.}$$

It is not likely that the result thus obtained will be mathematically exact. The order of magnitude, however, will be correct.

Comparison with some actual figures may be of interest. In a paper by Zeerleder, published in 1937, he reproduced the series of curves which are given in Fig. 6. Consideration of curve 5 in this graph shows that the aluminum-copper-magnesium alloy Avional D is reduced about 15 per cent in height at a temperature of 420 deg. C. (770 deg. F.)

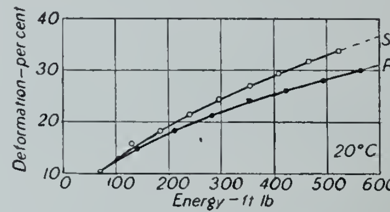

Fig. 8—Energy and deformation in single and repeated-blow drop tests at 20° C.

under a single blow of 70 ft.-lb., this having been the energy of the blow used in all the experiments referred to in this graph. The samples in these experiments were normal 20 mm. cylinders. It is somewhat remarkable that the point corresponding to $E=79$ and $d=15$ lies very close to, if not on, the straight line which was drawn in the fundamental diagram for half-inch normal samples (Fig. 5), from which one might guess, but only guess, that the energy of the single blow required to reduce a normal 20 mm. (0.79 inch) cylinder of Avional D by about 18.5 per cent would be about 120 ft.-lb. In Fig. 1 of Zeerleder's paper, here reproduced as Fig. 7, he shows that a normal 80 mm. (3.15 inch) cylinder of Avional D is reduced $\frac{80.0-65.2}{80}$ x $100 = 18\frac{1}{2}$ per cent by five blows of 1950 ft.-lb. capacity. Our very rough estimate of the energy of the single blow required to reduce such an 80 mm. cylinder would be

$$\frac{120 \text{ x } 80 \text{ x } 80 \text{ x } 80}{20 \text{ x } 20 \text{ x } 20}$$

$$= 120 \text{ x } 64 = 7{,}680 \text{ ft.-lb.}$$

The *actual* energy absorbed in reducing the cylinder in *five* blows was 5 x 1950 = 9750 ft.-lb.

In this same figure he shows that a similar cylinder of

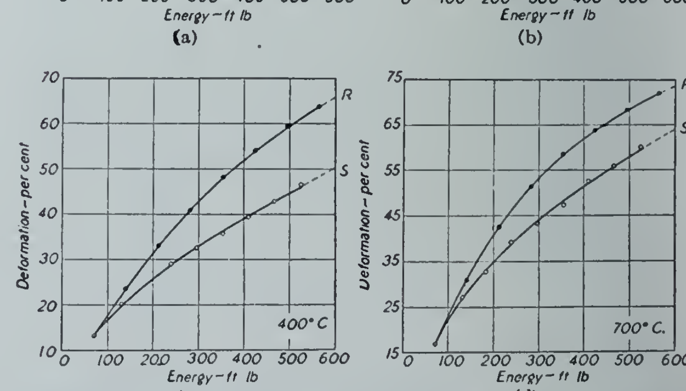

Fig. 9—Energy and deformation in single and repeated-blow drop tests at 250°, 300°, 400° and 700° C.

Avional D is reduced $\frac{80.0-51.3}{80.0}$ x 100 = 36 per cent by *ten* blows each of 1950 ft.-lb. Reference to the fundamental graph shows that a single blow of 310 ft.-lb. would reduce a 20 mm. cylinder of Avional D by 36 per cent of its height. Our estimate of the energy of a single blow required to reduce an 80 mm. cylinder of Avional D would then be

$$310 \times 64 = 19{,}840 \text{ ft.-lb.}$$

The *actual* energy absorbed in reducing the 80 mm. cylinder in *ten* blows was

$$10 \times 1950 = 19{,}500 \text{ ft.-lb.}$$

The author would be the last person to place too much stress on the fact that these estimates lie as close as they do to the experimental results, because he is well aware that, when metals or alloys are forged at temperatures at which the hardening effects of plastic deformation are immediately effaced by recrystallization, the energy absorbed in their deformation by a single blow may be considerably greater than that absorbed in producing the same deformation by a number of blows. Further, it must also be remembered that the fundamental diagram of Fig. 5 applies to normal half-inch samples, and not, as far as is known at present, to normal 0.79-inch samples.

Thus it might be expected that the estimates of the energy required to deform Avional D with a single blow would have yielded results somewhat higher than those

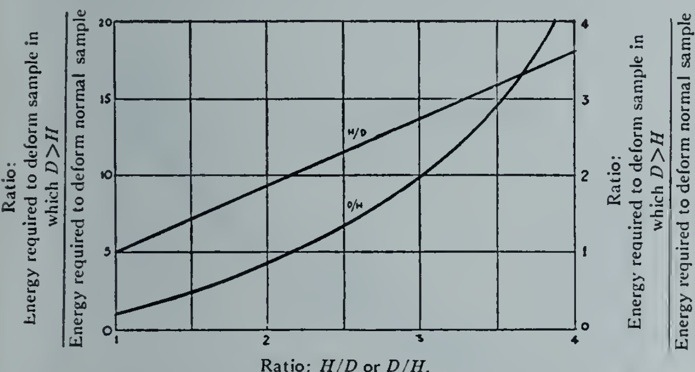

Fig. 10—Curves for estimating energy required for cylindrical samples whose heights are greater or less than their diameters.

obtained in Zeerleder's experiments with a number of blows. This may be illustrated by means of the two following diagrams which show the results of single and multiple-blow drop tests on normal three-quarter-inch cylinders of annealed copper having a Brinell hardness at room temperature of 11.5. Figure 8 comprises two curves, one showing the relationship between deformation and the energy of single blows of varying energy content (curve S) and the other showing the relationship between deformation and the total energy of repeated blows of equal energy content, viz., 70.6 ft.-lb. (curve R). All the tests were made at room temperature. A comparison of curves S (single) and R (repeated) brings out the interesting fact that, at room temperature, more energy is absorbed in forging a sample of copper in a number of blows than in a single blow or, conversely, a greater change in shape is produced by a single blow of given energy than is produced by a number of blows of the same total energy.

Similar pairs of curves could be drawn for the results of tests at 100 deg. C. (212 deg. F.) and 150 deg. C. (302 deg. F.). However, the curves for the tests at 150 deg. C. (302 deg. F.) lie very close together, though they do not coincide.

Curves for the tests at 200 deg. C. (392 deg. F.) are particularly interesting because they coincide in those parts which refer to the tests with blows of low energy (up to about 300 ft.-lb.), but separate in those parts referring to the tests with blows of higher energy. As is well known, the greater the degree of plastic deformation the lower is the

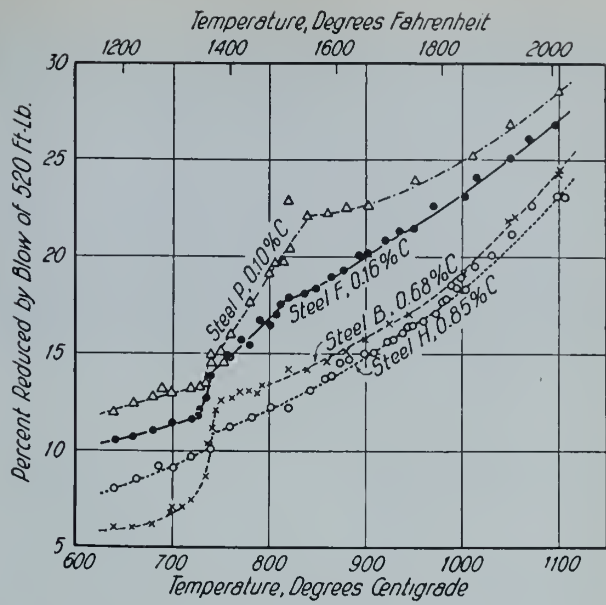

Fig. 11—Effect of carbon on forgeability of carbon steels.

temperature of recrystallization, and, since blows of high energy produce more flow than blows of low energy, it is not surprising that the curves for single and repeated blows do not coincide over their entire lengths, but tend to separate in those parts which refer to high degrees of plastic deformation or energies of blow. Curves for forging temperatures of 250 deg. C. (482 deg. F.), 300 deg. C. (572 deg. F.), 400 deg. C. (752 deg. F.), and 700 deg. C. (1292 deg. F.), which demonstrate the points just discussed, are shown in Fig. 9.

At forging temperatures of 400 deg. C. and higher the single and multiple-blow curves separate again, the former now always lying below the latter. Now, these relatively high forging temperatures are temperatures at which the hardening effects of forging are likely to be immediately effaced by recrystallization of the metal being forged. It can be said, therefore, that, at temperatures at which the hardening effects of plastic deformation are immediately effaced by recrystallization, the energy absorbed in deforming a metallic body by a single blow may be greater than that absorbed in producing the same deformation by a number of blows. The converse proposition is, of course, true, as reconsideration of the curves shown in Fig. 8 will show.

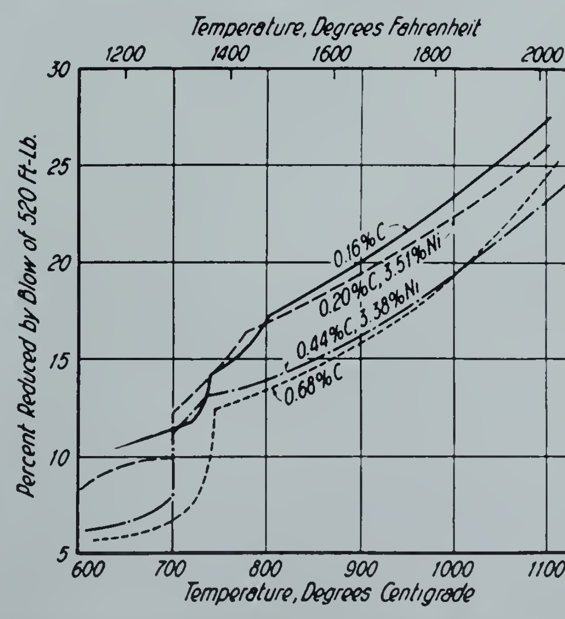

Fig. 12—Effect of nickel on forgeability of carbon steels.

Having attempted to show how the energy required to produce specified reductions in height in normal samples of different shapes and sizes can be calculated, given the energy required to produce a known reduction in height in a sample of known shape and size, a further step can be taken. Figure 10 shows two useful curves which enable rough estimates to be made of the energy, other things being equal, required to produce equivalent reductions in height in cylindrical samples whose heights are greater or less than their diameters, given the energy required to produce a given reduction in height in a normal sample. The curve marked H/D refers to cylindrical samples whose heights are greater than their diameters, that marked D/H refers to samples whose diameters are greater than their heights. If we know the energy required to produce a 25 per cent reduction in height of a normal cylinder of known analysis and state and it is desired to estimate the energy required to obtain a similar reduction in height in a cylinder of similar analysis and state whose height is three times its diameter, we first find the point of intersection of the ordinate marked 3 and the curve marked H/D, and then connect this point by an abscissa to the *right* hand side of the diagram. This gives the value 2.75±; that is, about 2¾ times the energy needed to deform a normal cylinder would be required to deform a cylinder three times as *high.* On joining the point of intersection of the ordinate marked 3 and the curve D/H by an abscissa to the *left* hand side of the diagram, the value 10.0± is obtained; indicating that about ten times the energy required to deform a normal cylinder would be required to deform a cylinder three times as *wide.*

It has already been mentioned that the critical points have an important effect upon the properties of steel. The next figures (Nos. 11 to 21 inclusive) cover this and other points of interest in regard to steel.

Figure 11 shows not only the importance of the critical points upon the forgeability of a group of straight carbon steels, but demonstrates (1) the marked effect of carbon, and (2) the influence of structure, on the forgeability of steel. At temperatures above the A_1 point (735 deg. C.—

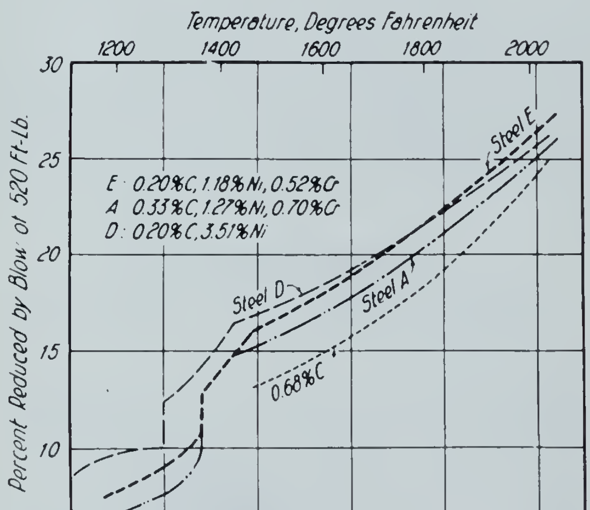

Fig. 13—Relative forgeability of a nickel steel and two nickel-chromium steels.

1355 deg. F.) the 0.16 per cent carbon steel is easier to forge than either the 0.68 per cent or the 0.85 per cent carbon steel, as might be expected. It is surprising to note, however, that below A_1, the particular 0.68 per cent carbon steel chosen for test was harder than the eutectoid steel with which it was compared. This can be accounted for only by assuming that the structure of the former was such as to make it harder than the latter. In all the experiments

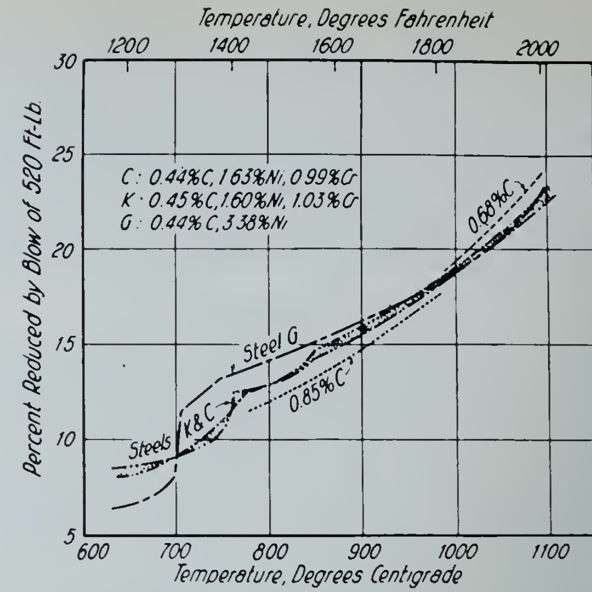

Fig. 14—Difference in forgeability of two nickel-chromium steels of very similar composition.

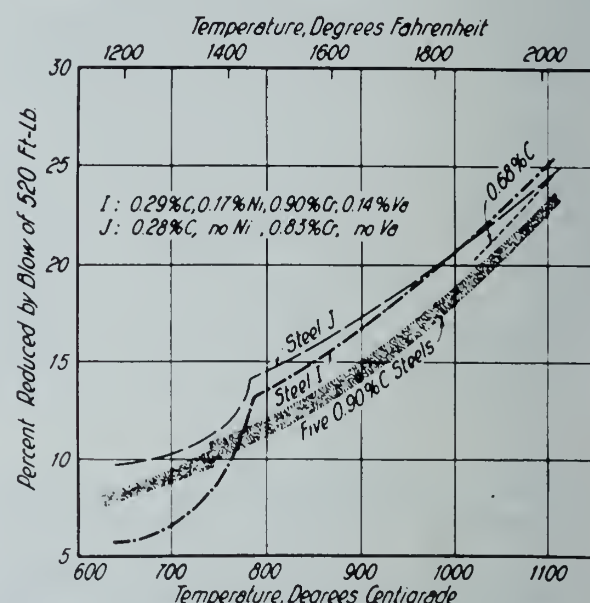

Fig. 15—Relative forgeability of two chromium steels, one of which contains vanadium.

the times of heating the samples, which were cut from bars "as rolled," were sufficient to ensure that they were uniformly heated throughout, but certainly not long enough to bring the steels to equilibrium.

Figure 12 demonstrates the effect of nickel, as compared with that of carbon, on the forgeability of steel.

Figure 13 makes possible a comparison between steel SAE 2320 (nickel) and steels SAE 3120 and 3130 (nickel--chromium). Note should be made of the preponderant effect of carbon upon the forgeability of these steels.

Figure 14 is inserted mainly for the purpose of showing how two steels of very similar composition can differ in their forgeability. Steel C contained 0.52 per cent of manganese and steel K 0.40 per cent of this element. Otherwise the two steels agreed very closely in chemical analysis. No studies were made of the microstructure of the steels after forging at different temperatures. Incidentally, it is of interest to note how similar are the two SAE 3245 steels to the SAE 2045 steel at forging temperatures above about 950 deg. C. (1742 deg. F.).

The forgeability-temperature curves for two chromium steels of similar analysis, one containing nickel (residual) and vanadium, the other free from these elements, is shown in Fig. 15.

Of recent years much has been heard of the high-yield low-alloy steels and the next three figures refer to the forgeability of three such steels as compared with straight carbon steels of equal carbon content.

Figure 16 deals with Cor-Ten, a steel containing about 0.10 per cent carbon, 0.30 per cent manganese, 0.80 per cent silicon, 0.45 per cent copper, 1.00 per cent chromium and 0.15 per cent phosphorus. The yield point of this steel is in the neighborhood of 62,500 lb. per sq. in., as compared with 45,000 lb. per sq. in. for straight carbon steel of the same carbon content. The forgeability of Cor-Ten is distinctly lower than that of SAE 1010, forgeability-temperature curves for two types of which are shown in this graph. These curves, it will be observed, differ quite materially from one another over the range 735 deg. C. (1355 deg. F.)—1000 deg. C. (1832 deg. F.). This can be accounted for by the marked difference in structure between the two steels (marked "Carbon steel" and "Steel P" in Fig. 16). Steel P, which had a very low silicon content, showed considerable banding and relatively large grain size in the ferritic areas, while the other SAE 1020 steel had a uniform structure and relatively small grain size (see Fig. 17).

Man-Ten is a typical SAE T1330 steel and can be compared with SAE 1030, as is done in the next figure, No. 18. There is little to choose between the two steels as far as forgeability is concerned. It is of interest to record that the forgeability-temperature curves for Man-Ten and a carbon steel of approximately the same tensile strength at room temperature, viz., a SAE 1040 steel, correspond closely to one another over the entire range 600 deg. C. (1112 deg. F.) to 1200 deg. C. (2192 deg. F.).

Another high-yield low-alloy steel is Sil-Ten, of which the following is a typical analysis:—

Carbon	0.36 %
Silicon	0.22 %
Manganese	0.68 %
Sulphur	0.024%
Phosphorus	0.017%

A sample of this steel, investigated by the author, had the following mechanical properties:—

Yield point	51,000 lb. per sq. in.
Tensile strength	88,000 lb. per sq. in.
Elongation	28%
Reduction of Area	54½%

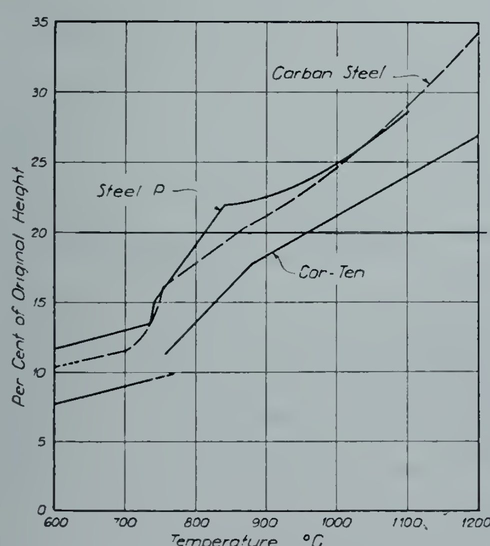

Fig. 16—Relative forgeability of Cor-Ten and two SAE carbon steels.

The mechanical properties of a SAE steel of similar carbon content, which was compared with this sample of Sil-Ten, were as follows:—

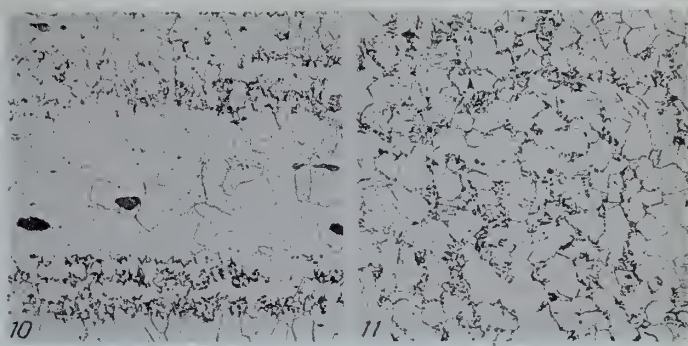

Fig. 17—Photo-micrograph of the two SAE steels of Fig. 16.

Yield point	44,000 lb. per sq. in.
Tensile strength	77,000 lb. per sq. in.
Elongation	30¾%
Reduction of area	52%

The forgeability-temperature curves for both steels are shown in Fig. 19, which brings out the interesting fact that the difference in mechanical properties between the two

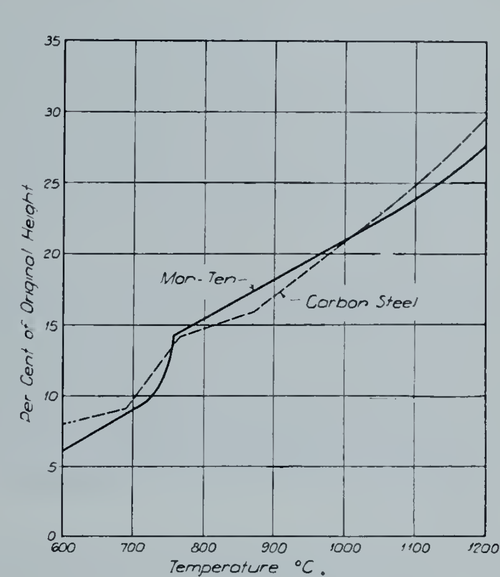

Fig. 18—Relative forgeability of Man-Ten and a carbon steel of similar carbon content.

steels shows itself throughout the entire range of these experiments. It should be noted that the grain size of the Sil-Ten tested by the author was coarser than that of the straight carbon steel, which suggests that the effect of silicon upon the forgeability of steel, while not profound, is sufficient to counterbalance the effect of grain size.

It may be asked why some of the curves in the figures intersect one another. One reason may be this: The grain sizes of these steels vary relative to one another at different temperatures. This is brought out in Figs. 20 and 21, the first of which shows the structures of two steels of practically the same analysis, one inherently coarse-grained, the other inherently fine-grained, after forging at temperatures of 900 deg. C. (1652 deg. F.), 1025 deg. C. (1877 deg. F.) and 1150 deg. C. (2102 deg. F.), respectively. The second (Fig. 21) shows the forgeability-temperature curves for the two steels. These intersect in the neighbourhood of 990 deg. C. (1814 deg. F.), where the grain sizes of the steels are almost identical, as was shown in Fig. 20. At temperatures below 990 deg. C. (1814 deg. F.) the inherently fine-grained is more resistant to deformation than the inherently coarse-grained steel, while at temperatures above 990 deg. C. the inherently coarse-grained steel is the less forgeable of the two. These experiments serve to emphasize how much more important are the effects of austenite grain size than inherent grain size on the forgeability of steel.

It may be of interest at this point to review some of the recent work which has been published on the hot forging of the alloys of the light metals, aluminum and magnesium. In this connection the author is specially indebted to an extended abstract on the subject which was published in *Light Metals*, in September, 1940.

Going back to the work of Zeerleder, reference to Figs. 7 and 6 will be helpful in this connection.

The first (Fig. 7) gives some idea of the comparative forgeabilities of aluminum, two aluminum alloys, 58/42 brass and mild steel. The samples, before forging, were 80 mm. high and 80 mm. diameter. It will be observed that the forgeability of mild steel at 1100 deg. C. (3012 deg. F.) is slightly greater than that of Avional D at 420 deg. C. (788 deg. F.).

The other, (Fig. 6), presents a series of ten curves referring to various alloys of aluminum; these curves show the percentage reduction in height of 20 mm. normal samples at various temperatures. Their similarity to the forgeability-temperature curves for steels at temperatures above the A3 point will be noted, though it justifies no further comment here.

Speaking generally, the technique of forging aluminum and its alloys at their relatively low forging temperatures, 360 deg. C. to 510 deg. C. (680 deg. F. to 950 deg. F.) is much the same as that of forging the heavy metals and their alloys at their relatively high forging temperatures. The alloys of magnesium, however, present a problem all their own; they verge on "hot shortness." In other words, they lack cohesion under stress at high temperatures. On this account they are extremely difficult to roll and to forge as cast, though they are less susceptible to rupture when forged after extrusion, owing to the consolidating effect of extrusion. Temperature too, has a profound influence on their forgeability. For example, the specific forging pressure of the light alloy (Electron A2M) containing 6¼ to 6¾ per cent of aluminum, ¾ to 1¼ per cent of zinc, 0.20 to 0.35 per cent of manganese and up to 0.30 per cent of silicon, the balance being magnesium, is increased threefold by reducing the forging temperature from 350 deg. C. (662 deg. F.) to 225 deg. C. (419 deg. F.). Further, the rate of deformation of this alloy, as of other ultra-light alloys, is of prime importance.

The sensitivity of ultra-light alloys requires that a special technique be adopted in their treatment. Before they can be forged under the drop hammer, or even the screw press, it is often desirable, if not essential, to consolidate them by free forging or under a hydraulic press, since slow rates of deformation are imperative in the early stages of forging. The first forging operations on these alloys are generally

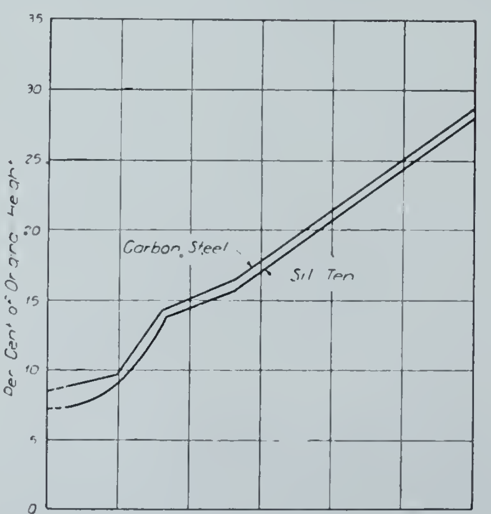

Fig. 19—Relative forgeability of Sil-Ten and a carbon steel of similar carbon content.

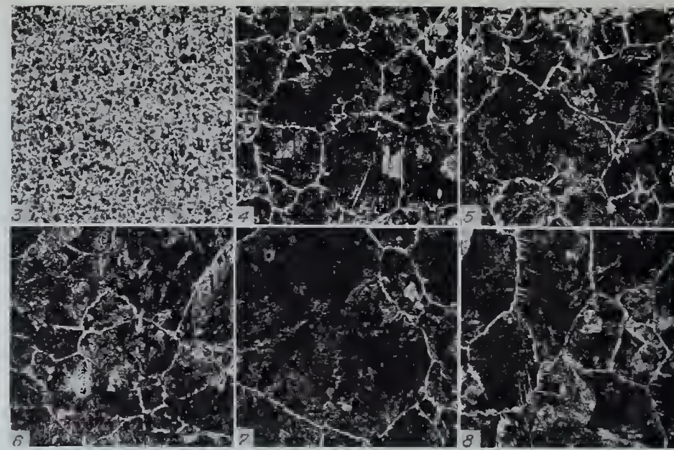

Fig. 20—Photo-micrographs showing variation of relative grain size of two steels.

carried out at the highest possible temperatures consistent with safe handling of the material.

In free forging it is essential that the blows be so controlled and directed as to guide, rather than to force, the material into the desired shape, if fissures and cracks are to be avoided in the finished article. Work must be applied to ultra-light alloys with the utmost uniformity. The hot material must be rotated and reciprocated after each blow. Surfaces should be forged slightly concave rather than flat. All these conditions presuppose both experience and skill on the part of the worker.

The later forging operations should be performed at successively lower temperatures than the first, so as to avoid

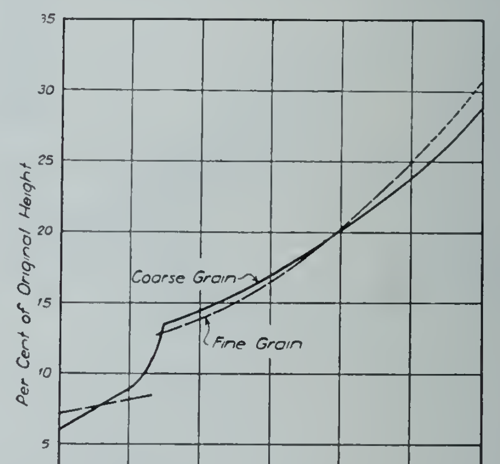

Fig. 21—Relative forgeability of coarse-grained and fine-grained steels of similar carbon content.

excessive grain growth at all stages in the formation of the parts. In order to retain as fine a grain as possible in the finished articles, they should be quenched in water immediately after forging. A fine grain size counteracts the directional effects of the fibre induced in the alloy by forging; further, it promotes homogeneity of structure and so facilitates the heat treatment of the finished forgings.

Magnesium and its alloys are as prone to grain growth on reheating as are other metals and alloys which have been subjected to critical degrees of cold working, but the deleterious effects of grain growth are, in their case, more pronounced. Hence, great care must be exercised in the reheating of components which have been forged at temperatures below the recrystallization temperature—reheating through the range where excessive grain growth is likely to happen should be as rapid as possible.

The rates of deformation of the ultra-light alloys should always be lower for equal weights and higher for equal volumes of material than those used in the forging of heavy metals. Speaking generally, rates of deformation should lie between those used in the free forging of the heavy metals and those used in the die forging of the aluminum alloys, other things being about equal. Rolled, extruded or forged stock, i.e., material that has received some preliminary consolidation, can be treated with somewhat less consideration than cast material—forging under the screw press or the drop hammer can be considered without fear. Because of the lower rates of deformation involved, drop hammers with heavy tups are to be preferred to those with light tups in die-forging these materials.

When die-forging under the drop hammer, the rate of deformation is not so readily controlled as in free forging

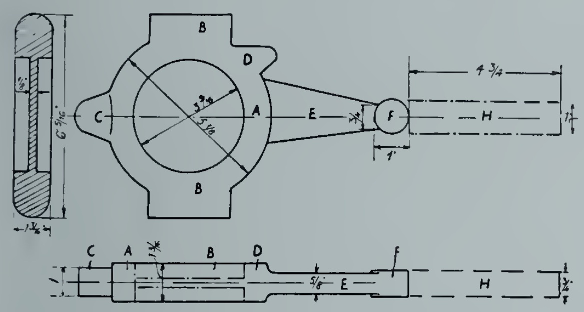

Fig. 22—Eccentric cam, workpiece for which forging schedules are discussed.

or in press-forging. A definite relationship should, therefore, be maintained between the size of the part being forged and that of the hammer employed.

The pre-heating time for dies to be used in forging light alloys of aluminum and magnesium, may be shorter than that for dies to be used with heavy material, owing, on the one hand, to the lower temperatures involved and, on the other hand, to their usually smaller size and lighter weight.

The choice of the method to be employed in the production of a component is one of considerable importance. Due regard has to be given, first, to the equipment available, then, to the forgeability of the alloy to be used, and, lastly, to the design of the component itself. There must also be borne in mind the fact that the change in shape produced by pressure may, even will, differ markedly from that produced by impact.

Finally, it will be of interest to discuss at some length the schedule of forging operations and times of forging of the typical light alloy component shown in Fig. 22 (again quoting from the article in *Light Metals* of Septenber 1940). Herein is shown an eccentric cam, the ring for which has to be increased in thickness from ¾ inch to 1 3/16 inch. This operation is better performed by hammering than by pressing, because the greater rate of deformation of the material under impact gives less time for lateral flow. In general, it may be said that for those operations involving the longitudinal extension of material it is best to use a hammer, whereas, for upsetting, the press is to be recommended. Under a press there is a greater chance of preferential flow of metal into the flash groove than into the die cavity proper. Not only is such flow itself undesirable, but, the metal being squeezed into a thin layer, opportunity is given for rapid cooling and subsequent formation of edge cracks in the finished parts.

Turning to the schedules, Table I presents the calculations involved in estimating the weight of the eccentric cam shown in Fig. 22. In this connection it is well to remember that, for any given component, its weight in light alloy will frequently be greater than that which would be deduced from a consideration of the relative specific gravities of light and heavy alloys, because the relative mechanical properties of the two materials must invariably be considered.

In Table II, which follows, there are presented the operations schedule and times for forging this eccentric cam (i) in light alloys—3.3 pounds, (ii) in heavy metal of equal volume—8.8 pounds, and (iii) in heavy metal of equal weight—3.3 pounds.

"Superficial consideration might lead to the conclusion that, with respect to production time and cost, no marked difference" would obtain "between heavy-alloy and light-alloy forgings and that, moreover, owing to the higher cost

Base time is composed of the main time and the necessary by-times. The base time is for instance the operating time of the machine. The base time is determined by time studies. Lost time is given as a percentage of base time. The sum of base time and lost time gives piece time.

of light alloys, per unit weight, the forging and pressing of these alloys might prove somewhat uneconomic." The fact is, however, that on a weight/strength basis a unit of light alloy may be taken as equivalent to at least two units of heavy alloy. This places the light alloys in a favourable position, since relatively smaller hammers, presses, etc., can be used in their fabrication. In particular, dies need not be so heavy or so expensive, while wasters and forging scrap command a relatively higher price. Where the same equipment has to be employed in the forging of both heavy and light alloys, these considerations naturally carry no weight.

To return to Table II, the material specified for this cam was an aluminum alloy of medium forgeability, an alloy such as No. 6 in Fig. 6. In the preliminary free forging of the blank a 220-pound compressed air hammer is used, while for the die-forging operation a 660-pound drop hammer with fixed anvil block is employed. The free forging is carried out in two operations, the die-forging in one.

The various stages in forging are shown diagrammatically in Fig. 23. The blank is preheated according to the recommendations for the material in question. It is then notched as in operation 2, after which operation 3 is performed. The purpose is to obtain a neck of reasonable length which fits better into the falling die. The notching operation is repeated (4) and the material subsequently drawn out (5). In this last operation the upper temperature limit for light-alloy forging, viz., 360 deg. C. (648 deg. F.) should not be exceeded.

The lower fillet is next shaped by means of a swage so that the component will fit the upper half of the forging die. In the same heat, waste metal is removed (6) and both parts separated. The workpiece is now again reheated and die-forging commenced (8). In this operation it is important that the dies be adequately heated in order that the light alloy be not unduly cool. The operation completed, the part is placed in the trimming die, from which it emerges in its final form (10).

Space will not allow full examination of the relative production costs of forgings of the same size and shape in steel and in light alloy. Comparisons are made in the article referred to above, these being based on the following points:—

(a) Production time for the light-alloy part is 35 per cent less than that for the steel part.

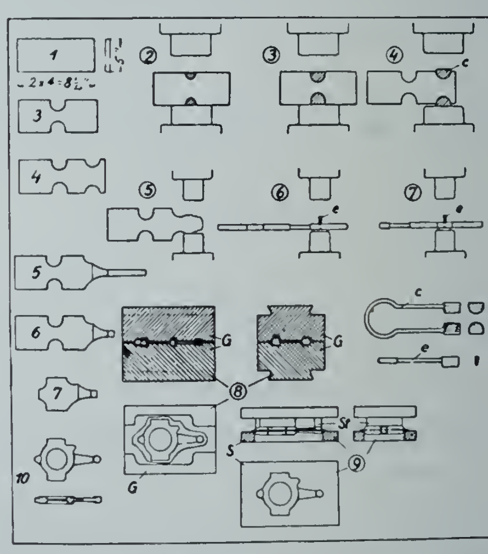

Fig. 23—Diagrammatic summary of operation schedule for eccentric cam forging.

(b) Aluminum-base alloys require lighter equipment than steel, hence, overheads can be reduced from 400 per cent to 250 per cent.

(c) Dies for the aluminum-base alloys are lighter than those for steel, and are made of a somewhat less expensive grade of steel which machines more readily than the expensive grade, hence die costs are reduced from about $204 to about $124.

The estimated cost per component—the cam which we have already considered—is $0.84 in steel, as compared with $1.05 in light alloy. The die costs are $204 in steel as compared with $124 in light alloy. To amortize the die costs in the case of the steel forging would require the production of about 240 cams, to do this in the case of the aluminum alloy forgings would require the production of about 117. Thus it appears that the use of special forging dies becomes economical for aluminum alloy forgings at an output less than one-half that for an equivalent forging steel.

This comparative study of the production of a component in steel and in an aluminum-base alloy of medium forgeability could be matched by a similar study of the production of a component in steel and in a magnesium alloy, but it will suffice to quote these words from the article to which the author is indebted for the preceding discussion—"It thus appears that, by the employment of improved methods of hammer forging and the use of *magnesium-alloy* dies, the production by die-forging of the forked lever cited becomes economical at an output figure more than 50 per cent below that required when using older types of equipment with the conventional steel dies. It is possible that still further reductions might be made in die costs due to the readiness with which magnesium alloys may be machined, and to the ease with which they may be handled owing to their light weight."

The use of magnesium-alloy dies in the hot forming of sheet is well known, but the practice referred to in the above quotation is unusual. There seems to be no question as to the reliability of the source of this information, but the remark may be made that "the satisfactory use of ultra-light alloys" in the manufacture of dies to be used in the production of solid forgings "would seem to demand either their operation at a temperature below the usual plastic range (say, not in excess of 250 deg. C.—482 deg. F.—for alloys of ordinary composition), or the use of special compositions not amenable to appreciable plastic deformation within the common range of forging temperatures."

CHEMICAL PROCESSES—THEIR PLACE IN DAILY LIFE

Dr. I. R. McHAFFIE

Manager, Research and Development Department, Canadian Industries Limited, Montreal, Que.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, on October 10th, 1940

SUMMARY—A non-technical paper offering a general view of present-day chemical industry with special reference to the production of heavy chemicals and of plastics by synthesis and polymerization.

The Beginning of Chemistry

The early man seems to have regarded with superstitious wonder the natural events which occurred around him. Chemical phenomena were supposed to be produced by indwelling spirits, and results were obtained by charms and incantations addressed to the particular spirit concerned. Such a philosophy is much more picturesque than that employed at the present time.

Failure to obtain a desired result could be explained by suggesting that astrological conditions were not propitious and, consequently, the spirit was sleeping. This is truly a much more romantic explanation than to admit a mere lack of knowledge.

Those who made any pretence of studying nature were suspected of dealings with evil spirits. During this period the study of chemistry was looked upon as a sort of black magic, and the names given to certain of the then known elements were very fanciful. Chemical processes were described in equally picturesque language; take for example the reaction between mercuric chloride and mercury: "The fierce serpent is tamed and the dragon so reduced to subjection as to oblige him to devour his own tail."

With such a mystic manner of describing the knowledge possessed at that time, it is not surprising that the study of natural phenomena, and chemistry in particular, was considered as impious and even forbidden.

In the second stage of philosophy man loudly proclaimed the supremacy and omnipotence of human reason. It was considered to be beneath the dignity of an educated man to conduct any experiments, and any knowledge obtained by observing nature was considered to be unworthy of attention. During this period it was held that all secret laws of nature could be invented by abstract thinking, and that real knowledge was to be obtained by reasoning, apart from all information furnished by the senses.

Thus, the early philosophers who looked with scorn on anyone who attempted to make observations on natural phenomena, actually hindered the real progress of knowledge for centuries. Their fanciful attempts to explain material things had, in many instances, little respect for truth or reality as we understand it to-day.

It is true that before the Christian era the Greeks seemed to be developing the "certain or exact type of philosophy," but the mysticism of the Middle Ages proved more attractive than any results obtained from observations, and the early teachings of the Greeks were soon forgotten. In fact, it was not until the thirteenth century that a proper view concerning nature and her phenomena began to appear. Man gradually realized that the truth was not in him, but was around him, and could be discovered by observation and diligent search.

This attitude became more evident in the seventeenth century, when the first scientific societies were formed, providing an organized means of discussing facts determined by experiment. The most outstanding of these were The Royal Society, founded in London, in 1660, and L'Académie des Sciences, established in Paris six years later. It is from this time that chemistry, as it is known to-day, had its beginning.

Arising from the study of combustion we have the first attempt at generalization in chemical phenomena. As numerous materials burned it seemed only reasonable that there must be some common explanation for this event. The earlier philosophers stated that combustible bodies contained an inflammable principle, which was little better than saying that the body itself was combustible. At the beginning of the eighteenth century it was recognized that there was a definite connection between the combustion of inflammable substances and the oxidation of metals to give oxides.

In 1772 Lavoisier's experiments on the oxidation of mercury in a given volume of air brought to light the true explanation of oxidation and combustion. His experiments proved that atmospheric air is made up of two gases—oxygen and nitrogen—of different, and even opposite, natures.

Many authorities on the subject fix this date as the birthday of our modern chemistry, and from this time onwards a constantly increasing number of experimenters added to the general fund of chemical knowledge.

The facts of chemistry, determined by a very large number of experiments, have been correlated and described in what are called the laws of chemistry. A chemical law is not something which must be obeyed, like a law governing our social behaviour, but is a description of some phase of the behaviour of matter. Chemistry is, therefore, a system whereby we can reason concerning the behaviour of matter, using as our premises the laws of behaviour which have been ascertained by experiment.

The study is, for convenience, divided into Inorganic Chemistry, dealing with mineral substances, and Organic Chemistry, which deals chiefly with compounds containing carbon. Originally the division was made because it was thought that certain animal and vegetable substances were produced under the influence of vital force and that the laws regulating their formation were different from those relating to mineral substances. This idea persisted until 1828, when Wöhler in one of his experiments discovered that he had produced urea by ordinary laboratory methods. This compound had been known for some time, but only as a constituent of the urine of certain animals. Subsequently, it was discovered that many other substances could be produced by standard laboratory methods which had hitherto been considered as resulting from the influence of vital force. This discovery was of outstanding importance, since it opened up a whole new field of endeavour for the chemist.

Chemical reactions are natural phenomena which occur and often are evident to visual observation; it is important to note that they are always accompanied by an energy change. When fuel is burned energy is liberated, and by utilization of this energy, in, say, a boiler plant, it can be converted to other forms which can be used to perform useful work. The energy changes accompanying other chemical reactions are not always so apparent, but for the chemist are of equal importance, and are an integral part of the study of the behaviour of matter.

Chemical Industry

Chemical industry might be described as an organized effort to put atoms to work for the benefit of mankind. But it must be remembered also that chemical plants established by nature are synthesizing compounds and producing many materials which are still of vital necessity to man. The truths that are concerned with the behaviour of matter are always the same whether matter be confined in a test tube in a chemical laboratory, whether it be the synthesis of substances in plants or animals, or the chemical reactions which occur in the most complicated industrial plants.

It is important that complete knowledge should be available concerning any chemical process which is to be adopted in industry. This can be obtained from the efforts and results of those who have carried out previous work in this particular field, or it may be necessary to acquire it through the prosecution of original research.

It has often been said that in chemical industry, if costs did not have to be considered, great things could be accomplished, but actually the industry must operate for the benefit of all mankind, and to survive it must, in our economic system, so operate as to make mankind richer. Therefore, the simplest and most direct method of production is to be desired, and waste products or unwanted products should not be produced in any process where they can be avoided. As an example, the synthesis of phenol from benzene may be cited.

Raschig in Germany has been responsible for the development of two processes of manufacture. His earlier process was to react benzene and sulphuric acid, obtaining benzene sulphonic acid. A further reaction between benzene sulphonic acid and caustic soda gives sodium sulphite and sodium phenate; sodium phenate on neutralization with sulphuric acid gives phenol and sodium sulphate. This may seem complicated, but the main point is that for this process the raw materials required are benzene, sulphuric acid and caustic soda, and, in addition to the phenol which it was desired to make, sodium sulphite and sodium sulphate are also obtained; unfortunately these two salts have little commercial value.

In the case of the second process, which has only lately been made public, benzene, hydrochloric acid and air are caused to react, and the resultant products are monochlorbenzene and water. The next step is to bring about a reaction between the monochlorbenzene and water, and this has been successfully taken. The products of the reaction are phenol and hydrochloric acid. Now, obviously, since hydrochloric acid is required as a raw material in the process, it may be returned to the first operation. This is a particular case of a type of reactions which are employed wherever possible, on account of their economy, and are generally referred to as cyclic processes.

Efficiency in Production

In applying chemical reactions to industrial production certain basic principles govern the construction of equipment. These are well illustrated in the design of equipment required for the production of sulphuric acid by the contact process, a specific case which serves to illustrate principles which are applied generally throughout the industry.

If the reactions in this process are expressed chemically, everything appears simple. Sulphur is burned in air to produce sulphur dioxide, the sulphur dioxide is reacted with more air, taking up more oxygen to form sulphur trioxide, which, on reaction with water, gives sulphuric acid. Passing over the methods whereby the sulphur is burned and the resulting gas cooled, it must be noted that this sulphur dioxide is dried by means of sulphuric acid.

Before describing how the desired effect is obtained, it is necessary to mention a few facts concerning the reaction whereby the sulphur dioxide is converted to the trioxide. The most important point is that heat is given off during this reaction, which takes place at a high temperature, but the heat given out is not sufficient to raise the gas directly to this temperature. Further, the speed at which the reaction occurs is greater at higher than at lower temperatures, therefore, at higher temperatures of operation a greater amount can be converted and, consequently, for a given output the equipment can be smaller. There is, however, always a "but" and in this case the difficulty has to do with chemical equilibrium, which is less favourable to the desired result at higher than at lower temperatures.

Without attempting to define equilibrium it may be explained that at the higher temperature more sulphur dioxide would pass through the equipment unchanged, than would be the case at a lower temperature. This would mean a lesser efficiency. It should also be stated that this reaction only takes place in the presence of a suitable catalyst, a substance which acts to increase the speed at which reactions occur without itself undergoing chemical change, and without affecting the chemical equilibrium. A good, but negative definition for a catalyst might be that if it is not present no reaction will take place. It is obvious that if the plant is to operate at its greatest efficiency some compromise must be reached between the desire for small equipment with a rapid reaction, and the desire to avoid loss of sulphur dioxide, or one might say loss of efficiency. This is accomplished by dividing the portion of the equipment wherein the reaction occurs into two separate parts. In the first reactor, or converter as it is called, the temperature is high, reaction is rapid, and 80 to 90 per cent of the reaction occurs. In the second reactor the temperature is lower, only 10 to 20 per cent of the reaction takes place, but the desired "clean up" of sulphur dioxide is obtained.

Heat Exchange

The means whereby the desired temperatures are maintained can best be described with reference to Fig. 1.

In the diagram we have two types of equipment, the heat exchangers and the converters. The heat exchangers consist of a steel shell with header plates near each end. These

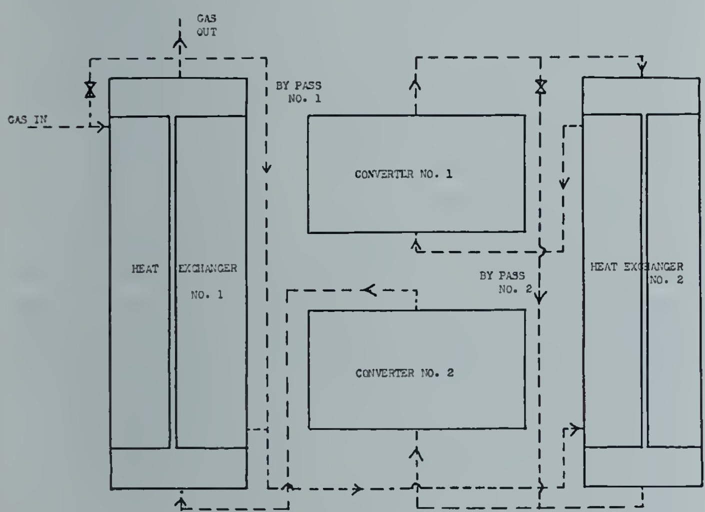

Fig. 1.

header plates are connected together by a number of tubes, and from the diagram it can be seen that gas can pass in one direction around the outside of the tubes while it can pass through a second path inside of the tubes. The converters have suitable trays for holding the catalyst used.

The dried gas, at atmospheric temperature, enters No. 1 heat exchanger, passing through it in the opposite direction to hot gas which is leaving from converter No. 2. It then passes through heat exchanger No. 2, where it meets still hotter gas leaving converter No. 1. It then enters converter No. 1 where reaction occurs, and there is a considerable rise in temperature due to the heat given up by the reaction. The gas leaving this converter passes down through heat exchanger No. 2, giving up some of its heat through the tube walls to the gas travelling in the opposite direction and therefore entering converter No. 2 at a lower temperature. Again there is a rise in temperature due to the reaction which takes place in No. 2 converter and the gas passes out through heat exchanger No. 1, giving up more heat to the incoming gas. Temperatures can be readily controlled by inserting by-passes across the heat exchangers, as shown.

If the temperature tends to rise, No. 1 by-pass can be opened and the amount of heat transferred in No. 1 heat exchanger lessened, thereby lowering the temperature of the gas finally entering No. 1 converter. Should No. 2 converter tend to run at too low a temperature No. 2 by-pass can be opened, thus admitting some of the hot gas direct from No. 1 to No. 2 converter.

In this equipment reaction does not occur until a fairly high temperature has been reached and to start operation it is necessary to provide means for heating the gas until the converters have attained reaction temperature. Once this temperature has been reached it is no longer necessary to supply any heat other than that given out by the reaction. Thus if gas of constant composition, or nearly so, is passed through the equipment the desired temperatures can be maintained almost indefinitely.

This ingenious arrangement saves a great deal of heat energy which would otherwise have to be furnished by fuel.

To illustrate difficulties of another kind that arise in chemical industry consider the gas which is leaving heat exchanger No. 1, and consists of air and sulphur trioxide. As previously stated, sulphur trioxide and water unite to give sulphuric acid; although this is perfectly true, if an attempt were made to scrub the sulphur trioxide from this gas with water, nothing of interest would happen, and the entire output of the plant would pass away as a white cloud.

It was, however, discovered that sulphur trioxide could be readily absorbed in solutions containing 98 to 100 per cent of sulphuric acid, and this is the absorbent which must be used. As sulphur trioxide is absorbed the acid strength increases, so that water must be added. It was mentioned earlier that the gas entering the plant was dried with sulphuric acid and, if desired, this weaker acid can be used, at least in part, to add the necessary water to the system. As the quantity of water added in this way is usually insufficient, an additional amount of water is added as such.

Use of Steam

The case just considered is one in which energy has been given out in the form of heat during the reaction, and while this is generally the case there are many processes in which heat energy is absorbed to attain a desired effect. The following is an example.

In a steam power plant the latent heat of vaporization of water represents energy much of which cannot be transformed into useful work. In chemical industry, however, it can be utilised more efficiently; as a medium for supplying heat, steam has a great deal to recommend it. The pressure at which it is used—which is readily subject to control—determines the temperature of the applied heat. The heat given up is due to condensation, and for this purpose, a high latent heat of vaporization is desirable. If steam must be furnished for process heating purposes it is advantageous to generate it at a higher pressure than required for the process, and to utilize the additional energy content for mechanical work, such as generating electrical power, before using the latent heat for process heating. In chemical plants where steam consumption is large this is frequently done and shows a very considerable economy of operation.

However, many industrial processes operate in such a way that the final product occurs in water solution, so that in order to recover the product the water must be evaporated. In this case the high latent heat of vaporization is not advantageous.

Wherever possible the heat required to boil off this water is obtained by condensing steam, and if for the moment questions of temperature differences, efficiencies, etc., are neglected it might be expected that the condensation of one pound of steam would boil off one pound of water and in so doing, produce one pound of steam. This second pound of steam could then be used to boil off a second pound of water, and so on. This idea finds extensive practical application in a system which is called "multiple effect" evaporation. The example shown in Fig. 2 is one working under pressure, the decrease in pressure from one step to the next can be noted from the diagram. If the temperature differences between the steam and the solution being evaporated are, in the three cases, 25 deg. C. in this particular system, then, for each pound of steam obtained from the boiler, $2\frac{3}{4}$ lb. of water would be evaporated from the evaporators making up the three effects. Such a system is not limited to three evaporators, as systems having quintuple, and even sextuple, effects are in operation.

Another system of evaporation which is worthy of mention is that of vapour recompression. In every evaporator where steam is being used as a heating medium steam is being condensed, and steam is also being given off by the evaporating solution. The condensing steam must be at a higher temperature than the solution being evaporated,

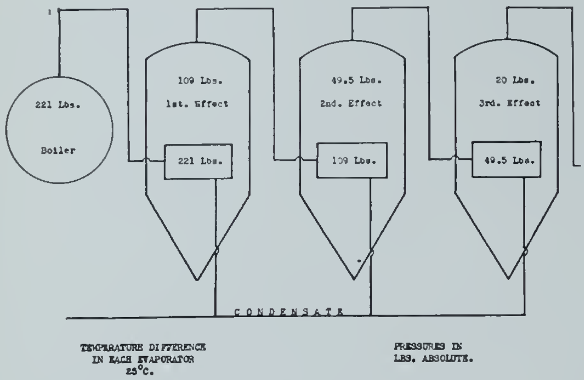

Fig. 2.

otherwise the desired effect would not be obtained. This means that the steam used for heating must be at a higher pressure than the steam formed by the evaporation of the solution. In order, therefore, to make this equipment self-supporting it would only be necessary to take the steam from the evaporating solution, raise its pressure, and then use it for heating, and this can be accomplished by means of a compressor. On compression, steam superheats, so there is no danger of any condensation occurring with mechanical damage to the machine due to the presence of water. In theory, such a system should be equivalent to an infinite number of effects, but owing to mechanical losses, actually has about the same efficiency as a quadruple effect system such as has been described previously.

Although these are only two illustrations of the means by which an economy of energy is effected in chemical industry they are illustrative of the problems which must be solved, and the manner in which chemical equipment operates.

Heavy Chemicals

The term "heavy chemicals" does not permit of exact definition, but refers to basic chemicals which are consumed in very large quantities. They might be termed the tools of industry, for they are used in practically every field of endeavour. They are consumed in such varied industries as soap, textiles, dyes, steel and metals generally, paints, fertilizers and by practically every producer who grows or makes anything. Although heavy chemicals are used in processing they very seldom form a constituent part of the finished article or material, but are discarded at some stage of the process, and in most cases their use is unknown to the ultimate consumer.

The raw materials which are required for the heavy chemical industry are surprisingly few. Energy, either in the form of coal or hydroelectric power, is, of course, a necessity. Water must be available, but all the minerals that are required are sulphur, salt and limestone. These are fairly well distributed over the earth's surface, and as they occur in a relatively pure state, can be readily transported. Herein lies a fundamental difference between the mining and the chemical industry; in mining it is necessary to erect the smelter close to the ore body and the life of the operation depends on the quality or grade of the ore. Chemical raw materials are abundant and the life of the operation depends on the process used. This has led to considerable secrecy concerning the methods whereby certain chemical operations are carried out and a general reticence about them outside the factory.

Sulphur finds little use in its natural state and is usually converted to sulphuric acid which has often been termed the backbone of the heavy chemical industry. Added to salt, sodium sulphate and hydrochloric acid are obtained. By means of the ammonia-soda process, salt and limestone may be made to yield soda ash and calcium chloride. Baking soda may also be obtained in this process. The electrolysis of salt in solution produces caustic soda and chlorine, these react to give sodium hypochlorite. Lime, on reaction with chlorine, gives bleaching powder. Soda ash may be causticized with lime to give caustic soda and so one continues.

Production of Organic Compounds

The only reason for the continued existence of any industry is that it contributes to the production of something which will ultimately be of value to the individual. The heavy chemical industry without doubt plays a very important part in this scheme. There has, however, been developed in the past few years that which might well be called a new kind of chemical industry and strangely enough it conforms to the division of chemistry into Inorganic and Organic Chemistry. The heavy chemical industry deals entirely with inorganic materials, and now an increasingly important field of endeavour deals with the production of organic compounds. It is true that organic compounds have been known since the earliest times, but their source has been from living plants, either from the plant itself or from their fruits or seeds, and even to-day for many of the more complicated products we must rely on plant growth for a source of supply. The synthesis of complex organic compounds by living plants is still a source of wonder and admiration to the chemist. These compounds, consisting as they do of carbon, hydrogen and oxygen in various combinations sometimes associated with nitrogen, sulphur and a few of the other elements are built up in some manner which has not as yet been explained. The source of these elements to the plant is carbon dioxide and water and products almost without number are produced from these two simple substances.

There is, however, a striking phenomenon in plant growth which is receiving considerable attention, namely, the necessity for the presence of what are known as trace elements in the soil in which plants are grown.

Such elements as iron, which is usually present in soils, nickel, cobalt, chromium, zinc, boron, etc., have been shown in many cases to be beneficial, if not essential. Modern organic synthesis is achieved through the use of various catalysts, and it is interesting to note that these trace elements are in many instances those which are employed as catalytic materials.

The raw materials for the organic chemical industry are almost as simple as those employed by plant life, as they are essentially carbon, air and water. There is, however, considerable difference in the method of synthesis, as in industry it is essential to carry out reactions at high temperatures and pressures, whereas plants are capable of synthesizing materials at normal temperatures, and possibly atmospheric pressures, and it seems to be an underlying principle of changes in chemical composition that low temperature, low pressure reactions are much more efficient than those carried out at high temperatures and high pressures.

Polymerization Products

Along with the development of synthetic organic chemistry a new type of reaction has been discovered which is called polymerization. This phenomenon has been known for some time, but its application to the production of useful materials has been extended very greatly in the last few years. The process is not identical with the usual chemical reaction, but is related to it.

A substance may be produced having a definite composition chemically, and may have all the properties of a liquid. In this liquid some changes may be brought about, whereby the substance becomes a solid, and this change takes place without any change in chemical composition as determined by analytical methods. It has been shown that this occurs by a grouping of the individual molecules together, by chemical attraction, to form much larger ones, thus producing a substance with different physical properties. Although the process has received considerable study, the mechanism is not entirely clear, but in some cases, an explanation for polymerization has been discovered. By analogy it can be likened to the assembling of freight cars to make up a train, where, initially, the individual cars have an existence as separate molecules, but when joined in a train they represent a single molecule.

Another type of polymerization occurs, which is more complex, but equally important. This change may be illustrated in the following manner: Let us suppose that we

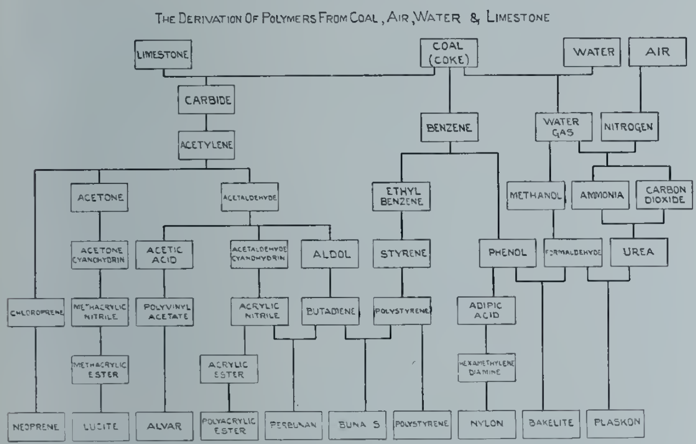

Fig. 3.

have a room full of people, that for some reason they are divided into pairs, and each member of a couple is holding his, or her, partner by both hands. In this case each couple would correspond to a molecule, say, in the original solution, and each couple is free to move independently of any other couple. Suppose that under some urge the people in this room decide to change the general pattern, whereupon every partner frees one hand and grasps the hand of a partner of an adjacent couple, thus possibly forming rings of ten or more people, or "figure eights" or any other odd figures in which all are holding hands. This new group must now move about as a whole and would correspond to a new and larger, or polymerized, molecule.

Much has been written concerning the many new products formed by this process of polymerization, most of which may be said to be manufactured from coal, air, limestone and water, and sometimes salt. The description of their manufacture would prove a very long story. Figure 3 is an attempt to show their relation to the basic materials named. In chemical synthesis coal as it occurs in nature is seldom used as such, but is first converted to coke. Many of the products obtained during the coking process find a useful place in industry.

The list of products shown in the figure is not intended to be exhaustive, but rather to illustrate the number of chemical steps required to reach the desired result.

From coke and water, methanol can be obtained. If nitrogen from the air be added it is possible to obtain ammonia, and at the same time, carbon dioxide is produced. Ammonia and carbon dioxide can be reacted to give urea, which, with formaldehyde obtained by oxidation of methanol, gives urea formaldehyde plastic, the best known of which is perhaps Plaskon. From coal, benzene can be obtained which can be converted to phenol, and this, with formaldehyde, gives rise to the well known material, Bakelite. Phenol can be converted to adipic acid, which, on treatment with ammonia yields hexamethylene diamine. The combination of the acid and the diamine gives rise to Nylon. Benzene can be converted to ethyl benzene, and thence to styrene, which, on polymerization, gives rise to polystyrene, a valuable plastic.

Calcium carbide is produced from lime and coke at high temperature and the carbide with water, yields acetylene. Acetylene with water at ordinary temperatures in the presence of a suitable catalyst yields acetaldehyde, and with steam, gives acetone. From acetaldehyde, through the aldol condensation, followed by removal of the elements of water, butadiene can be obtained. (A more usual source of butadiene is the by-product gases from oil refineries). The interpolymer of butadiene with polystyrene gives Buna S, a synthetic rubber. Again, acetaldehyde with hydrocyanic acid, which can be obtained from ammonia and menthanol, gives acetaldehyde cyanohydrin, and by removing the elements of water from the molecule, acrylic nitrile is obtained, and this, on interpolymerization with butadiene, gives Perbunan, another type of synthetic rubber.

These two rubbers were developed in Germany, and unfortunately have rendered the Germans almost independent of imports of natural rubber.

From acetaldehyde, acetic acid may be manufactured, and the acid, on reaction with acetylene, gives vinyl acetate which can be polymerized, and on further modification, gives a plastic commercially known as Alvar.

From acetone and hydrocyanic acid, through the cyanohydrin, methacrylic nitrile can be obtained, and on hydrolysis with water and esterification with methanol, methacrylic ester is produced. The ester polymerizes to give a colourless, highly transparent plastic, known as Lucite, Perspex and by various other trade names.

The addition of hydrochloric acid to the chart gives interesting products. From acetylene and the acid, vinyl chloride and chloroprene can be obtained. Chloroprene polymerizes to a synthetic rubber known as Neoprene. Vinyl chloride and vinyl acetate form an interpolymer which gives a plastic known as Vinylite, and from vinyl chloride, Koroseal may be obtained.

The list of products given above is by no means complete, but must be considered as illustrative only, and undoubtedly many new products will be added to these in the future.

The achievements of to-day are the result of painstaking effort on the part of numerous research workers and experimenters, who have, at all times, diligently sought out the truth of material things. All of them, including the earliest experimenters, and even the early philosophers, have had some part in building up that phase of endeavour which to-day is classed as chemical industry.

AERODROME CONSTRUCTION IN SASKATCHEWAN

G. T. CHILLCOTT, M.E.I.C.
District Airway Engineer, Department of Transport, Regina, Sask.

Paper presented before the Regina Branch of the Engineering Institute of Canada, December 20th, 1940.

Airports are generally defined as those serving a large centre, from which a number of branch lines may operate, whereas the term aerodrome is applied in a general way to fields used for more occasional or special service.

For the information of those not familiar with the different terms used in connection with airports and aerodromes, the following notes are given:

A Landing Strip—may be defined as an area forming part of an aerodrome, which area is of sufficient length and breadth, and which presents a surface of such a nature as to be suitable for the safe taking-off and landing of a specified type of aeroplane. (The minimum area which is considered satisfactory for the smallest aircraft is 1,800 ft. long, and 300 ft. wide. Dependent on the size and characteristics of the aircraft which are to be used, it may be necessary to increase the length to 5,000 ft., or even 6,000 ft., and it is desirable, in all circumstances, to have the strip at least 500 ft. wide).

A Runway—is defined as that portion of a landing strip, being not less than 100 ft. in width, which is artificially built up with crushed rock, asphalt, cement, or other material, to provide a satisfactory surface when, by reason of weather, the natural surface condition of the landing strip is unfit for safe operation.

A flightway—may be defined as an area extending along the course of a landing strip, its centre line coincident with that of the landing strip, being of a width 600 ft. greater than the width of the landing strip, and extending for an indefinite distance beyond the limits of the aerodrome in either direction.

A Taxi Strip—is defined as an area of suitable dimensions, and having a proper surface to permit the safe movement of aircraft on the ground from one part of the aerodrome to another. (As from landing strip to building area; building area to re-fuelling pumps, etc.).

In establishing the Trans-Canada Airways across the country, aerodromes were spaced between the airports roughly at intervals of about one hundred miles, so that they might be used in cases of emergency when conditions force a landing. The advantage of these intermediate fields is more distinctly felt by itinerant flyers, and particularly those aircraft that are not equipped with a radio.

In the case of airports which must serve large centres of population, the problem arises of locating a site, sufficiently close to the centre of the city, to be readily available to passenger and mail service, and at the same time far enough away to provide for a proper flight way to the runways.

In regard to the location of aerodromes for the British Commonwealth Air Training Plan, it was necessary to keep in mind that the flight-ways in the direction of prevailing winds should be clear of obstructions, that a supply of gravel should be available without a long haul, and that a supply of water could be obtained. The sites were chosen so as to avoid the construction of long power lines. It was desirable also that wherever possible, the aerodromes constructed to accommodate the personnel and trainees of the various flying schools should not be too far away from a fairly large centre of population. The sites also had to be chosen, having regard to drainage, and the amount of excavation required to level the field.

When this great plan was launched, the Department of Transport undertook to provide the necessary aerodromes, the buildings for which were to be constructed by the R.C.A.F. Saskatchewan's share in this scheme comprised nineteen fields—two of which are Bombing and Gunnery Schools, one situated near Mossbank and the other near Dafoe. Five Service Flying Training Schools have been developed near larger cities and towns. For each one of these schools three aerodromes were constructed—a main and two relief fields. This makes a total of fifteen fields for the five Service Flying Training Schools. Two schools were developed at Regina and two at Prince Albert for Elementary Flying Training classes and Air Observer's classes. This required extensions of the fields at these cities.

After the sites had been chosen a considerable number of survey parties were organized for the detailed survey of the fields. At this time, our engineering staff in Regina was very small. Help was kindly given by the Department of Highways, and the City of Saskatoon engineering staff. The City of Regina engineering staff promptly prepared the plans required for extension of the airport there.

Fifteen sites were surveyed. The contour plans showed the surface at two-foot intervals. The zoning plans indicated the precautions necessary on the area surrounding the site chosen to keep the flight-ways clear of obstructions. Soil charts were made up after test borings of each site had been completed. In the original programme for Saskatchewan there were to be two Service Flying Training Schools, two Bombing and Gunnery Schools, two Air Observers' Schools and four Elementary Flying Training Schools. A little more than half of these schools were to be established during 1940, but following the events of April and May in Europe, the programme was changed to develop nineteen aerodromes. At the present time (November, 1940), all but two of these can be used for training purposes. The construction of so many aerodromes in one season, has been a work of very considerable magnitude.

The grading operations necessitated the moving of 2,600,000 yards of earth. This, in terms of prairie highway construction, would be equivalent to grading approximately 260 miles at 10,000 cubic yards per mile.

Of the nineteen aerodromes which were surveyed, designed and constructed within a year's time, twelve were built with hard surfaced runways, and seven of the aerodromes were graded and seeded to be used as grass fields.

The hard surfacing of such large areas as are required in airport runways, presents a real problem. Great variations are encountered in soil characteristics in this province. Owing to the number of dust storms that have succeeded one another across the face of the prairies for centuries, the soil conditions in one spot may be vastly different from those of another, even fifty or one hundred feet away.

The soils in the south central and eastern parts of Saskatchewan and the southern part of Manitoba present this difficulty in an acute form. In places, these soils are capable of a change of volume up to sixty per cent. The amount depending on the moisture content. Such conditions make the use of concrete as a runway paving of very doubtful value. The use of plant-mix asphalt in material in the paving of runways did not offer a solution. Such runways were laid in Winnipeg and Regina in 1937, resting directly on a clay subsoil base. In 1938 they had failed to a point where it was necessary to replace them with runways of some new design. After consulting with the city and provincial highways authorities, it was decided to make use of stabilized gravel as a base course.

An east-west runway was built in Winnipeg in the fall of 1938 using a six-inch mat of well compacted stabilized gravel. After the subgrade was established, and the proper crown prepared, it was thoroughly rolled and compacted by the use of sheepsfoot rollers.

This runway stood up well and has not given any trouble except in places where insufficient compaction of the subgrade occurred. This runway also had the advantage of side drains which were built to take care of the surface water from the runway surface.

At the time it was constructed it was too late in the season to put down the plant-mix top of asphalt as originally proposed. The stabilized surface was merely primed and sealed. The type of stabilized gravel base used here was not that to which a small percentage of asphalt is added as is the case to-day. In some places this runway softened up owing to moisture finding its way into cracks in the surface. This was a small fault but one to be overcome.

The next year, after laboratory experiments it was found that the addition of from one to one and a half per cent of a light asphalt oil to the stabilized material rendered it almost impervious when properly compacted and set up. The next year this procedure was adopted in the construction of the N.W.-S.E. runway at Regina.

About this time it became obvious that great care should be given to the preparation of the subgrade. Methods of obtaining the maximum density of the soil were adopted. As a measure of precaution in bad soil conditions, the subgrade is now compacted to a depth of ten inches. This is carried out in two operations, each one handling five inches in a lift. The soil is just brought to its optimum moisture content in most cases by the addition of water and then rolled with sheepsfoot rollers until the required bearing strength is obtained. Having obtained its greatest density, the soil in some measure resists the absorption of further moisture and has no marked tendency to shrink.

In the construction programme of 1940, two types of base course have been used. One, known as the consolidated gravel base, was a mix-in-place crushed rock and gravel base with sufficient soil binder for compaction, and the other was, as before mentioned, a plant-mix stabilized gravel.

The consolidated base was found to be more economical since the control of the mix was not so exacting. It consisted of aggregate from 2 in. down with as large a proportion of crushed material as possible. It contained not more than 10 per cent of a cohesive soil. This type of base course differs from stabilized gravel mainly in that no effort is made to obtain density. Bearing values only are sought. It is not impervious to moisture and should have a fair amount of flexibility. The two types differ in design, but are meant to serve the same purpose.

All hard surfaced runways, except in the case of Regina, were given a two-inch cover of plant-mix asphalt. There is one exception to this. At Vanscoy a two-inch course of mix-in-place asphalt was laid.

The asphalt used for this two-inch layer is of two varieties. For Bombing and Gunnery Schools a harder quality of asphalt was used, known as 150-180 penetration. In all other cases the S.C. 2,000 or S.C. 5 heavy asphalt served the purpose.

All runway surfaces were protected by side drains except at Vanscoy and Dafoe. In most cases the side drains consisted of a perforated or open joint pipe laid in a deep trench and back-filled with gravel passing the 2-inch mesh and retained on the half-inch mesh. All drainage systems had an adequate number of catch basins available for cleaning the drains and as intakes for surface water.

At Dafoe, this method of drainage proved unsuitable owing to the nature of the soil. Here the subsoil was for the most part a fine sandy loam, 40 per cent of which passed a 200 mesh sieve. At this site it was found that the wash from the runway surfaces cut into the soil of the sides of the gravel-filled trench, rapidly choking the perforated drain pipes and finally the voids in the gravel back-fill. This soil was so light that it went immediately into suspension when contacted by flowing water. Catch basins on this aerodrome must then be relied upon for the intake of surface water and to provide drainage for the runways. Along one runway however, we experimented with a galvanized gutter trough filled with coarse gravel. This is provided with down pipes every 100 feet which feed into the main storm sewer buried along the side of the runway. So far this has proved successful.

Some statistics of the work accomplished during 1940 are as follows:

2,600,000	cubic yards of excavation
52.4	miles of storm sewers or drains
495	manholes
701,108	tons of gravel and clay in base courses.

206,139 tons of hot plant-mix asphalt, or enough material for 206 miles of bituminized gravel road in a two-inch layer twenty feet wide.

The amount of liquid asphalt used of all kinds was 3,040,000 gallons or from 380 to 400 tank cars.

Although only a little more than half the fields were seeded we did about 5,400 acres of seeding.

68 miles of fencing were erected of 4 strand barbed wire, using cedar posts spaced a rod apart.

Besides the work outlined above the supply of water to the fields had to be undertaken. At Moose Jaw, Swift Current, Saskatoon, Yorkton and North Battleford, water was piped from the cities. At Dafoe, Mossbank and Prince Albert wells were drilled to provide the supply. In all, seventeen miles of water main were laid.

Power had to be supplied to all but five aerodromes. To do this it was necessary to construct approximately 123 miles of power line. This does not include the secondary distribution lines within the building area at the sites. This work was all very capably carried out by the utility companies concerned. In order to insure proper service it was necessary to link together some of the distribution systems already established.

To clear obstructions both power and telephone lines had to be diverted in many localities.

Finally a proper telephone service had to be brought into the aerodromes which necessitated the establishment of their own switchboards. Lines of communication had to be constructed to connect the various aerodromes in each group and to provide connections to the bombing ranges.

Roads were built or are to be built or improved to connect up each group of fields and to provide access to the bombing ranges.

The field lighting necessitated the laying of miles of cable and installing of hundreds of lights of different kinds. The following figures give an idea of the amount of work of this kind:

1. Underground cable duct installed......	28,350 ft.
2. Boundary light cable installed.........	46,450 ft.
3. Contact light cable installed..........	55,000 ft.
4. Miscellaneous cable installed..........	10,000 ft.
5. Contact lights installed...............	412
6. Boundary lights installed.............	164

To build up an engineering staff capable of looking after so great a task it was necessary to increase the peace-time establishment by adding capable and experienced men. In this effective assistance was given by the Saskatchewan Department of Highways, the staff of the Prairie Farm Rehabilitation Act, the engineering departments of the cities of Saskatoon and Regina, the University of Saskatchewan and the Provincial Association of Professional Engineers.

The engineering staff then comprised one District Airway Engineer, two Assistant Engineers, and fifteen Resident Engineers.

In addition to these, instrumentmen, rodmen, chainmen and inspectors were secured through the Department of Highways, the Prairie Farms Rehabilitation Act staff and the University of Saskatchewan.

The engineers and contractors, together with the manufacturing firms, co-operated in meeting the emergency, and rapidly carried out one of the largest construction programmes ever projected in western Canada.

RESEARCH IN CANADA*

LIEUT.-GENERAL A. G. L. McNAUGHTON, C.B., C.M.G., D.S.O., M.E.I.C.
Officer Commanding, Canadian Army Corps, England, and President, National Research Council of Canada.

Paper read before the Royal Society of Arts, London, Eng., April 13th, 1941

(Abridged)

It is to your precept and example in 1916, in the organisation of the Honorary Advisory Council for Scientific and Industrial Research, and the suggestion then made by the Government of the United Kingdom to our Government, that Canada should set up a similar body, that we trace the genesis of our own National Research Council. In the year 1916, we were in the earlier phases of the first World War and it had taken the impact of that event to shake the British peoples, both here and in the Dominions, from their complacency as regards research. Previously we had left research mostly to the universities, where its results as "pure science" were made available impartially to all, for the benefit of friend and foe alike. On the other hand, in industry, where mutual help would have been of great advantage, whatever each company was able to develop in the way of new apparatus, materials and processes was regarded as a trade secret, to be jealously kept to themselves, and particularly to be denied to other firms in similar business in their own country, though not necessarily to foreign associated companies.

Contrast this situation with that existing in Germany, where research—pure, applied, and industrial—had very early been recognised as a matter of profound concern, and where its organisation and correlation had been taken under the auspices of the Government itself. Under this meticulous care, every idea and invention was seized upon and subjected to intensive development at the hands of comprehensive groups of trained scientists; eager business men stood ready to exploit whatever they produced. There are many who will remember how this, and neglect on the part of other nations, had reacted to the great advantage of German world trade and so to the creation of a vast potential for munitions production in war. You know also of the great difficulties which faced the Allies on the outbreak of hostilities by reason of the German monopolies. The German dye industry, for example, which had taken the invention of a British chemist and turned it into a great commercial undertaking, led directly to efficiency in the production of explosives and of poison gas. I have often wondered why this menace was suffered to develop without adequate counter measures being taken, and it seems, on looking back, that its very gradualness must have been the answer, men's minds becoming accustomed to it by degrees.

Once started, British research in its relation to the war effort of the country developed rapidly and effectively, and at the end of the first World War it could be said with truth that one of the essential contributions to victory had been made by British and Dominion industry, once scientific and industrial research was organised and brought into play. To illustrate what was accomplished in Great Britain I mention a few significant facts. In 1914 there was no optical glass industry in the United Kingdom. Germany and Austria had a practical monopoly in this field, and even the lenses of the sights of British guns were imported. Organisation of the scientists, followed by extensive basic and applied research, corrected this situation. To-day, the optical glass produced in Britain is of the finest quality in the world. I mentioned poison gas—chlorine—a product of the German chemical industry which was used against the French and the left flank of the First Canadian Division on April 22, 1915. The Germans used it against us thinking that the Allies would not be able to reply in kind (they were contemptuous of our scientific organisation), but by the summer of 1918, as a result of organised research, our chemical industries were producing mustard gas by a new process at a rate many times that which had been found possible by Germany.

The National Research Council and its Development up to 1939—As I have said, the organisation of research in Canada as a function of Government dates back to 1916, when we followed your example and set up an Honorary Advisory Council for Scientific and Industrial Research. It was not contemplated then that this Council would establish laboratories of its own; it was to act as an agency for consultation and co-ordination between those already carrying on research in the existing laboratories of the several departments of the Dominion and Provincial Governments, in the universities, and in industry. To give you some idea of the very limited facilities then available: a report prepared at the time indicates that the total annual expenditure on research in all Government laboratories, both Dominion and Provincial, amounted to considerably less than $100,000, and that of some 2,400 leading Canadian firms engaged in manufacturing which replied to the questionnaire sent out, only 37 possessed laboratories which even pretended to engage in research work.

Looking back at the history of the Honorary Advisory Council for Scientific and Industrial Research, in the war and early post-war periods, it is remarkable what was accomplished with the limited facilities at their disposal, but it is not to be wondered at that men who were informed on the subject should have realised the utter inadequacy of the provision which had been made and that they should have pressed for some improvement. As a result of the pressure of public opinion which developed, the matter was repeatedly considered in Parliament, and eventually the Research Council Act was passed in 1924, following in very close detail a draft which had been prepared by a non-party committee representative of both the Senate and the House of Commons. The Council's main laboratories, located at the junction of the Ottawa and Rideau Rivers, were commenced in 1930 and opened at the time of the Imperial Economic Conference in 1932.

As was perhaps to be expected in the era following the Armistice of 1918, it was very dificult to obtain adequate funds for scientific and industrial research. While the need for co-ordination of this work as a war-time measure had been evident, recognition of the equally vital needs of competitive industry in peace-time came only very slowly until 1935, when the Government, despite the depression then raging, saw fit not only to double the current appropriation, but to provide substantial sums on capital account to complete the equipment of the laboratories. These increased appropriations were maintained by succeeding governments and steadily increased until, by 1939, the Council's annual budget on current account was somewhat over $1,000,000. Meanwhile, an even more striking increase had taken place in the facilities in Canadian industry itself, and by 1938 it is estimated that these comprised upwards of 1,000 industrial laboratories for research testing and plant control, with some 2,500 professional workers employed full time. Similarly, in the Dominion Departments of Agriculture, of Public Works, and of Mines and Resources the last two decades have seen the creation of a number of research and testing laboratories related to their special functions and duties, all of which represent a very substantial asset. Elsewhere the most notable addition was the Ontario Research Foundation, which operates in the most friendly relation with the National Research Council.

In 1938, provision for a further large group of laborator-

* From *Engineering*, (London), July 25th, 1941.

ies, to provide the Council with additional facilities, particularly for aeronautical engineering, hydraulics, and high-voltage electrical engineering, was sanctioned by the Government. Construction was started in 1939, and is now advanced to the point that in some cases the buildings are in occupation. As a result of these measures, we had in Canada at the outbreak of the present war, in physical existence, the laboratories and trained staffs competent to act as a nucleus in undertaking the study of the problems presented in almost every field of war requirements, both within the sea, land and air forces themselves, and also in the industrial life of the country as it had to be re-oriented to produce the vast and complicated supplies needed in transition from peace to war basis.

I have been speaking of the actual research equipment of Canada, in the way of Government and industrial laboratories, as it stood at the outbreak of the war with a view to indicating the very favourable position in comparison with the situation on the previous occasion when we had to take up arms against Germany. But the adequacy of physical equipment and technical staff is only one side of the question, and what is probably equally important as an asset is the organisation of the Council itself as a going concern and the intimate relations which had been developed with every branch of science in Canada; with universities; with industry; with departments of the Dominion and Provincial Governments concerned with research problems; with the great professional societies in medicine, engineering, forestry, etc.; with the Canadian Engineering Standards Association in the field of industrial standardisation, and with many other organisations.

The National Research Council consists of fifteen members selected for terms of three years from among men prominent in scientific work in Canadian universities or in Canadian industry. The Council is required by statute to meet at least four times annually in Ottawa. There is a president, appointed by the Governor in Council for a term of years, who reports directly to the Privy Council Committee on Scientific and Industrial Research of which the Minister of Trade and Commerce is the chairman. The office of president is now filled by Dean C. J. Mackenzie, M.C., of the University of Saskatchewan, an eminent civil engineer who served with the Canadian Forces in the last war. The Council's membership is broadly representative of all parts of Canada, and includes persons qualified to speak with authority in education, science, industry, business and finance. Apart from administration which is organised much on the usual lines of a department of Government, the staff of the Research Council is grouped in a number of divisions, each of which is under a director.

The divisions of physics and electrical engineering, chemistry, mechanical engineering, including hydraulics and aeronautics, biology and agriculture, are responsible for the direction and conduct of the technical work in the fields indicated by their designations. There is a section on research plans and publications concerned with the collection, collation and issue of scientific information and with the general development of co-operative investigations through committees, etc. There is also a section on codes and specifications, matters which are in the highest degree important in relation to mass production in war. Provision is made for the closest co-operation and collaboration between all branches concerned in any particular problem. One of the great advantages possessed by an organisation such as the Council's own laboratories, with their comprehensive representation of all branches of science, is that experts in every line required can be brought together at short notice to study a problem and to work as a team for its solution. This facility is very important, for in most research problems related to industrial or agricultural production or processing we are usually confronted with limiting factors of many kinds, and it is not easy to determine in advance in which branch of science the answer should be sought.

Associate Committees and Co-operative Research—Under the wide responsibilities placed upon the Council by Parliament, there is a duty to bring about the best possible use of all the country's facilities for research, of which the Council's own laboratories now represent only a small part. In order to bring to bear the knowledge of scientific men in other institutions and in industry and to correlate the work of research in all organisations concerned, a number of so-called "associate committees" have been set up. The function of these committees is to direct co-operative research on the problems assigned to them; to settle the objectives; to indicate the individuals or organisations which should undertake the several component parts of the inquiry; to receive and co-ordinate the resulting information, and to make it available to those who will turn it to advantage. The Council endeavours to ensure that these committees are comprehensively representative of all interests, and we expect them, each in their proper sphere, to form a national plan into which all who are in a position to contribute information can fit their own particular lines of research. The actual investigations are carried out, not only in the Council's laboratories, but in the laboratories of the various universities, Government departments and industrial institutions throughout the country. I cannot too strongly stress the fact that much of the initiative in these committees lies with the outstanding experts from other organisations who have associated themselves with the National Research Council in this work.

Time does not permit me to recite to you the long list of these associate committees or to go into, in any detail, the important tasks which they are carrying out for Canada. But, in order to give some picture of the wide range of work involved, I should like, by way of illustration, to mention one or two in several diverse fields. In agriculture I would mention the committees in charge of grain research and of transport and storage of food—these, both by reason of the great importance of the subjects and also on account of the very substantial results which have been achieved in comparison with the trifling expenditures of money which have been made. In forestry, I would mention the committee, organised in co-operation with the forest service of the Department of Mines and Resources.

This Committee has concerned itself with such matters as the study and mitigation of forest hazards, through fire, insects and other pests, and the preparation of a manual giving advice as to the management of the "farmers' woodlot," a most important source of raw material. This manual is now in general use in the Maritime Province and Quebec. I could continue with examples of the work of many other associate committees in the fields of medicine, chemistry, physics and engineering; of the detailed and exacting work carried out by our joint committees with the Department of Finance in the preparation of a National Building Code for Canada, which is now, despite the war, in process of publication, and which should bring order into a situation which, under the conflicting jurisdiction of municipality, province and dominion had become most seriously confused to the disadvantage of the public. I could cite also the work on industrial codes and specifications carried out by the Canadian Engineering Standards Association, which is a body intimately related to the National Research Council, and serves Canada as the counterpart of the British Standards Institution in this country.

Encouragement of Research in Universities, etc.—In order to make use of the facilities for research which exist in a number of our Canadian universities and to encourage their further development, the Council, in the early years of its existence, instituted a system of assisted researches through which the professors in charge could be given financial assistance for the provision of needed apparatus, laboratory help and similar out-of-pocket expenses, other than their own salaries. Applications for such assistance are most sympathetically considered and by its aid much useful work has been accomplished, of value both for the new knowledge secured and, perhaps even more important, for the training given to the workers. Another aspect of the Council's concern with the training of research workers is represented by the scholarships which each year are awarded to some 70 or more post-graduate students. These are tenable at Canadian universities or, in special cases, abroad. Though these scholarships, which are being given year by year in increasing numbers, in addition to providing the needed supply of highly trained research workers, a deliberate attempt has been made to assist the building up of the post-graduate schools in the Canadian universities.

From what I have said about associate committees, assisted research and scholarships, I hope I have made it clear that while the Council has itself a number of very well-equipped laboratories in all lines, yet there has been no attempt to monopolise research; in fact, the very opposite, for it has long been realised that for the safety of the nation against peace-time industrial competition, let alone to meet the needs in war, you can never have too much research.

Research Information and International Affiliations—In peace, in order to maintain our contact with research work going on all over the world, the Council maintains membership in the principal International Scientific Conferences and meetings, arranges for Canadian representation where required, and collects in its library in Ottawa, for reference, copies of all papers, proceedings and other information of importance. This is made available as desired to Canadian workers. For many years also the Council has maintained the closest possible contacts with the Department of Scientific and Industrial Research and the British Standards Institution here. These contacts were strengthened and developed by the Imperial Conference of 1930 and the Imperial Scientific Conference of 1936, and again in August, 1939, on the occasion of the visit to England of a representative group of Canadian manufacturers, who had come to England to familiarise themselves with the needs of war-time industry, so that Canadian production could be directed to those articles which would be most required and most useful.

War-Time Developments—I have endeavoured to give you a brief picture of the origin and growth of the National Research Council up to the outbreak of the war in which we are now engaged. Relatively satisfactory as the situation had become when compared with 1914, I have not claimed that we had in Canada anything which was in any sense an adequate answer to the problems of competitive industry in peace, and certainly, as regards war, we scarcely dare, in the years of the ascendency of the Geneva school of thought, to admit that some of the research work in hand might even have an indirect value for defence. Apart from meeting the problems of the day as they presented themselves, what had been aimed at was the creation of a nucleus round which the research resources of the nation could be crystallized in order so soon as the real needs were recognised by public opinion and Parliamentary support was forthcoming. That such a nucleus was in fact created will, I think, be evident from what now I have to tell you with reference to the war-time developments of research in Canada. In this I am under the difficulty that no specific information which would be of value to the enemy can be disclosed, so I have to content myself with a few illustrative statements which must be rather general in character.

First, as regards finance. The funds placed at the disposal of the Council for the current year by votes from Parliament and grants-in-aid from the Naval, Land and Air Forces in the Department of National Defence are some five-fold greater than for the last pre-war year. In addition, the Council and its technical staff will be responsible for the scientific and technical organisation and advice in connection with other projects not directly administered, which will involve about twice to three times as much again. Further, in order to provide some measure of elasticity in the finances of the Council a number of Canadian corporations, large and small, and private individuals have joined together to establish a trust fund of well over a million dollars, with more available if required. The committee in charge has been enjoined by the donors to make it their business to ensure that no worthwhile project of research, related to the war effort of Canada, which is sponsored by the National Research Council, should be delayed or hampered by the lack of money. In this public-spirited group the mining industries of Canada have, as usual, been conspicuous for their generous support of research. Another example of the assistance received from this source is the support given to the Canadian Corps in the organisation and equipment of our Tunnelling Companies. One of these, as is well known, is now at Gibraltar making effective use of the modern machinery presented by the Canadian mining industry. The other Company is using similar equipment in this country.

What is, in effect, a further additional expansion of the Council's activities is represented by Research Enterprises, Limited, a wholly owned Government corporation which has been set up by the Canadian Ministry of Supply primarily to produce for the armed Forces, and for industry, inventions and apparatus which had been developed in the Council's laboratories. Already, optical instruments, including gun sights and range finders, radio gear and similar articles, are in production in the large new factory which has been erected, and very shortly the company will be turning out its own supplies of optical glass in quantity. Thus a small nucleus established in the optical and radio laboratories in the years before the war has been given substance and developed into a key industry of essential importance for our war effort. The Council's metrology laboratories are another example of a small but effective nucleus which has been expanded to large dimensions to care for the standardisation of the vast number of gauges necessary in the munitions industry.

In the field of radiology, special attention has been paid in the Council's laboratories for many years to the examination of castings, particularly those in light alloys required to carry stress in aircraft construction. Working with the producers, the technique of making sound castings had been developed before the war to a high degree of perfection, and the knowledge of this art is now proving of great value to the Canadian aircraft industry. X-ray photographs can be taken at up to 600 kV, which is sufficient to penetrate several inches of steel. For greater thicknesses a plentiful supply of radium is available by reason of the fact that the bulk of the world's new supply derived from the mines at Great Bear Lake and refined by the Eldorado Company at their Port Hope plant comes to the Council for test and certification. Turning to another of many fields, I should like to mention the very important programme which has been initiated by the Committee on Aviation Medicine under the chairmanship of the late Sir Frederick Banting.

In conclusion, I wish to assure you that all this great range of work of which I have been speaking is going forward in Canada in the closest sympathy and understanding, both with the authorities here and also with our mutual friends and colleagues in the United States. In order to help in the maintenance of effective contact the British Government has established a Scientific Liaison Office with the Council in Ottawa, and we have been privileged to receive first, Professor Fowler, and more recently, Sir Lawrence Bragg. At the present time a number of the senior members of the Council are in England to familiarise themselves with the latest methods and requirements so that our work may be kept related to problems of immediate practical importance. There is a constant flow and interchange of workers and the various problems are taken up as available facilities best indicate. Needless to say, there is no delay or reservation in making the results available for application and use.

EQUIPMENT AND ARMAMENT OF THE ROYAL AIR FORCE

LIEUT.-COL. W. LOCKWOOD MARSH
Editor of "Aircraft Engineering," London, Eng.

SUMMARY—The two articles which follow have been released by the censors, and give some data regarding new types of aeroplane now in production at the works of the British aircraft industry, and information as to the armament of some of them.

Planes of the R.A.F. and Fleet Air Arm

Since they came into prominence in the spring of 1940, both the Hurricane and Spitfire have been improved to give even higher performance. A more powerful Rolls-Royce Merlin engine is installed which develops some 1,250 horse-power. The later Hurricane is fitted with "stressed-skin" metal-covered wings, while the Spitfire, in the Mark III version, has had 22 inches taken off each end of the wings—the resulting square tips rather marring the appearance of the original elliptical shape—to give it an increase in speed to a figure which is only a few miles below 400 m.p.h.

Both have been used most successfully on moonlight nights in defence against the enemy bombers and the Spitfire III, at any rate, is frequently fitted with a shell-firing "cannon" gun. But both the Hurricane and the Spitfire are due for replacement by the new Hawker Tornado and Typhoon.

The Tornado has the new Rolls-Royce Vulture engine of interesting design, with 24 cylinders arranged in the form of an X, developing something over 2,000 horse-power. The Typhoon is equipped with the Napier Sabre engine which produces 2,400 horse-power. This engine is a development of the early Rapier and later Dagger engines—the latter fitted in the Hereford version of the Handley Page bomber, known as the Hampden when fitted with Bristol radial engines. All these Napier engines are designed by Major F. B. Halford and are unusual in that the cylinders are arranged in the shape of the letter H with the crankshaft and camshafts forming, as it were, the cross-bar in the middle.

The Sabre differs from the Rapier and Dagger, apart from the size, in being liquid-cooled instead of air-cooled. All Rolls-Royce engines are, of course, and have been for a good number of years now, also liquid-cooled. The Typhoon is officially stated to have a maximum speed "well over 400 m.p.h."—an American paper says 410 m.p.h.—and the Tornado's speed has been stated by an American paper (quoted by Lord Beaverbrook) to be 425 m.p.h.; but in fact, the former is probably slightly the faster.

NEW NIGHT FIGHTERS' RECORD

Two aeroplanes in the twin-engined fighter class have been produced—the Westland Whirlwind and the Bristol Beaufighter. The former is a single seater, low-winged monoplane, with two Rolls-Royce Merlin engines, of which no more details can be given. The Beaufighter is known to have been developed, as the name implies, from the Bristol Beaufort general-purpose type, with, of course, a smaller fuselage, as only a crew of two have to be accommodated.

Equipped as a long-range day and night fighter, the Beaufighter is an all-metal midwing monoplane, powered by two Bristol-Hercules engines developing 1,400 h.p. for the take-off.

This interesting aircraft mounts ten guns, has a range of 1,500 miles and flies at a nominal speed of 330 m.p.h. Great destructive power is provided by the four 20 mm. cannon guns in the fuselage and six Browning machine guns in the wings, while extensive fuel tanks make the plane suitable for long-range raids, escorting bombers on their expeditions and carrying out lightning attacks on enemy planes raiding Britain. Special hatches under the fuselage allow the crew to make a safe and speedy exit when necessary, and other devices which are still secret remain far in advance of anything the Germans have been able to develop. It has lately been revealed that Beaufighters made a highly successful attack upon aerodromes in Sicily on June 28 last, when between thirty and forty enemy aircraft were destroyed on the ground and many others damaged.

No performance figures are yet available for the Whirlwind but, like the Beaufighter, it is intended to provide effective fighter protection for long-range bombers, at a greater distance from its base than is possible with the single-engined type with its limited range, and also for seeking out and destroying enemy bombers, such as the Focke-Wolf Fw 200 Kurier which carries out marauding attacks on convoys in the Atlantic.

Pending the appearance of these two machines, the bulk of their work has been carried out by the Bristol Blenheim Mark IV bomber, modified to act as a twin-engined fighter. The Beaufighter has also been used with success for night protection against enemy raiders; as has, of course, the Merlin-engined Boulton Paul Defiant with four-gun power-operated turret.

An idea of the success that has been achieved by the new night fighting methods is shown by the fact that, in the month of April, 50 enemy machines were brought down by night fighters out of a total of 88 destroyed, This figure of 88, incidentally, compares with the previous "record" of 46.

NEW FOUR-ENGINED BOMBERS

A series of new four-engined bombers are coming into service, of which one—a Stirling—made a remarkable daylight raid on Emden on one of the last days of April, audaciously coming down to 1,500 feet from the ground to drive the attack home by machine-gun fire. This machine is the latest product of Short Brothers of Rochester who have hitherto concentrated on a long line of successful seaplanes such as the Empire flying boats and Sunderland reconnaissance boat, used by the Coastal Command of the Royal Air Force. It has been stated to have a wing span of 99 feet, range of 3,000 miles and maximum speed in excess of 330 m.p.h.

The "Hurricane" *Photo "The Aeroplane"*

Handley-Page have brought out the Halifax as a successor to the Hampden, of which it may be considered the four-engined development.

A new heavy twin-engined bomber is the Avro Manchester, powered by two Vulture engines—a high performance machine of somewhat unusual appearance. According to Lord Beaverbrook (quoting American papers) it has a wing-span of 90 feet and a speed of 325 m.p.h.

The Training Command has been strengthened by the acquisition of the Blackburn Botha, with two 930 horse-power Perseus sleeve-valve engines, originally designed as a torpedo-bomber.

The Fleet Air Arm of the Royal Navy has now been almost completely re-equipped with Perseus-engined Blackburn Skua dive-bombers and Roc two-seater fighters and the Fairey Merlin-engined Fulmar two-seater fighter and Albacore torpedo-carrying general reconnaissance bomber with a Bristol Taurus-engine.

Development in Aeroplane Armament

In any weapon of warfare—aeroplane, battleship, tank or machine gun, apart from such considerations as mobility (speed) and manoeuvrability, the final, dominating factor, when action is joined, is fire power.

It is interesting, therefore, to see how this has been developed by the two sides in the present struggle after two years' experience of combat. In September, 1939, there is no doubt whatever that this dominant importance of fire power had been better appreciated by the British than the Germans; the credit for which has been variously attributed to Air Marshal Sir Hugh Dowding, Air Officer Commanding the Fighter Command, to Mr. Mitchell, the designer of the Spitfire, and to others. Be that as it may, the two British fighters, the Supermarine Spitfire and the Hawker Hurricane, were overwhelmingly superior in offensive armament to those of any other nation. Each was fitted with eight .303 Browning machine guns—four in each wing—all firing outside the disk of the revolving airscrew, to avoid the necessity for interrupter or synchronizing gear, with a combined striking force of 9,600 rounds a minute (1,200 rounds per gun). By comparison, the German Messerchmidt Me 109E, though fitted for a 20 mm. shell cannon firing through the airscrew hub, was actually rarely equipped with this but relied on two 7.9 mm. Rheinmetal-Borsig machine guns mounted on each side of the engine, firing through the airscrew disk and interrupted each time one of the three blades passes across the muzzles, with two Oerlikon 20 mm. cannon in the wings. The rate of fire of the two cannon (200 rounds a minute) was, of course, nothing like so rapid as that of the machine guns and this, combined with the interruption of the steady flow of bullets from the centrally placed machine guns, meant that the volume of fire which could be brought to bear at close quarters in a short space of time was incomparably less than that of the eight Brownings of the British machines, being only about 2,000 rounds a minute—allowing for the effect of the interruption on the rate of fire of the machine guns. The Heinkel He 113, which was in any case not a success and was never used in great numbers, was similar to that of the Me 109E except that instead of the two wing cannon it had one, firing through the airscrew boss. The American fighters, such as the Curtiss Mohawk, were originally very lightly armed with only two machine guns, but for the Allies have been modified to take two .50 in the fuselage and four .303 in the wings; those mounted in the fuselage being, like the German, interrupted for firing through the airscrew disk.

Taking two representative types of the fighters we have mentioned—the Spitfire and the Me 109—it is interesting to see how their armament has been changed as the result of two years' experience. The Spitfire V has two cannon and four machine guns—all in the wings outside the airscrew disk. The Me 109 F.I. has one Mauser 20 mm. cannon firing through the airscrew boss and still the two "interrupted" machine guns on the fuselage. The rate of fire of the Spitfire has, therefore, been reduced to 5,000 rounds a minute, and the weight of projectile fired per minute reduced from 270 lbs. to about 240 lbs. a minute. The range at which firing can be started has, however, been considerably increased by the introduction of cannon.

Owing to the fact that the new Mauser cannon fitted in the Me 109F has the phenomenal, for a weapon of this calibre, rate of fire of 900 rounds a minute, the total rate of fire of this machine has theoretically been increased from 2,000 to 3,000 rounds a minute and the weight put up from about 180 lb. to some 800 lb. a minute. This figure is not, however, in practice so formidable as it sounds as, owing to the weight of the cannon, the aeroplane only carries 200 rounds for it—which are exhausted in about 13 seconds. After less than a quarter of a minute's engagement, therefore, its rate of fire is reduced to 2,100 rounds a minute and its weight of fire to about 50 lb. a minute—and even this is purely theoretical as it only carries 500 rounds for each machine gun, which are exhausted in about 30 seconds. This figure is, therefore, the extreme limit of time over which it can actually continue firing.

This compares with the 3,000 rounds for each gun carried by the Spitfire; giving a firing period of 2½ minutes.

The armament of the latest type of American fighter to be supplied to Great Britain—the Bell Airacobra—shows a formidable increase over earlier U.S. types. This unusually designed monoplane, the Allison engine of which is behind the pilot driving the airscrew by a long shaft between his legs, carries a 37 millimetre cannon, two .50 calibre and four .30 calibre machine guns. The cannon, which weighs about 110 lb., has a nominal rate of fire of 120 rounds a minute, and 30 shells are carried for it so that it can continue in action for 15 seconds. The .50 calibre machine guns have a rate of fire of 750 rounds a minute and 280 rounds are carried for each gun; giving a firing period of 22 seconds. The effective range of these two guns is 750 feet. The four .30 calibre machine guns have a nominal rate of fire of 1,200 rounds per minute (the same as those of the Spitfire) and 1,000 rounds is carried for each of them; giving a firing period of 50 seconds, which is the maximum period the aeroplane can maintain action. It will be seen, therefore, that the British fighters can continue

an engagement without having to break off for lack of ammunition longer than any of their contemporaries.

Reverting to the Me 109 F.I., it at first sight seems strange that having produced a new weapon offering greatly increased fire power the Germans have apparently failed to take advantage of it by thus limiting its period of effectiveness. This is, however, due to the necessity they felt of at the same time improving the performance of the Me 109 by enabling it to operate at greater heights and increase its rate of climb to those heights—requirements which were not compatible with any serious alteration in the weight of the armament, with its ammunition, carried by the aeroplane.

In the same way, the new Spitfire armament has involved

The Boulton Paul "Defiant."

some sacrifice in rate, and even weight, of fire in order to start hitting at a greater range with projectiles of increased striking force. The cannon and machine guns now installed may be likened to the "primary" and "secondary" armament of the 14-in. and 6-in. guns in a battleship; the former being used to open the engagement at long range and the latter reserved after closing in for "the kill."

Similar armament to that of the Spitfire V is believed to be fitted in the twin-engined single-seater Whirlwind long-range escort fighter, first mentioned in connection with a British raid on North West Germany early in August, when Whirlwinds accompanied a force of Blenheim bombers as far as the Dutch coast on the outward journey and met them again in the same area on their return, to escort them home.

Turning to other British types, the two-seater Boulton Paul Defiant made a dramatic appearance over Dunkerque in June, 1940, and swept the Junkers Ju 87 dive bombers out of the sky owing to its heavily armed power-operated electrically-driven North (Boulton Paul) turret fitted with no less than four Browning machine guns. This armament enabled it to come up on the beam of the Junkers and fire a broadside into their unprotected flanks, with a devastatingly surprise effect. At that time the Defiant was not equipped with fixed guns for the pilot to operate, which meant that it was itself vulnerable to attack from the front. This defect was remedied and it is now fitted with forward-firing machine guns, which makes it a most formidable machine—as it has proved in night-defensive operations. The latest British two-seater fighter, the twin-engined Bristol Beaufighters, has a heavy armament consisting of four cannon in the central fuselage, firing clear of the disks of the two wing-airscrews, and six Browning machine guns four in the starboard wing and two in the port wing. This gives it a total rate of fire of 7,400 rounds—or about 420 lb.—a minute. These guns are all operated by the pilot, the second member of the crew being observer-navigator cannon-loader, but it is hinted that a power-operated four-gun turret may be fitted in the observer's cockpit.

Two-seaters of the Beaufighter, and, to some extent, the Defiant type (although this, being a single-engined machine really intended for night-fighting is not quite in the same class) are designed for fixing guns firing forward and turrets firing on the beam and aft, so as to equip them to fight anything they may encounter when on the escort duty for which they are designed. Reasonably fast, with a maximum speed of about 330 m.p.h., and manoeuvrable they can meet enemy single-seater fighters with a greater firing power in front, while also having four trainable machine guns in the turret for defence, or offense, against enemy fighters or bombers.

It is undoubtedly the electrically-operated (Boulton Paul) and hydraulically-operated (Fraser Nash) turret which has given the British bombers—and more particularly, perhaps, the day bombers of the Blenheim and Wellington class—their superiority in effectiveness over those of other nations. Prior to its invention, and far-sighted adoption, all kinds of devices such as retractable fixed turrets, revolving windshields and counter-weighted and balanced gun rings had been evolved to overcome the effect of the air stream and make it possible for the gunner to train his gun and fire it in all directions. The bombers being supplied by the U.S.A. were at first, where possible, fitted with turrets on arrival in England but are now modified to be so equipped in the American factories. This will enormously increase the defensive powers of these, and future, types and make them much more valuable weapons. No other country, except Italy, seems to have made any serious attempt to develop this device, which gave England a great initial advantage. The Italians, however, have not, up to the present, been successful in producing a satisfactory turret and the Americans had previously been content for lateral defences to mount machine guns on ordinary mountings firing through windows or "blisters" in the side of the fuselage—a method which has been adopted as a temporary expedient in at least one type of British bomber. Another special machine-gun mounting which is at present in use in Blenheims and Beauforts is designed to meet the bugbear of all bombers—attack from the rear and below. This carries a rearwardly-pointing gun below the nose of the fuselage trained by indirect sighting through a mirror in the gunner's compartment. This is a modification of the ventral retractable turret (not power-operated) at one time fitted in the Whitely and Wellington, and still found in some German bombers. This indicates that the problem of defence against attack from this particular quarter has

The "Spitfire" Photo "The Aeroplane"

not yet been satisfactorily solved and it will be interesting to see what method is eventually adopted.

Generally, the tendency undoubtedly is to increase the armament, both offensive and defensive, in bombers as well as fighters, which is going to set a nice problem for the aeroplane designer, who already sees the gross weight of his fighter, for instance, approaching five tons. Meanwhile, the daily sweeps carried out by the R.A.F. over northern France with occasional raids far into Germany—all made in broad daylight—are sufficient proof of the adequacy, for immediate purposes, of the armament, offensive and defensive, of British fighters and bombers; particularly when the appalling losses suffered by the Luftwaffe when attempting similar operations over England in "The Battle of Britain" in September, 1940, are recalled.

CO-ORDINATION OF LIBERAL ARTS AND ENGINEERING EDUCATION*

WILLIAM P. TOLLEY
President, Allegheny College, Meadville, Penn.

An address delivered at the Sixth Annual Meeting of the Allegheny Section of the Society for the Promotion of Engineering Education, Pittsburgh, Penn., on October 26th, 1940.

If America can be said to have any one philosophy, certainly it is that of pragmatism. We are an active, energetic people. We prefer the man of action to the man of thought. We are a practical, tough-minded people. We put all ideas to the empirical test. We believe wholeheartedly in education, but we think education should be of practical value. We find it difficult to appreciate a higher learning that liberates the mind but leaves it without specific preparation for the earning of a living.

It is not surprising that technical training has outdistanced liberal culture. It is not to be wondered at that our brightest boys are seeking admission to schools of engineering rather than to colleges of liberal arts. Culture in America has been primarily a culture of the physical sciences. What would most impress a visitor from some other planet would be our great cities, our gigantic industries, and our magnificent public works.

There is no evidence that the temper of our people is changing. We shall undoubtedly continue to be hardheaded and practical. There is evidence, however, that the practical demands of our national life will bring about advance in areas that have been neglected. It is clear, for example, that the progress of the physical sciences creates a pressure that should soon result in equal progress for the biological and social sciences.

In his stimulating book "Man, the Unknown," Dr. Alexis Carrel makes the observation that "There is a strange disparity between the sciences of inert matter and those of life. Astronomy, mechanics, and physics are based on concepts which can be expressed, tersely and elegantly, in mathematical language. They have built up a universe as harmonious as the monuments of ancient Greece.... Such is not the position of biological sciences. Those who investigate the phenomena of life are as if lost in an inextricable jungle, in the midst of a magic forest, whose countless trees unceasingly change their place and their shape."[1]

In this field "our ignorance is profound. Most of the questions put to themselves by those who study human beings remain without answer. Immense regions of our inner world are still unknown....It is quite evident that the accomplishments of all the sciences having man as an object remain insufficient, and that our knowledge of ourselves is still most rudimentary."[2]

The change from the peace and solitude of the early village to the noisy confusion of the modern city, from a life of exposure and hardship to one of complete protection from the elements, from a diet of coarse flour and meat to one of fruit, dairy products, vegetables and sugar, from a day of walking to one of airplanes and automobiles, from a day of plagues and famines to one of sanitation and an abundant food supply, have all had a profound influence on social organization and the human system.

Dr. Carrel reminds us that cities that consist of "monstrous edifices and of dark, narrow streets full of gasoline fumes, coal dust, and toxic gases, torn by the noise of the taxicabs, trucks, and trolleys, and thronged ceaselessly by great crowds"[3] obviously have not been planned for the good of their inhabitants.

"Man," he says, "should be the measure of all. On the contrary, he is a stranger in the world that he has created. He has been incapable of organizing this world for himself, because he did not possess a practical knowledge of his own nature. Thus, the enormous advance gained by the sciences of inanimate matter over those of living things is one of the greatest catastrophes ever suffered by humanity. The environment born of our intelligence and our inventions is adjusted neither to our stature nor to our shape."[4]

And so he concludes that "since the natural conditions of existence have been destroyed by modern civilization, the science of man has become the most necessary of all sciences."[5]

What Dr. Carrel has said about the backwardness of the biological sciences he might have also said about the cultural lag of the social sciences. America was scarcely conscious that it had any social problems until Jacob Riis published his little book in 1890 on "How the Other Half Lives." Our cities had given practically no thought to the problems of poverty or housing, sweat-shops and child labor, the prevention of delinquency and crime, or of disease and sanitation. When Jane Addams organized Hull House in Chicago in the fall of 1889 there were no social workers. There was no department of sociology in any American university at that time. The first department of sociology established anywhere was created, with many misgivings, at the University of Chicago in 1892, less than fifty years ago.

If the public is still ill-informed on social questions, if we still have slums and child labor, out-moded penal systems and police third-degrees, sweat-shops and labor spies, entrenched privilege and hopeless poverty; if we still have soil erosion, dust storms, drought and floods, it is because the field of social relations has not been under the scrutiny of our best minds. Out attention has been elsewhere. We have been preoccupied with the practical problems growing out of our study of the physical sciences.

It should be noted, however, that it is not necessary to slow down the march of the physical sciences because other fields have not kept the same pace. Dr. Carrel should not feel too pessimistic. In the long run, progress in any one area promotes progress in every related field. When the automobile was first introduced, its market was restricted by inadequate roads. Before the automobile industry could thrive it was necessary to develop the oil industry, improve the quality of highway and bridge design, and speed up technical progress in a score of allied fields. Is it not possible that in somewhat the same way the pressure of mechanized civilization will force us into more and more research and exploration in both the biological and the social sciences? Because it is a practical problem, our people will insist that we begin an intensive study of the question of social direction and control.

This pressure is already felt by the engineering schools. Our engineering faculties have been made aware that it profits us nothing to train our young men in physical science if their sole purpose in life is to operate a bombing plane and destroy enemy cities. Somewhere in the programme of education attention must be given to a study of values as well as facts, to the problem of social control as well as technical advance.

The so-called three-two plan for engineering education

*Reproduced by special arrangement with the Society for the Promotion of Engineering Education.

[1] *Man, the Unknown*, by Alexis Carrel. Harper and Brothers, New York, 1935. p. 1.
[2] Ibid. pp. 2-3.
[3] Ibid. p. 25.
[4] Ibid. pp. 27-28.
[5] Ibid. p. 29.

has been proposed as partial answer to this problem. Under this plan a student spends three years in a college of liberal arts and two years in an engineering college. At the conclusion of the fifth year he receives the degree of Bachelor of Arts from the college of liberal arts and the Bachelor of Science in Engineering from the school of engineering.

The plan is not a Utopian solution. It has a number of disadvantages. From the point of view of the student, it is a disadvantage to be kept in college an extra year. If he is handicapped financially or is in a hurry to complete his engineering course, he may think of the additional year as time largely lost. There is also the disadvantage of a break in the continuity of his education. Just as he is beginning his advanced work at the arts college and enjoying his first experience of freedom and self-direction he is pulled up by the roots and transplanted in a new environment. It is possible, moreover, that his preparation in such subjects as Mathematics and Mechanical Drawing is less thorough in an arts college than it would be in a college of engineering. He may be handicapped in engineering subjects as he competes with students who have spent all their time in the engineering school.

There is a danger, moreover, that the engineering college may lay out a prescribed course for the pre-engineering students in the arts college which gives him little opportunity to study non-engineering subjects. Such a policy would, of course, destroy the chief reason for the five-year plan.

Even the arts college does not regard the plan as ideal. The faculty of the arts college does not like students to miss the vitally important senior year. They complain that the programme vocationalizes the arts curriculum and reduces a four-year college to the level of a junior college.

On the whole, however, the advantages greatly outweigh the disadvantages. The student's reward for the extra year is a second degree. By attending two institutions he becomes familiar with two points of view in higher education. These points of view are quite different and they are equally valuable.

If he takes his work in a small college of liberal arts it is probable that he enjoys more personal attention and has a closer relationship to full professors than would be the case in some large urban engineering schools. In the main, the laboratories designed and equipped for undergraduate work are quite as well adapted for the requirements of pre-engineering work as those of the engineering school. If, for any reason, his exploratory study of engineering shows that his talents do not lie in that field he can modify his course without loss of time.

It is an advantage to the liberal arts college to have more boys who have a serious intellectual purpose. The pre-engineering students are willing to work hard. They have a good influence on other students. If they follow syllabi or programmes outlined by the engineering school, departmental standards are likely to be raised. Some students who expect to attend only three years may become so interested in their work that they complete the four-year course before beginning their engineering studies.

It should also be an advantage to the engineering school. It makes it unnecessary to duplicate a complete arts programme and it is a step in the direction of making engineering a graduate course of study. Even if the methods of the engineering school are not followed in all of the pre-engineering work it is still true that students are a year older, have had a wider educational background, and are more mature.

In the beginning the advantage of the new plan may not be self-evident. If, however, it has sufficient trial it may mark the beginning of a new era in engineering education, when the mind disciplined in science will also be disciplined in arts. It will be a happy day when the engineer is broadly educated as well as technically trained.

DISCUSSION

WILLIAM R. WORK*

Dr. Tolley has presented strong arguments for inclusion of a social-humanistic programme in the education of engineers. He has described a plan by means of which there can be co-operation between liberal arts colleges and engineering colleges to secure this result.

The Carnegie Institute of Technology has this plan now in operation. Arrangements have been made not only with Allegheny College, but five others, Washington & Jefferson, Denison, Albion, Geneva, and Westminster.

The novelty in the plan is not in the transference of students from a liberal arts college to an engineering institution. That has always taken place. We have had many students, who after one, two, three, or four years at a liberal arts college, had then entered on a programme in our engineering college.

The novelty consists rather in devising a planned programme to conserve the student's time through a conscious effort to arrange courses of study in the earlier collegiate years so that a smooth transfer can be made to the engineering college.

A student who follows the three year pre-engineering programme in the liberal arts college may then enter on the engineering school as a regular Junior. All prerequisites for the technical courses will have been met and there will be no necessity for schedule irregularities of any kind.

The late Mr. Alan Bright, Registrar here at Carnegie for many years, studying certain statistics in his office, became impressed with the fact that a large number of students had had some liberal arts training. Further, he found that as a group these men had done very well; they had scholastic records distinctly above the average. In fact, in the particular year when Mr. Bright made these studies, it happened that the Electrical Engineering Senior Class had two men in it who had come to us as transfer students. At graduation they ranked respectively as No. 1 and No. 3.

About that time President Tolley had the idea that maybe some arrangement could be made whereby pre-engineering work in liberal arts colleges could be co-ordinated with a curriculum in engineering; this was the genesis of the 3-2 plan which was worked out first with Allegheny College and later with the five other colleges mentioned earlier.

Under the 3-2 plan, as we see it, neither the liberal arts college nor the engineering school gives up any rights or loses independence in any degree. We are not insisting that any liberal arts college must agree to work only with Carnegie. Any college may make similar arrangements with any other technical school. In fact, several of them have done so.

Since the 3-2 plan is so young, we have admitted but few students under it and none have graduated. Nevertheless we sincerely believe it will prove to be a forward step in education.

Possibly at some future session, when we have accumulated data based on several years experience with the plan, we will be able to discuss the actual results achieved.

*Professor and Head of the Department of Electrical Engineering, Carnegie Institute of Technology.

PIG IRON CONSERVATION IN GRAY IRON FOUNDRIES

Report of an investigation made in the Ore Dressing and Metallurgical Laboratories of the Department of Mines and Resources, Ottawa, Ont.

NOTE—The investigation which resulted in this report was carried by the Department of Mines and Resources as a means of helping small foundries conserve pig iron in the present emergency. The information contained in the report is intended in particular for small foundries in small towns scattered across the country which possibly melt a few tons a day, but which are using 35 to 40 per cent pig iron in their cupola charges. If the use of the pig iron could be reduced even by as little as five per cent, a considerable saving in the aggregate would be effected.

At the request of the Department, the editor is pleased to reproduce this report in the hope that it may help conserve supplies. Copies of the report may be obtained from the Chief, Bureau of Mines, Mines and Geology Branch, Department of Mines and Resources, Ottawa, Ont.

During the present emergency, an increasing shortage of pig iron will be encountered by gray iron foundry operators. This may be alleviated to some extent by substituting scrap iron for part of the pig iron requirements. The accepted practice in many gray iron foundries is to use pig iron and foundry returns with possibly small amounts of foreign scrap iron in making the mixtures for melting in their cupolas. Foreign or outside scrap iron is used to describe material which is purchased from outside sources and which was not originally cast in that particular foundry. It is so named in comparison with domestic or "own" scrap, better known as foundry returns, which is that particular foundry's own product consisting of gates, sprues, risers, shrink bobs or heads, over iron or gangway pig, defective castings, etc., all a necessary part of a previous melting operation.

Present Use of Scrap Iron and Steel

The use of large amounts of foreign scrap, both iron and steel, in cupola mixtures, as high at times as 60 per cent of the total charge, has been the general practice for quite a long time in the large, continuous-operating foundries of the so-called "production" type which require metal made and held to strict specifications at all times. This is made possible by very close supervision and control at all stages of the process. In smaller foundries with considerably less supervision available, it would hardly be advisable to try to duplicate this practice. However, it can be done on a smaller scale which, with careful attention to the various details of the melting process, should yield satisfactory results.

It should be stated at the outset, however, that conditions vary not only from one foundry to another making similar castings, but vary from time to time in the same shop. This calls for considerable application of common sense. The following remarks concern general conditions, not any one particular instance, to serve as a guide in the utilization of scrap.

The use of various classifications of steel scrap in gray iron foundries melting iron for various applications requiring superior physical qualities, usually known as "semi-steel" has been common practice for many years. The success of this operation has been mainly due to the close attention given to all foundry operations generally and the melting practice in particular. However, by application of the same careful attention to the details of operation, satisfactory iron for ordinary castings is being made, using considerable percentages of foreign scrap iron to replace part of the pig iron in the charge.

Preparations for Use of Scrap

Every gray iron foundry operator knows what constitutes good melting practice in a cupola. A foundry cupola given reasonable care and attention, with charges of pig iron, foundry returns with or without some foreign scrap in the mixture and a reasonably good grade of coke will produce an iron that will be satisfactory enough for the intended purpose. The substitution of part of the pig iron by foreign scrap will entail somewhat closer attention to the various details involved. Before commencing the substitution of scrap, it would be beneficial to check the various phases involved in cupola operation in order to obtain maximum efficiency in the melting operation.

The physical characteristics of a cupola, the tuyere area and ratio, the height of tuyeres about the bottom plate, and their type are usually determined over a considerable period of time, and for the present purpose should not be changed, unless found necessary for increasing the holding capacity of the crucible, tank or well that receives the metal when it is melting down.

The preparation of the cupola for the day's heat or cast should be conscientiously done with the proper care given to the chipping out, patching, the repair or replacing of tap hole and slag hole areas, and putting in the sand bottom.

After lighting up the cupola, special attention should be given to the burning in of the first coke bed and obtaining the proper height of the second coke bed before starting to charge the materials for melting. The proper height of bed for best melting conditions has to be determined by experience. When this height has been determined, it should be strictly adhered to. Commencing operations with the coke bed properly burnt in and of prescribed height is one of the most important considerations of efficient cupola operation regardless of the length of time metal is required, whether it be for one hour or eighteen.

The weight of each cupola charge, (the term used to describe the mixture of various materials to be melted together simultaneously), is usually determined by the cross sectional area of the cupola, with certain variations to meet particular conditions. It is important that the size of the various materials used be of the proper proportion to the cross-sectional area of the cupola in order to obtain uniform melting conditions and a homogeneous molten iron. Other very essential details are the accuracy of the weighing, the proper sequence of placing in the cupola, and the spreading of the materials evenly. The same care is also required in the weighing and placing in the cupola of the coke required to replenish the bed coke for melting the following charge.

One other important point to be considered is that of fluxing or "slagging" of the cupola, to remove the refuse which accumulates from the ash of the coke, the rust of the pig iron and scrap, and the burnt sand that adheres to the foundry returns by the addition of limestone on top of each coke charge. The "tapping-out" of the slag is as an essential operation as the "tapping-out" of the iron if smooth running cupola operation is to be insured.

One final point is uniformity of blast pressure, which, once determined for a desired melting rate of iron should be maintained, although slowing down is not as hazardous as speeding up which causes all kinds of trouble.

Classifications of Gray Iron Foundry Scrap

In contemplating either the substitution of foreign scrap for part of the pig iron or increasing the amount being used at present, consideration must be given to the kind of iron required for the general class of castings being made. The American Institute of Scrap Iron and Steel have a standard classification of scrap which is followed as a basis by the purchasers of large amounts, and may serve as a guide for those whose requirements will not be so great. For smaller foundries, consideration should be given to the kind and amount available in local scrap yards. The scrap classifications as given in Simplified Practice Recommendation R-58-36 of the U.S. Department of Commerce, 1940, for Gray Iron Foundries are as follows:

58. No. 1 Machinery Cupola Scrap—Clean machinery cast-iron scrap. Must be cupola size, not over 24 by 30 inches in dimensions, and no piece to weigh over 150 pounds.

59. No. 1 Machinery Breakable Scrap—Clean machinery cast-iron scrap, weighing over 150 pounds, and which can be easily broken by an ordinary drop into cupola size.

60. No. 1 Standard Cupola Scrap—Clean cast-iron scrap, such as columns, pipes, plates, and castings of miscellaneous nature, but free from stove plate and agricultural scrap. Must be cupola size, not over 24 by 30 inches in dimensions, and no piece to weigh over 150 pounds. Must be free from foreign material.

61. No. 1 Standard Breakable Scrap—Clean cast-iron scrap, such as columns, pipes, plates, and castings of miscellaneous nature, weighing over 150 pounds, and which can be broken by an ordinary drop into cupola size.

62. Burnt Cast Scrap—Burnt cast-iron scrap, such as grate bars, stove parts, and any miscellaneous burnt scrap.

63. Stove Plate Scrap—Clean cast-iron stove plate. Must be free from malleable and steel parts, window weights, plow points, grates, burnt iron, etc.

64. Agricultural Scrap—Cast-iron parts of agricultural machinery, including plow points. Must be free from steel, malleable, and full-chilled iron.

65. Cast-Iron Car Wheels—Cast-iron car and locomotive wheels.

66. Brake Shoes—Driving and car brake shoes of all types, exception composition-filled shoes.

67. No. 1 Radiator Scrap—Broken radiator castings, cupola size, with all steel parts removed. Must be free from excessive scale, rust, and corrosion.

68. No. 2 Radiator Scrap—Unbroken radiator castings. Must be free from excessive scale, rust, and corrosion.

69. No. 1 Malleable Scrap—Malleable parts of automobiles, railroad cars, and miscellaneous malleable castings. Must be free from steel and cast-iron parts.

70. No. 2 Malleable Scrap—Malleable parts of agricultural implements and other miscellaneous malleable castings. Must be free from steel and cast-iron parts. May include No. 2 rail steel, cropped rail ends under three feet long, 50-pound and over standard section.

These specifications are given as a guide only. For foundries operating with small diameter cupolas, the dimensions given would probably be too large and also too heavy. Classes 62, 65, and 66 should not be considered by the average shop and Classes 69 and 70 only in special cases.

Selection of Class of Scrap

The selection of the scrap to be used for any particular type of iron requires a certain amount of judgement. For example, it would not be advisable for a foundry melting iron for casting into small, light, easily machineable castings to endeavour to use heavy machinery cast scrap or scrapped automobile cylinder blocks or heads for the reason that the heavy machinery castings are usually made of an iron with a silicon content of 1.25 to 1.75 per cent, and the automotive scrap, although containing satisfactory amounts of silicon, as a rule contains appreciable amounts of alloys, nickel, chromium, copper, etc. In this case, it would be better to commence the use of scrap by using stove plate scrap, (No. 63) which in addition to clean stove plate usually contains other scrap parts of various small articles, sewing machines, lawn mowers, kitchen pumps, flat irons, etc. This material is usually made from iron with a minimum silicon content of 2.25 per cent and in addition with a fairly high phosphorus content, usually well above 0.50 per cent. Scrap of this classification can be used in substitution for part of the pig iron of the grade known as "Foundry." For foundries engaged in making a heavier class of work, consideration can be given to the other grades of scrap, and for those requiring a superior grade, stove plate scrap should not be considered.

Suggested Method for Commencing Use of Scrap

In commencing the use of scrap in the cupola mixtures, it is best to begin with the replacement of a small amount of the pig iron content, possibly two or three per cent. This amount can be increased at regular intervals of two or three operating days until such time as the maximum usable amount is reached. The highest possible yield of good, satisfactory castings is the desire of every foundry operator. The greatest percentage of scrap that can be used in the cupola mixture without affecting this yield can be considered the maximum usable amount under that particular foundry's conditions. It is not possible to replace all of the pig iron in the mixture but it is possible in many cases, with careful attention to details previously mentioned, to replace part of it, the amount varying—as conditions vary—in different foundries. It should also be remembered that the percentage of scrap in the cupola mixture as decided upon in any particular foundry may have to be changed from time to time, and at times it may even be necessary to return to the mixture previously used.

Percentages of pig iron used in cupola mixtures vary from foundries casting individual cast piston rings which at times require 70 per cent down to foundries using 10 per cent or less of specially made grades of pig iron.

Calculating Cupola Mixtures Using Scrap

In calculating the mixture, it may be necessary, especially if the scrap to be used is small and light, to allow for a slightly greater oxidation loss of the silicon and the manganese contents. If considerable silicon and manganese are required in the base cupola mixture as calculated, and it is not possible to obtain these contents from the material on hand, it is possible to increase these amounts by the addition of ferro-silicon and ferro-manganese. These ferro-alloys may be conveniently added in the form of briquettes which are made to contain a definite weight of the desired alloy. Since the sulphur content of the scrap is higher than that of pig iron, it is essential that, as previously mentioned, the cupola be kept properly fluxed. Careful observation of the results obtained will establish precedents to follow.

Control of Molten Metal

The character of the molten metal tapped from the cupola is usually observed by some manner of test. This consists of taking a small amount of the iron from the cupola stream and pouring it in some form of a wedge, step bar or other shape made in either a green sand or dry sand mould, and may or may not be cast against a chill. These allow for very rapid cooling and may be quickly broken for visual inspection. It is important that a standard routine be carefully followed to eliminate variations due to temperature, time, etc. Experience will tell the condition of the iron and if any corrections are necessary, the requisite action can be carried out immediately.

The test pieces in most general use in the automotive foundries, who have developed the control of the metal by chill tests to quite a high degree, are the triangular wedge and the "key-hole." The former test piece is in the form of a triangle approximately ⅝ x ⅝ x ⅜ in. and about four inches in height, cast vertically in a dry sand core. This is about the fastest test possible, as it can be poured, cooled, quenched, broken and inspected in much less than a minute. The "key-hole" test, so named from its resemblance to a key-hole in an ordinary door lock, is approximately 1¾ in. in its overall long dimension, 1 in. at the widest part with the key way portion ½ in. to ⅝ in. wide and about four inches in height, cast vertically in a dry sand core, with the key way bottom closed by placing the core against a metal chill. This test piece requires a little more time before it may be cooled and quenched, but with experience yields considerable information regarding the character of the metal. The utility of these tests for rapid control purposes can be readily seen, as the most rapid chemical analyses in specially set-up control laboratories require considerable time before results are available. However, the information on these two test pieces is offered as a suggested method, not a recommendation to replace the particular control tests that may now be in use.

The test pieces give a good indication of the operating conditions in the cupola, in addition to information on the characteristics of the metal. From observations of the depth of chill on test pieces, corrective measures may be immediately taken if such are required.

Need for Pig Iron Conservation

In normal times, the economy that might be obtained by substitution of foreign scrap for part of the pig iron in a cupola charge probably might not be worth the extra effort and vigilance required to maintain consistently a uniformly satisfactory product. In view of the seriousness of the pig iron supply at the present time, however, any assistance in even partially relieving this situation would be well worth the extra exertion required.

120-KVA FLASH BUTT-WELDING MACHINE

From *Engineering*, (London), July, 1941

Under present conditions, it is particularly important that no material should be scrapped when a simple repair with the minimum of new material will produce or reclaim a serviceable article. Welding processes have been used in a variety of ways with this object in view, and the welding machine described below merits attention for its utility in this direction. Flash butt-welding machines can make homogeneous joints in rolled-steel sections or tubes and are both quick and reliable in operation. No special machines are required for the preparation of the work prior to welding; neither are there any expensive finishing processes.

Briefly, flash butt-welding is a process of welding by bringing together the ends of two parts carrying a heavy current and separating them several times. One of the two parts is held in fixed jaws and the other in movable jaws. The current is switched on and the two surfaces to be welded are brought together by the movable jaws. Current flows through the joint and causes it to heat up, but when heated to redness the bars are separated again and the partly-joined surfaces are torn apart. This butting and separating procedure is repeated several times, so that all projections and impurities are burned away and the faces of the joint are brought up to a bright red heat uniformly over their whole area. At this stage, the flashing operation is started by separating the surfaces once again and bringing them together slowly so that a continuous flash is produced from the joint. This flashing is repeated until a predetermined amount has been burned off the ends of both bars and the two surfaces are then pressed together, or up-set, under a high pressure and the welding current switched off.

THE COST OF ABSENTEEISM DUE TO ILLNESS

By Kingsley Roberts and Martin W. Brown

From *Advanced Management*, April-June, 1941

Absenteeism due to illness is costing industry more than $60 per employee per year. It is costing the employees more.

On any given day, among every thousand employees, twenty are, productively speaking, non-effective; many more are only partially effective. Strikes in 1940 resulted in a loss of about two hours per worker per year. Absenteeism due to illness, which never makes the headlines, resulted in a loss of approximately eight days per worker. The toll of illness has been estimated as 400,000,000 man-days per year. Absenteeism due to illness, in effect, has closed more than a thousand factories each employing a thousand workers.

Sickness levies an indirect tax on industry. It causes turnover of personnel, transfer to new work, and increases the cost of employee training. For every absent employee, there are those in poor health at work. And this drags down the level of production. The psychological hazard of insecurity, the fear of illness and its consequent cost, breaks in on the concentration of the employee and affects his work.

The cost to industry of absenteeism due to illness runs into billions of dollars annually. The cost of the partially effective employee is incalculable. There is grave danger that industry will become complacent over the success of industrial medical services for the prevention and control of occupational injuries and diseases and will be blinded to the fact that they have under cultivation not a farm but a flowerpot. Occupational injuries and diseases cause less than 10 per cent of absenteeism due to illness. They constitute less than 10 per cent of the problem. In the present situation, the 90 per cent of absenteeism due to non-industrial illness must be the concern of responsible management.

ALUMINIUM WORKS IN AUSTRALIA

From *Engineering* (London), August, 1941

A work for the production of rolled plate, sheet and strip, forging billets, and extruded bar, rod, tubing and structural shapes of aluminium and aluminium alloys, has recently commenced operations at Granville, New South Wales. It is the property of Messrs. Australian Aluminium Company Proprietary, Limited, a firm established in February, 1939, and jointly owned by Messrs. The British Aluminium Company, Limited; Aluminium Limited of Canada; and The Electrolytic Zinc Company of Australasia, Limited. It is stated in *Tye Commonwealth Engineer* that virgin ingots of aluminium are imported from Canada and that all the alloys required are made up at Granville. In addition to wrought material, the new works also produces foundry casting ingots of various grades. The works includes a forge shop as well as rolling-mill and extrusion shops. The latter is equipped with a 3,000-ton extrusion press in which the forging billets, as well as extruded bars, rods, etc., are to be produced. The forging billets are to be used in the manufacture of aircraft propeller blades, aero-engine crank-cases and pistons. The forging department, the construction and equipment of which is now practically completed, contains a 35,000-lb. compressed-air hammer. Another material to be produced in the new works is Alclad, which, as is well known, consists of sheets of Duralumin coated with pure aluminium. It was anticipated that the works would commence production in May, 1940, but difficulties in obtaining equipment led to a delay of some twelve months; finally, the necessary plant was obtained from the United States. After the conclusion of hostilities aluminium foil and other materials not made under war conditions will be produced.

200-TON REINFORCED-CONCRETE BARGES

From *Engineering* (London), August, 1941

In a recent issue of *Engineering*, reference was made to the 200-tons deadweight reinforced-concrete barges, many of them of precast-slab construction, which have been built during the past twelve months or so to the order of the Admiralty. The brief particulars then given can now be supplemented by illustrations, Figs. 1 and 2, which show, the method of construction and the finished barge, ready for launching, and provided with the necessary wooden fenders and equipment of deck fittings. It will be seen that the type illustrated does not differ greatly from the conventional steel Thames barge; although it may be observed that even so unpromising an underwater form as that shown can be improved to an appreciable extent by careful design, as was demonstrated by the tests, in the William Froude Tank, described in a paper read in 1930 by Dr. G. S. Baker and Miss E. M. Keary before the Institution of Naval Architects. There is reason to suppose that the experimental work there summarised had some influence on the eventual design of the new concrete barges.

Fig. 1

Fig. 2

The decision of the Admiralty to turn once again to reinforced concrete as a shipbuilding material caused considerable surprise when their intention was realised, rather more than a year ago, for the concrete-ship programme of the last war was by no means an unqualified success. That scheme was mooted in 1917, though it was not adopted until the end of that year. Possibly it was launched on too ambitious a scale, and at so late a stage in the war that the man-power then available was of an even lower grade of average skill than was contemplated by the sponsors of the proposal. At all events, according to the *Official History of the War*, only one 1,000 ton barge had been completed by the end of October, 1918, although eight small shipyards were either laid out or adapted for the purpose, and over 200 orders had been placed. Some of the vessels were subsequently completed, and several tugs and at least one concrete coaster, the *Armistice*, eventually passed into private ownership and were operated commercially with a certain amount of success. They were not notably popular, however, especially among the repairers into whose hands they came periodically for survey and overhaul. There seems little reason to suppose that the present revival of the reinforced-concrete barge will outlast the period of the war, or that this method of construction will ever be able to compete successfully with steel under normal conditions.

CHEMICAL JOINT SEALING AND SOIL SOLIDIFICATION

By C. Martin Riedel, Civil Engineer, Chicago, Ill.

From *Engineering News-Record*, August 14th, 1941

Chemical solidification of loose soils, dry or wet, and sealing of joints in leaky masonry have been practised successfully in Europe for some years. One of the promising methods is the Joosten process, patented in this and other countries by Dr. Hugo Joosten, Dutch mining engineer. During the past three or four years the writer, representing Dr. Joosten in this country, has conducted numerous experiments and tests on this process in both laboratory and field, in collaboration with the Philadelphia Quartz Co., and the Solvay Sales Corp. Results of these tests indicate the chemical solidification process is adaptable to many problems encountered in this country in permanently consolidating troublesome soils encountered in foundation excavation and tunneling; also that it is satisfactory for sealing leaky joints and cracks in concrete and masonry walls and in tunnel lining.

The Joosten process is simple. It consists of consecutive applications, under pressure, of two chemicals into the ground or joint to be treated: (1) a commercial grade of silicate of soda, with certain other chemicals, diluted to the required specific gravity, followed by (2) a strong solution of calcium chloride. The composition and strength of the two chemicals and the proportions used, as well as the method of application, are covered by the patents. Several instances have come to my notice recently where the chemical process has been unsuccessful, but such cases are no doubt due to improper strength or proportions of the two chemicals. As far as the author knows no application of the Joosten process has proved unsuccessful when prepared and conducted correctly.

Unlike cement grout which, for fear of disrupting the mass or separating the cement and water, cannot be forced into all the fine pores and cracks of the material being treated, the chemicals reach into and fill all voids rapidly with an impervious gel that forms as soon as the two chemicals come into contact. This instantaneous action of the gel, together with its steady binding force, is another advantage over slow-setting cement grout.

Just recently the author sealed several badly-leaking joints and fissures in a section of the Chicago Freight Tunnel to demonstrate the effectiveness of the chemical process for such purposes. The section treated was a stub off the Franklin St. tunnel, 41 ft. below the surface and 1½ blocks east of the Chicago River. This stub formerly led to a warehouse, now abandoned, and a concrete bulkhead had been placed 6 ft. from the tunnel line to create a telephone chamber in the old stub section. Considerable water was coming through cracks, seams, joints and even through porous, disintegrated areas in the old concrete lining.

All leaks were effectively stopped by simply drilling 14 holes into the worst spots and applying chemicals by the Joosten process. Equipment used included a small electric-drive air compressor, a pneumatic rock drill with 1⅛-in. bit, two small electric force pumps for handling the chemicals, powered by a six-volt automobile battery, copper tubing from the pumps to a Siamese connection leading to a special rubber expanding sleeve wedged into the drill hole, and two five-gal. cans containing the chemicals.

THE DESTRUCTION OF UNEXPLODED SHELLS AND AERIAL BOMBS

By L. G. Fraser, B.E., A.M.I.E. Aust.

From *Journal of the Institution of Engineers Australia*, July, 1941.

Most shells and bombs contain high explosive, which, also, is usually employed to destroy them if they are found unexploded.

Explosives are unstable solids or liquids which on application of a suitable stimulus can be converted to more stable gaseous substances in a very short interval of time, with the liberation of much heat. The change in volume from solid to gas is of the order of 10,000 times for a "free" explosion. There are two ways in which explosives may change their state of being—first by the relatively slow process of burning and, second, by the rapid process of detonation. This constitutes the division between "low" and "high" explosives.

In detonation a wave, set up by shock or sudden heating, runs throughout the whole bulk of the explosive, decomposing each molecule almost instantaneously. An explosive may detonate in sympathy with another charge which has been fired, due to transmission of the shock of detonation through the air, water or earth.

With the high explosive the detonation and shattering are so sudden that the inertia of the air is sufficient tamping and an intense local effect is produced on whatever is in contact with the charge.

There is no such thing as a "dud" shell. After a shell has been projected all of the safety devices incorporated in the fuse are put out of action and the shell is armed and remains so.

The amount of high explosive in a shell is usually from 10 per cent to 12 per cent of the weight of the shell and it is necessary to use an intermediary or exploder in order to build up a detonating wave of sufficient intensity to detonate the large mass of the shell filling.

The fuse contains the first two steps in the train of detonation, and may be designed to operate on impact, on graze, or at any point in the trajectory. Safety devices are incorporated in the fuse to ensure safety in transport and storage, but once the shell has left the gun these cease to function and the shell is "live."

An unexploded shell should be treated with great caution. It should be exploded as it lies or very gently handled if it is necessary to remove it to a more suitable place.

There are four types of aerial bomb; general-purpose, semi-armour piercing, armour piercing and anti-submarine.

General-purpose bombs are made up to 500 lb. in weight and is the type of bomb most commonly used against civilian objectives. A 500 lb. general-purpose bomb is 7 ft. in length and 1 ft. 6 in. in diameter. Its destructive effect is very great and if dropped from an aeroplane flying at 200 m.p.h. at 10,000 ft. would penetrate, if of the delayed action type, 2 ft. 6 in. into reinforced concrete or up to 25 ft. into earth before exploding.

The method of dealing with an unexploded bomb depends on its location and accessibility. If it is set for delayed action, which is most likely the case, it may explode at any time up to seven days after falling, and it is officially recommended that an unexploded bomb should not be touched during that period.

The most effective type of incendiary bomb is that known as the electron bomb. It consists of a cylindrical case 9 in. in length and about 2 in. external diameter, with walls about ⅜ in. in thickness. The case is made of electron metal, a magnesium alloy containing 96 per cent of magnesium alloyed with aluminium, zinc and manganese. Its filling consists of a primary composition (barium peroxide and aluminium) and thermit. The principal incendiary agent, however, is the magnesium alloy case and the purpose of the filling is to raise the case to ignition temperature. One large bomber can carry from 1,000 to 2,000 incendiary bombs of this type, which are released in groups of ten or twenty. It is estimated, however, that only about 8 per cent of the bombs released actually cause fires.

LARGE TANKERS

From *Trade and Engineering*, September, 1941

Although there are now about 150 ocean-going tankers on order in American yards, totalling between 1,400,000 tons and 1,500,000 tons gross, it is generally believed that, when the war ends, there will be a great shortage of such vessels. Before the war a considerable volume of motor tanker tonnage was being built in Scandinavian yards, and even under present conditions it is understood that important numbers of oil-carrying ships are being constructed for Norwegian, Swedish, and Danish owners.

In most instances they are designed for speeds higher than those which were common before the war. At the Kockums works at Malmo a vessel of 16,250 tons deadweight, the Malmohus, was lately completed for the Trelleborgs S.S. Company, and a sister ship has been launched and is no doubt approaching completion, if she has not already run trials. The length is 500 ft. with a beam of 63 ft., and an eight-cylinder double-acting two-stroke engine of 5,500 b.h.p. gives a service speed of 14½ knots. A third similar ship for the Svea S.S. Company, of Stockholm, has also been launched, while two even larger tankers, the Julius and the R. Stenersen, are fitting out at the Gotaverken shipyard at Gothenburg. These are stated to be larger than any vessels yet built in Scandinavian yards, being 540 ft. in length with a beam of 66 ft., and having a deadweight capacity of 16,800 tons on a draught of 29 ft. 10 in. The propelling engine is a Gotaverken two-stroke unit, developing 7,000 i.h.p., and the service speed is 14 knots with the vessel fully laden.

All the tankers in question are wholly welded, and the R. Stenersen and her sister ship are constructed to a new design in which the longitudinal and transverse bulkheads are corrugated. It is claimed that the new construction increases the oil cargo capacity by 300 tons. The fact that all these new ships, as well as at least 90 per cent of those building in America, are designed for a speed of 14 knots or over will no doubt have a marked influence on ocean oil transport after the war.

SWEDISH ALUMINIUM

From *Civil Engineering and Public Works Review*, (London), August, 1941

In view of the important part that aluminium plays in modern engineering construction, the steps being taken in Sweden to develop its own sources of that metal are of considerable interest to engineers in this country.

The Swedish Aluminium Co. plans to begin construction soon of its new plant for the production of alumina from andalusite. In peace time the plant will be capable of producing 6,000 metric tons of alumina from bauxite annually, and in war time about 4,000 tons from domestic andalusite. The site of the plant has not been decided upon, but as access to low-cost electric power is necessary it will probably be in Northern Sweden. Negotiations have been conducted for its location at Kubikenborg, near Sundavall, in Northern Sweden, or at the deepwater harbour at Oavlo, also in Northern Sweden. At Kubilenborg ground drillings and other investigations show that the water supply apparently is not adequate, but it is believed that an adequate water supply can be provided. Andalusite is an excellent substitute for bauxite, and has an average alumina content of 50 per cent., compared with 60 for bauxite. However, andalusite contains large quantities of silica, which is difficult and expensive to remove. The Norwegian parent company has been successful in removing the silica by using the same method as for bauxite, with certain modifications. This new process is considerably more expensive.

COMMENT

By Ordway Tead

From *Advanced Management*, April-June, 1941

Morale is the total attitude resulting from the mobilizing of energy, interest and initiative in enthusiastic and effective support of some project or aim. Morale may arise or be striven for at numerous levels and for diverse ends. Defense is one major goal for which a high morale is wisely being sought today among the industrial workers engaged in defense production.

Industrial managers on the whole believe in and try to assure high morale among the upper supervisory staffs of their companies. Those efforts of personal acquaintance, friendliness, exchange of information, the proffer of praise where praise is merited—all contribute in a natural, almost spontaneous way to good morale at the executive levels. The entire defense programme will thrive if the morale of managers can be taken as representative of the morale of all workers. But that such an assumption is valid is open to grave doubt on the part of anyone at all close to the sentiment and attitude of the rank and file in our defense factories. This is not to impute lack of patriotism to the workers. This is not to conclude that all the newspaper alarms about strikes are to be taken as seriously as the headlines intimate. In fact, the strike record, comparatively with 1917 is phenomenally low.

Rather, the crucial point is that the goal of defense—which may at any moment become a goal of offense and positive military victory—is not the kind of goal which the American worker takes to his heart without some specific morale-building efforts taking place.

Let any who entertain doubts on this score re-examine the history of industrial relations and of industrial morale-cultivating programmes in 1917-18, when the gradual change in total attitude was tremendous, countrywide and unified to an unprecedented degree. Nor did this change arrive by chance. It came about by plan and might have come earlier had the need for the plan and the elements of a wise plan been widely recognized earlier. My purpose here is not to set forth the "how" but rather the "why" of this problem as managers confront it. And the "why" has to do with human desires and motives. How do we stir individuals into sustained effort toward a goal, is a question to be answered only as we know about basic drives, the mechanisms of substitute release, the effects of shared joint experience, the consequences of frustrations and the impact of personalities upon one another.

Indeed, I sometimes think that the big function of management itself, in so far as it is the task of personal, supervisory direction, has to be radically redefined to be seen in its true character. For, on its personal side, management is the continuing effort to bring the deep satisfaction of associated, co-operative experience to a group of persons bound together by ties of a responsibility having to be jointly assumed. Management is the summons to a sense of community and common striving among individuals who would rather be led to achieve than be left to atrophy. Management is the guidance of that subtle reality, a collective will to do because to do is to be and to register as alive.

If managers could once begin to grasp in its deeper meaning that familiar truth that "man is a social animal", they would see that to provide an experience on the job which is an experience of happy sociality, is in reality the big executive job. If we could assure among workers a warm, sensitive, secure awareness of social belonging, the entire outward expression of this awareness would become attentiveness to the creative activity of production. People's will to work has been vastly underrated—and chiefly because the social inducements to work have been so frightfully lacking. And high among those social inducements is or can be the sense of each worker that he belongs to a purposeful and friendly gang. He wants and deeply needs to be "a regular guy in a regular bunch of fellers".

Do managers try in the factory—and especially in the tensions of the defense drive—to provide conditions of happy sociality, of communal sense, of wholeness and unity of drive in common with others who are like-minded and like-feeling ?

If we do not attend to the provisions of these total attitudes toward the corporate and the national task, we are working against tremendous odds of psychic resistance and friction. Never yet, in the working of the machine economy, I venture to say, have we shown what we could do toward abundance of output, if we were collectively wise enough to summon people's communal sense into satisfying being.

MOTION PICTURE ENGINEERING

From *Trade & Engineering* (London), July, 1941

Although the use of the motion picture may not as yet have been fully exploited in this country as a means of either propaganda or education, cinematography will be closely wrapped up with the reorganization of industry and the training of employees after the war. As it is, the immensity of its scope in the field of entertainment has had an inevitable reaction on many branches of engineering and physical research, both of which have benefited by the adoption of scientific developments worked out initially for motion-picture purposes.

Cinematography is finding increased application in fields outside entertainment. Thus specially designed cameras are being used for the study of high-speed machinery and mechanical problems. Improvements in sound reproduction with 16mm. or substandard film and in the portability of the apparatus have made it possible for salesmen or trade representatives to carry about equipment which will both demonstrate the articles concerned and provide suitable sales talk. This development has been utilized on a wide scale in America, where the mere magnitude of business and the distances involved in travelling justify the expense.

Important changes in design have been seen in the newer motion-picture cameras, sound equipment, projection apparatus, and the theatre itself. Admirable projection, in daylight, can be made with travelling theatres; a recent instance is the Thornycroft mobile truck of the Ministry of Information, which carries a powerful arc projector throwing pictures on a translucent screen in the rear, and is fitted with direct and alternating current generators for the lamp and the sound equipment respectively.

The modern studio partakes more of the nature of an engineering shop than a stage. The complicated lighting of a set may demand a score or more of electricians to control the heavy lighting units on the floor and in the galleries; electricians, sound engineers and lighting experts may, indeed, completely outnumber the artists and photographers. Mechanical handling devices have added to the complication of the newer studios. In one of these the stage floor can be made to disappear at a touch, leaving a full-sized swimming pool in view, complete with glass sides and with lighting equipment which enables all kinds of under-water performances and illusions to be photographed. Among the acoustical problems of the studio efficient but completely soundless ventilating machinery has involved much arduous work.

A noiseless camera of recent design employs controlled hydraulic resistance in overcoming noise from friction when tilting or panning while following the action on the set. It is only one of innumerable improvements in construction. More conspicuous are the elaborate trucks on which the modern camera is mounted and manipulated by its crew of two or three standing or sitting on the platforms. A novel feature in the engineering field is a massively constructed camera taking 2,000 pictures a second, with an electric spark of pre-arranged frequency recorded on the edge of the film for timing purposes; this has proved of value in studying problems connected with aeroplane engines.

THE PLAGUE OF QUESTIONNAIRES

Everywhere one turns these days he faces a questionnaire. It may be issued by a governmental department, a commercial organization, a social body, a service club, a charity, a professional society or a voluntary group. Unfortunately, such forms are too frequently received with criticism and expressions of annoyance. Some persons even take time to express their feelings in withering communications intended, no doubt, to crush the responsible parties so that they cannot rise to repeat the offence.

Let us look at this questionnaire business for a moment—quietly, thoughtfully and rationally. In the first place, what is the purpose of such an inquiry ? Usually it is intended to bring to some well-meaning body information upon which some plans for the common good can be based. Invariably, these plans are in the interest of the individual himself as part of a group, and yet his reaction may be that he is doing a favour to the inquirer. Either the purpose of these questionnaires is misunderstood, or we have reached a stage of disinterestedness in national affairs.

The experience of the Wartime Bureau of Technical Personnel has been illuminating. A prompt, courteous return has been received from most prominent engineers, and the criticisms have come mostly from those whose records leave something to be desired in professional attainment. Too great a percentage has not made any return at all.

It looks as if the questionnaire approach to a problem were here to stay, at least for the duration. There appears to be no better way to get certain necessary information. It would be wise, therefore, to accept it, and work with, rather than against it. After all, it does not demand much of the individual, and it may be the basis of a real contribution to the war effort. It should be kept in mind that the sacrifice necessary to complete the form is nothing compared with that made by the individuals initiating the inquiry, and yet all the time and thought spent by them will be wasted if an insufficient number of completed forms are returned. Your co-operation may be of considerable assistance to someone else in a worth while effort to aid the national cause.

WARTIME BUREAU OF TECHNICAL PERSONNEL

Monthly Bulletin

The activities of the Bureau have now entered a new phase. At the suggestion of Sir Lawrence Bragg, British Research liaison officer, and C. J. Mackenzie, acting president of the National Research Council, a register is being set up to cover research and science workers throughout Canada.

Believing that personnel service is best rendered to any one group by someone from within that group, the Bureau has secured the co-operation of Dr. David A. Keys, Professor of Physics at McGill University, who is eminently fitted for the work. McGill University has done much for the war effort by loaning its facilities and its staff. This is but another example of its whole-heartedness in all things that have to do with the national emergency.

Dr. Keys is already at work on matters of procedure, and it is expected that shortly forms will be ready for distribution to all persons who come within this group. Basically, the mailing list will be made up of those who hold master degrees or higher. It is evident that such a list will include many names that were canvassed in the first list of the Bureau, but it is hoped this new form will be received with equal approval as naturally it contains several questions not asked previously. It affords a better opportunity to such persons to describe their .training and experience.

It has been proved with startling emphasis that research work has a tremendous influence on a country's effort in time of emergency. It may be a long time after the war before the whole story can be told, but already it is apparent in many places that great things have been done by the Empire's research groups. This is particularly true in Canada. Leadership has been given by the National Research Council, excellently supported by the universities, industrial organizations and provincial groups. This portion of the Empire's effort will bring great credit to Canadian workers and Canadian institutions, and should be the gateway to even greater things after the war. It is to utilize all persons who have had any research training that this new register is to be established. The proposal has the support of many of those scientists who are closest to the needs of the country.

CORRESPONDENCE

A Suggestion for the Conservation of Fuel, Money, and Man-power

605 Victoria Avenue,
Victoria, B.C.

The Editor,
The Engineering Journal,
Montreal, Que.

Dear Sir,

Certain orders have been issued by the Department of Transport, from the office of the Oil Controller, regarding the conservation of gasoline and other liquid fuels, regulating hours of sale, cutting out credit sales, etc., without regard to the regulation of transportation required in our daily life.

It appears that a much greater percentage of conservation in cities, could be accomplished if commodity deliveries were regulated, and truck and delivery runs were made illegal outside of defined areas, naturally in the location of the vendor or vendors, of essential and generally used articles.

Assuming that all standard retail articles are the same price at all distributors for that article, as they should be, then an area dependent on his clientele should be set for each distributor:—

(1) The distributor will then distribute his goods in that area and no other.

(2) No other distributor will be allowed to deliver similar goods in that area.

There are various commodities and goods such as milk, bread, gasoline, etc., of which the price and delivery can be and is controlled, and, while the matter requires consideration and deliberation and a lot of ground work before a working basis can be arrived at, the saving in mileage and therefore in gasoline and diesel fuel, would be enormous.

(a) It can safely be said that 25 per cent of the motored delivery vehicles would not be required, and their non-use would release the fuel and do away with the repairs they at present have to be supplied with.

(b) The man-power would also be reduced in releasing the drivers of these trucks and the service men who cater to their needs, for the more essential war duties.

(c) The workmen, tools and material necessary in manufacturing these vehicles would also be diverted to war effort.

(d) There would be added expedition in the delivery of goods at a lower mileage delivery cost.

(e) Fresher comestibles would be supplied than are available under present conditions, and this would lead to better relations and satisfaction to those concerned.

(f) The release of actual money is shown as not being expended on fuel and wages for labour.

It was noted on August 25th in an actual check up made in the city of Vancouver, B.C., between the hours of 8 a.m. and 9 a.m., that eighteen milk delivery trucks (all motor) were operating in four blocks on one street. These vehicles were owned by seven different firms whose headquarters were situated miles apart. This instance gives one food for thought in these days of exploration into avenues of conservation of fuel, money and man-power.

Taking Vancouver as one instance, where, as in other large cities, milk, bread, gasoline, fuel oil, and other commodities are all in the hands of comparatively few firms, as distributors, it is not outside the bounds of realism to suggest that even the distribution between wholesalers, jobbers and retailers, can be controlled and reduced to a minimum. In the first instance, it might be arranged through an interchange of customers and that, while only the entering edge of the wedge, could be evidently carried out quite amicably as, commodity prices being the same, no cash would be involved.

Naturally an undertaking of this nature would have to be put in operation and carried on as a Government measure, and would entail considerable census, mapping and statistical work, besides personal contact with all interested parties, but the cure would certainly pay for the treatment. It is not an impossible, although an intriguing situation, and it is not even improbable that steps will have to be taken and regulations made and carried out, in this respect, before long.

As the route from initial distributor to retailer would be shortened, there would be, as before stated, a curtailment of mileage, fuel and time. There would naturally follow a lower delivery cost and thus a saving in the delivered cost of the article made up from these savings which, the price of the commodity being pegged, would not be absorbed by the distributor or the retailer, but would be passed back to the producer and forward to the customer. In this manner the farmer, for instance, would get an enhanced value for his product and the customer better goods, being fresher, at a lower cost.

Similarly in the case of fuel distributors and retailers, the same applies and these savings in both cases would further release a considerable amount of money, which at the moment is unnecessarily and wastefully tied up, as the producer and the customer would have this extra cash to use.

The saving to the country at large would of course center principally in the fuel, the man-power and the time released by this set up and secondarily in the added cash in circulation in the hands of the producer and consumer.

While possibly the above thought may savour somewhat of dictatorship, if we, as Canadians, are at "total war" then it behooves us to bear in mind that we must pay for this war and how better than by starting at the root and cutting out the non essentials of our social life, rather than starving the fruitful branches of war effort.

(*Signed*) Jas. H. Blake, m.e.i.c.

MEETING OF COUNCIL

A meeting of the Council of the Institute was held at Headquarters on Saturday, September 13th, 1941, at ten-thirty a.m.

Present: President C. J. Mackenzie in the chair; Past-President J. B. Challies; Vice-Presidents K. M. Cameron and McNeely DuBose; Councillors J. H. Fregeau, J. G. Hall, H. Massue, C. K. McLeod, B. R. Perry, G. M. Pitts, J. A. Vance, and the General Secretary.

Out of the discussion of the Sir John Kennedy Medal ballot, a proposal was made that some change in the regulations should be brought about whereby it would not be necessary to have a unanimous vote before an honorary membership be awarded. It was pointed out by the president that it was an extremely difficult process to obtain an absolutely unanimous opinion on any nomination for this honour. The meeting was of the opinion that some changes could be made to advantage, and the general secretary was instructed to discuss this matter with Mr. Durley so that a definite proposal might be submitted to a later meeting.

Mr. Challies, chairman of the Committee on Professional Interests, reported that in New Brunswick an agreement had been approved of in principle. It had been submitted to the Institute's lawyers and certain changes which they had proposed had seemed less acceptable to the Association than the original wording. Mr. Challies suggested that Mr. Kirby, the secretary of the Provincial Association, might be able to come to Montreal to discuss this matter with him and the General Secretary. It was agreed that an effort should be made to have Mr. Kirby come to Montreal.

In Manitoba Mr. Challies reported that the situation was favourable. He hoped that during the proposed visit of the president and the general secretary to Winnipeg some further progress might be made.

The general secretary reported figures for the changes in membership due to the workings of the co-operative agreement in the Province of Alberta. It was suggested that the president go into these matters with the Association and with the branches when he is in Alberta.

The general secretary read a report from the Institute's committee on A.R.P. in which it was recommended that the Institute combine with other interested societies to form a joint technical committee which could co-operate on engineering matters with the Federal organization for A.R.P. This was in accordance with a suggestion made by Dr. Glidden, the general controller of A.R.P. work.

Council felt that Mr. Munro's proposal should be accepted, and to that end it was suggested that the National Research Council might call a meeting in Ottawa inviting representatives from all appropriate societies. This was agreed to and the general secretary was instructed to make this request of the Research Council.

Mr. Pitts reported that the architects were naturally interested in this work and was confident that they would be glad to co-operate through the medium of such a committee. He agreed to bring the matter to the attention of the executive committee of the Royal Architectural Institute of Canada at its next meeting.

The president indicated that in home defence work there were many matters requiring consideration by engineers and scientists. He thought it desirable that a meeting be called so that the matter could be discussed by all interested parties in all its aspects. He pointed out that the Institute was not interested in the ordinary phases of A.R.P. work, but principally those phases dealing with explosions, both from the angle of reducing the amount of damage done and methods of quick repair after attack. It was thought that organizations or individuals interested in public utilities, public works, architecture, chemicals and gases should be brought together for deliberations on this subject.

In the absence of the chairman of the Finance Committee, the general secretary presented the reports of two meetings, one held on July 22nd, and the other on September 12th. The financial statement to the end of August had been examined and approved, the situation between normal income and expenditure being slightly better than at the same time last year.

The Finance Committee recommended that Council approve of some method by which recognition might be made of professional engineers from other countries who are now working in Canada; these were principally English and Polish. The committee thought something should be worked out whereby all such persons would be given the privileges of branch meetings and perhaps also the *Journal.*

In this latter case some special consideration might be made whereby actual costs would be met. These people might be known as "Guest Members" or some other appropriate term.

The general secretary read a letter from the secretary of the Institution of Electrical Engineers in which this proposal was received very cordially, and it was suggested that if the Institute extended these privileges to the English members, the English institutions would like to have an opportunity to reciprocate towards those members of the Institute who are now in the Old Country.

It was the unanimous opinion of the meeting that everything possible should be done to make pleasant the stay of these people in Canada. Council was willing to approve of any definite proposals which were acceptable to the Finance Committee. It was stated specifically and emphatically that the arrangement to be worked out should be such that it would be possible for every such visiting engineer to participate in all Institute activities. The secretary was instructed to obtain from the English Institutions the names of any of their members in this country, and also to obtain a similar list from the members of the Polish Engineers' Association. He was instructed to communicate with each branch as soon as the plan was formulated, so they might get in touch with any members of this group who might be in their branch area.

The general secretary reported that contributions had been received from thirteen Institute branches but that twelve had not yet completed their campaign. It was expected in these latter cases that the matter would be reopened after the fall season commenced, and that satisfactory results would be obtained in each case. The secretary was instructed to write a letter to each of the branches in this latter group reporting on the results to date and asking for their co-operation.

The president gave a brief outline of his proposed visit to the western branches. He was leaving Ottawa on Saturday, September 20th, and would stop at the Lakehead Branch, Winnipeg, Regina, Calgary, Vancouver and Edmonton. He regretted that the urgency of business of the Research Council made it impossible for him to take in other branches such as Lethbridge and Victoria. Due to the pressure of these other business affairs it is necessary for him to make the trip within the minimum length of time. He said that he would be pleased to have any other members of Council accompany him who could do so. Vice-President Cameron announced that he expected to go with him at least as far as Winnipeg. The general secretary reported that due to further developments in the activities of the Wartime Bureau of Technical Personnel at Ottawa, it was necessary for him to be in Ottawa on certain dates so that he would only be able to be present at the Lakehead and the Winnipeg branches.

Councillor Perry presented a final report on the repairs to the building foundations. This report showed that the work had all been completed and paid for, and appeared to be very satisfactory. Councillor Vance said that it was readily evident that Mr. Perry had done a real service for the Institute in carrying out this work as chairman of the committee. He moved that a motion be recorded on the minutes of Council indicating Council's gratitude to Mr. Perry for his fine service. Council unanimously agreed to this proposal, after which the president called attention to the time which it had been necessary for Mr. Perry to devote to this work as head of the committee, for all of which he received absolutely no remuneration. Accordingly, it was moved and seconded that the Council of the Institute wishes to record its appreciation of the splendid service which has been rendered by Councillor Brian Perry, as chairman of the House Committee, in supervising the engineering work associated with the underpinning of the Headquarters' building. His careful planning and consideration for Institute finances have done a great deal towards producing an extremely satisfactory piece of work at a minimum cost.

The report of the Nominating Committee was presented by the general secretary, who reported that all nominees were in good standing, and that a written acceptance of nomination had been received from each nominee. Accordingly, it was unanimously RESOLVED that the list of nominees for officers for the year 1942, as submitted by the Nominating Committee, be accepted and approved.

The president indicated his desire that Dean C. R. Young, presidential nominee, be invited to all Council meetings for the balance of his term of office, and that minutes of all meetings be sent to him so that he might have an opportunity to familiarize himself in detail with the affairs of the Institute before actually coming into office. This was unanimously approved.

The general secretary read a report from Mr. Harry Bennett, chairman of the Institute's Committee on the Training and Welfare of the Young Engineer. This report outlined the work that had been done by the committee in preparing the manuscript of a booklet to be distributed among high school or secondary school pupils who might be contemplating proceeding to college to take up engineering. Mr. Bennett also submitted a copy of the manuscript for the approval of Council. The report included a statement of quotations which had been received for the printing, as well as recommendations as to quantity and distribution. It was agreed that Mr. Bennett's proposal for the manuscript itself, as well as his recommendations as to price, quantity and distribution be accepted by Council, subject to approval of the Publication Committee.

The general secretary reported briefly on the activities of the Wartime Bureau of Technical Personnel, emphasizing particularly that at the request of the National Research Council and Sir Lawrence Bragg, the liaison officer between the British research organizations and the National Research Council, the Bureau was undertaking a register of research workers and scientific personnel. It had been arranged that Doctor David A. Keys, Professor of Physics at McGill University, would head up this department of the Bureau's activities. His time had been made available by McGill University, although it was not expected that it would require his whole time, except perhaps in the organization stage.

The general secretary read a letter from the National Construction Council in which the co-operation of the Institute was asked in making surveys to determine what work might be planned for attention immediately after the war. It was reported that the Council had had a meeting of its executive and had gone into the subject in detail, the outcome of which had been that two resolutions were passed. The Council of the Institute was asked whether or not it could support these resolutions. After considerable discussion, in which it was clearly expressed that Council felt that after-war conditions could not be met by sectional planning but must be considered on a national basis, the general secretary was instructed to send copies of the National Construction Council's communication to all councillors so that they might prepare for a fuller discussion at subsequent meetings.

The general secretary read a communication from this organization which dealt with economic and social planning for the post-war period. Council agreed that this matter, too, should be considered on a national rather than on a sectional basis, and that these proposals should come up for discussion when the National Construction Council's communications were again before Council.

A number of applications were considered and the following elections and transfers were effected:

Admissions

Vice-President Cameron suggested that it would be a good idea to hold a regional meeting of Council in Quebec City. This met with unanimous approval. The President stated that he would very much like to have an opportunity to visit that branch. It was thought that the October meeting might be arranged in that city, and the selection of an actual date was left with the President.

The Council rose at one-thirty p.m.

LIST OF NOMINEES FOR OFFICERS

The report of the Nominating Committee was presented to and accepted by Council at the meeting held on September 13th, 1941. It is published herewith for the information of all corporate members as provided by Sections 19 and 40 of the By-laws.

List of Nominees for Officers for 1942 as Proposed by the Nominating Committee

President	C. R. Young	Toronto
Vice-Presidents:		
*Zone "B" (Province of Ontario)	J. L. Lang	Sault Ste. Marie
*Zone "C" (Province of Quebec)	H. Cimon	Quebec
*Zone "D" (Maritime Provinces)	G. G. Murdoch	Saint John
Councillors:		
†Victoria Branch	E. W. Izard	Victoria
†Lethbridge Branch	J. Haimes	Lethbridge
†Calgary Branch	S. G. Coultis	Calgary
†Winnipeg Branch	J. W. Sanger	Winnipeg
†Sault Ste. Marie Branch	A. E. Pickering	Sault Ste. Marie
†Hamilton Branch	W. J. W. Reid	Hamilton
†Niagara Peninsula Branch	P. E. Buss	Thorold
	W. R. Manock	Fort Erie North
	A. W. F. McQueen	Niagara Falls
†Ottawa Branch	T. A. McElhanney	Ottawa
†Toronto Branch	Nicol MacNicol	Toronto
†Peterborough Branch	H. R. Sills	Peterborough
‡Montreal Branch	J. E. Armstrong	Montreal
	R. E. Heartz	Montreal
†Quebec Branch	E. D. Gray-Donald	Quebec
†Moncton Branch	G. L. Dickson	Moncton
†Cape Breton Branch	F. W. Gray	Sydney

*One vice-president to be elected for two years.
†One councillor to be elected for two years.
‡Two councillors to be elected for three years each.

ELECTIONS AND TRANSFERS

At the meeting of Council held on September 13th, 1941, the following elections and transfers were effected:

Members

Alton, Jack, (Regent St. Polytechnic), designing engr., Canadian Bridge Co. Ltd., Walkerville, Ont.

Bullick, Clarence John, B.A.Sc., (Univ. of Toronto), asst engr., Tropical Oil Company, Barranca Bermeja, Colombia, S.A.

Dufort, Cleophas Leroux, B.A.Sc., C.E., (Ecole Polytechnique), Registrar, Corpn. of Prof. Engineers of Quebec, 354 St. Catherine St. East, Montreal, Que.

Estabrooks, Donald Steeves, B.Eng. (Civil), (N.S. Tech. Coll.), records engr., Price Bros. & Co. Ltd., Riverbend, Que.

Middleton, John, (Tech. Coll., Greenock), asst. engr., office of the engineer-in-chief, Naval Service Headquarters, Ottawa, Ont.

Scheunert, Hans, Mech. Engr. (Frankhausen Engrg. Coll.), production engr., aircraft divn., Canadian Car & Foundry Co. Ltd., Fort William, Ont.

Spriggs, William, B.Sc. (E.E.), (McGill Univ.), elec. design engr., Shawinigan Engineering Company, Montreal, Que.

Stickney, William Ralph, B.A.Sc. (Chem.), (Univ. of Toronto), welding engr., Canadian Bridge Co. Ltd., Walkerville, Ont.

Warnock, Samuel, B.A.Sc. (Elec.), (Univ. of B.C.), A/C Inspector, No. 15 Technical Detachment, R.C.A.F., Winnipeg, Man.

Williams, Ralph Emerson, B.A.Sc. (Univ. of Toronto), asst. engr., Defence Industries Limited, Winnipeg, Man.

Wrigley, Frederick Richardson Gordon, (City and Guilds of London Inst.), elec. engrg. dept., Aluminum Company of Canada, Montreal, Que.

Juniors

Dembicki, Steve, B.Sc. (Univ. of Alta.), M.Eng. (McGill Univ.), metallurgist, Defence Industries Limited, Verdun, Que.

Estabrook, James Pierce, B.Sc. (Chem.), (Queen's Univ.), junior chemist, Price Bros. & Co. Ltd., Riverbend, Que.

Gorowski, Charles S., B.Sc. (Elec.), (Univ. of Man.), engr., Canadian Associated Aircraft Ltd., Montreal, Que.

MacKenzie. Ian Donald, B.Sc. (Queen's Univ.), asst. geologist, Shawinigan Engineering Company, Shawinigan Falls, Que.

Affiliate

Matthews, Clifford Bruce, asst. to the city engr., Belleville, Ont.

Transferred from the class of Junior to that of Member

Kent, William Leslie, B.Sc. (Civil), (Univ. of Alta.), engr., Stuart Cameron & Co. Ltd., Lang Bay, B.C.

Pask, Arthur Henry, B.Sc. (Elec.), (Univ. of Man.), project engr., Canadian Industries Limited, Windsor, Ont.

Transferred from the class of Student to that of Member

Akin, Thomas Bernard Jr., Pilot Officer, R.C.A.F., B.Sc. (Civil), (N.S. Tech. Coll.), School of Aeronautical Engineering, 4895 de Bullion St., Montreal, Que.

Baldwin, William Alanson, B.Sc. (Elec.), (McGill Univ.), supt., High Falls Generating Station, Maclaren Quebec Power Co. via Buckingham, Que.

Howard, Henry Mervyn, B.A.Sc. (Mining), (Univ. of Toronto), metallurgical sales engr., E. Long Limited, Orillia, Ont.

Purves, William Franklin, B.Eng. (Elec.), (McGill Univ.), elec. engr., Schick Dry Shaver Inc., Stamford, Conn.

Transferred from the class of Student to that of Junior

Dunn, James Rankin, B.A.Sc. (Elec.), (Univ. of Toronto), Sub-Lieut., R.C.N.V.R., Halifax, N.S.

Goodspeed, Herbert Newcombe, B.Sc. (Elec.), (Univ. of N.B.), electrician, International Nickel Co. Ltd., Sudbury, Ont.

Howard, Albert Warren, B.A.Sc. (Univ. of Toronto), asst. elec. engr., Montreal Engineering Co. Ltd., Montreal, Que.

Mackie, George Arthur, B.Sc. (Elec.), (Univ. of N.B.), Lieut., 1st Brighton Fortress (E & M) Coy., R.C.E. (A.F.), Saint John, N.B.

Miller, Lindsay, B.Eng. (Mech.), (McGill Univ.), dftsman., Aluminum Co. of Canada, Kingston, Ont.

Monaghan, Cecil, B.Sc. (Elec.), (Univ. of Alta.), senior engrg. clerk, elec. light and power dept., City of Edmonton, Alta.

Myers, Gordon Alexander, B.Eng. (Elec.), (N.S. Tech. Coll.), res. engr. and acting mgr., Colas Nfld. Ltd., Clarenceville, Nfld.

McKibbin, Kenneth Holdsworth, B.Sc. (Mech.), (Queen's Univ.) Major, Dist. Ordnance Mech. Engr., Mil. Dist. No. 3, Kingston, Ont.

Wong, Henry Goe, B.Eng. (McGill Univ.), dftsman., Federal Aircraft Ltd., Montreal, Que.

Students Admitted

Abbott, Hugh Martin, (Univ. of B.C.), 5930 Granville St., Vancouver, B.C.

Berry, William Murray, (Univ. of Man.), 241 Harbison Ave., Winnipeg, Man.

Coupe, Herbert Ferguson, B.A.Sc. (Univ. of Toronto), Saguenay Inn, Arvida, Que.

Estabrook, Howard A., B.Sc. (Queen's Univ.), Saguenay Inn, Arvida, Que.

Frost, Paul Joseph, (Univ. of B.C.), 4261-12th Ave. W., Vancouver, B.C.

Hurley, James J., (Univ. of Toronto), 17 Lindsay Ave., Toronto, Ont.

Jagger, Paul S., (Univ. of B.C.), 1259 Gordon Ave., Hollyburn, B.C.

Kingsmill, Hugh Anthony Gault, B.A.Sc. (Univ. of Toronto), Saguenay Inn., Arvida, Que.

Miron, Jacques, (Ecole Polytechnique), 340 DeLanaudiere, Joliette, Que.

Moore, William Alan, B.A.Sc. (Univ. of Toronto), 17 Roxborough Drive, Toronto, Ont.

McEown, Wilbert Ross, inspr., Dept. of Trade and Commerce, Winnipeg, Man.

Ouellette, Robert Pascal, (McGill Univ.), 5363 Duquette Ave., Montreal, Que.

Personals

News of the Personal Activities of members of the Institute, and visitors to Headquarters

Lt.-Col. A. R. Sprenger, M.E.I.C., is at present engaged in the supervision of shipyard extensions with the Wartime Merchant Shipping Limited.

John C. Oliver, M.E.I.C., Registrar of the Association of Professional Engineers of British Columbia, has joined up for overseas service and his Council has given him indefinite leave of absence. Previous to taking the position as registrar of the Association in 1938, he had been for several years assistant city engineer at Vancouver.

A. D. Creer, M.E.I.C., has been appointed Registrar of the Association of Professional Engineers of British Columbia, replacing John C. Oliver for the duration of the war. Mr. Creer, who has been in private practice in Vancouver as a consulting engineer for several years, was at one time chairman of the Vancouver Branch of the Institute.

Capt. A. C. Rayment, M.E.I.C., has joined the staff of the Department of Munitions and Supply, Arsenals Branch, as technical officer. He has had a varied and extensive engineering experience in Canada, Britain and Australia. Since the beginning of the present war, he has been active in instructional military work.

S. D. Lash, M.E.I.C., has joined the engineering staff of Queen's University as Lecturer in civil engineering. Mr. Lash, who is an honour graduate of the City and Guilds Engineering College, London, England, and a Ph.D. of the University of Birmingham, came to Canada in 1929 as draftsman with the Northern Electric Company of Montreal, and later was employed with the Dominion Reinforcing Steel Company Limited, Montreal. In 1930, he went to Vancouver as a structural detailer with the British Columbia Electric Railway Company Limited. From 1931 to 1933 he did post graduate work at the University of Birmingham, England, and from 1933 to 1935 he worked as a research assistant with the Steel Structures Research Committee in England. Returning to Canada in 1935, he was instructor in civil engineering at the University of British Columbia until 1938, when he joined the National Research Council at Ottawa as a junior engineer. Lately Dr. Lash has been acting secretary of the National Building Code project with the National Research Council. He is a frequent contributor to *The Engineering Journal.*

Lt.-Col. John Handley, M.E.I.C., is now on active service with the Royal Canadian Engineers and is at present Second in Command of the Third Battalion at Noranda, Que.

L. G. Scott, M.E.I.C., has been transferred by the Hudson's Bay Company from Winnipeg, Man., to Vancouver, B.C.

Flying Officer K. Y. Lochhead, M.E.I.C., has completed his course at the School of Aeronautical Engineering, Royal Canadian Air Force, Montreal, and has been posted as Station Engineer Officer at Alliford Bay, B.C.

Jean Bouchard, M.E.I.C., is at present employed as field engineer with A. Janin and Company at Gaspé, Que. Lately he had been employed as assistant district engineer for the Civil Aviation Division of the Department of Transport.

W. G. Dyer, M.E.I.C., has been appointed division engineer with the Canadian Pacific Railway Company at Moose Jaw, Sask. He was previously located at Lanigan, Sask. He has been with the Canadian Pacific Railway Company ever since his graduation from the University of Saskatchewan in 1925.

C. H. McL. Burns, M.E.I.C., has recently been appointed assistant to the manager of munitions of Otis-Fensom Elevator Company Limited, at Hamilton, Ont.

R. K. Williams, M.E.I.C., has severed his connection with the Geo. S. May Company, and has accepted a position with Stevenson and Kellogg Limited, Toronto.

W. F. Campbell, M.E.I.C., is now employed with the Aluminum Company of Canada, Limited, at Arvida, Que. He was previously acting county engineer for the County of Holdimand at Cayuga, Ont.

Victor Michie, M.E.I.C., who is inspecting engineer with the Department of Munitions and Supply is temporarily located in Newfoundland. Mr. Michie is the chairman of the Winnipeg Branch of the Institute.

Eric Grant, M.E.I.C., has joined the Royal Canadian Air Force and is located at Halifax with the Works and Buildings Department. For the past two and a half years he was employed with the Canadian National Railways on design and drafting work for the Montreal terminal station.

J. S. Cooper, M.E.I.C., is now on active service with the Royal Canadian Navy and is attached to the Engineer-in-Chief's Division at Naval Service Headquarters, Ottawa. He had lately been employed as an inspector of tanks with the Inspection Board of the United Kingdom and Canada. Previously he was connected with the Wabi Iron Works Limited, at New Liskeard, Ont.

D. B. Rees, M.E.I.C., has been promoted from Flying Officer to Flight Lieutenant in the Royal Canadian Air Force. He is at present stationed with No. 4 Air Training Command at Regina.

A. M. Paull, M.E.I.C., has left the Department of Public Works, Highways Branch, of Alberta, and has been appointed a temporary Flying Officer with the Works and Buildings Department of the Royal Canadian Air Force at Edmonton.

J. A. Reynolds, M.E.I.C., has joined the staff of the Department of Munitions and Supply, Directorate of Engineering. He was previously employed as an aircraft inspector at Belleville, Ont.

G. R. Treggett, Jr.E.I.C., has severed his connection with the Montreal Tramways Company to accept a position with the Coca-Cola Company of Canada Limited at Montreal.

Squadron Leader A. D. Nesbitt, S.E.I.C., has recently received the Distinguished Flying Cross for his leadership and devotion to duty with the Royal Canadian Air Force in England. The citation of the Air Ministry states that "on a particular occasion in December, 1940, Nesbitt led a section of aircraft over the sea for two hours without wireless assistance in extremely adverse weather conditions. The visibility was practically nil. His judgment enabled the section eventually to land safely—although their petrol was practically exhausted—without loss to personnel. Nesbitt has destroyed two enemy aircraft." Squadron Leader Nesbitt has been in the thick of the fighting over Britain for the past fifteen months.

D. L. Rigsby, S.E.I.C., employed with the British Air Commission, has been transferred to Consolidated Aircraft Corporation at San Diego, Calif.

R. J. Brydges, S.E.I.C., has recently been transferred by the Northern Electric Company Limited from Montreal to Winnipeg. He was graduated from the University of Manitoba in 1938 and took a two-year apprenticeship course with A. Reyrolle & Company Limited, England. Upon his return to Canada in 1940, he joined the staff of the Northern Electric Company Limited in the Power Apparatus Division at Montreal.

H. W. Colditz, S.E.I.C., is now employed with the Bethlehem Steel Company, Shipbuilding Division, on Staten

Island, New York. He was graduated from McGill University last spring.

Jean Lacombe, S.E.I.C., is now employed with the Dominion Bridge Company Limited in the plate and tank department at Lachine, Que. Lately he had been on the staff of the Quebec North Shore Paper Company at Baie Comeau, Que.

W. B. McIntyre, Affl.E.I.C., who was employed with the Canadian National Railways at Toronto, has been transferred to Regina, Sask.

VISITORS TO HEADQUARTERS

T. Foulkes, M.E.I.C., Plant Engineer, J. R. Booth Co. Ltd., Ottawa, Ont., on August 22nd.

R. R. Oulton, Jr.E.I.C., Canadian Broadcasting Corporation, Sackville, N.B., on August 26th.

F. S. Small, M.E.I.C., Fraser Brace Co. Ltd., Montreal, on August 27th.

N. Beaton, M.E.I.C., Powell River, B.C., on August 29th.

J. W. Thompson, M.E.I.C., Debert Aerodrome, Debert, N.S., on August 29th.

G. B. Batanoff, S.E.I.C., Blaine Lake, Sask., on August 30th.

Geoffrey Stead, M.E.I.C., Saint John, N.B., on September 8th.

Jean Flahault, S.E.I.C., Aluminum Company of Canada, Arvida, Que., on September 10th.

K. M. Cameron, M.E.I.C., Chief Engineer, Department of Public Works, Ottawa, Ont., on September 13th.

R. M. Hardy, M.E.I.C., Professor of Civil Engineering, University of Alberta, Edmonton, Alta., Chairman Edmonton Branch, on September 15th.

J. L. Balleny, M.E.I.C., Canadian General Electric Co. Ltd., Toronto, Ont., on September 17th.

Mrs. F. A. Gaby, wife of Past-President Gaby, Toronto, Ont., on October 4th.

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Lionel Coke-Hill, M.E.I.C., died on July 7th, 1941, in England, as the result of an accident. He was born at Derby, England, on February 25th, 1872, and received his education at the local technical college, at the same time serving an apprenticeship in his father's office, the late A. Coke-Hill, architect.

From 1893 to 1902 he was employed as a draftsman and an inspection engineer in the engineering department of Bass & Company, Brewers, Burton-on-Trent, England. He came to Canada in 1903 and was employed for a few months with the Bell Telephone Company as draftsman and inspector of building construction in Montreal. In 1904 he joined the staff of J. A. Jamieson, grain elevator engineer, as a draftsman on concrete and steel elevator construction. He went to the United States in 1906 on similar work with the Macdonald Engineering Company at Chicago. The following year joined the staff of John S. Metcalf Company, in their Chicago office, and remained with this firm for a number of years. From 1908 until 1914 he was in Montreal as a designing engineer on Harbour Commissioners of Montreal and Canadian Pacific Railway elevators and many other plants of similar character. From 1914 to 1919 he travelled extensively in England, Siberia, Russia and France as European manager and engineer for the Metcalf Company. During the year 1919 to 1920 he was in charge of the company's business and construction of elevators at Buenos Aires, Argentine. He later returned to Montreal and became chief engineer and director of the company. For the past few years he had lived at Mickleover, Derby, England.

Mr. Coke-Hill joined the Institute as a Member in 1922.

Frederick George Cross, M.E.I.C., died at his home at Lethbridge, Alta., on September 9th, 1941, after a long illness. He was born at Exeter, Devonshire, England, on September 2nd, 1881, and received his education in the local schools, and in London.

He came to Canada in 1906 and entered the service of the Irrigation Department of the Canadian Pacific Railway Company on August 1st, 1907, at Calgary; from 1907 to 1914 he was engaged on location and construction of the irrigation systems, from rodman to general inspector, supervising concrete, steel and timber construction up to the time of his enlistment for overseas service in the last war. He served with the Canadian Railway Troops in France from 1915 to the termination of the war, retiring with the rank of Major. In 1919, Major Cross returned to the service of the Canadian Pacific Railway Company as canal superintendent at Brooks, Alta. In 1925 he was promoted to assistant superintendent of operation and maintenance of the Company's Lethbridge irrigation project, which position he held up to the time of his death.

F. G. Cross, M.E.I.C.

The late Mr. Cross was one of Canada's leading artists and his works hang in many parts of the world. At the early age of sixteen he exhibited two oil paintings in the Royal West of England Academy. During early construction days in Alberta he spent many evenings drawing and sketching animals on the range. Following the war he won a dual competition for a war memorial and record of service conducted by The Engineering Institute of Canada. Both bronzes are erected in the Institute's headquarters at Montreal. Paintings of the deceased are included in Canada's first water colour collection to Scotland in 1932-33. They are represented in Canada's collections to the Southern Dominions (Johannesburg Exposition). Some of his art was included in Canada's exhibition of paintings sent to London for the coronation of King George VI.

Some of Mr. Cross' works hang in Birmingham city's art gallery and many of his pictures are in private collections. He was a member of the Canadian Society of Painters in Water Colours, of whom there are only thirty-one in Canada. In 1937 he was honoured in his election by the Council of the Royal Canadian Academy as an associate member.

Mr. Cross joined the Institute as an Associate Member in 1912 and he was transferred to Member in 1932.

Alexander Scott Dawson, M.E.I.C., died on August 8th, 1941, at Guelph, Ont. He was born at Pictou, N.S., on September 6th, 1871, and received his education at McGill University, Montreal, where he was graduated in 1894. For three years after graduation he worked as assistant engineer with the Metropolitan Water Works Department at Boston, Mass. In 1899 he joined the Canadian Pacific Railway Company as assistant engineer at Winnipeg. In 1903 he became division engineer at Calgary, Alta. A year later he was made division engineer of the Company's irrigation department at Calgary, and in 1907 he became assistant chief engineer of the same department, later becoming chief engineer. In this capacity he had direct charge of the construction and operation of all the larger irrigation enterprises of the Company in Alberta. Since his retirement in 1932, he had lived in eastern Canada.

A. S. Dawson, M.E.I.C.

Mr. Dawson joined the Institute as a Student in 1889 and he was transferred to Associate Member in 1895. He became a Member in 1909 and was granted Life Membership in 1932. He was a charter member of the Calgary Branch of the Institute and was chairman of its Executive Committee in 1917. He was a vice-president of the Institute for 1925-1926.

Herbert Samuel Holt, LL.D., D.C.L., M.E.I.C., died at his home in Montreal, on September 28th, 1941, after a month's illness. He was born at Geashill, King's County, Ireland, on February 12th, 1856. He was educated at Albert Training Institute at Glasnerin, near Dublin. Upon receiving his diploma in engineering, land surveying and drafting, he came to Canada in September, 1873 and until December was employed as assistant to the engineer of the Toronto Water Works. From then until May 1874 he was assistant engineer and transitman on a topographical survey for the Credit Valley Railway, and following this became transitman and assistant engineer on the Victoria Railway. In the next year, he was division engineer on the Lake Simcoe Junction Railway, and he later returned to the Credit Valley Railway as engineer in charge of track, buildings, and bridges on 93 miles. When engaged on this work, Mr. Holt formed a friendship that was to have important developments. He met William (later Sir William) Mackenzie, and obtained a timber contract from him. In years to come these two men along with Donald (later Sir Donald) Mann, were associated in railway construction, public utility and other enterprises.

Mr. Holt's reputation as a railroad constructor was firmly established by the Credit Valley contract and when in the middle 80's James Ross, father of J. K. L. Ross, took over the task of building parts of the Prairie and British Columbia sections of the Canadian Pacific Railway, his young superintendent was placed in charge of the work. Mr. Holt later went into the contracting business for himself and under his direction stretches of the C.P.R. in Quebec, Maine and New Brunswick were built. Mr. Holt was one of the group who witnessed the historic ceremony of the driving of the last spike in the C.P.R. transcontinental line by Sir Donald Smith, subsequently Lord Strathcona and Mount Royal.

Mr. Holt also constructed railways in the United States and was a pioneer railroader in South America. He built a line over the Andes, after covering the whole ground with a surveying party on mule back.

He came to Montreal in 1901 and interested himself in the Montreal Gas Company. Then began the series of developments and mergers which resulted in the Montreal Light, Heat and Power Consolidated.

In 1908 Mr. Holt became president of the Royal Bank of Canada, which by absorbing such banks as the Union, the Traders, Northern Crown and Quebec, and acquiring the West Indian branches of the Colonial Bank of England, had widely extended its operations.

Mr. Holt received the honour of knighthood in 1915 for services to Great Britain during the Great War, when he made a survey of the war zone railways in France.

In recent years Sir Herbert had relinquished the presidency of the Montreal Light, Heat and Power Consolidated and of the Royal Bank of Canada, acting in each case as chairman of the board. He was director of a great number of companies as well as a governor of McGill University and president of the Royal Victoria Hospital in Montreal.

Sir Herbert S. Holt, M.E.I.C.

Sir Herbert was one of the senior members of the Institute, having joined as an Associate Member in 1889 and transferred to Member in December of the same year.

Earlier this year he was amongst the eight initial recipients of the Julian C. Smith Medal of the Institute granted "for achievement in the development of Canada." It had not been possible for Sir Herbert to be present at the annual meeting of the Institute last winter in Hamilton when these medals were presented, and it had been hoped that a special presentation could have been arranged this fall.

It may be appropriate to recall the citation which was read by the late General Sir Arthur Currie when he conferred upon Sir Herbert the honorary degree of LL.D., in 1927: "A leader endowed with strength for great responsibilities; clear sighted guide of many nationally important undertakings, who has devoted his organizing talents to Canadian industry; a believer in word and deed in Canadian capital for Canadian development; a citizen of firm faith in Canada's resources who has administered with broad vision a great many Canadian enterprises."

Robert Fitzgerald Uniacke, M.E.I.C., died suddenly at Toronto on August 25th, 1941. He was born at Sydney, Cape Breton, on April 10th, 1858, and obtained his education at King's College, now affiliated with Dalhousie University. He began his engineering career in 1880 when he was employed by the Nova Scotia Government on the construction of the Western Counties Railway. The same year he went to the United States to work on the location and construction of New York West Shore and Buffalo Railroad. From January, 1881, to October, 1883, he acted as assistant engineer on the construction of the Genesee Company division near Buffalo. He then returned to Canada and was engaged by the Nova Scotia Government as resident engineer on the Nova Scotia and Atlantic Railroad. A few years later he was employed with the Dominion Bridge Company in Montreal and the King Bridge Company in Cleveland. In 1904 he returned from Cleveland to become bridge engineer with the old National Transcontinental Railway and, during his ten years' association with the railroad, was responsible for all its bridges east of Winnipeg. Severing his connection with the railway in 1914, he was appointed chief penitentiaries engineer in the Department of Justice at Ottawa, and remained in this position until his retirement in 1926.

Two years before his retirement, he was awarded the Gzowski medal by the Institute in recognition of a paper he had prepared on the Salmon River viaduct in Quebec. During recent years he had lived abroad, returning to Canada in 1940.

Mr. Uniacke was one of the oldest members of the Institute, having joined as a Member the year of its incorporation as the Canadian Society of Civil Engineers in 1887. He acted as chairman of the Ottawa Branch for several years and was a councillor of the Institute from 1914 to 1916. He had been made a Life Member in 1926.

QUEBEC BRANCH

Paul Vincent, M.E.I.C. - *Secretary-Treasurer*

Le premier tournoi annuel de golf de la section de Québec, disputé sur les terrains du Royal Quebec Golf Club à Boischatel, le 15 septembre 1941, a été couronné d'un remarquable succès, en dépit de la mauvaise température. Le brillant soleil du début de l'après-midi fit place, vers les 4 heures, à une pluie torrentielle qui cependant ne réussit pas à décourager les joueurs. Les dames en particulier, qui avaient été invitées à prendre part au tournoi, firent preuve d'un excellent esprit sportif, et continuèrent la partie jusqu'à la fin.

Entre le dix-huitième et le dix-neuvième. M.M. Lionel Bizier, L. C. Dupuis, P.-A. Dupuis, le champion, et Lucien Martin.

La coupe donnée par la maison Geo. T. Davie & Sons, fut gagnée par P. A. Dupuis du Ministère des Travaux Publics qui enregistra le meilleur score brut. Le vainqueur devra défendre avec succès son titre pendant deux autres années consécutives, pour que la coupe emblématique du championnat reste en sa possession définitivement. Le "runner up" fut Lionel Bizier, du Port de Québec, qui enregistra deux coups de plus que le champion.

Pour le meilleur score net, la palme revient à Gustave St-Jacques, de la Régie des Services Publics. Huet Massue, de Montréal, le suivit de près.

Chez les dames, Mademoiselle Charlotte Dupuis, fille du président de la section de Québec de l'Institut, enregistra le meilleur score brut, tandis que le crédit pour le meilleur score net revient à Madame Léo Roy.

De nombreux prix de valeur, gracieusement offerts par différentes maisons de commerce de Québec, furent distribués aux vainqueurs à l'issue des matches.

Au diner qui suivit, dans le chalet du club, le président L. C. Dupuis avait avec lui à la table d'honneur, Hector Cimon, vice-président de l'Institut choisi pour l'an prochain, et Huet Massue, de Montréal, conseiller de l'Institut.

Le diner fut suivi d'une danse dans les salons du club.

Tous ceux qui ont pris part à cette fête, s'accordent pour reconnaître son succès, et se promettent d'y revenir l'an prochain.

Parmi ceux qui ont bravé la pluie, M.M. Edouard Gaudette, Ludger Gagnon, Joachim des Rivières Tessier, Huet Massue et Hector Cimon.

Groupe des golfeurs après le tournoi. Assis de g. à d.: M.M. Huet Massue, de Montréal; L. C. Dupuis, président de la Section de Québec; Louis Trudel, de Montréal; Hector Cimon, Adhémar Laframboise et Paul Vincent, secrétaire de la Section, tous trois de Québec.

ECPD ANNOUNCE ANNUAL MEETING IN NEW YORK CITY ON OCTOBER 30, 1941

The annual meeting of the Engineers' Council for Professional Development, although last year held in Pittsburgh, will this fall again return to its customary meeting place in New York City. The date selected, Thursday, October 30, follows immediately the yearly sessions of the National Council of State Boards of Engineering Examiners, which are also scheduled for New York on the three preceding days, October 27-29.

Although these two organizations are not meeting jointly, nevertheless it is expected that there will be a generous overlapping of attendance, and the focus for joint attendance is the annual banquet of the National Council of State Boards of Engineering Examiners on Tuesday evening. Similarly, the annual dinner of ECPD on Thursday evening is expected to attract many of those who are delegates to the earlier convention.

Three sessions of the ECPD meeting are in prospect for Thursday. In the forenoon reports from various committees will be received and discussed. Following lunch there will be an executive session, devoted to accrediting and similar confidential features of the work. At dinner the programme will be attuned to the special professional problems incident to the present national emergency.

The fine work being done by ECPD should be a matter of pride and interest to all engineers. Those interested are encouraged to attend the public meetings including the dinner at the Engineers' Club. Sessions will be held at the Engineering Societies Building. The chairman of ECPD is Robert E. Doherty, president of the Carnegie Institute of Technology, and for 1940-41 George T. Seabury, secretary of the American Society of Civil Engineers, is secretary.

ANNUAL CONVENTION, CANADIAN INSTITUTE OF SEWAGE AND SANITATION

The Annual Convention of the Canadian Institute on Sewage and Sanitation will be held at the Walper House, Kitchener, Ont., on October 16th and 17th. The programme will consist of four written papers and four guided discussions, Municipal plumbing, by-laws, treatment of activated sludge, refuse collection and salvage of wastes, and treatment by sprinkling filters will be among the subjects discussed; while the written papers will deal with sludge disposal, laboratory control in sewage treatment, the Grand River Conservation Project, and the cleaning and maintenance of sewers. A large attendance is expected.

POST-WAR CONSTRUCTION PROGRAMME

The minutes, recently issued, of the annual meeting of the National Construction Council of Canada, held at Toronto on May 29th, carry interesting news to the construction industry. The Council has appointed a standing committee to study and make plans for a post-war programme of construction along the lines of the recommendations made at the Government sponsored Conference of Building Trades Employers and Employees, held at Ottawa last winter. These recommendations are as follows:

1. Extension of the present Federal Housing Act and the broadening of its provisions to include opportunities for those in business to secure the same measures of assistance as other citizens.

2. Re-inauguration of the Home Improvement Plan and the broadening of this measure to include opportunities for small business men to secure assistance for necessary extensions.

3. A slum clearance programme and development of modern housing and town schemes, planning landscaping and garden home plans, and playground and park improvements.

4. Large scale development for the utilization of water power for the creation of electrical energy compatible with increased demands and modern development.

5. Reforestation.

6. Continuation and extension of the Prairie Farm Rehabilitation Scheme.

7. Highway development, to be progressively continued, that access may be provided to the national scenic beauties of Canada with the object of encouraging tourist traffic now recognized to be an important national asset.

8. Diversion and conservation of waters for a greater use of our lakes and rivers as a means of pure water supply.

9. Construction of sewage disposal plants for preventing the contamination of our lakes and rivers.

10. In the interests of health and sanitation, provision should be made to meet the requirements of numerous municipalities in Canada which lack the facilities of procuring a fresh water supply and proper disposal of sewage.

11. Extension to farmers of the advantages of science, by the installation of modern methods of sanitation and electrical energy.

12. Grade crossing elimination.

13. In co-operation with provincial and municipal authorities, undertake a survey of possible requirements of public buildings and schools and the establishment of a system of modernization.

14. To provide measures of protection for health, we suggest extensive development of a system of public baths and swimming pools and other recreation facilities.

SEPTEMBER JOURNALS REQUIRED

There has been an unusual demand for extra copies of the September, 1941, issue of *The Engineering Journal* and it would be appreciated if members who do not retain their copies would return them to Headquarters, at 2050 Mansfield Street, Montreal, Que.

ADDITIONS TO THE LIBRARY

TECHNICAL BOOKS

Aerosphere:

Edited by Glenn D. Angle. Including modern aircraft, modern aircraft engines, aircraft statistics, buyer's guide. New York, Aircraft publications, 1941. 8¾ x 11¾ in.

Design of Modern Steel Structures:

By Linton E. Grinter. New York, MacMillan Company, 1941. 6 x 9¼ in. $5.00.

Elements of Engineering Thermodynamics:

By James A. Moyer, J. P. Calderwood and Andrey A. Potter. 6th ed., rewritten. New York, John Wiley & Sons, 1941. 9¼ x 6 in. $2.50.

Experiments upon the Flow of Water in Pipes and Pipe Fittings:

By John R. Freeman. New York, American Society of Mechanical Engineers, 1941. 11¾ x 9¼ in.

Handbook of Chemistry:

Compiled and edited by Norbert A. Lange; a reference volume for all requiring ready access to chemical and physical data used in laboratory work and manufacturing. Sandusky, Handbook Publishers, Inc., 1941. 5½ x 8 in.

Metal Processing:

By Orlan William Boston. New York, John Wiley & Sons, Inc., 1941. 6 x 9¼ in. $5.00.

REPORTS

American Society of Mechanical Engineers:

Sixty-year index to A.S.M.E. technical papers, 1880-1939. New York, 1941.

American Society for Testing Materials:

Symposium on Colour—its specification and use in evaluating the appearance of materials. Philadelphia, American Society for Testing Materials, 1941.

British Standards Institution—Specifications:

Silver solder (grades, A, B and C), revised June, 1941; brass tubes, tubes for screwed glands and screwed glands for condensers, revised February, 1941; Hard drawn phosphor bronze wire, 1941; Naval brass die castings, October, 1940; Brass cravity die-castings, November, 1940; Cast brass bars (suitable for forging) and forgings, March, 1941; Leaded bronze ingots; leaded bronze castings. Nos. 206, 378, 384, 920, 932, 944, 960, 961, 962, 963, 964, 965.

Canada—Dominion Bureau of Statistics:

Libraries in Canada, 1938-40. Ottawa, 1941.

Canadian Engineering Standards Association—Specifications:

Canadian Electrical Code, part 2—Construction and test of all-asbestos and asbestos varnished cambric insulated wires and cables. Ottawa, May, 1941.

Electrochemical Society—Preprints:

Rochelle copper plating; Deposition potentials of cobalt nickel, and copper from chloride and bromide solutions; Contamination and electrolytic and cleaning of cold rolled steel; Solvent effect on semiquinone redox equilibria, effect of forming temperature on lead storage battery anodes; iron deposition; acid zinc plating; insoluble anodes in the electrolysis of zinc sulfate containing chlorine in solution.

National Council of State Boards of Engineering Examiners:

Digest of state laws governing the practice of professional engineering and land surveying. Columbia, April, 1941.

Ontario, Department of Mines

Forty-ninth annual report, volume 49, pt. 1, 1940. Toronto, 1941.

Quebec, Professional Engineers of Quebec:

Official list of members of the Corporation of professional engineers of Quebec, June, 1941.

Quebec, Statistical Year Book:

Statistical year book. Quebec, 1940. Quebec, 1941.

United States Department of the Interior—Bureau of Mines—Bulletin:

Contributions to the data on theoretical metallurgy; Petroleum and natural-gas fields in Wyoming. Bulletins, 434, 418.

United States Department of Commerce—Building Materials and Structures:

Structural and heat-transfer properties of "U.S.S. Panelbilt". Prefabricated sheet-steel constructions for walls, partitions and roofs. BMS74.

Highway Research Board:

Proceedings twentieth annual meeting, 1940. Washington, 1941.

National Asphalt Conference:

Proceedings of the thirteenth National Asphalt Conference, Dallas, Texas, 1940.

Society for the Promotion of Engineering Education:

Proceedings of the sixth annual meeting of the Allegheny section. Pittsburgh, Carnegie Institute of Technology, 1940.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet the books are not in the Institute Library, but inquiries will be welcomed at headquarters, or may be sent direct to the publishers.

ACCOUNTING FOR ENGINEERS

By J. R. Bangs and C. R. Hanselman. International Textbook Co., Scranton, Pa., 1941. 532 pp., illus., diagrs., charts, tables, 9½ x 6 in., fabrikoid, $4.00.

The subject material of this textbook, which is amplified by many diagrams, tables and examples, is divided into five major sections: theory of debit and credit; procedure at end of fiscal period; accounting practice; accounting applications; and costs. The method of presentation permits the use of the book as a general text in basic accounting principles. Sample financial statements are appended.

(The) AUTOMOBILE INDUSTRY, the the Coming of Age of Capitalism's Favorite Child

By E. D. Kennedy. Reynal & Hitchcock, New York, 1941. 333 pp., tables 9 x 6 in., cloth, $3.50.

Once more the genesis, development and current trends of the automobile industry are presented as a shining example of American industrial progress. Full of facts and figures, the separate chapters picture in strict chronological order the achievements and vicissitudes which have attended the making and selling of automobiles through the last five decades.

BETTER FOREMANSHIP

By G. Gardiner. 2 ed. McGraw-Hill Book Co., New York, 1941. 336 pp., tables, 8 x 5 in., cloth, $2.50.

In a direct, practical question-and-answer treatment this book presents modern industrial management for foremen. The subjects covered were chosen to give the foreman help both with fundamental functions and practices of foremanship and with the new problems resulting from recent changes in working conditions, labor relations and industrial methods.

(The) DESIGN OF MANUFACTURING ENTERPRISES, a Study in Applied Industrial Economics

By W. Rautenstrauch. Pitman Publishing Corp., New York and Chicago, 1941. 298 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $3.50.

Profitable operation of large and small manufacturing businesses is dependent on their efficient economic design. This book makes available the principles and methods of the economics of manufacture taken from practical experience in the designing of new, or the redesigning of existing businesses for improved operating characteristics. The first part of the text deals with business as a whole; the second, with selected problems from both process and mechanical industries.

DESIGN OF MODERN STEEL STRUCTURES

By L. E. Grinter. Macmillan Co., New York, 1941. 452 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $5.00.

This book and Vol. I of the author's "Theory of Modern Steel Structures" are intended to furnish the requisite material for undergraduate courses in statically determinate structures. A somewhat novel arrangement presents first the chapters on riveted, welded and other connections. Then follow chapters on tension and compression members, beams and girders, and stress determinations. Design procedures for roofs, truss bridges, buildings and continuous beams end the book, with the exception of a section giving abbreviated specifications issued by various engineering associations.

DIRECTORY OF MICROFILM SOURCES including Photostat Service,

Compiled by R. C. Cibella. Special Libraries Association, New York, 1941. 56 pp., diagrs., 10 x 7 in., paper, $0.75.

The main section in this timely directory is an alphabetical list of more than two hundred libraries and commercial firms which offer microfilm, photograph and photostat services. Microfilm collections are also indicated, and a geographical index to the list is provided. The reproduction of sample order forms from many of these sources adds a practical touch.

ELECTRO-PLATING AND ANODISING

By J. Rosslyn. Chemical Publishing Co., Brooklyn, N.Y., 1941. 224 pp., illus., diagrs., charts, tables, 9 x 5½ in., cloth, $2.50.

General principles and industrial processes for gold, silver, nickel, copper, chromium, cadmium and zinc plating are covered. Separate chapters deal with a number of specialized applications of electrodeposition such as in the printing industry, the hardware trade, etc. The final chapter is devoted to anodising and aluminum plating.

EMULSIONS AND FOAMS

By S. Berkman and G. Egloff. Reinhold Publishing Corp., New York, 1941. 591 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $8.50.

The importance of emulsions and foams in many industries, particularly the oil industry, has led to progressive development in their control. This monograph begins with a detailed treatment of the theory of emulsions and foams, continues with several chapters dealing with the practical knowledge and application of these states of matter, and concludes with a description of the laboratory methods used in the examination of emulsions. The bibliographies are extensive.

FRASER AND JONES' MOTOR VEHICLES AND THEIR ENGINES

By N. G. Shidle and T. A. Bissell with the assistance of T. Francis. 5 ed. D. Van Nostrand Co., New York, 1941. 339 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $2.50.

This book is designed to give a clear knowledge of the theory of operation and maintenance of modern automobiles to beginning students. Current design and practice are emphasized, and for practical purposes most chapters contain information on likely troubles, their reasons and common remedies. The descriptive material is confined to examples from the passenger-car field, but a considerable portion of this and the whole final chapter are applicable to motor trucks.

GAS-LIFT PRINCIPLES AND PRACTICES

By S. F. Shaw. Gulf Publishing Co., Houston, Texas, 1939. 156 pp., illus., diagrs., charts, tables, 9 x 5½ in., lea., $3.00.

The first half of this book is devoted to the history, principles and operation of gas-lift and its equipment, including a considerable amount of gas-lift performance data. The later chapters cover compressor plant installations and examples of actual gas-lift practice in various fields both domestic and foreign.

HANDLING AND STOWAGE OF CARGO

By A. G. Ford. International Textbook Co., Scranton, Pa., 1941. 213 pp., illus., diagrs., charts, tables, 8½ x 5 in., cloth, $2.25.

Efficient modern methods for packing and arranging commodities in a vessel for transportation by sea are described for the use of those engaged in directing, handling or arranging for such shipments. Review questions accompany each chapter, and practical arithmetical examples are included.

Imperial Institute, Plant and Animal Products Department

CHICLE, JELUTONG AND ALLIED MATERIALS (reprinted from the Bulletin of the Imperial Institute)

By E. H. G. Smith. Imperial Institute, London, 1940. 22 pp., tables, 9½ x 6 in., paper, 1s. (obtainable from British Library of Information, 620 Fifth Ave., New York, $0.30).

A reprint from the Bulletin of the Imperial Institute, this pamphlet deals with the botany collection and preparation, production and economics of chicle, jelutong and other similar substances used as a base for chewing gum. A list of references to other publications is included.

INTRODUCTION TO GEOLOGY

By E. B. Brenson and W. A. Tarr. 2 ed. McGraw-Hill Book Co., New York and London, 1941. 482 pp., illus., diagrs., charts, maps, tables, 9 x 6 in., cloth, $3.75.

Intended as a general text for students not majoring in geology as well as for those who are, this book avoids technicalities in presenting the outstanding principles of the subject. The fundamentals of both physical and historical geology are covered. Over four hundred photographs, maps and diagrams aid the beginning student in understanding the text.

(The) MANAGERIAL REVOLUTION, What Is Happening in the World

By J. Burnham. John Day Co., New York, 1941. 285 pp., 8½ x 5½ in., cloth, $2.50.

The author submits the thesis that the running of the world is coming under the control of "managers," "managers" being defined as those who direct activities and do not come within either the capitalist-owner or the labor group. Reasons are advanced to show why the capitalist regime is doomed, and why socialism will not be the displacing system.

MATHEMATICAL TABLES

By H. B. Dwight. McGraw-Hill Book Co., New York, 1941. 231 pp., tables, 9½ x 6 in., cloth, $2.50.

The values of both natural functions and logarithms of trigonometric functions are given to four or five places of decimals in hundredths of degrees rather than minutes and seconds. Exponential, hyperbolic and other commonly used functions are also included. Tabular differences are included wherever desirable.

METAL PROCESSING

By O. W. Boston. John Wiley & Sons, New York; Chapman & Hall, London, 1941. 630 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $5.00.

This volume constitutes a revision of the author's "Engineering Shop Practice" consolidated with more recent data. All steps involved in designing for production are covered briefly in the first chapter; manufacturing drawing, analysis and form of material used, operations and equipment desired, and plant layout. Subsequent chapters treat in detail the various classes of machines and processes and other factors dependent upon conditions of quantity and quality. A bibliography accompanies each chapter.

MODERN HIGHER PLANE GEOMETRY

By A. S. Winsor. Christopher Publishing House, Boston, Mass., 1941. 214 pp., diagrs., 8 x 5½ in., cloth, $2.25.

A résumé of some of the more familiar and important ideas in high school geometry is given in the first chapter. The author then presents, in the standard theorem, proof and exercise manner, certain advanced geometrical concepts concerning loci, harmonic ranges, polars, etc. Important features are a complete treatment of analysis and a discussion of the escribed circles of a triangle.

MODERN METALLURGY FOR ENGINEERS

By F. T. Sisco. Pitman Publishing Corp., New York and Chicago, 1941. 426 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.50.

This concise study of recent developments in ferrous and non-ferrous metallurgy provides essential data on the engineering properties of metallic materials, the variables affecting these properties, and their significance to engineers. The relation between constitution and structure of materials and properties is briefly shown in an elementary discussion of fundamental modern concepts of physical metallurgy. Review questions and a bibliography are appended.

OIL BOOM, the Story of Spindletop, Burkburnett, Mexia, Smackover, Desdemona, and Ranger

By B. House. Caxton Printers, Caldwell, Idaho, 1941. 194 pp., illus., 9½ x 6 in., cloth, $3.00.

The oil fields of Texas, Oklahoma and Arkansas in their early days presented a frenzied scene. The author has put into his book the personalities, boom town activity, fantastic profits and sad disillusionments which contributed to this brief phase of American history.

(The) PHOTOCHEMISTRY OF GASES (American Chemical Society Monograph No. 86)

By W. A. Noyes and P. A. Leighton. Reinhold Publishing Corp., New York, 1941. 475 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $10.00.

Photochemistry, the study of the effects produced on chemical systems by the action of electromagnetic radiations, is a progressing field. One portion, that of reactions in the gas phase, is considered in this monograph. The early chapters define the work, describe experimental techniques and present a survey of spectroscopy. Photochemical kinetics and the reactions following absorption by various atoms and molecules are discussed. A considerable amount of photochemical data in tabular form is given in appendices, and there is a large bibliography.

PLANE FACTS FOR AIRPLANE AND ENGINE MECHANICS

By B. A. Kutakoff. Military Book Co., New York, 1941. 241 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, $1.75.

This practical manual for airplane and engine mechanics presents the latest design and manufacturing practice in order to give an understanding of the structure of planes and engines. Maintenance and repair are also covered, and an extensive question and answer system facilitates review. The material conforms to Civil Aeronautics Administration regulations and practices.

PRINCIPLES OF MAGNAFLUX INSPECTION

By F. B. Doane. Magnaflux Corp., Chicago, 1940. 133 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $2.50.

This description of magnaflux inspection methods covers equipment, processes, the inspection medium, detectible defects, demagnetization and the evaluation of indications. There is a separate chapter on weld inspection. Basic physical principles are discussed briefly, and there is a bibliography.

REINFORCED CONCRETE CHIMNEYS

By C. P. Taylor and L. Turner. Concrete Publications, Ltd., London, 1940. 66 pp., illus., diagrs., charts, maps, tables, 9½ x 6 in., cardboard, $3.50 (obtainable from Engineers Book Shop, 168 East 46th St., New York).

This practical manual deals with the design of reinforced concrete chimneys in accordance with modern British practice. Standard types are described, design data are given for all important factors, and there is a chapter dealing with flue openings, linings, bands and other specific features. Special attention is paid to the scientific calculation of the stresses caused by hot gases.

RUNNING A MACHINE SHOP

By F. H. Colvin and F. A. Stanley. McGraw-Hill Book Co., New York and London, 1941. 449 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $3.50.

A practical manual which gives owners and managers of machine shops valuable pointers for more efficient and profitable operation. It covers everything from shop layout to inspection methods—equipment, routing and work handling, estimating, training of workers, etc. Methods and suggestions have been taken from the practice of leading shops of all types and sizes.

SAMPLING AND CHEMICAL ANALYSIS OF CAST FERROUS METALS (Special Publication No. 7, March, 1941)

By E. T. Austin. British Cast Iron Research Association, Birmingham, England. rev. and enl. ed. 140 pp., diagrs., tables, 10 x 6 in., linen, apply.

This manual has been prepared for the use of chemists and metallurgists in works and other laboratories. Sampling procedure and general laboratory technique are described, and detailed directions are given for the analysis of pig iron, plain, malleable and alloy cast irons, and ferro-alloys. Brief references to theory are included.

SCIENCE EXPERIENCES WITH TEN-CENT STORE EQUIPMENT

By C. J. Lynde. International Textbook Co., Scranton, Pa., 1941. 256 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, $1.60.

As indicated by the title, this small book contains a selection of simple experiments based on scientific principles. This third volume of a series designed primarily for high school classes deals with sound, light, electricity and magnetism. Explanations of the effects are given at the back of the book.

SURFACE TENSION AND THE SPREADING OF LIQUIDS (Cambridge Physical Tracts)

By R. S. Burdon. University Press, Cambridge, England; Macmillan Co., New York, 1940. 85 pp., illus., diagrs., charts, tables, 9½ x 5½ in., paper, $1.75.

This latest addition to a series of authoritative accounts of topical physical subjects discusses the general conditions affecting the spreading of liquids, and gives some account of various investigations based on the phenomena of spreading. In the last chapter dealing with liquids on the surface of solids, certain technical aspects are considered.

TEXTBOOK OF SOUND

By A. B. Wood. Macmillan Co., New York, 1941. 2 rev. ed. 578 pp., illus., diagrs., charts, tables, 9 x 5½ in., cloth, $6.50.

Subtitled "an account of the physics of vibrations with special reference to recent theoretical and technical developments," this text treats of vibrations of all frequencies, audible or otherwise. Vibrating systems and sources of sound are thoroughly covered, following a section on vibration theory. Sound transmission and the reception, transformation and measurement of sound energy are discussed. The final section deals with various important technical applications.

(The) THEORY OF RATE PROCESSES

By S. Glasstone, K. J. Laidler and H. Eyring. McGraw-Hill Book Co., New York and London, 1941. 611 pp., diagrs., charts, tables, 9 x 6 in., cloth, $6.00.

This book describes the development and application of a general theory of the kinetics of physical and chemical processes, usually known as the "theory of absolute reaction rates." The fundamental bases are explained, and homogeneous and heterogeneous gas reactions, reactions in solution, fiscosity, diffusion, and electrochemical phenomena are considered in terms of the theory.

TRAINING WORKERS AND SUPERVISORS

By C. Reitell. Ronald Press Co., New York, 1941. 182 pp., tables, charts, 8½ x 5½ in., cloth, $1.50.

This volume of training procedures is designed for executives of plant organizations which are undergoing rapid expansion. The first part deals with the principles and methods for selecting men employees. The succeeding sections cover specific training methods for quality and quantity production and the problems of human relations. There is a list of selected references.

AMOS EATON, Scientist and Educator, 1776-1842

By E. M. McAllister. University of Pennsylvania Press, Phila., 1941. 587 pp., illus., 9½ x 6 in., cloth, $5.00.

Amos Eaton, the founder, with the backing of Stephen Van Rensselaer, of what is now Rensselaer Polytechnic Institute, lived an eventful life. This exceedingly well-documented biography describes his early life, his ill-starred business and legal career, his noteworthy ventures into the natural sciences, particularly geology, and his final success as an educator.

AUDELS MACHINISTS AND TOOL MAKERS HANDY BOOK

By F. D. Graham. Theodore Audel & Co., New York, 1941. Section A, 1,126 pp., Section B, 98 pp., Section C, 300 pp., Section D, 42 pp., Section E, 10 pp., illus., diagrs., charts, tables, 7 x 5 in., cloth, $4.00.

The purpose of this book is to provide a complete course of study for those desiring to become machinsts, and to help machinists become tool makers. In considering each machine, the author first explains how it works, then describes its construction, and finally gives detailed instructions for all machining operations. Blueprint reading, shop mathematics and other useful topics are included. The book is profusely illustrated.

AUDELS NEW ELECTRIC SCIENCE DICTIONARY

By F. D. Graham. Theodore Audel & Co., New York, 1933, reprinted 1939. 525 pp., 7 x 5 in., cloth, $2.00.

Over nine thousand words, terms and phrases used in theoretical and applied electricity are defined in this dictionary. Numerous terms in related and independent subjects have been included to increase the utility of the work, and extended explanations are given for the more important entries.

CHEMISTRY OF PULP AND PAPER MAKING

By E. Sutermeister. 3 ed. John Wiley & Sons, New York, 1941. 529 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $6.50.

The important materials and processes in pulp and paper making are discussed with the object of giving all details which the chemist should have to understand the methods of manufacture. The mechanical features are subordinated to the chemical, and common methods of analysis, available elsewhere, are minimized in favor of more specialized material. Separate chapters are devoted to paper testing and printing. There are chapter bibliographies.

CIVIL PROTECTION, the Application of the Civil Defence Act and Other Government Requirements for Air Raid Shelters, etc.

By F. J. Samuely and C. W. Hamann. The Architectural Press, 45 The Avenue, Cheam, Surrey, England, 1939. 168 pp., diagrs., charts, tables, 13 x 9 in., cloth, 8s. 6d.

This practical manual presents an analysis and explanation of the British Government standards for the protection of civilians as required by the Civil Defence Act, and as set out in the publications of the several Ministers. All phases of the design and construction of air-raid precaution works, including the action and effects of bombs, are discussed, with numerous suggestions and recommendations. Architectural details are shown for all construction work.

DEVELOPMENT OF THE SCIENCES, 2nd series

By O. Ore, F. Schlesinger and others, edited by L. L. Woodruff. Yale University Press, New Haven, 1941. 336 pp., woodcuts, diagrs., 9½ x 6 in., cloth, $3.00.

This second series of published lectures (the first series appeared in 1923) comprises discussions by eight Yale scientists representing the fields of mathematics, astronomy, chemistry, physics, geology, biology, psychology and medicine. Each of the first seven lectures traces the development of basic sciences from their beginnings to the most recent results. The last lecture shows the interdependence of these various sciences as illustrated by specific examples in the history of medicine. The chapter bibliographies are brought together at the end of the book.

FIRE-HAZARD PROPERTIES OF CERTAIN FLAMMABLE LIQUIDS GASES AND VOLATILE SOLIDS

Compiled by Committee on Flammable Liquids of the National Fire Protection Association. Revised ed., 1941. National Fire Protection Association, 60 Batterymarch St., Boston. 48 pp., tables, 9 x 6 in., paper, 25c.

Over four hundred flammable liquids, gases and volatile solids are included in the table of data compiled in this pamphlet. In addition to the information upon fire-hazard properties there is also a column indicating the proper extinguishing agent for each material.

MINING ENGINEERS' HANDBOOK, 2 Vols.

By R. Peele, with the collaboration of J. A. Church. 3 ed. John Wiley & Sons, New York, 1941. Paged in sections, diagrs., charts, tables, 9 x 5½ in., lea., $15.00.

The long-awaited new edition of Peele's Mining Engineers' Handbook appears in two volumes, owing to the great expansion of the work. The extensive revision throughout the text includes new sections on petroleum production and geophysical prospecting, and much information concerning new methods and devices in mining practice. The comprehensive character of the book is retained and is evidenced by the large amount of useful data on machinery, power plant, electric transmission, structural design and metallurgy, for which the mining engineer often has need. A bibliography accompanies each section, and both volumes contain the complete index.

PRELIMINARY NOTICE

of Applications for Admission and for Transfer

September 29th, 1941.

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.–

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described at the November meeting.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science or engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

FARSTAD—CHARLES, of Grand'Mere, Que. Born at Meskanaw, Sask., Oct. 24th, 1914; Educ.: B.Eng. (Mech.), Univ. of Sask. 1941; 1938 (summer) chainman, rodman and instr'man. on survey for Cons. Mining & Smelting Co. at Kimberley, B.C.; 1940 (summer), constrn. and mtce. of large saw mill at Wynndel, B.C.; May 1941 to date, asst. engr., mech. dept., Laurentide Divn., Consolidated Paper Corpn. Ltd., Grand'Mere, Quebec.

Employment Service Bureau

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.

SITUATIONS VACANT

EXPERIENCED MECHANICAL DESIGNING DRAUGHTSMAN for general mechanical work and industrial piping. Apply Box No. 2375-V.

EXPERIENCED ARCHITECTURAL DRAUGHTSMEN required by large industrial concern for their Montreal office. Apply Box No. 2376-V.

JUNIOR CHEMICAL OR METALLURGICAL ENGINEER for work in plant installation and operation. Required immediately. Apply Box No. 2400-V.

STRUCTURAL AND CONCRETE DRAUGHTSMEN for industrial plant design. Apply Box No. 2401-V.

TIME AND MOTION STUDY: Opportunity for man who can prove his ability in setting of wage incentive standards, methods analysis, and plant layout. Give experience in detail. Address reply to Box No. 2439-V.

JUNIOR RESEARCH METALLURGIST required immediately, with one to five years experience. Apply Box No. 2440-V.

MECHANICAL GRADUATE ENGINEER, with machine shop experience, required for work in South America on important war contract. Apply Box No. 2441-V.

SALES ENGINEER with excellent technical or industrial qualifications, for work largely in the electrical industry. This is a splendid opportunity for a good man. Employment will be permanent. State training, experience and other qualifications. Apply Box No. 2451-V.

YOUNG ENGINEER wanted for newly opened Canadian office in Montreal, by a British company of furnace engineers, with headquarters in England and a branch in the U.S.A. Position with good prospects. Essential that applicants be good draughtsmen and desirable that they have shop experience. They must be willing to travel in Canada and the U.S.A. Apply Box No. 2452-V.

SITUATIONS WANTED

ELECTRICAL ENGINEER, B.Sc. in electrical engineering, age 43, married, available on two weeks notice. Fifteen years experience in electrical work. Including electrical installations of all kinds in hydro-electric plants and sub-stations. Maintenance and operation of hydro-electric plants. Electrical maintenance and installations in pulp and paper mill. Considerable experience on relays and meters. At present employed, but desires change. Apply Box No. 636-W.

GRADUATE CIVIL ENGINEER, M.E.I.C., 15 years engineering on this continent and five years overseas. Experienced in design and construction of dams, hydro-electric and industrial plants. Field engineer for construction on dams and transmission lines, considerable experience in concrete work. Desires position preferably as field engineer or construction superintendent. Apply Box No. 1527-W.

ELECTRICAL ENGINEER, Age 32 with the following experience—Eight years field work in general construction, supervision, estimating and ordering materials. At present employed in general construction but wants to enter the electrical field. Apply Box No. 1992-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, married. Two years city engineer, five years experience in highway work, including surveying, location, construction, estimating and inspection. Apply Box No. 2409-W.

ELECTRICAL ENGINEER, B.E., in electrical engineering, McGill University, Age 24, married, available on two weeks notice. Undergraduate experience, cable testing and cathode ray oscillography. Since graduation, five months on construction of large and small electrical equipment in plant and sub-station. One year operating electrical engineer in medium size central steam station paralleled with large Hydro system. At present employed, but is interested in research or teaching. Associate member of the American Institute of Electrical Engineers. Apply to Box No. 2419-W.

FOR SALE

Transit, Buff and Buff Mfg. Five-inch circle, brass telescope and sliding leg tripod. One nick in the vertical half-circle, but no other damage. Thirty-year old instrument, but not much used. Would sell for $225.00. Apply Box No. 45-S.

RESEARCH IN WOOD AIDING WAR EFFORT

Research on wood products is playing an important part in Canada's war effort, reports the Forest Products Laboratories of the Department of Mines and Resources. Ordinarily the manufacture and use of wood are associated with peacetime activities rather than with destructive warfare, but research work carried out in the past two years reveal that wood is a vital material for a wide range of war purposes.

Many and varied are the uses to which wood is being put during the present conflict, and technical problems in connection with its utilization have involved extensive laboratory investigation. The facilities of the laboratories have been utilized in planning the construction of wooden aerodromes and military camps; in the fire-retardant treatment of wood and plywood for military and naval requirements, and in the preservative treatment of timbers. Research has made possible amendments to United Kingdom specifications for wood used in war equipment built in Canada so as to permit using Canadian species as far as practicable instead of imported timber.

Problems relating to the design and testing of shipping containers of wood, fibreboard, corrugated board, and plywood for the consignment of munitions, foodstuffs and equipment, and the use of Canadian species of wood and plywood in the construction of aircraft, pontoons, life-rafts, and boats have been dealt with. Investigations have been made of types of glue required for different purposes, such as waterproof resin glues used in plywood for house siding, concrete forms, collapsible boats, ships' sheathing, aeroplane covering, and other exposed uses. The seasoning of timber for specific purposes calling for accurate control of moisture, as in the case of wooden airscrews, and the use of resinbonded, compressed plywood to replace metal for certain structural parts of war equipment have also received attention.

Wood is also used in the manufacture of pulp for cartridge wrappers and of gun cotton, smokeless powders, photographic film, collodion and celluloid plastics. Wood flour is used in the manufacture of dynamite for construction and demolition work. Producer-gas from wood or charcoal may be used as a fuel for internal combustion engines to curtail importation of gasoline and diesel oil. Charcoal from Canadian hardwoods is being used extensively in the manufacture of certain alloys used principally in the construction of aircraft.

Wood is being put to numerous other uses to serve the war effort, and many of the lessons learned from the present emergency indicate important fields for further exploration under more favourable circumstances.

SHEET GLASS NOW MADE IN CANADA

When the German hammer smashed at the Lowlands, the glass industry—like many others—became a refugee. The glassmakers sailed to Canada, bringing with them their ancient heritage, and European skill was wedded to the Dominion's resources to create a new industry in this country. Early this summer the only glass factory in the Dominion at present producing window and heavy drawn glass in sheet form was opened by the Industrial Glass Works Company Limited in the Town of St. Laurent on the outskirts of Montreal.

The actual process of manufacturing glass is as strange and wonderful as any tale of mediaeval alchemists searching for gold in bubling cauldrons. A group of raw materials, such as silica sand, salt cake, soda ash, limestone and cullet (broken or waste glass), is transformed from a molten mass into a thin, transparent sheet which withstands the corrosive effects of the elements and at the same time permits the passage of light. Patient research and chemical analysis in the control of processes and raw materials have made possible the mass production of modern window glass, virtually free from flaws and distortion, according to an article by Vic Baker in the September issue of C-I-L *Oval*.

In view of the fact that before the war Canada imported more than seventy per cent. of its window glass from Belgium, the transfer of this industry is a distinct gain for Canadian industry as a whole. Two hundred Canadian workers—all trained in the past few months by skilled Belgian craftsmen—will contribute much in their production output to the wartime domestic needs of Canadian homes, factories and the construction trade in general.

Industrial News

Industrial development — new products — changes in personnel — special events — trade literature

SURGE ABSORBERS

Presenting a comprehensive description of Ferranti Surge Absorbers and "Ferr-Anti-Surge" Transformers, bulletin No. 704, issued by Ferranti Electric Limited, Mount Dennis, Toronto, 9, Ont., contains 13 pages devoted to the presentation of details and oscillograms of a series of tests made with the "Ferranti Surge Generator." The application of this equipment is described and a great deal of other valuable information is included together with numerous installation and other illustrations.

VENTILATING EQUIPMENT

Catalogue, Form No. A 30029C, 40 pp., entitled "New Modern Ventilation and Comfort Cooling," was recently issued by Canadian General Electric Co., Ltd., Toronto, Ont. Divided into two parts: 1, Catalogue Section, and 2, Application Guide Section; this book features commercial, industrial and residential equipment manufactured by Canadian Sirocco Co. Ltd., and distributed by the above company. A wide variety of equipment is illustrated and described, accompanied by dimensional drawings and tables of capacities.

PLANT ENLARGEMENT

Seiberling Rubber Co. of Canada Ltd., is building a large modern addition to its plant in Toronto. The addition will incorporate many innovations in factory design and will be used to manufacture tires, tubes, and various other rubber items for consumer and defense demands.

NEW CHEMICAL PROJECT

A new division of Dominion Rubber Company, to be known as Naugatuck Chemicals Ltd., is announced by Paul C. Jones, President of the Company. The project will occupy enlarged and renovated buildings at the former site of the Elmira rubber factory in Elmira, Ont., a few miles north of Kitchener. Operating in liaison with the parent organization, the Naugatuck Chemicals Division of United States Rubber Co., the new company will produce aniline oil, required in the war effort, and accelerators and other chemicals important to the industry, which, Mr. Jones points out, will make Canada virtually independent of the importation of vital and strategic chemicals for the rubber industry.

SYRENS AND SOUND INSTRUMENTS

Burlec Limited, Toronto 13, Ont., has been appointed by Carters of Nelson, Lancashire, England, to manufacture their complete line of Syrens and Sound Instruments, including both horizontal and vertical types in a wide range from 2 to 10 h.p., and in 25- and 60-cycle units. This line of syrens, which has been approved by the Minister of Home Security in England, will soon be in production in Canada.

B.C. REPRESENTATIVE APPOINTED

Horton Steel Works Limited, Fort Erie, Ont., has announced the appointment of Gordon N. Russell, Pacific Bldg., Vancouver, B.C., as representative in British Columbia. The Company manufactures tanks and steel plate work and has sales offices in Toronto and Montreal and has been represented in the Middle West for many years by Mumford-Medland Limited at Winnipeg, Man.

PLANT EXTENSION AND NEW BRANCH OFFICE

An extension to the factory of Chatham Malleable & Steel Products Limited, in Chatham, Ont., which will cover a considerable area, will provide facilities to meet increasing production demands for the Company's products among which are the "Chatco Heat-Speed Unit Heaters" and "Chatco Heat-Speed Convectors" for apartments, offices, and homes, and a wide range of steel stampings. The Company has also opened a branch office at 901 Royal Bank Bldg., Winnipeg, Man.

BLOWERS

Ilg Electric Ventilating Co., Chicago, Ill., has issued a 64-page "Catalogue and Engineering Data Book," which features Ilg's four lines of direct-connected and belted blowers, plus the two lines of volume blowers—the construction of the Ilg-built motor—advantages of the Ilg-patented "variable air controller and floated drive"—and the complete group of marine blowers. Uses of each type, characteristic curves, dimensions and performance data are included. This is supplemented by fan performance laws, an altitide table, air friction and duct graphs, sample specifications and a chart of universal discharge arrangements.

CONTROLLER FOR TEMPERATURES AND PRESSURES

A folder No. 77-3-25, entitled "Busy Hands do not Always Indicate Efficiency," has been issued by Minneapolis-Honeywell Regulator Co. Ltd. Toronto, Ont. It describes the "Brown Non-Indicating Controller for Temperatures and Pressures," with photos and descriptive sectional drawing illustrating the principal features. Details of installation and a list of typical applications are given.

DEAERATORS

A new deaeration catalogue, Publication No. 3005, 36 pages, recently issued by the Cochrane Corp., Philadelphia, Pa., presents a comprehensive treatment of tray-type daearators, atomizing deaerators, deaerating hot water generators, and cold water deaerators in one publication. A section devoted to flow diagrams, photographs of the actual units described, and an appendix on corrosion control and pH control are included. Also included are line diagrams of operating features and cross-sectional photographs which sections are devoted to special designs, metering deaerators, recording systems and accessory equipment.

DUST COLLECTORS

Pangborn Corporation, Hagerstown, Md., has issued a 6-page bulletin No. 907. Under the title "Unit Type Dust Collectors," the company's new line of this type of collector is thoroughly described and illustrated. Details of construction and recommended applications are given. Designated as Type "CD-1," there are 4 sizes of these units.

HOISTING EQUIPMENT

The Yale & Towne Mfg. Co., Canadian Div., St. Catharines, Ont., has issued a 44-page catalogue No. 25-C. This comprehensive illustrated catalogue of Yale hoisting equipment—differential screw gear and spur-gear chain hoists, and electric hoists—contains detailed descriptions, illustrations and specifications. Dimensional drawings and tables of dimensions, information and prices are also included.

INSULATING MATERIALS SPECIFICATIONS

"Specifications for Donnacona Insulation in All Types of Construction," is the title of a 68-page book recently issued by Alexander Murray & Co. Ltd. Montreal, Que., which contains specifications, detail drawings and photographs covering the many applications of Donnacona insulating materials. These are segregated into four main classifications—panel board, plaster base, roof insulation, and decorative specialties. The specialties include sound absorbing tile, "Hardboard" and "Modernite" products. A final section is devoted to painting specifications.

ENLARGEMENT OF LEASIDE PLANT

Canadian Aircraft Instruments and Accessories Ltd., Leaside (Toronto), are erecting additions to their present plant. This company is manufacturing lines in association with Self-Priming Pump and Engineering Co. Ltd., Slough, England, and Korect Depth Gauge Co. Ltd., Croydon, England.

HEAD OFFICE MOVED TO TORONTO

Dairy Corporation of Canada Limited has moved the head office of the company from Winnipeg to Toronto where the address is now 80 King St. West.

MAGNETIC CHUCK WITH POWER PACK

A 2-page leaflet issued by Osborne Electric Co. Ltd., Toronto, Ont., describes, with illustrations, the Osborne "Magnetic Chuck," and "Hole Magnetic Chuck," designed to speed up production in the machine shop or tool room. Each is supplied with a "Power Pack" to convert A.C. to D.C., so that it can be plugged into any 110-v., A.C., lighting circuit. The "Hole Chuck" is especially designed for grinding punches and dies.

MAGNETIC PULLEYS AND SEPARATOR UNITS

The 16-page catalogue of The Stearns Magnetic Mfg. Co., Milwaukee, Wis., provides a comprehensive reference on the subject of magnetic pulleys and magnetic pulley separator units, with descriptive matter, illustrations, specifications, applications and other data.

NEW CARBOLOY PLANT IN TORONTO

Moving into a new four-storey factory on Lansdowne Ave., Toronto, The Carboloy Div. of Canadian General Electric Co., Limited, has now completed its expansion programme designed to appreciably increase production capacity. This plant is devoted entirely to the manufacture of Carboloy which was previously manufactured at the company's Ward Street Works. Carboloy is being used for machining shells, gun parts and other munitions at greatly increased machining speeds. An interesting feature of the new plant is the installation of fluorescent lighting throughout.

UNIT HEATERS

The advantages of unit heaters over radiators and steam coils for heating the "vital zone" where people work, shop or play, are presented in a colourful manner by the Ilg Electric Ventilating Co., Chicago, Ill., in their 36-page catalogue No. 141. The construction of these heaters is fully illustrated and described, followed by illustrations and data on Ilg's four lines of unit heater models. Engineering data, illustrations showing the proper location of units in various types of buildings, piping diagrams, etc., are also included, together with a "check-chart" comparing the Ilg product with other unit heaters on the basis of eleven essential features.

VIBRO-INSULATORS

A 12-page booklet, Catalogue Section 7900, issued by The B. F. Goodrich Rubber Co., Akron, Ohio, features the company's Vibro-Insulators, devices of metal and rubber for the isolating of vibration in machinery. Illustrated with installation pictures and engineer's drawings, it gives all pertinent information about each type. The selection of mountings and their application to various equipment; methods of mounting, and other fundamental data, are included.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

VOLUME 24 | MONTREAL, NOVEMBER 1941 | NUMBER 11

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

PROPERTIES OF HEAT INSULATING MATERIALS

E. A. ALLCUT, M.E.I.C.
Professor of Mechanical Engineering, University of Toronto, Toronto, Ont.

SUMMARY—A discussion of the character of heat insulating materials, the difficulties in determining their relative value experimentally, the effect of air spaces and surface resistance and the possibility of saving fuel by taking advantage of solar radiation and heat stored in the structure of the building itself. Mr. Hamly contributes an appendix describing his microscopic examination of a number of insulating materials.

Although insulating materials have been commonly used for many years on hot and cold surfaces such as those of steam piping and refrigerators, only recently has considerable attention been paid to the advantages of insulation in building construction. This change has been due, largely, to the ever rising cost of fuel, which has made the saving to the average consumer commensurate with the extra capital cost of the installation. As the more easily accessible sources of fuel supply become exhausted, the cost of working the remainder will continue to rise, and it is therefore probable that the tendency toward the use of heat insulation will increase correspondingly. The cost of insulating materials, their useful life, or rate of depreciation, and the expense of placing and maintaining economic quantities of them in the most advantageous positions, must inevitably become more important as time goes on, and therefore it is pertinent at this stage to give some consideration to the physical and thermal properties of those materials that are now used or are likely to become available for this purpose. This, of course, is a large subject and much of it has been, or is being dealt with elsewhere; the present paper is but a brief outline of some of its aspects, indicating more particularly some of the work done at the University of Toronto. Attempts have been made to ascertain the effects produced by variables, either in the materials themselves or in the conditions under which they operate, for the purpose of indicating what characteristics are desirable and how they may best be combined to form effective heat barriers.

Physical Structure

In most insulating materials the primary object is to make the most efficient use of still air. The latter is the real insulator because its conductivity is relatively low, ($k = 0.17$)

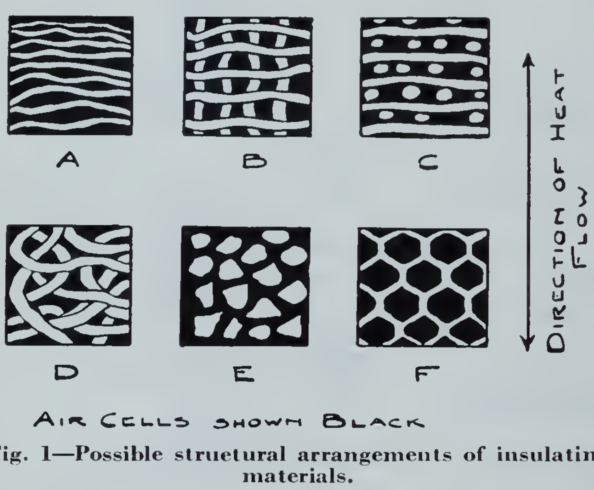

Fig. 1—Possible structural arrangements of insulating materials.

as compared with that of the associated substances which are employed to prevent air motion and to reduce radiation losses. The spaces between the fibres or granules are air cells which may or may not be inter-connected, and therefore the arrangement of the solid material relative to the air is important. In metallurgical work, the micro and macro-structure of metals indicate definite physical properties, and it is reasonable to suppose that a study of the structure of heat insulating materials along similar lines may produce comparable results. As a first approach, certain typical arrangements of material might be classified roughly as follows:—

(A) Fibrous materials with the fibres arranged at right angles to the direction of heat flow. Variables, diameter and length of fibres, density and uniformity of structure. (Fig. 1A).

(B) Fibrous materials in which some of the fibres lie parallel to the direction of heat flow, so that a considerable proportion of the heat is conducted along the fibres. Variables as in (A) and orientation of fibres. (Fig. 1B).

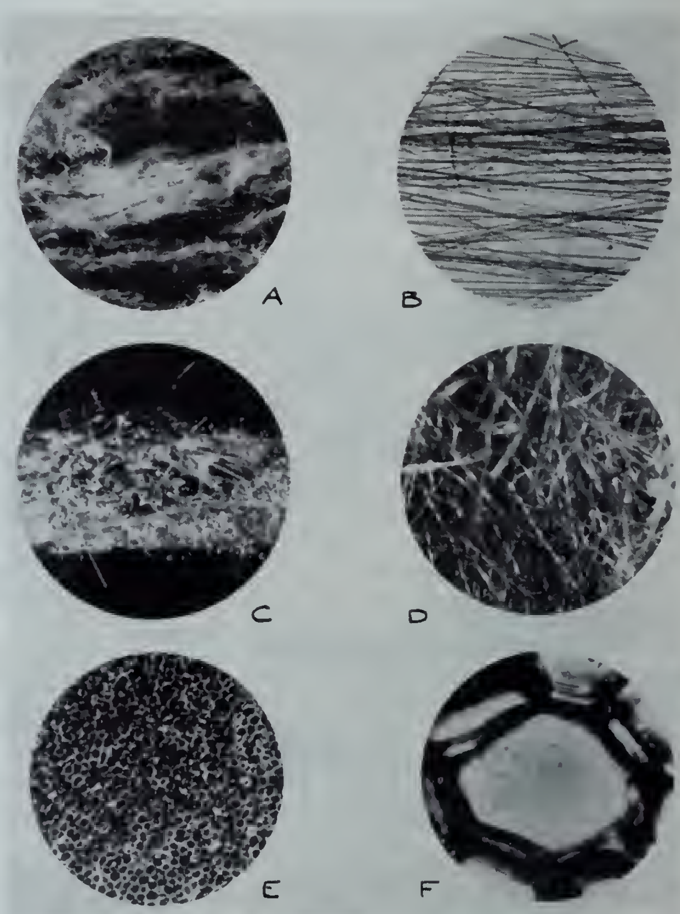

Fig. 2—Actual structure microscopically enlarged. A—Sectional view of fibre board showing laminar structure; B—Individual fibres of rock wool (parallel arrangement); C—Section of rock wool batt taken across fibres; D—Fibres of wood bark (random arrangement); E—Section of cork (cellular arrangement); F—Enlarged view of cork cell.

(C) Fibrous materials with fibres arranged in "lattice" form, so that the transmission of heat is facilitated by the existence of numerous points of contact where the fibres cross. Variables as in (A). (Fig. 1C).

(D) Fibrous materials with fibres arranged in a haphazard or random manner. Variables as in (B). (Fig. 1D).

(E) Granular materials with air surrounding solid granules. Variables, size, weight and form of granules, relative volumes occupied by air and solid. (Fig. 1E).

(F) Cellular materials where the air cells are not connected together but are surrounded by a solid sheath. Variables, size and shape of air cells, thickness of solid barrier. (Fig. 1F).

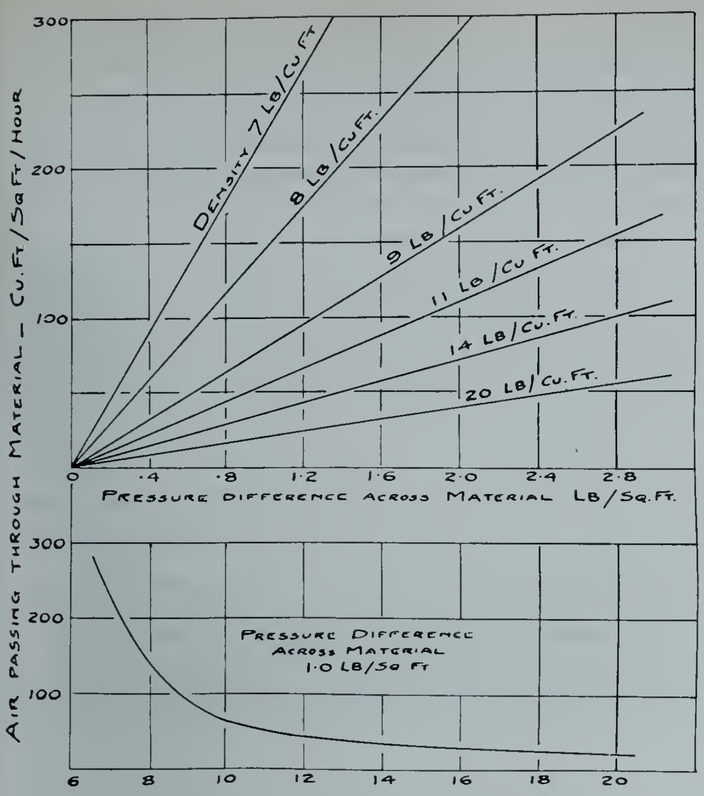

Fig. 3—Leakage of air through rock wool 4 inches thick.

In all of the above, the conductivity of the solid material concerned is a controlling factor, and in some instances its emissivity and specific heat may also be important. Common examples of these structures are glass wool or rock wool batts and fibre boards (Type A), loose rock wool (Type D) and cork (Type F), of which photographs are given in Fig. 2.

In structures A to E, air can either pass through the material or can circulate within it, and the amount of heat transmitted in this manner from the hot to the cold side of the material depends on the number of air cells present, their sizes and their inter-connections. This factor was investigated by passing air through specimens of various materials of different thicknesses and measuring the volume of air passing through the material at each pressure difference.[1] A characteristic example is given in Fig. 3, which refers to rock wool, four inches thick and packed to different densities. The air leakage through this and all other samples of loose fibrous materials was found to be directly proportional to the pressure difference across the specimen, and to fall rapidly with increasing density over the range of densities generally used in practice. Figure 4 consists of a set of similar curves for fibreboards of different densities and thicknesses. This shows that the thickness of such boards has little or no influence on their permeability, as the curves arrange themselves in order of density. It is probable, therefore, that the resistance offered by the surfaces of the material to air penetration is greater than that of the interior. This difference also appears to have some influence on the temperature gradient through the material[2] The application of a thin sheet of aluminium foil to one surface makes the fibreboard impenetrable at air pressures up to 35 lb. per sq. ft., and has the additional advantage of reducing the emissivity of the surface. Some protection also, is given by applying two or three coats of aluminium paint to one surface, the air leakage being then reduced to about 25 per cent of that for the bare board.[1]

A further observation is the greater "conductivity" of large specimens of packed fibrous materials as compared with small ones of the same density. It is possible that these differences may be produced by the circulation of air through the air cells and communicating channels, and in that event, such differences should be definitely related to the structural arrangement of the material. Experiments made on large specimens, sub-divided horizontally and vertically by thin partitions, gave substantial reductions of heat transmission as compared with the individual specimens, and thus provided some evidence confirmatory of this theory.[2] Also, cellular structures (Type F) in which there is little or no connection between the air cells, seem to be free from this "scale effect."

A microscopic study of some of the common fibrous materials used for insulating purposes was made by Dr. D. H. Hamly, and the results are analysed in Appendix I and Figs. 14 and 15. There is evidently a very wide variation in fibre diameters and in their distribution. Thus, the curve for loose rock wool (B) is tall and thin, indicating small fibres of relatively uniform diameters, while that for spun rock wool (C) shows large diameters with a wide range of variation. The term "mode" (Fig. 14) refers to the most frequently recurring diameter, while "median" is the average diameter. "Limits" are the smallest and largest diameters of 75 per cent of the fibres.

An experimental study of heat transfer was also made with the apparatus illustrated in Fig. 5. This consisted of two hollow glass cells, each 8 inches square with walls about ¼ inch thick, which could be evacuated and tested for heat transmission in a guarded hot plate. Tests were made with different vacua inside the cells down to a minimum absolute pressure of 0.2 inches of mercury. The results obtained were consistent down to a pressure of 1.5 inches of mercury, and then became somewhat scattered at lower pressures, probably indicating some variation in convection at low air densities. The tests were then repeated with sheets of thin aluminium foil on the hot and cold sides of the air cell to cut off about 95 per cent of the radiant heat loss, and the results are shown diagrammatically in Fig. 6. The lines "A" and "B" refer to the results obtained with and without the radiant heat shields, and therefore the difference between them probably indicates the amount of radiant heat that travels across the cell when its hot and cold sides are at 115 and 65 deg. F., respectively. Curves C, D, E and F were obtained when the tests were repeated under the same conditions with the hollow spaces filled, successively, with the following materials:—

Curve	*Material*	*Density lb./cu. ft.*	*Conductivity B.T.U./sq. ft/°F/ inch per hour*
C	Exfoliated vermiculite.........	8.5	0.47
D	Puffed wheat...............	3.6	....
E	Expanding blanket...........	3.1	0.29
F	Nodulated rock wool..........	8.0	0.27

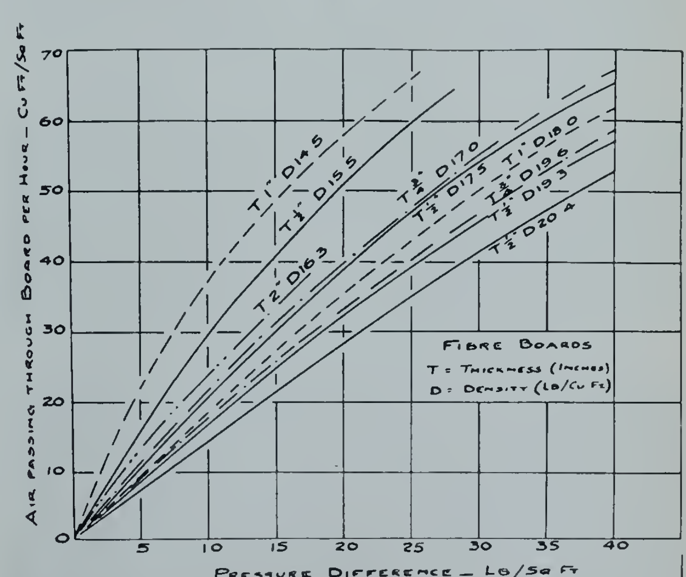

Fig. 4—Leakage of air through fibreboards of different densities and thicknesses.

Similar experiements were also made on glass wool at a density of 3 lb. per cubic foot, but the results obtained were somewhat erratic. The other materials give no indication of change in heat transmission as the air density is decreased, and therefore it is reasonable to infer that there is very little heat transmitted by convection in specimens of this

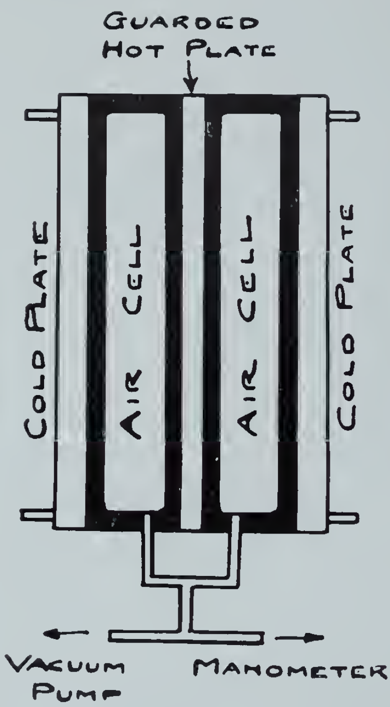

Fig. 5—Hollow glass cells for studying methods of heat transfer.

size. Experiments made on these materials with and without radiant heat shields gave the same results, and therefore radiation also is apparently negligible, so that conduction seems to be the only active agent concerned. The slope of curves A and B indicates the increasing importance of convection inside the cells as the air density increases.

Conductivity and Conductance

For practical purposes, the insulating values of the different materials are compared by means of their respective "conductivities." These are generally obtained by measuring the heat transmitted from the hot to the cold surface in a guarded hot plate, and calculating therefrom, the conductance (C), which is the heat transmitted through one square foot of the material, per degree temperature difference per hour. The conductance is multiplied by the thickness of the material to give the "conductivity" (k) per inch, and the procedure implies that neither the thickness nor the temperature difference across the specimen affect the value of the "conductivity" obtained in this manner. If this were the true conductivity, the above assumptions would be correct, as the true conductivity is a property of the material and is independent of its size and shape. In the author's experience, however, conductivities obtained from test results on thick and thin specimens, respectively, may differ considerably. A series of tests made on thin fibreboards (½ inch thick) varying both the areas of the specimens and the temperature difference between the hot and cold sides, gave both a constant value for the "conductivity" at a fixed mean temperature, and the same rate of increase as the mean temperature was raised. When these tests were repeated on thicker samples, however, it was found that the "conductivity" increased both with the temperature difference and with the thickness.[3]

Temperature gradients were obtained by placing thermocouples inside some of the materials, and, while these ultimately indicated a straight line relationship, there was, in some instances, an abrupt change of temperature at each of the surfaces. Thus, in Fig. 7, the temperature gradient would be $t_1\ t_3\ t_4\ t_2$ instead of the assumed line $t_1\ t_2$. The true conductivity is represented by $\frac{t_3-t_4}{X}$ instead of the value $\frac{t_1-t_2}{X}$ obtained from the hot plate test made in the usual way. In one material, having an apparent conductivity of 1.0, the temperature changes at the two surfaces were each found to be about 3 deg. F. Therefore, if t_1-t_2 is 40 deg. F., the true conductivity would be $1.0 \times \frac{40}{34} = 1.175$.

This superficial resistance, which has already been remarked in connection with air infiltration, is important when the variation of "conductivity" at different thicknesses is being investigated. Consider two specimens of thicknesses X and Y, respectively, (Fig. 7) and let the true conductivities of the two materials be the same. Then $\frac{t_3-t_4}{X} = \frac{t_3^1-t_4^1}{Y}$. But the apparent temperature gradients obtained from the hot plate tests will be, respectively, $\frac{t_1-t_2}{X}$ and $\frac{t_1^1-t_2^1}{Y}$, and if the surface resistances in both cases are equal, it is evident that the temperature gradient for the thin specimens will be greater than that for the thick specimens. That is, the measured "conductivities" of the two specimens of the same material will be different.

Results of this kind obtained on fibreboards were reported independently by four different laboratories, and it was found that when the resistances ($R = \frac{1}{C}$) were plotted against thicknesses (Material "A" Fig. 8) a straight line was obtained which did not pass through the origin. This implies the existence of a resistance when the thickness is zero, which can only be due to surface resistance. The "conductivities" calculated from this curve vary from 0.37 for half-inch boards to 0.44 for two-inch boards, a difference of 16 per cent. A similar pair of curves for a high tempera-

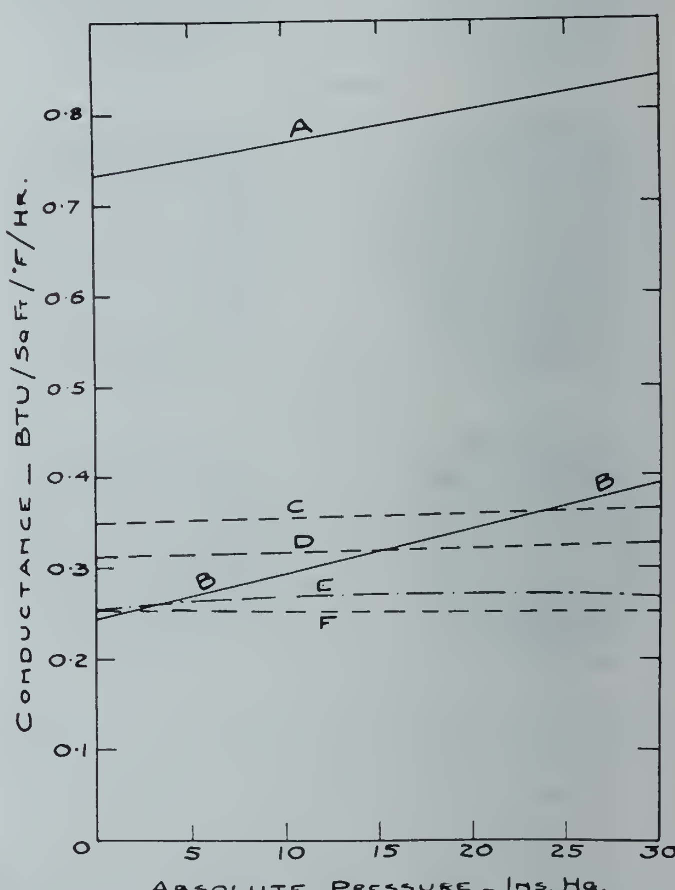

Fig. 6—Heat transmission through various materials with varying vacua.

ture insulation (Material B) is also given in Fig. 8 and shows still greater differences. It seems evident that the property described as $k = C \times thickness$ is not the true conductivity of the material, that it does not remain constant and therefore that it should be discarded in favour of "conductance," as the latter must be used in any case, for the calculation of heat transmission. Alternatively, a different

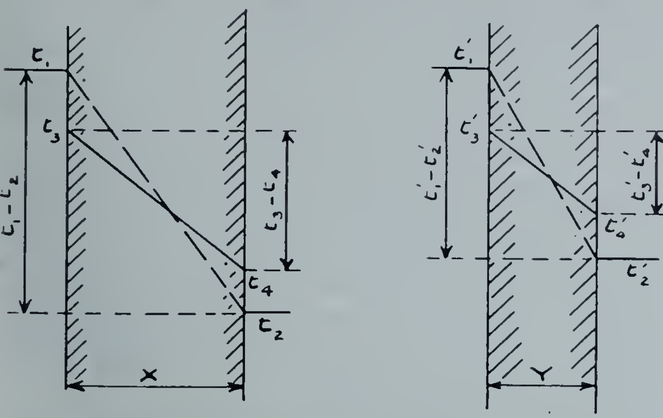

Fig. 7—Influence of thickness on temperature gradient through material.

and less misleading name might be adopted for "k", possibly "apparent conductivity."

Density

Some aspects of this property have already been considered, and the following refers only to its influence on heat transmission. In general, the lower the density, the greater is the percentage of air present, and therefore the lower the "conductivity" will be. This, however, is only partially true, as, if the density of fibrous materials is decreased below a certain value, the rate of heat transmission will again increase.[3] This is illustrated by the curves in Fig. 9. It has been suggested that the increased heat transmission at reduced densities is due to the greater influence of radiation, but the author's investigations do not confirm this, indicating rather that the higher loss is due to increased inter-communication between the air cells as the density decreases. This factor may be important with materials such as glass wool, which are sometimes used at very low densities (1.5 to 3 lb. per cu. ft.). The influence of density on air infiltration is very marked and it seems likely that the increased mobility of the air within the material has an appreciable effect on the transmission of heat, particularly in large specimens.

The fact that glass and mineral wools, which are composed of similar fibres, similarly arranged (but of different diameters) give substantially the same "conductivities" at widely differing densities, was somewhat difficult to understand until the influence of "shot" was taken into account. Table 3 in Appendix I indicates that, in the samples examined, "shot" or beads of siliceous material, account for 23.9 to 54.1 per cent of the weight of rock or slag wools, and only 1.5 per cent of the weight of glass wool. These beads or nodules (Fig. 10) are included in the weights from which the densities are calculated, but probably have no appreciable influence on heat transfer. Consequently, the weights of actual fibrous material present in the two kinds of material are not necessarily so widely divergent as their respective densities suggest. The amount of "shot" present also may be quite important in transportation work where useless weight must be kept at a minimum value. It is not claimed that the figures given above are average values, but they are an approximate indication of the nature of the differences between these two materials.

Another physical factor, allied to density, is the compressibility of the material. Fluffy materials can be compressed almost to any desired extent for transportation, inspection and testing purposes and, whatever method may be employed for measuring the thickness of the material, some slight degree of compression must be used in the measuring process. Another aspect of compressibility is the packing of powdered or other material into an enclosed space where the weight of superincumbent material compressed the lower layers and causes voids to form elsewhere, which may seriously affect the heat flow. The tests illustrated by Fig. 11 and summarized in Table 1 were made with a constant weight of each material which was compressed progressively and tested for heat transmission at each thickness. The conductance, "conductivity" and density are indicated by C, k, and D, respectively.

TABLE 1

Thickness ins.......		1.5	1.25	1.0	.75	.5		.215
Blanket	C	.195	.235	.305	.472	.785	BTU/sq.ft./°F/hr.	
Material	k	.292	.294	.305	.336	.392	BTU/sq.ft./°F/in/hr.	
	D	2.97	3.56	4.45	5.94	8.91	lbs./cu.ft.	
Rock	C	....	.214	.241	.330	.525		.....
Wool	k	....	.267	.241	.248	.262		.....
	D	....	4.92	6.15	8.2	12.3		.....
Glass	C	.206	.222	.271	.330	.514		1.269

	D	1.63	1.95	2.44	3.26	4.89		11.38

Referring again to Fig. 9, the heavier constructional materials have "conductivities" which increase in a fairly uniform manner with density and, in most cases, are reasonably consistent with the properties of the lighter materials.[4]

Figure 12 is a compilation of test results obtained in different laboratories for concretes of varying compositions

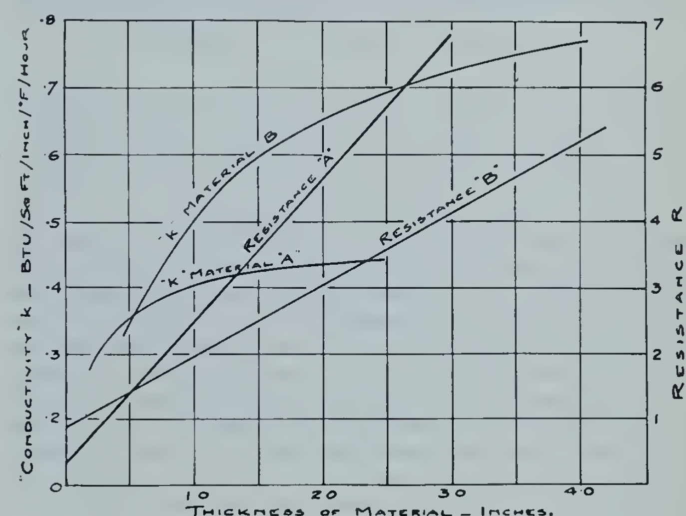

Fig. 8—Influence of thickness on resistance and "conductivity"

and their "conductivities" are apparently grouped round the dotted line shown. Most of the tabulations of conductivity in papers and books of references[5] give a characteristic "conductivity" of 12 B.T.U. per sq. ft. per deg. F. per inch per hour for a typical concrete weighing 140 lb. per cu. ft. This is a value considerably higher than any obtained by the author, and from the curve it would appear that a figure of 6 to 8 would be more reasonable.

Moisture Absorption

It is generally assumed that the conductance of insulating material varies directly with the percentage of moisture present, though this is difficult to prove because, in the process of testing, moisture is driven away from the hot side and toward the cold side of the specimen. This factor was investigated by testing a specimen 3½ inches thick, composed of 2 inch and 1½ inch fibre boards arranged in series. The mean density of the sample remained practically constant during the test, but the boards nearest the hot plate lost weight and those nearest the cold plate gained weight. This effect would not have been detected if the specimen had been made in one piece, as is usually the case.

Some materials such as cork, glass wool and mineral wools, absorb little or no water, but others, such as fibre boards, are hygroscopic. Experiments made on fibre boards of various thicknesses indicated that, with geometrically similar specimens exposed to air at 65 deg. F. and a relative

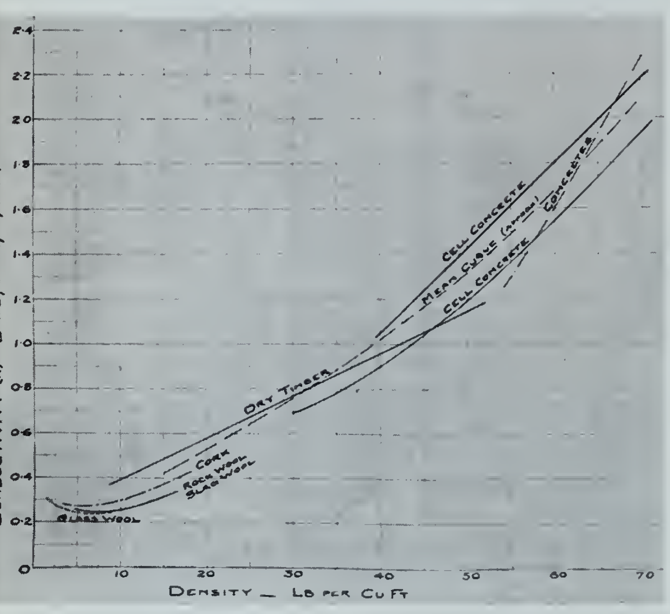

Fig. 9—Influence of density on "conductivity"

humidity of 85-90 per cent, the weight of moisture absorbed per cubic inch was practically constant for all thicknesses.[3] The moisture content was raised from an initial value of 4-6 per cent to a final value of 15-19 per cent by weight.

Whether the solid substance is hygroscopic or not, any material containing voids to which the air has access by infiltration, may be cooled below the dew point, and excess moisture will then be deposited, causing considerable loss and inconvenience, particularly if the temperature is below 32 deg. F., so that the water freezes inside the material. In such circumstances, it is submitted that the criterion of the permeability of the material is not difference of vapour pressure only, as is generally assumed, but is the total difference of pressure on the two sides of the material. Such infiltration should be prevented, wherever possible, by placing an impermeable barrier on the warm side of the insulation.[6][7]

Air Spaces and Surface Resistance

The small air cells that provide most of the insulating value of fibrous and other similar materials may be supplemented or replaced by hollow forms of construction. The effectiveness of the air spaces thus formed, depends on their dimensions and upon whether or not the parallel spaces through which the heat passes are protected from radiation by coverings or coatings of low emissivity, such as aluminium, copper or iron. The properties of these air spaces have been investigated by Rowley,[8] Queer,[9] Wilkes[10] and others, and their observations will not be repeated here, but some results obtained at Toronto may be of interest.

Tables giving the conductances of air spaces are usually based on the Minnesota experiments,[8] which gave a constant conductance at constant mean temperature for spaces more than one inch wide. Some experiments made by the author on air spaces 24 inches square and 3½ inches wide, give considerably lower conductances than those obtained on similar air spaces one inch wide, when tested under the same conditions. It appears that there may possibly be some exceptions to the general assumption.

The advantage of filling hollow tiles with finely divided material is illustrated by tests made on wall sections 5 feet high by 4 feet wide, in which the heat transmitted (air to air) through 8 inch hollow concrete blocks, was reduced by 15 to 30 per cent when the air spaces inside the blocks were filled with gravel or sawdust. Similar experiments made on a 4-inch hollow tile in a 24-inch hot plate, gave a conductance of 0.447 B.T.U., but when the centre was filled with sand the conductance was 0.376 B.T.U., a reduction of about 16 per cent. Large air spaces may be relatively poor insulators, but they are economical in material.

The reduction of heat transmission across air spaces by using coverings of low emissivity is well known, amounting to about 58 per cent with air spaces more than one inch wide. Where this method of protection is impracticable, metallic paint may be used with advantage. A roof slab, one inch thick, was tested in conjunction with an air space two inches wide, the conductance being 0.77 B.T.U. When the surface of the slab next to the air was painted with aluminium paint, the conductance was 0.545 B.T.U., a reduction of nearly 30 per cent.

The effectiveness of bright metallic surfaces as inulsators depends on the retention of their initial emissivity. Tests made by Wilkes[11] and Edwards[12] indicate that, in the case of aluminium, this is not seriously increased by ordinary conditions of use or by very thin protective coatings of lacquer. On the other hand, if the surface is exposed to dust or corrosion, considerable increases of heat transmission may result. A test made at Toronto on an air space divided vertically by a partition having one bright side, gave an increased conductance of 13 per cent when the bright surface was obscured by a very thin dust film. It was also found that a slightly better result was obtained with the

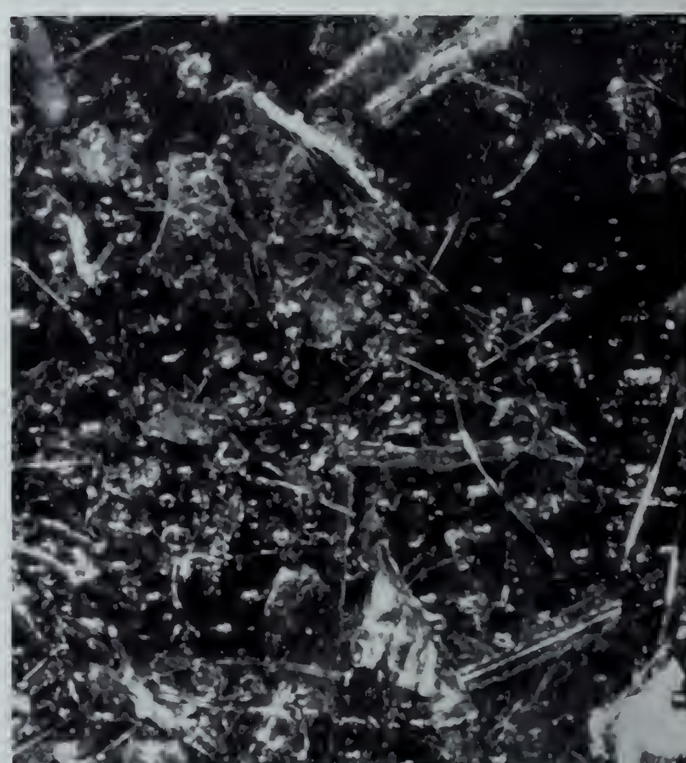

Fig. 10—Photograph of "shot" found in mineral wool

metal foil facing the hot side of the apparatus than when facing the cold side.

Thin air spaces can sometimes be employed advantageously. Some difficulties were experienced with condensation of moisture on the outside of tanks made of plastic material having a conductance of 3.59 B.T.U. per sq. ft. per deg. F. per hour. The addition of an air space 1/16 inch thick, faced

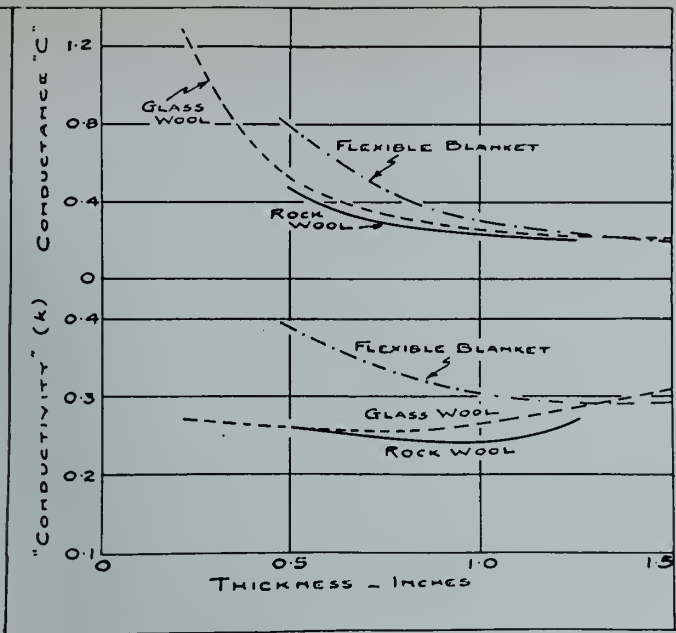

Fig. 11—Conductances and "conductivities" of materials when progressively compressed

by a bright metallic wall, gave a conductance of 1.50 B.T.U., a reduction of 58 per cent. The thickness of the air space was then increased to ⅛ inch and this arrangement gave a conductance of 1.10 B.T.U., being a reduction of 69 per cent from the original value.

The amount of heat lost from a steam pipe depends on the quantity of heat that is transmitted to the air from the outer surface of the insulation, and this factor has also received some preliminary study. The apparatus used is shown diagrammatically in Fig. 13. Temperature readings were taken by thermocouples at various points on the circumference both of the metal and of the insulation, and the results given in Table 2 are averages for each material and set of conditions. These figures are approximate only, as the work is incomplete at the time of writing, but they

TABLE 2

Material	*Temperatures °F.* Outside Surface of Pipe	Outside Surface of Insulation	Difference between Surface and Air	BTU lost per hour per sq. ft. Pipe Surface	Wind Velocity miles per hour	Percentage Increase of Heat Loss due to Wind

indicate that the heat losses from an 8-inch steam pipe, insulated in various ways to give an outside diameter of 11 inches, are increased from 4 to 16 per cent by exposure to a wind of 15 to 20 miles per hour. Covering the outside of the 1½ inch magnesia lagging by metallic foil reduced the heat loss in still air by about 12 per cent, and in a 15 m.p.h. wind by about 6 per cent, with pipe temperatures between 500 and 600 deg. F. Both copper and aluminium coverings were tried and the same results were obtained for each of these metals.

Heat Transmission Calculations

The kind and thickness of insulation required for pipes or structures are calculated from the conductances of the various materials. Unfortunately, the methods of testing, sizes and thicknesses of specimens and temperatures to be used have not, as yet, been standardized, although this

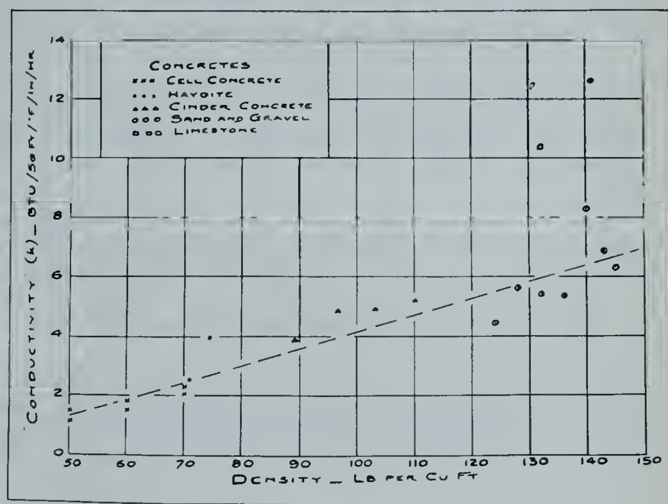

Fig. 12—"Conductivities" of concretes of various densities

question is now being considered by a committee of the American Society for Testing Materials. There is some hope, therefore, that figures comparable with each other will ultimately be obtained for the different materials that are now available. In the meantime, invalid comparisons are continually being made in advertising literature, sales letters and technical books, in which the fact is not disclosed that the figures quoted were obtained with different test conditions. The difficulty of applying such figures in practice is increased when thick sections are used and when

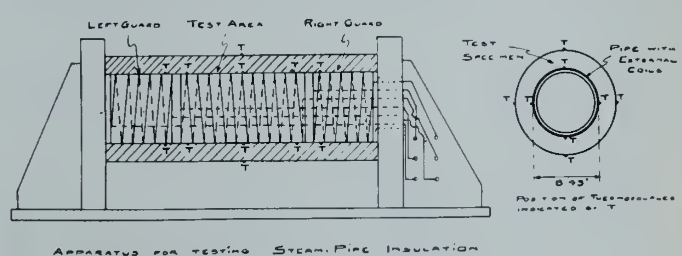

Fig. 13—Diagram of apparatus for testing steam pipe insulation

the material is exposed to variable temperatures. The inside of a building may be kept at a fairly constant temperature but, in the heating season, the outside is subjected to temperature changes between night and day, and also to those due to the action of the sun and wind. As a consequence of these fluctuations, the actual temperature gradient through the wall section is never straight, and therefore the assumptions upon which the heat transmission calculations are made may be quite different from the actual operating conditions. Tests made both at Illinois[13] and Toronto show that thermal equilibrium is seldom obtained in the wall of an average building, and therefore considerable discrepancies are liable to exist between the calculated and measured rates of heat transfer.

This "time lag" may be usefully employed, however, in evening out the temperature curve and in the alternate storing and returning of heat,[14] thus producing the effect of a "thermal flywheel." For this purpose, considerable thicknesses of material are used and their thermal capacities may then be as important as their heat transmissive properties. Several buildings have been designed and erected in Canada which incorporate this principle. These include a hospital in Prince Edward Island, where the thickness of insulation was 10 inches, and capacity of the heating plant provided was less than half of that required for similar hospitals using ordinary construction. This installation was a forced hot water system and the actual temperature of the water, which had been estimated to be 200-220 deg. F., with an outside temperature of 20 deg. F., below zero, was only 130 deg. F., under those conditions. The water temperature during most of the winter 1933-34 was 110-112 deg. F. A study of solar radiation enabled substantial reductions to be made in the size of radiators on the south-east side of the building, and it was found that the time lag between the atmospheric temperature change, and the corresponding change of water temperature, was 3 to 4 days.

Several unheated packing sheds and other buildings for storage purposes have been built by a Toronto architect, Mr. James Govan, in which temperatures above 30 deg. F. have been maintained consistently, in spite of the fact that the outdoor temperatures frequently fall to zero or lower.[15]

A more recent case is the new pavilion of the Toronto Western Hospital, which is described in Appendix III. This consists of an addition of 1,300,000 cu. ft. of new building to an existing hospital having a volume of 1,800,000 cu. ft.

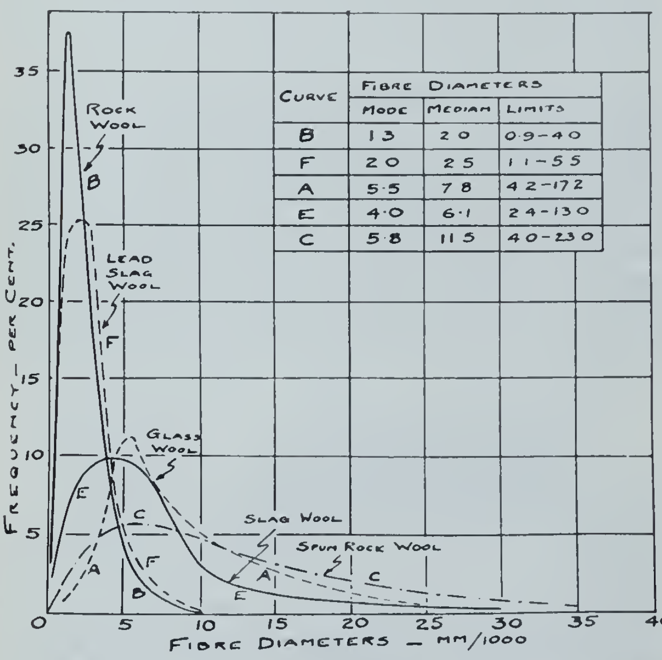

Fig. 14—Frequency curves for fibrous insulating materials

New heating boilers were installed having efficiencies of about 70 per cent, as compared with about 55 per cent for the original installation. The thickness of insulation employed was approximately 10 inches and the records show that the additional 1,300,000 cu. ft. of space is apparently being heated with little or no addition to the coal consumption.

These examples of practical application indicate that much more could be done, than is generally being done, in the matter of reducing heating costs.

APPENDIX I

MICROSCOPIC MENSURATION OF FIBROUS MATERIALS

By D. H. HAMLY

The volume of air moving at low rates varies approximately in inverse proportion to the area of the surfaces in contact with the air, as shown by experiments with capillary tubes of various lengths. An estimate of the surface area of fibrous materials can be obtained by calculation from the fibre diameters on the assumption that in a sample of suitable size both the diameters and the relative numbers of the various diameters will be fairly represented. Variations in fibre characteristics, such as changes in diameter along a length, or shape, or fibre twinning occur, but these are of little consequence and no statistical record was made of them. Variations in fibre length also occur within a sample, but these differences did not appear to be of sufficient importance to invalidate the calculations for a given sample. However great differences of length appeared in the insulating wools made by different manufacturers, there appeared to be no relationship between fibre length and conductivity other than that lower packing densities are possible with the longer fibred wools.

The method employed to determine the area constant for different insulating wools was as follows. After the scale of the microscope ocular had been calibrated for objects in air, ten small samples were selected from different parts of an approximately one lb. mass of bulk fibre chosen as representative of the material. The small samples were carefully spread out on microscopic slides and held in place with cover slips. Ten fibres from each slide were measured using a 45x (Leitz No. 7) objective and a 6x (Spencer scaled) ocular. Each fibre was chosen deliberately and without prejudice from a new part of the field. Thus, one hundred measurements were made from each kind of material, and tabulated as shown in Table 3, where the measurements and calculations for ten fibres from one sample are shown.

From the diameter dimensions obtained for 100 fibres, a frequency table (Table 4) was constructed.

Table 5 shows the total surface areas reported for materials A, B, C, D, E and F, obtained according to the above plan.

Figure 14 shows the frequency curves for diameters of the same materials. From these curves were obtained both the mode diameter, a dimension which indicates the fineness and the packing capacity of the material, and the median diameter for 75 per cent of the fibres, disregarding 12.5 per cent of the smallest and 12.5 per cent of the largest fibres, indicating the texture and general appearance of the material.

Specific Gravity, Packing Density and Shot Percentage

In making use of the surface area values obtained from the foregoing work, several factors have to be taken into consideration, chiefly specific gravity, packing density, and shot percentage.

Specific Gravity must be used in calculating the other values, and was determined according to the following method. Xylol was used for immersion, since much of the material is slightly oily and not readily wetted with water.

(a) The specific gravity of a quantity of xylol was determined, using a 100 cc. volumetric flask at 72 deg. F. This temperature was used in all determinations of volume and weight.

TABLE 3 (Material F, Lot 5)

Fibre No.	Readings		Difference	*MOcK* 0.0324	Diameter in micra

9	128	81	41	"	1.3
10	170	90	80	"	2.6

MOcK = Ocular calibration constant.

(b) The net weight of a mass of bulk fibre placed in the volumetric flask was obtained.

(c) Xylol was added to cover the fibre. The air originally trapped in the interstices of the fibre was removed by repeated use of reduced pressure and by holding the flask at 122 deg. F. for some hours with the stopper in place.

(d) The temperature was then reduced to 72 deg. F. and volume adjusted to 100 cc. The total weight of this quantity of fibre and xylol was then obtained.

(e) The specific gravity of the fibre was then calculated in terms of xylol and of water. The results are given in Table 5.

Packing Density governs the surface area per unit volume, but the presence of shot reduced the $\frac{\text{surface}}{\text{volume}}$ ratio in the bulk fibre and thus its efficiency as an insulator. Shot, prematurely solidified masses, are shown by the microscope to vary greatly in shape; horseshoes or hairpins of very heavy fibres, dumbbells of various sizes, spelterlike masses,

and more or less globular shapes with many projections from which fibres have been broken, may be seen in photomicrographs (Fig. 10). To determine the surface area in a sample of material, it is necessary to determine the relative amount of shot present.

Shot percentage determination is practical, for there are few fibres larger in diameter than 50 μ, and relatively few shot which will pass through a Tyler screen with spaces of 88 μ between the wires. However, the use of screens for shot separation is difficult and slow, because the shot projections catch in the wires of the screen. Water separation proved satisfactory and rapid when the fibre was first broken down by rubbing between pieces of cork carpet.

A mass of about 80 cc. of bulk fibre was weighed in a tared beaker, rubbed to a powder between cork, carefully transferred to a 300 cc. beaker and wetted with 95 per cent alcohol to insure thorough wetting with water. The beaker was then placed in a 2 by 10 by 12 in. tray and the mixture vigorously stirred with water flowing from a small rubber hose. A rapid overflow of water from the beaker was allowed as long as the fine broken fibre appeared to wash over without carrying shot with it. In the meantime the tray filled with water and with carried over material. Most of the fine fibre washed away, leaving the coarser fibre and shot, which was then separated by careful panning, checked by microscopic examination. The shot from the tray was then added to that in the beaker, and the whole carefully washed with distilled water. This was poured off and replaced with 15 or 20 cc. of 95 per cent alcohol. The operation was completed by pouring off the surplus, evaporating to dryness, and weighing at room temperature.

An estimate of the surface area of shot can be based on the size of the opening through which the shot can pass. By assuming that "the average shot" of various sizes in a material are similar, and that all bear the same surface relationship to the surface of a sphere capable of passing through the same aperture, a series of calculations of $\frac{\text{surface}}{\text{volume}}$ ratios were made for material "F", as shown in Table 6. By assuming further that the ratio of hypothetical shot surface to sphere surface of the same passing diameter is as 1:1, the relative importance of the shot can be determined. The net result of the computation shown is that the shot in this material possesses 1/200 of the surface area of the fibre. However, the ratio is actually smaller, for the surface area of irregularly shaped shot of the same weight is greater than that of spheres of a size capable of passing through the same aperture.

Fibre Arrangement

In evaluating the insulating importance of fibres with particular reference to transference of heat by moving air, some consideration must also be given to the arrangement of surfaces and the amount of conductance present. Table 5 shows that, even after allowance has been made for shot present, the surface area of the finer fibred wools is much greater than that of the coarser. However, the coarser and longer fibred wools permit lower density packing and

TABLE 7

Factors Governing Coal Consumption	1933-1934	1939-1940	Remarks
1. Total volume of building	1,813,000 cu. ft.	3,693,000 cu. ft.	
2. Increase in volume of building (1935)		1,880,000 cu. ft.	
3. Coal consumed from October to April inclusive	1,592 tons at 14,400 BTU per lb.	1,922 tons at 14,100 BTU per lb. =1,882 tons at 14,400 BTU per lb.	
4. Increase in equal heat value coal for 7 months period		=290 tons	
5. Patient-days during 7 months	60,789	102,422	
6. Increase in patient-days during 7 months period		41,633	
7. Estimated coal consumed in 1939-40 for heating water, cooking and sterilizing		0.00708 tons per patient-day (calculated)	Checked against July and August consumption and against results at other hospitals.
8. Estimated coal consumed for heating water, cooking and sterilizing in 7 months period due to increase of 41,633 patient-days		295 tons	Calculated on basis of Item 7.
9. Actual increase in coal consumed for all purposes, including heating		290 tons	On basis of BTU value per lb. equal to coal used in 1933-1934
10. Degree-days	7744	7411	

arrangement at right angles to the path of circulating air, as well as to the direction of the radiant heat.

Volume of Circulating Air

Though the transference of heat is directly related to the volume of the air circulating within the space partially filled by the insulating material, the limits imposed are not great even for packing densities of 1.5 to 10 lb. per cubic foot.

For material "A", sp. gr. 2.42 packed 1.5 lb. per cu. ft., the volume of air per cu. ft. is $\frac{62.5 \times 2.42 - 1.5}{62.5 \times 2.42} = 0.990$ cu. ft.

For material "B", sp. gr. 2.71, packed 10 lb. per cu. ft., the volume of air per cu. ft. is $\frac{62.5 \times 2.71 - 10}{62.5 \times 2.71} = 0.942$ cu. ft.

Thus, the circulating air in material "B" is only 5 per cent lower than in material "A", although the mass of the bulk fibre is 730 per cent greater. This factor is of minor importance compared to the changes in the surface area and in the contact constant.

The Contact Coefficient

In the conductance of heat across a space filled with fibrous insulating material the number of points of contact between fibres is the determining factor. The fine fibres of such materials as "B" obviously make far more contacts per unit volume than the much coarser fibres of such materials as "C". It may be assumed that the number of contacts is proportional to the packing density at any space filling density. The "contact coefficient," the relative number of contacts for a given material at a given packing density, is derived as follows:

The number of contacts in a given cross-section of material is proportional to the unit area divided by the cross-sectional area of a single fibre of median diameter, multiplied by the number of contacts per fibre (assumed to be 4), and by the packing density in lb. per cu. ft. (P.D.). In the following expression the unit area is 1 mm².

$$\frac{1mm^2 \times 4 \times P.D.}{\pi \frac{d^2_{med}}{2^2}} = \frac{1 \times 10^6 \times 4}{\pi \frac{d^2_{med}}{2^2}} \times P.D.$$

The constants of the above expression give rather large values and are reduced by 10^4:

$$\frac{16 \times 10^6}{\pi \times 10^4} \times \frac{P.D.}{d^2_{med}} = 509 \times \frac{P.D.}{d^2_{med}}$$

509 = Contact constant

$P.D.$ = Packing density in lb. per cu. ft.

d_{med} = Median fibre diameter in micra. $\left(\frac{m.\ m.}{1000}\right)$

Conclusion

Figure 15 shows clearly that the contact coefficients and the surface area for materials A, B, C, D, E and F are related. This figure was obtained by plotting the values found in columns 14 and 18 of Table 5 on loglog paper. This significant relationship does not appear when values uncorrected for the presence of shot and for packing density are employed.

The variation in the reported conductivity for the insulating materials samples is very small, being 0.27 to 0.25, as shown in Table 5, column 19, and the presumption is that transference and conductance are related, unless it can be shown that there is a significant variation in the other factor, radiation.

APPENDIX II

THE EFFECT OF ADDING LIME TO SAWDUST

Sawdust, being abundant and cheap, has been used extensively in some localities as an insulating material. It is necessary, in many instances, to mix this with about 10 per cent of slaked lime to avoid the effects of moisture and vermin. The following results were obtained on the hot plate apparatus at the University of Toronto, when sawdust made of mixed woods was tested, first alone, and then mixed with lime, in the above proportions. The sawdust was first dried at 215 deg. F., about 50 per cent of the weight being lost in the process. During the test the weight of the sawdust sample increased by 3 per cent, due to the re-absorption of moisture, while that of the sawdust-lime mixture increased by 9 per cent.

Material	Sawdust	Sawdust mixed with 10% lime
Density: lb/cu. ft.	9.03	9.03
Mean Temperature: °F	84.7	82.9
Conductance of Specimen 1 inch thick: BTU/sq. ft/°F/hour	0.309	0.319

The addition of lime, therefore, increases the heat transmission of dry sawdust by about 3 or 4 per cent.

APPENDIX III

THE USE OF THICK INSULATION

The new pavilion and other additions made to the Toronto Western Hospital in 1935 increased the volume to be heated by over 100 per cent. Moreover, the new pavilion is fourteen storeys high and has large exposed surfaces, and also considerable additional steam-using equipment was supplied. Table 7 gives a comparison of coal consumptions for the heating season of 1933-34 and 1939-40, respectively.

Thus, the increase in coal consumed by the additional steam using equipment was estimated to be 295 tons. The total difference in coal consumption (on a B.T.U. basis) was 290 tons, so that the extra cost of heating the additions to the original building and the new pavilion is practically nothing. A considerable error in the above estimate would not materially affect this comparison.

This economy is attributed to:—

(1) The use of new and more efficient heating plant. This might account for about 10 or 15 per cent of the difference.

(2) The use of thick insulation in walls and roof. The walls consisted of a brick or stone veneer (4 to 6 inches thick) backed by 8¼ inches of special Haydite blocks (65 lb. per cu. ft.). Behind this were asphalt and 1½ to 2 inches of cork (3 inches in some places). The roof was a concrete slab, 3 inches thick, topped with 2 inches of cork plus felt and gravel. Below this was an air space and hung ceiling.

(3) Double glazing, weatherstripping and caulking of practically all windows.

(4) The orientation of the new pavilion to get the maximum benefit from winter sunlight.

The use of wood shavings (6 to 8 inches thick), proper orientation and ventilation has enabled hog testing stations for the Dominion Government to be kept at a constant temperature of 50 deg. F. with a very small fuel cost. These buildings are in various parts of Canada from Alberta to Quebec, and the outside temperatures are frequently as low as −50 deg. F. The regulation of temperature is necessary for the elimination of surrounding conditions when measuring the inherited characteristics of pigs, as, when the temperature of the farm building is lowered, it is reasonable to assume that increased food consumption is necessary to maintain body temperature, and therefore the amount of food required to produce 100 lb. of pork varies accordingly. The buildings were, therefore, designed to eliminate this variable and have proved satisfactory for that purpose.

The author is indebted for this information to Mr. James Govan (Toronto architect) and Mr. J. G. Lefebvre of the Department of Agriculture, Dominion of Canada.

SOME PROBLEMS IN AIRCRAFT PRODUCTION

J. I. CARMICHAEL, S.E.I.C.

Paper presented before the Lakehead Branch of the Engineering Institute of Canada, on January 15th, 1941.

An industry exists to make, sell and collect payment for its products; thus its basic problems are to purchase the required material, to find suitable sources of labour, to obtain equipment for production, to develop and maintain the necessary organization, to design and manufacture the product and finally, to market the product and finance the manufacturing operations. At present, the market is boundless, while the production capacity is definitely limited. Thus marketing and financing presents no serious problem to Canada's aircraft industry.

Organizing, designing and manufacturing are internal problems while the remainder are external and are not under the control of the aircraft manufacturer, and for this reason have become critical under the present wartime industrial conditions. It is felt that the secondary industries of supply are not fully aware of their responsibilities to Canada's aircraft manufacturing programme. As the industry is more dependent upon these industries than ever before, some aircraft production problems will be presented so that the development of more efficient relationships may be aided.

Effects Of Design

The requirement that a product be designed for the most efficient performance is, in most industries, less important than its production at lowest cost, usually from standardized materials and processes. In the aircraft industry the opposite condition exists, as the designer must make every effort to obtain highest possible performance and cannot make concessions to cost or ease of production if they affect performance.

Aircraft components must be given special shapes and arrangements in order to obtain highest aerodynamic and operational efficiencies. These involve various design procedures, specialized types of construction, large numbers of parts and special forms of material, which require many difficult manufacturing processes. When the basic design has been established the reduction of weight affords the best opportunity for improving performance. This requires the use of specialized material specifications whose variations must be held within narrow limits; very low manufacturing tolerances and exceptionally high standards of workmanship must be specified; and inspection must be extremely critical to insure strict adherence to these requirements.

The types of construction most commonly used are welded tubular, bolted tube and gusset and semi-monocoque; each has special applications but the choice usually depends upon which is most adaptable to available material and production capacity. Semi-monocoque[1] is the most common type as it allows the use of easier and faster production methods and materials which have been standardized to a much greater extent than for other types.

Much effort is being spent upon the development of a full-monocoque[2] type of construction; when this is accomplished, aircraft will be produced much more rapidly and cheaply than by any method now in use; indeed the present aircraft industry will be revolutionized.

Most designs provide for interchangeability between major components and between many detail parts. This provision does not affect performance and is the most important contribution of the design towards aiding shop fabrication and assembly and maintenance in the field. This is done by specifying low tolerances on common dimensions of matching parts which are to be interchangeable, and by building this accuracy into their jigs, tools and fixtures. The first part is made in conjunction with its tools of which there are usually two or more, and is then offered up to its next assembly to check its inter-

[1] The theory underlying semi-monocoque design is that the stress is all carried in a thin skin, usually light gauge metal, which is internally supported by stringers, bulkheads, etc.

[2] Semi-monocoque construction is the result of limitations imposed upon fiull-monocoque by the lack of satisfactory materials and manufacturing processes. Full-monocoque construction has the skin carry the load free from any internal support. The so-called "plastic" airplane is of this type; the components would be molded in one piece usually with the application of heat and pressure. Materials such as phenolic-resin-bonded plywood have been successful in recent experiments; further progress is limited by the size of the component which can be turned out, the extremely high cost of equipment and also by the fact that research is not yet completed.

changeability. When the tools are thus cross-referenced, parts and components may be placed in production with complete assurance that they will be interchangeable. This is done with as many parts as possible in order that the work of fitting and otherwise completing on assembly may be kept to a minimum. Establishing interchangeabilities is a costly procedure and cannot be done on all parts for practical and economical reasons, but it is a distinct aid to production and thus is developed wherever possible.

The Hawker "Hurricane," now in quantity production at the Fort William Plant of the Canadian Car & Foundry Company, presents unusually difficult production problems because it is a mixture of several types of construction. The wings are of the stressed skin type and require approximately forty per cent. of the total productive man-hours for the aircraft; the remainder of the structure is bolted tube and gusset construction with minor applications of many other types of construction such as welded assemblies, wood fairings, etc. There are about six thousand parts required in quantities of one or more per aircraft; these include six hundred proprietary parts, eight hundred machined parts, three thousand three hundred detail fabricated parts, which are assembled into twelve hundred sub-assemblies and are later incorporated into one hundred main assemblies.

In addition there are three thousand standard details which are required in large quantities, so that the total number of items on the airframe probably exceeds sixty thousand. Machined and detail fabricated parts may be made from one of twenty-five types of construction, from thirty material specifications which are required in ten different forms. During their manufacture these parts undergo several of sixty fabricating processes and are completed by passing through one or more of twenty finishing processes.

From the foregoing it will be seen that the aircraft is composed of numerous intricate parts and that each of these must be designed for highest efficiency; the efforts to reduce weight cause additional complication by requiring great accuracy in design and construction; the designer then has no choice but to treat each problem as a particular case with its own special solution. This latter condition produces a lack of standardization in all details which is a most serious problem from the various view points of material purchasing, labour and equipment supply, plant layout, production control and economy, and speed of manufacture.

There is a growing tendency to give greater consideration to production problems and in many cases changes are being made which have little effect on performance but which greatly aid production. The majority of these problems will not be solved effectively until new methods of design and manufacture are introduced which will permit highest performance and at the same time allow lowest costs and much higher rates of production.

Labour Supply

Rapidity of industrial expansion is limited by the rate at which new personnel can be absorbed, new equipment can be set in operation and material can be procured for production. These are external problems among which the problems of labour supply are most easily solved by the manufacturer, despite the fact that there has been no general industrial training programme in Canada for many years and that today the aircraft industry is confronted by labour shortages.

One of the most important effects of the design is to specify extremely high standards of workmanship over a variety of very difficult fabricating operations. In addition, the numerous types of construction and large number of parts require that each workman be possessed of more than one skill and thus it is impossible to set untrained men and women at producing aircraft parts. Men and women with no industrial background must be given instruction in the fundamentals of aircraft shop practice before they can be put to work. This delays expansion.

Many government-supported industrial training schools are giving assistance but their graduates come to the aircraft factories relatively unskilled. These graduates usually spend another six weeks in company training classes or in the shop under close supervision before they are considered capable of performing simple tasks. After an additional four months they generally develop to a point where they can act with initiative and produce good work.

The possibility of absorbing large numbers of women workers is being explored; while actual numbers are unknown, one manufacturer has been able to employ women to the extent of approximately fifteen per cent of the total staff. It is estimated that this could be increased to thirty per cent. if necessary. This is being done for many reasons; women are not liable for military service; most male workmen are already employed, thus women represent a relatively untapped labour reserve; many tasks are more suitable for women either because of the delicate touch required or the monotony involved. Women are most readily adaptable to tasks such as stamping, welding, sub-assembly, detail inspection, rivetting, etc., but there are few tasks they cannot perform satisfactorily if sufficient traning is provided.

Most factories have been able to cope with the labour situation as outlined above, but their rates of expansion have been limited and production efficiencies have been lowered. If larger contracts were placed, manufacturing procedures could be reduced to their simplest elements and allow the use of less skilled workmen.

Material Supply

The aircraft industry is finding the location and maintenance of adequate sources of raw materials and proprietary articles to be a difficult external problem. The complexity of the design and general market conditions combine to make this so.

Previous to the outbreak of war, nearly all commercial aircraft manufacturers in Canada had experience with the production of American designs and were using material made to American specifications; for this reason little thought was given to the expansion of the production capacities of existing suppliers or to the development of new sources of material to British specifications. Despite the fact that it was difficult for the manufacturers, the first war contracts were given for the production of aircraft of British design. No sources were available in Canada for most of the material required, thus the manufacturers were forced to import their requirements from England. About six months later an export embargo was placed on these items and the development of Canadian sources for these materials became vitally important, in order to avoid stopping the various programmes before they were fairly started.

This situation would not have arisen if a vigorous programme had been previously undertaken to develop the Canadian sources of supply. If this had been done, the supply industries would have had a chance to solve the numerous practical and technical problems of producing these new materials; stocks of basic raw materials would have been accumulated and most important, the capacities of the supply industries would have been surveyed, coordinated and if necessary, developed. This was not done until the manufacturers were forced, for their own protection, to develop their own sources.

These sources were found among industries whose products, experience and equipment indicated that they would be capable of manufacturing and supplying the necessary materials. The purchasing, engineering and planning staffs of the aircraft factories made direct contacts with the key personnel of these supply industries; in this way they transmitted directly the necessary technical data and supervised the operations and progress made. When the supplier proved his ability to produce, the British Air Commission placed him on their approved list; from this time he was responsible to them and was considered to be a standard supplier of the particular item he had developed and was able to supply it to the whole industry.

Sources had to be developed for both raw material and proprietary parts. The former presented many difficulties because the materials were new and their specifications were much more rigid than anything previously produced. In the case of proprietary parts, the difficulties were mainly in the working of such materials. For nuts, bolts, rivets, forgings, castings, etc., the working characteristics of the new materials could be learned only by experience and this caused many unforeseen delays. For example a bolt manufacturer found he could not manipulate a certain alloy steel until he had developed new tools and fabricating procedures; a forging manufacturer had never before produced aluminum alloy forgings and found that he had to procure more powerful presses, redesign his dies, and develop completely new techniques of forging and heat treatment.

There were many items of raw materials and proprietary parts for which sources could not be developed economically in Canada. Such items are special alloy steels, radiators, tie rods, instruments, etc., in these cases American substitutes were readily adaptable or development could be more easily completed by firms working on American equivalents and for this reason they were purchased in the United States.

While this method of development has presented obstacles to Canada's aircraft production, it has advantages in that the direct contact was the best possible condition for rapid development and it ensured that priorities would be established and delivery promises would be met. The great disadvantage was that the industry was unprepared and the manufacturers were often forced to duplicate each others' efforts to develop sources and in many cases entered into competition with one another. This caused the wasteful use of what capacities were available and developed some sources which would have been more effective producing something else.

The continuously expanding aircraft industry will soon absorb the capacities of all sources now developed, and a serious situation will result if additional expansion is not undertaken immediately. There is a lack of co-ordination among the suppliers, particularly in the case of machined parts; this has caused inefficient production but may be eliminated by the setting up of a central control agency which would determine priorities, allocate capacities and control and co-ordinate deliveries.

The existing severe specifications and lack of standardization of material present many problems which can only be solved by considering production as well as performance. If American rather than English types could be produced in Canada, these problems would be less pressing, owing to the fewer materials required and the greater production capacities available.

Subcontracts

The problems of finding extra space and new equipment are also of importance. They are caused by conditions outside the industry and are becoming the major obstacles to rapid expansion. The construction of new buildings and the purchase of new equipment such as salt baths, presses and machine tools are requisites for expanded operation but market conditions present many delays.

The manufacturer finds the only solution is to approach well established industries in other fields and endeavour to make use of their production capacities for the manufacture of aircraft parts or components on a subcontract basis. Such an arrangement is made only when the subcontractor is experienced in the commercial production of parts similar to those required; this is mutually satisfactory, as the manufacturer obtains some additional capacity and the subcontractor has an opportunity to aid the war effort and keep his organization operating efficiently.

Items which may be subcontracted most effectively are machined parts, and wood and sheet metal assemblies and details. Machined parts are most important as they may be put into production immediately in numerous industries whose experience and equipment is readily adaptable; there is much more commercial productive capacity available; their production time is the major part of all work subcontracted; the tooling programme of the manufacturer is relieved considerably when the subcontractor makes his own tools; the existing machine capacity is reserved for the main contractor's tooling programme; and development and control of subcontracted machined parts is easier providing sufficient capacity has been found.

There are relatively few aircraft on which wood details and assemblies involve a large proportion of the work; where these do occur, they may be successfully subcontracted to commercial woodworking firms and thus present few problems. Sheet metal assemblies and details may be successfully subcontracted either to other aircraft manufacturers or to commercial industries which produce similar articles. When parts or components of this type are sublet, the subcontractor must possess experience and equipment which are readily adaptable to their manufacture, after a minimum of instruction; this shortens the development period and assures the success of the undertaking. As there is a relatively small amount of suitable commercial capacity available, this type of work can not be subcontracted as extensively or as successfully as machined parts.

It would be of great assistance to the aircraft industry if suitable sources were available for subcontract work; this is not the case and each manufacturer usually finds that he must undertake the development of his subcontractors in exactly the same way as he developed his sources of raw material, i.e. by personal contact and close supervision of the progress made. An ideal situation would exist if subcontractors could accept orders, drawings and relevant data from the main contractor and then proceed to buy material, develop tools and methods and finally to deliver the parts ordered on the dates specified. This is impossible at present as subcontractors are generally inexperienced with the materials and manufacturing processes required, have not the same access to markets or priorities as the main contractor and do not realize fully their responsibilities to the main programme. Thus the manufacturer must supervise and control all operations and usually must train the subcontractor in fundamental aircraft shop practice; in addition he must supply all material, special tools and manufacturing data and the first parts submitted must be checked very carefully before allowing production to proceed. This is slow and laborious for the manufacturer but when the development period has been completed, the subcontractor usually gives complete satisfaction.

In the case of machined parts these requirements may be relaxed if the subcontractor has sufficient experience, but sheet metal parts and assemblies will always require close attention. If an experienced subcontractor is capable of making and cross-referencing tools and detail parts and can manufacture a complete assembly, the problem is eased considerably as a check need be made only on the assembly and not on its component parts.

It is indispensable that manufacturers and subcontractors realize their mutual obligations. The manufacturer must give all help necessary and must allow a reasonable time before requesting deliveries and during this time he must continue to supply his own needs. This allows the subcontractor to develop his work properly, free from pressure for early deliveries. The subcontractor must realize that all assembly sequences are stopped when one part is lacking; if a promise for delivery of a part is broken, the manufacturer is forced to enter production on it at extremely short notice and often cannot avoid delay. when this happens material must be procured, often tools must be built, and the most expensive manufacturing methods must be employed in an effort to break the jam. This is particularly dangerous in the case of machined parts as they are more difficult to make and often the manufacturers' machine tools are working at full capacity on tooling or some other urgent programme. The danger of delaying the assembly line may usually be avoided if the subcontractor realizes his inability to meet his promise and issues a warning at least one week previous to the delivery date.

It is estimated that at least twenty-five per cent of the total production time may be subcontracted efficiently; thus the successful development and co-ordination of subcontractors is seen to be of vital importance to the expanding industry. The final stage in the development of present subcontractors will be reached in a few months and it would be of great assistance to the industry if an independent agency could be set up to co-ordinate their activities with those of the aircraft manufacturers.

Organization

The problems which have been discussed affect the industry externally but there are two major internal problems which are basically similar in all industries, i.e. departmental organization and manufacture.

There are two groups of departments, one directly, the other indirectly, responsible for the success of the manufacturing programme. The latter group includes the engineering, purchasing and costing departments, which have contact with production problems concerning the development of subcontractors and sources of material. For this reason no direct reference will be made to their responsibilities. The other group includes the inspection, stores, shop and production departments.

The British Air Commission supervises all activities of the inspection department, holding it responsible for seeing that the finished aircraft conforms to drawings in all respects; that standard manufacturing procedures are used and that proper standards of workmanship are maintained. The stores department is divided into two sections,—" finished parts " and " raw material " stores. In the first are received, stored, and issued parts made by the shop and subcontractors; in the second raw material and proprietary parts are received, stored, and issued for fabrication.

The inspection department supervises this department to prevent the issue of improper material and keeps a full set of records on the origin of all materials; in this way parts made from defective material may be traced and replaced.

The shop is primarily responsible for the manufacture and assembly of detail parts into the finished aircraft; secondary responsibilities are the maintenance of discipline and the education of new personnel. There are about thirty departments in most aircraft shops which are classified as detail, processing or assembly departments according to their functions. The detail and assembly departments each comprise about forty-five per cent of the total labour staff, the balance being required for processing departments. The shop is responsible to the inspection department for the standard of workmanship and to the production department for the completion of work on schedule.

The function of the production department is to co-ordinate the activities of the departments directly concerned with production problems, thus it is directly responsible for the success of the manufacturing programme. The project must be planned properly and effective control must be set up to secure this co-ordination. The first of these duties is performed by the planning department which plans the work in all its details and lays the foundation for the production programme; the second is done by the control department which sets the programme in motion and sees that it moves according to schedule.

The planning department has much to do before the project can be placed in production. Preliminary time study estimates and recommendations for necessary changes in personnel, equipment, etc. must be made; detail and master bills of material must be prepared for the use of the shop and purchasing departments; production methods and times must be investigated from which tool designs and department loadings are developed and production schedules are set. The tooling programme and construction of the first aircraft are very closely supervised by this department as they are developments from the primary responsibilities outlined above.

The control department is responsible for the control of material, despatching and recording production orders, routing parts through the various steps in their manufacture, for supervising the progress made and correcting it if necessary. The material control division supervises the distribution of all material and is responsible for the detection of impending shortages. When shortages are foreseen the purchasing department is urged to obtain more material; if the correct specification is unavailable, this group requests the British Air Commission to permit the use of a substitute. Present market conditions prevent the maintenance of satisfactory inventories on some items and under these circumstances effective material control is of vital importance.

Orders for the fabrication and assembly of detail parts are issued to the shop in accordance with the schedule laid down by the planning department. An even flow of orders and work through the shop is necessary for rapid and efficient production. Conditions such as material shortages, incorrect tools or improper department loadings must not exist, as they will impede this flow and cause a loss of control. The progress division routes all parts along their fixed paths from primary fabricating departments, through processing departments and inspection view-rooms to the department which requires them next. If this flow is delayed the progress division must take any corrective action necessary; they may request the use of new or additional tools, enlargement of the department, overtime work, or completion of shortages elsewhere in order that the work may proceed.

The control department is the one most directly affected by the various production problems described and is responsible for the progress made; for this reason it is the central and most important division of the organization. Problems of control arise from the design and are so numerous and complex that it is exceedingly difficult to maintain co-ordination. In spite of continuous efforts, serious conditions often develop and occasionally the control system fails completely; when this happens shortages are found to exist only at the instant the items are required. As any missing part can stop assembly operations completely, this will delay the whole programme; the prime duty of the control department under these circumstances is to ascertain and remove the cause of the delay as quickly as possible without consideration of cost.

Manufacturing Problems

During the development stage, and later when the programme has reached quantity production, the manufacturer is confronted with numerous problems arising from the basic design, the pressure of time under which the work must be completed and the relatively small quantities of aircraft he is allowed to produce. The period for developing a new contract does not end when the first machine flies; many refinements must be made in tooling, production methods, etc., before production " bugs " can be eliminated and full scale production can be entered. About twenty-five aircraft must be completed before this stage may be considered complete; the programme for the " Hawker " Hurricane required about fifteen months and an expenditure of about one million man-hours on tools and parts before the start of quantity production. Due to the dire need for aircraft and their rapid obsolescence, the pressure of time places tremendous obstacles in the way of the successful co-ordination and completion of the development and production programmes.

The first limitations on cost and ease of production are caused by design but nearly as important are those imposed by the quantity to be produced.

Many manufacturing problems are caused by the smallness of the orders placed, which prevents the use of equipment, methods and tools which would allow cheaper and faster production. It has been estimated that unit production costs are decreased by ten per cent each time the quantity to be produced is doubled. This saving is due to the combined effects of being able to use more efficient equipment and manufacturing methods which allow cheaper, faster and more continuous production; and simpler design methods which change forms of material and types of construction to ease production without affecting performance.

In the past, initial contracts usually have been placed for about fifty or one hundred aircraft. On this basis development and production were undertaken, tools and equipment purchased and methods set up to allow economical operation. When the programmes were nearly completed, they were usually extended by placing additional small orders. This necessitated the purchase or manufacture of many new tools, as the old ones were worn out or had to be replaced with different types to maintain economy of production; new methods had to be developed and often additional space had to be procured. This caused duplication of effort, wasted much money originally expended, lost precious time, and, most important, did not allow the manufacturer to set up the best conditions for his programme.

The importance of placing larger contracts may be demonstrated by comparing the estimated results to be obtained from producing an interceptor-type aircraft on contracts for forty and for fifteen hundred. Development of the former could be completed within ten months and production would be complete in another six months; the highest rate of production would be about four per week and production of the last few aircraft would require approximately twenty thousand man-hours. In the latter case, development could not be completed and the first machine flown in less than fourteen months; the programme would require another fourteen months for completion; the highest rate of production would probably exceed sixty per week and production time would drop to less than ten thousand man-hours per aircraft in the latter stages of the programme. Thus an increase of forty times in the size of the contract would reduce the productive effort by fifty per cent, would allow an increase of fifteen times in rate of output while requiring only twice as much elapsed time. The objections to placing much larger orders are that the Canadian aircraft industry has only recently proved its ability to handle such difficult tasks; the extremely high cost of these larger contracts; and the rapid obsolescence of all military aircraft. Under the present dire need for aircraft of all types, these objections are not as important as high rates of production and hence it is felt that the placing of larger contracts should be seriously considered.

It is often recommended that mass production methods be applied to a greater degree in the aircraft industry; for various reasons it has been found impossible to effect any considerable increase in efficiency by these means. Mass production achieves rapid and cheap production by establishing continuous manufacturing operations and material flow; this continuity is prevented by the complexity of aircraft design, which does not favour easy production. Further, the necessity of maintaining economical operation often requires inefficient fabricating methods and prevents the full development of interchangeability.

Conclusion

The more serious aircraft production problems have been presented so that secondary industries may appreciate these difficulties and thus give greater assistance. It has been shown that solutions of most of these do not fall directly within the scope of the manufacturer and require assistance from outside sources. Designers are striving for greater standardization but find it impossible to obtain this while present methods of construction are used and performance is held to be of first importance. Labour supply and organization problems are made more difficult by the design but are not impossible to solve. Sources of supply and subcontract capacities require coordination and further development if the industry is to continue to expand; as previously stated, an independent organization should be set up for this purpose. Manufacturing problems will always be serious particularly under the pressure of time but would be eased considerably if new methods and equipment were made possible either by the adoption of new methods of construction or the production of much larger quantities of present types.

SALT, ITS PRODUCTION AND USES

A. H. PASK, M.E.I.C.
Project Engineer, Canadian Industries Limited, Windsor, Ontario

Paper presented before the Border Cities Branch of The Engineering Institute of Canada, on April 12th, 1940

The common salt to which we are accustomed, is almost pure sodium chloride. It is the modern, cheap, form of a substance that has not always been readily obtainable, and at times, in some places, has had high intrinsic value. It is so necessary to our lives that it has been closely linked with the history of mankind.

Salt is as old as the earth itself and being water soluble, every stream has, for thousands of centuries, carried its small burden of salt to the ocean. Thus, with evaporation of the water, the saltness of the ocean has gradually increased. It has been estimated that the ocean contains as rock salt, nearly 5 million cubic miles, a bulk 14½ times that of the continent of Europe above high water.

However, there are stores of salt, apart from the ocean. These are the deposits of rock salt and of brine found in many parts of the world, usually quite deep in the earth. The rock salt, or halite as it is known to geologists, is believed to have been deposited from the ocean by evaporation. Large arms of the sea became cut off or partially cut off from the main body and by evaporation, the salt content was deposited. The overlying rock in later ages converted this by pressure into rock salt. If quite pure, it is a clear colourless mineral which breaks into cubical pieces. Usually magnesium and calcium compounds exist as impurities. The thickness of these deposits may be up to two or three thousand feet.

Locally, one bed of the deposit is about 230 ft. thick. This is at a depth of 1400 ft. Thinner beds are located up to the 1000 ft. level. This deposit is part of a vast salt basin formed, it is believed, about 350 million years ago. The Canadian portion of this, roughly, is west of a line between St. Thomas and Kincardine and north of a line between St. Thomas and Amherstburg. The area in this boundary is approximately 3000 square miles so the included quantity of salt has been estimated as sufficient to supply all the needs of the world at the present rate of consumption for 90,000 years. One square mile of the thickest local bed would satisfy all Canada's requirements as at present, for about 800 years. On the Michigan side of the river, this formation is north of a line running west of Wyandotte to Kalamazoo where it turns north west to Muskegon on the shore of Lake Michigan. Thus all northern Michigan is believed to be underlain with salt though at a greater depth than on the Canadian side.

Ages after the salt deposits were formed, when man found a need for salt, he only knew of the ocean, salt lakes and springs. To many inland peoples then, salt was almost unattainable. Therefore, a salt trade was built up and this early had its effect on trade routes and commerce. Desert caravan routes were built up from salt oases. Some ancient sea trade routes started with salt and salt fish. A special road was built by the Romans for salt traffic. This was the Via Salarina from the mouth of the Tiber across the peninsula to the Adriatic.

The economic importance of salt is indicated by the almost universal prevalence in ancient and medieval times and even to the present day in some countries, of salt taxes and government monopolies. In parts of Africa, salt cakes have been used as currency. Marco Polo found that salt was a medium of exchange in Chinese markets and that salt was very important to the financial system of the Mongol emperors.

Because of its necessity, scarcity and properties, salt had its effect on customs and religions. Salt springs were looked upon as a gift of the gods. Salt was early associated with religious offerings and feasts and in this regard, is noted in the Bible. In fact, among ancients, every meal that contained salt was held to have a sacred character so that a certain bond of piety and friendship was believed to exist between host and guest. Out of this arose certain Arab beliefs and phrases such as "There is salt between us" and "To eat a man's salt." Probably an outgrowth of this was the medieval English custom of distinguishing the rank of guests at the table by placing them above or below the salt, this being a large salt cellar on the table. To be above the salt was a mark of distinction and to pass the salt in those days was really an accomplishment.

Our word "salary" comes from the practice in early Roman times of giving the soldiers an allowance of salt. In Imperial times, money was given for this and was called "salarium", hence the word "salary". The phrase "Not worth his salt" therefore means "not worth his salary."

The natural method of salt recovery using sea water, was to evaporate the brine in shallow pools by the heat of the sun. An extension of this method is still employed today in sections having plenty of sunshine and relatively little rainfall. Salt is produced in this way on the shores of San Francisco Bay.

The sea water is first pumped to ponds a few hundred acres in extent where over the period of a year, the evaporation is sufficient to raise the proportion of salt to about 25 per cent., which is about the saturation point. Some impurities, as calcium sulphate, have a slightly lower degree of solubility than the sodium chloride and so most of this crystallizes out. When salt crystals commence to form, the brine is pumped to smaller crystallization ponds. As evaporation goes on, the salt collects to the depth of several inches. The mother liquor is drained off before more highly soluble impurities as calcium or magnesium chlorides or some bromine and potassium salts crystallize out. The salt is then gathered up or "harvested" by shovelling into small dump cars. A more modern method uses a machine to collect the salt and place it in the modern cars. The resulting salt is then drained, washed, and dried, but usually is not of high enough quality for dairy and table use so that often, for this market, it is re-dissolved and re-processed by artificial heat methods.

Another natural method of concentrating weak brines is the freezing method. This is based on the definite manner in which a solution of sodium chloride freezes. If a solution of 23.6 per cent. NaCl and 76.4 per cent. H_2O is cooled, it will freeze as a mass at -22 deg. C. If the solution is weaker than this, ice will crystallize out and continue to do so until the proportions are as noted before. If the salt were in excess of this ratio, its hydrate $NaCl\,2\,H_2O$ would be deposited until equilibrium had been reached. The whole mass would then solidify. This minimum temperature then is a eutectic point above which either salt or water will crystallize out, depending upon which is present in excess of the eutectic ratio. Thus, with a weak brine, the separation of pure ice takes place because the water is in excess and the remaining solution will be correspondingly stronger in sodium chloride.

This method is said to be practised with some degree of success in the northern part of Europe, the ice being removed as fast as it forms. The saturated solution thus obtained is then treated by one of the artificial heat methods of evaporation.

Where it is possible, beds of rock salt may be quarried or mined and this has been done for centuries. Salt mines in northern India were worked before the time of Alexander. In Poland, the great deposits near Cracow have been mined for 800 years. This is the famous mine which contains fine sculptured statues, vast ballrooms, reception halls, chapels, etc., carved out of rock salt. The depth of operations is from 200 to 1000 ft. In Canada, the only salt mine is at Malagash, Nova Scotia, where operations are 200 to 300 ft. below the surface. Nearer at hand, we have a mine in Detroit, which goes to a depth of over 1100 ft.

In mining, the process is one of removal of the rock salt by cutting and blasting and transporting it to the surface. Impurities are usually kept separate as much as possible, and the rock finally crushed and screened to different grades. Often, an artificial heat evaporation plant is operated to take care of fines and waste from the primary hand separation.

By far the largest output of salt is from brine wells. These may tap natural stores of brine or fresh water may be pumped down to dissolve rock salt and be returned to the surface as a saturated brine. Occasionally, a fresh water source tapped by the well at a higher level than the salt can be made to act as a fresh water supply.

The wells are drilled and cased to penetrate to the bottom of the bed. The fresh water is pumped down the casing and the resulting brine flows back up a smaller pipe inside the casing. Owing to the higher specific gravity of the brine, it may be necessary to use deep well pumps to raise it about ⅛ of the well depth. It is possible, after continued use of adjacent wells, to pump the water down one well and bring the brine up another.

The fresh brine is stored in large tanks to settle and is chemically treated to precipitate the impurities.

As another method of producing salt from brine, obviously man early would make use of artificial heat applied to vessels containing brine. This probably was first a kettle over an open fire but later was a flat pan over a fire enclosed in masonry. Then several pans in a row were used. As the salt formed, it was raked out by hand and placed in baskets to drain.

It is interesting to read of the specific directions given for salt making in the few works on the subject some 400 years ago in England. Such things were added to the hot brine as sheep's and cow's blood, beaten white of eggs, or a quart of the best beer or ale obtainable. The object of these peculiar additions seems to have been to remove dirt or, as they believed, " to granulate the salt ".

Of course, the salt from these direct fired pans was not uniform in grade owing to the differences in heat applied to each and therefore they were finally replaced by a single long pan. This somewhat improved the quality obtainable.

It was a short step, though a relatively recent one, to heat a long pan with steam coils and create the method of production now known as the grainer system. Generally, this uses a steel tank over 100 ft. long, about 16 ft. wide and 2 ft. deep, heated by steam coils near the bottom. By regulating the steam temperature, it is possible to control the grade of salt produced, thus better salt is produced with brine at 192 deg. F. and coarse salt at 175 deg. F.

The salt is removed by a continuous endless chain drag or a reciprocating rake. The latter has the advantage that it is not so exposed to the air to create rust. It is operated by a hydraulic cylinder at one end of the grainer and on the forward stroke pushes the salt ahead along the bottom but on the return stroke it rides above the salt. Thus, the salt is gradually and continuously pushed to one end of the grainer where it falls to a trough to be pumped to a filter.

As salt production is an evaporating process, it is natural that multiple effect evaporators should be widely used though their application is relatively recent. In this use, the evaporators are referred to as pans, though they in no way resemble an object we would recognize by the word " pan ". They are cylindrical at the centre with conical tops and bottoms. The diameter may be 18 ft. and the overall height about 40 ft. At the centre is the steam belt which contains tubes around which either the brine or steam circulates, depending on the design. The pans are connected in series so that the steam produced in one, passes to the steam belt of the next or from the last one to the condenser. The salt collects in the conical bottoms where it is drawn off by a slurry pump.

The principle of operation is the same as in similar evaporators in that a partial vacuum is created by the condensation of the evaporated steam and because of this reduced pressure boiling takes place at a lower temperature than normal. Then by the use of multiple effects, the steam supplied to the first pan precipitates salt in all the pans; thus the system is very efficient. The three-effect system is most popular and with this, it is possible to evaporate over 2½ lb. of water per lb. of low pressure steam supplied. The salt produced has a fine cubical grain that is little different in size due to the different temperatures. Three 18-ft. pans will produce about 22 tons of salt per hour.

The salt from both pans and grainers is usually handled in the same way. Pumps are used to transfer the salt in a brine slurry to a filter or centrifuge where the salt is separated from the brine. A centrifuge is simply a high speed rotating screen cylinder that removes the brine by centrifugal action. This leaves two or three per cent. of moisture in the salt. The filter is usually a slowly rotating horizontal screen cylinder on which the slurry is poured at the top. An exhauster removes the air and brine from the interior of the filter, thus forming a cake of salt on the screen. This is scraped off during the rotation. By enclosing the filter and supplying it with heated air, it is possible to produce moisture-free salt on the one machine. Otherwise, it is necessary to send the moist salt through a rotary dryer. This is merely a rotating cylinder about 30 ft. long and 6 ft. in diameter through which the damp salt passes counter to the direction of flow of hot air from steam coils or an oil furnace. This will remove the last traces of moisture. The hot salt must be cooled either in a similar device supplied with cold air or a water jacketted screw conveyor.

The salt is easily handled by belt, bucket, or screw conveyors and it is thus transported to storage or where required. For grading it is screened to different sizes and stored in special bins. Before packaging any required ingredients are added such as magnesium carbonate which makes the salt free running in damp weather or potassium iodide which is used in iodized salt. The former is added to the extent of 1 per cent. and the latter 0.01 per cent. Automatic machines are used for packaging and bagging. Salt blocks are made from ordinary fine salt pressed to shape in a hydraulic press. Salt tablets as used by the canning industry are made in a small mechanical press.

The uses of salt are numerous as it is a basic mineral necessary for modern civilization. Directly, or indirectly, it is said to have some 1400 uses that vary from seasoning of foods to a raw material in the manufacture of carborundum.

There are the household uses and what may be called a medical use as a vehicle for iodine to prevent goitre. It is a necessity of life, for the human body can exist for only a few hours with entire absence of salt. It is required for digestive purposes and also to prevent evaporation of body fluids and retain the fluid pressure in the cells.

For the same reasons, it is required by animals and so salt blocks are sold to farmers for their livestock. It is, of course, very necessary for butter and cheese manufacture so that special grades of specially purified salt are made for these purposes. In other food industries it is also required. For canning factories, special salt tablets of different sizes are made so that for accurate and easy salting of the product, one tablet is placed in each can by a machine.

In the packing industry, it is used for the curing of meats, a special salt for which is "smoked" salt. Hides and pelts are preserved with salt. An extensive use is in the curing of fish, where purity is of great importance as it affects the quality of the product. In refrigeration, it finds considerable use, as brine is often used as a heat transfer medium.

In transportation, salt is finding uses as a protection against frost. For railways, it prevents heaving of the ties and freezing of switches. On highways and streets, it is used to remove ice, for which it is very effective, as, at sleet forming temperatures one pound of salt will melt almost 50 lb. of ice. When mixed with sand, it greatly aids increased traction by partially melting the ice. If previously mixed with the sand piles, it has the advantage of preventing these from freezing. It is mixed at the rate of about 75 lb. per cu. yd. of sand, and the pile is often capped with more salt equal to another 25 lb. per cubic yard.

Salt is coming into use as a stabilizing material for unpaved roads. For this, it is mixed with aggregate and clay which is rolled on top of a good foundation. The thickness of this stabilized course is about three inches and the amount of salt used is about 15 tons per mile of 20 ft. roadway.

The resulting road surface is harder, more durable, and relatively dust free compared with the same road without salt. The reason for this is that the salt tends to prevent evaporation of the moisture from the road due to the lower surface tension of the salt solution, and so keeps the clay binder in a cohesive condition, and allows better compaction of the aggregate at the surface. The slow evaporation of the moisture leaves salt particles, filling voids in the surface, thus making it denser and reducing the evaporation. It also prevents cracks due to contraction of the clay. When it rains, the surface salt crystals are dissolved. The clay at the surface becomes dispersed in colloidal condition and so stops up the pores and prevents the water from penetrating the road. Drying again repeats the coagulation of the clay and crystallizing of the salt. The loss of salt in these processes is slight.

It is in industry that salt finds its greatest use. It has long been used in the metallurgical industries and the ceramic industry. One use in the former is as a flux and in the latter it improves some clays and gives glaze to some wares. Carborundum has salt as one constituent raw material.

Salt is also required in soap making, textile dyeing and some organic preparations. It is also a basic raw material for some of the newer plastics.

POWER INDUSTRY

G. A. GAHERTY, M.E.I.C.

President, Calgary Power Company Ltd., and President, Canadian Electrical Association.

An address delivered at the dinner of the Canadian Electrical Association, at Calgary, Alberta, April 16th, 1941.

My subject is the Power Industry and the War. The question is, are we as an industry and as individuals doing our utmost to further the war effort. Our difficulty is to approach such problems objectively. To illustrate this I will give a simple example.

Some years ago the Elbow River in Calgary was in flood. The rising waters had broken into the basement of the Victoria Park power plant in which are situated the bus bars over which a large section of the City is fed. We had bulkheaded off the room containing these bus bars and had every pump we could lay our hands on at work. At the height of our endeavours we got an impassioned appeal from a man connected with the company to send someone with a pump to unwater his cellar. He was pained when we did not comply with his request and could not understand why we had turned him down. His cellar was uppermost in his mind and he was unable to visualize the situation in its true perspective. Most of us to-day are busying ourselves pumping out our own cellars instead of devoting our energies to the common end.

Our politicians, naturally enough, are inclined to take the line of least resistance. Heavy taxation and conscription of manpower are unpopular, so the politician tends to belittle the menace and to magnify our war effort. He lulls us into a false sense of security by wasting huge sums on home defence, whereas our future will be decided in Europe or in the Far East. Only a military disaster can bring us to our senses. It took Norway to oust the procrastinators.

Let us not underestimate our opponent. Vast resources in manpower and in factories have been made available to him in the conquered countries. The new sources of raw material lessen the effectiveness of our blockade. Germany's power has not yet reached its zenith.

To avoid a stalemate we must organize for a total war. To this end we must devote the utmost of our energies to the war effort and more important still we must see that these energies are applied with maximum effort. We are told that the St. Lawrence Waterway will aid the war effort but actually a man's services flying a bomber over Germany are infinitely more valuable in the defence of our country than those same services used in building the St. Lawrence canal.

We must recognize that our economic morale has been sadly undermined through the infiltration of communist ideas over past years. Constant reiteration has resulted in an unreasoning belief in many of these teachings. I refer particularly to the "soak the rich" view so prevalent today, the baiting of corporations and the idea held by so many Canadians that there is something unmoral about the "profit motive." The demagogue finds them the very thing to rouse the jealousies of the "have nots." Already such propaganda has resulted in discriminatory taxation and other abuses which, if carried to their logical conclusion, would result in a collapse like that of France. To get everybody working wholeheartedly it is indispensable that all be treated alike, each according to his merits, whether at the front on active service or at home in the munitions plant, and that the necessarily heavy taxes be levied justly and impartially.

As regards the despised profit motive we must recognize that it alone provides the necessary incentive to the individual to do his utmost and rugged individualism suitably curbed spells efficiency. In this connection the Mexican Government, when the oil trouble was at its height several years ago, suggested that the oil operators form themselves into a syndicate similar to the labour syndicates. The representative of one of the operators remarked to me that if you were to put the seventeen operators in a room together you could not get any two of them to agree on anything, let alone the whole seventeen. That is where the politician comes in because he has mastered the technique of getting people to work together. What we need in the Ministry of Finance to-day is a Sir Herbert Holt to do the planning and a politician co-operating with him to put it over with the public. I use Sir Herbert Holt as an illustration because he, probably more than any other single man in Canada, is responsible for our present high standard of living. In his promotional activities he made money but only a small part of it was diverted to his own needs. The balance went either into taxes or into further enterprises. These in turn provided employment and more manufactured goods to raise the standard of living. Only the wealthy should invest their money in the riskier ventures and it is to their savings that we owe most of our progress. The "soak the rich" policy may be good politics but it is bad economics. Let us be fair to the Sir Herbert Holts. We need them to-day in our war effort, and fortunately one at least of the Government departments recognizes this—the Department of Munitions and Supply.

Aiming at the destruction of private capital, propaganda has been directed towards exterminating companies through confiscatory taxation, oppressive legislation and unfair competition from governmental agencies. The Canadian public has been only too ready to believe the worst of companies and not without reason in some cases. In England the law makers have recognized the service rendered by companies in the development of the community and companies as such are virtually untaxed, but in Canada, following American precedent, corporate income is taxed as such, and the very same income is taxed again when it passes to the shareholders, whereas in England the income is taxed only once and the tax is collected at the source. Companies after all are merely groups of individuals banded together for a common purpose and it is a manifest injustice to tax the individuals twice over merely because they are so banded together.

So long as the tax was low and was confined to the Dominion this injustice was not very harmful, but with the Provinces invading the field and with the high rates of taxation necessary for war purposes the double taxation becomes devastating. It results in the confiscation of the entire income of certain groups of investors while leaving the income of other groups untouched. Consider the case of a company financed in the ordinary way with bonds, preferred stock and common stock. The minimum Dominion tax on income is 30 per cent including 12 per cent of so called excess profits tax, and it applies on all income after deducting operating expenses, depreciation and interest but not amortization of bond discount or preferred or common dividends. So long as there is enough income left after setting up this amortization to pay the preferred dividends in full the entire tax comes off the income available for the common shareholders. As Dominion and Provincial taxes on income now absorb nearly half the taxable income it becomes next to impossible to pay common dividends in a company with any substantial amount of preferred stock outstanding. Thus, as the rate of tax is increased, the value of the common stock and the value of the preferred stock are in turn destroyed. Apart from the obvious injustice of the double taxation, the junior security holders, whose equity is thus confiscated, are the very ones who take the most risk and who in the interests of further development of the country should receive the most encouragement. The promotion of new enterprises will become impossible and unless the companies can pass the tax on to the consumers in inflated prices, they will become so weakened financially that they can no longer finance the replacement of wornout plant and so will pass out of the picture. To avoid state capitalism our income tax will have to be placed on a sound basis.

One evil arising out of the high income and excess profits taxes is that the Government in contrast to the last war is forced to put up nearly all of the money needed for new plants or extensions to existing plants to make munitions. Were the companies using their own money it would no doubt be spent with greater prudence, but with the profit motive effectively eliminated by the excess profits tax, companies dare not risk capital except with an assured return. Whether after the war these munitions plants will be closed down or will be sold to private companies for a song or will be operated by the Government in competition with private industry remains to be seen, but of one thing we can be sure and that is that had the companies invested their own money in the plants they would not leave a stone unturned to put them to some use.

In contrast to this practice the Government has taken the position, rightly I think, that the supply of power for war industries is the sole responsibility of the public utility operating in the territory. With only two minor exceptions, in so far as I know, the utilities are themselves putting up all the capital necessary other than in some cases the relatively small amount required for the customer's substation and tap. These two exceptions are the Summerside air training school where the Dominion Government provided the town of Summerside with a Diesel engine, and the Dundurn military camp where the Government advanced a substantial sum to the Saskatchewan Power Commission to enable it to carry out an elaborate interconnection scheme, the effect of which is to deprive of income two power companies who are heavy income tax payers.

Not only does the Government insist on the power companies providing any capital required but it expects service at rates comparable to those applicable to firm contracts yielding an assured revenue for a considerable period of years. Industrial rates such as these are highly competitive and do not admit of any substantial amount being applied by way of depreciation to the retirement of capital used for war purposes. Thus power companies, unlike most industries, cannot take advantage to any extent of the provision of the excess profits tax act allowing special rates of depreciation on war facilities. To make matters worse, the excess profits tax precludes the building up of a surplus out of war profits with which to pay the carrying charges on the idle facilities through a post war depression. Any increase in taxable income would almost surely be taxable at the rate of 79½ per cent (including income tax) and when provincial income taxes are added only a trifling sum is left as compared with the financial risks involved. The power companies recognize that a major war means sacrifice for all and they are ready to do their share. All they ask is that existing discrimination be eliminated and that taxes be levied justly and impartially.

This brings up the tax discrimination existing as between privately and publicly owned utilities. This year the power companies will contribute some twenty million dollars to the Federal treasury in income and excess profits tax, whereas the publicly owned utilities pay nothing except indirectly through any power they may happen to purchase from power companies. Were all taxed alike in proportion to the number of customers the Dominion would receive another twenty million dollars at least in this time of need. This is equivalent to a thousand Spitfires a year. To maintain a sound financial position and be able to finance the expanding needs of the public they serve, the power companies have to pass on the tax to their consumers, so that it is the consumers of the privately owned systems who are being discriminated against. The increase in taxation will for the moment have to be absorbed by the power companies but should the high rates of taxation continue it is only a question of time until the disparity in rates becomes excessive or the high standards of service can no longer be maintained. The power companies are not the only ones that are the victims of this discrimination. It applies to all situations where government agencies, wheat pools, co-operatives, etc., compete with private business. While it is recognized that socialistic propaganda has made too much headway for it to be expedient for the Government to subject these to equivalent taxation, the Government could right matters at one stroke by adopting the English system of income tax. The difficulties are not insurmountable and under war conditions rates could be instituted that would yield more tax revenue than now.

As far as the power companies are concerned the public need have no fear of a power shortage. It is only in the electro-metallurgical industry that very large blocks of power are required and so far only three or four of these situations have developed in the whole of Canada. It would be an undue burden on the consuming public for the power companies to maintain reserves of developed power against such remote contingencies. It is better to build power plants specially when the occasion arises. The reserves normally carried by power companies are adequate to cover any ordinary war load as well as the normal increase in customers requirements.

Before turning to what we in our business should do or avoid doing in order to further the war effort, we should realize just what is involved in a war economy. In a highly mechanized country like Canada the supply of manpower normally far exceeds the demand, but under war conditions this no longer holds, and we are rapidly moving into the position where manpower will be the bottleneck limiting our war effort. This means that governments, companies and individuals alike will have to scrimp and save, that the pick of our manhood will have to be released for active service from non essential industries, from agriculture, from the civil service, from commerce, from the so called essential services and even from the munitions industry itself. Where their jobs cannot be eliminated altogether their places will have to be filled by others less fit physically and by women. Every thing we can do without will have to be deferred until after the war.

Money is only a medium whereby goods and resources can be readily exchanged, but the underlying transactions are fundamentally barter. Whenever we make a purchase, we, in a varying degree depending upon its nature, draw on the country's resources in raw materials and manpower, which would otherwise have been available for war purposes, and we must accustom ourselves to thinking not in terms of money but in terms of the use or misuse we are making of these resources. When we build ourselves or somebody else a house we draw heavily on these resources and unless the house is urgently required for housing munition workers we are sabotaging the war effort. If we buy a house, however, it is merely a transfer of a capital asset and the war effort is not affected. We make no contribution whatever to the war effort when we borrow money to buy war bonds or sell other securities for this purpose, as the man we borrow from or sell to could just as well have bought the war bonds himself. *It is the savings that count* and the more we can reduce our current expenditures on such items as involve the use of our manpower or our industrial resources that would otherwise be available for war purpose the better it is for the war effort. It matters not whether these savings are used for the purchase of war bonds or are put in the savings bank or are paid out in life insurance premiums or are used to buy company securities, the money and the use of manpower and industrial facilities it commands are available to the Government just the same.

It may be argued that in the cutting down of our purchases we will throw a large number of men out of employment. This is so to a certain extent but wars cannot be won without somebody getting hurt, and drastic measures are necessary to force men to abandon their accustomed line of activity and enter war work. For example, the prairie farmer in the drought area is clinging desperately to his homestead. A war economy with the majority of the people engaged in war activities means far reaching readjustment. So long as men are required for the Army, the Navy, the Airforce and the munition industry all activities not directly or indirectly connected with the war should be cut to the limit regardless of the temporary unemployment this may create. This applies particularly to civil government which is one of the greatest sources of waste to-day. As yet none of our governments has made a serious effort to retrench.

A war brings about a far reaching redistribution of income. The few in the higher income brackets have their incomes drastically reduced but the great majority are far better off. Many work overtime, those that were casually employed work full time, and such of the unemployed as are employable can find work. Those who for years have been in straightened circumstances, break out in a spending rash as soon as they have some loose cash, and it is not the necessities of life that they buy but the luxuries. Worst of all, they mortgage their income by purchasing automobiles, radios, etc., on the instalment plan. This by creating activity in the non-essential industries diverts manpower and foreign exchange from our war effort. Thus, our war effort tends to defeat itself. Somehow or other *we must combine high industrial activity with a low standard of living for all.* The workers must reconcile themselves in the national interest to deferring the reward of their labours till after the war; that is, they must save till it hurts while the war lasts. When it is over the spending of these savings will create work and so avert a post war depression. With our production capacity greatly incresaed as a result of the war, we have the means of creating much better living conditions for those in the lower income brackets. We all should recognize that it would be a happier world if the great majority could be converted into capitalists as a result of the war. Compulsory saving along the Maynard Keynes plan as now being introduced in England would appear to be the answer.

The implications of this as applied to the power business are far reaching and not very palatable. As the war economy develops we likewise in our expenditures on capital and operating will have to be frugal in the use of manpower and industrial resources. Our revenues will be up and the temptation will be to spend it as fast as it comes in, particularly as our tax laws offer little incentive to thrift. Our aim should be to carry on our operations with the very minimum drain on the country's industrial resources and on manpower, except of course where power for war purposes is required. In the war interest we will have to taper off our promotional and load building activities, to defer maintenance wherever possible, to discourage new connections and to make fuller use of existing facilities at the sacrifice of the quality of the service rendered the public.

Our sphere of influence extends beyond our direct operations and we should make the most of it in aiding the war effort. We can induce our employees to save. It may soon be unpatriotic to encourage extravagant purchasing by customers. We may then have to eliminate time payments; stock only a limited range of "stripped" models and no knick-knacks. In our own purchasing we can standardize the articles we buy and do without the many gadgets that the manufacturers have developed to serve as selling points for their particular products. At least half the number of types and sizes of insulators, pole line hardware, transformers, etc., that are now being manufactured could be dispensed with without any hardship to any one; probably three quarters of these could be spared if we are willing to put up with some inconvenience.

If we could overcome the jealousies of rival manufacturers we might have one size of transformer made in one plant and another size in another. This getting down to the minimum number of stripped war models is a matter that might well be taken up by the Canadian Electrical Association in conjunction with the publicly owned utilities. If approached in a broad way our efforts should result in a great reduction in our demands on manpower and industrial facilities and so we might avoid the imposition of war priorities on our every day requirements with its consequent hampering of our operations. War priorities and control may speed up the production of certain articles but it is at the expense of production as a whole. Our aim should be to simplify our needs, and we should be broad enough not to chisel the manufacturer in the process. We will be far better off if we can anticipate changes before they are forced upon us.

We should recognize that this is one war that we cannot be half in and half out of. Governments, companies and individuals alike will have to scrimp and save. Companies and individuals will not flinch from the heavy taxation indispensable to victory so long as the taxation is just and impartial and the proceeds are used solely for *bona fide* war purposes.

STRESSES IN DRILL STEEL

Flt.-Lieut. L. O. COOPER, M.E.I.C.
Royal Canadian Air Force Headquarters, Ottawa, Ontario

The following analysis was made of the theoretical magnitude of stresses that occur in a length of drill steel during the drilling process, in order to investigate the possibility of decreasing the stress below the fatigue limit of the steel or raising the fatigue limit of the steel (by heat treatment or the addition of alloys) above the value of stresses encountered.

In operation, the drill steel is given a series of blows in rapid succession by the action of a piston in the air drill. At each blow, the cutting edge of the steel advances approximately 1/20 in. into the rock, a distance varying of course with the hardness of the rock and the sharpness of the bit. If the energy of the blow is considered as compressing the steel like a spring between the rock face and the piston or anvil block in the drill, the stress in the steel is found to be comparatively small. Actually, all parts of the steel are not stressed to the same degree at the same time, but, instead, a wave of stress travels back and forth along the steel with the velocity of sound, the stress at any point being at times much greater than the resultant stress would be if the piston energy were absorbed slowly by the steel.

Fig. 1—Curve showing variation, with respect to time, of stress at shank end for a 5′, 1″ quarter octagon rod and 80 ft. lb. blow.

On account of the small movement of the bit end, the actual condition in the steel is somewhere between that of a free rod being struck longitudinally on the end, and a rod with one end fixed being struck on the other end. The fixed end rod approaches more nearly the actual conditions and produces the higher stress and so is considered here; but it should be mentioned that as regards fatigue there is not as big a difference between the two cases as might be imagined since in the free rod almost complete reversals of stresses are encountered. The fatigue limit for a stress ranging from zero to maximum in the same direction is approximately 1½ times the fatigue limit for a stress undergoing complete reversal.

The relations between stress and velocity in a rod may be represented by the following partial differential equations:

1. $$\frac{\partial P}{\partial X} = -\rho \frac{\partial v}{\partial t}$$

2. $$\frac{\partial v}{\partial x} = -\frac{1}{E} \cdot \frac{\partial P}{\partial t}$$

Where P = stress
v = velocity
x = distance measured along the rod from bit end
t = time
ρ = density of steel
E = Young's modulus

Solving these equations by means of Heaviside's operational calculus with the proper boundary conditions gives the equations listed below for the stress in the rod:—

Symbols used:

P = stress in rod at point rL—poundals per sq. ft.
V = velocity of mass striking rod—ft. per second
ρ = density of steel in drill rod—lb. per cu. ft.
e = base of Napierian logarithms
c = velocity of sound in steel—ft. per second
m = weight of drill rod, lb.
M = weight of mass striking rod, lb.
L = length of drill rod, ft.
t = time measured from moment of impact, seconds
r = variable from 0 to 1. Point "rL" in rod is measured from bit end.

1. When $0 < t < \frac{L - rL}{c}$

$P = 0$

2. When $\frac{L - rL}{c} < t < \frac{L + rL}{c}$

$$P = V\rho c \cdot e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{L - rL}{c}\right)}$$

This is a maximum when t is a minimum, or

P max. $= V\rho c$

3. When $\frac{L + rL}{c} < t < \frac{3L - rL}{c}$

$$P = V\rho\, c. \left[e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{L-rL}{c}\right)} + e^{-\frac{m}{M}\frac{c}{M}\left(t - \frac{L+rL}{c}\right)} \right]$$

and P max. $= V\rho c \left(1 + e^{-2\frac{rm}{M}} \right)$

4. When $\frac{3L - rL}{c} < t < \frac{3L + rL}{c}$

$$P = V\rho\, c \left[e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{L-rL}{c}\right)} + e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{L+rL}{c}\right)} + e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{3L-rL}{c}\right)} - 2\frac{m}{M}\frac{c}{L}\left(t - \frac{3L-rL}{c}\right) . e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{3L-rL}{c}\right)} \right]$$

or P max. $= Vp\, c \left(1 + e^{\frac{-2m}{M}} + e^{\frac{-2m(1-r)}{M}} \right)$

5. When $\frac{3L + rL}{c} < t < \frac{5L - rL}{c}$

$$P = V\rho\, c \left[e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{L-rL}{c}\right)} + e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{L+rL}{c}\right)} + e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{3L-rL}{c}\right)} - \frac{2m}{M}\frac{c}{L}\left(t - \frac{3L-rL}{c}\right) . e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{3L-rL}{c}\right)} + e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{3L+rL}{c}\right)} - \frac{2m}{M}\frac{c}{L}\left(t - \frac{3L+rL.}{c}\right) . e^{-\frac{m}{M}\frac{c}{L}\left(t - \frac{3L+rL}{c}\right)} \right]$$

$$\text{or } P \text{ max.} = V\rho\, c \left[e^{\frac{-2m(1+r)}{M}} + e^{\frac{-2m}{M}} + e^{\frac{-2mr}{M}} - \frac{2mr}{M} . e^{\frac{-2mr}{M}} + 1 \right]$$

For all practical values of $\frac{m}{M}$, that is for all drill rods over 1½ ft. long, it can be shown from the stress equations that the maximum stress is reached during the first three passages of the wave of stress along the drill rod. Figure 1 shows the variation of stress at the shank end with time, while Fig. 2 shows the maximum stress reached at different points along the length of the rod. These curves have been worked out for a 5-ft,. quarter octagon drill steel being struck an 80 ft.-lb. blow with an 8½ lb. piston. In Fig. 1, the negative stress shown does not occur in practice at the shank end as there can be no tension between the end of the steel and the striking body.

It will be seen from the maximum stress curve that the steel should fail from fatigue near the bit or shank end. In a test against a manganese steel plate, the failure would probably take place just behind the bit as the shank heat-treatment usually extends a little further along the steel and raises the fatigue limits in this section. In actual drilling

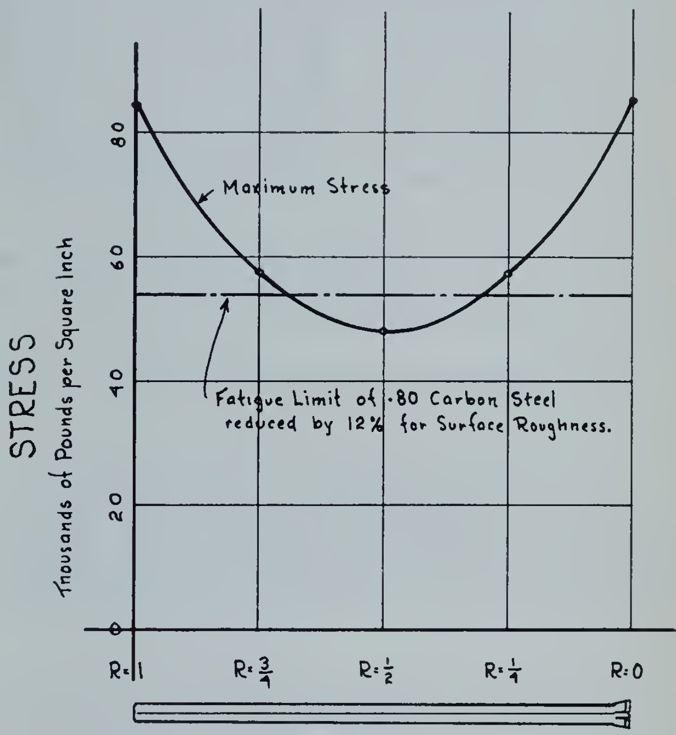

Fig. 2—Curve showing maximum stress in steel for a 5′ 1″ quarter octagon rod and 80 ft. lb. blow.

the breaks should probably be close to the shank end where the steel is unsupported and consequently the compression stress is raised slightly by bending stresses.

The stress equations show that the stresses depend mostly on the velocity with which the rod is struck, since in the expression $V\rho c$, the factors ρ and c are constants and the values of terms of the form $e^{-\frac{m}{M}}$ are very small. A lower striking velocity could be obtained by using lower air pressures, by using a heavier piston or by shortening the piston stroke so that a greater number of blows could be struck with a lower velocity. The advantage of any of these methods would have to be determined by experiment.

ALTERNATIVES FOR ALUMINUM PAINT

JOHN GRIEVE, M.E.I.C.
The Imperial Varnish and Color Company Limited, Toronto, Ontario.

The Government has found it necessary during this war period to control for specific war purposes, the available supply of aluminum. All stocks of aluminum powder are therefore being recorded and the sale of aluminum is restricted to war contracts under priority release.

This action by the Government practically takes aluminum powder, as a paint pigment, off the market for upkeep painting and forces the use of some alternative.

There is a natural and popular inclination towards aluminum as a bright clean wearing finish for up-keep painting, and this has been widely and well fostered by the attractive advertising campaigns during the past ten or twelve years.

The weakness of aluminum paint however, is that it has always been advertised as " aluminum " with little or no stress on the importance of the specific vehicles required when aluminum is recommended or used for special exposures.

The result is that because of this lack of information about the vehicle, aluminum paints have in many instances been recommended and used wrongly or extravagantly.

The following alternatives for aluminum for special exposures may be of interest.

Hot Surfaces (smoke stacks, retorts, etc.)

For these exposures aluminum has outstanding value and is difficult to replace because of the adhesive and non-burning nature of the bright aluminum powder. The best alternative is either a natural black amorphous graphite in a suitable vehicle or one of the heat-resisting bituminous blacks.

Structural Steel (bridges, roofs or steel exposed to weather)

Aluminum paint should never be recommended as a paint to be directly applied on steel for weather exposure; for this purpose it should always be used over a suitable anti-corrosive primer and only as a finish coat. The life wearing quality of black or dark coloured paints is at least equal to that of aluminum, and the cost is somewhat less than that of aluminum paint. Well formulated light gray paint will wear, as a field coat, almost as long as aluminum and cost about the same per coat, at existing prices.

For use where the heat reflecting value (i.e. roofs, tanks, etc.) is important, white or light coloured paints have an efficiency equal to or greater than aluminum paint.

Structural Steel (tanks)

The attractive appearance of aluminum on storage tanks is accountable for its general use. Aluminum powder in a good weather and moisture resisting vehicle does not chalk under weather exposure and therefore does not show dirty streaks from rain washing from the plate laps, as do white or light coloured paints. But the wearing value of aluminum paint is no better than that of well formulated light gray paint, and for evaporation loss, where volatile liquids are stored, white paint shows an economy of 3 or 4 per cent over aluminum paint.

Structural Steel (interior)

Aluminum has been used on many exposed structural steel frames for the interior of buildings. For this service, white or light gray will give equal service at less cost and at considerably increased light reflective value.

The light reflective value of aluminum is approximately 50 to 55 per cent. light gray 55 to 65 per cent. and white 85 to 90 per cent.

Radiators

Aluminum has been used as a popular radiator paint. For general heating systems, however, where radiators give off heat by convection, flat black paint will give off heat at from 15 to 20 per cent. increase over the aluminum paint. For general hot water or exhaust steam radiator installations, (metal surface not exceeding 200 deg. F.), well formulated dull finish, light coloured paints will give efficient service, equal to aluminum.

Repainting Asphalt or Bituminous Coated Metal

Some of the better resin and water-emulsion paints may be applied over the " Robertson " type sheeting or other asphaltic surface building siding, to prevent bleeding of the asphalt and allow light coloured paints to be used as a finish.

Priming Exterior Wood-work

The general run of aluminum paint in a varnish vehicle is too short to act as a good primer on wood. For this service a specially long oil vehicle mixed with the aluminum powder is necessary. The regular white wood primers formulated for two coat work or those recommended for refinishing old and perished wood surfaces, will give results equal to aluminum and at no increase at existing costs. These white primers also overcome any tendency to " grin-through."

Sealing Knots

The general formula for aluminum paint will not stop the bleeding of live knots and (because it becomes a dark gray when painted over) has a tendency to " grin through " when used as a knot sealer. White two-coat wood primer over a light coat of shellac will overcome this difficulty.

Interior Surfaces (brick, plaster or wood)

A great deal of research work has been done in the paint laboratories to develop light reflecting paints suitable for all structural surfaces.

Aluminum has a reflective value of approximately 55 per cent. while most of the whites can now be supplied in a cone-coat type which will give over 85 per cent. light reflective value and cost no more per square foot of area, than the aluminum, at existing prices.

To sum up:—while the Government restrictions on the use of aluminum powder may disappoint many users in the popular selection of aluminum paint until the war situation changes, it should be kept in mind that:—

(A) Aluminum powder is not specially suited as a paint pigment for universal use but must be formulated in proper proportions and with a suitable vehicle for each special exposure.

(B) It is possible, until the supply of aluminum is cleared by the Government after the war, and until the cost becomes more normal, to furnish coloured paints which have past records of service and may therefore be of real interest.

DISCUSSION OF GAUGES FOR MASS PRODUCTION

Paper by Dr. C. A. Robb, M.E.I.C.[1], published in *The Engineering Journal*, April, 1941

K. R. Ayer[2]

I would like to express my appreciation of the able manner in which Dr. Robb has condensed such a large subject, yet managing to bring out the essentials.

Gauges are the special instruments that allow speed of inspection. They must measure sufficiently accurately but not too accurately, as the more accuracy the less speed and speed is the essence of all mass production.

Gauges have a two-fold purpose:

1. To make measurements where they will increase the speed of inspection.

2. To make measurements that cannot be made with standard instruments.

Yet, there are certain cases where gauges should not be used:

1. Where not sufficient quantities of a part are being made to warrant their use.

2. Where the inspection can be done more quickly with a standard instrument.

3. Where the accuracy of the dimension to be measured is so fine that other means than gauges must be used.

Accuracy—Perfect accuracy of measurement is unattainable and unnecessary in mass production. Therefore, care must be taken to allow the utmost manufacturing tolerance that safety will permit. Nevertheless, ability to measure to the closest practical limit is essential in the gauge industry. An axiom that every gauge manufacturer should constantly remember is, "You can only manufacture accurately what you can measure."

Thread Gauges—Perhaps the least understood are thread gauges, especially those of British Whitworth standard, which have seven elements where errors may occur, usually with a cumulative effect; i.e., (1) Major diameter; (2) Minor diameter; (3) Effective diameter; (4) Pitch; (5) Angle; (6) Radius of crest; (7) Radius of root.

Male thread gauges can be measured with proper inspection equipment, but female thread gauges cannot be so measured. Check gauges must be utilized to ascertain if they fall within allowable limits of measurement. The minimum requirements to inspect a female thread gauge are: (1) A full form check gauge; (2) An effective diameter (only) Not Go check gauge; (3) A major diameter (only) Not Go check gauge; (4) A plain plug Not Go check gauge for the minor diameter if such is too small to be accurately measured with an instrument; (5) Examination of a cast in a 50 to 1 magnification projection apparatus.

Some manufacturers of gauges use seven check gauges: (1) A Go effective diameter (only); (2) Not Go effective diameter (only); (3) Go major diameter (only); (4) Not Go major diameter (only); (5) Go minor diameter (only) plain plug; (6) Not Go minor diameter (only) plain plug; (7) Go full form check gauge; and a cast to examine the radii of the crests and roots.

Effective diameter (only) check gauges have the radius at the crest completely removed, and the radius at the core cleared away. Major diameter check gauges have an accurate radius at the crest, but the angle of the flanks is reduced by five or more degrees.

Check gauges for the examination of threads should always be made by the same manufacturer as the gauges to be checked. This is necessary because the errors of the various elements may be cumulative, thus a check gauge with very minor errors on each element may have a cumulative error in one direction sufficient to reject perfectly good gauges with minor errors in the opposite direction.

[1] Power Consultant, Munitions Branch, Department of Munitions and Supply, Ottawa, Ont.

[2] Machine Tool and Gauge Division, Department of Munitions and Supply, Ottawa, Ont.

It is recommended that any one interested in accurate thread gauges should obtain "Notes on Screw Gauges," issued by the National Physical Laboratory, Metrology Department, Teddington, England; Fourth Edition September, 1938; published by His Majesty's Stationery Office, York House, London, W.C.2. These Notes cover very fully the methods of inspection and the allowable tolerances on all British Standard thread gauges.

Machine Tools—Engineers not familiar with the manufacture of gauges are apt to be surprised that the standard "cutting" machine tools are of much less importance, both as to accuracy and quantity, in gauge manufacturing plant than grinding machine tools.

One idea of the minimum machine tool requirements needed for a complete installation suitable for the manufacture of gauges is as follows:

"Cutting" Machine Tools
- 1—Power Saw
- 1—Do-All Profiler
- 1—High Class Engine Lathe (complete)
- 1—Bench Lathe (complete)
- 1—Universal Milling Machine
- 1—Small Vertical Milling Machine (complete)
- 1—Shaper
- 3—Bench Drill Presses
- 1—Jig Borer (complete)

Grinding Machine Tools
- 3—Surface Grinders
- 1—Rotary Surface Grinder (wet)
- 1—External Cylindrical Grinder (wet)
- 1—Internal Cylindrical Grinder (wet)
- 1—Thread Grinder complete with internal attachment
- 1—Radius and Angle Dresser
- 2—Magna Sine Chucks
- 1—Lapping Machine
- 1—Tool Grinder
- 1—Etching Machine

Inspection Equipment
- 3—Sets Johansson Blocks
- 2—Comparators (reading 1/10,000)
- 1—Super Micrometer
- 2—Projection Apparatus (50-1 Mag.)
- 1—Pitch Measuring Machine
- 1—2 Wire Measuring Machine
- 1—Magna Sine Plate
- 2—Surface Plates
- 1—Height Gauge
- 1—Depth Gauge
- 1—Hardness Tester

Complete sets of outside and inside micrometers, Vee blocks, parallels and indicators.

Such machine tools, with necessary small tools and the proper personnel, should be able to produce even the most complex gauges.

Not nearly enough has been written in Canada on the subject of gauges, and it is to be hoped that Dr. Robb's paper may bring out many of the highlights of gauge production that are important to those who are concerned with precision work.

W. G. Blakey[3]

I have read Dr. Robb's paper, "Gauges for Mass Production" with great interest and find that he has covered a considerable amount of ground, any part of which could be enlarged upon with advantage.

Others, much more capable than myself, will, no doubt, discuss the technical problems.

[3] Machine Tool and Gauge Division, Department of Munitions and Supply, Ottawa, Ont.

Mass Production—What does that term bring to mind? We think of a huge factory with many machines and innumerable workmen. We cannot help but marvel at the wonder of it all. What is the secret of this almost phenomenal accomplishment? It is the high degree of accuracy and the perfection of the production of gauges which, to-day, makes possible "MASS PRODUCTION" as we understand it.

And can the gauges also be produced according to the same system? They are simple enough looking bits of metal, but actually every gauge requires the individual and personal attention of the toolmaker, without whom there would be no gauges. His pride in his work is great. He looks upon a measurement of one one thousandth of an inch as the ordinary man looks upon a foot. He measures with certainty to one ten thousandth of an inch and is always willing to back his judgment as to measurement against all the measuring devices which are used in the inspection laboratories.

Doctor Robb refers to the number of manufacturers now engaged in gauge production in Canada and mentions that some years ago the annual import was valued at about $290,000. To-day in Canada, orders are being placed for "Inspection" gauges only at the rate of about $300,000 per month and at a rough estimate "Shop" gauges are being bought to at least a comparable amount.

Naturally this has meant the development of gauge manufacturing shops of which there were none, as such, before the war. The toolrooms of manufacturing establishments have co-operated exceedingly well and real gauge producing capacity has been built up in Canada by encouraging the management of these toolrooms to enlarge their capacity for fine gauge work by persuading them to install precision inspection and measuring devices, precision machine tools and the like.

This effort of the toolmakers and manufacturers has not been appreciated by the general public and it would appear that the Institute might take steps to remedy this.

R. H. Field, M.E.I.C.[4]

Canadian engineers were confronted with many problems when the manufacture of munitions was undertaken in the Dominion just prior to the outbreak of the present war. The provision of gauges was one. In the great bulk of military material, particularly in ammunition, interchangeability of pieces is of great importance. A fuse machined in one part of the world must be fitted, at a critical moment, into a shell made thousands of miles away. A cartridge case or shell jamming in a gun may have fatal results for the crew, or mean the loss of a position in battle. For reasons of this kind certainty in interchangeability is much more necessary than in ordinary manufacturing, where an occasional defective dimension usually results in little worse than delay.

The use of gauges, as understood to-day, really came to the fore in the war of 1914-18. Before that time limit machining was not widely practised and in munitions much reliance was placed on the "sealed sample," to which products must conform. In the later stages of that war, and in the subsequent period, gauges became of greater importance in manufacturing, and contributed to the cheapness of machined parts made in quantity. Steels were developed, precision grinding and finishing tools produced, measuring devices designed and, as a result of the labours of committees and individuals—e.g., The Gauge Committee of the A.S.M.E. in the U.S.A., and the National Physical Laboratory, working in conjunction with the B.S.I. in England, gauge constants were decided upon and tabulated.

It followed that much less spade-work was required in the matter of devising gauges and the means of producing gauges when Canadian engineers prepared to transfer their attention from pruning hooks to spears. On the other hand, as Dr. Robb points out, previous to the present war, few gauges were made in Canada (outside, possibly, the large automobile shops), and there was very little control service available. Thus, in the early days of the present war Dr. Robb was greatly handicapped in his endeavour to make mechanical engineers and others "gauge conscious." He must be given credit for his pioneer work in this connection, which has resulted in many Canadian shops co-operating in producing a supply of gauges, and in the acquisition of the special machine tools and other necessary aids.

For reasons already indicated munitions gauges must conform to national standard measures—it is impracticable to have a set of master reference gauges for each item. Fortunately the widespread use of Johansson type, or slip gauges, has simplified the standardization problems both of the manufacturer and of the metrologist. Besides the ease with which length intervals in steps of 0.0001 inch, or even finer, can be built up, these blocks have the advantage that they can be measured absolutely in the laboratory by the application of optical interferometry. Before the introduction of these blocks lengths were obtained by studying the sub-divisions of a standard rule of one metre or one yard, which in turn had been compared with a reference length derived from the ultimate standard. This was a laborious operation, to which had to be added the almost equally laborious calibration of the micrometer screw used for obtaining fractions of the established length. To-day, in a few hours, it is possible by interferometry to measure the length of a set of slip gauges which, in combination, will permit lengths in minute steps to be used with a knowledge of the errors to something of the order of 0.00001 inch, or even finer if special precautions are taken.

As adjuncts to Johansson, or slip gauges, various sensitive comparators of simple design have been developed—for example, the Sheffield Comparator,—which permit the toolmaker or gauge inspector to make measurements beyond the precision of the machinist's micrometer. Measuring machines which, up to the last war, had hardly progressed beyond the creation of Whitworth, are now fitted with sensitive indicators and less reliance need be placed on the screw. Comparators have even been constructed which permit differences being determined to two millionths of an inch, or less. In these cases, too, slip gauges replace micrometer screws, and the measuring machine is only called upon to determine a difference of a few thousandths, or less.

Thread gauges, which Dr. Robb rightly lists as difficult to produce without adequate equipment, can now be measured quickly and accurately, especially by the use of the well-designed apparatus originating in the National Physical Laboratory, and so widely used in England. Most trouble in the laboratory arises from gauges of types that do not lend themselves to measurement by direct methods, and which require special fixtures or set-ups.

Despite the improvement in manufacturing technique the relative positions of metrologist, gauge maker, and machinist does not seem to have changed. Improved machine tools permit, and modern mechanical engineering demands, much finer limits in finished parts. This, in turn, necessitates closer tolerances for the gauges; but the toolmaker is assisted by improved grinding machines, abrasives and measuring tools. The metrologist, who undertakes the responsibility of certifying the gauges as conforming to standard dimensions, is also assisted by improved laboratory technique and appliances. Hence, beyond the effect of an increased complication, it is doubtful if any of us have more headaches than our predecessors of 1914-1918 and we all endeavour to make the Dominion's contribution in the present need exceed, relatively, that given during the former.

In conclusion, I must express my appreciation of Dr. Robb's paper, particularly in his ability to compress his subject, which could fill several papers. His account should be of special interest to those engineers who do not come into contact with actual gauge making and measurement.

[4] Metrologist, National Research Council, Ottawa, Ont.

H. F. Gorth[5]

In the making of gauges to the close tolerances demanded by present day gauging standards there are four essentials that must be taken care of before good results can be expected.

First: We must have all the necessary machine tools, lathes, milling machines, shapers, grinders, etc., and all must be in good condition.

Second: The gauge makers must be the best type of tool makers, possessing not only skill but unlimited patience if good results are to be obtained.

Third: Usually the hardest essential to obtain is an even or uniform temperature all through the gauge room, so that all gauges, tools, etc., can be maintained at the same temperature. This is imperative if the gauges being worked on are of any considerable size.

Fourth: The inspection equipment and tools must be of the best, as they not only have to check against the work done in the shop but the work they pass must be acceptable to the inspection departments of the company the gauges are being made for.

In the making of these gauges the most important machine of course is the finishing machine. In most cases these are precision grinders, divided into three types: external cylindrical for circular outside grinding and internal cylindrical for inside or hole grinding, with the surface grinder taking care of all flat surfaces.

Along with the machines and equally important are the necessary precision measuring tools, surface plates to give a plane surface to check from, height gauges, indicators reading in ten thousandths, etc., and most important of all the precision gauge blocks, commonly known as Johansson blocks. These blocks when new are supplied in three grades: A laboratory set accurate to two millionths of an inch, an inspection set accurate to four millionths and the working set accurate to eight millionths. These working gauges are the blocks most commonly used in the shop and are used both for taking actual measurements and as a master for size and a comparison made from them to the point being worked on by the use of ten thousandth indicators.

The actual use of these blocks inevitably affects their accuracy, as it is only by wringing these blocks together in their various sizes that we obtain any desired size. This wringing together causes wear and consequently reduction in size of the gauge blocks. It is therefore necessary either to buy new sets of blocks or to find some method whereby we can check our blocks for wear and post the size of each individual block, so that the user of the blocks can allow for the errors when building up to the desired size.

In a plant using a number of sets of blocks, continually buying new sets would mean a very large outlay. To eliminate this we use an inspection set of blocks as a master set and a comparator measuring direct to twenty-five millionths of an inch but easily divided to eight millionths. By comparison with our master set we can check and chart each block to the accuracy they originally had.

The types of gauges being made to-day can be classified in general as:

Plug gauges for the gauging of holes; these are generally double ended, one end to the high tolerance and the other to the low.

Ring gauges for gauging over male forms, these usually being made in pairs, one to the high and the other to the low tolerance.

Thread gauges are designed in general the same as plug and ring gauges but are much more difficult to make, requiring special and very costly machinery to grind the threads of the gauges and for each size of gauge masters and laps must also be made.

Profile gauges cover almost every variety of shape and form and in general are not held to as fine tolerances as other gauges, being for the most part gauges for visual inspection.

Snap gauges are made in a number of styles. Some are made with a forged or cast frame with inserted hardened and ground points set for high and low dimension. These are adjustable for wear and when the points become deformed too badly for use new points can be inserted. This type of gauge is generally used only for dimensions greater than one inch. The other type used is made from flat plate hardened and ground and when the tolerance is very small hand lapped. This type is not adjustable and when the wear allowance has been reached the gauge must be scrapped or in some cases reground for a slightly larger size. These gauges are in most cases made double for gauging on two sides, one to the high and the other the low tolerance.

The so called fixture gauges are the most difficult of all to make. These are built up of a number of pieces. Each gauge of this type usually controls a large number of dimensions all held to close tolerances, and as the relationships of one part to another require the same close tolerances, the difficulty in making is obvious.

It is on these gauges particularly that good or bad design can make all the difference between a satisfactory or a poor gauge. Many gauges are being designed to-day by men with no conception of how the gauge can be made as designed or whether it will stand up under use after it is made. The cost of providing gauges can only be held to a minimum if the designer is familiar with gauge making technique; designs his gauges with the question continually before him: Can the gauge be made any easier way and how will it stand up under use ?

In addition to a tool room with all the necessary machine tools and measuring instruments the gauge shop must own and maintain an inspection department for this work alone equipped with many types of precision inspection equipment.

In the inspection room it is also necessary to duplicate all the small tools in use in the shop. All tools here must be of the highest quality and kept in the best of condition.

Colonel G. B. Howard[6]

There is little to add to Dr. Robb's excellent paper on Gauges for Mass Production.

If it is not outside the scope of the paper, it is thought that some mention might be made of the essential differences between "production gauges" and "acceptance inspection gauges."

Production gauges are required to ensure that the product or component will pass inspection when completed; consequently the tolerances they permit are normally well within the drawing tolerances. For this reason, extreme accuracy in the manufacture of production gauges is not so essential, and greater wear may be permitted. They are also designed differently, since they are used at the machines or after each operation, while acceptance inspection gauges are used to gauge completed articles and components.

Acceptance gauges are so designed to permit the maximum tolerances allowed on the drawing, to ensure the acceptance of all articles within drawing limits. To ensure rejection of all articles outside drawing limits, acceptance gauges must be made to very accurate dimensions and relatively little wear is permissible.

Some mention might be made also of the trend, in industry, towards the use of mechanical and electrical comparators instead of limit gauges. This practice permits change of dimensions or design without provision of new gauges, since comparators are adjustable over wide limits. Wear also may be neglected. Such gauging methods are also advantageous when selective assembly is required.

[6] Inspection Board of the United Kingdom and Canada, Ottawa, Ont.

Chester B. Hamilton, Jr.m.e.i.c.[7]

I have read this article carefully and think Dr. Robb has done a very good job, though a few points might have been stressed more. The weak points in the gauge programme in Canada were (1) lack of advance planning, and (2) ordering gauges in lots too small to permit efficient production.

Dr. Robb does not make it clear that the accuracy requirement for the gauge has a direct relation to that for the part being measured, usually about one eighth or one tenth the tolerance. A wide tolerance on the gauge cheapens gauge production, but increases cost of part production because it narrows the part tolerance by that much.

In regard to thread gauges, Dr. Robb does not mention a very important class,—the truncated thread gauges. These have straight line profiles, the top and bottom being cut straight across omitting all the curves of the Whitworth tip and root. The straight flanks also may be, in some cases, shortened to less than the straight part of the Whitworth. Thus only a band above and below the pitch line is measured, but it gives all the necessary information for a good working fit on production inspection. This type of gauge is far cheaper to make and accuracy is more easily attained than the full Whitworth. Its use, of course, would not be right for establishing and checking the threading tools, or the first part produced, but in parts production it checks axial pitch, thread thickness, pitch diameter and pressure angle, which is all that can be required, once the original tools have been proved.

As a design element, the sacred Whitworth thread is probably one of the most hampering things to which our enemy could wish to see us tied.

Owen W. Ellis, m.e.i.c.[8]

As Dr. Robb has pointed out "nitrided steel has a very hard surface." According to the type of steel nitrided the hardness may vary from somewhere below 1,000 to somewhere above 1,100 Vickers Diamond Penetration Number. Certain Nitralloy steels are slightly harder immediately below the nitrided surface than on the nitrided surface, so that removal of 0.001 inch from the surface of a nitrided article may actually result in an increase in its hardness. Since an increase in diameter of 0.002 inch in material having a case depth of 0.030 inch serves as a fair example of the growth which takes place on nitriding, it will be appreciated that the effect of bringing a gauge back to size after nitriding may be to leave it with a harder surface than that produced by the nitriding operations per se.

One of the objections that has been put forward to the use of nitrided steels in the manufacture of gauges is that they are not easy steels to finish perfectly to a hundred thousandth or a millionth of an inch. Nitrided steel slip blocks have been found extremely difficult to wring and the use of nitrided steels in this connection has, on this account, been discontinued. There does not seem to be much doubt that the difficulty of wringing these steels is related to the difficulty of finishing them satisfactorily. The question of finishing would not of necessity loom large in all gauges, but is one that cannot be overlooked. It is not impossible that new nitriding steels will be developed which, after nitriding, will have satisfactory finishing qualities.

Paul V. Miller[9]

In the opinion of the writer Dr. Robb's paper covers the subject of gauges thoroughly, and there is little that the writer could add unless he were to go into greater detail as to the design or manufacture of one or more of the types discussed.

There is, however, one point which might well be mentioned in a discussion of the production of gauges, and that is the matter of standardization of gauge blanks which, at a time like this, is really of vital importance. Some sixteen years ago work was started on this subject and several different edition of a subsequently developed Standard have been printed. The most recent edition is entitled, "Commercial Standard CS8-41" published by the United States Printing Office, and it gives complete dimensional data regarding recommendations for gauge blanks of various types. Before the present War broke out in Europe some progress was made in England toward the adoption of certain parts of this standard, and the writer understands that some gauge manufacturers in England are now using the dimensions recommended for plug gauges and snap gauges.

The writer is enclosing a copy of this American Standard covering Gauge Blanks, and would suggest that some mention of this be made in the discussion of Dr. Robb's paper, for, no doubt most of the gauges which Canada is purchasing from manufacturers in the United States will be made to these dimensions, and it would probably result in some saving and economy if Canadian manufacturers were to adhere to these dimensions where practical.

Colonel A. Theriault[10]

I have read this article with much interest and believe there is very little that we can add.

In connection with the last sentence under the heading "The Gauging Surface," in which Dr. Robb says that internal grinders are available for diameters as low as ¾ of an inch, it may be of interest to know that we are presently grinding internally here down to diameters of 0.308 of an inch in the regular course of our work, and we have ground as small as 0.208 of an inch.

Regarding the paragraph on Special Machines, I wish to say that we are the proud possessors of a Swiss Jig Boring and Measuring Machine on which the table can be located to within .0003 of an inch for any position of the table, horizontally in two directions and vertically, by direct reading dials and verniers.

The Author

In his discussion Mr. Ayer has stressed the dearth of scientific literature on gauges. In peace time the lack of demand for such books may be accounted for by the fact that the whole question of gauging has rested lightly on many types of manufacturing. However, Mr. F. H. Rolt, Metrologist, National Physical Laboratory, has ably presented the fundamentals in " Gauges and Fine Measurements " published in two volumes by Macmillan & Co., London, 1929. The machine tools and inspection equipment required by the gauge manufacturer depend upon the type or types of gauges which he can deliver at a satisfactory price.

While quick dissemination and application of information on novel developments and ideas on gauge production and inspection problems during war save time and expense, the secrecy may require that these be not published but be reserved for the benefit of the gauge and munitions manufacturers, the gauge inspection laboratories and the inspectorate.

Mr. Blakey has aptly described the special part which the competent tool maker and precision machine operator plays in the production of munitions gauges.

In creating the gauges for the inspector and in dealing with production troubles, " the perversity of inanimate things " frequently places a severe strain on the tool maker's sense of humour. Like the artist, his reward is largely in the appreciation of his splendid creations.

Mr. Field has outlined the role of the metrologist and his equipment in certifying the gauges as conforming to

[7] President, The Hamilton Gear and Machine Company, Toronto, Ont.

[8] Director, Department of Engineering and Metallurgy, Ontario Research Foundation, Toronto, Ont.

[9] Manager, Small Tool Division, The Taft-Peirce Manufacturing Company, Woonsocket, Rhode Island.

[10] Chief Superintendent of Arsenals, Dominion Arsenal, Quebec, Que.

standard dimensions. With characteristic modesty he has omitted to state the indispensable function which the metrologist and his laboratory perform in connection with the educational efforts of gauge production representatives, who have to encourage suitable manufacturers to undertake the production of gauges. In many cases, the gauge laboratory provides the first opportunity for the manufacturer to observe the equipment for gauge inspection, to become familiar with the standards of quality which are required and learn about the technique of the metrologist in making precise measurements. The gauge laboratory is the arena in which gauge production troubles are diagnosed and recommendations for their correction given. It provides fertile ground for new ideas and novel applications of some all but forgotten tricks of the craftsman. It was largely due to the provision of this service, quickly organized by Mr. Field and his associates of the National Research Council, that Canadian manufacturers were enabled to reach a monthly output of inspection gauges by mid-July, 1940, equal to that received in Canada from all sources of supply on this continent during the month of November, 1917.

Mr. Gorth has stated the case for the manufacturer. Other reviewers have covered certain points raised in this discussion.

Tool makers will second his appeal to the designer for consideration of the question, " Can the gauge be made in any easier way ? "

It sometimes happens that the tool maker is able, without disturbing the fundamental design, to construct the gauge in a manner which greatly facilitates its inspection.

Colonel Howard's explanation of the difference between " production gauges " and " acceptance gauges " is timely. A third group of so-called " master inspection gauges " find a very limited application, although during the last war they were much in evidence. Gauge and munitions manufacturers will appreciate Colonel Howard's interpretation of the trends in industry.

Mr. Hamilton has expressed the relation of the gauge tolerance to that of the part to be measured and to the cost of production. It may be added that, when time and quantity schedules are known, the objective to be attained is a minimum cost per unit manufactured, the expense for gauges being included in the total.

Truncated thread gauges have interesting possibilities for quality control and were reported during the autumn of 1939 as in use elsewhere. However, in Canada this service has generally been included in the function of other types of gauges.

Mr. Ellis' contribution on nitrided steel acceptably fills one of the gaps in the gauge story, and Canadian engineers will welcome his report on this development, which has been the subject of investigation in his laboratory during recent years.

Mr. Miller's discussion on standardization of gauge blanks and his reference to the recent publication of the United States Printing Office, " C S 8—41 " (For sale by the Superintendent of Documents, Washington, D.C. — Price 15 cents) will be appreciated by gauge designers. It is noted that some gauge manufacturers in England are using the dimensions recommended for certain types of gauges.

" Armament Production Policies "—1941, from the press of the Reinhold Publishing Corp. New York (Price $1.00), contains brief references to gauges.

Colonel Thériault's report on developments in internal grinding serves to report a further achievement of the Dominion Arsenal at Quebec.

Abstracts of articles appearing in the current technical periodicals

THE ACOUSTIC MINE

From *The Engineer* (London), September 19th, 1941

In the course of his recent review of the war in the House of Commons, Mr. Winston Churchill, the Prime Minister, made reference to the anti-mining service. Almost every night, he said, thirty to forty enemy aeroplanes were casting destructive mines, with all their ingenious variations, in the most likely spots to catch our shipping. The attack was begun with the ordinary moored mine, but it has been continued with the magnetic mine and the acoustic mine. It was now being continued, said Mr. Churchill, with the acoustic mine as well as the magnetic mine in many dangerous combinations. The acoustic mine, like the magnetic mine, does not depend on actual contact with a ship in order to detonate it, and it can therefore be dropped from aircraft in the shallow waters of harbours and narrow channels. The mine contains an electrical relay, which is adjusted to fire the charge when the ship's propeller is near enough for the ship to be blown up. It is known that our minesweepers are now equipped to deal with both magnetic and acoustic mines or their combinations. This means an added complication to their equipments, but they are continuing to discharge their task of keeping our harbours and channels clear with complete efficiency. Mr. Churchill stated that 20,000 men and 1,000 ships toiled ceaselessly to clear our ports and channels every morning. Thanks, he said, to the resources of British science and British organization, the menace had been largely mastered. Reference was also made by the Prime Minister to the work of the salvage service, which, he said, had recovered since the beginning of the war in every circumstance of storm and difficulty, considerably upwards of 1,000,000 tons of shipping which would otherwise have been cast away.

CONTROL OF CIVIL ENGINEERING

From *Civil Engineering and Public Works Review* (London), September, 1941

The British people have always regarded their personal rights as sacrosanct, something that must never be interfered with by others. The fundamental basis that lies at the bottom of the present war is the struggle to maintain personal freedom of thought and religion and the freedom of action, provided it is not to the detriment of others. In a struggle between such mighty forces there is little chance for survival if there is a lack of cohesion and of co-operation. To fight tyranny organized for war and dragooned to the sternest forms of discipline and self-sacrifice, it is necessary that the forces of freedom must steel themselves to the same, or even greater sacrifices. The clear-sighted men of the nation have realized this from the beginning of the struggle, but in a nation where freedom of thought and action holds such a grip on the public mind, the people of Britain have been slow to recognize the necessities of the hour. This characteristic may be a weakness, but if it is a weakness it is also a source of great strength and forms the stabilizing influence which prevents hasty experimentation and action without mature thought.

As the war has progressed, "right" after "right" has been surrendered by the nation and dictatorial powers have been bestowed upon the Prime Minister and his Government. No one of standing has challenged the wisdom of the surrender of those rights, though many have declared that the organization of the nation has proceeded far too tardily. As each problem has arisen, it has been dealt with in its turn and the national needs have been met, when it has been proved necessary, by the surrender of personal liberty of action and the placing in the hands of the Government an increase in power over the individual citizen, his business, and his wealth.

The development of the war in the air has produced a problem which the nation has to face. The destruction of buildings and works of public utility has created a situation that has compelled the Government to review the position of those industries and professions immediately concerned. The problem is complicated by the demands for Government work on the construction of new factories, aerodromes and suchlike essential war work.

There are many professional men, civil engineers, surveyors, and others who are intimately connected with this problem. Besides these there are the trade unions and the manufacturers and producers of raw materials such as bricks, gravel and cement. Again, there are the many reinforced concrete firms, plant manufacturers and plant hirers.

At present there is no central organization representative either of all these varied interests and of builders, contractors and the operatives. The number of workers engaged in peace time in the building industry and the civil engineering industry was about 1,400,000. Already more than half this number have been diverted to the main war construction and building industry, A proper co-ordination of this great force of professional and skilled labour is essential. At present the Minister of Works deals with many individual industries. The Minister has decided that there shall be a proper co-ordination of the many ramifications of the industry and for this purpose the Building Industries National Council has been expanded to bring in other interests not yet represented, thus furnishing him with a council to help in the administration of the various powers and responsibilities.

Membership of the Council is confined to those interests most directly and immediately concerned—employers and operatives, with a few professional and independent members. The members have been chosen by the Minister and are not delegates of sectional interests.

The chairman of this new Works and Buildings Council is Mr. Hugh Beaver, M.Inst.C.E., M.I.Chem.E., M. Inst.T., Director-General Works and Buildings and previously a partner in Sir Alexander Gibb and Partners, Consulting Engineers, and the secretary is Mr. E. J. Rimmer, B.Sc., M.Eng., A.M.Inst.C.E.

The Minister will look to the Council for advice on all matters affecting the building and civil engineering industry. The Council has, however, the right of initiative and may make representations on any matters affecting the two industries.

The steps taken by the Minister will, without doubt, be welcomed as a move in the right direction, as it will assist in a proper control of the industry and help to direct the civil engineering and building effort of the country into channels most conducive to the benefit of the nation's war effort. It will tend to an allocation of tasks to the firms most suited to their performance. A central body such as has been created must bring about a smoother co-operation between the various branches of the industries and greatly increase their efficiency. This gain in national efficiency will certainly more than offset any advantage the civil engineer might have possessed without the compulsory co-ordination, and will thus, we are confident, be welcomed by all members of the profession.

THE SHORT STIRLING BOMBER

From *Trade and Engineering*, September, 1941

Limited details may now be published concerning the Short Stirling, the R.A.F.'s latest four-engined bomber which has already taken part in a number of successful daylight and night raids and has proved itself a first-class machine in every way. Its most noticeable feature is its size. It is 87 ft. 3 in. in length, 22 ft. 9 in. in height, and has the tremendous wing-span of 99 ft., which is 4 ft. shorter than the U.S. Flying Fortress. A midwing monoplane, it has wings set well back from the nose, with a noticeable dihedral. The trailing edge tapers sharply to the tip, which is rounded to meet the leading edge. The root, where the wings are swept into the fuselage, is markedly thick.

Power is derived from four radial engines, either Bristol Hercules 14-cylinder air-cooled of 1,400 h.p. each, or Wright Cyclone double-row 14-cylinder air-cooled motors. The outer engines are mounted mid-wing and the inner are underslung and set forward of the outer pair. The fuselage is rectangular. The cockpit is well over the nose, some distance forward of the engines, and the bomb aimer's position has been set immediately under the forward gun turret. The depth of the fuselage permits easy access to the rear gun turret. The top line of the fuselage runs back straight and level to the tail, the lower line being swept up to the tail well back from the wings. The fin and single rudder are high and narrow. The tail planes are of extremely wide span, with the leading edge well tapered and set level with the fin. Details of the armament remain secret, but, as may easily be imagined from the presence of turrets fore and aft, it is extremely powerful.

The Stirling contains several special features. The wheels of the undercarriage, which retract into the nacelles of the inner engines, are more than 5 ft. in diameter, and their tips show under the nacelles when retracted. A novel feature is the fitting of twin tail-wheels, which retract into a compartment with flush-fitting doors. Glass which is faired into the sides of the fuselage ensures a well-lighted interior the whole length of the fuselage. Another detail which cannot yet be mentioned is the bomb load, but the fact that the bomb doors extend to approximately half the length of the fuselage shows that it is exceptionally heavy.

Pilots and crews who have taken part in operations in the Stirling say that it has exceedingly good flying qualities. Some of the features, noticeably the tail, proclaim the relationship of the Stirling to another famous Short product, the Sunderland flying-boat, which continues to give excellent service with the R.A.F. Coastal Command.

FATIGUE RESISTANCE OF AUTOMOTIVE BEARINGS

Abstracted from *S.A.E. Journal*, August, 1941

Any metallic bearing, if run under completely ideal conditions and if run long enough, eventually will fail due to fatigue, provided the load exceeds the endurance limit of that particular metal or alloy. It might be said that the bearing dies of old age.

With respect to fatigue, we can rate bearing alloys in the following order:

1. Copper-lead
2. Cadmium Alloys
3. Tin-base and Lead-base Alloys (Conventional Type).

The evidence of fatigue is the presence of numerous fine cracks in the bearing metal. These cracks invariably start at the bearing surface. The first phase may be considered as the birth of the crack. In the second phase, the crack works inwardly toward the bond line, its actual path being influenced greatly by the location of the grain boundaries in the bearing metal. The third phase is quite astounding and is very probably the immediate cause of most bearing failures. Here the crack turns at right angles when it has proceeded to within a very short distance of the bond line. The crack will then run in a plane somewhat parallel to the interface between bearing metal and backing metal. When this crack meets another crack which has worked down from the surface, the effect is to produce a small section of loose bearing material. The disastrous results of a number of these small loose pieces can readily be visualized.

From the foregoing explanation on the mechanism of fatigue, it can be seen why the performance of the thin-layer bearings should be far superior to the conventional type bearing. The manufacture of thin-layer bearings of the Trimetal and Micro type requires a precision and a technique not thought possible just a few years ago. However, there are many millions of both of these types of bearings in successful operation today.

Corrosion Resistance

With respect to resistance to corrosion by acids formed in the oxidation of oil, the four general alloys group themselves somewhat differently. Here the tin-base and lead-base alloys are practically immune to any type of corrosion so far encountered in the field. On the other hand, the cadmium alloys and copper-lead are definitely susceptible to attack if corrosive conditions are allowed to exist.

Future Bearings

It is quite evident that the trend of future bearing developments is toward a very thin lining of a recognized bearing material backed by steel or steel and an intermediate layer of bronze. As production methods with respect to bearings and engines are improved, we may expect even thinner linings than are in use at the present time. In closing, it may be of interest to mention that "Micro" and "Trimetal" bearings have been produced by laboratory methods which have successfully sustained mean unit pressures in excess of 10,000 psi.

ENGINEERS' EARNINGS

From *Engineering* (London), September 26th, 1941

In normal times, professors of engineering give considerable time to efforts enabling graduates of their colleges to make a start on a technical career. Frequently they are helped in this activity by appointment boards, which now operate in connection with most universities, while assistance may also be rendered by the professional institution of which any particular graduate may be a student member. The whole of this type of activity is now in a state of suspension. No graduate whose technical attainments make it desirable that he should be employed in some phase of war industry, rather than pass into one of the Services, finds any difficulty in obtaining an appointment. This state of affairs is not likely to endure after the war, except possibly during a period of hurried reconstruction, and in due course engineering graduates will again be faced by the old problem.

The particular branch of engineering to which a young man passes after leaving college is frequently determined by chance; he takes whatever job is offered. In some cases, however, selection is possible. In that case his choice will be largely determined by the course of training which has been followed, and to some extent by the particular interests and enthusiasms of the teaching staff to which he has been subjected. There is also a fashion in these things. At one time, a majority of young engineers were attracted by electrical work, due possibly to the remarkable progress that particular branch of engineering made in the course of some twenty years. More recently, the internal-combustion engine, in its various phases, has proved one of the major attractions. The proportion of graduates entering any particular branch of engineering is necessarily affected by the arrangements which that branch makes to receive it, and the institution of graduate-apprentice courses by some of the large electrical firms enabled them, at one time to take the pick of the graduate available. Various other branches of engineering have now realized the value of building up their technical staffs by facilitating the entry of selected graduates into their works, and matters are not so one-sided as they were.

Probably few young men to whom a choice between various branches of engineering is offered base their selection on a consideration of which is likely ultimately to provide them with the largest salary, although the immediate emolument offered is often a factor not to be ignored. The late Dr. Rosenhain once told us that, when he was interviewing candidates for a post at the National Physical Laboratory, one young man, asked if research work was of particular interest to him, replied that his real interest was to obtain a job which would furnish him with a salary of 1,000£ a year, as soon as possible. It was suggested that in that case he had come to the wrong shop. The point of view of this particular candidate is, we think, unusual. Most young men do not speculate whether electrical or mechanical work is likely ultimately to be more profitable. Even if they did, they generally have no data on which to base a conclusion. The graduate who chooses a particular line of work because of family or other connections, which will ultimately place him in a good position, is, of course, a special case.

It is no one's business to determine whether an engineering graduate, who joins a firm of contractors and specializes on tunnel work, is, on the average, likely ultimately to make more money than one who joins a firm of electrical engineers, or devotes himself to radio transmission. As a result, co-ordinated statistics on the matter are not available. A recent publication by the United States Department of Labour, with one aspect of which we dealt in our issue of August 22, does, however, contain some incidental information on the subject. This publication, entitled *Employment and Earnings in the Engineering Profession, 1929 to 1934*, was prepared at the request of the American Engineering Council in order to determine the effect of the business depression of 1930-1934 on professional engineers. The figures of earnings which it quotes, as they refer to American practice during a special period of stress, have no direct application to this country. It is possible, however, that the relative earning value of different types of activity which is disclosed may have some bearing on British conditions.

The figures in the report were collected and are considered from the point of view of the effect of the depression on engineering earnings, and the relative position occupied by different types of occupation was not quite the same at the beginning of the period studied as at the end. In general terms, however, it was found that, in private employment, mining and metallurgical engineers were paid the highest rates, followed by those engaged in chemical and ceramic engineering, mechanical and industrial engineering, civil engineering and electrical engineering, in that order. In public employment, civil, electrical and mechanical engineers earned less than in private, except for civil engineers engaged on new construction. The particular section of any of the main branches of engineering on which a man was engaged had considerable influence on salary, and it is stated that "engineers engaged in general administration make from half again to twice as much as those engaged in design, construction or operation." Consulting, teaching and sales averaged less than administration, but more than design, construction and operation.

These figures were obtained by means of a questionnaire which brought in 52,589 effective replies. Of these 3,900 were from chemical and ceramic engineers and 19,981 from civil engineers. Whether these two figures fairly represent the proportionate numbers of the two types of engineer in the United States we do not know, but the higher position in the salary scale occupied by the chemical engineers can partly at least be explained by the fact that a smaller proportion of them than of any other class was engaged in public employment. With civil engineers the position was reversed and in most fields earnings in public employment were less than in private industry. An inquiry in this country might disclose the same thing, but in our case public employment usually carries pension rights, which are, in effect, equivalent to an addition to salary. This apparently does not hold in the United States. "The degree of economic security among professional engineers, as evidenced by possession of an employment contract covering some period of time, or by pension privileges, was negligible."

The leading position found to be occupied by chemical engineers is possibly to be explained by the fact that they are engaged in an industry which has greatly extended in recent years, particularly in the plastics branch. As the number of men who have taken a degree in chemical engineering is certainly much smaller than those who have done the same thing in, say, electrical engineering, and expanding industry, competing for the supply available, might tend to raise the standard of salary offered. A condition of this kind however, would not necessarily be permanent. There is a further factor which may have had an influence on the matter. The proportion of first-degree engineering graduates found in the ranks of ceramic engineers, a branch of the chemical engineers, was, at 77.3 per cent. higher than in any other sphere. The higher standard of education marked by the possession of a degree was, in fact, found to influence earnings.

The inquiry revealed that, although non-graduate engineers had an advantage in the early years, owing to the fact that they were establishing themselves in industry while the graduates were at college, they lost their lead at a time corresponding to five years after graduation. Even two years after graduation the difference in earnings between the two groups was very small. After this initial period the graduates drew ahead, and advancing age showed a considerable advantage in their favour, indicating that, in general, they tended to obtain the better-paid posts. The returns, as a whole, showed wide variations, as might have been expected, and many important positions were occupied by non-graduate engineers. On the average, however, the graduates tended to show the larger earnings in the long run, their emoluments continuing to increase for several years beyond the point of maximum earning capacity of non-graduate engineers. In the case of the latter, the average condition was found to be that their salaries either remained stable, or declined, after the age of 53 years.

NEW SWISS GRINDING AND MILLING MACHINES

By Alfred Rickenmann

From *Schweizerische Bauzeitung*, April 1941.

Abstracted by *The Engineers' Digest* (London), July, 1941.

At the 1940 Basle Fair some new thread grinding and milling machines were introduced by the Swiss firm, Reishauer-Werkzeuge A.G., which are subsequently described.

Owing to its great versatility, the universal thread grinding machine, type NRK, can be used for grinding threads of all descriptions, such as right and left hand, internal and external threads with a pitch of about 0.4 to 0.8 mm. The grinding wheel is adjustable from both sides up to about 25 deg. helix angle. The machine can work with a single or a multi profile grinding wheel of 40 mm. maximum width. With a single profile grinding wheel it makes use of the longitudinal traverse grinding method, while with a multi-profile wheel it operates by the plunge-cut method. The first method is used for spindles, worm gears, long screw taps, and thread gauges, that is whenever the length of the thread exceeds 40 mm., or when it would not pay to prepare a multi profile wheel. For short taps, or for grinding threads on bolts, screws, etc., made of high quality steel the second method is advantageous. It eliminates rough machining of the thread, and hence the adjustment of the grinding wheel in the rough thread.

The single profile wheel is formed by means of a diamond, while for the multi profile wheel crushing rolls are used which are pressed against the wheel. For precision work the machine is fitted with a hardened and ground grinding spindle and a special pitch correcting, change speed, gear. For easy setting of the grinding wheel in rough machined threads, a telescope with a revolving graticule is provided. The electrical machinery consists of four motors, all controlled by press buttons. The reversing of the slide is hydraulically operated, and so is the relief grinding motion of the slide.

Another new model introduced by the same firm is the R. 1. This machine is a combined Internal, Thread and Hole Grinder with provision for dealing with parallel or taper holes. Thread grinding is always performed with multi-profile grinding wheels.

Since the speed of travel for thread and plain hole grinding is different, provision is made for a quick change over from one type of work to another. For this purpose two table slides are provided, one above the other, the lower oen for the fast traverse when hole grinding is being hydraulically operated, and the other for thread grinding operated through gearing.

The speed of the machine can be steplessly varied between wide limits. Three internal spindles are provided with a range of speeds from 4,000 to 28,000 r.p.m. to amply cover the various grinding wheel diameters that will be required for the range of work of which the machine is capable. A tachometer indicates the spindle speed. Work speeds are variable from 0.5 to 256 r.p.m. in 32 steps.

The short thread milling machine, Type KBH, is principally a thread groove milling machine. The work spindle provides the longitudinal and transverse motion for the pitch and the depth of thread. After the work is finished the spindle is brought automatically to its original position. Operation of the machine consists only of feeding the work to the machine and starting the motor. All other work is automatically performed.

The machine is especially suitable for cutting short internal and external threads. The following operations are hydraulically controlled; clamping and releasing of the work, advancing and returning the work slide, fixing the slide into position, and automatic operation of a milling cutter protection cover during changing of work.

THE CHANNEL TUNNEL

By Rolt Hammond, A.C.G.I.

From *The Central* (London), June, 1941

There are few projects about which so much has been written and debated for nearly a century and a half than the Channel Tunnel. Ideas, fantastic and practical, have been put forward during that period in profusion, and a very brief history of these may be of interest at the present time.

It is generally believed that the first idea was put forward in 1802 by the French mining engineer, Mathieu, when he presented his plans to the Emperor Napoleon, during the First Consulship. The Emperor welcomed the scheme, which even found favour with the eminent British statesman, Charles James Fox; Mathieu's plans were exhibited at the Luxembourg and at other galleries in Paris, but it is unfortunate that no trace of them can now be found.

De Gamond was another French engineer who devoted a vast amount of time and energy to the solution of this problem. For more than forty years he studied various schemes, and considered in turn a submerged tube, a submerged concrete roadway, a train ferry and finally a tunnel. For building the submerged roadway he proposed to use forty submarine boats of his own invention; with these, and with the aid of 1,500 sailors and navvies, for a sum of £10,000,000 he guaranteed to provide a Channel crossing lasting thirty-three minutes.

The Great Exhibition of 1851 gave rise to a crop of suggestions, most of which were fantastic and smacked more of the romances of Jules Verne than of practical engineering projects. In 1856 we find De Gamond once more on the warpath, this time with a proposal for a tunnel. He planned to build thirteen islands in the Channel, through which he would sink shafts to *terra firma*; from these shafts he proposed to drive tunnels east and west until the different sections met one another. At that time this was the only known method of driving long tunnels, for by such means it was possible to divide the work into sections of manageable length. The obvious objection to his scheme was the permanent obstruction which would be caused by the islands in the Channel, and it was therefore not surprising that the idea was rejected by Napoloen III and Queen Victoria, to whom it was presented simultaneously.

Undaunted by his failure to produce a workable scheme, De Gamond then turned his attention to the idea of a bridge, which he proposed to construct between East Ness Corner and Calais. This again would have entailed great obstruction to navigation, and any bridge project has the further disadvantage of being extremely vulnerable.

It is interesting from an historical point of view to mention that the bridge project put forward by Schneider and Hersant in 1889 received the support of such well-known bridge engineers as Sir John Fowler and Sir Benjamin Baker; details of the bridge were given at a meeting of the Iron and Steel Institute in Paris. Crossing the Channel from Cap Gris Nez to Folkestone, the longest spans were to be 1,638 ft. in length (as compared with 1,640 ft. in the case of the Forth bridge), while the shortest was to be 320 ft. The columns of this huge structure were to rest on masonry supports, each 130 ft. high, providing a minimum height of 180 ft. above water level.

In the 'sixties and 'seventies of last century many suggestions were again put forward, one in particular creating considerable interest. This was due to James Chalmers, who published a book in 1861 in which he described his proposal for a submerged tube to be laid on the bed of the Channel, and to be ventilated by three huge towers rearing their heads above the sea. Obviously any form of submerged tube has grave disadvantages, for it would affect tides and currents very considerably, and probably cause considerable silting.

The year 1867 may be considered as the most momentous in Channel Tunnel history, for in that year William Low, M.Inst.C.E., conceived a plan of attack which has never been bettered, and he was the first engineer to put forward a scheme based on thoroughly sound engineering practice. Low was one of the best-known civil and mining engineers of his day, and carried out a large amount of railway and tunnel work. His scheme for the Channel Tunnel provided for twin tunnels, each 18 ft. in diameter and 33 miles long, the submarine portion having a length of 24 miles. These two tubes were to be connected by transverse galleries at intervals of about 110 yards to help ventilation and the tunnel was to be located about 150 ft. below the Channel bed.

Detailed plans for this scheme were presented by Low and G. F. Thomas to Napoleon II, in the same year, the Emperor being greatly intrigued by the ventilation possibilities of the twin tunnels. With typical Gallic wit he remarked: "I see perfectly; you give us English air through one tunnel and we shall send you French air through the other."

The formation of the Channel Tunnel Company in 1872 was followed in 1875 by a concession being obtained by the French Channel Tunnel Company from their Government, and a shaft was sunk at Sangatte, near Calais. From this shaft they subsequently drove a heading about 1½ miles in length and in the same year the South-Eastern Railway voted £20,000 for research. The Channel Tunnel Company also obtained powers to make trials at St. Margaret's Bay, near Dover. Low's plan for a railway tunnel was adopted by the railway company in 1881 and two shafts were sunk, one at Shakespeare's Cliff and one at Abbot's Cliff; from the former a 7-ft. heading was driven for about 2,000 yards, and from the latter a similar heading 880 yards long.

From all this it would seem that the great project was at last launched upon its course when, like a bolt from the blue, came a permanent injunction, sponsored by Mr. Joseph Chamberlain in 1882. Matters of national defence and high policy intervened to stop the venture.

Since that time the matter has been thrashed out from every conceivable point of view, but the author considers that there is only time to deal with the technical side of the problem, itself a fascinating study. Geologists have proved that the grey or Rouen chalk extends in a thick continuous bed across the Channel, and it is believed that there should be no insuperable difficulty in tunnelling through this material.

The Channel Tunnel Committee Report, presented to Parliament in 1930, is an extremely interesting document and worthy of close study. The Committee were assisted by three well-known firms of consulting engineers, who reached the conclusion that a pilot tunnel would be essential to prove the feasibility of the whole scheme; this would cost £5,600,000 and would take five years to construct. The main tunnels, which would be twin tunnels, as proposed by William Low, would involve the expenditure of £25,300,000 and would take another three years to construct and equip for an electric railway. After weighing all the evidence, which covered every aspect of the scheme the Committee came to the decision that although some interests would be adversely affected, the Channel Tunnel, would be of economic advantage to the country.

So the matter rests today, but at present we must obviously regard with the greatest suspicion, in view of recent bitter happenings, any project which tends to make us more vulnerable than we already are to unscrupulous gangsters who pretend to represent their countries. Let us hope that in the not too distant future it may prove possible to reconsider the scheme, but this will have to be in an atmosphere purged of traitors, parachutists and similar pests.

One of the most important points which occurs to the author is that it will be useless to incur this vast expense if the works have to be flooded in wartime. Under such conditions the whole effort and expense would go for nothing.

Finally, the author is convinced that this great work could be carried out and that if political conditions could be stabilized on the Continent, then it would be of inestimable advantage to all. Let us hope that such conditions will speedily come to pass, but this may be delayed for a long time yet.

THE "HALIFAX" FOUR-ENGINED BOMBER

From *The Engineer* (London), September 19th, 1941

On Saturday, September 13th, details were released by the Air Ministry of the Handley-Page bomber, which, together with the "Stirling" and other types, forms the spearhead of the Royal Air Force offensive on Germany. The "Halifax" is an all-metal midwing monoplane, having a wing span of 99 ft. and a length of 70 ft., with a height of 22 ft. It is powered with four Rolls-Royce "Merlin" twelve-cylinder liquid-cooled engines, and has three-bladed airscrews. The fuselage is rectangular in shape and the position for the bomb aimer is arranged under the forward turret. It carries heavy defensive armament and is furnished with slotted flaps for the purpose of giving improved take-off. De-icing equipment is fitted, not only, as usual, to the wings but to the tail unit and to the airscrews. It is mentioned that points in the construction which may assist identification include square wing tips, and a rectangular tailplane with the twin fin and rudder units at its extremity. During last week Lord and Lady Halifax visited a Southern aircraft factory, and Lady Halifax, who a few weeks ago launched the thousandth bomber from a certain American aircraft works on its way to England, performed the naming ceremony for a new Halifax bomber. In a speech made by Lord Halifax reference was made to the part that that type of machine had recently played in heavy bombing attacks on Berlin and Turin.

ELECTRICITY SUPPLY IN THE BRITISH EMPIRE

From *Engineering* (London), September 26th, 1941

In his address to the London Students' Section of the Institution of Electrical Engineers, on August 27, Mr. J. R. Beard, the President of the Institution, gave an interesting account of the various ways in which the organization of public electricity supply has been carried out in the different countries of the Empire. He began by pointing out that the ultimate possibilities of electrical development in the vast areas concerned was almost impossible to visualize. Many of the countries were but sparsely populated and it was to this country, as the chief manufacturing centre of the Empire, that they would look for electrical equipment for many years to come. It was probable that the majority of his hearers would ultimately be concerned with Empire electrical development, either by taking some part in manufacture at home, or proceeding to some Dominion or Colony for the erection or operation of plant. The close connection of the Institution with this great sphere of electrical enterprise was illustrated by the fact that already one-fifth of the total membership was made up of overseas members; these were mainly domiciled in the Dominions.

The fields of major importance were naturally furnished by Canada, Australia, New Zealand, South Africa, India and the Far East, but many of the smaller countries offered considerable scope for future development. As an example, there were enormous sources of potential water power in British Guiana, as well as in the West Indies, West and East Africa, and Palestine, the relatively small installations at present existing representing only the beginnings of power supply over large areas. The electrical manufacturing production of Great Britain for home use was valued at 109,000,000£ ,per annum; for export to the Empire 18,000,000£, and to foreign countries 7,000,000£. In 1938, Great Britain supplied 70 per cent of the electrical imports of Australia, 16 per cent. of those of Canada and 51 per cent. of those of India. The figures for Eire, New Zealand and South Africa were respectively, 66 per cent., 61 per cent., and 60 per cent. In Australia there was an electrical manufacturing industry which, in 1938, had an output valued at 5,200,000£, the corresponding output in Canada having a value of 20,000,000£.

Turning to the organization of electricity supply in the various countries, Mr. Beard first dealt with Canada. In that country, 93 per cent. of the total generating capacity was in the form of hydro-electric plant which produced 98 per cent. of the total annual output. One quarter of this was off-peak power utilized for industrial heating, in paper works, for aluminium production, and extensively for domestic water heating. The general standard of consumption was four times that of Great Britain, possibly due to the general availability, especially in rural areas. The United States standards of 110 volts to 115 volts and 60 cycles, dominated Canadian practice. Canada, like Australia, was a Federation of Provinces and the Federal Government took no part in electrical matters. In the organization of electricity supply, Ontario and Quebec were of chief interest as they accounted for more than 80 per cent. of the Canadian output.

Mr. Beard then dealt with the organization of the Hydro-Electric Power Commission of Ontario, which came into existence in 1907. It is not necessary to reproduce this part of his address as the matter was dealt with on page 232 of our issue of last week. Some additional figures he gave may, however, be quoted. The Commission now owned 45 power stations, of capacities ranging up to 400,000 kw. and had a total load of 1,500,000 kw. It acted as agent and trustee for a partnership of 850 municipalities. In Quebec, the Provincial Government had hitherto exercised little influence over the electric-supply industry, which was mainly in the hands of a number of large companies. A Provincial Electricity Board was, however, established in 1937, to act as a regulating and controlling authority. A National Electricity Syndicate was also set up to develop generating plants and distribution systems, particularly with a view to the supply of rural areas. These organizations were roughly counterparts of the Electricity Commissioners in this country and the Hydro-Electric Commission in Ontario. It seemed probable that a provincially-controlled system of generation and distribution would ultimately replace private enterprise. Other provinces, such as Nova Scotia, Manitoba and Saskatchewan had smaller organizations based on the model of Ontario, but in British Columbia supply had been left entirely to private companies and the municipalities.

In New Zealand, where the sole right to use waterpower was vested in the Crown, over 90 per cent. of the annual output was obtained from hydro-electric stations. The first undertakings were established by local authorities and companies to which the government granted rights to develop certain areas. The Government itself entered the industry in 1910 when it began work on the Lake Coleridge scheme. Since that time operating through the Public Works Department, it had built or purchased plant and transmission lines forming complete interconnected systems in each island. The installed capacity in the North Island was 194,000 kw. and a further 174,000 kw. was under construction. In the South Island there were 73,500 kw. installed and 77,000 kw. under construction. In 1939, Government stations generated 90 per cent. of the 1,400 million units produced. The standard distribution voltage was 400-230. Although the policy of the Government had been to generate bulk power, retail distribution had been left to local authorities or Electric Power Boards responsible for sparsely populated areas. There were 31 such boards. Conditions in New Zealand were unusual in that generating and bulk supply were in the hands of an ordinary Government department.

In Australasia, various arrangements were in operation. On the mainland of Australia, practically all development was confined to the neighbourhood of the large cities, Sydney, Melbourne, Adelaide, Brisbane and Perth. In Brisbane, the Government was encouraging the amalgamation of various small private concerns into a private monopoly, ultimately to be taken over by the Government. Sydney had several large stations for municipal and urban supply, the 75,000 kw. installation at Balmain being of considerable technical interest as it operated at 1,200 lb. per square inch and 900 deg. F. The New South Wales Railways supplied its 311 miles of electrified track from its own generating station in Sydney. Melbourne had 439 track miles of suburban electrified line. In Victoria, a State Electricity Commission had been formed to undertake generation and bulk and retail supply. It had 10,000 miles of high-tension line.

In India, as in Australia, while certain districts were extensively electrified, others, particularly rural areas, were practically undeveloped. About half the total power was generated in hydro-electric stations. These were mainly situated in the North West Frontier District, the Punjab, the Tata group near Bombay, Madras and Mysore. Steam generation predominated in the United Provinces, Calcutta and Hyderabad. There was a certain amount of railway electrification, but the average consumption of the country was very low, being only five units per head of population. In Ceylon, Burma, the Malay States, Hong Kong and Shanghai, steam power predominated. Electrification, in general, was confined to the large towns, although the supply to the tin-mining area served by the Perak River undertaking was an important exception. In South Africa, the main development had also been in the neighbourhood of the large towns, such as Johannesburg, Cape Town, and Durban. In Natal, however, the supply for the railway from Durban to the Transvaal had been tapped at intervals to supply outlying towns. Owing to the influence of continental practice due to the strong Dutch interest, the standard supply in South Africa was given at 380-220 volts.

ATMOSPHERIC POLLUTION

From *Engineering* (London), September 5th, 1941

The Department of Scientific and Industrial Research has announced that the various bodies co-operating in the study of atmospheric pollution have agreed to a proposal to suspend publication of the annual reports for the duration of the war. The suspension applies to the 26th annual report for the year ended March 31, 1940, but, for the information of the co-operating organizations, a summary of the work done during that year, has been prepared by the Superintendent of Observations. This shows that the numbers of instruments maintained were as follows: deposit gauges, 127; automatic filters, 11; volumetric sulphur apparatus, 12; lead-peroxide apparatus, 60. On the outbreak of war, observations with some instruments were discontinued; in most cases, however, only temporarily.

The results obtained with the deposit gauges as summarized, by the figures for the total solids deposited, were as follows, the results for the previous year being given in brackets in each case: Class A, 31 (26); Class B, 69 (72); Class C, 0 (1); Class D, 0 (0). This shows that, in the year under review, there was an increase in the number of stations where the deposit ranked as Class A; in other words, the deposit over the whole country, as measured by the gauges, had decreased. This result continues the improving trend indicated by the diagram, Fig. 1, on page 88 of the previous annual report. The highest total deposit measured during the year (395 tons per square mile) was recorded at Manchester, and the lowest (57 tons) at Loggerheads. Both of these figures were less than the corresponding recordings in the previous year.

There were only three complete sets of results with automatic filters, namely, those from Cardiff, Coventry, and Stoke-on-Trent, and these alone are insufficient to provide a basis for comparison with previous figures; but the average monthly suspended impurity does show interesting characteristics (notably maxima) in January, 1940, which was unusually cold. This increase in suspended impurity was due, undoubtedly, to increased domestic heating, despite local shortages of fuel. All three places show such an increase in October, followed by a minimum in November, although the average temperature for that month was lower than the average for some 50 years. It is conjectured that the extension of Summer Time until November 20, 1939, and the restrictions imposed by the fuel rationing scheme, were responsible to some extent for the minima recorded during that month. Complete results for the measurement of sulphur-dioxide concentration by the volumetric method were obtained from the stations at London (Beckton and Crossness), Salford and Sheffield. The averages were slightly lower than those for the previous year. The measurement of sulphur gases by the lead-peroxide method did not show any unusual features.

Measurements of suspended impurity made in Central Park, New York City, by means of the automatic filter, showed that the air was purest between 1 p.m. and 3 p.m., whereas the measurements for British cities have invariably shown that the early morning air was the cleanest. This difference is presumed to be due to the greater convectional turbulence of a continental climate in the day time, resulting in a distribution of the pollution through a greater depth of atmosphere, and a corresponding reduction in the concentration at ground level. Further measurements made in Dublin showed an interesting correspondence between the concentration of sulphur dioxide and the suspended impurity, the two curves of average monthly values showing noticeable parallelism. Results with the automatic filter at Leinster Lawn, Dublin indicated a ratio of domestic to industrial pollution of 3.3 to 1 in winter and 2.3 to 1 in summer.

SANITATION FOR AMERICAN ARMY CAMPS

From *Engineering* (London) August, 1941.

In connection with the establishment of a number of permanent camps for the United States Army, a firm of consulting engineers has drafted the basic requirements for sewage treatment plants. The systems of treatment vary widely, including sludge digestion, activated sludge, preliminary and secondary filtration, chlorination, and single-stage and double-stage bio-filters. The quantities assumed average 70 gallons per capita per day, with a maximum of 140 for several hours, and a peak of 210 gallons. Suspended solids will average 460 parts per million, or 0.27 lb. per capital per day. Grit chambers are not generally used, but if provided they should be cleaned by hand and the grit disposed of by burial. Bar screens of 1 in. to 1½ in. openings may be cleaned by hand or by mechanical devices, the screenings to be buried or burned in an incinerator. In primary sedimentation tanks the period is three hours for trickling filter plants, 1½ hours for activated sludge and 6 to 7½ hours for bio-filter plants. Trickling filters are designed for 5,000 population per acre-foot in mild climate, or 4,000 where severe winters prevail. Final sedimentation tanks, 10 ft. to 12 ft. deep, are to have a flow not exceeding 800 gallons per square foot per twenty-four hours, or 1,600 gallons in two-stage bio-filter plants. Heated sludge digestion tanks are to have 2 to 3 cubic feet per capita, or 50 per cent more capacity for unheated tanks or for activated sludge plants. For Imhoff tanks the capacity to be 2 to 2½ cubic feet per capita with plain sedimentation alone, or 3 to 3½ cubic feet with trickling filter. For sludge drying beds in warm climates, without underdrains or filtering material, the capacity may be 2 to 3 square feet per capita. For plants of the trickling filter type the figures may be ½ to 1 square foot, or 1 to 1½ square feet for plants of the activated sludge type. In any case, provision is made for chlorination of the effluent. The selection of system of treatment depends largely on size and area of the camp and the general character of its surroundings.

DNJEPROGES DAM

From *Civil Engineering and Public Works Review* (London), September, 1941

The reported destruction of the great Lenin-Dnjeproges Dam, at Zaporoje, on the Dnieper River, by the retreating Russian armies under Marshall Budenny, comes as a shock to civil engineers. This deliberate act in the pursuance of the "scorched earth" policy so faithfully followed by the Russian people, brings into clear relief the ugliness of war in all its grim reality. This great dam was the pride of all Russia and was always instanced as a example of the success of the new regime and its determination to make Russia independent of foreign manufactured goods.

The great dam, built of ferro-concrete, was finished in 1932 mainly by the use of American skill and knowledge. At the dam was situated what is generally considered to be the largest hydro-electric plant in the world and was planned to have an annual output of 3,000,000,000 kilowatt hours. The passage of ships along the river was arranged for by means of locks.

The great Ukraine industrial centres were in large measure dependent upon power from these works. The iron mines of Krivoi Rog were entirely dependent upon its power, so, too, were the manganese mines of Nikopol, over a hundred miles east at Stalin Makeyevka. Kharkoff, the great Ukrainian industrial centre, was largely dependent upon this hydro-electric plant for its power. The magnitude of the disaster is realized when it is considered that 30,000,000 people are dependent for their livelihood upon the power derived from this dam.

CO-OPERATION IN NEW BRUNSWICK

Negotiations which have been carried on for some time between the Council of the Association of Professional Engineers of New Brunswick, and the Institute's Committee on Professional Interests have resulted finally in a draft of a co-operative agreement which is to be submitted to the members of the Association and the members of the Institute within the province.

The text of the agreement appears in this number of the *Journal*. A ballot will be sent shortly to all Councillors of the Institute and to corporate members in the province, in accordance with the requirements of By-law No. 78.

This will be the fourth agreement to be negotiated with the professional associations, and it is hoped that it will receive the same enthusiastic support by ballot as was accorded those in Saskatchewan, Nova Scotia, and Alberta. The successful result of the other agreements is a convincing proof of the value of such understandings and arrangements between engineers.

ECHOES OF THE ANNUAL MEETING

Those who attended the annual meeting this year in Hamilton, will well remember the address delivered at the banquet by Dr. W. E. Wickenden, president of the Case School of Applied Science. His topic "The Second Mile" gave him an opportunity to emphasize the professional possibilities of the practice of engineering.

It was interesting to see the amount of attention that was given to this address both in Canada and the United States. It was referred to in many places. A recent number of the weekly bulletin of the Cleveland Engineering Society partially sums up the case, and again pays tribute to a masterful accomplishment. It reads in part as follows:

"There are certain inspired moments in our lives which enable us to put into words thoughts which seem to take wings and soar into the realm of immortal expressions. Such an occasion was the address delivered by Dr. William E. Wickenden, President of Case School of Applied Science, at the Annual Banquet of the Engineering Institute of Canada in Hamilton, Ont., this past February. Since that address was first given it has been reprinted in part, or commented on in countless Engineering Bulletins throughout our nation. 'The Baltimore Engineer' reprinted it in its entirety, the 'Rochester Engineer' devoted four columns to it. Mr. Everett S. Lee of the General Electric Company wrote: 'Would that every engineer would read and study the address on 'The Second Mile' delivered by Dr. Wickenden.' Mr. Stetson, editor of "Mechanical Engineering' in the April, 1941, issue wrote: 'We ought to pluck Dr. Wickenden out of his many duties and send him around the country to carry this message to all engineers.' Dr. Wickenden quoted a preacher who was reproached for straying too widely from his text and who replied: 'A text is like a gate, it has two uses; you can either swing on it, or you can open it and pass through.' "Let us pass through" was Dr. Wickenden's conclusion.

"To be useful, they, the engineers must be team workers; and they must be prepared to deal with 'men and their ways,' no less than 'things and their forces.' The engineering profession will exercise a far greater influence in civic and national affairs. It will probably never be able to define its boundaries precisely, nor become exclusively a legal caste, nor fix a uniform code, of educational qualifications. Its leaders will receive higher awards and wider acclaim, the rank and file will probably multiply more rapidly than the elite, and rise in the economic scale to only a moderate degree."

"It is unfortunate that our space will not permit a more detailed account of the many gems found in Dr. Wickenden's article, but let us in the writer's words "open the gate and pass through it to the Second Mile." We are proud that Dr. Wickenden is a member of our Cleveland Society."

WARTIME BUREAU OF TECHNICAL PERSONNEL

MONTHLY BULLETIN

Several interesting things have been disclosed by the examination of the twenty-five thousand questionnaires which have been returned to the Bureau, but perhaps the most interesting is that practically everyone who was not engaged on essential work answered question number seventeen in the affirmative. This question asks if the person is willing to transfer to war work under certain specified conditions, including no reduction in income.

The questionnaire also shows that the majority do not ask for more money in any new position to which they might be transferred. In fact, in many cases, the services have been offered for war work at a substantial reduction from present earnings.

It is strikingly apparent that the professional group has a high concept of its obligations and duties to the nation. The information gathered from the questionnaires is corroborated by interviews in the office and subsequent correspondence. The opinion is expressed generally that the individual is willing to be told where he should work, and desires some form of regulation that will make certain that he shares with others in the war effort.

Many persons have sent pleading letters, that their services might be used in the national emergency and have offered to go any place, for any occupation, at almost any wages. It is true that the war requirements at the moment do not seem to offer suitable work for all these people, but it is significant that they desire to get in and help without profit to themselves.

The demand for mechanically trained engineers continues to be great, and the supply of unemployed in this group is a thing of the past. The Bureau has found persons who are competent to fill important positions in war industry occupied at least partially in non-essential work. The negotiations to get these men released for more important work have been long and not always successful. If hundreds of men are to be secured this way to fill the hundreds of openings that have been reported to the Bureau, it is going to be a long drawn out and not very efficient procedure.

At present there is no machinery to adjudicate on the value of the work being done as compared to other work which is seeking the services of an engineer. If some authority were established to rule quickly in such cases, and to authorize the transfer when such action seems to be in the best interests, it would not only speed up the work of finding the necessary personnel, but would be welcomed by employer and employee as a solution of their common problem.

The questionnaires for the research science group are now being distributed, and the inquiries for persons of this type are increasing. Already placements have been made in important places, and it is expected this division of the Bureau's activity will shortly gain momentum and importance.

PROPOSED AGREEMENT BETWEEN THE ENGINEERING INSTITUTE OF CANADA AND THE ASSOCIATION OF PROFESSIONAL ENGINEERS OF THE PROVINCE OF NEW BRUNSWICK

MEMORANDUM OF AGREEMENT made in duplicate at the City of Saint John, in the Province of New Brunswick, this............ day of.................., 194....

BY AND BETWEEN:

THE ENGINEERING INSTITUTE OF CANADA, a corporation duly incorporated under the laws of the Dominion of Canada, having its head office in the City of Montreal, in the Province of Quebec, herein acting by its President and General Secretary, duly authorized for the purposes hereof by a resolution of its Council passed at a meeting duly called and held on the............day of ...., 194.., hereinafter called the Institute,

Party of the First Part,

and

THE ASSOCIATION OF PROFESSIONAL ENGINEERS OF THE PROVINCE OF NEW BRUNSWICK, a corporation duly incorporated under the laws of the Province of New Brunswick, having its head office at the City of Saint John, in the Province of New Brunswick, herein acting by its President and Secretary duly authorized for the purposes hereof by a resolution of its Council passed at a meeting duly called and held on the............day of...................., 194.., hereinafter called the Association.

Party of the Second Part.

WHEREAS it is desirable in the interest of the engineering profession that there be close co-operation between the Institute and the Association and

WHEREAS such close co-operation will be promoted if, so far as is practicable, there is effected:

(a) A common membership in the Institute and in the Association in the Province of New Brunswick.

(b) A simplification of existing arrangements for the collection of fees.

(c) A common interest in the training of young engineers.

NOW THEREFORE, the parties hereto agree with each other as follows:

1. (a) Every person resident in the Province of New Brunswick who, on the date of this agreement, is registered as a professional engineer under the provisions of Chapter 55 of the Statutes of the Province of New Brunswick, 10 George V (1920), and amendments, and is not a corporate member of the Institute, shall have the right, under the provisions of this agreement, to become a corporate member of the Institute. Any such registered professional engineer shall notify the secretary of the Association in writing within the first year of the term of this agreement if he desires to become a corporate member of the Institute under the conditions of this agreement.

(b) Any person resident in the Province of New Brunswick registering as a professional engineer in the Association subsequent to the date of this agreement, who is not a corporate member of the Institute, shall upon such registration become a corporate member of the Institute unless he notifies the Secretary of the Association of his desire to the contrary.

(c) Every person resident in the Province of New Brunswick, who is enrolled as an Engineer-in-Training with the Association, may become a Junior of the Institute providing he becomes and remains a subscriber to *The Engineering Journal*. Every person resident in the Province of New Brunswick, who is enrolled as a Student with the Association, shall also be a Student of the Institute.

(d) Members, Engineers-in-Training or Students of the Association who become Members, Juniors or Students, respectively, of the Institute, under the provisions of this agreement, shall not be required to pay the entrance or transfer fees of the Institute.

2. (a) Any corporate member of the Institute who is, at the date of this agreement, or who, within twelve months of such date becomes, a resident of the Province of New Brunswick, shall have the right to become a member of the Association, such right to be exercised by written notice to the Secretary of the Association, and all entrance fees otherwise payable to the Association shall be remitted, provided that application for membership in the Association is made within the first twelve months of the term of this agreement.

(b) Any corporate member of the Institute who becomes a resident of the province subsequent to twelve months from the date of this agreement, may become a Member of the Association, if qualified for such membership, upon payment to the Association of the difference in the amount of the entrance fee already paid to the Institute and the current entrance fee of the Association, providing that application for membership is made within twelve months of the date of his becoming a resident of the Province of New Brunswick.

(c) Every Junior or Student of the Institute resident in the Province of New Brunswick shall be enrolled with the Association as an Engineer-in-Training or a Student, respectively.

(d) Juniors or Students of the Institute who become enrolled as Engineers-in-Training or Students, respectively, with the Association, under the provisions of this agreement, shall not be required to pay the entrance fees of the Association.

3. (a) The Association shall, on behalf of the Institute, collect from each Member of the Association, who is also a corporate member of the Institute, the sum of six dollars ($6.00) per annum, which fee shall be in lieu of the ordinary annual corporate membership fee of the Institute. This fee shall entitle the member of the Association to the Institute classification of Member (M.E.I.C.) and to those privileges of the Institute membership provided by its by-laws, and shall include the annual subscription to *The Engineering Journal*. The payment of the six dollars ($6.00) shall not apply in the case of an Honorary, Paid-up or a Life Member of the Institute.

(b) The Association shall, on behalf of the Institute, collect from each Engineer-in-Training of the Association, who is also a Junior of the Institute, a fee in lieu of the ordinary annual Junior membership fee of the Institute, which shall be mutually agreed between the Secretary of the Association and the General Secretary of the Institute but which shall not be less than one dollar ($1.00) per annum, and from each Student of the Association, who is also a Student of the Institute, a fee so agreed in lieu of the ordinary annual Student membership fee of the Institute, which shall not be less than fifty cents (50c.) per annum.

(c) Such fees shall be due to the Institute on the............day of..................of each year, in respect of the year commencing on such due date, and shall be paid by the Association to the Institute as collected by the Association. Such fees shall be billed together with any fees due to the Association as one total fee.

4. It is agreed that the branches of the Institute in New Brunswick shall continue actively to function as such during the term of this agreement, and that the Association shall contribute to their support. To enable such functioning there shall be set up and continued from year to year during the term of this agreement a committee of five members, all of whom shall be members of both the Association and the Institute to be known as the Joint Finance Committee; two of said members shall be appointed annually by the Council of the Institute; two members shall be appointed annually by the Council of the Association, and the fifth member shall be appointed annually by the four members aforesaid and shall be the chairman of the Committee. In case the four members aforesaid fail to appoint the fifth member within thirty days from the date of their appointment, the said fifth member shall be appointed by the president of the Institute within a further period of thirty days. The said committee shall recommend to the Council of the Association, annually, the sums of money to be paid to the branches of the Institute for their operation, and such sums to be paid by the said Association shall be such that the ordinary revenue of each branch shall be the same as if this agreement were not in effect.

5. Nothing in this agreement shall prevent either party hereto from exercising its rights and privileges with respect to the disciplining, the suspension, or the expelling of any of its members, in accordance with its charter and by-laws.

Before final action is taken by either party with respect to the disciplining, the suspension, or the expelling of one of its members affected by this agreement, it shall furnish the other party with sufficient information to enable it to determine whether the circumstances warrant action by the other party, but neither party shall be affected by the lack of action by the other party.

6. This agreement is intended to apply to the residents of the Province of New Brunswick only, and no person who is not a resident of the Province of New Brunswick may become or continue to be a member of the Institute in good standing under this agreement, but may continue to be a member in good standing, on the same conditions as if he had been admitted as a member of the Institute without reference to this agreement.

7. The terms and conditions of this agreement may be amended by mutual consent, in writing, between the Councils of the parties hereto duly authorized where necessary by their respective bodies and executed by their accredited officers.

8. The term of this agreement shall be the period commencing on the....................day of.................., 194.., and ending on the..................day of................, 194.., but unless either of the parties hereto has given notice to the other at least six months prior to the said..........day of.................., 194.., that this agreement shall terminate on the said..............day of................, 194.., it will continue in full force and effect after the said.......... day of.................., 194.., from year to year, subject to termination, at the end of any such subsequent year, by six months' prior notice of intention to terminate given by either of the parties hereto, to the other. Notice of termination of this agreement shall be given by the delivery by one party to the other party of a certified copy of a resolution of the Council of the one party to that effect.

9. This agreement shall not come into operation unless a percentage of the membership of the Association, acceptable to the Council of the Institute and to the Council of the Association, takes full advantage of its provisions.

In witness whereof these presents have been duly executed on behalf of the parties hereto on the date and at the place above written.

CORRESPONDENCE

The Editor, Ottawa, October 25, 1941.
The Engineering Journal,
Engineering Institute of Canada,
2050 Mansfield Street, Montreal, Que.

Dear Sir:

Would you be good enough to allow me space in your publication in which I may thank your readers who have co-operated with the Wartime Bureau of Technical Personnel by completing the recently circulated questionnaire. Many thousands of engineers, chemists, and architects have placed their records with the Bureau, and thus have aided materially in the Bureau's problem of finding technical personnel for the active service forces, departments of government, and war contractors.

Many questionnaires have been circulated recently by various organizations and frequently one hears adverse comments about such things. Doubtless there is some reason for this criticism, but on the other hand, I feel it should be recognized that under many circumstances this is not only the best but the only method of securing fundamental information.

I would like your readers to know that the Bureau is functioning with considerable success. I am gratified to find that so many men have been placed, and that actual costs have been kept at a low figure. As technical personnel, and tax payers, your readers will be interested in this information.

Some people have misunderstood the purpose of the questionnaire, and have felt that they should have received some communication or offer of work after they had registered. On the form it was explained that it was not an application or offer of work, but simply a record of the person's qualifications and availability. We have had letters at Ottawa which indicate that there has been some confusion on this point.

Many persons have written letters offering their services immediately, and in some instances have expressed the thought that they were especially equipped to do important work. Unfortunately, employers to whom we have submitted these records have not always agreed on this point, and consequently acceptances of the offers have not followed. It is easy to understand that some persons may become impatient when their services are not immediately snatched up, but I am certain that if they had a better understanding of the needs of industry, they would appreicate the difficulty of finding quickly an opening where they could be used to advantage.

It is not right to regard the Bureau as an employment agency in the ordinary sense. Under existing conditions, its real purpose is to find men who can fill openings which are recorded with the Bureau, rather than to find openings for men who happen to be out of work or who desire to take a greater part in the war effort. I have seen some letters where persons have expressed indignation at the failure of the Bureau to place them. Naturally, we regret such instances, but we can only place men when the prospective employer finds them to be suitable.

The leadership that the engineers, chemists, and architects have given in establishing and supporting the Bureau must bring a great deal of satisfaction to your readers, as well as to many others. It is my belief that the future operation of the Bureau will add materially to this satisfaction.

While the principal purpose of this letter is to thank your readers who have met our requests, I would like to speak also to those who have not returned the questionnaires. The work of the Bureau is of great importance to the individual, as well as to the nation's effort, and yet without a complete record of information, the work cannot be done satisfactorily. May we count on your support ? If by chance the original questionniare has been mislaid, a duplicate will be sent to you upon request. Thank you.

Yours truly,
(*Signed*) E. M. Little, *Director.*

To the Editor:

Sir:

On page 23 in the advertising section of *The Engineering Journal* for September, 1941, there appears, referring to the new power plant on the St. Maurice River at La Tuque, the statement, "Pozzolith Concrete used in bulkheads". To supplement this statement, may I remark that some sever per cent of the concrete placed in the east bulkhead contained Pozzolith. For the west bulkhead, the figure was under three per cent.

Very truly yours,
J. B. Macphail,
Montreal, 28th October, 1941. M.E.I.C.

COVER PICTURE

The picture on the cover of this issue is that of the new bridge over the Richelieu river between Beloeil and St. Hilaire, Que., on the Montreal-St. Hyacinthe highway.

This bridge consists of a 258-ft. central swing span flanked on each side by three continuous plate girder spans—two of 103 ft. 6 in. and one of 102 ft.—and by a 66-ft. reinforced concrete approach span forming a total length of 1,008 ft. The substructure units, of reinforced concrete, comprise nine piers and two abutments with a protection pier (defence) for the swing span. The flooring of the bridge is of reinforced concrete with the exception of that of the swing span which consists of a creosoted-wood floor covered with asphalt planks. The roadway is 33 ft. wide with a 5-ft. sidewalk on each side and the bridge is provided with a modern electric light system.

The clearance under the swing span at mean water level is 30 ft. and the horizontal clearance 100 ft. Each of the two 66-ft. approach spans forms a viaduct over the roads that pass on both sides of the river. Construction work was started in the latter part of June 1940 and the bridge was opened to traffic on September 22nd 1941. Communications with both shores were made possible in the past by means of a ferry-boat service and the bridge now forms an important link in the Montreal-St. Hyacinthe-Quebec highway.

This bridge was built under the direction of the Department of Public Works of the Province of Quebec at an approximate cost of $525,000.

MEETING OF COUNCIL

A meeting of the Council of the Institute was held at Headquarters on Saturday, October 18th, 1941, at ten-thirty a.m.

Vice-President K. M. Cameron was in the chair; Vice-President deGaspe Beaubien, Councillors J. G. Hall, H. Massue and G. M. Pitts; Secretary-Emeritus R. J. Durley, Mr. Trudel and the general secretary were present.

Secretary-Emeritus Durley presented a revised report on prizes and awards. Each item was dealt with separately, and a very full discussion developed. Several minor changes were proposed, and Mr. Durley was asked to incorporate these in the recommendations.

The general secretary was instructed to supply each councillor with a copy of the revised report so that everyone might have an opportunity to study the proposals in detail. It will be considered again at a later meeting of Council and perhaps submitted at the annual business meeting next February.

The secretary reported that following discussions with Mr. C. C. Kirby, who had come to Montreal for the purpose, a revised draft of the proposed agreement between the Institute and the Association of Professional Engineers of New Brunswick had been prepared. It was expected that at an early date this proposed agreement would be submitted to the members of both bodies for approval.

The president had undertaken to discuss with the committee in Alberta the results of the agreement in that province. His report had not yet been received, but a letter from the registrar of the Association indicated that they were well satisfied with the percentage of members of both organizations who had taken advantage of joint membership.

The general secretary reported that he had met with the executive of the Winnipeg Branch at the time of the President's visit to that city, and had discussed the affairs of the branch and in particular the programme for the coming season.

The secretary reported that copies of the communications received from the National Construction Council and the Canadian Association of Social Workers regarding plans for post-war conditions had been sent to all councillors, but that no comments had been received. It was decided to hold this question for discussion at a later meeting of Council.

The financial statement up to the end of September had been examined by the Finance Committee and found to be satisfactory. Income was substantially ahead of the same time last year, and expenditures were approximately the same.

In view of the increased responsibilities of Mr. Trudel, due to Mr. Wright's frequent absence in Ottawa on work of the Wartime Bureau of Technical Personnel, the recommendation of the Finance Committee that Mr. Trudel be given the title of Assistant General Secretary, rather than Assistant to the General Secretary, was unanimously approved.

The general secretary reported that the Department of Labour had requested the Wartime Bureau of Technical Personnel to expand its organization so that it could take care of developments which would follow certain proposed changes in the present procedures. New regulations were being drawn up by the Department which would place a much greater responsibility on the Bureau. Among other things, this responsibility would require that offices be opened in several parts of Canada. At the moment it was considered that suitable places for such offices would be Vancouver, Winnipeg, Toronto, Montreal and Halifax.

The general secretary reported receipt of a letter from an engineer in one of the refugee camps, requesting permission to write the Institute examinations with a view to receiving some kind of a qualifying certificate to be used as a future reference. These men are classed by the government as friendly aliens, but, being of enemy nationality, could not join the Institute at the present time, even if released from the refugee camps. It was the feeling of members present that favourable consideration might be given to such a request, but it was decided to defer action until a report had been received from the Wartime Bureau of Technical Personnel which is investigating the status of these refugees and the possibility of them being released from camps, providing satisfactory work can be obtained for them.

The general secretary reported that H. J. Vennes, councillor for the Montreal Branch, had written to inform Council that he had moved to the United States, and therefore submitted his resignation. This news came as a distinct surprise and disappointment to Council. The secretary was instructed to write Mr. Vennes and inform him that under the circumstances there was no alternative but to accept the resignation and at the same time explain Council's sincere regret that such a valuable member of Council and of the Institute should be lost, at least temporarily, from the Montreal Branch activities.

The secretary reported that letters had been received from several of the branches expressing willingness to co-operate with Council in extending the facilities of the Institute to professional engineers from other countries now working in Canada. A similar letter had been received from one branch, pointing out that as many of these engineers were getting well established in Canada they should join the Institute in the usual way. It was decided to bring this matter up for further discussion at the next meeting of Council which will be held in Quebec City.

A number of applications were considered, and the following elections and transfers were effected:

ADMISSIONS	
Members	2
Juniors	3
Affiliates	2
TRANSFERS	
Junior to Member	1
Student to Member	3
Student to Junior	3

The general secretary reported that following correspondence with the Quebec Branch, it had been decided that the November meeting of Council would be held in that city on Saturday, the fifteenth. Present arrangements included a branch luncheon at one o'clock with a branch meeting at two-thirty, at which the president would speak. The Council meeting would be held later in the afternoon. This arrangement would give out of town councillors an opportunity to reach Quebec during the morning, and, if necessary, return to their homes that evening. It was suggested that motor transportation from Montreal to Quebec might be arranged, details of which will be available at a later date.

The Council rose at one o'clock p.m.

ELECTIONS AND TRANSFERS

At the meeting of Council held on October 18th, 1941, the following elections and transfers were effected:

Members

deBondy, Joseph Agapit, metallurgist, Manitoba Steel Foundries Ltd., Selkirk, Man.

Neave, Roger, B.Sc. (Elec.), (Univ. of Man.), designing engr., gen. engrg. dept., Imperial Oil Limited, Sarnia, Ont.

Juniors

Gravel, Maurice, B.A.Sc., C.E., (Ecole Polytech.), Prov. Road Dept., Beauport, Que.

Kline, Joseph Douglas, B.Eng. (Civil), (N.S. Tech. Coll.), Defence Industries Ltd., Oshawa, Ont.

Mable, Wilfred H., B.Sc. (Elec.), (Queen's Univ.), elec. design engr., H. G. Acres & Co. Ltd., Niagara Falls, Ont.

Affiliates

Hebert, Adjutor J. G., designing engr., Plessisville Foundry, Plessisville, Que.

Malkin, Alfred, elec. engr., Canadian Car Munitions, Ltd., Montreal, Que

Transferred from the class of Junior to that of Member

Ramsay, William Wallace, B.Sc. (Civil), (Univ. of Man.), asst. engr. (P.F.R.A.), Dept. of Agriculture, Winnipeg, Man.

Transferred from the class of Student to that of Member

Cooper, William Everett, B.Eng. (Elec.), (McGill Univ.), i/c of engrg., Saguenay Power Co. Ltd., Isle Maligne, Que.

Strong, Robert L., B.A.Sc. (Univ. of Toronto), S.B. (Mass. Inst. Tech.), inspection work, Associated Factory Mutual Fire Insurance Companies, Boston, Mass.

Young, William Richard, B.Sc. (Civil), (Univ. of Man.), engr., E. G. M. Cape & Co. Ltd., St. Johns, Nfld.

Transferred from the class of Student to that of Junior

Buchanan, Arnold Amherst, B.Eng. (Mech.), (McGill Univ.), Engineer Officer (F/O), R.C.A.F., Camp Borden, Ont.

Giles, John Oscar, B.Sc. (Mech.), (Queen's Univ.), engrg. dftsman., Imperial Oil Limited, Sarnia, Ont.

Mackay, William Brydon Fraser, B.Sc. (Elec.), (Univ. of Man.), B.Met.E. (Univ. of Minn.), Fl.-Lieut., R.C.A.F., No. 1 Air Navigation School, Rivers, Man.

Students Admitted

Baxter, John Frederick (McGill Univ.), Belgrave Ave., East Saint John, N.B.

Baylis, Walter John, B.Sc. (Elec.), (Univ. of Alta.), 76 East Ave. No.; Hamilton, Ont.

Davis, Bruce Lumbers, B.A.Sc. (Univ. of Toronto), Saguenay Inn, Arvida, Que.

Dunbar, George G., (McGill Univ.), P.O. Box 588, Stellarton, N.S.

Extence, Alan Barr, (Univ. of Toronto), 103 Westmount Ave., Toronto, Ont.

Eyre, Alan M., (Univ. of B.C.), 4606 West 9th Ave., Vancouver, B.C.

Farago, William James, B.Sc. (Mech.) (Univ. of Sask.), 83 George St., St. Catharines, Ont.

Hogarth, James Earle, Instr'man., Dept. Works & Bldgs., R.C.A.F., St. Johns, Que.

Kraft, Robert William, M.Sc. (Queen's Univ.), Saguenay Inn, Arvida, Que.

Loane, George Herbert, (Univ. of N.B.), Campbellton, N.B.

Love, John Gordon, (Univ. of Toronto), 321 Bloor St. W., Toronto, Ont.

Mundec, Lawrence Sterling, (Univ. of N.B.), 352 Duke St., West Saint John, N.B.

Wells, James Edwin, (McGill Univ.), 4412 Draper Ave., Montreal, Que.

Personals

News of the Personal Activities of members of the Institute, and visitors to Headquarters

C. D. Howe, Hon.M.E.I.C., Minister of Munitions and Supply, has recently been awarded an Honorary Membership in the American Society of Mechanical Engineers, which will be presented to him at the annual meeting of the Society in New York in December.

C. R. Young, M.E.I.C., Dean of Engineering at the University of Toronto, was guest speaker at the Cleveland Engineering Society on the occasion of the general meeting of the fall season in Cleveland, Ohio, on October 14th. He spoke on "Transition from Peace to War" with particular reference to the engineers' share in it.

At noon the same day, a group of Toronto graduates entertained him at luncheon. There were nineteen "Schoolmen" present, including one from the class of '95, and one from '38. Dean Young also visited the Case School of Applied Science.

Dr. A. Surveyer, M.E.I.C., was appointed a director of the Shawinigan Water & Power Company, Montreal, at a meeting of the board held last month. Dr. Surveyer, a past president of the Institute, is a well-known consulting engineer.

Brig. Gen. J. P. Mackenzie, D.S.O., M.E.I.C., has recently been promoted to this rank and appointed to command infantry brigades with the Canadian army overseas. Before the war he was general manager of the Western Bridge Company, Limited, at Vancouver, B.C.

T. M. Moran, M.E.I.C., vice-president of Stevenson & Kellogg, Ltd., management engineers, is now permanently located in Toronto. He was previously connected with the Montreal office of the company.

E. G. Patterson, M.E.I.C., has recently been appointed general manager of Ottawa Car and Aircraft Limited. He became associated with the company in 1940 as assistant to the general manager and spent several months in Great Britain at the works of Handley-Page Limited with a view to preparing the manufacture of Hampden bombers in Canada. Previously he was associated with the St. Lawrence Paper Mills Ltd., the Canadian International Paper Co. Ltd., and the Northern Electric Company.

H. J. Vennes, M.E.I.C., special products engineer, Northern Electric Company Limited, Montreal, has been transferred to the specialty products division of the Western Electric Company, Kearney, N.J., and has taken up residence at Westfield, N.J. He had been connected with the Northern Electric Company since 1921 when he came from New York, where he had previously spent five years with the engineering department of the Western Electric Company to which he is now returning. During his stay in Canada, he has been connected with the designing and installation of the many carrier current telephone and telegram systems, radio broadcasting stations, sound pictures and public address systems in this country. He was responsible for several new developments along those lines.

Mr. Vennes will be greatly missed by the several friends that he had made in Canada and particularly in the Institute where he has been very active. He was chairman of the Montreal Branch in 1940 and at the time of his return to the States, he was a Councillor of the Institute. On several occasions he has delivered papers on various subjects some of which have been published in the *Journal.*

L. P. Cousineau, M.E.I.C., has recently joined the staff of Dufresne Engineering Company Limited of Montreal. He was previously connected with the Quebec Streams Commission and has been stationed for the last two years on the Ottawa River, where he acted as assistant resident engineer on the construction of the power development just completed at Rapid No. 7 near Cadillac, Que.

Mr. Cousineau was graduated in civil engineering from the Ecole Polytechnique in 1936 and he did post graduate work in Paris at the Ecole Supérieure de Soudure Autogène, from which he was graduated as a welding engineer in 1937. Upon his return to Canada, he had been with Marine Industries Limited, at Sorel, Que., for two years, where he was connected with the construction department, later becoming welding superintendent.

Major C. N. Mitchell, V.C., M.C., M.E.I.C., has been appointed to command a field company, Corps Troops, R.C.E. with the Canadian Army overseas.

John H. Legg, M.E.I.C., has recently been appointed superintendent of the Wakefield, Que., plant of the Aluminum Company of Canada Limited.

Col. D. A. White, M.E.I.C., has been appointed commandant, Canadian Army Trades School at Hamilton, Ont. He is president of D. A. White & Company Ltd., Montreal.

Malcolm D. Stewart, M.E.I.C., has obtained a commission as second lieutenant with the Royal Canadian Engineers and is at the present time attending the officers' training centre at Brockville. He was previously with Hugh C. MacLean Publications, Toronto.

J. Leslie Smith, M.E.I.C., has been loaned by the Department of Transport of Canada to the Federal Aircraft Limited, Montreal, as aeronautical engineer. He has been connected with the aeronautical engineering division of the Federal government at Ottawa since he came from England in 1930.

J. G. Welsh, M.E.I.C., has been appointed design engineer for the Bouchard Works of Defence Industries Limited, Ste. Therese, Que. He joined the engineering department of Defence Industries Limited in May, 1940, and was transferred to the Bouchard Works in June of this year acting as assistant to the resident engineer, in which capacity he took charge of the mechanical equipment section during construction.

R. W. Dunlop, M.E.I.C., has been transferred from Sarnia to Regina, Sask., with the Imperial Oil Limited.

A. J. Mickelson, M.E.I.C., is now employed as assistant engineer with The Great Lakes Paper Company, Limited, Fort William, Ont. He was previously on the engineering staff of C. D. Howe Company, Limited, at Port Arthur.

Roland Lemieux, M.E.I.C., has recently accepted the position of city engineer and secretary-treasurer of the municipality of Sillery, just outside of Quebec city. He was previously employed as assistant to the district engineer, District No. 1, with the Department of Roads for the Province of Quebec. Mr. Lemieux was graduated from the Ecole Polytechnique in 1937.

R. McD. Richardson, M.E.I.C., has joined the staff of the New Brunswick Telephone Co. Ltd., at the head office in Saint John, N.B. Since his graduation in 1924 he had been with the Bell Telephone Company of Canada Ltd.

M. W. Huggins, M.E.I.C., has joined the staff of the department of civil engineering at the University of Toronto. He was formerly lecturer in civil engineering at Queen's University, Kingston, Ont.

Lieut. Philip Hughes, R.C.N.V.R., M.E.I.C., is at present serving as engineer officer on H.M.S. Ramillies.

Flying Officer W. E. Seely, M.E.I.C., who joined the Royal Canadian Air Force a few months ago, has been posted as engineer with the works and buildings department, No. 8 Service Flying Training School at Moncton, N.B.

E. R. Brannen, Jr.E.I.C., has joined the staff of Spruce Falls Power & Paper Company at Kapuskasing, Ont. He was previously connected with the Canadian Johns-Manville Company, Limited, at Asbestos, Que.

E. A. Russell, Jr.E.I.C., has received an academic fellowship in sanitary engineering at the University of Toronto. He was previously on the maintenance and construction staff of Canadian Industries Limited at Beloeil, Que.

J. W. Brooks, Jr.E.I.C., is at present employed with the H. G. Acres Company at Niagara Falls, Ont. He was previously a lecturer in civil engineering at Queen's University.

Roger K. Cheng, S.E.I.C., has recently been commissioned a second lieutenant in the Canadian Army and is attending a signals course at Brockville. He was graduated in electrical engineering from McGill University in 1937. Lieutenant Cheng is said to be the first Chinese to receive a commission in the Canadian Army.

C. E. Green, S.E.I.C., is at present employed with the engineering department of Defence Industries Limited at Ste. Therese, Que.

Jean Lacombe, S.E.I.C., was erroneously reported, in the last issue of the *Journal*, as having joined the staff of Dominion Bridge Company, Limited, Montreal. Mr. Lacombe is still employed with the Quebec North Shore Paper Company at Baie Comeau, Que., on the engineering staff.

B. D. McDermott, S.E.I.C., is employed with Fraser Brace Engineering Co. Limited at Shawinigan Falls, Que. He had previously been located at Nobel.

A. J. Ring, S.E.I.C., has recently been transferred from the Montreal to the Toronto office of Defence Industries Limited.

J. L. Vaillancourt, S.E.I.C., has recently been commissioned as a pilot officer in the Royal Canadian Air Force and will report this month at No. 1 Air Navigation School at Rivers, Man. In the last few months he had been with the city of Outremont, Que. He was graduated from the Ecole Polytechnique in 1940.

Harold T. Kummen, S.E.I.C., is employed on the staff of the Aluminum Company of Canada, Limited, at Arvida, Que. He was graduated in electrical engineering from the University of Manitoba last spring.

Edward I. Wigdor, S.E.I.C., is employed as a technical officer with the British Air Commission at the Vultee Aircraft Limited, Los Angeles, Cal.

J. M. Courtright, S.E.I.C., is employed with the Shell Oil Company of Canada, Limited, in their refinery at Montreal. He was graduated in civil engineering from Queen's University last spring.

E. W. McKernan, S.E.I.C., has joined the staff of Canadian General Electric Company Limited and is at present taking the test course at Peterborough, Ont.

William Tkacz, S.E.I.C., is employed as process engineer with the Ottawa Car and Aircraft Limited at Ottawa. He was graduated in mechanical engineering from Queen's University last spring.

J. F. Ross, S.E.I.C., is employed with the Aeronautical Inspection Directorate, Royal Canadian Air Force, and is stationed at Winnipeg, Man.

VISITORS TO HEADQUARTERS

C. C. Kirby, M.E.I.C., secretary, Association of Professional Engineers of New Brunswick, Saint John, N.B., on September 29th.

P. E. Cadrin, Jr.E.I.C., Sorel Industries Limited, Sorel, Que., on September 29th.

John E. Cade, M.E.I.C., assistant chief engineer, Fraser Companies Limited, Edmundston, N.B., on October 2nd.

P. Turner Bone, M.E.I.C., Calgary, Alta., on October 2nd.

J. M. Courtright, S.E.I.C., Ottawa, Ont., on October 2nd.

Flt. Lieut. J. M. Pope, Jr.E.I.C., Royal Canadian Air Force Headquarters, Ottawa, Ont., on October 4th.

Ernest Davis, M.E.I.C., comptroller of Water Rights and member of Water Board, Province of British Columbia, Victoria, B.C., on October 9th.

T. A. Lindsay, M.E.I.C., sales engineer, Canadian Telephones and Supplies Limited, Winnipeg, Man., on October 9th.

H. Lloyd Johnston, Jr., M.E.I.C., Canadian Industries Limited, Windsor, Ont., on October 9th.

K. A. Brebner, M.E.I.C., plant engineer, Price Bros. & Co. Limited, Riverbend, Que., on October 14th.

Robert W. Tassie, M.E.I.C., vice-president, Emprezas Electricas Brasileiras, Rio de Janeiro, S.A., on October 15th.

Jacques P. Leroux, Jr.E.I.C., resident engineer, Mont-Joli Airport, Mont Joli, Que., on October 16th.

Sidney Hogg, M.E.I.C., Saint John Drydock and Shipbuilding Co. Limited, Saint John, N.B., on October 16th.

Brig. G. R. Turner, M.E.I.C., Headquarters Canadian Corps., England, on October 17th.

L. E. Westman, editor, *Canadian Chemistry & Process Industries*, Toronto, Ont., on October 22nd.

T. S. Mathieson, M.E.I.C., designing mechanical engineer, Falconbridge Nickel Mines, Falconbridge, Ont., on October 27th.

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

William Israel Bishop, M.E.I.C., of Montreal died suddenly at Joliette, Que., on September 29th, 1941. He was born at Montreal on July 7, 1875, and received his education in the local schools. He served his apprenticeship as a land surveyor with Joseph Rielle, Montreal, and J. N. Patton, and later with G. H. Massey, civil engineer. He held the position of assistant engineer with the City of Westmount from June, 1895, to March, 1896, at which time he joined the staff of T. Pringle & Son, Montreal, as chief engineer.

William I. Bishop, M.E.I.C.

In 1902 he went with the Pittsburgh Reduction Company at Pittsburgh, Pa. From 1905 to 1906 he was superintendent and engineer for the T. A. Gillespie Company, contractors, of New York and Pittsburgh. In 1906 he went into business as an engineer and contractor and carried out a large contract for the construction of a power house and factory buildings for the Northern Aluminum Company at Shawinigan Falls, Que. Later he was engaged on important engineering projects with James Stewart & Company, Toronto, Foundation Company of Canada in Victoria, B.C., and in New York and also with the Raymond Concrete Pile Company in Montreal.

During the Great War he was manager of a group of five shipyards, building wooden and steel vessels for the Allies. In 1920 he established his own company, William I. Bishop Limited, in Montreal, and at the time of his death was still president. During his career he was engaged on some of the most important construction projects in Canada and the United States, among these being development work in Shawinigan Falls and the St. Maurice river area and with the Southern Canada Power Company. He designed the Gouin storage reservoir at the head of the St. Maurice river, one of the largest in the world. He was a member of the Montreal Tramways Commission having been appointed in 1934.

Mr. Bishop joined the Institute as an Associate Member in 1889 and was transferred to Member in 1907.

James Munro Bloomfield, M.E.I.C., died at Kamsack, Sask., on September 20th, 1941, after a few weeks illness. He was born at Thurmah Factory, Behar State, India, on December 22nd, 1888, and received his education at Heriot Watt College, Edinburgh, Scotland. He served his apprenticeship with British Thomson Houston Company Ltd., Rugby, England, and with the Lancashire Dynamo & Motor Company Ltd., of Manchester.

He came to Canada in 1913 and was employed with the Cunningham Electric Company at Calgary. A year later he went with Bowness Improvement Company Limited at Calgary. He served overseas in the Great War with the Canadian engineers from 1915 to 1918. Upon his return to Canada he joined the firm of General Engineers Limited, Calgary, as a junior partner and was engaged in the repair and maintenance of electrical apparatus and layout of distribution systems. In 1923 he was appointed superintendent of utilities with the Town of Kamsack, Sask., a position which he occupied until his death. Under his supervision the electric power plant of Kamsack was greatly improved and the service was extended to Pelly and Verigin.

Mr. Bloomfield joined the Institute as an Associate Member in 1929.

George Henry Davis, K.C, died in the Winnipeg General Hospital on May 27th, 1941, after a short illness. Born in London, England, on May 14, 1872, he came to Canada as a boy of 14 and worked on a farm near Brandon. Coming to Winnipeg in 1894, he entered Manitoba College and after graduation was a lecturer in French at the college for two years. He articled as a law student with the firm of Munson and Allan in 1900, and became a member of the firm when he was admitted to the bar in 1903. He was created a King's Counsel in 1925 and was associated with the law firm of Allan, Laird & Davis until the time of his death.

Mr. Davis' interests were wide and varied: he was a former president of the Canadian Club, a member of the International Institute of Foreign Affairs, the St. Charles Country Club, the Manitoba Club, and the Motor Country Club.

Although engaged in the profession of law, Mr. Davis was intensely interested in all engineering projects. For a number of years he made a study of large bridges, and had one of the most up-to-date libraries and files on the world's famous bridges, most of which he had visited at some time, either during their construction or after their completion.

Mr. Davis had been associated with the Institute as a Branch Affiliate for several years and had always taken a keen interest in the affairs of the Winnipeg Branch.

Joseph A. Vermette, M.E.I.C., died in the hospital at Ottawa on October 10th, 1941. He was born at Hull, Que., on November 16, 1879, and was educated at Ottawa College. After spending some years in the service of the Quebec Government as a civil engineer, he went to the Dominion Department of Public Works at Ottawa in that capacity and won promotions rapidly reaching the position of senior assistant engineer, which he held at the time of his death.

Mr. Vermette joined the Institute as an Associate Member in 1914.

News of the Branches

Activities of the Twenty-five Branches of the Institute and abstracts of papers presented

HAMILTON BRANCH

A. R. Hannaford, m.e.i.c. - *Secretary-Treasurer*
W. E. Brown, Jr.e.i.c. - - *Branch News Editor*

On the evening of Thursday, October 2nd, a joint meeting of the branch was held with the Hamilton Group of the Toronto Section of the American Institute of Electrical Engineers, in the Westinghouse Auditorium. The Speaker was Mr. A. H. Frampton, assistant engineer, Hydro-Electric Power Commission of Ontario, and his subject was **The 220 kv. System of the Hydro Electric Power Commission.** The speaker stated that the new 220 kv. system was commenced in 1927, following a contract between the Commission and the Gatineau Power Company, under which 260,000 hp. was to be supplied from the Paugan development on the Gatineau River, some 250 miles east of Toronto. The first 220 kv. receiving station was located at Toronto as the load there was sufficiently large to absorb all of the original contract, with a large margin to spare for future needs. Since the expansion of the 220 kv. system, constant study has been made to determine the amount of power that may safely be transmitted under the changing conditions. One of the most important phases has been that of a system of stability, in which a development of the Westinghouse Company has been one of the most valuable tools, namely, the A.C. network analyzer. Transmission lines, being built in the open, are subject to all the hazards resulting from the forces of nature, such as wind, sleet and lightning. Every reasonable precaution has been used in the construction of these new transmission lines so that they will not collapse under normal anticipated stresses. They are designed to withstand 60 miles-an-hour gales while covered with a half inch of ice and will undoubtedly withstand a higher wind velocity. Lightning flashovers and the accidental contact of conductors while they are moving under what is known as "galloping" conditions, and excessive wind storms are the things that engineers are striving to eliminate so that industry may work along without delays. The new station at Burlington, Ont., was described together with the whole system reaching from Montreal.

The lecture was followed by three motion pictures which showed the building of the giant towers which hold the voltage wires and the construction of the lines into the north over miles and miles of barren land to supply the distant industries that are helping with the war effort of Canada. Many of these lines were built in sub-zero weather and the workmen worked with tremendous speed to complete these lines whose towers are made of the lumber cut and formed at the site of the lines. The address was most instructive to all engineers.

James T. Thwaite, chairman of the Hamilton Group, A.I.E.E., introduced the speaker and after the lecture a vote of thanks was made by Mr. Porter. W. A. T. Gilmour, chairman of the Hamilton Branch, E.I.C., opened the meeting, as chairman of the evening, and the usual custom of this joint meeting was followed in that the chairman of the Electrical Engineers occupied the chair during the lecture which was enjoyed by 154 engineers and visitors.

LAKEHEAD BRANCH

W. C. Byers, Jr.e.i.c. - *Secretary-Treasurer*

A special meeting was called on August 16th at 4.00 p.m. to take advantage of the opportunity to make an inspection tour of Temporary Grain Storage Buildings and conveyor galleries being constructed for the bulk storage of grain. The storage buildings inspected were those being constructed for the United Grain Growers Limited at Port Arthur.

There are two storage buildings of wood construction with a combined capacity of 4,000,000 bushels. The first building is 144 ft. x 600 ft. and the second one is 144 ft. x 572 ft. and the side walls are 21 ft. 6 in. high with the roof sloping up at about 5 in 12. A cupola is constructed along the top of each building to house a conveyor belt, walkways on each side of the conveyor belt, and a moveable plow which removes the grain at any desired point along the building. The roof of each building is supported by braced towers 9 ft. 6 in. x 9 ft. 6 in. spaced at 28 ft. 6 in. centre to centre longitudinally and transversely. The walls are constructed of 2 in. x 6 in. cribbing and 12 in. x 14 in. posts with 2 in. diameter tie rods to resist the grain pressure. A concrete slab was used as a floor and footing for the interior towers and crib walls. A concrete tunnel runs along the centre of each building to house a conveyor belt which will be used to remove the grain from the Temporary Storages through spout openings in the tunnel walls.

At the luncheon of the executive of the Lakehead Branch—from left to right: G. H. Burbridge, W. H. Bird, W. L. Bird, W. H. Small, President C. J. Mackenzie, G. R. Duncan, P. E. Doncaster, B. A. Culpeper, S. E. Flook, W. C. Byers, J. I. Carmichael, J. M. Fleming, R. B. Chandler, Miss E. M. G. MacGill, H. G. O'Leary and Vice-President K. M. Cameron.

A system of galleries and one timber tunnel run from the Terminal Elevator to the Temporary buildings a distance of 1,260 ft. The gallery towers and trusses are constructed of British Columbia fir and ring connectors are used throughout. The gallery trusses vary from 64 ft. to 97 ft. span.

J. Antonisen thanks the speakers. From left to right: Secretary-Treasurer W. C. Byers, J. Antonisen, H. G. O'Leary, Vice-President K. M. Cameron, R. B. Chandler, President C. J. Mackenzie, Chairman B. A. Culpeper.

Power is supplied from the existing terminal substation and is distributed by an open feeder run along the top of the galleries and storages. The first storage requires 190 hp. to fill and 280 hp. to empty, while the second requires 230 hp. to fill and 320 hp. to empty.

Protective floodlighting is provided around the storages and galleries to facilitate inspection by the night-watchmen.

Mr. Wilson of the British Air Commission, W. H. Small, Vice-President K. M. Cameron, and R. B. Chandler.

The tour of inspection was conducted by the engineering staff of C. D. Howe Company, and forty members and guests were present. After the tour of inspection refreshments were served in one of the storage buildings.

The President, Dr. C. J. Mackenzie visited the Lakehead Branch on Monday, September 22nd. He was accompanied on his visit by Vice-President, K. M. Cameron and the General Secretary, L. Austin Wright.

The president, vice-president and general secretary were taken on a tour of inspection of the Port Arthur Shipyards during the morning and at 12.45 p.m. were guests at an executive luncheon. A tour of inspection of the Canadian Car & Foundry was made during the afternoon.

A dinner meeting was held in the Royal Edward Hotel, Fort William, commencing at 6.45 and thirty members and guests were present.

The Chairman, B. A. Culpeper, presided at the meeting and welcomed the president, vice-president and general secretary to the Lakehead. P. E. Doncaster introduced Dr. Mackenzie and mentioned a few highlights of his distinguished career.

Dr. Mackenzie expressed his appreciation of the welcome shown by the members of the Lakehead Branch and then spoke on the **National Research Council in Relationship to the War.** He dwelt on the importance of scientific

In the foreground: Miss E. M. MacGill chatting with Chairman Culpeper. In the background: Councillor J. M. Fleming, G. R. Duncan and H. G. O'Leary.

research and how it had made the British supreme in the air. He mentioned the radio locator which had done away with continuous patrolling of the air and made it possible to assign planes to a definite location.

He stated that the war had developed into an engineers' war and that the engineers had risen to the occasion and were pooling their resources and were working together as a team.

He mentioned how the National Research Council had increased in importance since the war began and this evidence is shown by the large donations made by industrialists and individuals, whereas, before the war small amounts of money were difficult to obtain.

Scientific research to-day meant the full co-operation of all the individuals from the Ph.D's to the mechanic at the bench and the importance of one individual over another was not considered.

When preparing for an industrial war it was not possible to spring to arms overnight except emotionally. There are four steps in an industrial combat. First there was research and development; second, engineering design; third, industrial production; and fourthly, the operations by and equipment of the men.

When war broke out the research council had a staff of 267 with a budget of $800,000.00. Next year it is planned to employ a staff of 900 and spend from five to six millions of dollars.

The council operates under four divisions, mechanical engineering, physics and electrical engineering, chemistry and biology. The council had 150 projects under consideration with 56 in the aeronautical field. The Council is investigating stability of various aircraft, bomb sights, instruments fuel and de-icing.

Councillor J. M. Fleming introduced vice-president K. M. Cameron. Mr. Cameron expressed his appreciation of being able to be present at the meeting and referred to the development of the Lakehead Community and mentioned the harbour improvements that had been made and the large sums of money spent by the public works on the breakwater.

R. B. Chandler introduced L. Austin Wright who spoke on the work of the **Wartime Bureau of Technical Personnel** and also described the work done on the repairs to the Headquarters building.

J. Antonisen gave a vote of thanks to the visiting speakers for their addresses.

LONDON BRANCH

H. A. Stead, Jr.E.I.C. - - *Secretary-Treasurer*
A. L. Furanna, S.E.I.C. - *Branch News Editor*

The opening fall meeting of the Branch was held on Wednesday, October 1st, 1941 in the Officers' Mess of the Talbot St. Armouries. Mr. J. A. M. Galilee, assistant advertising manager of the Canadian Westinghouse Company was the speaker.

Speaking on the **Recent Research and Development Work in Electric Equipment,** Mr. Galilee stressed the value of research in the war effort. He said that scientists were fighting many difficult battles behind the locked doors of the laboratories and that although science has given Hitler many of his tools of war, science would also finally spell his doom.

Unbelievable possibilities, he said, rested in the uranium atom U235. When all the potential energy of this element is realized, houses may be heated for an entire winter with a piece of uranium the size of a headache capsule. A piece the size of a walnut would release energy equivalent to that of 1,250 tons of coal.

Experiments were performed to illustrate many other new principals. In the field of metallurgy, Mr. Galilee demonstrated the bi-metal strips, the addition of tungsten powder to steel in order to eliminate bounce, some small but very powerful permanent magnets and a new transformer steel with reluctance so low that it became magnetic when placed in the direction of the earth's field.

Some of the many uses of ultra violet light were also shown. One of the most interesting applications was in the modern fluorescent lighting. Ultra violet light may also be used as a germicide and to produce colour effects. Another lighting marvel on display was polarized light. This is now being used in the strength analysis of structural shapes. Polarized light also holds the answer to the automobile headlight problem. Unfortunately, this cannot be applied until after the war because the system would have to be used exclusively in order to be effective.

Among the electrical experiments an electric eye was used in the transition of sound waves into light waves and light back to sound.

Mr. Galilee was introduced by the branch chairman, Mr. R. W. Garrett, and Mr. V. A. McKillop proposed the vote of thanks.

PETERBOROUGH BRANCH

D. J. Emery, m.e.i.c. - *Secretary-Treasurer*
E. Whiteley, s.e.i.c. - *Branch News Editor*

At their opening meeting for the 1941-42 season, on September 27th, Peterborough Branch were joined by Toronto Branch of the American Institute of Electrical Engineers. At 2 p.m. members of both groups gathered at Kawartha Golf and Country Club where golf was arranged for those who wished it, and trips through the Peterborough Works of the Canadian General Electric Company Limited were organized for the others.

All were back at the club by 7.30 p.m. in time for an excellent dinner. Mr. J. Cameron, chairman of the Peterborough Branch, served as toast master. Mr. R. Robbin distributed prizes (donated by the Western Clock Company Limited) to several lucky members.

After a pause and some re-arrangement of chairs the meeting came to order again for a technical discussion of **Electromagnetic and Heating Effects of Fault Currents.** Mr. O. Titus, chairman of the Toronto Branch, A.I.E.E., took the chair.

After several short prepared papers by Mr. Langley, Dr. F. G. A. Tarr, Mr. D. V. Canning, of the Canadian General Electric Company, Mr. J. T. Thwaites, Canadian Westinghouse Company, and Dr. J. H. Thompson, Ferranti Electric, others gave their comments until a surprising amount of information had come out. The effects of heavy fault currents on bus structures, cables, switchgear, relays, transformers, motors, were all mentioned.

The meeting was well up to the standard set by a similar event last season, and encourages those who hope it will be an annual affair. 108 members and guests were present.

SAGUENAY BRANCH

D. S. Estabrooks, m.e.i.c. - *Secretary-Treasurer*
J. P. Estabrook, Jr.e.i.c. - *Branch News Editor*

The Saguenay Branch met at Arvida, Que., on the evening of October 14th with chairman N. F. McCaghey presiding over the meeting.

The speaker on this occasion was Mr. V. G. Younghusband, vice-president of the Foundation Company of Canada, presenting as his subject **Construction Problem.**

Mr. Younghusband described several of the interesting projects he had been associated with in his wide experience in construction engineering, dealing first with a construction railroad used in connection with excavation work for the Granby Mining and Smelting Company. He then reviewed the construction of the University of Saskatchewan and the reconstruction of the central block of the Parliament Buildings at Ottawa.

On the Comeau Bay construction job, transportation was the chief difficulty to be faced, stone being the only local material used in building the mill and townsite. The construction of a pipe line over 17 ft. in diameter and 5,900 ft. long was of particular interest. Various materials were considered for the construction of the pipe but wood stave was given preference over steel and pre-stressed concrete.

In concluding Mr. Younghusband stressed the labour problems to be faced by industry after the war and expressed a hope that any slowdown at that time would be of short duration. He pictured Canada as coming into her own with her industrial capacity and population doubling in size as a result of decentralization of industry in Great Britain and expansion to Canada. In connection with this, he called for closer co-operation between construction men and engineers. This was his expressed hope for the advance of each group in the future.

SAINT JOHN BRANCH

V. S. Chesnut, m.e.i.c. - *Secretary-Treasurer*

At a meeting of the Demolition Committee of Air Raid Protection held on August 19th it was decided to adopt the English system, as laid down in publication of the British Home Office, for organization of Rescue Parties and Clearing of Debris.

It was arranged that following an air raid the Municipal Demolition Officer would be on duty at A.R.P. Headquarters with liaison officers under him. A Demolition Officer will be assigned to each City Ward to work in co-operation with the A.R.P. Captain of Wardens for that Ward.

In recognition of the fact that buildings may become wrecked without fire occuring in them and that the Fire Department and Police services will be fully occupied with other duties, a system of Rescue Parties will be organized for each Ward. These Rescue Parties will be of two kinds, Light and Heavy and will be led by experienced construction foremen. They will comprise a nucleus of skilled men and be equipped with tools and appliances. A proportion of the men in each Light party will be given a first aid course in order to succour persons who may be trapped, until other first aid parties can arrive.

A Light Party will be first despatched to the scene of a casualty, to be followed up by a Heavy Party with more extensive equipment should the need for further assistance be evident.

The primary task of Light Parties will be to rescue living persons who are trapped in the wreckage and remove the bodies of persons killed in the collapse of a building, where this can be done without further risk of life at the moment.

The services of Construction companies will be organized for heavier types of demolition work and clearance of debris and for assistance to civic forces in clearing and repairing streets and restoring services.

The Light and Heavy rescue parties will be under the orders of the Ward Demolition Officer and will assemble at designated points upon the sounding of an alarm.

Volunteers for the personnel of these rescue parties will be called for in the near future. A considerable number of carpenters, masons, plumbers and other skilled construction personnel will be needed.

SAULT STE. MARIE BRANCH

O. A. Evans, Jr.e.i.c. - *Secretary-Treasurer*
N. C. Cowie, Jr.e.i.c. - *Branch News Editor*

The fifth general meeting for the year 1941 was held in the Grill Room of the Windsor Hotel on Friday, September 26th, 1941, when 17 members and guests sat down to dinner at 6.45 p.m. The business portion of the meeting began at 8.00 p.m. with L. R. Brown, vice-chairman, presiding in the absence of E. M. MacQuarrie. N. C. Cowie replaced the secretary who was also away.

At the conclusion of the business portion of the meeting Mr. T. F. Rahilly addressed the club on **The Blast Furnace Plant of the Algoma Steel Corporation.**

After the discussion A. M. Wilson moved the adjournment.

TORONTO BRANCH

J. J. Spence, m.e.i.c. - *Secretary-Treasurer*
D. Forgan, m.e.i.c. - *Branch News Editor*

The first meeting of the Toronto Branch of the Institute was held in Hart House, University of Toronto, on October 16th. An excellent attendance attested to the apparent interest in the subject for the evening's discussion, and, it is hoped, to interest in the activities of the branch in general. A satisfactory feature was the large number of younger engineers who turned out. It is hoped that this interest will continue to be shown to at least as great an extent for the rest of the season. The programme which has been adopted for the ensuing meetings is one which should hold the interest of both experience and younger engineers alike.

A cosmopolitan atmosphere was given to the gathering by the presence of a group of 12 Polish engineers now located in the Toronto area. It was the desire of the branch to show its appreciation of the spirit of these people who are now our Allies in the War, and who after great hardships are endeavouring to establish themselves in this country.

In the course of his opening remarks, Mr. H. E. Brandon, the branch chairman, formally tendered in a most happy vein the branch's congratulations to Professor C. R. Young of the University of Toronto on his recent appointment as Dean of the Faculty of Applied Science. The enthusiasm with which the meeting received Mr. Brandon's address indicated the universal and sincere pleasure which Dean Young's appointment has given to all those who have been fortunate enough to come in contact with him and his work.

During his response Dean Young commented on his association with the Polish forces in the last Great War, and then introduced to the meeting each of the Polish engineers present. Of interest were the brief biographical notes he gave on each individual and the route by which each at last reached this country. He then introduced the speaker of the evening, Mr. W. J. Jakimiuk, an eminent aeronautical engineer who now holds the position of chief designer of the de Havilland Aircraft Company of Canada.

Mr. Jakimiuk was formerly chief engineer of the National Aircraft Corporation of Poland. His subject was **Plastic Laminated Wood in Aircraft Construction.** It is expected the paper will be published in full in the *Journal* at an early date. In his address Mr. Jakimiuk showed that wood was extensively used in aircraft construction in earlier periods of aviation until 1925-1930. At that time, wood was pushed out by steel and light alloys, especially with the advent of stressed skin construction.

Wood is a good structural material with high strength to weight ratio, but possesses many defects which have slowed the development of wooden aircraft construction.

About 1935, synthetic resins were introduced in wooden construction and most of the defects were eliminated when laminated plastic wood was developed. Laminated panels made of wooden veneers of proper thickness and properly assembled with synthetic adhesives are fairly uniform in strength and volume. Thermosetting synthetic adhesives such as phenol formaldehyde and urea formaldehyde give very good and reliable joints.

Experimental work on plastic moulded wood development is carried out in Canada at the National Research Council, Ottawa, the Massey-Harris Company, and de Havilland Aircraft of Canada.

The pressure tank moulding method is fairly well developed. Other methods, such as curing of resins by high frequency electro-static fields, are experimental. De Havilland is making a wooden wing for one of the metal aeroplanes produced in Canada. The paper was most interesting well presented and well received.

Mr. O. Holden, chief hydraulic engineer of the Hydro-Electric Power Commission of Ontario, presented the second portion of the programme. This consisted of a coloured motion picture and coloured stills, showing various features in the construction of the Commission's Barrett Chute development on the Madawaska River. Work on this development, designed and constructed by the Commission's staff, was put in hand September, 1940, and is scheduled for completion in the early summer of 1942. It will have an installed capacity of two 57,000 hp. units. The pictures were excellent examples of the beauty and clarity of good colour photography. Considerable added interest was given to them by Mr. Holden's brief description of the salient features of the development and his descriptive comments on each operation and feature shown on the screen.

The new seating arrangements in the Debates Room at Hart House added considerably to the comfort of the audience, most of which joined in the light refreshments which were provided after the meeting and which afforded an opportunity for further discussion and meeting with old friends.

WINNIPEG BRANCH

C. P. Haltalin, m.e.i.c. - *Secretary-Treasurer*
T. A. Lindsay, m.e.i.c. - *Branch News Editor*

The Winnipeg Branch was highly honoured in September by the visit of President C. J. Mackenzie, who was accompanied by Vice-President K. M. Cameron and General Secretary L. Austin Wright.

Mr. Cameron and Mr. Wright were present at a luncheon meeting of the executive held at the Engineer's Club on September 23rd, at which meeting various Institute matters were discussed by Mr. Cameron and Mr. Wright. Several problems of special interest to the Branch were brought up and valuable advice and opinions were advanced by the members from Headquarters.

President Mackenzie held an informal reception at the Fort Garry Hotel on the evening of the 23rd, in order to make the acquaintance of the executive and various members of the Branch, and to renew old acquaintances.

A general luncheon meeting in honour of the visiting party from Headquarters was held in the Georgian Dining Room of the Hudson's Bay Company on Wednesday, September 24th, at which 65 members were present.

Winnipeg Branch Executive with visitors from Headquarters. Front row, from left to right: Councillor J. W. Sanger, President C. J. Mackenzie, Vice-Chairman D. M. Stephens, Vice-President K. M. Cameron, Dean E. P. Fetherstonhaugh. Back row: Secretary-Treasurer C. P. Haltalin, H. L. Briggs, T. E. Storey, E. S. Braddell, S. G. Harknett, C. V. Antenbring, J. T. Dyment, H. B. Brehaut, H. W. McLeod.

The head table at the general luncheon meeting. From left to right: Dean E. P. Fetherstonhaugh, Vice-President K. M. Cameron, President C. J. Mackenzie, Vice-Chairman D. M. Stephens, Councillor J. W. Sanger, Secretary-Treasurer C. P. Haltalin, left foreground, J. T. Dyment.

Mr. D. M. Stephens, vice-chairman of the branch, presided in the absence of the chairman, Mr. V. Michie. Mr. Stephens welcomed the Headquarters party and expressed the pleasure of the branch at having them present.

President Mackenzie, the main speaker of the occasion, was introduced by Councillor J. W. Sanger. Dean Mackenzie emphasized the value of the Institute to all engineers, and gave a personal example of how committee work in the Institute had benefited him after the last war.

He outlined the part that engineers were playing in the present war not only with reference to military service, but also to industry and research work.

As acting president of the National Research Council he was able to give the audience a particularly stirring account of the work of the Council. Although he pointed out that with the short time at his disposal he could only touch on the highlights, he gave very interesting outlines of the jobs being done by the various divisions of Aviation Medicine, Physics, Radio, Optics and Chemistry.

Prior to Dean Mackenzie's address, Vice-President K. M. Cameron was introduced by Mr. Stephens, and he conveyed the greetings of the Ottawa Branch to the Winnipeg Branch. He also outlined the relationship of a vice-president to Institute affairs, and touched on some of the problems of Council.

Mr. Wright reported on results of the Headquarters Building Fund, and pointed out that while the results to date were gratifying, the objective of $10,000.00 had not yet been reached.

A general view looking towards the head table.

As assistant director of the Wartime Bureau of Technical Personnel, Mr. Wright explained the purpose and use of the questionnaires that had been sent out. He also elaborated on the work and aims of the Bureau, and urged his listeners not to be too impatient for results, pointing out that the wholehearted co-operation and support of all engineers was necessary for the success of the Bureau.

Dean E. P. Fetherstonhaugh expressed the thanks of the meeting to President Mackenzie and his party from Headquarters, which was thoroughly concurred in by members present, through hearty applause.

The Winnipeg Branch, at the invitation of the local branch of the C.I.M.M. attended a luncheon meeting on September 27th to welcome the president of the C.I.M.M., Mr. W. G. McBride, who was accompanied by Secretary Carlyle and Mr. E. M. Little, Director of the Wartime Bureau of Technical Personnel.

From left to right: J. J. White, Registrar of the Association of Professional Engineers of Saskatchewan, A. W. Davison, G. M. Pearston and George Clark.

Mr. Little, who was the main speaker at the meeting, gave a talk on **Industries' Help in the War Effort.** Mr. Little divided his subject into two parts, the first being an outline of the work of the Bureau, and the latter part being devoted to the relationship between engineers and industry in the war effort.

Left-hand row, facing the camera: Major N. M. Hall, W. M. Scott, S. J. Hadden, J. E. Granich, V. C. Jones, A. Blackie, R. A. Sara, E. V. Caton.

EDMONTON BRANCH

F. R. Burfield, M.E.I.C. - *Secretary-Treasurer*
L. A. Thorssen, Jr.E.I.C. - *Branch News Editor*

On his visit to the western branches, President Mackenzie stopped at Edmonton, on October 1st. In the evening, he met with the executive of the Branch, together with Mr. P. M. Sauder, Dean Wilson and Professor Boomer, representing the University. The meeting took place in the Jasper Room at the Macdonald Hotel, where Dean Mackenzie gave an interesting and confidential talk on his work with the National Research Council.

On Thursday evening, October 2nd, several members of the branch attended the banquet of the western convention of the Canadian Institute of Mining and Metallurgy, at which Dean Mackenzie spoke.

Professor W. G. McBride, M.E.I.C., president of the Mining Institute, presided at the head table.

Dean Mackenzie spoke on the achievements of the National Research Council. "There is no doubt," said the President, "that the scientific integrity of the British is easily on a par with that of the Germans. We are doing a great deal of work with the three services, navy, army and air force, and Canada may well be proud of the accomplishments of her scientific men. They are making a great contribution to the war effort."

Day and night research is being made, Dr. Mackenzie said. "We are working on plastic airplanes and just as vigorously on de-icing instruments for planes." Aviation medicine is being studied hard for the welfare of the pilot at high altitudes and during steep dives and other situations."

Dr. Mackenzie revealed research had been made so the British were "well prepared" for chemical warfare.

"I do think if we were not so well prepared in chemical warfare the Germans would have started on this type of war before this," Dr. Mackenzie declared.

Dr. Mackenzie said he believed scientific research was responsible "for saving England last July and August." He said the integrity and bravery of British pilots played an important and essential part, but he believed it was the scientific research that made the British planes superior to those of the Germans and resulted in the Nazis not invading England at that time.

This was the opinion of many British military authorities, including such men as Lt. Gen. A. G. L. McNaughton, commander of the Canadian Corps.

Finances of the council are being well spent, Dr. Mackenzie said. "There is no doubt whatever the research council has become a very important part of the war effort."

Library Notes

Book notes, Additions to the Library of the Engineering Institute, Reviews of New Books and Publications

ADDITIONS TO THE LIBRARY

TECHNICAL BOOKS

Canada Year Book, 1941:
Dominion Bureau of Statistics, Ottawa, 1941. 9 x 6¼ in., $1.50.

Electrical Engineering Fundamentals:
By George F. Corcoran and Edwin B. Kurtz. New York, John Wiley & Sons, Inc., 1941. 9¼ x 6 in., $4.00.

Elements of Electrical Engineering:
By Arthur L. Cook. New York, John Wiley & Sons, Inc., 1941. 9¼ x 6 in., $4.00.

Fatigue of Metals:
By D. Landau. New York, The Nitralloy Corporation, 1941. 45 pp., pamphlet.

Photoelasticity:
By Max Mark Frocht. Vol. 1. New York, John Wiley & Sons, Inc., 1941. 9¼ x 6 in., $6.00.

Practical Solution of Torsional Vibration Problems:
By W. Ker Wilson. Vol. 2, 2nd edition. New York, John Wiley & Sons, Inc., 1941. 5¾ x 8¾ in., $8.50.

Traffic Accidents and Congestion:
By Maxwell Halsey. New York, John Wiley & Sons, Inc., 1941. 6¾ x 10 ⅛in., $4.00.

REPORTS

Canadian Broadcasting Corporation:
Annual report for the fiscal year ended March 31, 1941. Ottawa, 1941.

Canadian Chamber of Commerce:
14th Annual report, September 17-18, 1941.

Canada Department of Mines and Resources—Bureau of Mines:
Physical and chemical survey of coals from Pictou County Coalfield. Memorandum series, No. 79, 1941.

Canada Department of Mines and Resources—Mines and Geology Branch—Geological Survey Memoir:
Mineral industry of the Northwest Territories, No. 230.

Canada Department of Mines and Resources—Mines and Geology Branch—Geological Survey Papers:
Preliminary map Redcliff, Alberta; preliminary map Bighorn River, Alberta. Papers 41-11 and 41-9.

Canadian Engineering Standards Association—Specifications:
Canadian Electrical Code, part 2, Construction and test of isolating switches, No. 58. Standard specification for cast iron soil pipe and fittings, B70-1941.

Canadian Government Purchasing Standards Committee — Specifications:
Rubber hot water bottles, for general use; rubber coated cotton sheeting, for hospital use.

Bell Telephone System—Technical Publications:
Notes on the time relation between solar emission and terrestrial disturbances; Vario-losser circuits; Crystalline behavior of linear polyamides; Heat of absorption of water by papers: Design and operation of new copper wire drawing plant—parts 1 and 11; Single sampling and double sampling inspection tables; Insulation of telephone wire with paper pulp; Television transmission over wire lines; Abrasion resistance of anodically oxidized coatings on aluminum; Electrical breakdown for checking thickness of anodized finishes; Surge characteristics of a buried bare wire; Development of the civil aeronautics authority instrument landing system; Debt of modern physics to recent instruments; Measurements of orchestral pitch; An interferometric dilatometer with photographic recording; Ultrasonic absorption and velocity measurements in numerous liquids; effect of the earth's curvature on ground-wave propagation; After-acceleration and deflection; engineering requirements for programme transmission circuits; Kiln drying longleaf southern pine poles; An electrical test for moisture content in southern pine timbers; A new mirror light-modulator; Time division multiplex systems; Steady state delay as related to aperiodic signals; Steady state solutions of transmission line equations; Engineering problems in dimensions and tolerances; Room noise spectra at subscribers' telephone locations; reduction of magnesium oxide by tungsten in vacuum.

Electrochemical Society—Preprints:
Alloy plating; Studies on the electrolytic deposition of copper; Porous carbon electrodes; Treatment by electrolysis of weak ammonia liquors produced in by-product coke plants; Platinized porous graphite as a hydrogen electrode; Nickel plating; Chromium plating; Alkaline tin plating; Electrolytic reduction of benzophenone in acidic and in alkaline media; Cadmium plating; Acid copper electroplating and electroforming; Electrolytic reduction of sorbic acid; Electrolytic reduction of acetone; electrodeposition of tin from acid solutions; Cobalt plating; General principles and methods of electroplating; Copper-lead alloys from ethylene diamine solution; Silver plating; Cyanide zinc plating baths; Brass plating. Nos. 18 to 37.

National Research Council of Canada:
Twenty-fourth annual report, 1940-41. Ottawa, 1941.

U.S. Department of Commerce—Building Materials and Structures:
Survey of roofing materials in the North Central States, BMS75.

U.S. Department of the Interior—Geological Survey Bulletin:
Geology of area between Green and Colorado rivers Grand and San Juan Counties Utah; Fineness of gold from Alaska Placers; Ore deposits in the vicinity of the London fault of Colorado. Bulletins 908, 910-C, 911.

U.S. Department of the Interior—Geological Survey Water-Supply Paper:
Surface water supply of Hawaii, July 1, 1938, to June 30, 1939; Flood of August, 1935, in the Muskingum river basin, Ohio; Ground water in Keith County, Nebraska. Paper 885, 869, 848.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet the books are not in the Institute Library, but inquiries will be welcomed at headquarters, or may be sent direct to the publishers.

AEROSPHERE, 1941, including Modern Aircraft, Modern Aircraft Engines, Aircraft Statistics, Buyers' Guide,
Edited by G. D. Angle. Aircraft Publications, New York, 1941. 948 pp., illus., diagrs., tables, 12 x 8½ in., cloth, $10.00.

In this second edition the historical section describing the world's aircraft engines of all time has been omitted and will henceforth be available in a separate volume. The construction, performance and characteristics of all current types of aircraft and aircraft engines are given in the first two sections. Statistics, records and other useful data are included in the third section. A buyer's guide, containing first an alphabetical list of firms for each country, and second a product directory by countries, completes the volume. Hundreds of photographs and cross-sections accompany the descriptions.

AIRCRAFT ENGINES, Vol. 2
By A. W. Judge. D. Van Nostrand Co., New York, 1941. 446 pp., illus., diagrs., charts, tables, 9 x 5½ in., cloth, $9.00.

The theoretical and experimental aspects of aircraft engines having been covered in Volume I, the present volume is devoted principally to detailed descriptions of a large number of representative engines from various countries. Certain design and theoretical considerations concerning lubrication, ignition and exhaust systems, torque and balance, and other topics not previously dealt with are also included.

AIRCRAFT MECHANIC'S POCKET MANUAL
By J. A. Ashkouti. Pitman Publishing Corp., New York and Chicago, 1941. Diagrs., tables, 7½ x 5 in., cloth, $1.50.

Prepared for the man in the shop, this manual contains basic data on aircraft production. Pattern layout, materials, finishes, tools, tolerances, and standard parts approved by the Army and Navy are covered in separate sections. Aircraft identification standards and a large glossary of aeronautical terms are also included.

AIRCRAFT TEMPLATE DEVELOPMENT
Compiled and edited by Aero Publishers, Inc. Aero Publishers, Glendale, Calif., 1941. 312 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.00.

Fundamental principles involved in the developing and making of aircraft templates are presented in this comprehensive, practical textbook for students, apprentices and trainees. There is a large section of sample problems, including blueprints and suggested procedures. A brief glossary is appended.

ARCHITECTURAL GRAPHIC STANDARDS for Architects, Engineers, Decorators, Builders and Draftsmen
By C. G. Ramsey and H. R. Sleeper. 3 ed. John Wiley & Sons, New York: Chapman & Hall, London, 1941. 344 pp., diagrs., charts, tables, 12 x 9½ in., cloth, $6.00.

Standards and recommended practices in building, with many other data constantly used by architects and designers, are presented here in an unusually convenient form for quick reference. The book consists entirely of plates with a very full index. It covers a broad field, including not only building construction but also landscaping and site development, the planning of sports fields, furniture and miscellaneous equipment for various types of buildings.

DAVISON'S TEXTILE BLUE BOOK, United States, Canada and Mexico

76th Year, July, 1941, Handy edition, Davison Publishing Co., Ridgewood, New Jersey, 1,200 pp., maps, 8 x 5 in., fabrikoid, $5.00.

This annual publication lists geographically manufacturers of cotton, woolen and worsted, silk and rayon, and knit goods; dyers and finishers; commission merchants, dealers and importers; domestic and foreign raw cotton firms; and other groups useful to the trade. There are two special lists of pertinent associations and railroads serving the various mills, and an alphabetical index to mills and dyers is included.

DEEP WATER

Published by New York Marine News Co., New York, N.Y.; printed by Recorder Press, Plainfield, New Jersey, 1941. 77 pp., illus., maps, tables, 11½ x 9 in., fabrikoid, apply (not for sale).

A series of descriptive articles on the major inland waterways of the United States is presented in this volume, in an endeavour to point out the benefits to the public from the development and use of these facilities. Statistical and technical information is included, and there are numerous illustrations.

DESIGN HANDBOOK FOR PRACTICAL ENGINEERS

By A. Cibulka. Apply to author, Dr. Alois Cibulka, Baytown, Texas, 1941. Diagrs., charts, tables, 12 x 9 in., paper, $10; reduced price in lots of three or more.

The five parts of this compilation of design data and formulae cover respectively: strength of materials, steel and concrete structures; pressure and vacuum vessels, piping and metals; hydraulics and heat transfer; mathematical tables and general engineering formulas. Most of the material is in the form of tables and charts, with such explanation as is considered necessary.

(The) DRILLING EQUIPMENT DIRECTORY 1941-42

Published every two years by Petroleum Directory Publishing Co., affiliated with the Oil and Gas Journal.
Petroleum Directory Publishing Co., Tulsa, Okla., 1941. Paged in sections, illus., diagrs., charts, tables, 11 x 8½ in., fabrikoid, $10.00

The special feature of this biennial directory is the several hundred pages of classified practical engineering, A.P.I. and reference data, with each section of which is included the advertisements of related manufacturers. A complete classified buyers' guide lists all companies offering equipment or services required in the drilling of oil and gas wells.

ECONOMICS OF OIL INVESTMENTS IN COLUMBIA

By E. Ospina-Racines. 1941, paged in sections, diagrs., charts, maps, tables, 13 x 8½ in., cloth, apply to author, E. Ospina-Racines, Apartado Nacional 27-23, Bogota, Colombia.

As an aid in promoting a better understanding of oil exploitation in South America the author presents a discussion of the nature of the principal economic problems connected with that industry. Although the situation in Colombia is taken as an example, the broad treatment of the various aspects allows the conclusions to be applied as well to other South American oil countries. Much of the factual material appears in tabular or graphic form.

ELECTRICAL ENGINEERING FUNDAMENTALS

By G. F. Corcoran and E. B. Kurtz. John Wiley & Sons, New York, 1941. 450 pp., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.

The subject matter presented in this textbook is intended as first course material and is designed to prepare electrical engineering students for specialized courses. Special emphasis has been given to the arrangement and explanation of basic principles and concepts, although certain chapters deal with more advanced topics, such as the electrical structure of matter, electrochemistry and field mapping.

ELEMENTS OF ELECTRICAL ENGINEERING

By A. L. Cook. 4 ed. rev. John Wiley & Sons, New York, 1941. 622 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.00.

The fundamentals of electrical engineering and their application in practice are dealt with in this textbook, which is intended for both electrical engineering students and students specializing in other branches of engineering. All the material has been revised in the light of recent developments, and some chapters have been completely rewritten. An entirely new set of problems has been included.

ELEMENTS OF ENGINEERING THERMODYNAMICS

By J. A. Moyer, J. P. Calderwood, A. A. Potter. 6 ed. rewritten. John Wiley & Sons, New York; Chapman & Hall, London, 1941. 217 pp., diagrs., charts, tables, 9½ x 6 in., cloth, $2.50.

In the present edition, as in the previous ones, this book is designed to stress the fundamental principles of engineering thermodynamics as a foundation for the more advanced and practical applications of the theory. It is intended particularly for use in technical colleges having special courses in advanced thermodynamics, steam turbines, internal combustion engines, heating, refrigeration and other applications of thermodynamics.

ENGINEERING DESCRIPTIVE GEOMETRY AND DRAWING

By F. W. Bartlett and T. W. Johnson. John Wiley & Sons, New York; Chapman & Hall, Ltd., London, 1941. 572 pp., illus., diagrs., charts, tables, cloth, $4.50.

This comprehensive textbook, developed for use at the U.S. Naval Academy, consists of three parts: I, Line drawing, which is chiefly concerned with the manner of handling the instruments; II, Engineering descriptive geometry, which deals with the rules of orthographic projection applied to simple geometrical shapes; and III, Engineering drawing, which describes the application of the general principles of drawing to engineering purposes with emphasis on detail drawing.

ENGINEERING ENCYCLOPEDIA, 2 Vols.

Edited by F. D. Jones. Industrial Press, New York, 1941. 1,431 pp., diagrs., charts, tables, 9½ x 6 in., fabrikoid, $8.00.

This two-volume reference work supplies such practical and useful information as the various important mechanical laws, rules and principles; physical properties and compositions of a large variety of materials used in engineering practice; the characteristic features and functions of different types of machine tools and other equipment, etc. The 4,500 topics included are alphabetically arranged and cross-indexed for convenient reference, and have been selected for their usefulness in the mechanical industries.

(The) ENGINEERING PROFESSION

By T. J. Hoover and J. C. L. Fish. Stanford University Press, Stanford, Calif.; Humphrey Milford and Oxford University Press, London, 1941. 441 pp., diagrs., charts, maps, tables, 9½ x 6 in., cloth, $5.00.

This book describes the qualifications and duties of the professional engineer and his habit of mind, and indicates the rewards that an engineering career has to offer to qualified men. It presents an extended analysis of the sphere and status of the profession and points out its capacities for future development. The study will be especially valuable to young men contemplating a career in engineering and to instructors, because of the light it throws on the engineering method and its relation to school work, but should also prove of interest to the practical engineer.

GENERAL CHEMISTRY

By H. N. Holmes. 4 ed. Macmillan Co., New York, 1941. 720 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $3.75.

This excellent textbook meets the needs of those who are studying chemistry for cultural purposes and is also suitable as an introduction to advanced study of the subject. In addition to the extensive revision necessary to keep up with recent advances in chemical theory and industrial practice, a short timely chapter on strategic raw materials has been added in the present edition.

Great Britain, Dept. of Scientific and Industrial Research, Building Research Wartime Building Bulletin No. 15. STANDARD DESIGNS FOR SINGLE STOREY FACTORIES FOR WAR INDUSTRIES, WITH NOTES ON SITING AND LAYOUT

His Majesty's Stationery Office, London, 1941. 36 pp., diagrs., tables, 11 x 8½ in., paper, (obtainable from British Library of Information, 620 Fifth Ave., New York, 30c.).

In this bulletin designs previously issued have been revised in the light of experience of air attack, and further types have been added to the series. Notes are also given upon the choosing of sites and the layout of factories for war industries.

Great Britain, Ministry of Transport EXPERIMENTAL WORK ON ROADS

Report for 1938-39 of the Experimental Work on Highways (Technical) Committee. His Majesty's Stationery Office, London, 1939. 179 pp., tables, 9½ x 6 in., paper, (obtainable from British Library of Information, 620 Fifth Ave., New York, 75c.).

Beginning about the year 1929, the Ministry of Transport has built a number of experimental roads in Great Britain, in order to study the behaviour of various types of construction. The present report covers the condition of these roads after an added year of use, and gives interim conclusions as to their suitability. Roads of concrete and cement-bound macadam, roads with bituminous surfacings and with thin surfacing coats are described. Surface dressings, rural footpaths and bicycle tracks are also considered.

HANDBOOK OF CHEMISTRY

Compiled and edited by N. A. Lange and others. Handbook Publishers, Sandusky, Ohio. 4 ed. rev. and enl., 1941. 1,603 pp.; Appendix, Mathematical Tables and Formulas, 271 pp.; Index, 35 pp., diagrs., charts, tables, 8 x 5 in., fabrikoid, $6.00.

This extensive collection of chemical and physical data for chemists, engineers and physicists has again been revised to conform with recent developments. New tables have been added, and previously included ones have been extended, in addition to changes in the standing matter throughout the work. All the information is presented in convenient form for ready reference.

HEAT ENGINES, Steam, Gas, Steam Turbines and Their Auxiliaries

By J. R. Allan and J. A. Bursley. 5 ed. McGraw-Hill Book Co., New York, 1941. 576 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.00.

The essential principles of steam engines, boiler plants, internal-combustion engines, steam turbines and their auxiliaries are presented in this introductory textbook. In the present revision particular attention has been given to boiler auxiliaries, steam turbines and the internal-combustion engine, and there is a new chapter on air compressors and refrigerating machinery.

HOTEL ENGINEERING, Vol. 2. Electric Current Consumption, Costs and Savings

By G. C. St. Laurent. American Hotel Association of the United States and Canada, 221 West 57th St., New York, 1941. 43 pp., tables, 11 x 8½ in., paper, $1.50.

This booklet is the second in a series of four covering important subjects of hotel engineering, of which the first, published in 1940, dealt with water consumption, cost and savings. The present issue covers hotel electric problems and trends, and discusses ways of saving electric current. Considerable statistical data are included in tabular form.

HOW TO DESIGN AND INSTALL PLUMBING, Materials and Methods of Standard Practice

By A. J. Matthias. American Technical Society, Chicago, 1941. 442 pp., illus., diagrs., tables, 8½ x 5½ in., cloth, $3.00.

This textbook for home study and for use in vocational schools provides a practical course in the selection and installation of modern plumbing equipment in residences, hospitals and other buildings. A new chapter containing an illustrative example in plumbing estimating, including blueprints drawn to scale, has been added in this edition.

IMPACT RESISTANCE AND TENSILE PROPERTIES OF METALS AT SUB-ATMOSPHERIC TEMPERATURES

Prepared by H. W. Gillett, Project No. 13 of the Joint A.S.M.E.-A.S.T.M. Research Committee on Effect of Temperature on the Properties of Metals, August, 1941; authorized reprint from Proceedings of American Society for Testing Materials, Phila., Pa. 112 pp., diagrs., charts, tables, 9 x 6 in., board, $2.50.

This report contains information and data collected from laboratories interested in low-temperature work. Much of the material is in tabular form for convenience. There is a full discussion of impact resistance, followed by impact data for both ferrous and nonferrous materials, and some fifteen pages relate to low-temperature tensile properties. There is a bibliography.

INDEX TO THE LITERATURE ON SPECTROCHEMICAL ANALYSIS, 1920-1939. 2 ed.

By W. F. Meggers and B. F. Scribner; publication sponsored by Committee E-2 on Spectrographic Analysis of the American Society for Testing Materials, Phila., Pa., 1941. 94 pp., 9 x 6 in., paper, $1.00.

Nearly 1,500 references are contained in this second edition of an index which appeared originally in 1937, constituting a fifty per cent increase. The literature from 1920 to 1939 is covered chronologically, with the authors alphabetically arranged within each calendar year. There is a detailed subject index.

MACHINE SHOP TRAINING COURSE, 2 Vols.

By F. D. Jones. 2 ed. Industrial Press, New York, 1941. Vol. 1, 538 pp.; Vol. 2, 552 pp., illus., diagrs., charts, tables, 9½ x 6 in., fabrikoid, Vols. I and II, $6.00; either Vol. separately, $4.00.

Especially designed for shop courses, vocational schools and self instruction, this treatise covers fundamental principles, methods of adjusting and using different types of machine tools, measuring instruments and gages, screw-thread cutting, thread grinding, gear cutting and precision toolmaking methods. The chapter subheadings are in the form of questions which are answered in a practical manner, with typical examples. There is a large glossary with full definitions, and the new edition contains a chapter on blueprint reading.

MACHINE TOOLS IN AIRCRAFT PRODUCTION

By R. R. Nolan. Pitman Publishing Corp., New York and Chicago, 1941. 158 pp., illus., diagrs., tables, 8½ x 5 in., cloth, $1.50.

It is the purpose of this book to acquaint the vocational student, the beginner or the young mechanic with the fundamentals of aircraft machine tools and the underlying theory of their application. The more important machine tools and their operations are discussed, and there is a general guide for the selection of machines for various types of aircraft parts.

MATHEMATICS (The Pennsylvania State College Industrial Series)

By J. W. Breneman. 210 pp., $1.75.

MECHANICS (The Pennsylvania State College Industrial Series)

By J. W. Breneman. 141 pp., $1.50.

STRENGTH OF MATERIALS (The Pennsylvania State College Industrial Series)

By J. W. Breneman. 145 pp., $1.50.

BLUE PRINT READING AND SKETCHING (The Pennsylvania State College Industrial Series)

By H. R. Thayer. 141 pp., $2.00.
McGraw-Hill Book Co., New York, 1941. illus., diagrs., charts, tables, 9½ x 6 in., cloth,

The texts included in this new series are designed to give simplified presentations of the fundamentals of their respective subjects. Intended for the student or apprentice with limited mathematical background, the theoretical treatment is held to a minimum. Stress is laid on the application of principles of these subjects to important practical problems that are common in industry. Further volumes on engineering drawing, machine design, electricity, etc., are to be included in the series.

(The) TECHNOLOGY OF MAGNESIUM AND ITS ALLOYS, a translation from the German by the technical staffs of F. A. Hughes & Co. Limited and Magnesium Elektron Limited, of "Magnesium und seine Legierungen"

Compiled by A. Beck. F. A. Hughes & Co., London, 1940. 512 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, 30 s.

This important treatise is a translation of a German work written by a number of specialists, and is the only comprehensive work on the subject available in English. The magnesium ores and the methods of producing the metal are described. The metallography of the metal and its alloys and their physical and mechanical properties are set forth extensively. Chemical behaviour, corrosion and surface treatment are discussed. Methods of casting, forging, rolling and machining are thoroughly treated. A chapter is devoted to magnesium in pyrotechnics and thermochemistry, and a list of patents is provided. The translators have corrected errors and made some additions.

MECHANICAL ENGINEERING PRACTICE, a Laboratory Reference Text

By C. F. Shoop and G. L. Tuve. 3 ed. McGraw-Hill Book Co., New York and London, 1941. 506 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.00.

Originally intended as a manual of laboratory practice, this book also provides a comprehensive reference text on experimental mechanical engineering. Major topics covered are: methods and instruments for mechanical measurements, friction and lubrication, heat transfer, properties of gases and vapors, fluid flow, pumps and compressors, steam power generating units, refrigeration and internal combustion engines. The revision includes many laboratory experiments in such newer fields as fluid mechanics and air conditioning.

MECHANICAL ENGINEERS' HANDBOOK

Edited by L. S. Marks, 4th ed. McGraw-Hill Book Co., New York and London, 1941. 2,274 pp., diagrs., charts, tables, 7½ x 5 in., lea., $7.00.

Most of the sections in this well-known reference work have been completely rewritten as a result of the great advances which have occurred since the appearance of the last edition in practice, in theory, and in the systematization of existing knowledge in the field of the mechanical engineer. Among the new subjects are the theory of models, plastic behaviour of materials, stress concentration, creep, packings, wind pressure on structures, sound and noise, automatic process control, and power metallurgy. The present edition of this authoritative handbook is the result of the co-operation of more than ninety specialists.

MINERALS YEARBOOK, Review of 1940. U.S. Bureau of Mines

Published by Government Printing Office, Washington, D.C., 1941. 1,459 pp., charts, tables, 9 x 6 in., cloth, $2.00.

The new edition of this valuable annual contains seventy-two chapters prepared by specialists in the field of mineral economics and technology. A general summary of the principal developments during the year precedes the chapters on specific metals and non-metals, in which production statistics and market conditions are given. "Strategic" minerals receive special consideration in the present volume. There is a short section on mine safety conditions.

MODERN GLASS PRACTICE

By S. R. Scholes. Industrial Publications, Chicago, 1941. 289 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $6.00.

A comprehensive account of modern glass-making, this book covers materials, processes, properties, coloring methods and special uses. It is intended primarily for students of glass technology, but will also be of use to glass makers and others who wish a general account of current practice.

PHOTOELASTICITY, Vol. 1

By M. M. Frocht. John Wiley & Sons, New York; Chapman & Hall, London, 1941. 411 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $6.00.

The two-volume work, of which this text is Vol. I, contains the essential material for a thorough understanding of the theoretical principles and experimental procedures for the exploration of all two-dimentional stress systems by the method of photoelasticity. This first volume is confined to the strictly photoelastic methods for plane stress analysis, which are based entirely on the stress pattern and the isoclinics.

PRACTICAL SOLUTION OF TORSIONAL VIBRATION PROBLEMS, Vol. 2

By W. K. Wilson, 2 ed. John Wiley & Sons, New York, 1941. 694 pp., illus., diagrs., charts, tables, 9 x 5½ in., cloth, $8.50.

Owing to the extensive revision and enlargement of the new edition of this work, it was divided into two volumes. The second volume deals with the determination and measurement of stresses owing to torsional vibration, the analysis of torsiograph records, damping devices and rotating-pendulum vibration absorbers, and the dynamic characteristics of electrical-mechanical direct-coupled systems. Many practical examples are worked out, and an appendix contains a discussion of harmonic analysis, a bibliography and a selected list of British patents.

PRINCIPLES AND PRACTICE OF HEAT TREATMENT

By J. Winning. Emmott & Co., Manchester and London, 1941. 99 pp., illus., diagrs., charts, tables, 7½ x 5 in., paper, 2s.

This concise, rational account of modern heat treatment methods and the principles on which they are based is intended for the engineer whose work is affected by heat-treatment problems. The alloys considered have been selected as representative of their particular class as well as being industrially important.

PYROMETRY

By W. P. Wood and J. M. Cork. 2 ed. McGraw-Hill Book Co., New York and London, 1941. 263 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $3.00.

This text is designed for a college course in the subject. Introductory material on temperature scales and fluid thermometers precedes the chapters devoted to the description and use of thermoelectric, optical and total radiation pyrometers and resistance thermometers. Temperature recorders and controlling devices are considered, and there is a brief discussion of transition points. Problems and outlines for laboratory experiments are included.

(The) Second Yearbook of RESEARCH and STATISTICAL METHODOLOGY BOOKS AND REVIEWS

Edited by O. K. Buros. Gryphon Press, Highland Park, New Jersey, 1941. 344 pp., 11 x 7½ in., cloth, $5.00.

This book consists of carefully selected critical reviews of books dealing with statistical methods and techniques in a variety of fields. Three hundred and fifty-nine books published since 1932 are included. The work thus provides a list of the latest publications on the subject and also the means for evaluating them. There are indexes of titles, subjects and reviewers.

SHIPFITTER'S MANUAL

By A. F. Crivelli. Pitman Publishing Corp., New York and Chicago, 1941. 145 pp., diagrs., charts, tables, 8½ x 5½ in., cloth, $1.50.

The purpose of this manual is to provide the groundwork upon which the student shipfitter may build a thorough knowledge by practical application of its contents. The first chapter contains an illustrated glossary of shipbuilding terms. The succeeding chapters cover materials, equipment, the various phases of shipfitting in ship construction, plan reading and electric welding practice.

SPECIFICATION DOCUMENTS FOR BUILDING MATERIALS AND CONSTRUCTION, 1941 ed.

Pacific Coast Building Officials Conference, 124 West Fourth St., Los Angeles, Calif. 400 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, $5.00.

Sixty-two standard and tentative specifications and test programmes, to which reference is made in the Uniform Building Code of the Pacific Coast Building Officials Conference, are combined in this volume. The material is classified and arranged for ready reference. Like the previous editions, this comprehensive collection of structural standards should prove a great convenience to structural engineers, architects and specification writers.

(The) SPOTTER'S HANDBOOK

By F. Chichester. George Allen & Unwin, London, 1941. 149 pp., diagrs., tables, 7½ x 5 in., cloth, 2s 6d.

The spotter's job of watching for and warning of the approach of enemy aircraft is particularly important for the efficient operation of industrial plants. The author describes the proper organization of this duty including requirements. He explains which indications are most important and why, and gives definite rules for the recognition of all types of airplanes. The behavior of bombs is discussed.

STANDARD HANDBOOK FOR ELECTRICAL ENGINEERS

Edited by A. E. Knowlton and R. M. Shoop. 7 ed. McGraw-Hill Book Co., New York and London, 1941. 2,303 pp., diagrs., charts, tables, 9½ x 6 in., lea., $8.00.

The plan and general character of earlier issues of this well-known handbook have been retained in the present edition. There has been, however, considerable change in the text and grouping of subject matter, owing to recent developments, the many new contributors and the intention to provide primarily an encyclopedia of directly applicable information. Condensation of the material on abstract principles allows the practical aspect to be stressed. The enlarged format is designed to facilitate the use of the book as a reference tool.

STEEL SQUARE POCKET BOOK

By D. L. Stoddard. 6 ed. rev. and enl. Scientific Book Corporation, New York, 1941. 183 pp., diagrs., charts, 6 x 4 in., cloth, $1.00.

The practical application of the steel square to many of the problems which must be handled by carpenters and mechanics is clearly described in this small book. Roofs, stairs and various types of framing are among the topics covered. The use of exact engravings of the square laid on the work simplifies or eliminates otherwise long descriptions.

STRENGTH OF MATERIALS, Pt. 2. Advanced Theory and Problems

By S. Timoshenko. 2 ed. D. Van Nostrand Co., New York, 1941. 510 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.50.

This standard textbook for advanced students, research engineers and designers has been revised after a period of eleven years. The material, both theoretical and experimental, which has been added, represents recent developments in the fields of stress analysis and experimental investigation of mechanical properties of structural materials. For the most part these additions are applicable to current problems such as airplane construction.

STUDIES IN THE HISTORY OF SCIENCE (University of Pennsylvania Bicentennial Conference)

By E. A. Speiser and others. University of Pennsylvania Press, Phila., 1941. 123 pp., diagrs., charts, tables, 9 x 6 in., cloth, $1.50.

Four of the eight lectures contained in this small volume cover certain periods of development of various phases of medicine and surgery. The remaining four lectures deal respectively with ancient Mesopotamian science, early astronomical concepts, philosophy and mathematical thought.

SYMPOSIUM ON COLOR—Its Specification and Use in Evaluating the Appearance of Materials; jointly sponsored by the American Society for Testing Materials and the Inter-Society Color Council.

Washington Spring Meeting, American Society for Testing Materials, Phila., Pa., 1941. 79 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $1.25, paper, $1.00.

Six extensive technical papers, affording a broad view of the various aspects of color research, are contained in this symposium. The following list of titles indicates the scope: introduction to color; color specifications of transparent materials; hiding power and opacity; color standards for opaque materials; spectrophotometry and color evaluation; photoelectric tristimulus colorimetry.

TABLE OF NATURAL LOGARITHMS, Vol. 1. Logarithms of the Integers from 1 to 50,000

Prepared by the Federal Works Agency, Work Projects Administration for the City of New York; conducted under the sponsorship of and for sale by the National Bureau of Standards, Washington, D.C., 1941. 501 pp., tables, 11 x 8 in., cloth, $2.00, payment in advance.

Continuing the series of mathematical tables being compiled by the Work Projects Administration, this book constitutes Vol. 1 of a projected four-volume table of natural logarithms. The natural logarithms are given here to sixteen decimal places for the integers from 1 to 50,000. Succeeding volumes will carry to 100,000 and cover the range from 0 to 10 at intervals of 0.0001.

TABLES OF PROBABILITY FUNCTIONS, Vol. 1

Prepared by the Federal Works Agency, Work Projects Administration for the City of New York; conducted under the sponsorship of and for sale by the National Bureau of Standards, Washington, D.C., 1941. 302 pp., tables, 11 x 8 in., cloth, $2.00, payment in advance.

The present volume of this series of mathematical tables extends the range of previous tables of the error function and provides a smaller tabular interval. As in all the volumes of this series, provision has been made to facilitate both direct and inverse interpolation. Entries are given to fifteen decimal places.

THERMOCHEMICAL CALCULATIONS

By R. R. Wenner. McGraw-Hill Book Co., New York and London, 1941. 384 pp., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.

A comprehensive introduction is provided to the principles, methods and data available for the solution of a wide variety of practical laboratory and technological problems. Features of the book are presentations of (1) the fundamental principles of thermodynamics of primary interest to the chemist and chemical engineer, (2) the practical contributions of the theoretical physicist to the field of thermodynamics, and (3) various semiempirical methods for the estimation of thermodynamic functions of value in solving technical problems.

TRANE AIR CONDITIONING MANUAL

Published by The Trane Company, La Crosse, Wisconsin, 1941. revised ed. 376 pp., illus., diagrs., charts, maps, tables, 11½ x 8½ in., cloth, $5.00.

Primarily concerned with the application of the fundamental facts of engineering to the design of air conditioning systems, this publication touches on all phases of the field. Heat and its transmission, physical comfort, air properties and supply, psychrometry, refrigeration and ventilation processes, the functions of water in air conditioning and a chapter on ducts and fans, new in this edition, are all covered in this comprehensive treatment of the subject. Diagrams, tables, problems and numerical examples add to its practical value.

UNITED STATES TENNESSEE VALLEY AUTHORITY

The Pickwick Landing Project, Technical Report No. 3, 1941. 431 pp., Government Printing Office, Washington, D.C., illus., diagrs., charts, maps, tables, 9½ x 6 in., cloth, $1.00.

The Guntersville Project, Technical Report No. 4, 1941. 423 pp., Tennessee Valley Authority, Treasurer's Office, Knoxville, Tenn., illus., diagrs., charts, maps, tables, 9½ x 6 in., cloth, $1.00.

Facts about the planning, design and construction of the Pickwick Landing and Guntersville projects on the Tennessee River are presented in these two technical reports. The general programme of the Tennessee River system is considered in each case, and the descriptions of the particular projects cover all phases from the preliminary investigations to complete statistical summaries of equipment and costs. Bibliographies are included.

PRELIMINARY NOTICE

of Applications for Admission and for Transfer

October 25th, 1941.

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.–

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described at the December meeting.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science or engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BREKKE—HANS KRISHAN ANDREAS, of Winnipeg, Man. Born at Skjerstad, Norway, Oct. 13th, 1890; R.P.E. of Man., 1931; Educ.: Civil Engr., German University, Prague, 1925; 1912-13, railroad constrn., instr'man.; 1913-14, Bodo city engrg., constrn. foreman; 1917-20, designer, power developments, Groendahl & Kjorhott; 1927-28, dftsman., Dominion Bridge Company; 1928-31, hydraulic designer, and 1931 to date, hydraulic engr., City of Winnipeg Hydro Electric System, Winnipeg, Man.

HARE—WILFRED ALMON, of 833 Kildare Road, Windsor, Ont. Born at Halifax, N.S., May 4th, 1875; Educ.: B.A.Sc., Univ. of Toronto, 1899: 1900-02, dftsman.; 1902-03, engr. on new plant for Rhodes, Curry & Co., Amherst, N.S.; 1903-04, engr. for changes in steam plant, Illinois Steel Co., Joliet, Ill.; 1904-07, asst. engr. and later chief engr., Underfeed Stoker Co., Toronto; 1907-16, Hare Engineering Co. Ltd., Toronto, mfg. mech. stokers for power plants, also designed and built heavy shell turning lathe for shell plants; 1916-17, chief engr., stoker divn., James A. Brady Foundry Co., Chicago, Ill.; 1917-18, James E. Morrison Co., Consltg. Engrs., Detroit, Mich., as advisory engr. on steel heating equipment and forge plant design; 1919-26, vice-president and chief engr., The Houstoker Corpn., Detroit, Mich.; 1926-29, partner, engr. and mgr., Hare-Luers Stoker Company; 1929-32, mgr. and engr., Stoker Divn., Whitehead & Kales Co., River Rouge, Mich.; 1932-35, on death of Mr. Whitehead assets of above company purchased by Hare Stoker Corpn., Detroit, Mich. President and gen. mgr. until 1935, when interest in company sold to others; 1935-38, consltg. mech. engr., Detroit; 1938 to date, partner and mgr., Sawyer-Hare Furnace Company, Detroit, Mich.

HOWSE—GEORGE WESLEY, of Port Nelson, Ont. Born at Beamsville, Ont. June 29th, 1884; Educ.: I.C.S. Corres. Course, Electrical; 1906-07, power house operator, Almonte Power Co.; 1907-08, asst. supt. on power, for W. E. Edwards, Ottawa; 1908-10, constrn. engr., Can. Gen. Elec. Co.; with the H.E.P.C. of Ontario, as follows: 1910-11, constrn. engr., 1911-14, chief operator, St. Thomas, 1914-20, elec. inspr., St. Thomas, and 1920 to date, district electrical inspector, Hamilton, Ont. Consltg. on large power installns., checking plans, and specifications and approving same.

McKERLIE—JARDINE, of 54 Rowanwood Ave., Toronto, Ont. Born at Glasgow, Scotland, July 23rd, 1896; Educ.: 1911-14, Royal Technical College, Glasgow, concurrently with apprenticeship as shipwright, Barclay, Curle & Company, Whiteinch, Glasgow; interrupted by military service, 1914-16. 1916-17, completed apprenticeship by transferring to elec. engrg. with W. C. Martin & Co., Glasgow; after war, home study and corres. courses with McKinley-Roosevelt Univ. of Chicago, receiving B.Sc. in Engrg. (Elec. and Mech.), 1938, and Ph.D. in Education, 1941; 1917-19, supt. of elec. contracts on naval ships being fitted by W. C. Martin & Co.; 1919-21, elec. contractor on own account; 1921-23, mgr., Milligan's Wireless Station, Glasgow; 1923-25, chief engr., Webb's Bakery, Toronto, Ont.; 1926, sales engr. and transportation analyst, Ward Motor Vehicle Co., Mount Vernon, N.Y.; 1926-34, various positions in Toronto and Montreal as agent and partially on own account, and in partnerships concerned in elec. refrigeration and air conditioning sales and engrg.; 1934-38, editor, "Refrigeration and Air Conditioning"; Concur-

(Continued on page 565)

Employment Service Bureau

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.

SITUATIONS VACANT

EXPERIENCED MECHANICAL DESIGNING DRAUGHTSMAN for general mechanical work and industrial piping. Apply Box No. 2375-V.

CONCRETE DRAUGHTSMEN for industrial plant design. Apply Box No. 2401-V.

MECHANICAL GRADUATE ENGINEER, with machine shop experience, required for work in South America on important war contract. Apply Box No. 2441-V.

SALES ENGINEER with excellent technical or industrial qualifications, for work largely in the electrical industry. This is a splendid opportunity for a good man. Employment will be permanent. State training, experience and other qualifications. Apply Box No. 2451-V.

ENGINEERING DRAUGHTSMAN with experience in machine and structural design, proficient in steel design calculation, and having ability for estimating. We require a man with at least five years' industrial experience, preferably in the paper mill field. Position is permanent· State experience and give physical description. Include small photograph and a sample of draughtsmanship. Apply to Box No. 2458-V.

MECHANICAL DRAUGHTSMAN, experienced in making layouts for various installations, piping, etc., around a paper mill. Applicant must be a college graduate. State previous experience, wages expected, etc. Apply to Box No. 2461-V.

ALLOY METALLURGISTS for research laboratory of large industrial firm. Men should be between 20 and 30 years of age preferably post-graduate students. They should have had educational training in physical chemistry or elementary metallography. Apply to Box No. 2464-V.

ASSISTANT ENGINEER wanted immediately for newsprint mill near Quebec City. General engineering including equipment layouts and raw material surveys. Salary depends on ability. Applications will not be considered from persons in the employment of any firm, corporation or other employer engaged in the production of munitions, war equipment or supplies for the armed forces, unless such employee is not actually employed in his usual trade or occupation. Apply to Box No. 2471-V.

SITUATIONS WANTED

ELECTRICAL ENGINEER, B.Sc. in electrical engineering, age 43, married, available on two weeks notice. Fifteen years experience in electrical work. Including electrical installations of all kinds in hydro-electric plants and sub-stations. Maintenance and operation of hydro-electric plants. Electrical maintenance and installations in pulp and paper mill. Considerable experience on relays and meters. At present employed, but desires change. Apply Box No. 636-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, married. Two years city engineer, five years experience in highway work, including surveying, location, construction, estimating and inspection. Apply Box No. 2409-W.

ELECTRICAL ENGINEER, B.E., in electrical engineering, McGill University, Age 24, married, available on two weeks notice. Undergraduate experience, cable testing and cathode ray oscillography. Since graduation, five months on construction of large and small electrical equipment in plant and sub-station. One year operating electrical engineer in medium size central steam station paralleled with large Hydro system. At present employed, but is interested in research or teaching. Associate member of the American Institute of Electrical Engineers. Apply to Box No. 2419-W.

PRELIMINARY NOTICE (*Continued from page 564*)

rently, acted as constrn. engr. for the erection of air conditioned paper warehouse accommodation and building for Garden City Press, Gardenvale, Que.; 1938-39, director of training, Industrial Training Systems Limited, Toronto, subsidiary of Industrial Training Corpn., Chicago; Sept., 1939, appointed Inspr. of Guns and Carriages, M.G.O. Branch, Dept. of National Defence; Feb., 1940, transferred to office of Chief Ordnance Mech. Engr.; June, 1940, appointed Asst. Chief Ordnance Mech. Engr.; Dec., 1940. transferred to General Staff, Canadian Army, and appointed Director of Technical Instruction, Canadian Army Trade School; May, 1941, transferred to position of Division Manager, Ontario-Great Lakes Division, Wartime Merchant Shipping Ltd., a branch of the Dept. of Munitions and Supply.

STARK—JOHN EDWARD, of 65 Wendover Road, Toronto, Ont. Born at Plumstead, Kent, England, May 15th, 1892; Educ.: 1906-07, British Govt. Scholarship, Royal Arsenal & Woolwich Polytechnic. Mech. drawing and design, machine and tool shop training; R.P.E. of Ont.; 1907, machine shop, Toronto Bedding Co.; 1907-10, press set up work with Warwick Bros. & Rutter, Nilne Bingham Co., and Brown Searle Co.; 1910-15, with Warden King Ltd., heating equipment design and layouts. Also private contract work on bldgs. in Toronto and Detroit. Also some specialized work with Minneapolis Honeywell, etc.; 1915-19, with C.E.F. Dec., 1916, commissioned with appointment as officer i/c Technical Equipment, 2nd C.R.T., and continued in this capacity until end of war. Mostly rly. and bridge work —some survey work; 1919, with D.S.C.R., i/c Vocational Board; 1919 to date, with H.E.P.C. of Ontario, constrn. dept., first on elec. installn. and costing; later i/c of office; 1924-28, head office superintendence of bldg. structure (stations) constrn. throughout Ontario; 1928-31, field supt. of constrn., Leaside Transmission Station; 1932 to date, head office supt., station constrn.

Industrial News

Industrial development — new products — changes in personnel — special events — trade literature

LIFT TRUCKS

A folder containing 22 loose leaf pages and entitled "Facts about Towmotor," has been issued by Towmotor Co., Cleveland, Ohio. This folder is essentially a file of operating data and specifications, accompanied by short descriptions and illustrations of this company's various models of lift trucks.

SAFETY POSTER SERVICE

The Consolidated Optical Co. Ltd., Toronto, Ont., has announced that it will be glad to place any industrial firm's name on its mailing list for a free safety poster service which was inaugurated several years ago. At certain intervals during the year, dramatic, colourful safety posters, driving home to workers the value of safety precautions, are made up and mailed to concerns desiring the service.

INSULATION TESTING SET

A 2-page folder issued by Milton-Thompson Electric, of Toronto, Ont., features the "Megometer," an instrument for testing the insulation of electrical installations, domestic appliances and small motors, etc., which operate on voltages up to 250 v. It may be used also as a voltmeter. The instrument is made in England.

EXPANDED METAL MESH

The Pedlar People Limited, Oshawa, Ont., is distributing a 6-page booklet which features a few of the many applications of "Pedlar's 'Steelcrete' Expanded Metal Products" and includes numerous progress photographs showing the use of various types of mesh in industrial plants, for floors and tunnels, bank vaults, skywalks, storage bins, partitions, safety guards, etc.

TRADE MARK ADOPTED

The B. F. Goodrich Rubber Company of Canada, Limited, announces the adoption of this new trade mark in line with the parent company in the United States, and it is already becoming a familiar sight on B. F. Goodrich advertising, dealer signs, and station identification. It will be noted that the new design features the famous initials "BFG" and the date "1870," the large "G" being partially enclosed in a laurel wreath.

SYNCHRONOUS MOTOR CONTROLLERS

English Electric Co. of Canada, Ltd., St. Catharines, Ont., feature its Type "FX" Synchronous Motor Controllers, in a new 8-page bulletin, No. 1354B, which provides details of construction and operation with a diagrammatic illustration of the sequence of operation. Other data given include adjustments and maintenance.

ELECTRODES

"Stelco Electrod" is the title of a 24-page booklet issued by The Steel Co. of Canada, Ltd., of Montreal and Hamilton, which features the various types of "Stelco" coated electrodes. Numerous photographs show the application of the products to actual jobs, while each type is described under the headings, application, properties, procedure, recommended currents and qualifications.

BIOFILTRATION SYSTEM

With photographs and descriptive matter, a 20-page bulletin, No. 7311, issued by The Dorr Co. Inc., Toronto, Ont., tells what the "Biofiltration System" is, what it does and how it does it. It also contains flowsheets, plant layouts, operating data, cost analyses, general dimensioned drawings of the major equipment units and data upon which design can be based.

ELECTRICAL CONNECTORS

In a 2-page folder, Canadian Line Materials, Ltd., Toronto, Ont., describes various types of "Burndy Electrical Connectors" which provide "permanently tight connections with the turn of a wrench." Several types are illustrated which take care of most ordinary connection jobs. Many other types are shown in the company's catalogue No. 41.

EAR PROTECTORS

A 4-page bulletin No. HA-1, issued by Mine Safety Appliances Co. of Canada Ltd., Montreal, Que., contains a description of this company's recently announced "Ear Defenders," which are designed to greatly modify loud noises common to industrial plants. These small devices fit snugly into each ear, reducing the volume of loud sounds but permitting the wearer to hear warning signals and ordinary conversation.

PORTABLE PLATFORM SCALES

A folder of The Canadian Fairbanks-Morse Co. Ltd., Montreal, Que., describes the Fairbanks all-metal scale with steel clad platform; contains illustrations, specifications and a general description setting forth the special features of the scale.

BUILDING INSULATION

Fiberglas Canada Limited, Oshawa, Ont., are distributing a 6-page booklet entitled "Fiberglas Insulating Blankets and Junior Bats" which describes the use of these products for the insulation of buildings and gives an illustrated outline of how to apply "Roll Blankets," "Bat Blankets" and "Junior Bats."

POTENTIAL TRANSFORMERS

The new 24-page bulletin, No. 404, published by Ferranti Electric Ltd., Mount Dennis, Toronto 9, Ont., replaces former bulletin No. 404 and features several major and a number of minor changes. The compound-filled Type PW-4 outdoor unit for 4000-v. service has been replaced by the oil-filled Type PWA-4. Also, the PW-110 outdoor potential transformer for 115,000-v. service is included in the standard line. Additional data on standards and a description of how to determine the ratio and phase-angle errors at any burden from the standard curves, are incorporated.

PACKINGS AND GASKETS

Canadian Johns-Manville Co. Limited, Toronto, Ont., has announced the publication of a 44-page catalogue, designated as "Form PK-12A, which contains detailed information on J-M packing and gasket styles and includes tables as guides to proper packing selection for various types of equipment under such service conditions as steam, brine, ammonia, acids, caustics and oils. An analysis of factors determining packing performance and a section on "How to get the best results from packings" are also included.

BROWN BOVERI CELEBRATES 50th ANNIVERSARY

On October 2, Brown Boveri & Company, Limited, celebrated its fiftieth anniversary at the head office and factory in Baden, Switzerland.

From a modest beginning in 1891, when it was founded by Messrs. C. E. L. Brown and Walter Boveri, it has grown into one of the great engineering firms of the world. In 1891 the firm had seventy employees. To-day, in Switzerland and around the world in overseas branches and affiliated firms, the total number of persons employed by the company is forty thousand.

When the firm was established for the purpose of manufacturing all types of electrical machinery which had hitherto been produced in small workshops, Mr. Brown was already renowned as an engineer. He had previously designed the 40-pole, 3-phase alternator with claw type pole-wheel and concentric coil fields for the Lauffen Power Station. Stepped up to 25,000 volts by 3-phase transformers—which, the company states, was the first oil-cooled transformer ever built—the current from this machine was transmitted over a line 175 km. long to Frankfort-on-the-Main. This transmission of power demonstrated the practicability of transmitting large power over long distances by means of high voltage, single-phase, or three-phase current. The generators, motors, transformers, etc., manufactured by the company found the largest part of their market in Switzerland, where, about the middle of the 1890's, the beginning of the development of Swiss water power opened up an intensive field of operations.

The Company points out that in 1900 Brown Boveri became the first concern on the continent of Europe to build steam turbines, and parallel with this development, the construction of generators for direct coupling to steam turbines was taken up. While the largest machines built during the first year of development were only for a few hundred kva, two-pole machines (3,000 and 3,600 r.p.m. at 50 and 60 cycles, respectively) are now being built for outputs up to 45,000 kva. and 4 pole machines (1,500 and 1,800 r.p.m. at 50 and 60 cycles, respectively) for outputs up to 100,000 kva. without reaching limiting sizes. This development was only rendered possible by constructing the rotors as cylindrical drums and milling out the slots for the field windings—one of the most ingenious inventions of C. E. L. Brown—as this is the only design in which the centrifugal forces produced at the high speed of rotation can be withstood.

Located, as it is, in one of the last strongholds of democracy on the European continent, the Brown Boveri Company, in looking back over the past 50 years, faces the future with quiet confidence. The firm is represented in Canada by its subsidiary, Swiss Electric Company of Canada Limited, Montreal.

RATIONAL COLUMN ANALYSIS

J. A. VAN DEN BROEK, PH.D.
Professor of Engineering Mechanics, University of Michigan, Ann Arbor, Mich., U.S.A.

Paper to be presented before the General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., on February 6th, 1942

TABLE OF CONTENTS

INTRODUCTION

In mathematical analyses we need as many equations as there are unknowns. If we can guess the value of one of the unknowns intelligently, we can dispense with one of the otherwise necessary equations and thus materially simplify our analysis. In column analysis we may simplify our efforts by following this procedure. In "Euler's Column Formulae"[1] (see Figs. 8a, 9a and 11a) the type of elastic curve which the column would assume was determined by guess with complete accuracy, and what are recognized as "exact" strength formulae were obtained. In "Columns Subject to Transverse Loading"[2] the type of elastic curve was guessed with a quite high degree of accuracy and the resulting formulae proved accurate to within a fraction of one per cent. In this and the following analyses we propose to follow the same procedure and obtain formulae which are either technically "exact" or approximate, depending on whether or not we are able to determine in advance the true type of elastic curve.

In the appendix the results of some column tests are presented. *The significant feature of these tests is that, first, the eccentricity (or lack of eccentricity) is quite definitely controlled up to the point of failure; second, the load-axial deformation relationship is recorded far beyond the critical load.*

THE SECANT FORMULA

In the analysis of eccentrically loaded prismatic columns we are able to determine exactly what is the type of elastic curve which the columns will assume, and thus we obtain what is recognized as the "exact" formula.

Figure 1c[3] shows an eccentrically loaded column. When the eccentricity e approaches zero as a limit the elastic curve approaches a sine curve. When e approaches infinity the elastic curve approaches an arc of a circle as a limiting curve. The true curve, then, will fall between a sine curve and an arc of a circle.

The free-body sketch for the portion BD of Fig. 1a as well as for the portion BD of Fig. 1c is, in either case, given by Fig. 1b. Therefore, BD of Fig. 1c and BD of Fig. 1a are identical. The curve ABCDE of Fig. 1a is a sine curve, and if we adopt mathematical usage we may say it is a full arch of a sine curve. The portion BD of this curve is then an arc of a full arch of a sine curve. By virtue of the identity which we have just established the portion BD of Fig. 1c also is an arc of an arch of a sine curve. Once we are agreed on this fact the mathematical development is direct and relatively brief.

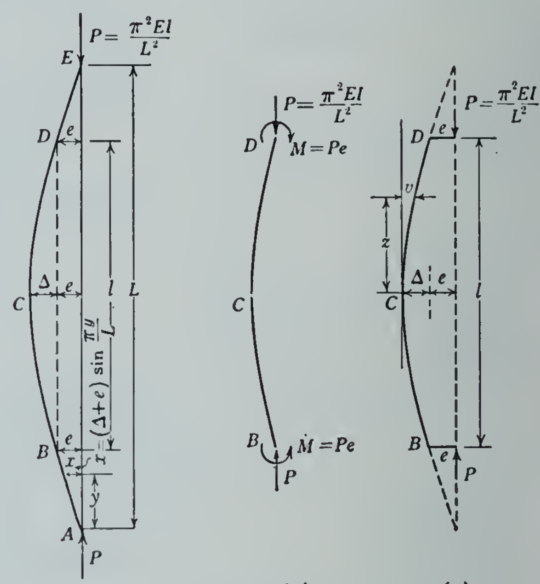

Fig. 1

The equation for the curve ABCDE in Fig. 1a, or for the curve BCD in Fig. 1c, is:

$$x=(\Delta+e)\sin\frac{\pi y}{L}$$

$$e=(\Delta+e)\sin\frac{\pi(L-l)}{2L}=(\Delta+e)\cos\frac{\pi}{2}\frac{l}{L} \qquad \text{(a)}$$

$$\frac{dx}{dy}=(\Delta+e)\frac{\pi}{L}\cos\frac{\pi y}{L}$$

$$\frac{d^2x}{dy^2}=-(\Delta+e)\frac{\pi^2}{L^2}\sin\frac{\pi y}{L}$$

The curvature, or $\frac{1}{R}=\dfrac{\frac{d^2x}{dy^2}}{\left(1+(\frac{dx}{dy})^2\right)^{3/2}}$

This expression is a maximum for the value $y=\frac{L}{2}$

Thus $\quad (\frac{1}{R})_{max}=-\frac{d^2x}{dy^2}=(\Delta+e)\frac{\pi^2}{L^2}=\frac{s}{Ec}$

in which s is stress due to curvature in the extreme fibre of the column at point C.

$$s=\frac{\pi^2Ec}{L^2}(\Delta+e)$$

This stress s, due to curvature, is augmented by a stress P/A, due to the direct load. Thus the equation

$$s = \frac{\pi^2 Ec\,(\triangle + e)}{L^2} + \frac{P}{A}$$

gives a general load-stress relationship for the midpoint of the column on the inside of the elastic curve. But since this relationship is not linear it throws no light on the strength of the column. An estimate of the column strength can be made only when we assign a definite maximum value for s, say the elastic limit stress s_1, and simultaneously define the corresponding load P as being equivalent to the limit load, critical load or maximum load, which the column can carry. With s_1 and P so defined we may write.

$$s_1 = \frac{\pi^2 Ec\,(\triangle + e)}{L^2} + \frac{P}{A}, \text{ or}$$

$$(\triangle + e) = \frac{L^2}{\pi^2 Ec}\left(s_1 - \frac{P}{A}\right) \qquad \text{(b)}$$

Eliminating $(\triangle + e)$ between equations (a) and (b), we obtain

$$e = \frac{L^2\left(s_1 - \frac{P}{A}\right)}{\pi^2 Ec} \cos\frac{\pi l}{2L}$$

From Fig. 1a we have $L^2 = \frac{\pi^2 EI}{P}$ and $\frac{l}{L} = \frac{l}{\pi}\sqrt{\frac{P}{EI}}$. Substituting these values in the foregoing equation we obtain

$$e = \left(s_1 - \frac{P}{A}\right)\frac{I}{Pc}\cos\frac{l}{2}\sqrt{\frac{P}{EI}}$$

$$s_1 - \frac{P}{A} = \frac{ecP}{I\cos\frac{l}{2}\sqrt{\frac{EI}{P}}}$$

$$s_1 = \frac{P}{A}\left(1 + \frac{ec}{i^2}\sec\frac{l}{2}\sqrt{\frac{EI}{P}}\right) \qquad \text{Formula 1}$$

Approximate Eccentric Loading Formula

Formula 1 is quite exact, but to say the least it is awkward because we can effect a solution only by cut and try procedure. This awkwardness can effectively be avoided by the simple procedure of assuming a compromise curve in place of an arc of a full arch of a sine curve. An analysis based on the assumption that the shape of the elastic curve in Fig. 1c is a second degree parabola gives very satisfactory results. The mathematical development will appear in Elastic Energy Theory[4]. The resulting formula is:

$$\frac{P}{A} = \frac{1}{2}\left[s_1 + \frac{9.6\,E}{\left(\frac{l}{i}\right)^2}\left(1 + \frac{ec}{i^2}\right) - \sqrt{\left\{s_1 + \frac{9.6\,E}{\left(\frac{l}{i}\right)^2}\left(1 + \frac{ec}{i^2}\right)\right\}^2 - \frac{38.4\,s_1 E}{\left(\frac{l}{i}\right)^2}}\right]$$

Formula 2

A graphical comparison between Formula 2 and the secant formula was published in the closing discussion of the author's paper on "Columns Subject to Uniformly Distributed Transverse Loads"[2] in the *Engineering Journal* of September, 1941.

Initial Crookedness or Wow

Assume a column to be initially curved in the shape of a complete arch of a sine curve with an initial offset and radius of curvature at the midpoint equal to e' and R respectively (Fig. 2). As the column is loaded with a load P the deflection will increase an amount $\triangle$. The bending moment area is one half of the area bounded by the line of action of the load and the elastic curve. The maximum ordinate of this bending moment area is at the midpoint and equals $P\,(e' + \triangle)$. The deflection $\triangle = \frac{Area\ \bar{y}}{EI}$. The Area in question, shown cross hatched in Fig. 2, is $2/\pi \times$ the circumscribed rectangle. Thus $Area = \frac{2}{\pi}P(e' + \triangle)\frac{l}{2}$. The $\bar{y}$ of an area under a sine curve, shown in Fig. 2, is $\frac{l}{\pi}$.

Therefore $$\triangle = \frac{Area\ \bar{y}}{EI} = \frac{Pl^2}{\pi^2}(e' + \triangle) = \frac{Pl^2\triangle}{\pi^2 EI} + \frac{Pl^2 e'}{\pi^2 EI}$$

or $$\left(EI - \frac{Pl^2}{\pi^2}\right)\triangle = \frac{Pl^2 e'}{\pi^2} \qquad \text{(c)}$$

From the theory of strength we have:

$$\frac{1}{r} - \frac{1}{R} = \frac{M}{EI} = \frac{s}{cE}$$

$$\frac{d^2x}{dy^2} = \frac{1}{r} = \frac{\pi^2(\triangle + e')}{l^2}$$

$$\frac{d^2x}{dy^2} = \frac{1}{R} = \frac{\pi^2 e'}{l^2}$$

$$\frac{1}{r} - \frac{1}{R} = \frac{\pi^2\triangle}{l^2} = \frac{s}{cE}$$

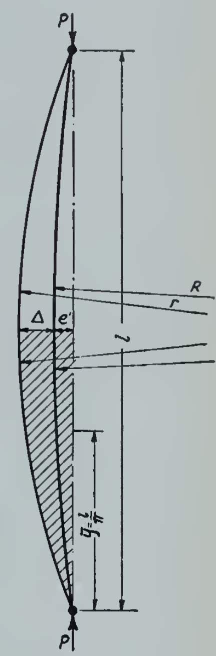

Fig. 2

The stress due to the increase in curvature therefore is:

$$s = \frac{\pi^2\triangle cE}{l^2}$$

This stress is augmented by the stress P/A due to the direct load.

Thus the resulting extreme fibre stress on the inside of the curve at the midsection of the column is:

$$s = \frac{\pi^2\triangle cE}{l^2} + \frac{P}{A}, \text{ or}$$

$$\triangle = \left(s - \frac{P}{A}\right)\frac{l^2}{\pi^2 cE} \qquad \text{(d)}$$

Eliminating $\triangle$ between equations (c) and (d) we obtain

$$\left(EI - \frac{Pl^2}{\pi^2}\right)\left(s - \frac{P}{A}\right) = Pe'cE, \text{ or}$$

$$P^2 - \left(\frac{\pi^2 EI}{l^2} + sA + \frac{\pi^2 Ee'cAi^2}{l^2 i^2}\right)P + \frac{\pi^2 EIsA}{l^2} = 0$$

If we let $\frac{\pi^2 EI}{l^2} = P_{cr}$, then the solution of this equation gives

$$P = \frac{1}{2}\left[\left\{sA + P_{cr}\left(1 + \frac{e'c}{i^2}\right)\right\} - \sqrt{\left\{sA + P_{cr}\left(1 + \frac{e'c}{i^2}\right)\right\}^2 - 4\,P_{cr}\,sA}\right]$$

or

$$\frac{P}{A} = \frac{1}{2}\left[\left\{s + \frac{\pi^2 E}{\left(\frac{l}{i}\right)^2}\left(1 + \frac{e'c}{i^2}\right)\right\} - \sqrt{\left\{s + \frac{\pi^2 E}{\left(\frac{l}{i}\right)^2}\left(1 + \frac{e'c}{i^2}\right)\right\}^2 - 4\frac{\pi^2 E}{\left(\frac{l}{i}\right)^2}s}\right]$$

The last two expressions give a relationship between the load P and the maximum stress in the column. This relationship is purely academic and of no interest to the designer. If we define s as being equal to the elastic limit stress s_1, P immediately assumes special significance because it then becomes the symbol for the limit or maximum load which the column can carry. The resulting formula for the limit load P then is:

$$\frac{P}{A} = \frac{1}{2}\left[\left\{s_1 + \frac{\pi^2 E}{\left(\frac{l}{i}\right)^2}\left(1+\frac{e'c}{i^2}\right)\right\} - \sqrt{\left\{s_1 + \frac{\pi^2 E}{\left(\frac{l}{i}\right)^2}\left(1+\frac{e'c}{i^2}\right)\right\}^2 - 4\,\frac{\pi^2 E}{\left(\frac{l}{i}\right)^2}s_1}\;\right]$$

Formula 3

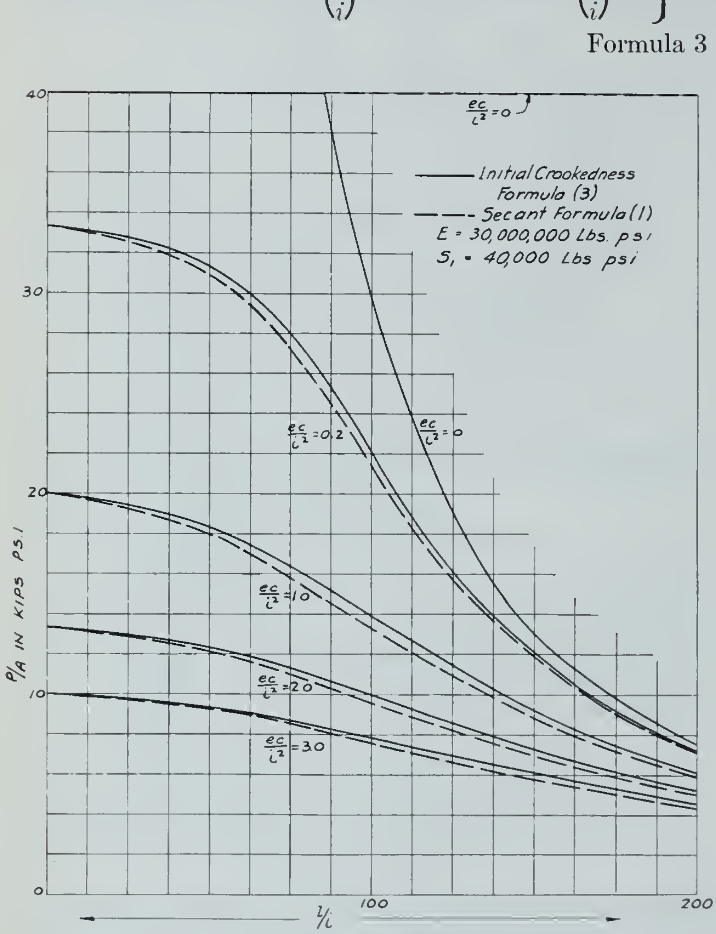

Fig. 3—Comparison between wow formula and secant formula.

Figure 3 shows graphically a comparison of values obtained by Formula 1 (the secant formula) with those obtained by Formula 3 (the wow formula). It shows that for all values (even for values of e' which are much greater than any that can reasonably be expected) the two formulae give results which are nearly the same. More important than Fig. 3 is Fig. 4 which shows how the limit strength of columns is affected by a wow expressed as a function of the length of the column for the following values of e', namely:

$$e' = \frac{l}{600};\ e' = \frac{l}{1000};\ e' = \frac{l}{2000};\ e' = \frac{l}{5000}\ \text{and}\ e' = \frac{l}{\infty} = 0.$$

It appears that for slender columns the weakening effect of initial crookedness is insignificant.

Objectives and Sense of Value

Much confusion and misunderstanding concerning the column phenomena appears to result from an incomplete agreement among engineers as to proper objectives. This disagreement seems to stem from a failure to distinguish clearly between factors of primary and those of secondary importance. To avoid, if possible, such uncertainties and to eliminate this possible cause for misunderstanding in this paper, the author will set forth in some detail his sense of value in regard to the column problem.

No one, including the scientist, is immune to psychological pitfalls. It seems to the author that, in the science of strength, we have fallen into a rut in over-emphasizing the concept "stress" to such a degree that it obscures the problem of "strength." The author regards as basically unsound the practice of dividing an ultimate stress, or an elastic limit stress, by a factor of safety to arrive at a working stress. This tradition was harmless enough in the era which lies behind us—the era of statically determinate construction. It is harmless so long as a linear relationship exists between stress and load. In the present era of redundant construction, a type of construction in which the linear relationship between stress and load is not maintained until the limit load is reached, and in stability problems in which the relationship between stress and load is never linear, the author regards the emphasis on working stress as archaic, generally confusing, and often misleading.

In our formulae we introduce the term P/A. We do so in order to present these formulae in their most general form, which is the form that best lends itself to effective graphical representation. We do so with one misgiving. The first strength formula the engineer learns is P/A = stress. This is no reason for invariably interpreting P/A as stress. The author objects to mathematical terms in engineering science to which he is unable to give a physical interpretation. The term P/A in our formulae is such a term. A is explicitly defined as the cross-sectional area, and P with equal explicitness defines the capacity or maximum load, the load which will induce the elastic limit stress in the column. The term P/A then has no physical significance. It assumes such significance only after it is multiplied by A. Then it yields the load P, the maximum load the column can carry. Once the designing engineer knows the maximum load which would cause his column to fail, he certainly will know how to apply a factor of safety with which to avoid this failure load by a safe margin.

Eccentricity, End Moments or Partial Restraint, and the Ratio of Effective Length over Geometric Length ($n = L/l$) are Identities

Consider Fig. 5 which schematically represents a column with built-in ends under varying loads. Perfect straightness and zero eccentricity are both abstractions and both are

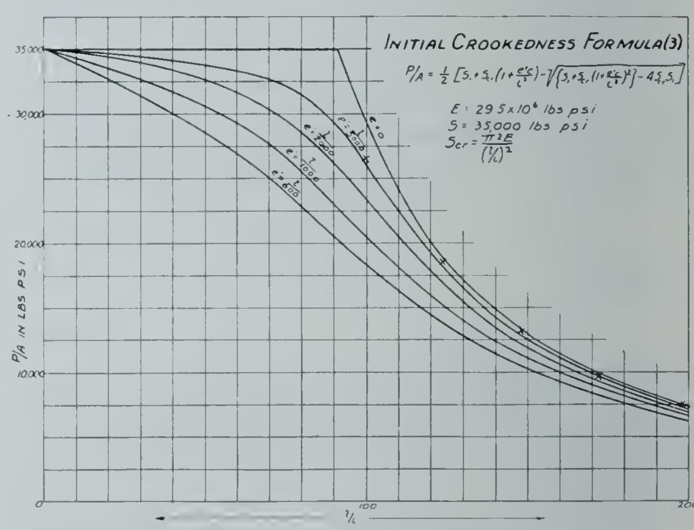

Fig. 4—Strength of columns as affected by wow expressed as a function of the length.

unobtainable. As the column is loaded, either a slight initial crookedness or a slight eccentricity to one side or the other of the centre line determines the direction in which the column deflects. Of the two, initial eccentricity is more likely to be the determining factor. Figure 5 represents the column as a free body. The force and moment or partial restraint shown acting at point A are opposite in sign but otherwise the equivalent of the single force acting with an eccentricity e at point C. As the column deflects the initial eccentricity, or for that matter any intermediate eccentricity, does not concern us in the least. If our aim is to determine the strength of the column then the only eccentricity which would concern us, if we were able to determine it, is that which prevails at the instant the elastic limit stress s_1 is reached on the inside of the curve at point B. The fact is we may determine this eccentricity for any particular column, but we can determine it only as the climax of a complete solution of the column problem. It is never ascertainable as initial data upon which the column analysis may be predicated, except possibly for short struts. Note that in Fig. 5, while the eccentricity is variable, the point of inflection always coincides with the quarterpoint. Thus, while the eccentricity e changes, the ratio $n = L/l$ is a constant up to and including the load condition at which the elastic limit stress in the column is first induced. In this connection we stress the following points.

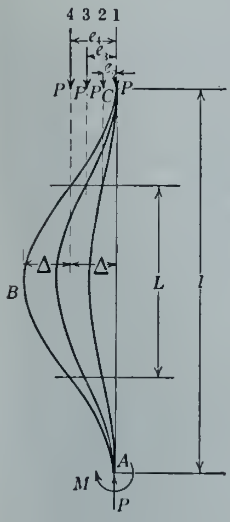

Fig. 5—Fixed-end column in various stages of loading

1. The logic upon which we base the contention—that eccentricity, partial restraint or end moments, and the L/l ratio, are identities—is a logic involving only the theory of equilibrium (statics). It thus supersedes any argument given in terms of elasticity. The theory of equilibrium is the most basic, the most fundamental, theory we have. Our conclusions as to the identity of L/l ratio, eccentricity and partial restraint thus seem irrefutable.

2. The word identical is a strong word. It means "the same in every conceivable respect." This being the case we should be privileged to confine our attention solely to one of the three concepts without in any way doing violence to sound logic.

General Column Formula

The characteristic feature of the pin-ended column, the Euler column, is that when it deflects it assumes the shape of a sine curve. Our development of the secant formula makes it clear that the eccentrically loaded column is but a special case of the concentrically loaded (Euler) column. The analysis of the initially crooked column was also predicated on the assumption that the elastic curve of the column was a sine curve before loading, and remained a sine curve after loading. In the author's paper, in the *Engineering Journal*, on "Columns Subject to Uniformly Distributed Loads"② it was shown that very satisfactory results are obtained if the analysis is based on the assumption that the column subject to uniformly distributed transverse loads assumes the shape of a sine curve. If we keep in mind that eccentricity may effectively, very advantageously in fact, be replaced by the coefficient $n = L/l$, then we may proceed with the derivation of a general formula for a prismatic column of elastic material subject to eccentricity (end moment or end restraint) to wow and to uniformly distributed transverse loads. If the elastic curve assumes the shape of a sine curve under any one of these loadings individually, it will do so under the action of any combination of these loadings collectively.

In Fig. 6b the dashed line represents the shape of the initially-crooked column. The solid line represents the shape of this same column under the combined action of the axial load P and the uniformly distributed load kuA (u is weight per unit volume, A is the cross-section area of the column, $uA = w$ or weight per unit of length, $uAl = W$ or weight of entire column, k is a constant. Thus, for example, if an aeroplane manoeuvres with an acceleration of kg, any strut in this plane placed parallel to the axis of the wings would be loaded with a uniformly distributed inertia loading of $w = kuA$ lb. per inch. In a top chord of a bridge the constant k expresses the maximum inertia effect caused by the vibration of the bridge)③. From the fundamental elastic energy equation,④

$$F\,\triangle = \int \frac{mMdx}{EI},$$

we obtain:

$$\triangle = \frac{Area\ x}{EI},$$

where area represents the bending moment area for one half of the column. This bending moment area consists of two parts, the bending moment area due to the load P which is the area bounded by the elastic curve and the line of action of the load, and the bending moment area for a simple beam subject to a uniformly distributed transverse load. Thus the deflection

$$\triangle = \frac{P\,(\triangle + e')l^2}{\pi^2 EI} + \frac{5kuAl^4}{384EI} \qquad \text{(e)}$$

The identity $F\,\triangle = \int \frac{mMdx}{EI}$ is independent of the principle of superposition. It forms the basic philosophy of all the author's earlier publications on columns ①, ③, ④. Its applicability is contingent on the two assumptions, that the material is elastic, and that m, the moment caused by the auxiliary load F, remains constant.

Rearranging equation (e), we obtain:

$$(EI - \frac{Pl^2}{\pi^2})\,\triangle = \frac{5}{384}\,kuAl^4 + \frac{e'l^2P}{\pi^2}$$

$$s = \frac{Ec\pi^2\triangle}{l^2} + \frac{P}{A}$$

$$\triangle = (s - \frac{P}{A})\,\frac{l^2}{\pi^2 Ec} \qquad \text{(f)}$$

Eliminating $\triangle$ between equations (e) and (f) we obtain:

$$(EI - \frac{Pl^2}{\pi^2})\,(s - \frac{P}{A}) = \frac{5\pi^2 kuAcEl^2}{384} + Ece'P$$

or

$$P^2 - (P_{cr} + sA + P_{cr}\frac{e'c}{i^2})\,P - \frac{5}{384}\,\pi^4 kuA^2cE + P_{cr}\,sA = 0$$

Solving this quadratic equation we obtain:

$$P = \frac{1}{2}\left[\left\{sA + P_{cr}\,(1 + \frac{e'c}{i^2})\right\} - \sqrt{\left\{sA + P_{cr}\,(1 + \frac{e'c}{i^2})\right\}^2 + 5.07\,kuA^2cE - 4P_{cr}\,sA}\right]$$

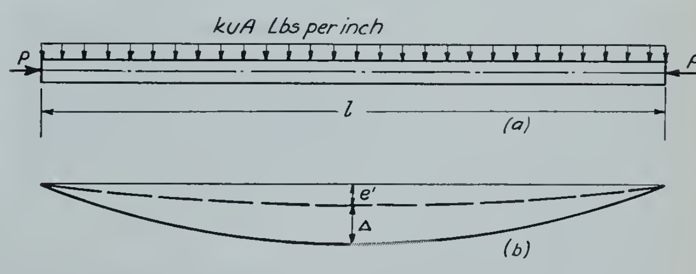

Fig. 6—Column subject to wow and to uniformly distributed loads.

We have already discussed why a non-linear load-stress relationship throws no light on the strength of a column when the controlling stress is not properly specified. We thus define s_1, the elastic limit stress at the midpoint and on the inside of the elastic curve of the column, as this controlling stress, and simultaneously define the corresponding load P as the load which induces this elastic limit stress or as the capacity load which the column can carry. We have also discussed in detail why eccentricity, end moments, and partial restraints, are identities. This effect on a column may therefore be fully expressed by a constant

n by which the length l is multiplied. To express the column formula in its most general terms we divide through by A. After we apply all these three steps to the above equation we obtain:

$$\frac{P}{A} = \frac{1}{2}\left[\left\{s_1 + \frac{\pi^2 E}{\left(\frac{nl}{i}\right)^2}\left(1+\frac{e'c}{i^2}\right)\right\} - \sqrt{\left\{s_1 + \frac{\pi^2 E}{\left(\frac{nl}{i}\right)^2}\left(1+\frac{e'c}{i^2}\right)\right\}^2 + 5.07kucE - \frac{4\pi^2 E s_1}{\left(\frac{nl}{i}\right)^2}}\right]$$

Formula 4

When $n = 1$ and $k = 0$ Formula 4 reduces to Formula 3, the initial crookedness formula. When $n = 1$ and $e' = 0$ Formula 4 reduces to the formula which was first presented in the author's paper on "Column Subject to Uniformly Distributed Transverse Loading"[2]. When $n = 1$ and both k and e' are zero then Formula 4 reduces to:

$$\frac{P}{A} = \frac{1}{2}\left[s_1 + \frac{\pi^2 E}{\left(\frac{l}{i}\right)^2} - \sqrt{\left\{s_1 - \frac{\pi^2 E}{\left(\frac{l}{i}\right)^2}\right\}^2}\right] \quad \text{Formula 5}$$

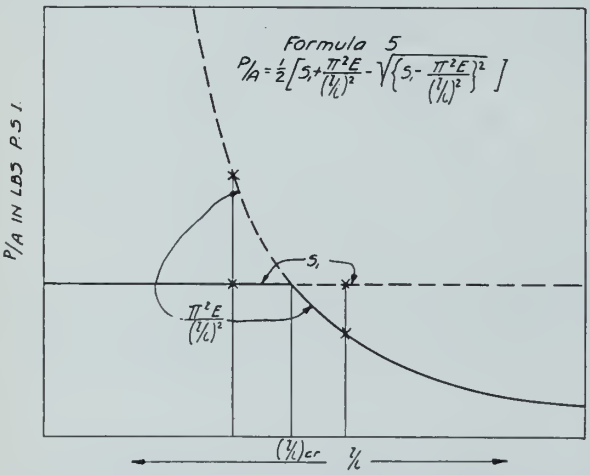

Fig. 7—Graphical representation of Formula 5. For all values of l/i, except $(l/i)_{cr}$, two roots are obtained, marked by crosses. The smaller of the two roots, represented by the solid line, is always the controlling one.

At first glance Formula 5 appears identical with Euler's formula, $\frac{P}{A} = \frac{\pi^2 E}{\left(\frac{l}{i}\right)^2}$, yet it has one attribute which the latter formula lacks. When l/i approaches zero, then P/A in Euler's formula approaches infinity. It is the custom (more or less arbitrary) to cut the graph for Euler's formula short and bring the curve in along a horizontal line for all values which the formula would give as $P/A < s_1$. If we plot Formula 5 we find that the curve automatically turns a sharp corner as a result of the manner in which it is expressed, and presents a horizontal line for all values $0 < l/i < (l/i)_{cr}$. (See Figs. 3 and 4).

NOTE—*Euler's curve appears as a limiting graph of Formula 5 (Figs. 3, 4, and 7).* The solution of a quadratic equation provides two roots. We might have written Formulae 3, 4 and 5 with a $\pm$ sign in front of the radical, and stipulated that the smallest of the two roots be always selected. Thus, in Formula 5 we would obtain two results, either $P/A = s_1$, or $P/A = \frac{\pi^2 E}{\left(\frac{l}{i}\right)^2}$. If we plot graphs for these two expressions (Fig. 7) and select the lower ordinate of the two graphs, we obtain the limiting curve for Euler's formula as we have described it. However, we do not require any stipulation as to selecting the lowest value root, and we obtain identical results by using only the minus sign before the radical in Formulae 3, 4 and 5, if we proceed as follows. In case $\frac{\pi^2 E}{\left(\frac{l}{i}\right)^2} > s_1$, the quantity in the brackets is negative. When we square this quantity it becomes positive. After extracting the square root we select the positive root. The sign before the radical changes this to a negative value and $P/A = s_1$ results for all value of $\frac{l}{i} < \left(\frac{l}{i}\right)_{cr}$. Note also that in Fig. 3 and Fig. 4 the Euler curve, with the horizontal line and the sharp corner, appears clearly as the limiting curve for the case when $e' = 0$. It similarly appears as a limiting curve in the formula for "Columns Subject to Uniformly Distributed Transverse Loads[2]" when $k = 0$, that is, when the transverse loading is zero.

Theory, Tests and Practice

The author regards as a contradiction the statement that theory and practice may conflict. Any real conflict between theory and practice is *prima facie* evidence of a deficiency in the theory if not of its utter worthlessness. The merit of an engineering theory lies in the effectiveness with which it correlates and interprets engineering phenomena, and not in the medium in which it is expressed. The best theory in this paper is the proof of the identity of eccentricity and the L/l ratio. This theory involved no mathematics whatsoever in its expression. The theory of columns is nearly two hundred years old and the amount of literature on the subject is overwhelming (see "Columns," by E. H. Salmon[5]). Some of this theory is philosophically perfect, and yet as an aid to engineering design completely worthless. *The secant formula* (Formula 1) is a case in point. The theory involved in the development of the secant formula is perfect, it is beautiful, yet the formula is futile. The author has never heard of anyone suggesting how the eccentricity e, which prevails at the instant the column collapses, may be determined in advance of a solution of a slender column design problem. (For very short columns, in which the value of e is determinable with reasonable accuracy, the formula $s = \frac{P}{A} + \frac{Mc}{I}$ or $\frac{P}{A} = \frac{s_1}{(1 + ec/i^2)}$ applies).

Yet a reliable and accurate pre-determination of this eccentricity e is absolutely essential for an effective use of the formula. Possibly the author may be criticized for the inclusion of a formula in this paper which is well known and which he regards as futile. He stated that he regards the secant formula as worthless for design purposes. In this paper it serves a useful purpose.

The author has no difficulty in convincing his students. The less they are burdened with preconceived ideas about columns the easier they are to convince. It is his friends, the experts in the theory of elasticity who sometimes appear to have forgotten their elementary statics, that need convincing. Our proof of the secant formula is directly predicated on the identity of eccentricity or partial restraint and the L/l ratio. Therefore, if we base our proof of a recognized and accepted formula on this identity, we add further evidence toward the establishment of this identity.

Our primary interest lies in columns as they function in office buildings, bridges, transmission towers, aeroplanes and other engineering structures. Yet as a rule we do not study them as integral parts of complex structures, but instead we draw lines on paper and philosophize about these lines, and we take columns by themselves and test them in the laboratory. Tests on complete structures, if large, may be out of the question. Yet tests on complete transmission towers and aeroplanes are common practice. So far as the author knows, a systematic and rigorous analysis of column-functioning in such tests still awaits attention.

Column tests frequently suffer from two defects. They fail effectively to simulate the conditions prescribed by the assumptions on which the theory is based, and they also fail effectively to simulate end conditions of restraints—such as are met with in practice.

The tests recorded in the appendix are of specimens so small in size that to some they may appear as hardly worthy of being considered as columns. The special feature of these tests lies in the fact that they come quite close to

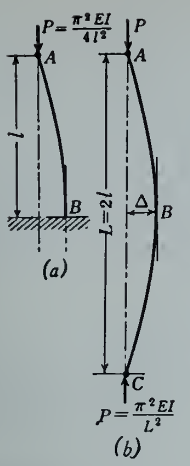

Fig. 8

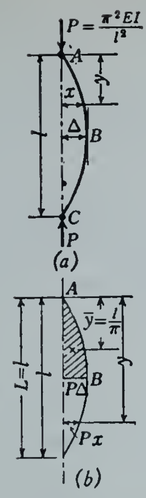

Fig. 9

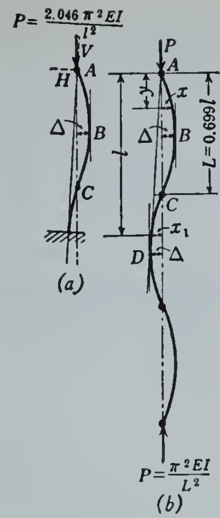

Fig. 10

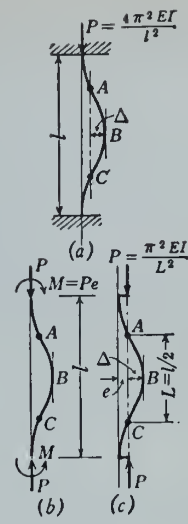

Fig. 11

Columns subject to various conditions of end restraint.

simulating theoretical conditions. They contribute toward establishing the fact that the column theory is as sound and reliable as any theory we have in the general theory of strength. The theory completely fits ideal, laboratory controlled, conditions. The major requirement is to make the theory fit ordinary practice conditions. Tests with million-pound capacity testing machines may give empirical data of value. They are not likely to contribute to a rational column theory because the laboratory machine does not provide conditions of end restraint as found in practice. Tests on actual structures such as transmission towers, many records of which are available, have already been suggested as a hopeful field of investigation with a view towards perfecting rational column theory. The column theory being accepted as basically sound and reliable, we offer in this instance a paper investigation of end restraint conditions as the most promising procedure.

Determination of Constant $n = L/l$

Figures 8a, 9a, 10a and 11a③ present four types of column loading in which the coefficient n may readily be determined. In Figs. 8a, 9a and 11a, n or L/l may be determined by inspection to equal 2, 1 and ½ respectively. In Fig. 10a the coefficient n or L/l may, with the aid of purely geometric considerations, be shown ⑩⑨ to equal 0.6992. The critical load for Fig. 10a, therefore, is

$$P = \frac{\pi^2 EI}{L^2} = \frac{\pi^2 EI}{(0.6992\ l)^2} = \frac{2.046\ \pi^2\ EI}{l^2}$$

These four cases of column loading are commonly treated in texts, but they are all quite hypothetical. They never occur in practice quite as represented. One of the major arguments of this paper is to the effect that all prismatic columns are but special cases of the ideal Euler, pin-ended, column. Our problem is to obtain some estimate of the value of n which is likely to occur in a column which acts as an integral part of a complex structure.

Columns generally are part of a complex structure. Loads ordinarily are transmitted to columns through floor beams, tie rods, diagonals, etc. In addition to forces coincident with the axis of the column these connections generally transmit moments. As we have seen the combination of a moment and a force gives rise to an eccentricity e. A vital point to keep in mind is that any load-moment or eccentricity relationship that may prevail under initial loading conditions generally has little or no bearing on the column-strength problem. The only exception is when the column is very short and stiff. This fact we elaborate upon later when we discuss Figs. 13 and 14.

Figure 12a represents a frame consisting of two horizontal 24-W.F.-74 lb. beams and two vertical 12-W.F.-25 lb. beams. The connections at the corners are not shown in detail but are assumed to be absolutely rigid. The horizontal beams are loaded with a uniformly distributed load. The vertical beams are placed with the minimum axis of moment of inertia perpendicular to the paper. The horizontal beam was purposely chosen heavy to insure column failure in the

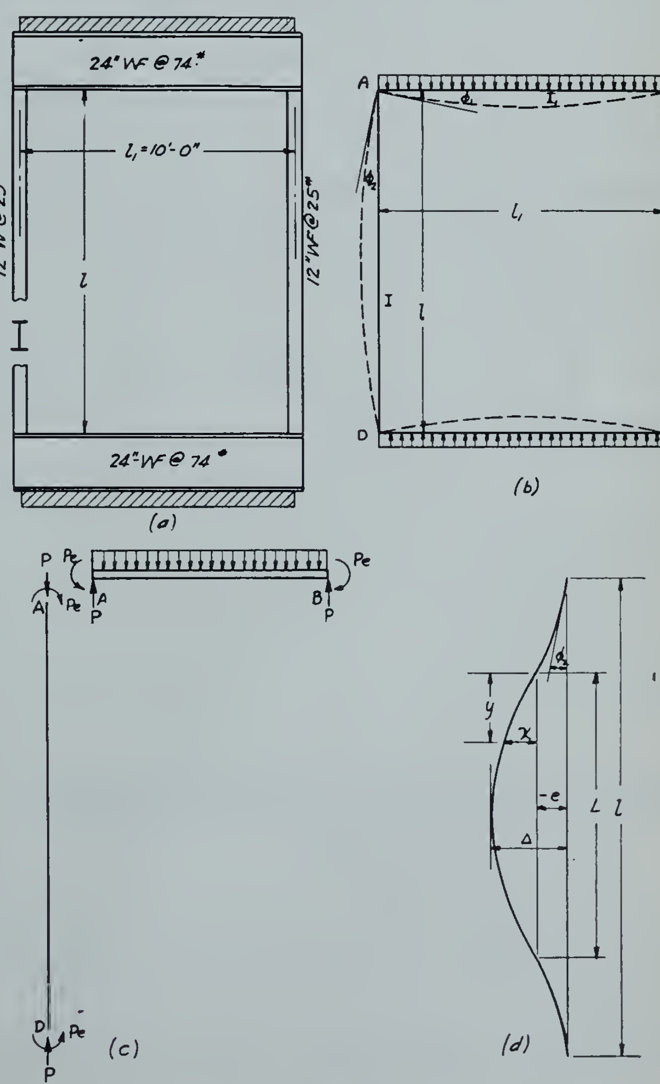

Fig. 12

vertical beams. As the loading over the horizontal beam is gradually applied the resultant load transmitted to the column is offset with a positive eccentricity. As will be shown for all values of $l/i \geqq 103$, this positive eccentricity decreases as the loading progresses and finally becomes negative. This tells us that, for all values of $l/i \geqq 103$, n is less than unity and the column is strengthened rather than weakened by the horizontal beams.

The dashed line in Fig. 12b shows the structure schematically in the deformed state. Figure 12c shows free body sketches of both beam and column, and Fig. 12d shows the deformation of a column under positive restraint or negative eccentricity.

From Fig. 12b it follows that $\phi_1 = \phi_2$

$$\phi_1 = \frac{1}{EI_1}\left(\frac{wl_1^3}{24} - \frac{Pel_1}{2}\right) \qquad (g)$$

From Fig. 12d we obtain an expression for ϕ_2 in the following manner.

$$x = (\triangle + e)\ sin\ \frac{\pi y}{L}$$

$$\frac{dx}{dy} = \frac{\pi}{L}(\triangle + e)\ cos\ \frac{\pi y}{L}$$

For small angles $\phi_2 = \frac{\pi}{L}(\triangle + e)\ cos\ \frac{-\pi(l-L)}{2L}$

$$= \frac{\pi}{L}(\triangle + e)\ sin\ \frac{\pi l}{2L} \qquad (h)$$

$$e = (\triangle + e)\ sin\ \frac{-\pi(l-L)}{2L}$$

$$= (\triangle + e)\ cos\ \frac{\pi}{2}\frac{l}{L}$$

$$\therefore \quad \triangle + e = +e\ sec\ \frac{\pi}{2}\frac{l}{L} \qquad (i)$$

Combining (h) and (i) we obtain:

$$\phi_2 = \frac{\pi e}{L}\ sec\ \frac{\pi l}{2L}\ sin\ \frac{\pi l}{2L} = \frac{\pi e}{L}\ tan\ \frac{\pi l}{2L} \qquad (j)$$

Since $P = \frac{\pi^2 EI}{L^2}$,

$$\frac{\pi}{L} = \sqrt{\frac{P}{EI}} \qquad (k)$$

Substituting (k) in (j) we obtain:

$$\phi_2 = e\sqrt{\frac{P}{EI}}\ tan\ \frac{l}{2}\sqrt{\frac{P}{EI}} \qquad (l)$$

Equating equations (g) and (l) we obtain

$$\frac{1}{EI_1}\left(\frac{wl_1^3}{24} - \frac{Pel_1}{2}\right) = e\sqrt{\frac{P}{EI}}\ tan\ \frac{l}{2}\sqrt{\frac{P}{EI}} \qquad (m)$$

From Fig. 12c we have $P = \frac{wl_1}{2}$, and Formula 1 gives us

$$s_1 = \frac{P}{A}\left(1 + \frac{ec}{i^2}\ sec\ \frac{l}{2}\sqrt{\frac{P}{EI}}\right)$$

In our problem, Fig. 12a, the following constants prevail:

s_1 = 18 tons per sq. in.
E = 15,000 tons per sq. in.
l_1 = 10 ft. = 120 in.
l = variable

For beam AB, Fig. 12, 24-W.F.-74 lb.—I_1 = 2034 in.^{4}; $\frac{I_1}{c}$ = 170.4 in^3.

For column AD, 12-W.F.-25 lb.—I = 14.5 in.^{4}; A = 7.39 in.^{2}; i = 1.40 in.; c = 3.25 in.

Substituting these values in (m) we obtain:

$$.00236\ w - .00000197\ Pe = e\sqrt{\frac{P}{14.5\ E}}\ tan\ \frac{l}{2}\sqrt{\frac{P}{14.5\ E}}$$

Substituting in this expression $\frac{2P}{l_1} = \frac{P}{60} = w$ it reduces to:

$$e = \frac{0.0000394\ P}{0.00000197\ P + \sqrt{\frac{P}{14.5\ E}}\ tan\ \frac{l}{2}\sqrt{\frac{P}{14.5E}}}$$

Substituting the constants of our problem in Formula 1 it reduces to:

$$e = \frac{133.0 - P}{1.66\ P\ sec\ \frac{l}{2}\sqrt{\frac{P}{EI}}}$$

The last two equations are solved by the trial and error method.

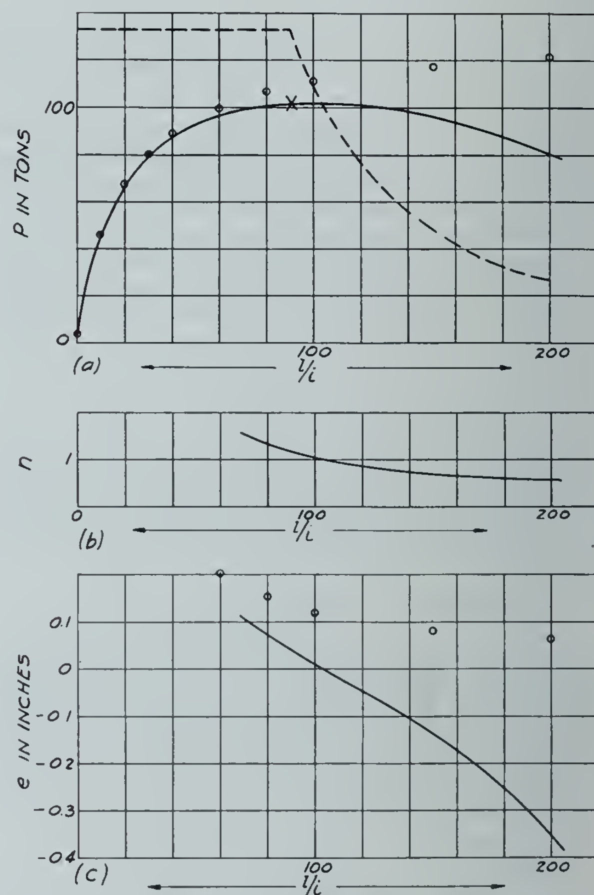

Fig. 13—Comparison between strength P, fixity ratio n, and eccentricity e, for side legs of a culvert analyzed, (1) as a column (superposition not applicable) represented by solid line, (2) as struts (superposition assumed applicable) represented by circles.

The result of solutions for varying values of l are shown graphically in Figs. 13a, b and c. The cross (x) on the solid line curve of Fig. 13a marks the value for $\left(\frac{l}{i}\right)_{cr}$ = 90.6. It appears from Fig. 13a that, for all values of $l/i > 103$, e becomes negative by the time the load grows to be large enough to induce in the column the elastic limit stress s_1. The graph of Fig. 13a is particularly elucidating. It shows that for a range of values for l/i extending from l/i = 70 to l/i = 150 the value of P varies no more than 6 per cent. The dashed line of Fig. 13a shows the Euler values for column AD (Fig. 12) based on the assumption that the column is ideally pin-ended. The values permitted by all design formulae lie below the ideal Euler curve. It would seem, then, that these design formulae for values of $l/i > 100$

are unduly conservative. This seems especially true in light of the fact that the example just discussed was selected with a view to giving to the column a loading pattern as unfavourable as we can imagine.

For small values of l/i the side legs of the culvert, Fig. 12, would be regarded as beams rather than as columns. That is, the principle of superposition would be assumed to apply, and some elementary strength theory, such as area moments or end moment distribution, would be used to find the moments which act at top and bottom of the vertical beams. If so computed, the moment at the corners of the culvert, Fig. 12, is:

$$M_1 = \frac{wl_1^3 I}{12\ (lI_1 + l_1 I)}$$

The elastic limit stress in the vertical beam is:

$$s_1 = \frac{P}{A} + \frac{Mc}{I} = \frac{P}{A} + \frac{wl_1^3 c}{12\ (lI_1 + l_1 I)} = \frac{P}{A} + \frac{Pl_1^2 c}{6\ (lI_1 + l_1 I)}$$

Therefore $$P = \frac{6s_1 A\ (lI_1 + l_1 I)}{6\ (lI_1 + l_1 I) + l_1^2 cA}$$

If we substitute the constants pertaining to the beams shown in Fig. 12, this expression reduces to:

$$P = \frac{133(2034\ \frac{l}{i} + 1243)}{(2034\frac{l}{i} + 1243) + 41170}$$

From the fundamental relation, $M = Pe$, we obtain

$$e = \frac{1}{6}\frac{Il_1^2}{(lI_1 + l_1 I)} \text{ or } \frac{24860}{(2034\ l/i + 1243)}$$

The graphs of these equations are represented by small circles on Figs. 13a and 13c respectively. It is thus seen that for small values of l/i the elementary theory, which assumes the principle of superposition to apply (small circles in Fig. 13a), and the more correct theory, based on the fact that the principle of superposition is not applicable (solid line Fig. 13a), give identical results for the limiting case when l/i approaches zero, give nearly the same results for values of $l/i < (l/i)_{cr}$, and give widely differing answers for values of $l/i > (l/i)_{cr}$. The graph represented by the small circles approaches the value $P = s_1 A$ asymptotically, while the solid line graph approaches the Euler curve asymptotically which in turn makes an asymptotic approach to the value $P = 0$.

Figure 14 shows curves similar to those of Fig. 13 for a culvert with longer and thus more flexible beams and with correspondingly lighter columns. The beams are 24-W.F.-100 lb. and the columns are 10-W.F.-21 lb. The proportions are again such as to insure failure in the columns rather than in the beams. Note that the maximum stress in the beam, when the column fails, is of the order of magnitude of 18 tons per sq. in.

The foregoing theoretical discussion is supplemented with experimental results presented in detail in the appendix. Figure 22 shows the results of tests on two columns that were identical except for the condition of end restraint. One column was tested under conditions simulating as closely as possible the ideal pin-ended column. Its strength experimentally determined agrees very closely with the value prescribed by Euler's formula which is marked x on the curve. The other column, identical with the first except that it was flat ended, manifests a strength three and a half times as great as that of the pin-ended column.

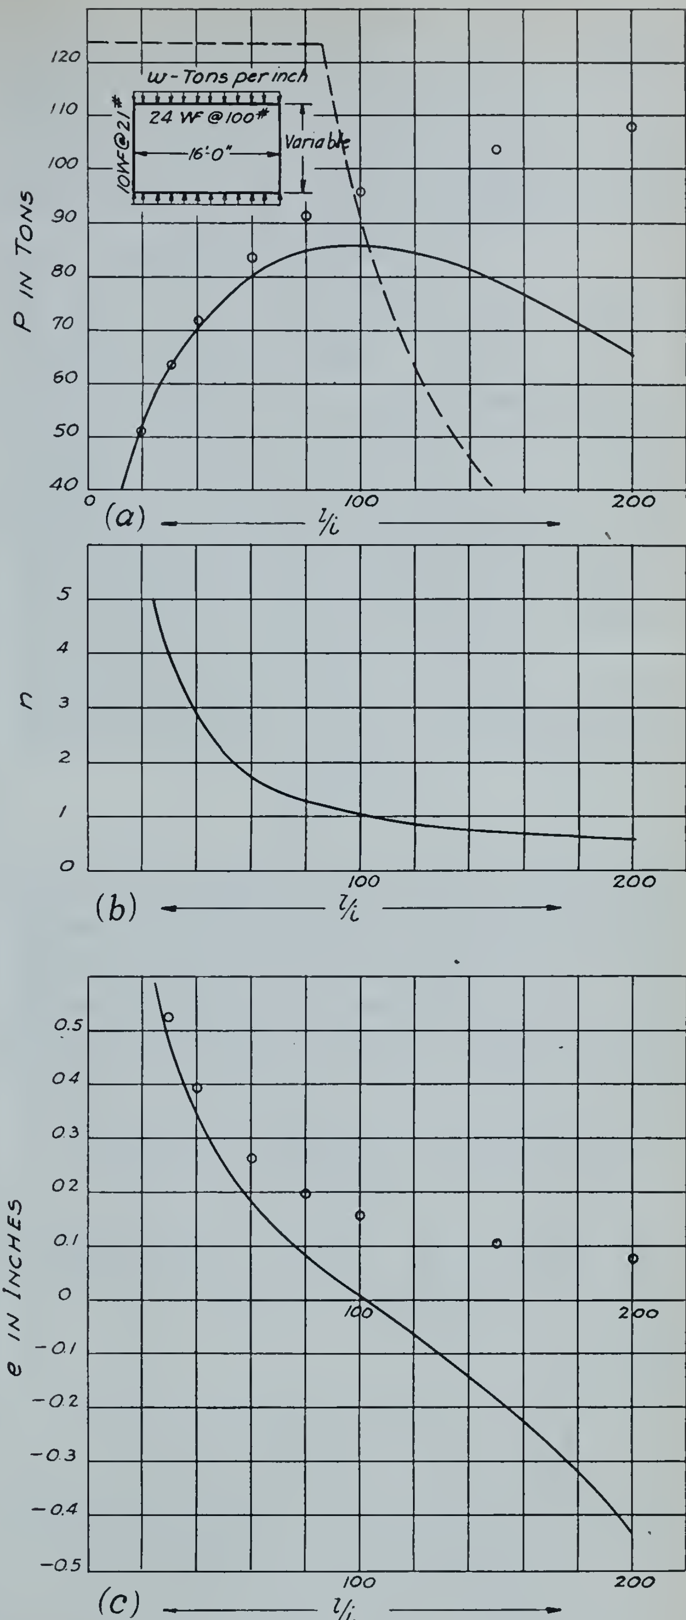

Fig. 14—Comparison between strength *P*, fixity ratio *n*, and eccentricity *e*, for side legs of a culvert analyzed, (1) as a column (superposition not applicable) represented by solid line, (2) as struts (superposition assumed applicable) represented by circles.

Elastic Deformations of Columns Subject to Critical Loading

When a prismatic, ideally pin-ended, column is loaded concentrically it remains substantially straight until the critical load is reached. Then it deforms unhampered under the action of this constant critical load. The load-carrying capacity of the column does not begin to diminish until the curvature becomes acute enough to cause the elastic limit stress s_1 to be induced in the column. When that condition is reached the column continues to deform under a decreasing load. The curves on Figs. 16 and 17, representing load-deformation curves for actual columns, illustrate this column behaviour. The author wants to direct particular attention to the curve on Fig. 16 which is labeled $l/i = 198$.

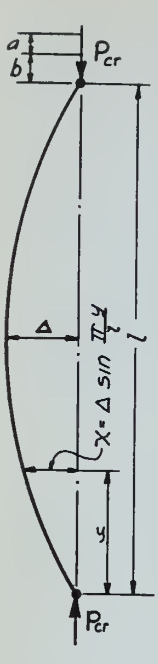

Fig. 15

The horizontal part of this curve is defined by two vertical lines labeled B and C. This horizontal distance BC represents the elastic deformation of the column under a constant load. This deformation is of vital importance in the theory of limit design. It is this quantity which we propose to discuss and for which we shall develop a formula.

As the concentric, axial, loading is applied to the column, illustrated in Fig. 15, the load waxes from zero to P_{cr}. During this stage of the loading the column remains substantially straight and the deformation marked a (Fig. 15) is $a = \frac{P_{cr}l}{AE}$. (The distance AB on curve $l/i = 198$, Fig. 16, represents the quantity P_{cr}/AE). Once the load P_{cr} is attained, the column assumes the shape of a pronounced sine curve. The column buckles, kicks sidewise, or a wow represented by $\triangle$ develops. Simultaneously the point of application of the load moves through a distance b. It is the relationship between b and $\triangle$ with which we are here primarily concerned. Note that, as both quantities b and $\triangle$ develop, the load P_{cr} remains constant. The work done by P_{cr} then equals $P_{cr} \times b$. The stress on any section of the column is given by the formula

$$s = \frac{P_{cr}}{A} + \frac{Mv}{I}$$

In this formula the term P_{cr}/A is constant while M varies as a function of $\triangle$. (v is the distance from the neutral axis of a cross section of the column about which the bending takes place, and is measured perpendicularly to this neutral axis. It varies between zero and c, the distance to the extreme fibre, and is positive when measured to one side and negative when measured to the other side of the neutral axis). The total elastic energy of the deflected column is

$$\int_A\int_l \frac{s^2}{2E}\, da\, dy = \frac{1}{2E}\iint\left(\frac{P_{cr}}{A} + \frac{Mv}{I}\right)^2 da\, dy$$

$$= \iint\frac{P_{cr}^{\,2}\, da\, dy}{2EA^2} + \iint\frac{2P_{cr}Mv\, da\, dy}{2EAI} + \iint\frac{M^2v^2\, da\, dy}{2EI^2}$$

Since $\int vda = 0$ the middle term is zero.

The first term,

$$\int_A\int_l \frac{P_{cr}^{\,2}\, da\, dy}{2EA^2} = \frac{P_{cr}^{\,2}\, Al}{2EA^2} = \frac{P_{cr}^{\,2}\, l}{2EA} = \frac{P_{cr}\, a}{2}$$

This is the energy stored in the column due to the direct compression effect. All that remains is the third term, or

$$\iint\frac{M^2v^2\, da\, dy}{2EI^2} = \int_0^l \frac{M^2\, dy}{2EI}$$

This, then, is that part of the total elastic energy stored in the column attributable solely to the buckling phenomenon. Since the load P_{cr} remains constant while the column buckles, the work done by this load equals $P_{cr} \times b$. By virtue of the law of conservation of energy, this expression for energy ($P_{cr} \times b$) must equal the elastic energy expression $\int_0^l \frac{M^2\, dy}{2EI}$ (Note that the principle of superposition is not involved in this logic. The only approximations here made are those commonly accepted in column theory. We regard l as constant and replace dl by dy).

$$P_{cr} \times b = \int_0^l \frac{M^2\, dy}{2EI} = \int_0^l \frac{(P_{cr}\, x)^2\, dy}{2EI} = \frac{(P_{cr}\, \triangle)^2}{2EI}$$

$$\int_0^l \left(\sin\frac{\pi y}{l}\right)^2 dy$$

$$= \frac{(P_{cr}\, \triangle)^2\, l}{4EI}$$

$$\text{Thus,}\quad b = \frac{P_{cr}\, \triangle^2\, l}{4EI} = \frac{\pi^2 EI\, \triangle^2\, l}{4EIl^2} = \frac{\pi^2\triangle^2}{4l}$$

The maximum curvature of a sine curve occurs at its midpoint and amounts to:

$$\frac{1}{R} = \frac{\pi^2\triangle}{l^2} = \frac{s}{Ec}\,.$$

Thus, $\triangle = \frac{sl^2}{\pi^2 Ec}$ in which s represents the stress increment in the extreme fibre at the midpoint of the column. This stress increment is due solely to curvature or to bending. The column already carries a stress equal to P_{cr}/A. The stress increment which it can suffer, therefore, without exceeding elastic functioning of the column is $s_1 - \frac{P_{cr}}{A}$ or $s_1 - s_{cr}$. Substituting this value for s in the above expression ($\triangle = \frac{sl^2}{\pi^2 Ec}$) we have

$$\triangle = \frac{(s_1 - s_{cr})\, l^2}{\pi^2 Ec}$$

Substituting this last expression for $\triangle$ in the expression $b = \frac{\pi^2\triangle^2}{4l}$ we obtain:

$$b = \frac{(s_1 - s_{cr})^2\, l^3}{(2\pi cE)^2}$$

The average axial deformation (not to be mistaken for strain), the distance BC shown in Fig. 16, is

$$\frac{b}{l} = \left\{\frac{(s_1 - s_{cr})\, l}{2\pi cE}\right\}^2 \qquad \text{Formula 6}$$

Computations given in Table I for the distance BC or b/l are made for the $1\frac{1}{2}'' \times 1\frac{1}{2}'' \times \frac{1}{8}''$ angles. s_1 and E are taken to be 40,000 lb. per sq. in. and 29,500,000 lb. per sq. in. respectively. At the time of the test (before Formula 6 was developed) the particular direction of the buckling of each individual column was not noted. Thus in applying Formula 6 to the curves of Fig. 16, two values of c are possible and b/l values are computed for both c_1 and c_2, which have been calculated for the particular dimensions of each angle column. On the curve for $l/i = 306$ it may be noted that the large double circle is within the distance BC. That the horizontal portions of the curves on Fig. 16 appear to be longer than the calculations indicate may be due to the very gradual decrease of the load-carrying capacity of the columns after the elastic limit has been passed.

Table I

l	l/i	s_{cr}	c_1	c_2	b_1/l	b_2/l

Conclusions

The requirement that a theory, to be acceptable, should agree with practice is not only good business but it is the first requirement of sound philosophy as well. To substitute for practical conditions laboratory tests which fail to simulate accurately conditions of end restraint as they occur in practice, and to assign preferential value to such tests over theoretical analysis may be open to serious question. Our theory is predicated on the assumption that the columns are prismatic, homogeneous and elastic. The argument that such a theory does not rigorously apply to wooden columns or riveted columns is readily conceded. The vast majority of columns, however, are either H-sections, W.F. sections or tubes. The reliability of the theory of elasticity in connection with column tests, when the assumptions which are involved are rigorously satisfied, is too well established to be open to question.

We draw two major conclusions—one as to sense of value and the other as to theory. In regard to sense of value the bothersome question of eccentricity may be dismissed when we substitute its equivalent, namely the coefficient $n = L/l$. While we found that we could replace eccentricity e with a coefficient n, we cannot so replace initial crookedness e'. We thus find e' incorporated in our general Formula 5. The initial crookedness, e', seems to have received more attention in the literature on the subject than it deserves. Do we not inevitably introduce a factor of safety, which factor covers a multitude of uncertainties? It is supposed to neutralize our doubts concerning dimensions, material, workmanship, assumed loading, theory, etc. Is this factor, initial crookedness, so dominant that it demands special treatment? Are we not justified in covering the uncertainty of initial crookedness by a factor of safety? The committee on Steel Column Research of the American Society of Civil Engineers[6] apparently thinks this should not be done. Its final conclusion, No. 6 (Vol. 98, p. 1461), reads: "For columns bent in single curvature, an eccentric ratio of $ec/i^2 = 0.25$, to include both crookedness and eccentric application of load, and a free length of three-fourths the full length for riveted connected members are suggested as reasonable values for ordinary trusses". The author is inclined to interpret this recommendation as founded on empirical data and in contradiction to sound logic. To introduce one factor (ec/i^2) which would weaken the column and another ($n = L/l = 3/4$) to strengthen it, especially in the light of our claim of identity of the two factors, appears clumsy if not illogical. The author personally inclines to taking account of eccentricity by a proper selection of coefficient n and to ignore initial crookedness, or rather to cover any uncertainty as to initial crookedness by means of the factor of safety. Our test results appear to support this contention. We show, by crosses (x) on Fig. 4, the maximum values of P/A obtained from the tests on pin-ended 1½″ x 1½″ x ⅛″ angles as they are recorded in Fig. 16. Figure 21 shows another such curve obtained from run-of-the-mill specimens. Such initial crookedness as was present in the test specimens apparently did not materially affect the strength of the columns.

As to theory, we may have presented little new, unless it be a new sense of value of the theory. Everything we have said points to the supremacy, the all sufficiency, of Euler's equation. Our form of Euler's equation, which gives the value $P/A = s_l$ for all values of $(l/i \leqq (l/i)_{cr}$, may be unconventional, may even be new, but it is nevertheless Euler's equation. Since this paper is not directed to any special field of engineering, the author leaves to the engineer in any special field the problem of determining the coefficient n for his type of construction if he should wish to do so. We merely point out that this cannot be done in the laboratory. It could be done by testing actual structures to the point of destruction. It can also be done in many cases, with a high degree of precision, in the manner we have illustrated. The author is inclined to the opinion that for many types of construction our column design formulae are too safe, too conservative, which he regards as the greatest engineering sin second only to that of not being safe enough.

Acknowledgement

Acknowledgement is expressed to Mr. P. C. Hu for his faithful and very competent assistance; to Mr. C. M. Goodrich, M.E.I.C., Consulting Engineer of the Canadian Bridge Company, for his untiring interest and inspiration; to Mr. L. A. Paddock, President of the American Bridge Company, and to the Horace H. Rackham School of Graduate Studies of the University of Michigan for financial support and encouragement.

APPENDIX

The objectives aimed at in the tests herein described are two-fold. 1. To secure definite and predetermined eccentricities or concentricities which would remain constant throughout the entire loading range from zero load to well beyond the failing load. 2. To obtain load-axial deformation relationships for a load range extending from zero load to well beyond the maximum load.

The device used to obtain the first objective, that of definitely controlled eccentricities, consisted of partial spheres through which the load was transmitted to the specimen. As the column began to deflect the partial sphere rolled on the bearing block. The point of application of the load on the partial sphere naturally shifted, but so long as the partial sphere was not permanently deformed, so long as it remained perfectly elastic, the resultant of the load passed through the centre of the partial sphere. One of the problems was to locate definitely the centre of the partial loading sphere in a pre-determined position on top and at bottom of the test specimens. In the tests on one-inch round columns this was accomplished by making the partial sphere an exact semisphere and providing it with an extension into which a hole was drilled either concentrically or with a pre-determined eccentricity. The bottom of the hole coincided with the plane of the semisphere. Figure 17 shows the arrangement schematically, while Fig. 25 shows a photograph of an eccentrically loaded specimen in the testing machine. In the tests on angle irons the location of a predetermined eccentricity or concentricity was accomplished in the following manner: The outline of the cross-sectional area of the angle iron was first carefully located and then cut out of a brass templet of 6 in. diameter and ⅛ in. thickness. The templet was slipped over the specimen. A steel bearing plate of 6 in. diameter and ⅜ in. thickness was then placed on the column. Into this bearing plate was machined a concentric depression of a depth of ⅛ in. and of a size just big enough to contain the partial loa sphere.ding This partial loading sphere was not a semisphere, but had its centre located at the bottom of the bearing plate, that is, at the top of the specimen. The bearing plate was lined up by tightening a steel band around the templet and bearing plate jointly. Figures 16 and 21 show this arrangement schematically, while Fig. 24 shows a photo of a specimen provided with this loading apparatus.

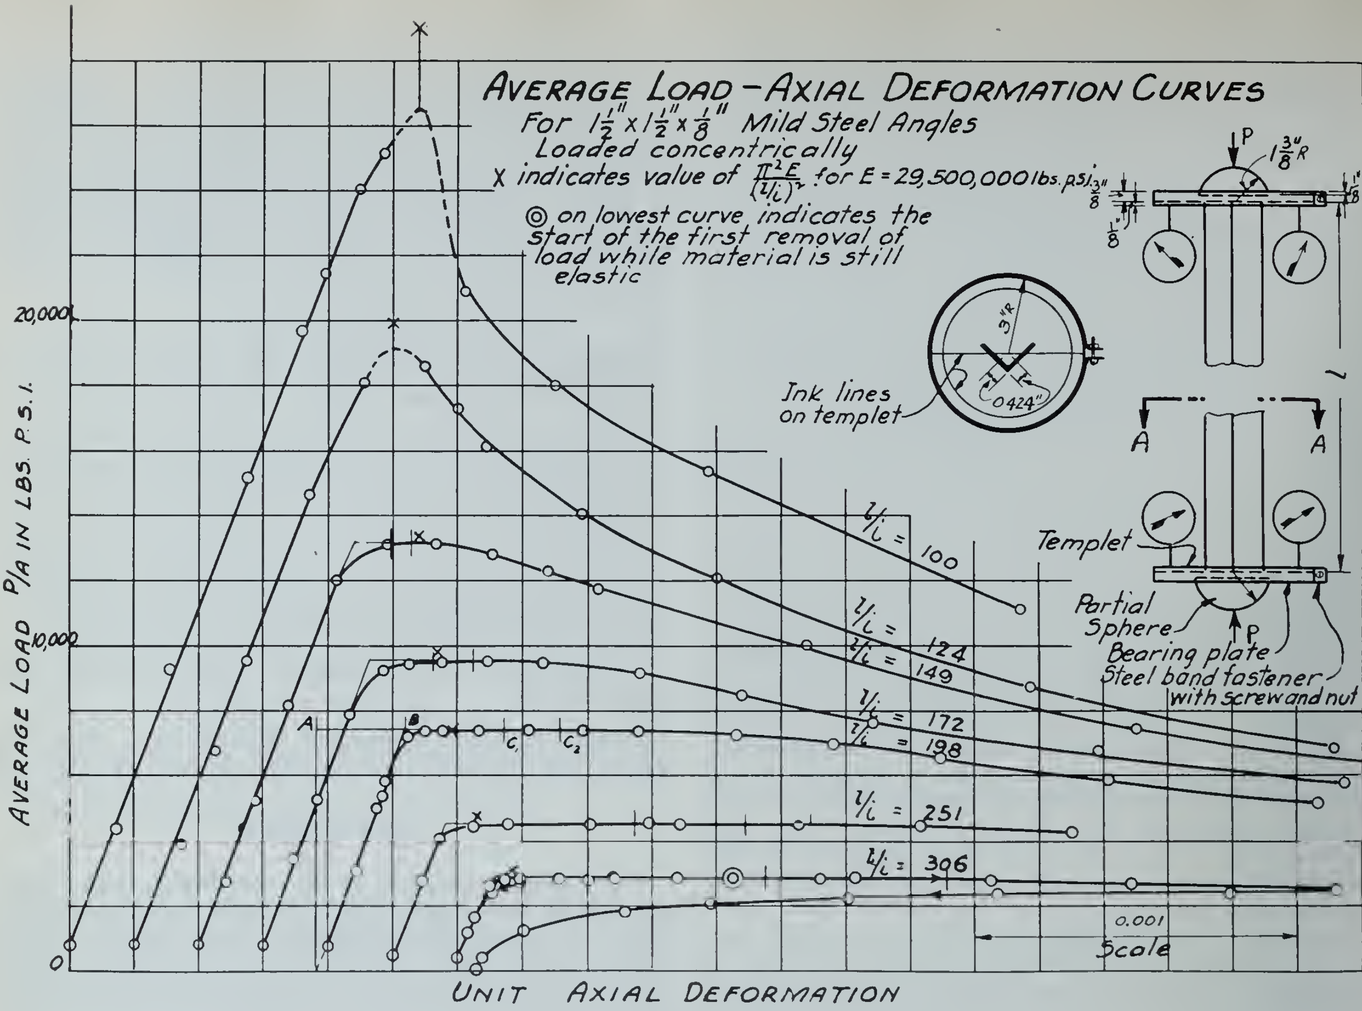

Fig. 16

The specimens tested consisted of one-inch rounds and 1½ by 1½ by ⅛ in. angles of mild structural steel and of 3 by 3 by 9/64 in. silicon steel angles. If these times had been normal we might have attempted to obtain specimens from the mill and be assured that they were from one rolling. As things were, we obtained the entire supply of one-inch rounds and of 1½ by 1½ by ⅛ in. angles from the University of Michigan storehouse, while the 3 by 3 by 9/64 in. angles were generously supplied by the Canadian Bridge Company of Walkerville, Ontario. The lack of special care in the selection of specimens is an important point to keep in mind in judging the test results. The specimens were literally common run-of-the-mill variety. Flaws such as dents and lack of straightness, it would seem, would likely be greater in our test specimens than they would be in specimens of more normal proportions. The one-inch round specimens suffered one defect common to hot-rolled stock in that, though they were nominally round, they were actually somewhat elliptical. The hot-rolled stock was nevertheless selected in preference to the cold-drawn stock because the annealing of cold-drawn stock ten feet in length appeared impracticable. Keeping in mind the inevitable imperfections of the specimens the results seem highly gratifying.

Figure 16 shows the test results on the 1½ by 1½ by ⅛ in. *angles concentrically loaded*. We were fairly successful in securing a very nearly zero eccentricity. This was apparent from the fact that, though all specimens naturally buckled about the minimum axis of moment of inertia, some failed with the outstanding flanges in tension and others failed with the outstanding flanges in compression.

Another and significant check on these tests are the theoretical values for the Euler load which are indicated by a cross on the curves of Figs. 16 and 17. Theoretically the slender column, after buckling, deforms under a constant load. This phenomenon is effectively illustrated by the horizontal part of the curves for specimens of $l/i \geq 150$. Once the load-axial-deformation curve begins to dip down, the elastic limit stress in the column is exceeded. On the curve for the specimen of $l/i = 306$, Fig. 16, the large circle locates a position in the test when the load was gradually removed. Under a decreasing deformation all the experimental results fell at first on the original horizontal line. The return curve seemed to cut corners slightly, which could possibly, though not probably, be explained by hysteresis. Under zero load there was no observable permanent set, not even as much as 0.001 in.

The device used for the tests recorded in Figs. 16 and 17 is illustrated in Fig. 24. A 2 by 6 in. wooden plank, with an elliptical hole cut out in its centre, was firmly bolted to the

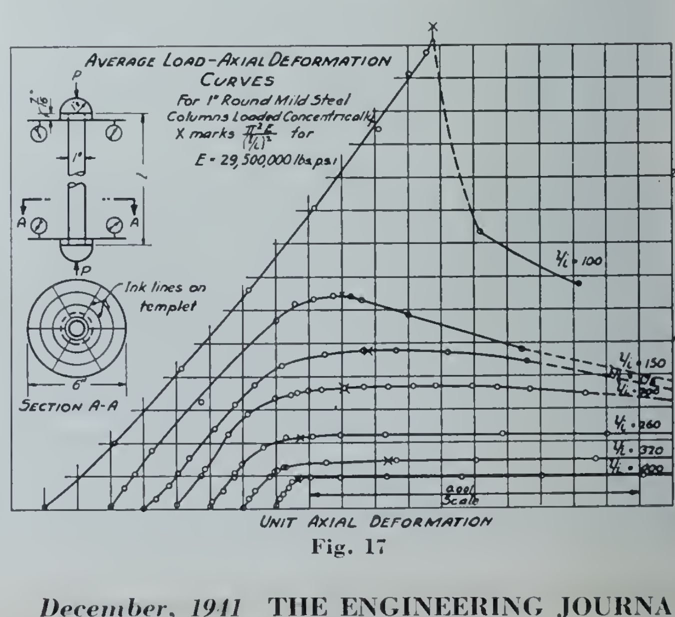

Fig. 17

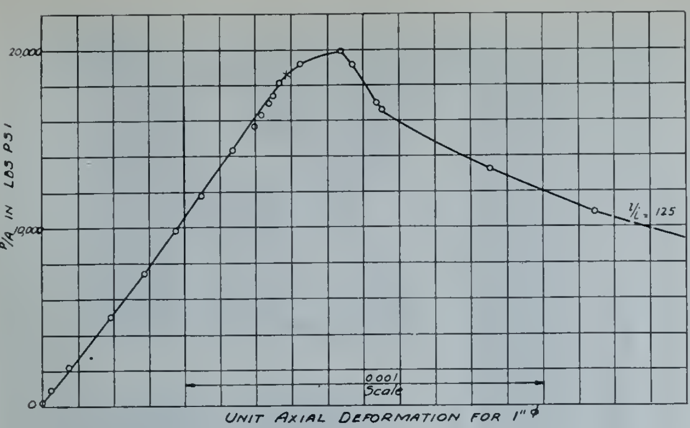

Fig. 18—Average load—axial deformation curve for one-inch round mild steel column.

rigid posts of the testing machine. This plank could be moved up and down and served as a table to support the top two dials. The dials were placed on a diameter of the brass templet, this diameter being initially bisected by the line of action of the load. After the column starts to buckle the specimen rolls away slightly from its original position, causing a shift in the application of the dial points relative to the diameter of the templet on which they were at first placed. This shift called for correction in the reading after buckling commenced. This correction has been incorporated in all curves shown in Figs. 16 and 17. It may be noted, however, that the curve for specimen $l/i = 125$ is not shown in Fig. 17. Through oversight the readings necessary to make the aforementioned correction were not taken for this specimen. This curve for the round bar of an $l/i = 125$ is shown separately in Fig. 18 because, even though its horizontal scale is slightly in error, its vertical scale is correct. This vertical scale shows a test load greater than Euler's load. This appears theoretically possible under only one of two conditions. Either, first, the loading spheres are permanently deformed, or, second, the column suffers a slight eccentricity at the end and at the same time suffers an initial crookedness which more than neutralizes this eccentricity. The end eccentricity and wow effects may be of the same or of opposite sign. When of opposite sign the effect may well be a test load greater than the theoretical Euler load. We believe this to be the explanation for the load in excess of Euler's load in Fig. 18, since there was no evidence of a permanent deformation of the partial loading sphere.

Figure 19 shows test results of one-inch round bars loaded with an eccentricity of 3/8 in. or an ec/i^2 ratio of 3. Figure 25 shows a specimen in the testing machine. The test results parallel the theoretical curve fairly closely. That there is not closer agreement between theory and test in this instance is the result of an error which was not discovered until after the test. The zero readings of the Huggenberger gage (shown in the photograph) were taken after the specimens in the machine were subjected to a slight initial load. The stresses, therefore, were all higher than those indicated by the gage, and this is why the experimental curve falls above the theoretical one. These curves would not be shown or discussed if Fig. 19 did not also contain a curve for the limit load, the load corresponding to the state of

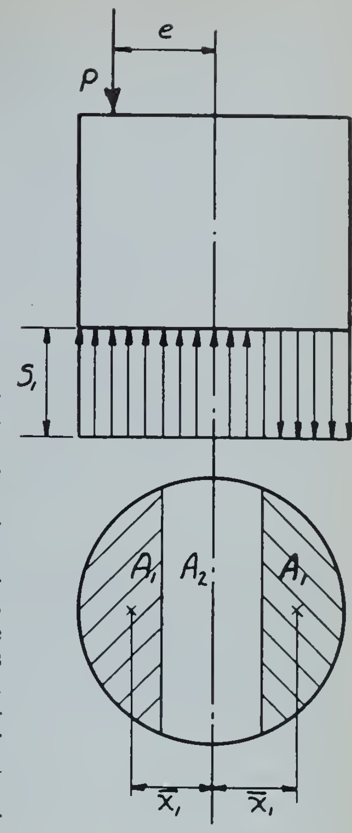

Fig. 20—Stress distribution over section of eccentrically loaded round column under limit load.

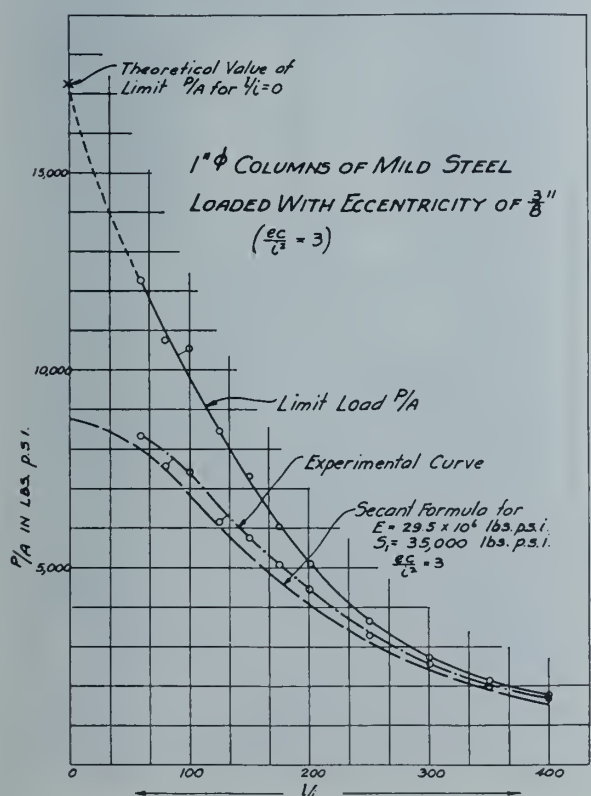

Fig. 19

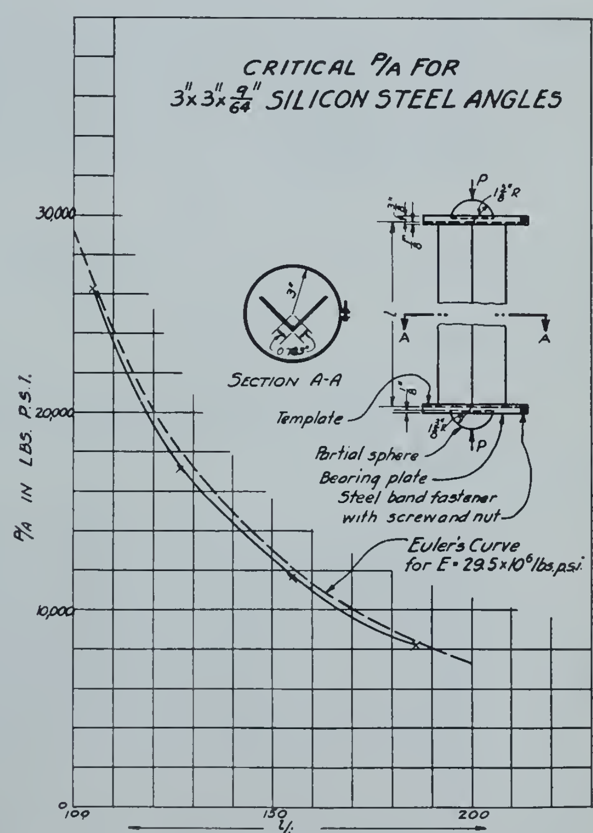

Fig. 21

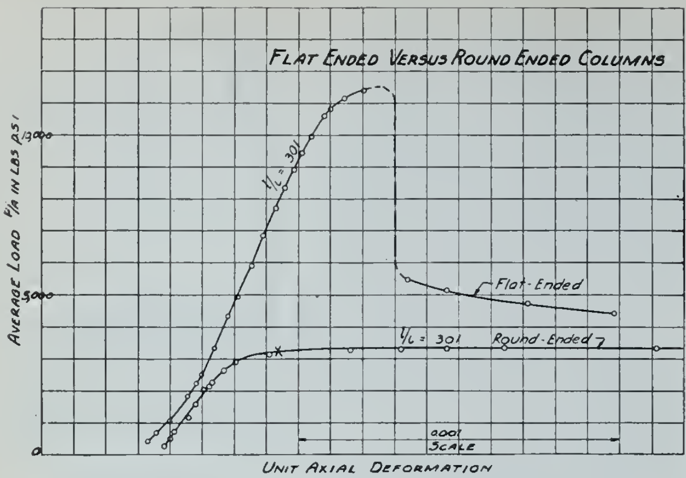

Fig. 22

completely ductile stress distribution in the columns. The limit load curve represents the maximum values of P/A obtained in the tests. This curve is not affected by any initial load readings. Of the three curves shown in Fig. 19 this is to us the most interesting one, and to the designing engineer the one of greatest significance. Only one value on the limit load curve could be theoretically determined, the value of P/A for $l/i = 0$. When $l/i = 0$ then the stress distribution over the cross section of the column appears as shown on Fig. 20. For this stress distribution the following conditions prevail:

$$s_1A_2 = P$$

$$2s_1A\,\bar{x}_1 = Pe$$

$$2A_1 + A_2 = A$$

Solving the above three equations simultaneously, we obtain

$$A_1\bar{x}_1 = (\frac{A}{2} - A_1)\,e$$

Fig. 23—Loading of flat-ended column after buckling.

In this last equation A and e are known, and A_1 and $\bar{x}_1$ form only one unknown, since either of them may be easily calculated if the other is known. The solution of these equations for a one-inch round column with an eccentricity $e = \frac{3}{8}$ in. yields the following result:

$$A_1 = 0.272\ A$$

thus $$A_2 = A - 2A_1 = 0.456\ A$$

and $$P = s_1A_2 = 0.456\ s_1A$$

Finally $$\frac{P}{A} = 0.456\ s_1$$

With the yield point of the one-inch round specimen at about 38,000 lb. per sq. in., the limit P/A is:

$$0.456 \times 38{,}000 = 17{,}300 \text{ lb. per sq. in.}$$

It appears, in agreement with theoretical considerations, that the critical load P, when the elastic limit stress is first attained, and the limit load P, when the state of complete ductility in the column is reached, are very nearly the same for slender columns. However, there is a very marked difference between them in case of short columns. This is a vital consideration in the theory of limit design.

Figure 21 shows Euler load values obtained from silicon steel 3 by 3 by 9/64 in. angle specimens. Under a full load of 20,000 lb. the

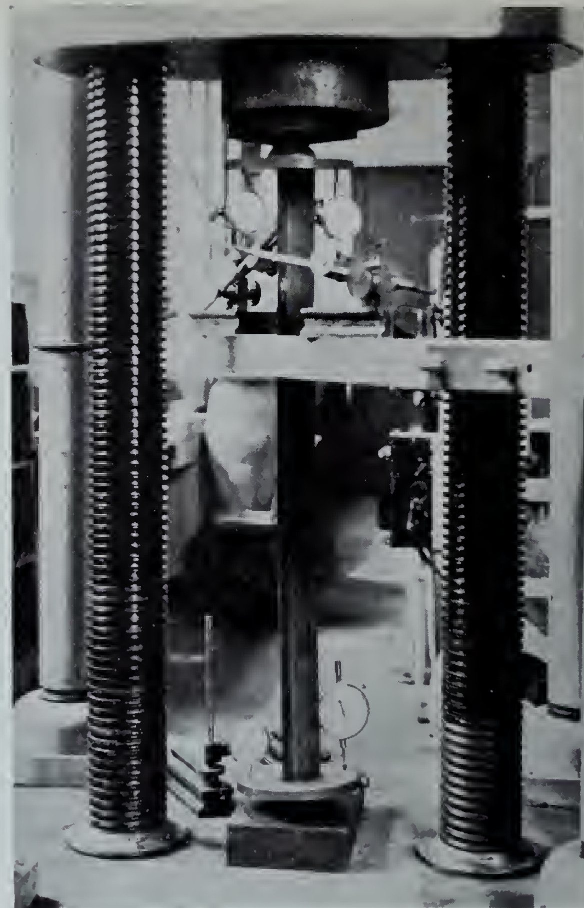

Fig. 24—Tests of steel angles.

Fig. 25—Eccentric-loading tests.

specimens could still be easily turned by hand about the axis of loading. Again we were successful in loading with an eccentricity which was nearly zero, as some of the specimens failed with the outstanding flanges in compression while others failed with the outstanding flanges in tension. All of those which failed with the outstanding flanges in compression manifested twisting, as may be observed in the photograph, Fig. 26. It is of interest to note that this twisting, this secondary failure of the flanges, did not commence until after the specimen had failed as an Euler column.

Figure 22 shows load-axial-deformation curves for two identical one-inch round specimens. *The one was tested with spherical ends.* The other specimen was tested with flat ends. So long as the flat ends remain parallel we have the equivalent of a fixed-ended column. Note that the maximum load of the flat-ended column is 3.5 times greater than that of the theoretical pin-ended one. The most striking feature of the test, to us, is that for the flat-ended specimen the load drops suddenly once the maximum load is reached, but for the spherical-ended specimen it remains constant while the deformation increases. After the flat-ended specimen fails the load drops markedly, to be sure, but it remains greater than the critical load of the pin-ended column of the same length. This fact is as theory prescribes. Once the flat-ended column fails the loading condition undergoes a sudden and radical change. The column then is neither flat-ended nor pin-ended, but definitely becomes a column loaded with a pronounced negative eccentricity (see Fig. 23). This column loaded with a negative eccentricity naturally offers greater resistance than the one loaded with zero eccentricity.

Under the heading Theory, Tests and Practice, we discussed the inadequacy of laboratory tests because of failure to simulate actual working conditions. The author wonders whether the common idea, that column load-carrying capacity is suddenly destroyed when the column buckles, is not due to an erroneous picture created by over familiarity with flat-ended column tests. Such flat-ended column tests give a wrong picture of characteristic column behaviour because the flat-ended column neither simulates assumed theoretical conditions nor actual conditions as met with in practice.

Fig. 26—Column failures.

MUNICIPAL MANAGEMENT AND THE ENGINEER

JEAN ASSELIN, M.E.I.C.
Town Engineer and Manager, LaTuque, Que.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, on October 30th, 1941.

Only 25 per cent. of city managers are engineers. The remaining 75 per cent. is composed of men whose ability is not questioned. The city manager profession stands by itself. Even city managers would not accept in their association engineer members just because they are engineers. The question arises, why are there not more engineers in the field of government and specially municipal government? After all, the engineer is the link between capital and labour. Why then should he not be the link between government and the tax payers?

Engineers have been calculating, designing, translating facts into figures and figures into facts, with the result that steam, electricity, and gasoline have transformed the world we live in. They have done it so quickly that very few realize even the physical evolution of the community.

Mr. G. S. Mooney has recently described very clearly the growth and frantic progress which changed the nature of urban life in Canada.* He points out that the most important of our national resources, and the one in terms of which all others have to be judged, is human life. He remarks that the safety, welfare and happiness of the Canadian people are the end for which all these resources are merely instruments. The manner of life of our people, the problems they face, and the hopes and desires they cherish for improvement in their existence and the advance of our civilization, should be the supreme concern of government. In that spirit, let us discuss a special form of local government which has been in existence for the last quarter of a century.

There is no doubt that the inventions which characterize our age have changed our ideas of values such as space, time and money. Modern inventions being the product of a minority, it was quite natural that the philosophy of the majority could not keep pace with progress. While industry was improving its efficiency, government seemed to be lagging. Social internal strains followed. We saw industry wanting to industrialize government and government trying to democratize industry. The war has brought a truce. But we should not forget that engineers have some responsibility in this matter, because they have put in the hands of the masses tools which have brought havoc to the world.

Unfortunately, there is, amongst certain business men and politicians, a feeling that engineers, in their operations, forget about the human factor. Some of us have experienced that handicap. Not only do aldermen and members of Parliament think we are not practical; if they look at us as ingenious fellows, they also view us as very active spenders of public funds.

Some industrialists have mentioned this weakness of our profession. For example, Dr. Walther Mathesius, Vice-President, United States Steel Corporation, of Delaware, speaking last year at a sectional meeting of the Society for the Promotion of Engineering Education,** said " While these technical graduates can solve specifically assigned and difficult engineering problems, their trained engineering mind tends to focus narrowly upon their task in its designing, construction or production phases and it fails to grasp the importance of essential economic, sociological and other fundamental relationships. Yet it is frequently more important, in industry, and so much more in government, that the needs for an improvement and its consequences, if made, be carefully and intelligently analysed in their commercial, social and

* G. S. Mooney—Our Cities, Their Role in the National Economy —*Engineering Journal,* Aug. 1941, pp. 394-399.

** *Engineering Journal,* Sept. 1941, p. 439.

economical aspects rather than the mechanics of the proposal be designed to the highest degree of perfection and precision."

Even in our own society, the question has been asked why so few engineers concern themselves with public affairs. How many of us would dare step into the ring of organized politics? How many of us would consent to run or be run by party machines? Actually if an engineer showed himself on the hustings with his plans, and his reasoning as his only weapons, he would fall an easy prey to the foxy politician. Years of concentration on technical matters have tended to produce in us an inferiority complex towards the electoral side of public affairs.

There is another reason why engineers have kept away from government. We feel that democratic methods have been distorted in the hands of unscrupulous politicians, who rely too much on human nature and not enough on science in solving the problems of government.

The present world conflict has put our institutions to the test. Many of the flaws in our social set-up are more evident than in peace time. If public interest has now focussed on local government, let us take advantage of this, with the proviso that we, city managers, take for granted that democracy should be defended in peace as well as in war.

Before considering local government, we should agree on some general principles related to democracy. These are:

1—Democracy does not mean lack of power; it does not mean debate without decision.

2—There is no danger in power, if only it be not irresponsible.

3—Authority is commensurate with responsibility. In fact, the best form of democratic government, is one in which a man, to keep his office, must achieve open and honest success.

In municipal government a fundamental distinction between legislative, executive and judiciary activities, as defined in the constitutions of both Canada and United States, has been successfully put into effect in the council-manager form of government. Self government does not mean taking a hand in everything, any more than housekeeping means cooking one's own dinner.

The International City Managers' Association explains the plan thus:

" The central idea of the council-manager plan is a far-reaching attempt to resolve the apparent conflict between democracy and efficiency. Democracy is preserved in the popular election of a small council, on a short ballot which does not overtax the capacity of the citizen to understand his government. Efficiency is achieved by the employment of a manager professionally trained for the technical job of administration. The danger of bureaucracy, irresponsible and unresponsive to the will of the community, is met by giving the council complete control of the manager's tenure in office. It is definitely understood that the council deals with administration only in a formal manner through the city manager, and that administrative functions are at no time delegated to committees or individual members of the council."

" The city manager is appointed by the council as a whole. The exercise of administrative authority is concentrated in this appointed executive who is accountable to the council. He provides the council with information which enables it to determine municipal policies, advises the council in matters of policy if the council so desires, and executes the policies determined by the council. He introduces the best principles of advanced administrative organization and practice, and is held responsible for the proper co-ordination of all administrative activities under his direction."

The duties of the city manager, as set forth in most council-manager charters, broadly stated, generally require him:

1—To see that all laws and ordinances are enforced.

2—To exercise control over all departments and in accordance with civil service regulations, appoint, supervise, and remove department heads and subordinate employees of the city.

3—To make such recommendations to the council concerning the affairs of the city as may seem to him desirable.

4—To keep the council advised of the financial condition and future needs of the city.

5—To prepare and submit to the council the annual budget.

6—To prepare and submit to the council such reports as may be required by that body.

7—To keep the public informed, through reports to the council, regarding the operation of the city government.

In addition the charter generally states that the manager is to perform such duties as may be prescribed by the charter or required of him by ordinance or by resolution of the council.

To summarize, the underlying principles which make the success of the plan are: separation of functions, delegation of authority and respect of the public will in formulation and execution. The elected council rules, the chief administrator carries out the decisions within the charter. The charter should reflect the will of the people. The people, to make decisions, must be well informed. There we have the closed cycle essential to democracy.

Elimination of patronage and a ban on the spoils system, by killing petty politics, clear the atmosphere for true democracy.

Managers through their association which acts as a clearing house, have carried the technique of management to a point which enables cities like Cincinnati, Westmount, or Outremont to boast with good reason. City managers have adapted tools to municipal administration such as budgetary control, cost accounting, planning, merit system, reporting, and so forth. Of course, managers do not pretend to have invented these methods, but it is in the council-manager form of government that we find them used most effectively.

To use efficiently such means as engineering and accounting, and to enforce legislation, managers depend on an unbroken chain of authority down to the last garbage collector. They have also devised a tool which is entirely their own, at least in the municipal field, for they have, on the administrative side of government, drawn a distinction between staff and line functions. This may be explained as follows: A foreman may know the ins and outs of his job, he may be a good leader of men besides, but if he has to lose time in computing figures, or compiling statistics, his overall efficiency will be reduced, even if he were also a good mathematician. To preserve that efficiency and to improve methods, managers usually appoint men, whose duty is not to command, but to report, whose role is not to spy, but to translate into standard measurements the activities of the complex machine which the modern city constitutes. Then, if reporting is done in the reverse direction of the delegation of authority, that is from down up, we have a check on the whole of the operations. Budgetary control working only one way is pure dictatorship. It is unjust to the taxpayer as well as to the employee. Drastic cuts in the budget may be called government by some, but in themselves do not constitute real administration.

With his mastery of these tools, the manager is ready, under the control of the council, for the job of " resolving the apparent conflict between democracy and efficiency."

Since the days when the taxpayers used to gather around the stove of the general store to fix the course of destiny, the democratic system has become more and more complicated. Decades ago, the people were the government. They made the laws and enforced them, and the laws were very few. Gradually direct-participation democracy was replaced by representative government, and full-time officials took over the task of administration. As the village grew a gap opened between the people and the government. Popular interest and vigilance weakened with the widening of the breach between the public and its representatives. Correspondingly, council members lost their sense of responsibility.

One day a political boss, with amateur ability, through vast unplanned public works, steered the ship of state on the shoals of financial trouble. His successor, a hitherto unknown financial wizard, saved the ship by throwing the sinking fund overboard. (After this encouraging debut, he discovered the original plan of meeting bond issues. . . . with bond issues.) All that time the public works department had been resting on a comfortable routine. To satisfy some candid electors, laws and by-laws, ordinances and resolutions had been passed and have filled unread volumes. The venerable charter, so often amended that its patches overlap, had become a cosy retreat for lawmakers, solicitors, barristers, attorneys and lobbyists. By that time the village had become a large city, proud of its achievements, proud of its legal labyrinth, proud of its fiscal puzzles, proud of its haphazard city plan, proud of its vice rackets. That is a pessimistic view of the hypothetical city the manager has had to reform with a new council not yet informed as to the virtues of the " govern as you go " formula.

Let us follow the reform step by step. First, the manager must be satisfied that the council is not opposed to the necessary measures for success. Second, he must draw up a chart of the organization. Then, get the council to describe in short and clear, though legal, form, the duties and functions of the executive and department heads. Third, with the powers thus conferred, the chief executive, with each department head, including welfare's, sets a tentative detailed organization chart, checking on the ability of the personnel. Fourth, he draws up a plan of work for each department, beginning with the treasury. An inventory of revenue together with a survey of the debt and a compilation of fixed charges, until extinction of the debt, will permit a hit and miss budget for the coming fiscal year. The legal department is set to work boiling down the hundreds of by-laws to plain regulations to be approved later by the council and codified. Usually a general overhaul of the police and fire departments, together with a new line up in public works may be considered good practice, though much tact must be used in seasoning the dish.

It will be found that budgetary control, cost accounting, planning, personnel administration, and reporting will restore balance in services. The personnel and the public will develop interest and pride in the work. The prestige of government and its representatives will gradually build up. In practice this goal will appear out of reach, but it may seem closer after a period varying from five to twenty years depending on the manager, the council, industrial depression, war, elections, and many other factors.

Finally, managers are not machines. If we blame the engineer for having neglected the human aspect of efficiency, the manager should be very cautious to avoid the same pitfall. It does not mean that the manager should indulge in the good-natured generosity of the politician, but he should not forget that he is dealing with men, in the highest form of civilization, the democratic. Therefore city managers are very touchy on professional etiquette.

The manager is in no sense a political leader. In order that policy may be intelligent and effective, he provides the council with information and advice, but he encourages positive decisions on policy by the council rather than passive acceptance of his recommendations.

He realizes that it is the council, the elected representatives of the people, which is entitled to the credit for the success of municipal policies and leaves to the council the defence of policies which may be criticized.

He keeps the community informed on municipal affairs but himself remains in the background.

The council-manager form of government was first tried in 1908 at Staunton, Virginia. The plan as known today functioned as early as 1913, in Sumter, South Carolina. On September 15th last, the profession counted 504 recognized manager-members. In the United States, one city out of five over 10,000 population, and 22 per cent. of the 92 cities over 100,000 population, now operate under the council-manager plan. The largest proportion, 27 per cent., is to be found in the cities of 50,000 to 100,000 population.

The National Municipal League, headquarters in New York, incorporated the manager plan in its Model City Charter as early as 1915. Since then it has conducted dozens of surveys in different cities where this form of government has been in effect. Comparative reports between the old and the new system and comparisons between cities, convinced the League that the council-manager form of government is the best and most democratic way of solving the municipal problem. The office of the League, 299 Broadway, New York, can furnish a complete list of publications which should prove of great value to members of the Institute interested in the improvement of the community. For many reasons this form of city government should appeal to engineers. It attracts and retains the best candidate aldermen.

We should apply to city management the opinion of Dr. Mathesius which he expressed as follows: " It is obvious that engineers must be effective technologists, but it is also necessary that this profession, in order that it may render creditable services to the interest of the nation, be able to recognize and analyze correctly the many varied and complex economic, commercial or human problems which beset the majority of industrial developments today. . . It is not enough to drive for cost reduction and improved production methods, but that systematic attention must, of necessity, be given to public and industrial relations, to personnel administration and to research in these directions as well as in strictly engineering matters. . . . all of these subjects must be considered as rightfully belonging within the sphere of technological influence."

Here is a challenge so direct that it cannot be ignored.

Whether we like it or not, democracy, like all human ideas, must develop with time. Progress in its physical manifestations has been free-wheeling during the last half century. The engineer must do his share in adapting physical progress to human needs. Only after machines and methods have been set to work effectively from a social standpoint, can we say that civilization has progressed.

There is no reason why the men who built the modern city should not supervise its operation, or at least, take a large part in its management, utilizing the facilities which they have put in the hands of the masses; having in mind the happiness of all, materially and socially.

(In the compilation of this paper, the author has been indebted to many fellow managers, from whose literary work he has taken very liberally.)

THE PORTLAND-MONTREAL PIPE LINE

WALLACE R. FINNEY
President, The Portland Pipe Line Company, New York City, N.Y., U.S.A.

Paper presented before the Montreal Branch of the Engineering Institute of Canada, on November 27th, 1941

The story of the pipe line began near Oil City, Pennsylvania, a few years after the famous Drake well was drilled in August, 1859. It was a primitive affair only a few miles long, made of two-inch wrought iron pipe, but it represented the faith and vision of its builders and from this humble beginning the pipe line industry has grown to 130,000 miles of main lines, moving close to 4,000,000 barrels of oil each day.

The early pipe lines were made of heavy iron with caulked and bolted joints but it was not long before steel pipe came rolling from the mills with threads and collars. This type of pipe was used for most of the lines that now serve every oil field on this continent and criss-cross the country in a binding network as an integral part of our national economy and defence.

The first pipe lines were limited to the movement of crude oil as the leakage through the various types of joints discouraged their use for gasoline and other refined products. This situation lasted for almost forty years but was finally changed by the development of the oxy-acetylene welding method, and it was not long before this new welding process was applied to pipe line construction in the field. Oxy-acetylene welding was introduced in 1914 with the electric method following a few years later and in a short time all lines throughout the country had welded joints from one end to the other.

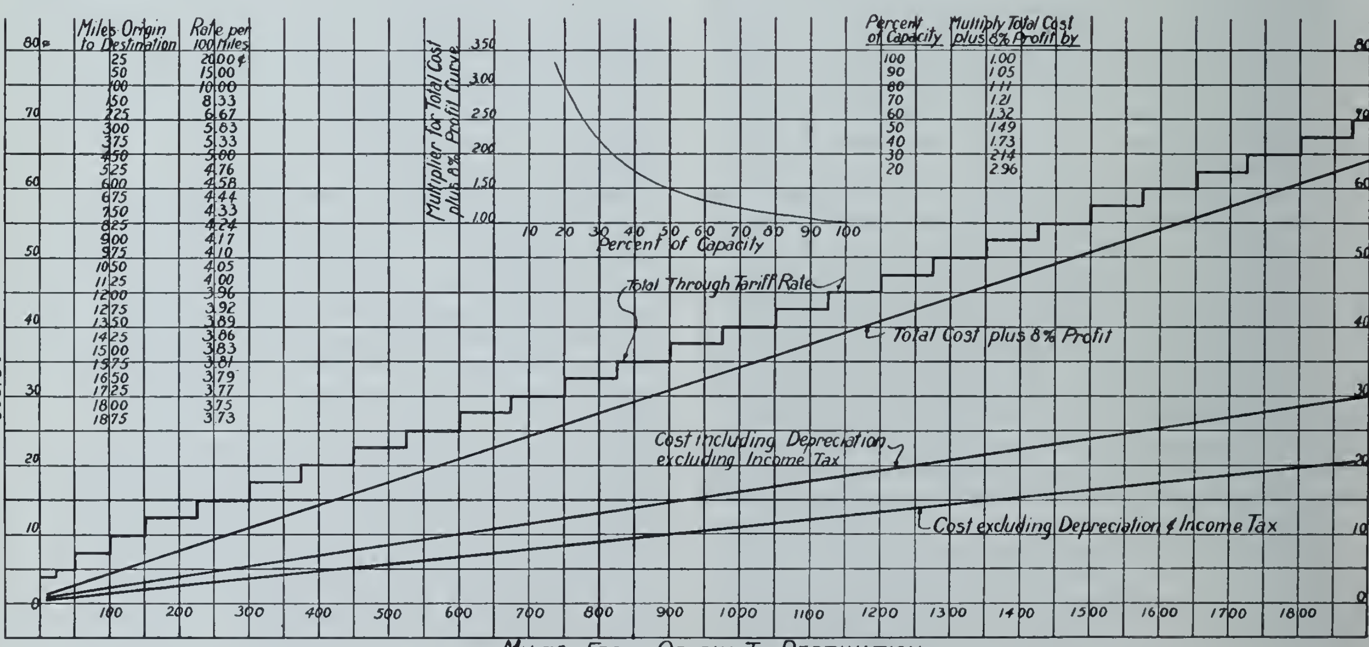
The success of welded lines led to their adoption for refined products. One of the first gasoline lines was laid in Wyoming in 1917 and while old pipe line men scoffed at the plan it was a complete success from the first and the pipe line loss which had proved such a problem in the early days was eliminated. From about 1920 it has been general practice to weld both crude and products lines and such progress led to the adoption of double-length joints of pipe to reduce the number of welds. This required improvements in actual welding technique to speed up the work and lower the cost, and while both gas and electric methods have certain things in their favour, the latter is more widely used.

Better welding required better steel which hastened the development of the specially rolled, electrically welded pipe made from plate, and was followed by the perfection of seamless tubing. With these improvements in material and workmanship it is now possible to lay a solid welded pipe line up hill and down, under rivers, and across plains without any fear of failures, nor is there any need to worry about the kind of joint as the plain beveled end, welded type is as strong as the pipe itself. These welds are free from metal intrusions, called icicles, and make a perfect joint.

The success of the welded pipe line allows the claim that it is a safe and satisfactory way to move crude oil and refined products across the country under almost any condition. This is especially true in times of trouble as a buried welded line is least subject to damage and interruption from outside causes.

The first pipe line in the early days of Pennsylvania was forced on the oil producers by the highhanded methods and exorbitant demands of the teamsters. This same competitive situation has existed through the years and even to-day no pipe line can expect to secure and retain any of the oil transportation business unless it can meet the competition of tankers, barges, railroads, tank cars, and trucks. This is a fundamental rule and determines the success or failure of any new pipe line project.

If we assume that a pipe line can meet competition, the next consideration is construction costs, then the probable operating expenses, and finally a return on the investment. The average costs of several different sizes of crude oil pipe lines together with the diesel engine-driven reciprocating pumps, are shown in Table I. These figures compiled in June, 1941, must be revised to meet the higher labour and material costs in effect to-day. They are on a basis of 50 per cent standby capacity in pumping equipment which is often required to meet the summer and winter fluctuations as well as to handle oils with different pumping characteristics. The deliveries in barrels per day, shown in Table I are based on 36 gravity A. P. I. Mid-Continent crude with working pressures up to 1,000 lb. per sq. in. and the usual station spacing of approximately 30 miles, with allowance



NOTE: These estimates were made in June 1941 and must be revised to meet increased Labour and Material Costs since then.

Fig. 1—Chart showing the theoretical tariff required for crude oil pipe line operation based on 10 in. pipe.

These figures were compiled June, 1941, and must be revised to meet increased labour and material cost since then.

for differences in elevation. Working pressures and wall thickness of the pipe depend on the grade of steel and, in this study, follow a factor of safety of four. The operating figures shown in the right half of Table I are based on using an average rate of depreciation of 3¼ per cent, which is generally allowed for crude oil pipe lines and the last figure in each case indicates the revenue necessary to return 8 per cent on the investment after an allowance for income taxes. This table shows that the cost per barrel for a single 100 miles is higher than the cost per 100 miles as a part of a 1,000-mile line. This is to be expected as overhead, office and general expense cost per barrel is lower for the longer distance. The figures given are estimates based on general experience with various size lines handling different crudes at many locations and must be modified by existing conditions if used as a guide for any new project.

The theoretical tariff required for crude oil pipe lines is shown in Fig. 1. The interpretation of this chart requires some explanation. For example, if oil is to be moved 500 miles the chart indicates that the revenue needed to cover operation expense, income taxes and profits will be 17.5c. per barrel. This serves as a guide in establishing the tariff but in so doing the varying load factor must be considered which makes it necessary to set the tariff slightly higher, at 22½c. per barrel. This has been worked out on a zoning system which allows a certain freedom in meeting the competitive rates of other pipe lines and carriers. This means that the tariff of 22½c per barrel can cover a zone from 450 to 525 miles, and the same pattern can be used for other distances. Various modifications on account of load factor, location, line size and kind of oil must be made.

There is one conclusion that can be drawn from the many years of pipe line operation and that is, they must meet competition and in so doing are entitled to a reasonable return on a fair valuation. This varies for different locations, and short-lived projects require a higher earning to prevent loss. Pipe lines should be allowed a liberal fluctuation in their net earnings to carry them through bad years and protect them against unforeseen difficulties.

The comments in the preceding paragraphs have applied to common pipe line practice and can be further amplified by a few remarks on the Portland-Montreal pipe line.

This project was first conceived because of the tanker shortage and was decided upon as a means of delivering crude oil to the Canadian refineries in Montreal without interruption during the emergency period brought on by the war. Therefore it can be properly classified as a defence measure. It has the additional advantage of providing year round service whereas the St. Lawrence is closed to oil-carrying tankers about five months each winter. The Portland-Montreal line has a further claim in that it eliminates the 12-day tanker haul of 2,000 miles around

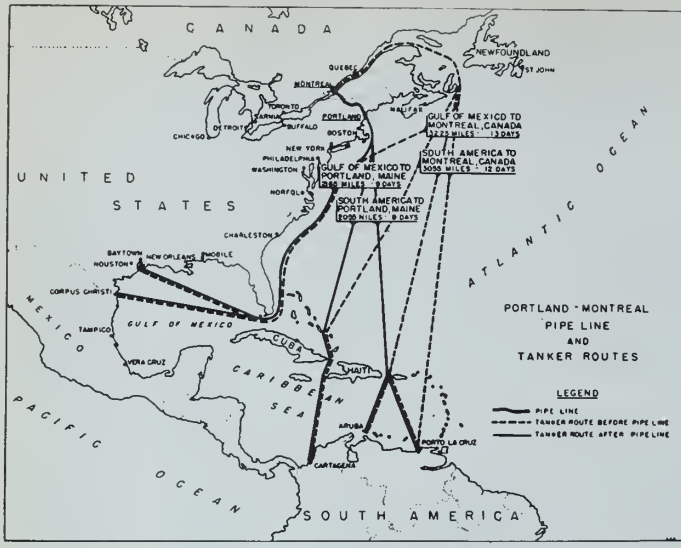

Fig. 2—Map showing normal tanker route from South America to Montreal.

Nova Scotia and results in a net saving of four ocean-going tankers. This is important when boats are needed for so many purposes. The normal tanker route from South America and the Gulf Coast and its relation to the Portland-Montreal line, and the St. Lawrence river, is shown in Fig. 2. The new line in relation to the existing pipe line system in the United States and Canada is shown in Fig. 3.

When the decision was made to build this line, the first step was to select the best route, and an aerial survey of the area from Portland, Maine, northwest to Montreal was made. This proved that a straight line could not be followed as it was necessary to work out a route through the mountain gaps to maintain reasonable difference in elevation. The early reconnaissance work was followed by the land survey and the mapping which was used in securing the right-of-way. The actual route of the line and the location of the pump stations are shown in Fig. 4.

While the route was being selected, the engineers in charge of the design and construction completed the specifications and placed the orders for all the pipe and equipment needed. It was decided to lay a 12-in. line, which has a normal delivery of 60,000 barrels per day when handling a light grade of crude oil. This system called for eight pump stations, two of which will be driven by diesel engines. The other six are motor driven as electric power is available at these localities. All of the pumps are of the reciprocating type as the line must handle several different

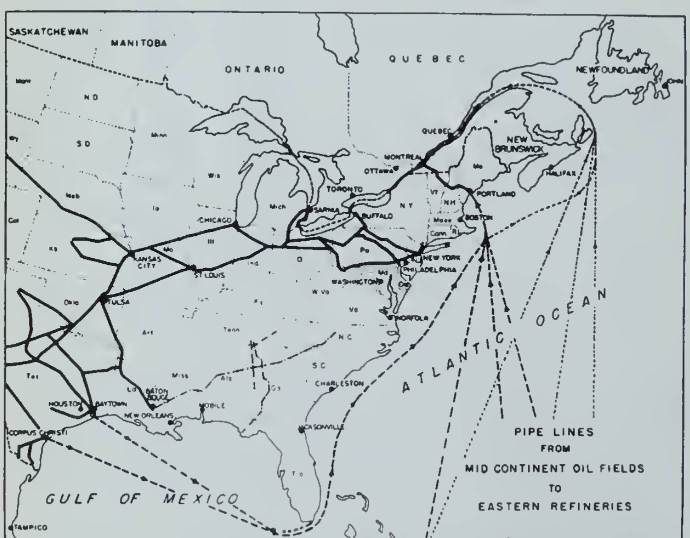

Fig. 3—Map showing Portland-Montreal pipe line in relation to the existing pipe line system in United States and Canada.

grades and gravities of crude oil, some with high viscosities which eliminate the use of centrifugal pumps, especially during the severe months of winter. The line will not be heated in the winter so the oil must have a cold test below 32 deg. F.

After all the new material and equipment was ordered it was a simple matter to let the contracts for the construction of the line. Pipe line contractors are a hardy lot and are willing, and at times even anxious, to take a contract at a flat price per foot to construct the entire line. This practice was followed and the two contractors hauled the pipe from the railroad stations, strung it along the route, dug the ditch, welded the pipe and laid it in the trench, then backfilled it, all subject to the usual inspection and supervision of the Pipe Line Companies' representatives. The pipe line construction programme, which was handled by Williams Brothers and the Oklahoma Contracting Company, was started in July and finished in October.

In addition to the pipe line which is 236 miles long and the eight pump stations referred to, the Portland Pipe Line Company was obligated to provide a complete terminal for sea-going tankers. Casco Bay, at South Portland, which has a channel open the year round was selected. This terminal necessitated dredging and the construction of a complete new pier, the erection of six 140,000-barrel steel

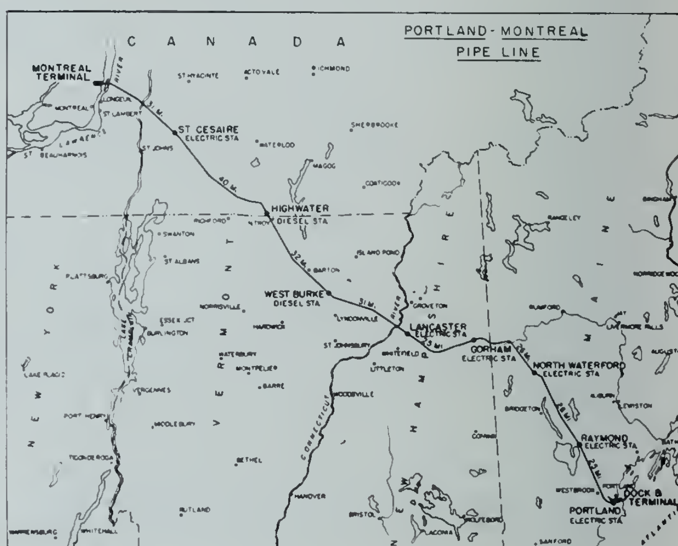

Fig. 4—Map showing the route of the new pipe line and the location of the pumping stations.

storage tanks together with a transfer pump at the water's edge and lines leading to the tank farm at the edge of the town where the initial mainline pump station is located.

All of the terminal work was done under the direction of Ford, Bacon & Davis, Consulting Engineers, and was planned and is being built to enable the Pipe Line Company to handle several grades of crude without delay night and day during the entire year.

The Pipe Line Company was also required to build a terminal at Montreal and made every effort to avoid interruption in service by laying double lines under the St. Lawrence river with separate distributing branches to each customer. This company will have its own complete office in Montreal and will function as an independent Canadian unit ready to serve the customers in every reasonable way.

The South Portland harbour, in its relation to the Atlantic Coast, is shown in Fig. 5, and the location of the pipe line across the St. Lawrence river and the several refineries in Montreal can be seen in Fig. 6.

The construction of the Portland-Montreal pipe line through the mountain country of Maine, New Hampshire and Vermont proved a difficult task. It is a beautiful country but a large part of it has solid granite only a foot or

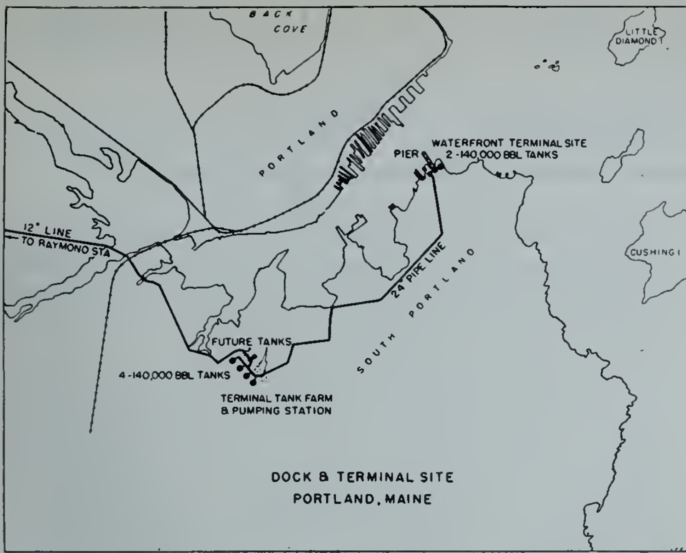

Fig. 5—Map showing the layout of the South Portland harbour.

two under the surface so when the contractors came through the country to dig the pipe line ditch it required rock work and blasting about 80 per cent of the way. The reverse was true in Canada as most of the route was through level productive farming country. In addition to construction problems there was a considerable delay in obtaining pipe line equipment. This was especially true of the large reciprocating pumps which forced the company to borrow motor-driven centrifugal units for temporary installation. The many difficulties in construction and installation were gradually overcome one by one by the experienced staff of pipe line engineers and contractors so that the entire line was welded and the pumps set in the record time of four months. This required long hours every day in the week and extra expense, but the effort was justified.

The first boat arrived in Portland harbour on November 4th, carrying a light grade Colombian crude oil but the new pier was not complete so it was tied up to the Pan-American dock and started pumping out its cargo into the Portland Pipe Line Company's storage tanks. The main line pumps were put into service on the morning of November 5th to test the pumping facilities and the pipe line leading to Montreal. The trial run was continued with some losses of oil and minor troubles for a number of days until the line was declared officially open at a ceremony in Portland on November 10th which was attended by Governor Sumner Sewell of Maine, and other notables. The oil reached Canada on November 16th and the line is now in steady service.

The Portland-Montreal pipe line is now in a position to serve the refineries in the Montreal area with crude oil, the products of which are so vitally needed in Canada's industrial life and defence activities. This transportation unit will make every effort to handle different grades of crude for all customers without delay or loss and stands ready to meet competitive methods of transportation at all times.

In our efforts to complete this economic link of defence between the United States and Canada we have had the

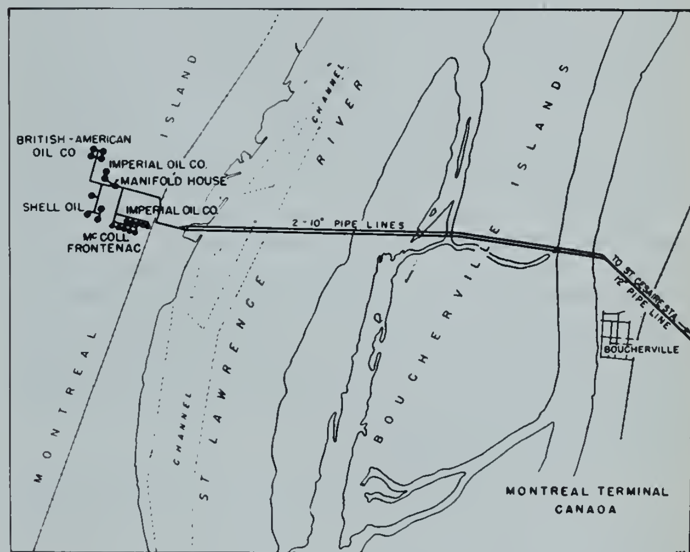

Fig. 6—Map showing the location of the pipe line across the St. Lawrence and of the refineries at Montreal.

wholehearted support and co-operation of all local, state, and national agencies of both countries, for which we are duly appreciative. This is especially true of the river, harbour and customs officials. Likewise, the author wishes to offer tribute to his company associates, Messrs. H. M. Stevenson, George Lee, J. H. Slaughter, A. H. Chapman, and all the others who made this early completion of a difficult task possible. We also are grateful to Mr. F. C. Mechin, M.E.I.C., Mr. Jack Simpson and our many friends in Montreal and Canada who have done so much to help us bring this project to a successful conclusion.

PLASTIC LAMINATED WOOD IN AIRCRAFT CONSTRUCTION

W. J. JAKIMIUK

Chief Designer, The de Havilland Aircraft of Canada, Limited, Toronto, Ont.; formerly Chief Engineer of the National Aircraft Corporation of Poland

Paper presented before the Toronto Branch of The Engineering Institute of Canada, on October 16th, 1941.

Wood is a natural grown material which has fine structural properties, but also some serious defects. Wood was the only material used by aircraft constructors at the earlier stages of aviation, but towards the end of the first world war other materials made their appearance. Mild steel in tubes and wires was always used in small quantities in aeroplanes; with the development of the art of welding, steel became a serious competitor of wood.

Soon after the first war chrome molybdenum weldable steels of high strength were developed, and competition between steel and wood increased. It became usual to make fuselages, undercarriages and engine mountings of welded steel tubes; wings and control surfaces were made of wood. This state existed until about 1925. At that time, light alloys made their appearance in the aircraft industry. Aluminum and magnesium alloys were known much earlier, but their application had not been extensive. When steel had replaced wood in fuselages light alloys began to push wood out of the wing structure. This struggle between wood, steel and light alloys resulted in victory for the latter when the so-called stressed skin construction was developed.

In earlier aeroplanes, there was a main structure or frame and a skin which existed only for streamlining purposes and did not contribute to the strength. It was found that the total weight could be reduced, if the skin and frame both participated in the structural strength of the aeroplane. The separate frame disappeared and the stiffened skin transmitted all forces. Light alloys were particularly suitable for this stressed skin construction, which started about 1930, developed very quickly especially in the United States, then was adopted on the European continent and was accepted in England rather reluctantly and quite lately. In fact, even today several well-known English aircraft are not of the stressed skin type, for instance the Vickers " Wellington " and the Hawker " Hurricane." It may be said that since the beginning of the second world war light alloys have almost entirely eliminated wood from aircraft construction except in some types of light planes and in the Italian aircraft industry where wood was used because of the shortage of aluminum.

This temporary passing of wood out of aircraft construction may be explained by the defects of wood which limited its use in modern aeroplanes. About 1935 new methods in wooden aircraft construction made their appearance. Certain new synthetic resins were applied in wooden construction with great success, opening an era in which the employment of wood has been revived.

In order to better understand the influence of synthetic resins on wooden construction we may note some properties of wood. One of its main advantages for aircraft construction is high strength-to-weight ratio. Spruce, one of the best aircraft woods, has a tensile strength parallel to grain, 9400 lb. per sq. in., and specific gravity 0.40. Thus its strength-to-weight ratio is 23500; for high tensible steel the figure is 22900 and for duralumin 22100. One of the most valuable properties of wood is its excellent shock and vibration absorbing quality. Unfortunately, wood is not homogeneous. Its cells are arranged in longitudinal fibres and the molecular bond between cells is greater along the grain than normal to the grain. The strength of wood in tension is considerably higher than in compression and the strength parallel to the grain is higher than that normal to the grain. These directional variations of strength create considerable difficulties in aircraft construction. The greatest disadvantage of wood is change of volume and strength caused by variation in atmospheric conditions and in its moisture content.

The crushing strength of green or wet spruce is increased over fourfold merely by drying. In addition, timber changes its dimensions and tends to warp or crack with variation of its moisture content. Alternate shrinking and swelling causes unpleasant working of the wood. Radial shrinkage averages about three fifths as great as tangential shrinkage, but is many times greater than longitudinal shrinkage. Many physical defects diminish the structural value of wood. These defects are: knots, pitch pockets, wavy, curly and interlocked grain, mineral streaks, etc.

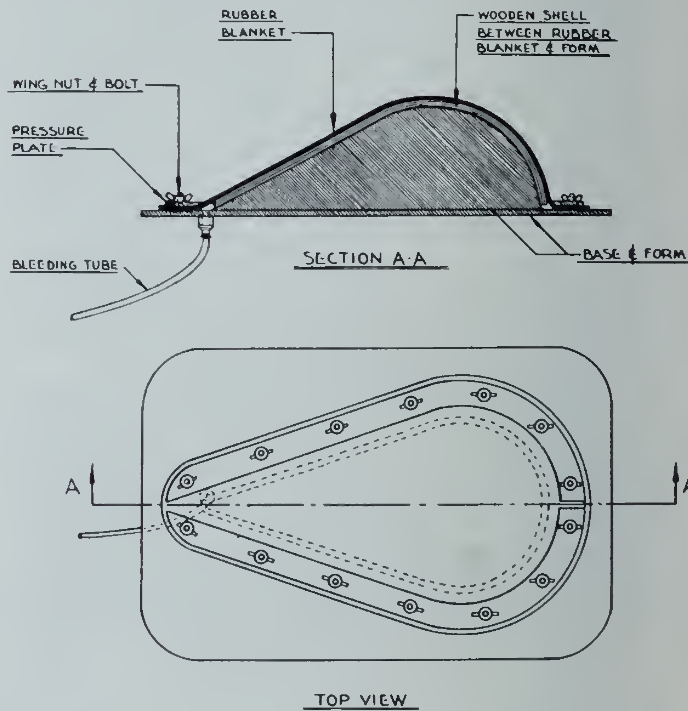

Fig. 1—Diagram showing method of moulding with male die.

Wooden structures in aircraft construction are held together mainly by glue. The average engineer is apt to treat glues and gluing with contempt. Even the aeronautical engineer often considers glue as being rather unreliable. Actually, there is no reason to doubt the reliability of a properly glued joint which has been designed with sufficient gluing area to take ultimate stress.

There are two main types of adhesives, reversible and irreversible. The former has the peculiarity that the bond produced may be loosened at any time by dissolution or softening of the bonding agent, because no setting takes place. Adhesives of this type are, for instance, gum arabic, fish glues, hide glue and thermoplastic cements such as acetyle cellulose.

The irreversible type is characterized by a chemical reaction within the adhesive during the gluing process which results in a setting of the glue. This type is represented by animal albumen glues (coagulation of albumen at the gluing temperature), by casein cold glue (chemical

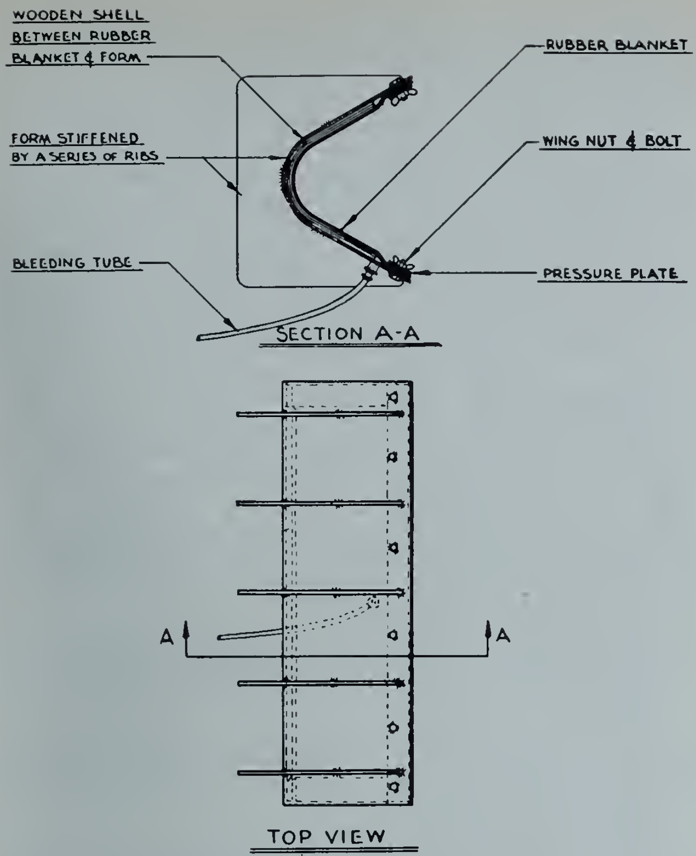

Fig. 2—Diagram showing method of moulding with female die.

bondage of protein by alkalies), and by phenol formaldehyde (resin stage C reached through condensation and polymerization). When gluing timber the bonding forces existing in the glue joints are forces of molecular adhesion between the closely contacting surfaces (specific adhesion) and a purely mechanical connection caused by the interlocking of minute glue pillars which become imbedded in the open pores and cells of the contacting surfaces (mechanical adhesion).

Adhesives used in earlier periods of aircraft construction were albumen glues and casein glues. Joints made with these adhesives were quite strong but not resistant to water and bacterial decay (mould), a great disadvantage of wooden aeroplanes in the competition with metal aircraft.

Wood is a very easy material to work with. It does not require highly skilled labour and costly tools and where only a small quantity has to be made wooden construction is much cheaper than metal. But considerable difficulties arise when great quantities of aeroplanes are needed and a quantity production method has to be devised.

The greatest difficulty in applying quantity production methods in wooden construction was the impossibility of forming wood by presses, hammers, etc., methods easily applicable to sheet metal materials. This, with such disadvantages of wood as non-homogeneity of strength properties, variation of volume and strength properties with the moisture content, physical defects, unreliability of animal glues and unsuitability for quantity production hindered the development of wooden aircraft construction for many years.

The most serious obstacle was the unreliability of the glues then available, but when this difficulty was overcome others could be easily dealt with.

The return to the use of wood began with the advent of adhesives made of synthetic resins, which are either based upon phenolic formaldehydes (so-called bakelite), or upon urea formaldehydes or carbamides. During their transition period from the soluble stage (stage B) to complete condensation or polymerization (stage C), these synthetic resins make excellent adhesives for timber.

Synthetic resins are the only glues which are moisture resistant after solidification and are immune to bacterial and mould attack. Their inherent strength may be used for improving the natural strength of timber.

The advent of synthetic resins started a new era in wooden aircraft construction and after considerable efforts made by engineers most of the disadvantages of wood have been eliminated. The lack of uniformity of strength of wood, its susceptibility to variation of moisture content and lack of homogeneity because of physical defects, are remedied by employing laminated wood. This material is made of wooden veneers sliced or rotary cut, assembled with a proper adhesive under pressure. In modern wood construction synthetic resins are used almost exclusively. By a suitable arrangement of veneers, combining different thicknesses, using different kinds of wood and disposing grain at suitable angles it is possible to build wooden panels and beams of fairly uniform strength and of constant shape and volume; the strength and moisture resistance of this material is greatly improved by the presence of synthetic resins.

The experimental work in modern wood construction is carried on by several organizations in this country, for instance, in the National Research Council by Mr. W. T. Reid, under the supervision of Dr. Parkin; in the Massey Harris Company by Mr. Lezier and Mr. McIntyre, and by the Experimental Department of de Havilland Aircraft of Canada. The author's connection with the latter company enables him to describe some of its work.

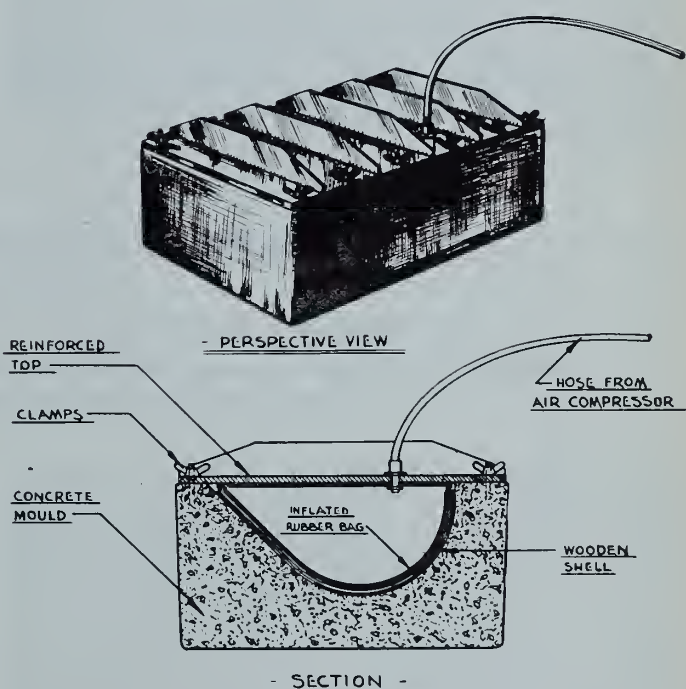

Fig. 3—Diagram showing method of moulding with "cold set" adhesive.

Experiments are carried out with three objects: finding the best arrangement of veneer in composite laminated panels, determining the most suitable adhesive and developing production methods comparable to methods used in metal construction.

A series of systematic tests have been made on composite panels made of Sitka spruce and yellow birch veneer. The effect of different factors has been investigated and among them the influence of angle of grain with the direction of main force applied, thickness of veneer, etc. Composite panels of very satisfactory and

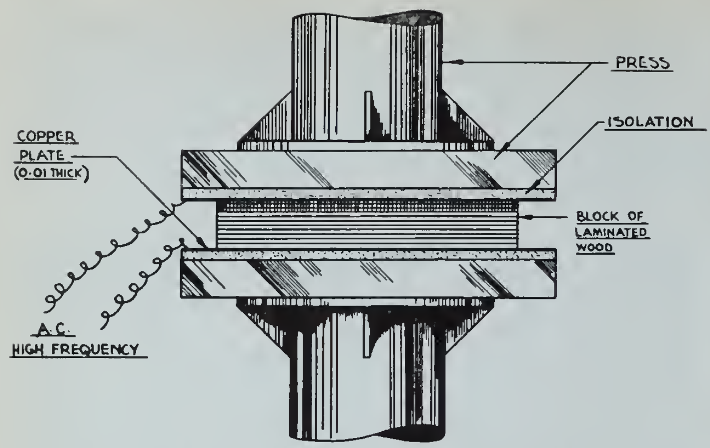

Fig. 4—Diagram showing method of moulding with high frequency electrostatic process.

uniform strength have been developed. The tensile strength of spruce panels was raised from 9,400 to 12,000 lb. per sq. in. and the compressive strength from 5,000 to 8,000 lb. per sq. in. Tests were made on adhesives of different kinds. Phenol formaldehyde or bakelite resins of Canadian make have given good results. All phenolic adhesives tested were of the hot setting type. A solution of fusible resin is used for assembling veneer. In order to pass into the final insoluble stage the resin must be cured at about 300 deg. F., after which it becomes insoluble and when heated again does not melt. After extensive tests it has been found that bakelite resin TR. 9066 is very suitable for manufacturing composite laminated panels.

A large family of urea formaldehyde resins was investigated and it was found that glues manufactured by the Plaskon Company, Toledo, Ohio, give very good results. There are cold setting Plaskon glues which do not require hot cure and are very convenient for the assembly of aeroplane components.

Considerable work has been done in elaborating processes which may make large production of wooden aeroplanes possible. A method which is being extensively tried is that of moulding in a pressure tank.

Let us assume that a double curvature surface, for instance a part of a streamlined fuselage skin, is to be manufactured. A wooden form of the required shape is made. Strips of skin veneer 1/32-1/16 in. thickness are laid in several layers on the form, and are spread with a solution of resin and dried. The form, with veneers, is put in a rubber bag with a valve. The bag is closed and the air is exhausted from the bag. Then the bag, with the contents, is put into a pressure tank (autoclave). The interior of the bag remains in communication with the atmosphere. Steam under pressure of about 70 lb. and temperature about 300 deg. F. is admitted to the tank, supplying the pressure and heat necessary for curing the resin. After a suitable interval of time the bag is removed from the tank and the form taken out of the bag. The veneers laid on the form are found to be moulded into a smooth rigid surface of the desired shape. Another method of forming laminated surfaces makes use of a female die and the result is much the same.

If urea resins are used, only 220-230 deg. F. temperature is needed and in that case, a combination of steam and compressed air is used.

Another very promising process is in preparation, in which the curing heat is generated by a high frequency electro-static field of about 50,000,000 cycles. The pressure is applied by a hydraulic press.

The Experimental Department of the de Havilland Company is making a wing for one of the metal aeroplanes in production in this country using moulded plastic wood construction. Other experiments are under way and there is reason to suppose that there will be a new branch of aircraft industry based on the product so abundant in this country contributing to the war effort and helping to put an aeroplane within the reach of the average man.

CO-OPERATIVE ENGINEERING EDUCATION*

DOUGLAS F. MINER

George Westinghouse Professor of Engineering, Carnegie Institute of Technology, Pittsburg, Pa., U.S.A.

An address delivered at the Sixth Annual Meeting of the Allegheny Section of the Society for the Promotion of the Engineering Education, Pittsburg, Pa., on October 26th, 1940.

The preparation of engineers for positions of responsibility in industry involves training in two steps. The first step covers the learning of general principles of technical and allied subjects, chiefly through recorded and spoken means, or in other words from formal teaching. Hereby the mental tools of the profession are provided, and instruction given for their use. Knowledge is imparted by telling or demonstrating what other people have found out or are at present doing. Laboratory and shop practice emphasize and supplement this information by having the student gain manual and visual verification of the findings of his predecessors. Knowledge then becomes a part of his own experience. So far he has made no productive contribution to society. As a physical analogy, he has been practicing in a gymnasium by lifting weights, swinging clubs, and flexing his muscles, acquiring strength and skill in their use, for later application to useful pursuits. He has not yet shoveled any dirt or hoisted a load or felled a tree.

The second phase of training, just as necessary as the first, is learning through actual work how to apply the knowledge acquired. Such development may be a planned procedure under educational guidance, or it may be the trial and error and observation method of the individual in growing up in a job. Here what he does counts in dollars and cents for good or bad. When the exercise is over, the elements cannot be taken apart and put back on the shelf, as with laboratory equipment or the familiar constructional toys. The result stands as an irretraceable event. In this phase the student learns by doing and as his judgment and experience increase, his responsibilities grow. He learns to select and choose from the tools he has forged and sharpened in school to suit the problems presented.

The two parts of this educational problem are both essential and must be acquired either formally or by self-effort. The fundamental instruction can best be done on the college campus, where facilities and staff are available for this kind of work. It seems unnecessary and a duplication of facilities for industry to set up engineering colleges within the factory gates. Likewise, it is somewhat futile for the engineering college to maintain up-to-date shops and production facilities in which comprehensive instruc-

* Reproduced by special arrangement with the Society for the Promotion of Engineering Education.

tion can be given. Such equipment in industry is constantly changing, as are the engineering and manufacturing procedures that go with it; and what is the latest word to-day may be obsolete next year. Design procedure also changes rapidly, so that the materials and methods of to-day are gone to-morrow. Only the essential principles are of permanent value to the student. This part of the job, of adjusting the man to his work and teaching him to get desired results that are measured for good or bad in dollars and cents and not in A's and F's, can be left to industry for the most part. In fact, the detailed training desirable for one factory may be useless in another. Studying the methods of a foundry may be wholly unnecessary for a man entering a textile mill.

While it is clear that there are two distinct phases of technical training, it must not be concluded that the two are independent and unrelated. Co-ordination is useful and productive of best results. If the two parts of education are locked in separate brain compartments, the one will not supplement the other. The student must on one hand know why he is learning the principles of static mechanics, and in what kind of situations his knowledge may be applied. On the other side, he must " spot " in every new or puzzling practical problem, its breakdown into simple parts and must recognize into what classification the elements of the unsolved difficulty can be placed. Then he will be able to select the principles to apply, from his accumulated knowledge. Let us illustrate. The laws of heat dissipation by conduction, radiation, and convection will take on new significance when the young engineer goes through the process of calculating temperature rise in an electrical machine. And on the other side, when the engineer is confronted with failures of high-speed turbine blades, he will first consider that here is a combination of heat, alternating stress, impact stresses, and erosion of steam, which may all be in the picture. He will find methods of measuring the stresses and vibration amplitudes, will study how his chosen materials behave at the temperatures observed, and will then begin to apply principles of static and dynamic mechanics, thermal behavior of metals, and the metallurgical facts he may require, all resulting in a better design.

If he is having trouble with drying a lacquer, he will start brushing up on vapor pressures, rates of evaporation, and how these vary with temperature and humidity.

To bring about this element of co-ordination, between scientific principles and their use, the various known plans of co-operative education have been devised. Interspersed or concurrent school and factory work have been thereby combined to give the needed twofold training.

The historical development of co-operative engineering courses was very interestingly related by Professor K. L. Wildes,* who states that the alternating or " sandwich " system of education existed in Scotland a century ago. The six months' university term was followed by a six months' work term, because of financial necessity. Any correlation between the work and school was incidental. In 1824 in this country Rensselaer Polytechnic Institute supplemented classroom work with inspection trips to selected factories as a means of illustrating classroom subjects. In 1868, Worcester Polytechnic Institute was established to teach skill in the industrial arts, along with training in science; and for that purpose a factory was built on the campus which manufactured articles for sale. Student apprentices supplemented the skill of journeymen artisans. This shop is still in operation, the students using the commercial facilities but no longer producing goods for sale. Then in 1880, Massachusetts Institute of Technology established a shop on the campus in which manufacturing methods could be seen and tried as laboratory practice by the students. Subsequently, most engineering schools included more or less campus shop practice in the courses offered.

There have been many types of co-operative courses in successful operation, each designed to follow a definite plan for the accomplishment of certain objectives. It should be recognized that the immediate purposes may not all be the same in co-operative education. Some plans have been expressly designed as a standard type of course for all or most students entering the institution. Courses and shop assignments must then be adapted to handling large groups of students. Other plans have been directed toward special training of a limited group of selected students, aiming at the development of the best that a combination of good human material and good special training can attain.

A description of the Cincinnati Plan and the Massachusetts Institute of Technology Plan will illustrate the principles of the two types, the standard course and the selective course.

The Cincinnati Plan, originating in 1906, started with a 6-week cycle of work and study, which was later changed to 4 weeks. The basis is an alternating four weeks of school, followed by four weeks of shop work, throughout the year, which is divided into three terms, 18 weeks, 16 weeks, and 18 weeks, with two vacations of one week each during the last week of each of the two 18-week terms. The course involves a total of five years' training, comprising 120 weeks of shop experience and the same amount of classroom work, all leading to a B.S. degree. The campus time is thus reduced from the usual 144 weeks to 120. This general plan with modifications has been adopted by more than twenty colleges, including Antioch, Georgia Tech, University of Tennessee, Alabama Tech, University of Akron, Newark, and Case. In some, the periods are lengthened to 13 weeks, or even as long as a semester (Alabama Tech). In all these plans, the students are grouped in pairs, having alternate schedules. One of each pair works, while the other is in school. In this way, a given factory job is continuously filled.

The Massachusetts Institute of Technology Plan was started in 1917 with Professor Timbie in charge, to develop selected men for top industrial positions. In this scheme, the selection of certain outstanding men taking the regular courses is made at the end of the second year. Co-operative work begins with the third year and continues for three years, at the end of which the student is granted two degrees, B.S. and M.S. The schedule for the three co-operative years is divided into three sections, the two school semesters and the summer. Each of the co-operative years comprises an average of 23½ weeks' work, 23½ weeks' school, and 5 weeks' vacation. The work periods are of term length, varying in length from 15 to 19 weeks. During the last term of the fifth year, the two alternate groups are reunited at school to complete the requirements for the M.S. degree.

Instruction is continued during the work periods by classes conducted by the school staff. The work periods are given all by one company for a given student, although several companies have entered the Plan. The students are thus trained for the business and usually enter the concern at which they obtained their experience. During the work period, two school subjects are conducted after working hours and are completed for credit in four work cycles. This permits enough credits to obtain the two degrees at the end of five years. The hours spent total 11 per week in two periods per week.

The M. I. T. Plan, keeping in mind its aims, offers the advantage of a trial period for the candidates. Only those who successfully complete the first two years, thereby demonstrating their interest in and adaptability for, an engineering career, are eligible for the co-operative train-

* Co-operative Courses: Their Development and Operating Principles. A.I.E.E., July, 1930.

ing. Selections are the joint responsibility of the college and the co-operating company.

It is the practice at some colleges to broaden the outlook of the student during his work periods by supervised reading and report writing. At Drexel, this plan has been admirably worked out. During each of the seven work periods, three books must be read and reported, ultimately covering all twelve selected subjects such as economics, history, travel, religion, psychology, biology. In other words, the fields are chosen deliberately outside of engineering. It is reported that 80% of the students read more than the required minimum, and in addition have formed an Industry Club for the discussion of cultural subjects.

Some schools have recognized the 15 months' plan, in which the student leaves school after the junior year and spends 15 months in industrial practice, returning to finish the final year. This procedure is sometimes followed by the student for financial reasons, apart from any educational motive. Taken by itself, the 15-month work period can hardly be called a co-operative plan of education, unless there is real co-ordination between school and factory.

There are inherent virtues in both the Cincinnati and M. I. T. types of plan, and both have been successful in several schools. This has been attested both by the college and by the co-operating industry. Representative of the many favourable opinions of industry is the paper by A. S. Hotchkiss, Director of Training, Tennessee Coal, Iron, and Railroad Company, " Our Purposes and Aims in Employment of Co-operative Students."* He states that the present improvements in educational methods can be greatly aided by the tremendous facilities of industry used as a laboratory for co-operative learning. Co-operative work shows up what a diploma does not. It brings out the following bad points, if existent, in sharp relief: the wrong attitude toward work, habits of carelessness, tendency to absences, lack of mental and physical alertness, abuse or waste of equipment, slow learning rate. On the other side, it will show energetic attack, acquisition of poise, discipline of mind and body, appreciation of the feelings of others, refraining from " frank " criticism, and a co-operative spirit.

We wish now to present a description of a new co-operative plan devised by the Westinghouse Electric & Manufacturing Company and the Carnegie Institute of Technology, and put into operation in 1938. Before starting, let us re-examine the goals of engineering education aimed at industrial positions.

Much has been written on the subject of engineering education, setting forth the proposed objectives. We will not now repeat an extensive treatment of the subject, but give a few high points which have been found important. A negative approach might conceivably be made to what is wanted in young engineers by listing what we know that we want to avoid. Thomas Spooner** analyzed the apparent causes for failure of young engineers from a large number of case histories and found only a small proportion of failures were from lack of technical training. He notes the following negative attributes: lack of co-operative ability, diffidence, unimpressive personality, lack of initiative, inability to sell one's self, lack of ambition, lack of resourcefulness, lack of analytical ability. The opposites of these defects seem to be remote from the content of an engineering curriculum, but are of vital interest to industry, particularly for leading positions. Admitting that the reverse of these characteristics is desired, can they be produced by engineering courses or by any type of education? Some believe that a man either has acceptable qualities or does not have them, and that no amount of training will create something that does not exist. Carl Snyder in his book, *Capitalism the Creator,* devotes considerable space to proof of the universality of inequality—that resources of nature and abilities in man are inherently poorly distributed, according to Pareto's Law, and no amount of human muddling can change the unequal division of nature's bounties. If we were to accept this fully, all we can do, then, is to develop a satisfactory means of selection of the leaders and relegate the rest to mere existence. But most of us are not quite that despairing of human intelligence. Frequently human minds remain incompletely developed until some impulse stirs the native abilities most of us possess. Snyder admits that each of us has some ability, probably, to do some things better than the average person can; and the hope of civilization lies in discovering what each of us can do best. This is relevant to the square peg and round hole concept. The very word " education " implies a " drawing forth," presumably of something we already have. And so, technical education involves first the selection of men having innate abilities above the average in technical fields and then a drawing out or developing by various means of encouragement and stimulation. If there is sufficient exposure of the promising student to industrial conditions and problems and a guidance in tying in the formal study with its application, more rapid development of the man is attained, provided that a suitable subject has been selected in the first place.

One thing a co-operative course can accomplish is a prompt adjustment of the student to industrial life. Often a student entering his first job is bewildered by the situation in which he finds himself. The routine of school life with direction at every point is cast aside. He is thrown in with people who know the job better than he does and know short cuts through daily practice. He has to make his own decisions, small ones at first, but nevertheless by his own thinking, and is hesitant to act thereupon. He begins to work with things that count in dollars and cents. No longer are the problems mere exercises or play. It is the difference between a child's world and a man's world. He is often bewildered by the complexity of the daily picture, why things are done in a certain way and how the complex organization functions. Recognizing this state of affairs, many firms hiring engineering graduates have a training programme designed to bridge this gap, a procedure long ago proven to be worth its cost in time and money. If this readjustment can be made during the school years through co-operative training, much is to be gained. Such a plan permits a gradual and controlled initiation into the ways of industry, to the advantage of all.

Another advantage of co-operative education is the mutual education of the educators. Often industry understands little of the process of administering a college; and likewise, many college staffs have slight acquaintance with the " work-a-day " world, a condition less marked in engineering colleges, however, than in other types. When both sides have a hand in preparing a student for his job, entering into the plan with whole-hearted understanding, the best known to both sides can be effectively combined.

The Westinghouse-Carnegie Co-operative Scholarship Plan, inaugurated in 1938, was patterned after the selective scheme. Representatives of the Westinghouse Company and the Carnegie Institute of Technology undertook an extensive study of possible alternatives and developed the present plan of procedure. The aim is to select and train a limited number of exceptional students, with the hope that several will rapidly develop into the leaders of the future. Some people have claimed that there can be an excess of opportunity which turns young men's heads, creating a sense of snobbish superiority. This might happen with some students, but such a result would cast suspicion on the method of selection of

* S. P. E. E., June, 1938.

** " Characteristics of a Group of Engineers," A.I.E.E., Dec. 1934.

candidates. If the best that can be offered in the curriculum, supplemented by the best that can be given in industrial experience, fails to produce superior men, the blame can be placed on a lack of knowledge of how to select candidates, a possibility which cannot be ruled out when we consider the inexactness of our methods of mental measurements.

The financial obligation the Westinghouse Company undertook in this programme consisted first of an endowment sufficient to establish a professorship of engineering for the supervision and correlation of the Plan. Second, the Westinghouse Company offers ten co-operative scholarships each year, with a total value of $3,420 each. In addition, responsibility is assumed for placing the students in work which is adapted as far as possible to the training planned by the George Westinghouse Professor of Engineering, for the individual student.

The Carnegie Institute of Technology assists in selection and rating of the candidates and enrolls the scholars in the regular engineering courses. It accepts the summer factory experience as substitution for any summer shop or laboratory work usually required on the campus.

The scholarships, ten of which are awarded each year, cover a period of five years, during which time a four-year engineering course is completed and two years of industrial experience accumulated. Each summer, including the months between graduation from high school and entering the Carnegie Institute of Technology, the scholar spends at a Westinghouse plant. In addition, he leaves school in the middle of the junior year and spends a full year in the factory, returning to finish the remaining one and one-half years. During the whole period of five years, the Westinghouse Company pays the scholar a monthly stipend starting at $50 per month. At graduation there is an expectation that the engineer will enter the employ of the Westinghouse Company if he so desires, but there is no stated obligation on either side. When the plan is in full operation there will be fifty men in training, for which the Westinghouse Company is paying $34,200 a year as an investment to produce future leaders.

Early each year announcement of the scholarships is publicized through Westinghouse offices all over the United States. The process of selection of ten boys from the hundreds of applicants then starts with a comparison of high-school records. Most of the boys stand near the top of their high-school classes, and a choice on this basis only is difficult to make. One straight-A record looks about the same as another. Considerable attention is given to participation in student activities and outside interests such as publications, sports, etc. In the application the boy is asked to describe some technical device as an indication of his aptitude in engineering subjects. After all the records are collected and compared, about 150 of the most promising candidates are selected for an examination. This test is of the mental aptitude type and is given on the same day at as many as 50 locations over the United States under the supervision of a Westinghouse representative. These two criteria (high-school record and examination) constitute the basic means of selection; but to these are added several others. Letters of recommendation are considered, and personal interview of each candidate is used as an essential procedure in bringing out some personality factors. Some effort is directed toward obtaining good geographical distribution of the candidates, other factors being equal. It is advantageous to both the Company and to Carnegie Tech to have representation from many sections of the country.

Among the present 30 scholars, 6 are from Pittsburgh and vicinity, 8 from Pennsylvania outside of Pittsburgh, and the remaining 16 from 10 states spreading from Washington to New Jersey and from Wisconsin to Georgia and Texas.

The selection of courses by the successful candidates has embraced most of the engineering courses offered, as segregation of the present 30 students shows:

Chemical Engineering	5
Electrical Engineering	8
Management Engineering	5
Mechanical Engineering	8
Metallurgical Engineering	2
Physics	2
	30

We come now to an attempt to evaluate the results attained thus far. One tangible criterion is the scholastic grades made by the scholars. By that standard, the record is good. Translated into factors (4.00 maximum), the first two groups have established the following averages:—

1938 Group	
First Year	2.85
Second Year	2.81
1939 Group	
First Year	3.44

At the end of the first year, the 1939 Group captured the four top places in their class, and all ten were in the highest 20%.

The campus activity interests of the Westinghouse Scholars have been varied and many. Encouragement has been given to active participation in something for every man, in accordance with his natural talent or tendency.

Activities of 1938 and 1939 Groups (20 Men)

Activity	No. of Men Participating
Class officer	1
Dormitory officer	4
Fraternity offices	3
Undergraduate honoraries	3
Y. M. C. A. Cabinet	4
Publications	13
Musical Organizations	7
Camera Club	2
Debating	2
Rifle Team	2
Hockey	1
Basketball	1
Tennis	2
Swimming	2
Misc. Social Activities	4
Intramural and Dormitory Athletics	12

The industrial assignments during the summers have covered three general locations: laboratories, engineering offices, and factory offices. Several students have had interesting experiences in the Research and other laboratories. One worked on the Westinghouse atom-smasher, helping make adjustments and measurements during its assembly. The job ranged from setting up electronic measuring circuits for counting electrons to cleaning soot out of the tank after an accidental fire occurred in some insulation. Although the metallurgical knowledge of a high-school student is obviously limited, one boy found himself in the summer before entering Carnegie preparing single metal crystals. Measuring the electrical properties of new organic compounds rather had one fellow in over his depth, but after he returned to school the principles of Physics and Chemistry took on new meanings. The uses to which Analytical Chemistry can be put in the inspection of incoming raw materials occupied the time of a young Chemical Engineering student. Another job was to follow through in the shop the trial of a new insulated wire and see what troubles were encountered.

Some of the Management students have helped study costs of manufacture. What are the parts of which a device is made, and how much does each operation cost? Is there a means of eliminating a machining operation, or can two parts be fastened at one operation? Another factory job was finding possible applications for newly discovered or developed methods. A new type of brazed joint was thought to be excellent for making tips for contactors. Would it be satisfactory and save money?

Students in the engineering design offices have acted as messengers, going all over the shop for drawings, correspondence, or information. Some have had experience in drafting and others in working with drawings, learning how they are made and used, and how the necessary clerical system of numbers on drawings functions. Translating experimental data on new designs into quickly comprehended curves helped another student to learn the language of expressing engineering facts. Some design experience included the calculation of critical speeds of machines, using some of the short-cut methods that have been evolved. Estimating the weight of machine parts from the drawing proved to be an interesting job.

This last summer, six of the students were sent to Westinghouse plants in other cities to get experience on specific subjects. Two were interested in large quantity production. Another wanted to find out how transformers were built. From such assignments the organization and operation of a large company can be studied.

In all this work the department heads at the plants have taken a keen interest and have paved the way for a maximum of useful experiences; but the boys obtain no special favours and are expected to put out a day's work the same as regular employees. Adjustment to the ways of industrial life is gradual, and the students get to feel at home among factory and office surroundings.

It has been noted that this practical experience has motivated the subsequent school work. The uses to which technical information is put become apparent; and, more important, the need for more training is emphasized. Every day a new problem is met, and the answer requires information the student does not have. He feels he wants to learn more on specific subjects, so he will know why certain devices behave the way they do. Perspective is increased notably, and all the various subjects become integrated into a harmonious picture. The effect of some of the summer work has been decisive in steering the students' programmes. Some have found confirmation of their original interests, and others have had an awakening in new channels sufficient to warrant a change of course.

Four of twenty scholars changed courses at the end of the first year because of new interests brought out by their experiences.

We feel fully confident after two years' operation of the Carnegie-Westinghouse Scholarship Plan that we have embarked on a successful venture, and that some of the admitted difficulties in engineering training may be solved by a process of learning which includes us all. Carnegie Institute of Technology will have a more adequate appreciation of the problems and needs of an industry, and Westinghouse will learn that the education of engineers is not all football and vacations.

DISCUSSION

J. Harrison Belknap*

Dr. Miner's paper is so complete that I shall not attempt to cover more than the mechanism of the plan.

Each year as we make our arrangement for the selection of the ten scholars, we seek the help of our district offices —located in all principal cities—in spreading the announcement of the opportunity to the high schools of their areas. In this action we obtain a remarkably large coverage but, through the personal effort of our Westinghouse associates and others, a still larger spread of information concerning the scholarships is had.

Applications received from all sources by Westinghouse are next sent to the Registrar's Office at Carnegie Institute of Technology. The grades as reported on the transcripts are weighted in terms of the high school standing and, after due consideration of all points in connection with the student's academic record, a numerical value is affixed to the application.

The first elimination of application papers is on the basis of the Carnegie requirements as agreed upon when the plan was developed. During the past year we considered only those applicants whose grades were above 3.4, 4.0 representing a straight A record. This plan without question eliminates all who would not be found in the upper 15% of their respective classes.

Dr. Miner has briefly mentioned our consideration of the extra-curricular activities of the student. We do give the participation in significant high school student body and class activities a very careful examination and look to the testimonials submitted by the applicants' teachers and others for supporting evidence of well-rounded characteristics. The high scholastic standing of the great majority of the applicants justifies critical consideration of other characteristics, aptitudes and interests.

After the second step in eliminations mentioned in the foregoing, competitive examinations are arranged for as many geographical locations as are necessary to meet the requirements. Last year groups of from 1 to 95 were given the examination in 42 different cities. The examinations were administered in accordance with a carefully prescribed plan by a Westinghouse representative assisted by a local high school principal.

The careful comparison of examination papers, high school records, outside activities, aptitudes and interests results in the appointment by Westinghouse of 10 George Westinghouse Scholars. In the final selections consideration is given to the interests of the candidates as related to the typical Westinghouse requirements from the various classifications such as electrical engineering, mechanical engineering, metallurgical engineering, etc.

I may emphasize that we operate with meticulous care as we proceed through the various steps leading to the appointments. All applications are acknowledged and all candidates are advised of their standing. Notices of acceptability for appointment are made by telegraph and confirmed by letter with complete advice as to reporting. The parents have a part in the final arrangements.

It may interest you to know that all out-of-town scholars are met by a Westinghouse representative upon their arrival. Assistance is given as they locate rooming accommodations and finally a wire is sent to the parents advising of their son's location in our community. I can assure you a definite personal interest in the welfare of the newcomers is evident.

The first day at the East Pittsburgh plant is given over to an explanation of the initial assignment, a trip through the factory, a group meeting with the older scholars, a luncheon and finally a personal introduction to the one under whom each will serve during the first summer.

A little later the several groups are called together for a garden party at which time the individual scholars give a short report of their activities on their first assignment. Assemblies for the purpose of "seeing what the other scholars are doing" continue throughout the summer. These informal meetings are of real benefit as a part of the plan of orientation. Facts uncovered as the "work and learn" programme continues, together with counsel with

* Manager, Technical Employment and Training, Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa.

the "older heads," enables the scholar to judge as to the correctness of his choice of engineering field. Changes in programme may be made, and factory experiences may be altered accordingly. There is complete flexibility in the plan.

Finally as the plan continues into the 3rd, 4th and 5th years, there will be complete co-ordination with our graduate student programme, as the groups, upon the completion of their academic preparation at Carnegie, will indeed become an additional source of technical personnel. We believe that the scholars will be entirely oriented and definitely productive after graduation. Westinghouse is very glad indeed to be associated with Carnegie Tech in this new co-operative arrangement.

THE ENGINEER AND THE POST-WAR PERIOD

E. R. JACOBSEN, M.E.I.C.

The Atlantic Charter

Prime Minister Churchill failed to show up for a christening and President Roosevelt had gone fishing. For three days they conferred somewhere in the "gray reaches" of the North Atlantic. True, their general staffs also conferred, but the announced result of this historic meeting was the now famous "Charter of the Atlantic." Previously, it had not been considered quite the thing to discuss war aims beyond the patent necessity of winning. But ordinary people everywhere had not forgotten the frustrations and disillusionments of the last twenty years. They knew that we must do more than win. We did that much last time. And so the Atlantic Charter is the promise, for free and conquered peoples alike, not only of victory but of a better world. It is the recognition of the fact that men and women will fight better and endure more if they are given a vision of a brighter future and the assurance that practical steps are being taken to implement that vision. Serious and detailed discussions of our post-war plans are now coming to be recognized as an essential part of our war effort and an important contribution to our morale.

Quite apart from the psychological value of starting our post-war planning now, there are also the most urgent practical reasons. We dare not wait for victory before starting the foundations for a better world. By the time victory is won, much of the world will be exhausted, depleted and embittered. The tension and unity and enthusiasm of a great effort to meet a great emergency will be lost. The problems of survival may eclipse all others and the chaos which would attend an unplanned transition might well provide the opportunity for which extremists with no love of democracy are even now laying their plans. Further, the problems which will await the decisions of free peoples will be so unprecedented and so far reaching that only a long period of education and preparation will make correct decisions more sure and prevent the hesitation and division which would open the way for the demagogue.

A Job for Engineers

The post-war period may be divided into two phases. The first has to do with the transition from war to peace. This phase includes the most obvious and immediate problems which, to a certain degree may be studied from a national or even local point of view. Upon the success with which these problems are solved will depend our opportunity to join with others in facing the second phase—the great task of producing a better world. Local economic collapse and dislocation would immeasurably complicate the more important long term problem. Further, there is the danger that such collapse and dislocation might be used as a pretext for converting the extensive governmental controls made necessary by total war into the permanent machinery of a totalitarian state.

It is becoming more and more clear that only a carefully planned programme of capital expenditure on a scale at least commensurate with our war-time expenditure will suffice to tide us over this dangerous period. At this point, it should be repeated emphatically that the problems of reconstruction will demand solutions far beyond a mere physical construction programme. What is being urged in this article, however, is the suggestion that such a programme if properly planned, will bridge a chasm into which all our more important plans might otherwise collapse.

Such a programme of capital expenditure should arise in part from governmentally inspired public works, in part from capital expansion on behalf of private investment, and in part as the result of enterprises springing from technological advances or pioneering ventures.

It is very probable that in the early stages of the post-war period, the state will be called upon to assume the major portion of the burden. But it would be unwise to rely entirely upon the conventional type of public works programme, especially if it were improvised at the last moment. Such a solution might tend to prolong governmental bureaucracy; it would delay the return to normal peace economy; it would increase the burden of taxation; and it would be at least subject to the dangers of patronage and partisan short-sightedness. Nevertheless, the government and the public who support it should be persuaded that public expenditure must continue with little diminution from the war-time level for several years after the war. This expenditure should be so skilfully planned and directed that it will then taper off in such a manner that private business may be encouraged to take up the difference.

Private industry, once assured of this type of co-operation, should be willing to start planning its own capital expansion now and to begin putting it into effect as soon as the war is over. The extent to which such private initiative can be persuaded to supplement governmental initiative will be a direct measure of the speed of our return to normal conditions of peace-time production.

Apart from capital expenditures for the extension, improvement, maintenance and repair of our present plant and equipment, what new developments will Canada need and support? What technological advances in Canadian engineering might contribute to her advantage? How are we to use our unharnessed water power? How are we to open up our great North West? How can we use synthetics and plastics and the soy-bean to bring industry and farming closer together? Are we to try to attract the bombed industries of Britain to rebuild in Canada? What special development in low-cost housing might result from the conjunction of Canadian weather and Canadian ingenuity? What are to be the peace-time products of our greatly expanded chemical industry? What are the engineering implications of the Hyde Park and Ogdensburg agreements? Writing in the Carnegie Report,[1] Eugene Staley

[1] Report of the Commission to Study the Organization of Peace, *International Conciliation*, April, 1941.

says, "All over the world there are tools to be made and installed, roads to be built, swamps to be drained, rivers to be controlled, waterfalls to be harnessed. It is probably in concerted efforts to do this job that the peoples of the world stand the best chance of finding what William James called the moral equivalent of war." Now Canada is one of the great exporting nations of the world. Are Canadian engineers technically and psychologically prepared to take a commensurately important place in the international field?

Public works and private investment and technological advance cannot and should not be considered in separate categories. All of them require long and careful advance planning and their very interdependence adds to the problem. Committees and reports and recommendations on reconstruction, valuable as these are, are not enough. By the time the peace is signed, there should be in vaults across Canada—in the vaults of architects and engineers, government and municipal departments, engineering and contracting firms—completed plans and drawings for all manner of necessary projects. Sites should be chosen and surveyed; land purchased or appropriated; estimates made; methods of financing worked out and even the allocation of work planned in advance.

The Problem of Control

Another very important aspect of the problem which will demand careful thought and pre-arrangement is the constitution of proper controlling authorities. Problems of control will be far beyond the capacities of the town council or the local politician. Just in this connection, it may be that the discovery of the proper type of decentralized control board, with specialized functions, working autonomously within a given framework, will furnish the middle way between the extremes of an unplanned chaos and the despotic centralized state. The British Electricity Board, the B.B.C., the London County Council, the Port of New York Authority, the Ontario Hydro, or the Tennessee Valley Authority may well be sign posts pointing the way to a new type of democratic control. If so, it is significant for engineers to note that they are all primarily engineering undertakings.

Of course, it would be very foolish to underestimate the difficulties involved in the above recommendations. The author's indulgence in dogmatic statements—far from being a measure of the simplicity of the problem—is directed merely to the ends of brevity and provocation.

British and U.S. Plans

It is not the purpose of this paper to pursue this subject much beyond the stage of easy generalities. We might, however, sketch in a few outlines.

The first step which suggests itself is the critical examination of all projected non-war work with a view to seeing whether it could possibly be postponed. Indirectly, this is being done through the medium of the various material control boards. A study of the rate of deterioration and obsolescence would be a useful guide in laying future plans. In listing new works which might be embarked upon with profit or social advantage, the whole field of both public and private enterprise should be canvassed. In Britain, where this problem is being taken very seriously and where no fewer than three cabinet ministers are charged with post-war planning responsibilities, they are laying down construction programmes ranging up to thirty years in the more severely bombed sections. In the United States, the National Resources Planning Board was set up by the Executive Order of President Roosevelt who has recently called upon it to work out a six year "post defense" programme. The *Engineering News Record* quotes its basic objectives as follows:

"In order to provide a 'shelf' or 'reservoir' of public construction projects of tested value, the National Resources Planning Board recommends:

1. Continuous and invigorated efforts to secure the preparation of six year programs or capital budgets by federal agencies, state governments, and other agencies, public and private, anticipating a large volume of construction activity.

2. Development of alternative lists of projects included in the six year programs according to size of the project, types and location of skilled and unskilled labor involved, materials needed, rapidity of beginning, and flexibility of termination.

3. Immediate inauguration of surveys, investigations, and preparations of engineering plans and specifications for selected projects through allocation of aids to federal and non-federal agencies from a revolving fund to be administered by the President through his executive offices; and reimbursed to the revolving fund as part of the cost of contruction of the project."

More specifically charged with the task of "post defense" planning is the newly formed Public Works Reserve Board.

Financing

The cost of financing post-war planning might be regarded as a legitimate part of the cost of our war effort. Compared with the vast cost of the war, it would be a very small part and might well pay for itself many times over as a sheer investment in morale. The "revolving fund," mentioned above, is a self liquidating scheme. There is also a bill at present before the U.S. Congress which would authorize the making of financial advances for future planning.

Engineers Too Busy

One of the most obvious difficulties is that engineers already have more work than they can manage. About the only answer to this is that we usually have to choose the busiest man to do the extra job. In the past, engineers have either been too busy to worry about their responsibilities to themselves and society or they have had nothing to do except reflect that opportunity had again passed them by. It is said that this is an engineer's war.

Problems Being Closely Studied

In closing, it should be pointed out that leaders in Canadian life are keenly aware of these problems. As chairman of a national committee on post-war reconstruction, it has been part of the author's task to find out what is being done in official, semi-official and private circles in respect to post-war planning. His bibliography of books, reports, publications and articles on reconstruction already covers four closely typed sheets. An entire article could be written on the important beginnings already made in what may prove to be a movement so essentially democratic that the very future of democracy will depend upon it. But the most inspired leadership is powerless under democracy if it has not the support and encouragement of an educated and a roused public opinion. This time, leaders with vision must not be repudiated by their own people, nor should the leaders be allowed to proceed in ignorance of their peoples wishes and intentions. This article suggests that engineers should take an important place in helping to build an educated public opinion; it carries the implication that engineers will be called upon to be the shock troops in our own "peace offensive" and makes the plea that they be not found wanting.

Editor's Note:—The author has made available to Headquarters a limited number of copies of a bibliography on the subject of this paper. A copy will be sent, upon request, to members of the Institute who may be interested.

THE 40-mm. ANTI-AIRCRAFT CANNON

By Major Daniel J. Martin, Ordnance Dept., U.S. Army

From *Army Ordnance*, Nov.- Dec., 1941

The funnel-mouthed Bofors 40-mm. " automatic field gun " has inspired international acceptance probably quite beyond any dreams of its designers—if cannon designers may be said to dream hopefully for popularity of a product. The gun already was in production by Bofors in Sweden when the Spanish War demonstrated the truth of a long-held military conclusion: that intermediate calibre automatic cannon would be a requisite in future action for defence against low-flying aircraft.

Great Britain has continued to be partial to the 40-mm. Bofors gun, and there have been many published reports attesting its efficiency and reliability. There have been stories that it was this gun in great numbers which enabled the British to make their successful withdrawal at Dunkerque. There are others which attribute the loss of Crete to absence of these weapons. Still others report that German fliers shy away from areas known to be protected by 40-mm. Bofors guns.

In 1940, the 40-mm. Bofors gun was the subject of exhaustive tests at Aberdeen Proving Ground, Md. Results of these tests, together with authoritative information on their European performance against low-flying aircraft, combined to effect standardization of a gun of this type by the Ordnance Committee early last spring as the " U.S. Army 40-mm. gun M1."

Contracts for manufacture of the gun have been awarded and the first pilot models were turned out in early summer. The Chrysler Corporation of Detroit has the prime contract for the gun and the Firestone Tire & Rubber Company of Akron, a prime contract for the carriage. Chrysler is sub-contracting its work throughout its large organization, and Firestone has spread its work among 368 subcontractors.

It has been widely known for some time that aircraft most dangerous to field forces do not fly high. Moreover, bombardment of cities and industrial areas has been conducted for months at low and intermediate altitudes, as well as from greater heights. Higher aircraft speeds and aircraft armor also are considerations. The 40-mm. Bofors antiaircraft automatic cannon (termed by the manufacturers the " 40-mm. automatic field gun ") has proved itself under these conditions of aircraft attack. The object of its fire is to put aircraft out of action by direct hits. Its shells are detonated instantly on impact. " Point-blank " fire is made possible by tracking aircraft with reflecting sights and adjusting the corrector with great accuracy. Use of tracer shell permits making necessary corrections and observation of the shell group near the target.

Fire is usually in bursts of four to five rounds, full automatic. The gunner may use further continuous automatic fire if his observations show it can be effective. High muzzle velocity, 2,850 ft. a second, results in a virtually straight trajectory up to about 3,280 yds. Short firing time makes it possible to regulate the fire quickly. This is now necessary because the faster bombers remain within effective range for not more than ten seconds. The sooner the bursts reach the target, the more rapidly can any necessary corrections be made. The 40-mm. Bofors gun can be aimed with great rapidity before an attack made at extremely short range can accomplish all the intended results.

General data of the 40-mm. gun are as follows: Rate of fire, 120 to 140 rounds a minute; weight of gun in firing and travelling position, 4,300 lb.; maximum range, 11,000 yd. horizontal; weight of projectile, 2.205 lb.; weight of powder charge, 0.628 lbs.; weight of fixed cartridge, 4.63 lb.; muzzle velocity, 2,850 ft. a second; vertex for time of flight of 11.5 sec., high-explosive tracer shell, 5,391 yd.; range for time of flight of 11.5 sec., high-explosive shell, 5,413 yd.; gas pressure, maximum, 42,630 lb. per sq. in.; elevation field, minus 5 deg. to plus 90 deg.; traversing field, 360 deg.; length of recoil, 7.874 in.; wheelbase, 125.98 in.; maximum vertical range for 11.5 sec., 5,391 yd.

Following are the general characteristics of the gun: the barrel is provided with a counter-recoil spring and flash hider. The latter prevents the flash from blinding the crew, particularly during night firing. The barrel has no water jacket, and the counter-recoil spring consists of a cylindrical coil spring installed around the barrel. The front of the recoil spring bears against a nut screwed to the barrel and the rear of the spring bears on a washer housed in the front casing. The muzzle is conical and its exterior is provided with a screw thread for the flash hider. The bore consists of the chamber, the transition cone and sixteen rifling lands.

"WITH GOOD CONFIDENCE"

From Robert Williamson, London, Eng.

Mr. Winston Churchill has written to the Federation of British Industries expressing the Government's gratitude to all sections of industry for their war effort.

The Prime Minister was congratulating the Federation upon the twenty-fifth anniversary of its formation during the Great War. A message from the Grand Council of the Federation expressed their sincere and heartfelt admiration for Mr. Churchill's leadership and courage during these stern months.

" They assure you," it ran, " that the F.B.I., which came into being in the midst of the last Great War, is proud once again to help in the marshalling of the forces of production to the single end of victory.

" They recognize that in this great struggle for liberty the ' workshop front ' has a vital contribution to make. Industry is determined, under your inspiring leadership, to carry out its part in the double task of equipping the fighting forces with the instruments of war and maintaining in health and all possible safety the normal life of the nation."

In reply, Mr. Churchill said: " Thank you for your kind message, which I greatly value, and which will be a source of encouragement both to myself and my colleagues.

" In conveying to the Grand Council of the Federation of British Industries my warmest congratulations upon the 25th anniversary of the foundation of the Federation and upon its many achievements in the industrial field since it was first set up, I shall be glad if you will also express the gratitude of H.M. Government for the magnificent contribution which all sections of industry have made and are making to the war effort.

"We value their counsel, we welcome their advice and assistance. Our fortunes in the struggle in which we are engaged depend no less upon the industrial than upon other aspects of our effort, and if we all pursue our course in the spirit of co-operation which animates your message, we may march forward with good confidence."

PERSONNEL AND WAR PRODUCTION

Excerpts from a speech by Mr. Ernest Bevin, Minister of Labour and National Service, at the Institution of Production Engineers' luncheon, Friday, September 26th, 1941

From *The Engineer*, (London), October 3rd, 1941

I was very interested to note that you have adopted as one of your principles that, as a scientific organization hours and conditions of labour were no concern of yours, but that the training and the use to be made of labour were matters to which you could properly devote your attention. In so far as the payment of wages is concerned, it is no doubt a wise decision, but I should like to have seen more attention paid by the production engineering organizations to the working out and application of an optimum labour effort. In my view, sufficient attention has not been paid to this subject, neither has there been due consideration of the fact that workers have had to carry on through two "black-out" winters with long hours on intense production. What has been proved, however, is that serious difficulties have been caused in the world of production during this past year by irregular hours, some of them necessarily due to the circumstances of the moment, but others enforced and operated without regard to the most precious and valuable of all machines —the human. I have done my best to get industry to pay more attention to this matter, for I was convinced that the long hours that were expected of the workers were having a bad effect on our total production. It seems to me that in war this question of optimum hours is not so much one of bargaining but one demanding a scientific approach which takes account of all the factors involved at any given time, and recognizes the need for adjustment as those factors change. Those responsible for the direction of production should quickly, energetically, and scientifically deal with the problem and make such adaptations as are necessary in order to preserve the physical strength of the human being, his morale, and create the feeling that the well-being of the industrial army is being properly taken care of. I have been reluctant to make Orders on this question of hours because they tend to become inflexible, and cannot be changed quickly enough in wartime to meet necessary changes—changes which may not apply universally, as legal Orders, of course, must.

* * * * * *

I particularly want to place before you my conviction that in designing, planning, and working out the proper utilization of our productive units there is an imperative necessity for much closer collaboration between the personnel manager and the rest of the executive, including the production engineer. The functions are equally important; the best of plans can be totally upset and much effort vitiated if the important human factor is not adequately considered and measured as a part of the general plan of production. In fact, there should be constant collaboration, owing to the changes that war produces.

* * * * * *

In the lay-out of this war effort there was not sufficient attention paid to the personnel problem. It took us a long time to get industry as a whole to appreciate the need for proper canteens, to imagine what "blitzes" would be like, or to have regard to the very severe nerve strain that would follow air attacks. I emphasize this now because, although we have had a respite, we shall have to face it again, and the longer the war goes on the more necessary it becomes to pay greater regard to this personnel side of the industry. The absence of a proper understanding of the problem has been one of our greatest handicaps in this great struggle. Remember, thousands of people have had to be moved, their homes broken up, and billeted sometimes under conditions that were not too good. All these factors have a bearing on the inevitable human problems which are bound to arise; hence my additional plea for the personnel manager, who should be specially trained, to have an equal position in industry with other members of the executive. Indeed, I am sure that our post-war position will be materially helped and the future of British industry enhanced by a full appreciation of this important fact.

* * * * * *

It is well to remember in this mechanized war that our factories and productive capacity are pitted against not merely those of Germany, but also those of the countries the Nazis have over-run. We have a smaller population, our raw materials have to be brought from overseas, and, in addition, the enemy had many years' start. Therefore, if this deficiency on our side is to be made good and parity reached, spasmodic effort is not enough. It may serve as a momentary stimulus, but its effect is not usually lasting. The factors that will count are the timing, flow of materials, components, and the sustaining of effort over a long period with a continuously increasing rhythm. Nothing, I suggest, is so irritating to the workpeople as to be screwed up to a great pitch and then have a period of reaction and slack work and idling. A study of the curve of production over a period of months reveals that the final result achieved by spasmodic effort is not so good as that resulting from well-organized and sustained effort.

* * * * * *

It is sometimes not appreciated that we started this war with a dearth of really skilled people, and we have been compelled to ration them out so that we can maintain production and at the same time open up new factories and train more workers. We created labour supply committees, training establishments, labour inspectors, and everything that human ingenuity could devise to try to make good our deficiency. As the programme expands, and it must expand more and more, I must ask everyone responsible for production to turn his attention to getting the greatest possible use out of our total available skill. The differences in achievement in this direction are very striking. The ratio of skilled people to trainees and others in one works doing the same operation may be much larger than at another, and it is essential to establish a standard that will guide our inspectors. This is an aspect of our problem which production engineers might profitably consider in the light of the war development, and the great need for distributing our skilled labour to the best advantage, and thereby give us the advantage of any recommendation they care to make.

* * * * * *

I am sure, to a gathering of this kind, there is no need for me to emphasize the imperative necessity for more training. At this point I would like to say how much it has been borne upon me since I have had to deal with this man-power problem what a great mistake the State made in maintaining such a low school-leaving age for the last twenty years. How valuable it would have been to the State now if those children had been kept at school and under the control of the educational institutions of the country for another couple of years, and a portion of that period devoted to some form of training in order at least to give a basic knowledge of production, not merely in industry, but in agriculture.

* * * * * *

We have shown to the world in this war that there is virtually no such thing as an unemployable person, unless really mentally and physically incapable, if proper training is given to him and opportunity for employment afterwards. Hence the importance of the medical and nursing services as part of the production organization, and this should be linked up with treatment outside and a great national rehabilitation service. This will see to it that no producing unit is allowed to be wasted and no person who is injured as a result of enemy action or is a victim of an accident in our great industrial arena is left with a hopeless outlook for the rest of his life. It may lead to the necessity of adapting machines to the man, instead of the man to the machines, but that is not difficult, and I would ask you specially to study this problem.

* * * * * *

One gets a little tired of the constant demand for the return of people from the Army, and the resistance to the call to make up units to a proper fighting strength. If we listened to all the demands we would never have an Army and certainly it would never be properly trained. I assert, having regard to the task which we expect will have to be performed before this war is over, that the numbers allocated to the Services is not too large.

* * * * * *

We hear constantly of wasted efforts in industry. To what extent there is truth in it, it is impossible accurately to say, but the demand made in the productive field for man-power is just colossal. It must be remembered that when working in buildings and factories your man-power is static; you do not get a drain away continuously to provide drafts to make up wastage as you have in the Services. In other words, you do not give six months' training and then draft your people out to the Middle East or some other theatre of war, and then have to train another lot. Industry has a better chance of progressive improvement in the skill and further simplification of operations in order to make up any deficiency. Therefore I would urge that everyone responsible for production in the country should endeavour, first, to foster the co-operative spirit in the works, and, secondly, to make the fullest possible use of all available labour, and to consider, having regard to the claims made upon us, how far you can by change of methods, adaptation or adjustment reduce the demand and so facilitate the building up of a properly balanced force for a total war. In this connection I would urge that the most tremendous efforts should be made to get the full twenty-four-hour use of machine tools. I know the difficulties and the problems that confront you, but I believe if all divisions between management and labour could be broken down, the whole factor of production regarded as one service, and a right leadership developed—a leadership which produces confidence in the minds of the humblest worker—even better results than we have yet achieved would result.

* * * * * *

I am convinced there is a great untapped reserve of managerial and productive energy and drive in this country that must now be called out. It is like bringing up your reserves and this drive must be directed to a great objective. We must sustain at least a six to twelve months' drive, so as to enable us during that period to hand to Russia out of our own production, and the addition we can create, a great flow of equipment to aid her in her defence and our mutual final victory.

THE VIEWS OF INDUSTRY

From *Trade & Engineering* (London), October, 1941

The executive council feel that in view of the steps which are being taken in other directions it is essential that those who are responsible at present for the direction and control of industry should be in a position to present to the country a considered policy for the solution of the difficulties with which the industrial community, employer and employed, will be faced after the war is won. While it cannot be denied that there is a general desire to discuss the policy to be adopted after the war, it has to be remembered that no one can predict what the position will be and anything in the nature of a hard and fast policy is out of the question. Last month we drew attention to the experience of the London Chamber of Commerce in the War of 1914-18. That body set up a strong committee in 1916 to consider the policy to be adopted after the War. Three reports were issued, but in view of the unexpected turn of subsequent events it was found necessary to reconstitute the committee in 1918 to revise the original findings. We are entirely favourable to the idea of collecting all relevant information and putting it into a form in which it can be used, but it is too early to arrive at conclusions as to the form that post-war policy should take. Probably the greatest benefit will be derived from clearer definition of the nature of the problems to be solved and their extent. It seems clear that far-reaching changes are inevitable in almost every direction and it is well that men should be prepared to adapt themselves to new conditions.

FURTHER DEVELOPMENT IN FIGHTER DESIGN

By Dr. Ing. Aurelio C. Robotti. From *Revista Aeronautica*, Roma, Sept., 1940

Abstracted by *The Engineers' Digest* (London), Eng.

The impetus for a new design of fighter aircraft can be derived and justified by the needs of to-day's air warfare. In meeting these needs the designer is facing many new problems.

The advantages and disadvantages of monoplanes as compared with biplanes are now well known. Monoplanes are aerodynamically superior, while biplanes offer greater structural strength combined with lower empty weight and greater manoeuvrability. As the chief task of the fighter aircraft is to destroy the enemy bomber its speed is dictated by the bomber in both types of fighters, i.e., pursuit planes and interceptors. This requirement of superior speed necessitates the adoption of the monoplane design.

Future bombers will undoubtedly be fitted with more powerful engines and will be aerodynamically still more refined. It is strategically justifiable to reduce the safety factor, and thus to build the bomber lighter and faster.

On the other hand it is by no means an easy matter to reduce the weight of a fighter, or achieve improvements by reducing the drag. An increase in speed obtained by increasing the power of a single-engined fighter cannot be achieved without dangerously lowering its stability and lateral manoeuvrability. Neither does higher engine speed together with reduced air-screw diameter give a satisfactory solution, as the speed of sound is at present assumed to be the limit for the air-screw tip speed.

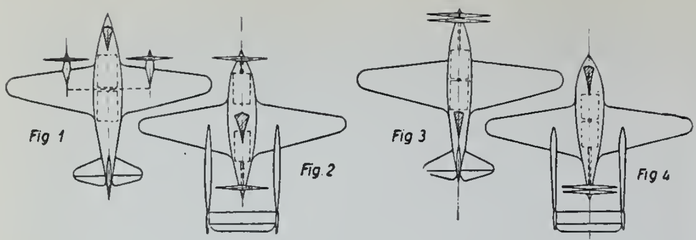
These considerations appear to indicate that the modern fighter must be two-engined, and the engine power must be utilized so as to free the aircraft from undesirable yawing and rolling which would be experienced with a single-engined fighter of the same power.

Although two-engined fighters are being manufactured by many countries, the question of engine location is far from being settled.

There are four immediate possibilities, several of which are already adopted in practice.

Fig. 1. Both engines located in the fuselage, and the power is transmitted to two counter-rotating air-screws arranged symmetrically about the rolling axis. Such a design is free from great lateral inertia which would result if the engines would be mounted in the wing.

Fig. 2. Two engines fitted so that the " contra props " are at the nose and stern respectively of the " centre-section " to which the fuselage shrinks, while booms are necessary to carry the elevator and rudders.



Figs. 3 and 4. These solutions are principally the same; two co-axial oppositely rotating air-screws are used, fitted as tractor or pusher unit respectively.

To a successful realization of these designs a great deal of development work on engines, aircraft and propellors has to be carried out.

Actually the problem of this research is that of "high speed flying" and controlability, and in the design all features affecting aerodynamical efficiency must be retained, such as retractable undercarriage, high-finish surfaces, flush riveting, and utilization of exhaust and duct propulsion.

NEW "CONTRA-PROPS"

From *Trade & Engineering* (London), October, 1941

Following the recent announcement by Rotol Airscrews, two other firms have now revealed that they have produced contra-rotating airscrews. The Fairey contra-rotating variable-pitch airscrew is the first of its type in the world to be flight tested. America, Italy, and other countries have flown aircraft with contra-rotating airscrews, but these were with fixed and not variable pitch. It consists of two airscrews which rotate in opposite directions, and the technical achievement of incorporating variable-pitch is of very considerable importance.

The Fairey Aviation Company is the pioneer in contra-rotating airscrew development in this country. Five years ago it began investigation and design, and the following year manufacture was started. On completion of manufacture hangar testing was carried out, and by October, 1939, the airscrew was through its "teething" troubles and was operating satisfactorily. The next stage was flight testing, and this began in February, 1940. Since then valuable flying experience and knowledge have been gained.

The Fairey Aviation Company, well known for its Fleet Air Arm aircraft, was from its knowledge of this type of machine fully aware of the advantages to be obtained by using contra-rotating airscrews. These advantages are even greater in the case of ship-borne aircraft, which must operate from the confined space of a deck, than for land craft. The airscrew has been designed chiefly for Fleet Air Arm work, as the contra-rotating principle enables the following advantages to be gained:

(1) A smaller diameter airscrew disk can be used, constituting a valuable asset for aircraft which have to take off, land, and be stowed in the limited space of an aircraft carrier.
(2) A shorter chassis with consequent structural gains can be employed.
(3) Swing is eliminated by the absence of torque, thus facilitating a straight take-off; this is also a great advantage when the machine is taking off cross-wind. The contra-rotating airscrews also give a straight slip-stream over the fuselage with consequent aerodynamic gain and better manoeuvrability in flight.

The Fairey airscrew is electrically operated by a single reversible electric motor. It is possible to constant-speed or stop the airscrew at any intermediate pitch. At the end of the pitch range a clever electrical device is incorporated for automatically switching off the motor. This scheme has worked very satisfactorily. The general operation is by means of gears. There is nothing complicated, as the whole unit is so designed that production presents no problems. Another point of interest is that the front and intermediate gear boxes and the airscrews can be removed as complete units. Thus, from a servicing point of view the Fairey contra-rotating airscrews are as easy to handle as other types of airscrews now in use by the R.A.F. and Fleet Air Arm. The difficult problem of lubrication has been successfully solved, and designs are available for obtaining a rapid rate of pitch change, full feathering, and hydraulic operation as an alternative to electric.

The airscrew was originally intended for a type of engine still on the secret list, but designs are available to make it adaptable for Service types of engines.

A number of test and Service pilots have flown behind this airscrew and they have all been very impressed with the performance. They have also been able to compare the flying qualities of a standard machine with that of one fitted with the contra-rotating airscrew, and they have found the rudder, elevator, and ailerons much more positive in operation. This contra-rotating airscrew has been produced for the same weight as a single airscrew which absorbs the same engine power.

PROTECTING CABLES FROM INCENDIARIES

From *Electrical Review*, London, Eng., October 17, 1941

During an air raid on Erith an incendiary bomb fell through the roof of an electricity substation, which consisted of asbestos sheeting, and dropped into a position within a few inches of the electric cables shown in the picture. The bomb remained in this position until it was completely burnt out, without causing any damage to the cables.

The interesting point is that until the war these particular cables were untreated and were carried below ground level in a trench with a wood batten cover. Shortly after the outbreak of war when the fire danger was fully realized the wooden covers were removed and the trench was filled to ground level with moist sand. The cables themselves were treated with gypsum plaster and hessian. The hessian simply forms a binder, of course, and does not contribute to the fireproof qualities.

It is remarkable that, although the incendiary bomb completely burnt itself out almost in contact with the centre cable, the cable covering is quite undamaged. The dividing box shows a deposit of magnesia from the burning of the bomb. The whole method of cable protection is extremely cheap and was carried out by the Erith Electricity Department's own workmen. No special rights of any sort are claimed for the method, and Mr. E. A. Logan, the borough electrical engineer, tells us that the idea of using gypsum plaster arose from seeing a demonstration of the ignition of thermite charges upon plaster boards. The plaster board in these demonstrations resisted the extreme heat of the thermite very well indeed, and it was explained that this was due to the fact that gypsum plaster contained a large percentage of water of crystallization which prevented the raising of the temperature on the side remote from the heating agency until the whole of the plaster had been calcined; calcination of the plaster proceeded very slowly from the outer to the inner surface.

Fifty-sixth

ANNUAL GENERAL MEETING
AND
GENERAL PROFESSIONAL MEETING

THE ENGINEERING INSTITUTE OF CANADA

MONTREAL - Thursday and Friday
February 5th and 6th, 1942

The Montreal Branch has set up a special committee under the chairmanship of W. G. Hunt, M.E.I.C., to handle all arrangements.

All sessions will be held at the Windsor Hotel.

Preliminary Programme

THURSDAY, FEBRUARY 5TH

9.00 A.M.	- -	REGISTRATION
10 00 A.M.	- -	ANNUAL MEETING
12 30 P.M.	- -	LUNCHEON—CHAIRMAN, J. A. LALONDE SPEAKER, HON. C D. HOWE
2 30 P M.	- -	TECHNICAL SESSIONS
8.00 P.M.	- -	MONTREAL BRANCH ANNUAL SMOKER

FRIDAY, FEBRUARY 6TH

9 30 A M.	- -	TECHNICAL SESSIONS
12 30 P M.	- -	LUNCHEON — CHAIRMAN, deGASPE BEAUBIEN
2 30 P.M.	- -	TECHNICAL SESSIONS
7 30 P.M.	- -	ANNUAL DINNER - CHAIRMAN, DEAN C. J MACKENZIE
10.30 P.M.	- -	DANCE

News of the Institute and other Societies, Comments and Correspondence, Elections and Transfers

THE FIFTY-SIXTH ANNUAL GENERAL MEETING

Notice is hereby given in accordance with the by-laws, that the Annual General Meeting of The Engineering Institute of Canada for 1942 will be convened at Headquarters at eight o'clock p.m. on Thursday, January 22nd, 1942, for the transaction of the necessary formal business, including the appointment of scrutineers for the officers' ballot, and will then be adjourned to reconvene at the Windsor Hotel, Montreal, at ten o'clock a.m. on Thursday, February 5th, 1942.

L. Austin Wright, *General Secretary.*

BALLOT ON THE NEW BRUNSWICK AGREEMENT

Publication of this issue of the Journal was delayed in order that the results of the ballot on the proposed agreement between the Institute and the Association of Professional Engineers of New Brunswick could be announced. The report of the scrutineers for the Institute ballot, which closed on December 5th, is as follows:

Ballot of members of Council:

Total ballots received		33
Valid ballots	32	
Invalid ballot	1	
Votes approving agreement		32

Ballot of corporate members in New Brunswick:

Total ballots received		47
Valid ballots	47	
Votes approving agreement		46
Contrary vote		1

The secretary has reported the following results for the Association ballot, which closed on December 6th:

Total ballots received	87
Votes approving agreement	80
Contrary votes	7

ANNUAL MEETING

Attention is called to the page elsewhere in this number which gives information on the annual meeting for February 5th and 6th, 1942. The decision to hold the meeting has been based on the thought that if confined to certain fields it might aid materially in the country's war effort. Accordingly, the papers are restricted to war topics.

The committee has obtained the support of the Minister of Munitions and Supply, the Honourable C. D. Howe, Hon. M.E.I.C., who has agreed to open the proceedings by speaking at the first luncheon. Papers will deal with the manufacture of war implements and *matériel,* and will emphasize the new fields into which Canadian industry and Canadian engineers have entered with success.

A feature of the meeting will be discourses on the effects of bombing and gun fire on utilities and structures. It is expected that discussion on this important topic will be led by an engineer who will have investigated the whole problem right in England. The engineering phases of civil defence in Canada have not been given the consideration which their importance would seem to justify. The Institute's decision to investigate this field is important. First hand information will be invaluable, and leadership thus provided should be helpful to the country as a whole as well as to individual communities and corporations.

The Montreal Branch extends a warm invitation to engineers all over Canada to attend this important professional meeting. Their attendance will be the reward for "a good job well done." There will be much to learn, and to enjoy. Make a note of the dates, and a resolution to attend.

INVITATION FROM THE MONTREAL BRANCH

To all members of the Institute,

On behalf of the Montreal Branch of the Engineering Institute of Canada I extend a cordial invitation to all members of the Institute and their friends, to attend the annual meeting in Montreal, February 5th and 6th, 1942. They will receive a hearty welcome.

This meeting will be of special interest at this time, since the technical portion of the programme will deal mainly with certain engineering features of the country's war activities, many of which are along lines new in Canada.

Arrangements are being made for distinguished speakers, including responsible officers from departments and organizations concerned with wartime research, manufacture of guns, instruments and aircraft, air-raid precautions and civilian defence. It is expected that those who attend the discussions will hear much that will enable them to assist in the nation's war effort.

Details of the various events arranged for this occasion will be found elsewhere in this issue of the Engineering Journal.

It should be noted that 1942 will be a good year to visit Montreal—it is the 300th anniversary of the foundation of the city—

Plan to attend this important meeting.

R. E. Heartz, *Chairman.*

REGIONAL MEETINGS OF COUNCIL

The November meeting of Council was held in Quebec city. Meetings at other times this year have been held at Hamilton, Toronto, Kingston and St. Johns, N.B.

The practice of Council meeting frequently at places other than Montreal has met with general approval. This year fifty percent of all meetings were at branches. In the last four years a similar percentage has obtained, and in that time, meetings have been held at twelve different centres. Already there are discussions about a further expansion for next year.

Regional meetings have much to recommend them. Not only are they good for Council but they are good for the branch. To such meetings are invited past councillors of the branch, past officers resident in the district, members of the branch executive, and any others who have shown a special interest in Institute affairs.

They bring together many people who are still interested but who get few chances to know of the workings of the governing body.

The excellent attendance indicates the popularity of such meetings. Not infrequently it runs to over fifty. The advantage of having the opinions of so many people on problems that affect the whole membership is great and the opportunity to give consideration to local problems is very helpful.

It is a source of satisfaction and inspiration to see so many officers of the Institute journey long distances at their own expense to attend regional meetings. At a meeting held in Halifax there were present three officers from Quebec and at meetings held in Calgary there have been as many as four officers from the east. At the latest meeting in Quebec city, there were four officers from Ontario as well as several from other branches within the province.

A continuation of this policy will do much towards reminding members all over Canada that the Institute is really national in scope.

AERONAUTICAL PAPERS

The Institute has an agreement with the Royal Aeronautical Society whereby certain special privileges are available reciprocally to members of each organization. The agreement calls for the Institute to publish, from time to time, in reprint form its papers on æronautical topics, which are then distributed by the Royal Aeronautical Society to its members.

Another "Aeronautical Reprint" is now ready. Members of the Institute may also secure copies by applying to Headquarters. All papers have been published in the *Journal*, but it may be advantageous to some members to have them in booklet form.

Herewith is a list of titles and authors:

Practicable Forms for Flight Test Reporting
Elizabeth M. G. MacGill, M.E.I.C.

Factors Affecting the Mass Production of Aeroplanes
Elizabeth M. G. MacGill, M.E.I.C.

Aerodrome Construction for the British Commonwealth Air Training Plan
J. A. Wilson, M.E.I.C.

Aircraft Engineering in Wartime Canada
Elizabeth M. G. MacGill, M.E.I.C.

Estimating Production Costs in Aircraft Manufacture
A. T. E. Wanek, M.E.I.C., A.R.Ae.S.

Air Traffic Control
Ewan D. Boyd

ENGINEERS' COUNCIL FOR PROFESSIONAL DEVELOPMENT

The annual meeting of the Engineers' Council for Professional Development is an important occasion. This year the Institute participated for the second time, as a member, and sent to New York a delegation which included the president, the three members of Council, and representatives on four committees.

A detailed account of the meeting is printed in this number of the *Journal*, which gives a good idea of the nature of the proceedings. From time to time as space permits it is proposed to publish the reports of various committees.

Without doubt the work of E.C.P.D. is one of the most important endeavours in the profession today. Representing as it does the senior engineering societies of North America, the Council is in a position to give great weight to all matters that concern the profession. With this backing it can call to its committees the best minds to think out the problems of professional development, and the most useful persons to place these findings before the societies where they may be used to advantage.

Already E.C.P.D. in its eight years of existence has done a great work. It has entered boldly into fields which hitherto resisted approach, and has brought order out of chaos in many matters that previously confused the minds of engineers and public alike. Perhaps its greatest achievement, in that it made all other achievements possible, is that it represents "the first wholly successful co-ordinated, co-operative institution in the engineering profession in America." The quotation is from the Chairman's Report for 1939.

The interests of the Council are shown by the names of the Committees, i.e.,

Committee on Engineering Schools
Committee on Professional Recognition
Committee on Professional Training
Committee on Student Selection and Guidance
Committee on Information
Committee on Principles of Engineering Ethics.

In reporting on behalf of the Engineering Institute of Canada, Past-President Challies who represents the Institute on the executive, called attention to the work already done in Canada towards the objectives of E.C.P.D. All Council's objectives are of great concern to Canadians, although the accrediting of curricula has not seemed necessary because of the high entrance requirements of our universities. Mr. Challies pointed out that the membership of the Engineering Institute in proportion to population was equal to the membership of all the seven other constituent organizations put together. He introduced the members of the Institute party and received great applause when he pointed out that the Institute had in attendance at this meeting every representative on E.C.P.D. and, in addition, its president and an additional past president—a total of nine.

The work of E.C.P.D. is far from finished. Ground has been broken in several fields, but it may take years of patient, intelligent endeavour to complete the selected tasks. Its interest in the finer things of the profession gives greater promise to the future of engineering than anything hitherto attempted.

"SPURIOUS"

Recently Headquarters has received several letters inquiring about an organization calling itself the Canadian Institute of Engineering Technology. The use of words almost identical with the title of the Engineering Institute has brought other letters to Headquarters that were intended for the outfit just referred to. An inquiry has revealed a deplorable state of affairs, and the purpose of commenting on it in the *Journal* is to assist in the circulation of information that may be helpful in bringing this thing to an end.

The so-called Institute of Engineering is offering correspondence courses in engineering and allied subjects. Our information is that a man named Marsh is soliciting business in parts of Quebec where there are industrial developments, such as at Arvida. Subscribers have complained that the courses were not satisfactory and they have declined to continue payments.

Inquiry at the Better Business Bureau of Montreal has elicited a reply that leaves no doubt. We quote, "Their status as a school is ill-defined and they appear to have no permanent address other than a post-office box. . . . . We have received complaints charging non-fulfillment of contract and also from persons who have been sued for the balance of their contracts."

The same organization or individuals have operated in Ontario as well, but we have before us a report from an Ontario official which shows what happened there. Again we quote, "Re your inquiry about the Canadian Institute of Engineering Technology, this is a spurious organization being promoted by Mr. J. H. Marsh. For a time Mr. Marsh attempted to do work in Ontario under the name of the British Canadian Institute of Engineering Technology but was never given registration and after some difficulty we were able to eliminate him from this Province through the working of the Trade-Schools Regulation Act. In this Province we had to resort to the use of the Courts and even the Provincial Police to put an end to his activities. As far as we are able to find out he has nothing reliable to offer and those who pay him money simply throw it away. Behind him there is no reputable organization or even facility to provide for what he claims to sell. It may be necessary for the Province of Quebec to deal with him as has the Province of Ontario."

Letters have been written by Headquarters to provincial officers urging that some action be taken to protect the citizens of this province from such persons and methods. It is suggested that members circulate this information as quickly as possible in order to curtail these harmful activities.

ANNUAL MEETING OF ENGINEERS' COUNCIL FOR PROFESSIONAL DEVELOPMENT

Representatives of Constituent Bodies Report Favourably and Offer Suggestions at 1941 Annual Meeting of the Council

Most significant of the many features of the 1941 Annual Meeting of the Engineers' Council for Professional Development, held at the Engineering Societies Building, New York, N.Y., on October 30, were the reports of representatives of the constituent bodies of the Council on its effectiveness and its accomplishments. These reports were gratifying because of their favourable nature and because they afforded opportunity for individual assessments and for suggestions for future action. An attempt will be made later in this review to present the highlights of these reports.

By far the largest attendance ever recorded at a meeting of the Council was attributed to a number of guests who found opportunity to attend because of the annual meeting in New York earlier in the week of the National Council of State Boards of Engineering Examiners, one of the eight constituent bodies of E.C.P.D. Another notable fact in connection with attendance was the delegation of nine representatives of the Engineering Institute of Canada, headed by C. J. Mackenzie, president of the Institute.

Officers and Committees to Serve in 1941-1942

Officers for the year 1941-1942 were elected as follows: chairman, R. E. Doherty, president, Carnegie Institute of Technology, reelected; vice-chairman, H. T. Woolson, member American Society of Mechanical Engineers (A.S. M.E.), executive engineer, Chrysler Corporation reelected; secretary, H. H. Henline, national secretary American Institute of Electrical Engineers (A.I.E.E.); and assistant-secretary, A. B. Parsons, secretary American Institute of Mining Engineers (A.I.M.E.).

Chairman of the Council's committees for the coming year will be as follows: Committee on Engineering Schools, D. B. Prentice, member A.S.M.E., president Rose Polytechnic Institute; Committee on Professional Recognition, C. F. Scott, member A.S.M.E. (reappointment); Committee on Professional Training, E. S. Lee, member A.S.M.E., engineer, General Engineering Laboratory, General Electric Company, Schenectady, N.Y.; Committee on Student Selection and Guidance, R. L. Sackett, fellow A.S.M.E., (reappointment); Committee on Principles of Engineering Ethics, D. C. Jackson, member A.S.M.E. (reappointment).

The personnel of the Executive Committee for the ensuing year will be as follows: George W. Burpee, consulting engineer, Coverdale and Colpitts, New York, N.Y., American Society of Civil Engineers (A.S.C.E.); A. R. Stevenson, Jr., staff assistant to vice-president in charge of engineering, General Electric Company, A.S.M.E.; James F. Fairman, Consolidated Edison Company of New York, Incorporated, A.I.E.E.; C. C. Williams, president, Lehigh University, Society for the Promotion of Engineering Education (S.P.E.E.); B. F. Dodge, professor of chemical engineering, Yale University; American Institute of Chemical Engineers (A.I.Ch.E.); Charles F. Scott, professor-emeritus of electrical engineering, Yale University, National Council of State Boards of Engineering Examiners (N.C.S.B.E.E.); and J. B. Challies, vice-president, The Shawinigan Water and Power Company, Montreal, P.Q., Canada, The Engineering Institute of Canada (E.I.C.). The representative of the A.I.M.E. on the Executive Committee has not yet been announced.

Standing Committes Report Progress

Reports of the committees, which had been mimeographed and distributed in advance of the meeting, were not read, but were briefly summarized in order to afford time for the presentation of reports of delegates from the sponsoring organizations. In view of the fact that the highlights of these committee reports are mentioned in the report of the chairman to the Council, which will be reproduced in an early issue, no attempt will be made at a summary in this review. The reports were accepted and will be published by the Council in its Ninth Annual Report.

Unified Engineering Profession in Prospect in Canada

What the constituent bodies of E.C.P.D. think about its work, what their own societies have been doing in forwarding the purposes of the Council, and what might be done in the future formed the general scheme of reports presented by the representatives of those bodies.

The Engineering Institute of Canada was greatly impressed with the Council's accomplishments, said Mr. Challies, first of the representatives to report. He gave a brief summary of what the Institute had done and was planning to do to enhance the status of the engineering profession. He doubted that members of the Council had full knowledge of the Institute, which was an all-embracing engineering society, the only one of national scope in Canada. On the basis of comparative populations of Canada and the United States the membership of the Institute was equal to the combined membership of the other constituent bodies of E.C.P.D.

Registration and licensing of engineers in Canada had been initiated by the Institute. A "model act" had been drafted. Provincial associations of registered engineers worked closely with the Institute and concerned themselves with administration of the registration acts, leaving the Institute to foster the technical interests of engineers. Relationships between the associations and the Institute were cordial and further co-operation was being actively undertaken with the result that a truly unified engineering profession in Canada was imminent.

Of present activities, Mr. Challies said, there was little to report owing to the war economy. A committee had been set up to investigate "the servicing of young engineers," and a Canadian edition of E.C.P.D.'s guidance booklet "Engineering as a Career," was in progress under the title "The Profession of Engineering in Canada." As to the future, he concluded, engineers could count on the Engineering Institute of Canada pulling its load, the first duty now however being to help Britain win the war.

A.I.Ch.E. Looks Forward to Further Co-operation with E.C.P.D.

Relations with E.C.P.D. were valued highly by the American Institute of Chemical Engineers, Mr. Kirkpatrick reported, and it was their hope that that appraisal was reciprocated. Although differences of opinion, viewpoint, and procedure might have been disturbing, chemical engineers who had worked intimately with both organizations believed that better understanding and greater co-operation were fast developing.

As to the future, Mr. Kirkpatrick expressed the hope that the Institute and E.C.P.D. would work together more closely. The Institute would welcome an opportunity for a joint meeting along the lines of the A.S.M.E.-E.C.P.D. programme at Kansas City in June, 1941.

A.S.C.E. Serves Notice of Charter Revocation on Chapters in Unaccredited Schools

Reporting for the American Society of Civil Engineers, Mr. Burpee stated that that society's Committee on Engineering Education had suggested that E.C.P.D. might well limit its work of accrediting curricula to the five major fields and general engineering. This committee's views had been reaffirmed by the A.S.C.E. Board of Direction in April, 1941. The committee agreed with Dr. Jackson's report that "undergraduate curricula should be made broader and more fundamental through increased emphasis on basic science and humanistic and social studies," including "the abandonment of effort to develop the stabilized skills that are now emphasized."

The A.S.C.E., Mr. Burpee said, had continued its active participation in the programme of student guidance, and through its 121 student chapters and junior branches of local sections was attempting to foster the development of a professional viewpoint. Student chapters had been furnished copies of the E.C.P.D. bulletin, "Suggestions to Juniors."

At its recent meeting, Mr. Burpee continued, the A.S.C.E. Board of Direction had voted that "student chapters at institutions where civil-engineering curricula had not been accredited by E.C.P.D. would have their charters withdrawn on January 1, 1944, unless these curricula had been accredited by that time."

A.S.C.E. members, he concluded, were greatly concerned with the solidarity of the engineering profession during these times and looked to E.C.P.D. to stimulate the consciousness of the profession at large and particularly to devise tools to use in the development of young engineers in their technical training, their engineering experience, their objective and scientific approach toward their problems, and their ethical attitude toward their undertakings.

Suggests Greater Publicity for E.C.P.D.

A "vote of confidence" in E.C.P.D. was extended by Mr. Fairman speaking for the American Institute of Electrical Engineers. The Institute's faith in E.C.P.D. had taken concrete form, he said, by the doubling of its annual contribution toward the Council's activities. As one of the Institute's representatives he had secured approval of the publication in *Electrical Engineering* of President Doherty's report "E.C.P.D. Should Look Ahead."

Booklet for Engineering Graduates Proposed

Stating that as incoming American Institute of Mining Engineers representative on the E.C.P.D. he had been asked at the last moment to prepare a report, Mr. Chedsey said that what he had to say had not been approved by his colleagues because of lack of time.

The activities of A.I.M.E. which lay in the field of E.C.P.D., he said were mostly covered by its Mineral Industry Education Division. There was also a Student Relations Committee which concerned itself mostly with relations with undergraduates and worked mostly through student chapters and affiliated student societies. The central committee aided by securing speakers for student meetings, by arranging for visits by A.I.M.E. officials, and by establishing contacts for field trips. No workable method had as yet been found to cover the need for systematic contact with young engineers after graduation, although the subject had been given consideration.

Two suggestions as to what additional activities E.C.P.D. might undertake were made by Mr. Chedsey. The first was a booklet for engineering graduates "setting forth why and when they should consider becoming registered as professional engineers, with a brief summary of the laws or regulations of the various states that would be of help to them in this procedure." He also outlined other matters that the booklet might cover. His second suggestion was the encouragement, and possibly some aid in direct development, by a committee of E.C.P.D., of personnel methods, through the use of scientific and engineering aids, in other words, assisting in the development of so-called "Human Engineering." During the year, Mr. Chedsey said, the A.I.M.E. had contributed in several ways toward furthering the objectives of E.C.P.D.

What E.C.P.D. Might Do and What N.C.S.B.E.E. Has Done to Help

The report of N. W. Dougherty for the National Council of State Boards of Engineering Examiners was divided into two parts: (1) What E.C.P.D. might do that it is not doing to make the programme of professional development, and (2) what the National Council had done during the year, or plans to do, toward furthering the objectives of E.C.P.D.

Dean Dougherty summarized his suggestions as follows:

"1. Determine causes or reasons why students select different fields of engineering.

2. Accredit graduate curricula.

3. Closer co-ordination between E.C.P.D. and N.C.S.B.E.E. in the field of professional training. E.C.P.D. is looking toward the right kind of mental activity, N.C.S.B.E.E. is primarily interested in the right kind of experience. Both are needed to develop the young engineer.

4. Might gather information and publish a booklet for students and junior members. "Engineering, a Career" is for parents and the beginner. A booklet for professionally orienting students and for directing recent graduates would be a great help.

5. By aiding in securing uniform laws by raising the quality of weaker laws; and by supporting efforts to maintain high standards in their administration."

What the National Council has done was summarized as follows:

"1. On professional training the National Council has been very active. Emphasis has been placed on qualifying experience rather than education. Studies are being made of examinations as measures of education.

2. On professional recognition a committee has tried to appraise the effects of registration on the engineering profession.

3. The Committee on Legal Procedure has made study of legal practices used in protecting the engineer and the public against the unqualified.

4. What more may be done. (a) Assist with the guidance programme. (b) Revive the Committee on Engineering Education. (c) Take a broader attitude toward the young engineer. Boards are not trying to prevent registration; they are trying to see that applicants are competent. (d) Cause every member of State Boards to thoroughly inform himself about E.C.P.D."

Dean Sackett Announces President Doherty's Address on E.C.P.D. at 1941 A.S.M.E. Annual Meeting

In the absence of the American Society of Mechanical Engineers representative, A. R. Stevenson, Jr., who was to have reported for the Society, Dean R. L. Sackett reviewed briefly what had been done during the year to further the objectives of E.C.P.D. He told how the A.S.M.E. had increased its annual appropriation to E.C.P.D. in common with other constituent bodies and about the joint sessions of the Society and the Council at the Kansas City meeting in June, 1941, under the sponsorship of the Committee on Education and Training for the Industries. Copies of the eighth annual report of E.C.P.D. had been sent to chairmen of the Society's local sections with the request that they study it and transmit questions and comments to the Committee on Education and Training. Articles relating to E.C.P.D. and its work, including President Doherty's report "E.C.P.D. Should Look Ahead,"[1] had been published in *Mechanical Engineering*.

At the 1941 A.S.M.E. Annual Business Meeting, to be held at the Hotel Astor, New York, N.Y. on Monday, December 1, at 2 p.m., Dean Sackett announced, President Doherty would deliver an address on E.C.P.D.

Recommends More Practicing Engineers on E.C.P.D.

The Society for the Promotion of Engineering Education had had a large part in the activities of E.C.P.D. said Dean Seaton in reporting as representative of this Society, and this included the services of five members of the E.C.P.D. Executive Committee. He pointed out that on a per capita basis the S.P.E.E. was making a larger contribution financially than any of the constituent bodies.

Dean Seaton's major suggestion was that an effort be made to appoint a greater number of practicing engineers to E.C.P.D. inasmuch as educators had made up a major part of the Council's membership to date. The services of practicing engineers were particularly desirable on the accrediting committees, he asserted. They were also greatly needed as lecturers in engineering schools and as members of boards of regents and trustees. In some institutions practicing engineers had been helpful in fostering research programmes. In his opinion E.C.P.D. should urge participation of practicing engineers in such institutional relationships.

The S.P.E.E., he announced, had limited its institutional memberships to engineering schools whose curricula had been accredited by E.C.P.D., with the exception of Canadian schools where E.C.P.D. accreditation had not been undertaken.

Professional training had been advanced by the schools' participation in the Engineering Science and Defense Training programme of the U.S. Office of Education which had an enrollment of 150,000, of whom 90 per cent were engaged in in-training courses. It was his hope that ways would be found to continue this type of adult education of men in industry after the emergency should have passed.

In Dean Seaton's opinion, uniform admission requirements and membership grade qualifications of engineering societies were desirable. He favoured the extension of industrial-employment opportunities for engineering school undergraduates between their junior and senior years and for young instructors of engineering schools. Engineering registration should be promoted also.

In closing, Dean Seaton characterized E.C.P.D. as practically the only co-ordinating agency in the engineering profession.

Annual Dinner Surveys E.C.P.D. Programme

The 1941 Annual Dinner was held at the Engineers' Club, New York, on Thursday evening, October 30, with President Doherty acting as toastmaster. Addresses were delivered by N. W. Dougherty, dean of engineering, University of Tennesse, who spoke on " Relation of E.C.P.D. to Registration Boards "; by A. H. White, president S.P.E.E., whose subject was " Relation of S.P.E.E. to E.C.P.D.; " and by James F. Fairman, Consolidated Edison Company of New York, Inc., who analyzed the " Relation of E.C.P.D. to the Engineering Societies. "

President Doherty also introduced Dr. C. J. Mackenzie, president of the Engineering Institute of Canada, C. R. Young, dean of engineering, University of Toronto; Virgil M. Palmer, retiring president, N.C.S.B.E.E., and E. A. Holbrook, president National Society of Professional Engineers, all of whom responded briefly.

Dean Dougherty Praises Work of E.C.P.D.

Asserting that there must be some idealism in engineering, Dean Dougherty cited the addresses of W. E. Wickenden, " The Second Mile,[2] " before The Engineering Institute of Canada, and that of Vannevar Bush,[3] before the American Engineering Council in 1939, in which it had been stated that " if there is no central organization which had as its creed the best service of the profession to the society of which it forms a part then there will be in the end no engineering profession. "

It was the function of E.C.P.D., he said to admit desirable young men to the profession and to keep out the undesirable ones, and it was the function of the N.C.S.B.E.E. to cast out of the engineering profession all unqualified engineers who attempted to practice in it.

In the accreditation of engineering curricula, Dean Dougherty pointed out, E.C.P.D. and N.C.S.B.E.E. had a common objective. Registration boards had benefitted by the accrediting programme because they made effective daily use of the list of accredited curricula.

The National Council, he said, had set up a committee on professional training to parallel the E.C.P.D. committee on this subject. It had also inquired into the question, " What is qualifying experience satisfactory to the board? " and had arrived at a definition of the term " satisfactory to the board. " In the work of the boards, he continued, it was often difficult to distinguish between " eminent " and " beginning " qualification, and it was the board's duty to deal with minimum qualifications.

He paid tribute to the E.C.P.D. Committee on Engineering Schools for the effect of its work on the schools, and concluded by stating that E.C.P.D. must secure the same recognition of the value of the work of its other major committees that had been accorded the work of the Committee on Engineering Schools, so that all engineers would feel that they were a party to the E.C.P.D. programme.

Growing Importance of Engineering Education Acclaimed by White

In speaking of the relation between education and engineering, President White said that the history of the beginnings of the E.C.P.D. deserved to be recorded as the Council had become a co-ordinating factor in engineering development. The engineering schools, he argued, were like a factory. Partially fabricated material was received, inspected, shaped, tempered, and passed on so that it could be fitted into the organization of the engineering profession. In this process the E.C.P.D. was the " boss " of S.P.E.E. and the colleges inasmuch as it set the specifications for the college president.

Engineering colleges dealt with adolescent engineers, he pointed out, while the National Council dealt with their admission to the profession. There had been a time when the engineer had been called a " roughneck. " This was not so to-day. Engineering had come into its own because it had been recognized that engineers thought clearly from cause to effect. It had been his observation that many arts students did not think clearly and did not work hard. There was too much " Do as you please and we hope you will do what is right, " and not enough stress on the discipline of accuracy and every day work.

Engineers must look to the future, he continued; E.C.P.D. had indicated what must be done. Twenty-five years ago engineers had worked 12 hours a day and seven days a week. They had been too tired to engage in other activities. But to-day, with a 40-hour week, they had time and energy for constructive work, and E.C.P.D. had laid out for them a programme for continued growth not only in technical but in cultural fields as well.

Fairman Tells of Experiences on E.C.P.D.

Making it clear that he was speaking solely for himself and not for the engineering societies, Mr. Fairman developed a " master and servant " analogy of the relations between the engineering societies and E.C.P.D. in which the societies were the master and E.C.P.D. the servant. He likened the professional development to a beautiful mansion which the masters seldom inhabited but which was well staffed with servants who were accustomed to

---

[2] *Engineering Journal,* March, 1941, pp. 111-114.

[3] " The Professional Spirit in Education," by Vannevar Bush, *Mechanical Engineering,* March, 1939, pp. 195-198.

send an annual greeting to their masters. Apparent indifference of the masters, he said, had led some of the servants to dream about how nice it would be if they owned the mansion, so that they forgot their places as servants and became guilty of insubordination. It would be better, he asserted, if the servants were to stop dreaming and get back to their jobs.

Turning to what he termed his conclusions, Mr. Fairman asserted that great care should be exercised in the selection of representatives to make up the E.C.P.D. These should be made on the basis that appointment was to a job, not an honour. It must be ascertained that the appointee had time and capacity to do the job. It was a failing of bodies like engineering societies to assign too many jobs to the same man, on the theory that a busy man had the most time, but he for one felt that there was a limit to the wise application of this theory.

Officers and directors of participating bodies, he declared, should review what they were getting for the money contributed to E.C.P.D. He criticized the practice of setting up new organizations to handle new tasks on the theory that a new group would best do the job, when, as a matter of fact, he said, continued interest and sustained effort were essential.

In conclusion, Mr. Fairman emphasized again the statement that he was expressing his personal opinions and not those of any group and his conviction that "we are not doing what we might do."

WARTIME BUREAU OF TECHNICAL PERSONNEL

Monthly Bulletin

The distribution of questionnaires to research and science workers which was announced previously is practically complete. The establishment of a satisfactory mailing list for this group has been more difficult than in the case of engineers, chemists, and architects, because there are no societies to which they belong in quantities that adequately represent the group. However, through universities, the National Research Council, and the Royal Society a list of over two thousand names has been set up which it is believed covers the field.

Under war conditions the importance of research work is multiplied many times. The need of attacking the many new problems and of completing the details of those already under way is great. More problems mean more workers. The Bureau is now in a position to aid in this expansion by furnishing information on the availability and qualifications of most persons experienced in this field.

The demand for mechanical engineers continues. It is difficult to see how the hundreds of openings can be suitably filled under the present method of distribution. It is the opinion of the Bureau that many qualified persons are still engaged in non-essential work, and that others while employed by an essential industry are themselves not wholly engaged in war work that uses their abilities to anything like capacity.

The fact is being slowly evolved that new measures will be necessary if anything like an even distribution or an efficient utilization of mechanical engineering skill is to be obtained in this country. Beyond a doubt engineering ability is being wasted right now. Groups which are crying for more men are competing with each other in their search and yet none seems to be utilizing efficiently those already in its service.

It is the opinion of the Bureau that a survey of the work being done by engineers will reveal the fact that such persons are being used in great numbers for work which is not engineering at all. For instance, an officer of the Bureau was shown by an engineer in the employ of a large industry where in one office two engineers out of seven were being wasted. The men themselves made the survey. They found that between them they were spending almost thirty per cent. of their total time in work which could be equally well done by clerks. Here is a specific case which probably is repeated over and over in plants all over the country. Perhaps similar surveys by all employers would yield similar results, and would assist in solving their own problem of engineering shortages.

The Bureau is impressed with the serious shortage of technical help in many vital activities including the armed forces, and believes that present methods will not solve the problem quickly enough. Under any conditions it will not be solved easily, and may never be solved entirely, but there are things which can be done now that will help a lot. The total supply of technical help—limited as it is—should be spread out in proportion to the needs. This will require the sympathetic co-operation of engineer, employer, and government, but it should not be impossible of attainment.

MEETING OF COUNCIL

A regional meeting of the Council of the Institute was held at the Château Frontenac, Quebec, on Saturday, November 15th, 1941, at four o'clock p.m.

President C. J. Mackenzie (Ottawa) was in the chair; Past-President J. B. Challies (Montreal); Vice-Presidents K. M. Cameron (Ottawa) and deGaspé Beaubien (Montreal); Councillors J. H. Fregeau (St. Maurice Valley), A. Larivière (Quebec), W. R. Manock (Niagara Peninsula), H. Massue (Montreal), J. A. Vance (Woodstock), and General Secretary L. Austin Wright were present.

There were also present by invitation—Past-Presidents A. R. Decary and O. O. Lefebvre; Past-Vice-Presidents Hector Cimon (Quebec), J. H. Hunter (Montreal), W. G. Mitchell (Montreal), and A. B. Normandin (Quebec); Past-Councillor B. Grandmont (Rimouski); Dr. A. H. Heatley, chairman of the St. Maurice Valley Branch; Dr. Paul E. Gagnon, past-president of the Canadian Chemical Association and honorary treasurer of the Canadian Institute of Chemistry; L. C. Dupuis, chairman, E. R. Gray-Donald, councillor-elect and vice-chairman, Paul Vincent, secretary-treasurer, T. M. Déchêne, A. Laframboise, P. Méthé and Gustave St-Jacques, members of the executive of the Quebec Branch.

The general secretary reported that the amount received from the branches towards the building fund to date was approximately $7,000.00, of which more than $5,500.00 had been contributed by the Montreal Branch. Several of the branches were continuing their campaign, and it was understood that further amounts would be received. The president felt that the Institute should be very grateful to the Montreal Branch, and expressed his own personal appreciation of their splendid effort on behalf of the fund. He also described his pleasure at the success of the efforts of the other branches.

The general secretary reported that as the annual meeting committee of the Montreal Branch desired to have a paper or papers dealing with the engineering phases of civil defence he had cabled the Institution of Civil Engineers in London to see if there was any possibility of one of their members who was familiar with this work coming to Canada at that time to participate in the meeting. The secretary of the Institution replied that it was not expected that any of their members familiar with this important subject would be so situated that they could assist with the annual meeting, but suggested that the Institute might send a member to England to investigate the field for himself, and that in such circumstances the Institution would afford every facility.

The secretary reported that from conversations with President Mackenzie and Vice-Presidents Beaubien and Cameron it appeared that it might be possible to carry out such a proposal, and that in view of the Institute's desire to give leadership in this matter it was advisable to bring the proposal before Council for further consideration and decision.

In the discussion which followed several councillors and guests expressed themselves as favouring such an activity. The president announced that Vice-President Cameron had offered to make available one of the engineers in his department who was competent to do the work. The advantages of having a government engineer undertake the work was apparent to everyone, and it was unanimously agreed that Mr. Cameron's offer be accepted, and that the Institute do everything possible to secure for the use of government and civilian bodies throughout Canada the information which would be helpful in protecting and repairing public utilities and structures which might be subject to attack by bombing or gun fire. It was also agreed that the representative, while in England, should gather the latest information on anti-sabotage methods for the protection of utilities. The arranging of details was left with the president, Vice-President Cameron, and the general secretary.

The general secretary reported that a list of engineers and scientists of German and Austrian origin, who are now in refugee camps in Canada, had been furnished to the Wartime Bureau of Technical Personnel with the information that such men could be released for war work in Canada providing satisfactory positions were offered to them. A subsequent proposal had been reported to the Bureau wherein it was indicated that the government was considering setting up a manufacturing plant in which all these refugees could set to work on the same or similar projects.

In view of the fact that such persons, if competent, could readily find employment, it was agreed that the need of writing Institute examinations in order to establish their qualifications became unnecessary. Therefore, in view of the expense involved in setting papers, the secretary suggested that nothing be done for the present about giving examinations to those who requested it. The original proposal from the refugees had been that they might write the Institute's examinations to obtain membership, but upon being informed that by a recent ruling of Council membership could not be given to enemy aliens, they had requested that the examinations be given to them in any case as a means of establishing their status in Canada for purposes of finding employment.

On the recommendation of the Montreal Branch executive committee it was unanimously resolved that Mr. Walter G. Hunt be appointed councillor to represent the Montreal Branch until the next annual election, replacing Mr. H. J. Vennes who had resigned. It was also unanimously resolved, on the recommendation of the Montreal Branch, that Mr. Hunt's name be submitted on the forthcoming Officers' Ballot, as councillor for the years 1942 and 1943, completing Mr. Vennes' term of office.

The general secretary reported that the various branches had been written to with a suggestion that they might extend the facilities of the branch to engineers from other countries now in Canada. Letters offering to co-operate had been received from several of the branches, and accordingly the names of the members of the Association of Polish Engineers and of the Institution of Electrical Engineers which had been received at Headquarters had been sent to the branches concerned.

The Toronto branch had made a good start by inviting fifteen Polish engineers as their guests at a dinner held previous to their opening meeting, at which a Polish engineer was the guest speaker. Letters received indicated that such hospitality was very much appreciated.

Vice-President Beaubien, as chairman of the Finance Committee, reported that the finances of the Institute were in a healthy condition. Revenue had increased over last year and over the budget; expenditures had increased slightly over last year, but not over the budget, which placed the Institute at this time of the year in a better position than it has been for a long time. Mr. Beaubien pointed out that this was rather an unusual occasion, in that for the month of November, the Finance Committee had absolutely no resignations or removals from the membership list for other reasons, to consider.

Past-President Challies reported that at a recent meeting in Montreal, at which six past-presidents were present, including three of those who originally established the Past-Presidents' Fund, Council's request for a reconsideration of the purposes of the award was discussed. The past-presidents did not wish to make any fixed decision that would bind Council. They explained that the fund had been collected originally for the purpose of assisting the Institute in establishing prizes and building up its finances. Opinions were expressed by the past-presidents that it was thought desirable to continue an award known as the Past-Presidents' Prize with a value of about $100.00 to be paid out of interest on the fund. The balance of the fund might be used for whatever purposes Council felt would be most useful at the time.

Mr. Challies also reported that there was a discussion as to whether or not contributions to the fund by past-presidents should be continued. In view of the fact that since Dr. Lefebvre's presidency the custom had been established of presidents visiting all the branches it was thought that the fund might be of some financial assistance to those presidents whose personal incomes could not meet this cost without considerable inconvenience.

Past-President Décary thought that the privilege of contributing to the fund should be continued, and Past-President Lefebvre agreed with him, stating at the same time that he thought that the interest should be used every year and that any increase in the total amount should come only from new contributions.

Finally, at Past-President Challies' suggestion, it was agreed that the final decision as to the use of the interest and the future of the fund should be left to the Finance Committee to determine. It was also suggested that in view of the report on prizes and awards being drawn up by Mr. Durley some further consideration be given by him to the Past-Presidents' Prize and included in the report.

In view of the fact that the Julian C. Smith Medal was a new award and final regulations have not yet been agreed upon, Vice-President Cameron recommended that the awards for this year should be determined in the same manner as the original awards of last year. By this means the names of the candidates will be selected by the Provisional Committee of Past-Presidents, and will be submitted to Council for approval. The final regulations for the medal are included in Mr. Durley's report, but it is necessary to make this year's selections before the report can be presented for approval.

The secretary reported that the dates set for the Annual General Professional Meeting in Montreal were Thursday and Friday, February 5th and 6th, 1942. A meeting of the annual meeting committee of the Montreal Branch had been held recently, and the programme for the meeting was now practically complete. The principal papers are on war industries, such as guns and aircraft manufacture, research enterprises and the manufacture of munitions. This had the approval of the Hon. C. D. Howe, Minister of Munitions and Supply, who had consented to speak at the opening luncheon. It was also expected that there would be an exhibit of war materials being made in Canada for the first time.

On Thursday night the Montreal Branch would hold its Annual Smoker, and on Friday, the Annual Dinner of the Institute.

To comply with the by-laws, it was unanimously resolved that the Annual General Meeting be convened at Headquarters on Thursday, January 22nd, 1942, at eight o'clock p.m., the meeting to be adjourned and reconvened at the Windsor Hotel, Montreal, at ten o'clock a.m. on Thursday, February 5th, **1942.**

Past-President Challies, as the Institute's representative on the executive committee of the Engineers' Council for Professional Development, reported briefly on the annual meeting of that body, which had been held recently in New York City. A full delegation of Institute members had been present, including the three representatives on the governing body of the Council, the representatives on each of the standing committees, the president of the Institute, and Past-President Cleveland, of Vancouver. In Mr. Challies' opinion, the Institute was taking a very creditable part in the work of E.C.P.D. A detailed account of the meeting appears in this issue.

The general secretary, as assistant director of the Wartime Bureau of Technical Personnel, made a brief progress report on the activities of the Bureau. He indicated that the work was expanding, both in volume and in importance, and that members of the Bureau realized that they had a very serious problem on their hands. He mentioned that regulations were now being drawn up in Ottawa which would strengthen the hands of the Bureau considerably, but at the same time would place greater responsibilities upon it.

The secretary reported that the ballots for approval of the co-operative agreement in New Brunswick were now in the hands of all councillors and corporate members in the province, and were returnable on December 5th. It was unanimously resolved that Messrs. H. Massue and W. G. Hunt be appointed scrutineers to open the ballot and report to Council.

In view of war conditions it was unanimously agreed that the Institute would not send out Christmas cards this year as has been done in recent years, but would instead send a suitable letter to the presidents and officers of sister societies in Great Britain and the United States.

An invitation to participate in an Inter-American Congress of Engineers and Geologists to be held in Chile in January of next year had been received through the Consul General of that country. Correspondence had indicated that it might be possible to include the subject of hydro-electric power development, in which case the Institute might be able to participate.

Mr. Challies thought that the Institute should be represented at such a conference if at all possible, and suggested that it be left with the president and the general secretary to do whatever was necessary in the best interests of the Institute. It was possible that Mr. Hunter would be in Chile at that time. Mr. Hunter explained that although his plans were rather indefinite at the moment, he would keep in touch with the general secretary, and would be very pleased to represent the Institute if he should be in Chile at the time of the Congress.

A number of applications were considered, and the following elections and transfers were effected:

Admissions	
Members	2
Juniors	2
Students	61

Transfers	
Student to Member	1
Student to Junior	1

It was left with the president and the general secretary to decide on the date for the December meeting of Council.

The president expressed his appreciation of the hospitality of the Quebec Branch, his only regret being that it had been necessary to hurry through the business of the Council meeting in order that he and other out-of-town members might catch the evening train to Montreal.

Dr. Gagnon expressed his appreciation at being invited to the meeting, a privilege which he had greatly enjoyed. Similar acknowledgments were made by other out-of-town guests.

ELECTIONS AND TRANSFERS

At the meeting of Council held on November 15th, 1941, the following elections and transfers were effected:

Members

Fraser, John Hugh, gen. supt., steel divn., Dominion Steel and Coal Corporation, Sydney, N.S.

Parry, Thomas M., B.Sc. (Elec.), (Univ. of Alta.), Technical Vice-Principal, Western Canada High School, Calgary, Alta.

Juniors

Farstad, Charles, B.Eng. (Mech.), (Univ. of Sask.), asst. engr., mech. dept., Laurentide Divn., Consolidated Paper Corporation Ltd., Grand Mere, Que.

Hoseason, Harry J., B.A.Sc. (Univ. of Toronto), sales engr., H. H, Robertson Co. Ltd., Toronto, Ont.

Transferred from the class of Student to that of Member

Lecavalier, Jean-Paul, B.A.Sc., C.E., (Ecole Polytechnique), asst. district engr., Quebec Roads Dept., Quebec, Que.

Transferred from the class of Student to that of Junior

Harding, Charles Malcolm, B.Sc. (Elec.), (Univ. of Alta.), elec. engr. Calgary Power Co. Ltd., Calgary, Alta.

Students Admitted

Bowman, William A., (Univ. of Man.), Hudson, Ont.
Dixon, Frederick, instrument dept., Bepco Canada Limited, Montreal.
Glenn, Clayton H., (Univ. of Man.), 655 Mulvey Ave., Winnipeg, Man.
Harvie, John Duncan, (Univ. of Man.), 1185 Wolseley Ave., Winnipeg, Man.
Johnston, Bruce Fraser, (McGill Univ.), 3520 McTavish St., Montreal, Que.
Lawson, Glenn William, (Univ. of Man.), 760 14th St., Brandon, Man.
Merkley, Murray Roy, (McGill Univ.), 257 Strathearn Ave., Montreal West, Que.
O'Brien, William Smith, 4278 Sherbrooke St. West, Montreal, Que.
Pink, John Frederick, (Univ. of Man.), 371 Inglewood St., St. James; Man.
Smith, Robert Lovelace, (Univ. of Man.), 38 Furby St., Winnipeg Man.
Swerdfeger, John Harvey, (Univ. of B.C.), 1065 S.W. Marine Drive, Vancouver, B.C.
Verdier, Paul André, 1610 Sherbrooke St. West, Montreal, Que.

Students at the Ecole Polytechnique, Montreal, Que.

Auger, Roland, 1131 Laurier Avenue West, Outremont, Que.
Bédard, Jacques, Ecole Polytechnique, 1430 St. Denis St., Montreal.
Berthiaume, Joseph-Alphonse, Contracoeur, Verchères Co., Que.
Bouthillier, Jean, 2564 Desjardins Ave., Maisonneuve, Que.
Brunette, Charles Edouard, 1468 Gilford St., Montreal, Que.
Caron, Lucien, 1690 St. Hubert St., Montreal, Que.
Dumont, Lomer, P.O. Box 513, Amos, Abitibi County, Que.
Dury, Jean, 3621 St. Denis St., Montreal, Que.
Ewart, Philip, 121 Second Ave., Verdun, Que.
Grenier, François, 440 Cherrier St., Montreal, Que.
Joubert, Max Nowlen, 607 Merton Ave., St. Lambert, Que.
Julien, Roger, 684 Radisson St., Three Rivers, Que.
Labrosse, Fernand, 3668 St. Hubert St., Montreal, Que.
Lalande, Jacques Bernard, 6270 St. Denis St., Montreal, Que.
Laroche, Jean-Luc, 4128 St. Hubert St., Montreal, Que.
Lavallée, Jean-Charles, 1451 Sicard St., Viauville, Montreal, Que.
Laverdure, Jean Conrad, 4311 Fabre St., Montreal, Que.
Laviolette, Jean-Guy, 2324 Orléans St., Montreal, Que.
Laviolette, Jean-Paul, 3921 St. Hubert St., Montreal, Que.
LeBrun, Hubert, 3683 Laval Ave., Apt. 6, Montreal, Que.
Lacavalier, Robert, 6280 St. Denis St., Montreal, Que.
Leclerc, André, 6824 St. Denis St., Montreal, Que.
Lemieux, Jacques Raymond, 108 Dufferin St., Sherbrooke, Que.
Livernoche, Roger, 113 rue des Sulpiciens, L'Epiphanie, Que.
Mailhiot, Fernard A., 4174 Oxford Ave., Notre-Dame-de-Graces, Montreal, Que.
Marcotte, Benoit Wilfrid, 4439 Adam St., Maisonneuve, Que.
Marsolais, Irenée Wilfrid, 1612 St. André St., Montreal, Que.

Ménard, Jean, 837 Cherrier St., Montreal, Que.
Ménard, Robert, 5840 Chabot St., Montreal, Que.
Mousseau, J. A. Francois, 3457 Laval Ave., Apt. 1, Montreal, Que.
O'Bomsawin, Gérard, 4785 Ste. Emilie St., St. Henri, Montreal, Que.
Palmer, Joseph Paul Victor, Ecole Polytechnique, 1430 St. Denis St., Montreal, Que.
Pauzé, Jean, 382 St. Joseph Blvd. East, Montreal, Que.
Pépin, Georges Alphonse Maurice, 134-9th Ave., Longueuil, Que.
Proulx, Jean-Noël, 7964 St. Gérard St., Montreal, Que.
Rochon, Georges André, 1029 Lafontaine Park, Montreal, Que.
Rolland, Gilbert Lucien, Mont-Rolland, Que.
Ross, Miville, Ecole Polytechnique, 1430 St. Denis St., Montreal, Que.
St-Laurent, Aurèle, 865 Roy St. East, Montreal, Que.
Sansfaçon, Jacques, 441 Malines St., Montreal, Que.
Séguin, Bernard, 2925 Gouin Blvd. East, Montreal, Que.
Sicotte, Bernard, Ecole Polytechnique, 1430 St. Denis St., Montreal.
Smith, Paul M., Ecole Polytechnique, 1430 St. Denis St., Montreal.
Thauvette, Laurent, 3664 Lafontaine Park, Montrea,l Que.
Thibault, Sylvain, 4080 St. Hubert St., Montreal, Que.
Troalen, Pierre, 4281 Chapleau St., Montreal, Que.
Trudeau, Jean, 7764 DeGaspé St., Montreal, Que.
Turcotte, Leonel, 7656 Boyer St., Montreal, Que.
Turgeon, Joseph Alfred Maurice, 526 Sherbrooke St. East, Montreal, Que.

COVER PICTURE

The picture on the cover of this issue shows members of an East Coast anti-aircraft battery at one of the listening devices which are trained on the sky night and day. So sensitive is this equipment that the sound of a locomotive whistle a mile away creates an almost deafening racket in the ears of the operators.

COMING MEETINGS

Association of Professional Engineers of Ontario—Annual Meeting and Dinner, Royal York Hotel, Toronto, Ont., on January 17th, 1942. Walter McKay, Secretary-Treasurer, 350 Bay Street, Toronto, Ont.

The Engineering Institute of Canada—Fifty-sixth Annual General and General Professional Meeting, Windsor Hotel, Montreal, Que., February 5th-6th, 1942. L. Austin Wright, General Secretary, 2050 Mansfield Street, Montreal, Que.

Personals

News of the Personal Activities of members of the Institute, and visitors to Headquarters

Dr. J. B. Challies, M.E.I.C., vice-president of Shawinigan Water and Power Company, and past-president of the Institute, was inducted recently as chairman of the board of governors of the United Theological College, Montreal. He has been for several years a prominent layman in Dominion-Douglas Church.

Dr. T. H. Hogg, M.E.I.C., chairman and chief engineer of The Hydro-Electric Power Commission of Ontario, and past-president of The Engineering Institute of Canada, was invited to deliver the "Brackett" Lecture at Princeton University on Tuesday, November 18th, 1941—a tribute that has only been paid to one other Canadian engineer, Sir Henry Thornton, who some years ago gave a Brackett Lecture on Transportation.

The subject of Dr. Hogg's lecture was "The Hydro-Electric Power Commission of Ontario—a Study in Public Service." He explained how the Commission was formed, how it operates, how it is meeting the requirements of the present war emergency, and described the social and economic benefits it has achieved during its thirty years of operation.

The Cyrus Fogg Brackett Lectureship was established in 1921 at Princeton University in the School of Engineering, by the Princeton Engineering Association—the official graduate body of Princeton engineering alumni. The lectureship is in memory of Dr. Cyrus Fogg Brackett, the Henry Professor of Physics at Princeton from 1873 to 1908—one of Princeton's greatest and most beloved teachers. The Brackett Foundation has brought to Princeton, as lecturers, many of the leaders of America, including Irving Langmuir, Samuel Insull, the late Sir Henry W. Thornton, and many others. Its objective is to bring before the students and faculty men of prominence in engineering, finance, law and business, and to give to Princeton students a better understanding of the implications of engineering in the affairs of the world.

T. W. Fairhurst, M.E.I.C., is at present in Canada on business. He is a director of Ruston and Hornsby Limited, London, England. Several years ago he was connected with the Vancouver Machinery Depot, Limited, and he also spent several years in the United States before going to England.

Lieut.-Col. K. S. Maclachlan, M.E.I.C., has resigned his post as deputy minister of the Department of National Defence for Naval Services at Ottawa in order to undertake active service with the Royal Canadian Navy. In commenting on Colonel Maclachlan's resignation, the Minister of Naval Services said: "Colonel Maclachlan's work as associate deputy minister of National Defence for the first year of the war and from July, 1940, to date as deputy minister for Naval Services was marked by thoroughness, efficiency and a great zeal. He entered into all the work of the Department with earnestness and vigour and his experience in business of various kinds, together with his military knowledge, were great assets to the Department."

Lieut.-Col. W. S. Wilson, M.E.I.C., secretary of the Faculty of Applied Science and Engineering at the University of Toronto, since 1927, has in addition recently been appointed assistant dean of the Faculty.

Major J. F. Plow, M.E.I.C., is now overseas with the Canadian army. He had been stationed for sometime at Petawawa, Ont. Major Plow was assistant general secretary of the Institute from 1930 until 1938 when he went with Chas. Warnock & Company, Limited, Montreal.

Ernest Smith, M.E.I.C., who was with the provincial Department of Public Works of British Columbia, has recently been transferred from New Westminster to Nelson, where he is district engineer.

E. H. Beck, M.E.I.C., formerly connected with the construction of the new National Research Council Laboratories at Ottawa, has recently joined the staff of E. G. M. Cape and Company at Botwood, Newfoundland.

H. M. Black, M.E.I.C., is manager of the Longueuil Plant of Dominion Engineering Works Limited at Longueuil, Que. He has been with the firm since 1940 when he left English Electric Company of Canada Limited, St. Catharines, Ont., where he was sales manager.

Thomas Lees, M.E.I.C., has recently been transferred from Calgary to Vancouver, where he is district engineer for the Canadian Pacific Railway Company. He has been in the service of this company since 1905 and has occupied the position of district engineer at Calgary since 1923.

Neville Beaton, M.E.I.C.

Neville Beaton, M.E.I.C., has recently been appointed to the consulting branch of Wartime Merchant Shipping Limited, Montreal. He had resigned his position as resident engineer of the Powell River Company Limited, Powell River, B.C., in which capacity he had had for the past eight years, charge of plant properties, projects and engineering developments, including the recently completed $1,000,000 constant angle arch dam at Lois River.

Gérald Molleur, M.E.I.C., has been transferred from Quebec to the Montreal Office of the Public Service Board of the Province of Quebec. He was graduated from the Ecole Polytechnique in 1924 and after a year spent with the National Research Council, he went with Quebec Streams Commission where he remained until 1936, except for a few months in 1927, when he worked with the Quebec Pulp and Paper Mills Limited. He joined the Quebec Electricity Commission in 1936 and became in charge of the Quebec office, a position which he occupied until his recent transfer.

W. L. Kent, M.E.I.C., has accepted the position of assistant to the project engineer for construction with Basic Magnesium Incorporated, Las Vegas, Nevada, U.S.A. He was previously on the staff of the Stuart Cameron Company Limited at Lang Bay, B.C.

Flying-Officer G. S. G. Henson, M.E.I.C., has obtained a leave of absence from the Winnipeg Electric Company and has enlisted with the Royal Canadian Air Force, Aeronautical Engineering Branch. After completing his course at the aeronautical school in Montreal, he was recently posted at Yorkton, Sask.

R. P. Freeman, M.E.I.C., has joined the staff of Wartime Merchant Shipping Limited, Montreal, where he is in charge of the Maritime operations of the Company. Lately he had been connected with Defence Industries Limited at Montreal.

R. L. Morrison, M.E.I.C., who is employed with Messrs. Airspeed (1934) Limited at Portsmouth, England, has been for the past eight months chief technical liaison officer, co-ordinating the work of various sub-contractors, workshops, inspection departments, and drawing office. He also advises on problems of plant efficiency.

J. Lyle McDougall, M.E.I.C., who until recently was on the staff of H. G. Acres and Company at Niagara Falls, Ont., is now located in Montreal with the Canadian Pulp and Paper Association, where he acts as assistant co-ordinator for the Wartime Machine Shop Board.

J. B. Snape, M.E.I.C., has joined the staff of the Works and Buildings Department of the Naval Service and is at present stationed at Halifax, N.S. He was previously connected with the National Parks Branch of the Department of Mines and Resources, as resident engineer, at Jasper Park, Alta.

Flying-Officer D. S. Patterson, M.E.I.C., has been commissioned in the Royal Canadian Air Force, and has been posted to the Vancouver station. He was previously connected with the Department of Highways of Ontario at Kenora, Ont.

W. E. P. Duncan, M.E.I.C., general superintendent of the Toronto Transportation Commission, addressed the sixtieth annual convention of the American Transit Association and affiliated organizations held in Atlantic City, New Jersey, recently, on the subject, "Transit Operations in Wartime."

F. S. Stratton, M.E.I.C., is in the employ of the industrial sales division of Exide Batteries of Canada Limited at Toronto. He was previously connected with the Montreal Light, Heat and Power Consolidated, Montreal.

Lieut. R. F. Shapcotte, Jr.E.I.C., has left his position with Pacific Mills Limited, at Ocean Falls, B.C., to accept a commission with the Royal Canadian Engineers, and is at present stationed at Gordon Head, B.C.

Pilot-Officer M. F. Baird, Jr.E.I.C., who is serving with the Royal Air Force Ferry Command is now overseas.

Pilot-Officer W. M. Diggle, Jr.E.I.C., has left his position with the Canadian Bridge Company at Walkerville, Ont., to join the Royal Canadian Air Force and is at present stationed at the School of Aeronautical Engineering at Montreal.

R. C. Peck, Jr.E.I.C., has accepted a position with Demerara Bauxite Company at Mackenzie, British Guiana, S.A. He was graduated in civil engineering from the University of Alberta in 1940.

Capt. J. T. Hugill, S.E.I.C., has recently returned from England and is at present located at the experimental station at Suffield, Alta.

James O. Dineen, S.E.I.C., has recently accepted a position at the University of New Brunswick in the Royal Canadian Air Force radio technicians' school, as a radio instructor, and is also assistant in the department of electrical engineering at the university.

J. G. Wall, S.E.I.C., is now employed as a junior radio engineer by the Department of Transport. He was graduated in electrical engineering from the University of New Brunswick in 1939.

VISITORS TO HEADQUARTERS

G. R. Duncan, M.E.I.C., Fort William, Ont., on October 30th.

J. G. D'Aoust, M.E.I.C., Consolidated Paper Corporation Limited, Port Alfred, Que., on November 3rd.

D. W. McLachlan, M.E.I.C., Department of Transport, Ottawa, Ont., on November 11th.

O. Quévillon, S.E.I.C., city engineer, St-Hyacinthe, Que., on November 11th.

T. S. Mills, M.E.I.C., chief engineer, Department of Mines and Resources, Ottawa, Ont., on November 12th.

J. A. Vance, M.E.I.C., general contractor, Woodstock, Ont., on November 15th.

Major J. Ormond Riddel, M.Am.Soc.C.E., Port of Spain, Trinidad, B.W.I., on November 19th.

R. B. Young, M.E.I.C., testing engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont., on November 23rd.

A. C. Northover, Jr.E.I.C., Trinidad, B.W.I., on November 25th.

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

George Phillips, M.E.I.C., died suddenly at his home in Victoria, B.C., on November 4th, 1941. He was born at London, England, on March 21st, 1868. He joined the Admiralty service at the age of eighteen, being for several years with the works department before he came to Canada in 1898 as a representative of the Admiralty. In that capacity, under the Imperial service, he served at Esquimalt as Admiralty agent until 1910, when the Canadian Government took over the dockyard. At their request, he remained a short time in the Canadian service to train the dockyard staff.

At the end of that period he transferred permanently to the Canadian Government service. His family, which had been waiting his return to England, joined him in Victoria, where he was in charge of the dockyard until his transfer to Halifax in 1917. There he remained two years until his appointment to the Naval Defence Department in Ottawa in 1919. In 1922 he was transferred back to the dockyard in Esquimalt, serving as superintendent until his retirement in 1933.

Mr. Phillips helped to negotiate the purchase of the two submarines secured by the Government during the regime of the late Sir Richard McBride, and helped to outfit the hospital ship, *Prince Robert,* which made the port of Victoria its headquarters during the last war.

It was during his time at the dockyard that the Stefansson expedition left for the Arctic, and in that year, 1918, he played an important part in helping to outfit the expedition. Phillips Strait memorializes this connection, it being named after him by Stefansson.

Mr. Phillips' well-known interest in music predated his coming to Canada, as he was a member of the Royal Choral Society in London. Immediately on arriving here, he associated himself with various musical activities. He was a charter member of the Arion Choir of Victoria, of which he was president for some years.

He was one of the founders of the Victoria Choral and Orchestral Union and held the office of secretary-treasurer. Until recent years he was active in dramatic and musical comedy performances, his name figuring in many entertainments during the last war and since, both in Victoria and Halifax.

After his retirement in 1933, he became secretary of the Naval Veterans' Branch of the Canadian Legion, which position he still occupied at the time of his death.

Mr. Phillips joined the Institute as an Associate Member in 1904, and he became a Life Member in 1934.

Malcolm Sinclair, M.E.I.C., died in the hospital at Yorktown, Sask., on October 12th, 1941. He was born at Edinburgh, Scotland, on the 11th of May, 1880, and received his education at the Edinburgh University and Watt College, where he served his apprenticeship from 1900 to 1906 in the office of James D. Gibson, Civil Engineer, Edinburgh. He spent the next five years with various firms of consulting engineers and was engaged in general construction work. He came to Canada in 1911 and for the next four years was connected with the Dominion Land Survey Department at Moose Jaw, Sask. During the first world war he was inspector of munitions at Moose Jaw. Following the war he became city engineer at Moose Jaw and remained in this position for ten years. During that time he did a great amount of construction, developing parks, buildings and water works. In 1930 he became city engineer of Yorktown, Sask. Lately Mr. Sinclair had been connected with construction work on the British Commonwealth Air Training Plan airports in the vicinity of Yorktown.

Mr. Sinclair joined the Institute as an Associate Member in 1917 and he became a Member in 1940.

News of the Branches

Activities of the Twenty-five Branches of the Institute and abstracts of papers presented

CALGARY BRANCH

P. F. Peele, M.E.I.C. - *Secretary-Treasurer*
F. A. Brownie, M.E.I.C. - *Branch News Editor*

The following is a summary of our recent meetings:

A talk on **Oil Exploration** was given by Mr. W. H. Gibson, engineer with the McColl-Frontenac Oil Co., on October 9th. Mr. Gibson described five methods in use for locating possible oil structures. Soil analysis whereby an increase in the hydro-carbon content provides a possible clue to the existence of an oil-bearing structure. Measurement of the electrical resistance of the earth as well as the determination of the strength of the vertical component of the earth's magnetic field provides another means of locating possible oil structures. Both of these methods must be supplemented by more accurate alternatives.

Another and more accurate method consists in measuring the variations in gravity over the piece of ground to be explored. Delicate gravimeters show the difference in mass distribution and hence the presence or absence of rock strata.

The seismic method is the one considered most accurate at the present time. Reflected and refracted waves from explosives can be accurately measured and subsurface structures mapped.

On October 23rd Mr. H. K. Dutcher gave a very interesting account of the **Building of the Terraleah Power Plant** in Tasmania. A comparison was made between working conditions there and in Canada. The Australian workman proved to be very efficient and took a keen interest in the work. The lack of standard railroad track gauges proved a handicap in transporting equipment.

On November 6th Flight-Lieutenant W. Thornber of R.C.A.F. No. 4 Training Command in Calgary gave a very interesting talk on **Modern Military Aircraft**. The importance of striking power and safety to the crew is uppermost in the minds of the designers, and present trends are in the direction of increased speeds and heavier armament.

The speaker outlined the salient features of both allied and enemy aircraft. By means of slides he was able to show the means used in identifying the more common types of planes.

The Calgary Branch recently formed a special committee to assist local military and airforce engineers in selecting suitable recruits for commissioned ranks. This committee is composed of two members from the Alberta Professional Association so that there will be a proper tie-in between the two organizations. It is proposed to invite the chief engineer of our local military district to be present at any meetings of this committee.

HALIFAX BRANCH

S. W. Gray, M.E.I.C. - *Secretary-Treasurer*
G. V. Ross, M.E.I.C. - *Branch News Editor*

The first dinner meeting since May was held Thursday, October 23rd, at the Halifax Hotel. Sixty-seven members and guests were present, an unusually large attendance for this Branch.

The guest speaker was Mr. Guina, Assistant General Manager of Canadian Colloid Company, who spoke on **Boiler Feed-water and its Control**. Mr. Guina outlined the sources of impurities in feed waters, the chemical composition of harmful ones and the condition they produce in a boiler. He then dealt with the reagents used in water treatment and the chemical reactions and results which each one produced in the boiler, and illustrated testing apparatus and control charts for use in boiler plants.

Although Mr. Guina's paper was quite technical it proved to be interesting and informative even to those who have no contact with feed-water problems. The discussion which followed covered everything from small heating plants to battleships until Chairman Fultz called a halt.

Lieutenant Moore, R.C.N., supplied the comedy. His skill in card dealing is such that few of those present would care to sit in with him for even a friendly game.

HAMILTON BRANCH

A. R. Hannaford, M.E.I.C. - *Secretary-Treasurer*
W. E. Brown, Jr.E.I.C. - *Branch News Editor*

On Thursday, November 7th at 8 p.m., the branch visited the plant of the Dominion Foundries and Steel Limited, Hamilton. The occasion was **War Production**, and on this account only Members, Juniors and Students of the Institute were invited.

The members, numbering 65, assembled in the firm's board room where Chairman W. A. T. Gilmour introduced the party to Mr. W. D. Lamont.

Chief Metallurgist Lamont welcomed the party on behalf of his management and then gave a descriptive talk on peace-time and present production of the plant, together with a volume of information of the work we were about to see. He stated that peace-time production of the steel foundry was castings of which a large percentage is alloy steel. The castings are electric steel exclusively. Until very recently they operated the only plate mill in the Dominion of Canada. Five years ago they started the only tin plate mill in the Dominion and are still operating the only cold reduction tin plate mill in Canada. In normal times railway car forged axles accounted for a share of the plant's production.

Dealing with the change of operation due to present needs, Mr. Lamont said that having available a 1,000-ton steam hydraulic press, their position was ideal, in fact unique, for making gun barrels; also the fact that they had plate mills already in operation made possible the immediate start on production of rolled armour plate.

The Canadian Government asked the Dominion Foundries and Steel Limited to attempt to produce homogeneous rolled armour plate; which up to this time had never been produced in the Empire, except in the British Isles. The attempt was made and the first war material produced was bullet-proof plate which is necessary in the construction of the Bren gun carrier. This first attempt stood up against all the British Government ballistic tests and, since that effort, every month production is being improved and vastly increased.

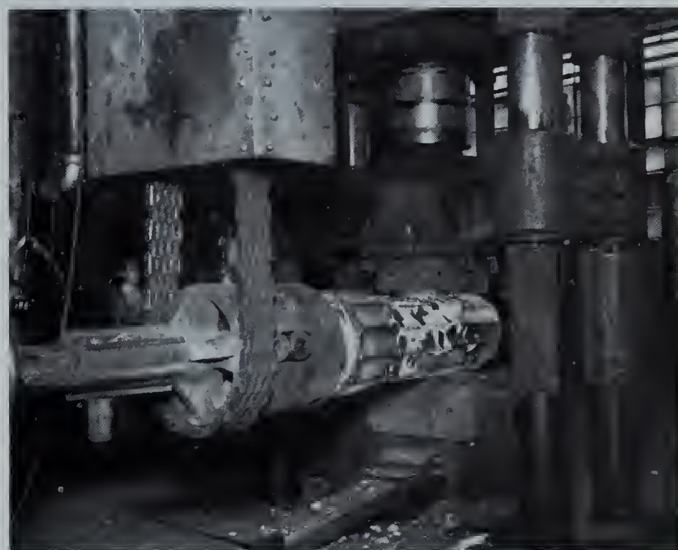
At the same time, as previously referred to, the Alloy Steel Foundry placed the firm in an excellent position to produce armour castings for use in both the British and the American designed tanks which are being fabricated and assembled elsewhere in Canada.

The above explains briefly why the firm was able to enter the war production business and the following will outline what the E.I.C. members saw in the foundries and shops.

The arrangement of guides was very good as each party consisted of five or six members only, so that in some of the noisy shops each person could hear their guide's information.

We first witnessed the forging of a gun barrel blank, from an 8,000 lb. ingot, under the dies of the 1,000-ton hydraulic press. During this operation the forging is balanced in an endless chain manipulator, which handles the hot metal with the skill of a human juggler. When the forging is completed it is heat treated for machinability.

The foundry is busy producing armour castings for tanks and Bren gun carrier castings.



First blow of 1,000-ton press.

Next we went to the Machine Shop and saw a piece being turned on a low swing eight-tool lathe. This operation is completed in four hours following which the piece is bored on a double-ended boring lathe to a size that we are requested to call " blank." The guns are then heated in a 30-ft. deep electric furnace and are treated in pairs, in each furnace, suspended from a jig that passes through the furnace door and then rests hanging on a beam or bracket that crosses over the top of the furnace. The furnace is about 7 ft. in diameter and the top is about 4 ft. above the shop floor; thus the " door " referred to is the top or hatchway of the furnace.

This circular furnace or well is divided into 5 zones, each of which is under close pyrometric control and each of these zones can be controlled to a + or — 5 deg. range. This is very different from the old fuel-fired furnaces.

It is very impressive to see the two 20-ft. long barrels brought up, vertically, from out of this white hot electrically heated well.

The barrels are now carried a short distance to a similar well, except that it is 35 ft. deep and filled with oil. The hot metal is rapidly lowered into the oil and quenched. After 45 minutes in the oil they are again raised and placed in another vertical furnace for temper.

At the end of this shop, six machines stand close by where tests are prepared for observation and acceptance—or rejection—by the British representatives.

Passing into the Armour Plate Department we saw the processing of armour plate and bullet proof plate ranging in gauge from 3 to 60 millimetres. Here we also saw the cast steel tank turrett. This complete casting, in one unit, supersedes the former fabricated turret which was made up of rolled plate and castings which involved considerable cutting and fitting. This new unit enables a saving of 75 per cent. of man-hours machinery time. This development was conceived by this plant during the past few months and had to receive the approval of the British Government after it had been devised.

Next we went to the Melting Department. All the gun

Close up of lathe rough turning gun.

and armour plate steel is melted in electric arc furnaces. There are two 10-ton furnaces and one 25-ton furnace. Nearing completion is a 50-ton electric furnace which will have a transformer capacity of 12,000 kva. and this branch of the Institute was pleased to hear that this unit of the furnace is built by the Canadian Westinghouse Company.

The " open hearth " capacity consists of four 60-ton Isley control furnaces. This kind of furnace is found to be most suitable for melting and refining of the " bottom poured " steel the firm is producing.

Next we went to the Tin Plate Mill. The processing of tin plate starts with the continuous pickling of the hot roll strip, which is then cold reduced in either the 36-inch or the 42-inch four high cold reduction mill. The processing of tin plate strip in this type of mill is revolutionary and marvellous and it was hard to get the party away from this operation. The pressure exerted by the main screws on this mill runs as high as 1,000,000 lb. on each screw.

The processing was carried through the cleaning line where the surface is de-greased and made chemically clean and then on through the annealing department. In the Annealing Department the coils are annealed in radiant tube inert atmosphere furnaces. From there to the Temperature Mill the strip is reduced 1, 2 or 3 per cent. to give it the desired temper. For example, the temper required for a bottle top is quite different to that required for a sardine can.

Next it goes to the shear line in which a " flying shear " cuts the travelling strip faster than one can count. An electro limit gauge segregates heavy or light gauge material automatically. These bright steel sheets then go to the Tin House to be given their coating of tin. This is done automatically, the sheets being fed singly into the tin pot by a system of magnetic rolls. The steel sheet is now completed and becomes known as " tinplate."

After inspection and packing the tin plate is shipped to some of the many packing factories of the Dominion.

After the members had completed the tour of the works, they were taken back to the cafeteria where a most enjoyable light supper was served.

Mr. C. H. Hutton proposed a vote of thanks to Mr. Lamont for his lecture and the able way he had conducted the visit and asked him to thank the management, and particularly Mr. F. A. Sherman and Mr. F. A. Loosley, both Hamilton branch affiliates, for this most instructive evening.

LAKEHEAD BRANCH

W. C. Byers, jr.e.i.c. - *Secretary-Treasurer*

A dinner meeting was held at the Italian Hall in Port Arthur on October 15th at 6.45 p.m. There were 34 members and guests present.

The chairman, B. A. Culpeper, presided at the meeting and five short addresses were given.

G. H. Burbidge spoke on **Lakehead Winds**. He mentioned the various mythical conceptions of winds and with charts he described the causes and actions of the various prevailing and trade winds and showed the differences between cyclones, tornados and thunderstorms. He then described a diagram showing statistics of average velocities and maximum wind recordings of Lakehead winds.

J. Koreen explained briefly the **Building of a Ship.** He referred to the building of the Ark, the length of which was six times its width, the same proportions as are used in modern ship construction. Previous to 1840 all ships were made of wood and seldom exceeded 200 ft. in length. He showed pictures of the first British passenger ship, the *Comet,* which was 43 by 11 by 5 ft. and the latest, the *Queen Mary,* which was 1018 by 118 by 135 ft. He described various phases of shipbuilding and illustrated these with plans and photos.

S. T. McCavour spoke on the **Trials and Tribulations of the Pulp and Paper Industry in Wartime.** During the first two years of the war the industry provided $400,000,000 of foreign currency, and has the largest Canadian industrial payroll being approximately $50,000,000 annually plus woods operation. It consumes about half the industrial electrical energy sold in Canada. The industry met the needs of the United Kingdom when European markets were cut off. The speaker then described problems arising from the war and how the industry was meeting them. Every Canadian mill is practically running at capacity.

R. J. Prettie talked on **Pre-fabricated Hangars.** He described the methods of preframing and the use of ring connectors for joining the timbers. Timber shrinkage presented no problems because the wood was treated with a chemical which attracts moisture and thus keeps the wood from becoming absolutely dry. The speaker illustrated his talk with plans and photos.

H. P. Sisson gave an address on the **Building of a Road.** He reviewed the history of road building in the Thunder Bay district, the earliest account of which was found in a report of 1857 made by the Red River expedition. He described the work of survey parties and the constant struggle to open up the country. Most of the earlier work was done voluntarily. He outlined work done by the provincial government; the establishment of a colonization road branch in the late 19th century; the organization of the Department of Northern Development in 1911, and the change-over in 1937, when the maintenance and construction of local roads was taken over by the Department of Highways. There are now 1595 miles of roads in the district.

W. H. Small tendered a vote of thanks to the various speakers.

LONDON BRANCH

H. G. Stead, jr.e.i.c. - *Secretary-Treasurer*
A. L. Furanna, s.e.i.c. - *Branch News Editor*

The branch held its regular meeting on Wednesday, October 29th in the drill hall of the Talbot Street armouries.

The chairman, R. W. Garrett, introduced Mr. Saunders of the Canadian General Electric Company who showed moving pictures of the present war. These pictures are the property of Mr. H. R. Henderson of Woodstock, who loaned them in aid of the " Milk for Britain " Fund.

The first scenes were of the Russian invasion of Finland. Following these were pictures of the German pocket battleship *Admiral Graf Spee* taken as it limped into the port of Montevideo after its engagement with units of the British fleet. Other pictures showed the ship partially submerged, twisted and burning where it lay scuttled by its own crew. Then was shown the German march into Denmark and Norway. These pictures included several in which the British fleet was seen in action during a raid on the port of Narvik. Following these were pictures of the German advance through the Netherlands and Belgium, then into France and the Maginot Line. Some of the most remarkable pictures were taken during the retreat at Dunkerque. The third reel was of the Italian invasion of Ethiopia, Albania and Greece and ended with scenes of the British campaign against the Italians in Africa. The final reel was a colour film of the Royal visit taken in Ottawa and Toronto.

The large number of members and guests in attendance included several officers from the headquarters of Military District No. 1.

A silver collection was taken in aid of the "Milk for Britain" Fund.

NIAGARA PENINSULA BRANCH

J. H. Ings, M.E.I.C. - *Secretary-Treasurer*
C. G. Cline, M.E.I.C. - *Branch News Editor*

In connection with the opening of the Rainbow Bridge recently constructed over the Niagara River at Niagara Falls, a dinner meeting of the Niagara Peninsula Branch was held at the General Brock Hotel on October 29th. The branch chairman, A. L. McPhail, presided and there was an attendance of 105.

Mr. C. E. Kaumeyer, general manager of the Niagara Bridge Commission, introduced the first speaker, Mr. Shortridge Hardesty, LL.D., of Wardell and Hardesty, who spoke on the design of the bridge, using lantern slides to illustrate his subject. The new bridge was built for the Niagara Falls Bridge Commission to replace a former two-hinged arch span, owned by the International Railway Company, which was destroyed by ice in January 1938. The new bridge is 400 ft. downstream from the old bridge and the deck was raised to cross over roadways on each bank and give better approach conditions. The springing points of the new arch were raised 30 ft. and the span was lengthened 110 ft. to give a total span of 950 ft., which makes this the longest plate-girder arch ever built. The first preliminary designs were for a two-hinged arch, but the hingeless arch design was adopted finally to give greater stiffness. The two box-type ribs are 144 ins. deep and 54 ins. wide and are stiffened by internal plates and by angles. The ribs are spaced 56 ft. on centres and have K-type lateral bracing at the top and bottom flanges, the struts at each panel point being trussed to form a sway frame. The deck framing is supported by square spandrel columns which were left unbraced to improve the appearance. The approach structures at each end of the main span are of reinforced concrete. Further details can be found in an article by Dr. Hardesty published in the September issue of *Civil Engineering*.

The second speaker was Mr. E. L. Durkee, erection engineer of the Bethlehem Steel Company, who described the general erection procedure and commented on the motion pictures taken during erection. The method of erection was described in the Branch News section of the August *Journal* in the report of the June meeting of the branch. Even those who had heard Mr. Durkee before, found much of interest in this second showing of the pictures.

Councillor W. R. Manock moved a vote of thanks to the two speakers.

OTTAWA BRANCH

R. K. Odell, M.E.I.C. - *Secretary-Treasurer*

The initial event of the fall and winter season of the Ottawa Branch was a noon luncheon at the Chateau Laurier on Thursday, October 23rd, at which President C. J. Mackenzie spoke upon the subject of **The Role of the Research Worker in War**. Dr. Mackenzie indicated the place in the war effort now occupied by the National Research Council, of which he is acting president.

Workers who had been engaged on pure research before the war, both in Great Britain and Canada, are now engaged on problems of immediate and vital importance to the war effort, declared the speaker. These trained men had had to turn their talents away from pure research to *ad hoc* problems and were found to be excellently suited to carrying on such work. This is just one more argument in favour of keeping up research work during peace times, for the value of research in wartime, has been established beyond question. "If scientists had not been able to overcome the magnetic mines used by the enemy, and to do that quickly, there is no need for going into details of what might have happened," stated Dr. Mackenzie.

In the present effort, team-play counts for a great deal. Any resemblance to a caste system, maintaining differences between research men, and the mechanics who work with them, can no longer be found. Quite often the most valuable team is the university man, and the workman at the bench, working together and there is always fine harmony between them.

There is one thing that must be remembered, however. Under war conditions, time is a vital element and radical changes involving extensive delays are not feasible. Unless we can put the equipment in the hands of the man in the field, it is of no use. In some cases, therefore, it is better to go ahead with inferior equipment than to try to make the effort to change. This would be the case with large items when major changes involved an extensive time element.

With small items it is possible to effect changes in a reasonable length of time and these can be made. Also in the "middle field" of tanks, planes and other like equipment, changes may have to be made as the battle goes on in order to keep pace with or keep ahead of the enemy. This is a very difficult field in that the development end and the production end of the whole process may have to be "telescoped" as much as possible. Quite often a compromise has to be made and a design "frozen" at some point in order to go ahead with production.

Since the war started, real studies have been made in many fields in Canada. There exists an excellent liaison between scientists in this country and those of Great Britain and United States, through personal contact and interchange of personnel, thereby enabling the work to be correlated. "We are not working in a vacuum in Canada", stated Dr. Mackenzie.

T. A. McElhanney, chairman of the Ottawa Branch presided, and included among the guests at the head table were three past-presidents of the Institute: G. J. Desbarats, Dr. Charles Camsell, and Dr. J. M. R. Fairbairn.

Previous to the president's address, the chairman announced that a mantel clock with chimes had been sent by the Branch, to the officers' mess of the Royal Canadian Engineers' Training Centre at Petawawa. It was sent to them following a visit of the branch to the training centre during the summer, and was acknowledged by the commanding officer and the mess president.

PETERBOROUGH BRANCH

D. J. Emery, M.E.I.C. - *Secretary-Treasurer*
E. Whiteley, S.E.I.C. - *Branch News Editor*

At the technical meeting on October 23rd, Mr. A. E. Byrne of the appliance and merchandise department, Canadian General Electric Company Ltd., Toronto spoke to Peterborough Branch about **Plastics**.

Mr. Byrne described in broad outline the field of plastics as it is to-day and the probable trends. The main classes of plastics were shown, their derivation, outstanding properties and typical uses being mentioned in each case.

This was one of those papers, particularly useful in these days of restricted material supplies, which can

At the Regional Meeting of Council in Quebec City. From left to right, A. B. Normandin, Past-Presidents O. O. Lefebvre and A. R. Decary, Alex. Larivière, Hector Cimon and Bruno Grandmont.

greatly assist the puzzled engineer in an intelligent appreciation of as many available materials as possible and their field of usefulness.

QUEBEC BRANCH

Paul Vincent, m.e.i.c. · *Secretary-Treasurer*

The president of the Institute, Dean C. J. Mackenzie, honoured the Quebec Branch with his visit on November the 15th.

At 1.30 p.m. a reception at the Chateau Frontenac was given to officers of the Institute, who had come to Quebec to attend the regional meeting of the Council. Besides

The president was guest of the Quebec Branch at the luncheon before the Council meeting. From left to right, President C. J. Mackenzie, Chairman L. C. Dupuis, Past President O. O. Lefebvre.

the president, there were among the guests Vice-Presidents de Gaspé Beaubien, Montreal; K. M. Cameron, Ottawa; Councillors W. R. Manock, Fort Erie; J. A. Vance, Woodstock; Huet Massue, Montreal; A. Larivière, Quebec; J. H. Frégeau, Three-Rivers; Treasurer John Stadler, Montreal and General-Secretary L. Austin Wright, Montreal; Past Presidents O. O. Lefebvre, J. B. Challies, A. R. Decary; Past Vice-Presidents J. H. Hunter, W. G. Mitchell, Hector Cimon, and A. B. Normandin; Dr. A. H. Heatley, chairman of the St-Maurice Valley Branch; Dr. Paul Gagnon, of Laval University, Quebec, the officers and several members of the Quebec Branch. This was an excellent occasion for all to meet and chat.

At two o'clock, all sat for the luncheon which was presided over by L. C. Dupuis, chairman of the Quebec Branch. Mr. Dupuis welcomed the Headquarters party, expressed the pleasure of the branch at having them present and introduced the president.

Dean Mackenzie expressed his delight for this opportunity to visit the Quebec Branch and his appreciation of the hearty welcome of the members.

He then spoke in an informal way on the **National Research Council Work in Relation to the Present**

L. D. Swift, Jean Saint-Jacques, René Dupuis, Théo. M. Dechene, Adhémar Laframboise.

War. As acting president of the National Research Council Dean Mackenzie described the work done by this organization. He gave a very interesting outline of the tasks undertaken in every field, and especially in aviation.

He stated that the present war had developed into an engineer's war and the engineers and the technicians were working together as a team by pooling their resources. Through this scientific research Canadian engineers, he mentioned, helped greatly to make the British supreme in the air.

Scientific research to-day meant the full co-operation of all the individuals from the Ph.D. to the mechanic at the bench and the importance of one individual over another could not really be established.

He expressed that we had to be prepared for a long and hard industrial war, which included four steps: research and development; engineering design; industrial production; and fourthly, the operations by and equipment of the men.

In view of this fact, the National Research Council

From left to right, Branch Chairman L. C. Dupuis, Past-Presidents O. O. Lefebvre, J. B. Challies and Past Vice-President J. H. Hunter.

·Bruno Grandmont, Philippe Méthé and Alex. Larivière.

R. B. McDunnough, W. R. Manock, J. A. Vance and Gustave St-Jacques.

was planning to increase its staff of nearly two hundred to some nine hundred and to spend five times more money than their last budget of $800,000, in order to operate on a much larger scale in the four divisions of the Council: mechanical engineering, physics and electrical engineering, chemistry and biology.

Past Vice-President Hector Cimon thanked the speaker in the name of all members.

A short recess followed the lunch, after which Council members invited all Past-Presidents, Past Vice-Presidents, and the officers of the Quebec Branch to the regional meeting. This meeting was adjourned at 5.30 p.m.

At the close of the meeting, Dr. A. H. Heatley and Dr. Paul Gagnon moved a vote of thanks for the kind invitation which had been made to them to attend Council's deliberations.

SASKATCHEWAN BRANCH

Stewart Young, M.E.I.C. - *Acting Secretary-Treasurer*

A special meeting of the Saskatchewan Branch was held in the Saskatchewan Hotel on Thursday, September 25th, to meet the president Dean C. J. Mackenzie. At the noon luncheon, at which the attendance was thirty, Dean Mackenzie spoke of his activities as acting president of the National Research Council of Canada. The meeting adjourned at 2 p.m. to meet at 4.30 when Dean Mackenzie addressed the meeting on the activities of the Institute Both meetings were entirely informal and at the conclusion, Mr. L. A. Thornton moved a hearty vote of thanks to the president, expressing gratitude at his being able to stop over for the day in Regina.

TORONTO BRANCH

J. J. Spence, M.E.I.C. - *Secretary-Treasurer*
D. Forgan, M.E.I.C. - *Branch News Editor*

The Debates Room, Hart House, was filled almost to capacity on November 6th for the second meeting this season of the Toronto Branch of the Institute. Mr. H. E. Brandon, branch chairman, conducted the meeting.

The speaker of the evening, Mr. D. C. Tenant of the Dominion Bridge Company, who is well known in both Toronto and Montreal, was introduced by Dean C. R. Young. His subject was **Air Raid Precautions, Structural Defence,** and the large attendance testified to the widespread interest felt in this timely subject. It is expected that his paper will be printed in an early issue of the *Journal.* Mr. Tenant's most interesting talk was illustrated by lantern slides, and at its conclusion a further vivid description of the actual results of German bombing in London, profusely illustrated by actual photographs, was given by Captain Gordon Kennedy. The latter has spent several months in London and England until returning to Canada recently. At the conclusion of both talks a considerable amount of discussion took place, during which some illuminating information in regard to the behaviour and structural protection afforded by various building materials, was brought out. The thanks of the meeting were expressed by Mr. W. E. P. Duncan.

Owing to its conflicting with other previously scheduled engineering affairs, the third meeting for the year which was to have been held on November 20th, has been cancelled.

VANCOUVER BRANCH

T. V. Berry, M.E.I.C. - *Secretary-Treasurer*
A. Peebles, M.E.I.C. - *Branch News Editor*

The branch opened its season with a dinner-meeting in honour of Dean Mackenzie, president of the Institute, during his recent visit to the western branches. The meeting was well attended, and members were treated to a splendid address by Dean Mackenzie.

He spoke principally of his experiences with engineers who are engaged in war production and training. In his position as head of the National Research Council, Dean Mackenzie comes into intimate contact with all branches of war work, both in industry and in the services. His descriptions of the work done by the engineering profession, and the part taken by members of the Engineering Institute of Canada, were both illuminating and of deep interest to the Vancouver Branch.

Others who spoke briefly were two past-presidents of the Institute, Major G. A. Walkem and Dr. E. A. Cleveland. Dean J. N. Finlayson, branch chairman, presided over the meeting.

The first programme meeting of the season was held in the Medical Dental building on October 16th. The speaker was Mr. Jack Cribb, superintendent of West Coast Shipbuilders Ltd. His subject was **Some Marine Salvage Experiences of the Pacific Coast.**

Mr. Cribb traced the marine salvage history of the Pacific coast, in which he has played a prominent part. He then recounted in detail some of the most interesting and spectacular salvage jobs which have been carried out on this coast. From the narrow channels and rocky shores of northern British Columbia to the sandy beaches of Guatemala and Mexico, each salvage job presents its own problems. Every branch of engineering is involved to some degree, and the salvage superintendent must understand the methods of mining, logging, civil, electrical and mechanical engineers, as he may have to apply any or all of these to some particular salvage operation. One ship will be rescued by hydraulic dredging of sand, another by building a cofferdam around her, or by blasting away the rocks on which she is grounded. Again, the cargo may be salvaged by a logger's skyline, and in every case the salvor must set up and keep in operation many types of equipment and machinery under difficult conditions of weather and remoteness. On occasions he may have to contend with hostile government agents or hijacking beachcombers, and must be able to deal tactfully and successfully with the numerous interested parties who cluster around the wrecked vessel. Some operations are highly remunerative, others are just the opposite, but in every case the risk is high, and those who undertake it must not be lacking in ability or the courage to work in the face of great odds.

In closing, the speaker expressed the opinion that nine out of ten marine mishaps are the direct result of incompetence and carelessness on the part of someone, be it the builder, owner, or captain of the vessel.

A vote of thanks was tendered the speaker for his delightfully informal and non-technical story, by Mr. W. H. Powell. Several among the thirty-two members and visitors present, contributed to an informal discussion.

Tool Steels—Their Use from the Viewpoint of the Shop. This was the subject of a paper presented to the branch on November 6th, by W. O. Scott, vice-chairman of the branch, and assistant superintendent of the Dominion Bridge Company in Vancouver.

Mr. Scott first gave a list of the tools and equipment requiring a special quality of steel which would be found in the average shop not engaged in mass production work. These included punches, dies, chisels, rivet snaps and dies, shear and saw blades, drift pins, taps and dies, hand tools, drills and blacksmith tools. Other special equipment depending upon the nature of the work done includes, in the case of a structural shop, lattice bar punches and dies, square hole punches and dies, spacing tables for multiple punching, boring and milling machine tools, rotary planer tools, threading tools, reamers, as well as various small machine parts which are subjected to severe shock or wear. The items requiring some special type of steel will number many thousand, and these must be made and repaired in the shop itself in most cases, as it is not always possible to secure the necessary item quickly enough from a machine tool manufacturer.

The common requirements of a special steel for such tools and parts are hardness, toughness, high cutting speed, resistance to impact, durability at high temperatures, machinability, and the properties necessary for dies of intricate design. These properties will be desired in varying degrees for each purpose, and the selection and treatment of a material will determine its subsequent behaviour in service.

Most of the ordinary tools may be made from a straight carbon steel. The controlling factor is the carbon content which may range from 0.4 to 1.4 per cent, thereby providing a wide variety of steels for different types of service. The speaker showed a chart of carbon steels, indicating the range of carbon contents for each tool in common use.

In many cases, desirable qualities can be improved by the use of an alloy steel. Alloys will also provide more accurate dies and tools, due to the reduced shrinkage and distortion under heat treatments. A comprehensive chart was displayed, showing the effects produced by the common alloy metals, manganese, chromium, nickel, tungsten, vanadium and cobalt. Some of the desirable qualities of the steel will be increased and some will be decreased by the addition of the above metals. This is according to whether the alloy metal tends to unite with the ferrite portion or the iron carbide portion of the steel. The phenomenon of grain growth, which is a factor in hardness and toughness, is also affected by alloying. Grain growth at high temperatures is retarded, which preserves better these qualities under such circumstances. Another quality acquired in alloy steels is greater uniformity of heat treatment throughout the thickness of the piece. Carbon steels are usually hardened to a very limited depth below the surface, leaving the interior relatively soft.

At the present time there are many tool steels on the market under trade names. These are merely alloy steels of a definite composition, and they will perform the same work as any other steel of the same composition. They should not be treated any differently, regarding the work which they are expected to do, than any tool steel of some specific chemical composition. It is necessary to follow a manufacturer's specifications closely when the composition of his product is not furnished, just as it is necessary to use the correct treatment with any steel of standard composition. Tools are also available, made by casting, pressing and sintering materials other than iron. These are special purpose tools which require different treatment and application than steel tools.

Some discussion took place after Mr. Scott's address, and a vote of thanks was proposed by Mr. P. Buchan. Dean J. N. Finlayson, branch chairman, presided, and thirty-five members and guests were in attendance.

VICTORIA BRANCH

Kenneth Reid, M.E.I.C. · *Secretary-Treasurer*

Spans in Time and Space was the intriguing subject of an address presented before the Victoria Branch of the Institute by Sir Heaton Forbes Robinson, C.G.M., M. Inst. C. E., on the evening of Monday, October 27th. The meeting was preceded by a dinner to which were invited all engineers serving locally in any of His Majesty's Services, whether members of the Institute or not. Twelve engineers in the naval and army services were guests of the branch on this occasion. Altogether thirty-two members and visitors were present.

Sir Heaton Forbes Robinson is an engineer of wide distinction having practiced extensively on the continent of Europe, in South Africa, and in the Argentine in South America. He is now retired and living in Victoria and this Branch is fortunate in securing him as a speaker. Sir Heaton is a graduate of the University of London and a Member of the Institution of Civil Engineers of Great Britain.

In introducing his subject, Sir Heaton Forbes Robinson contrasted the working conditions of half a century ago with those of to-day when an engineer paid for his apprenticeship and worked from 6 to 6. Wonderful advances have been accomplished during the past 50 years. What have the next 50 to offer? Looking back, tremendous developments have taken place particularly with regard to tools, material and fundamental principles connected with bridge building and design. The speaker went on to trace this development from as early as the stone age showing the advance in the use of clean cutting edges, the chisel, axe, saw, file and the turning lathe, a transition from the wheel. The advance in development of materials, wood, stone and metals contributed its effect. Improvements in fundamental principles contributed to the suspension bridge, lintel, corbel, cantilever and arch.

Various types of early bridges in use in widespread parts of the world were then described and the development of modern structures traced from them down to the modern suspension bridge. By means of carefully prepared charts, the speaker showed the fundamental types of spans; the lintel and posts, the truss, which was a tappered lintel with the inside cut out; plate girders, exaggerated lintel; lattice girders, such as used on the Quebec bridge; and the arch.

Sir Heaton concluded by a comparison of music and bridge building; the fundamental principles of each being few but equally interesting. He compared the musical symphony to an automobile; the changing tempo to the changing gears—the automatic gear shift is equivalent to the perfect musical score; the model T Ford to the silly symphony.

A hearty vote of thanks was accorded the speaker for a most interesting address.

Seven reels of motion pictures showing mechanical equipment engaged in actual fire-fighting scenes in the forests of British Columbia and kindly supplied and operated by Mr. J. H. Blake of the Provincial Forestry Department completed the evening.

On the evening of November 10th the members of the Victoria Branch met to witness the showing of the Institute's motion picture film on the **Tacoma Bridge Disaster**. The meeting was preceded by the customary dinner at Spencer's dining room.

Sufficient comment has already been made concerning this marvelous film. As was stated by many present, the Institute is to be congratulated on its enterprise and initiative in acquiring and distributing this film to the various branches across Canada. It has virtually to be seen to be believed, and provides an opportunity for study and comparison of such bridge structures and the possibility of unforseen behaviour under unfavourable conditions.

During, and following the showing of this film, the branch was fortunate in having Mr. A. L. Carruthers, provincial bridge engineer, to augment the descriptive portion of the picture. Mr. Carruthers was very familiar with this bridge and its behaviour subsequent to construction. He explained the unusual behaviour and the building up of periodic vibrations until dangerous proportions could be reached. His remarks were illustrated by the aid of several slides from his own collection. This combination of motion pictures and descriptive comment proved a most interesting subject indeed.

Further moving pictures shown by Mr. J. H. Blake of the provincial forestry department depicting the opening of the Big Bend Highway and other subjects rounded out a very interesting and instructive evening.

WINNIPEG BRANCH

C. P. Haltalin, m.e.i.c - *Secretary-Treasurer*
T. A. Lindsay, m.e.i.c. - *Branch News Editor*

The Winnipeg Branch held its first meeting of the 1941-42 season on October 16th in the Broadway Building of the University of Manitoba.

A motion picture, **The Tacoma Bridge Failure** was presented to an excellent attendance of one hundred and forty-one members and visitors.

Mr. J. C. Trueman, designing engineer, Dominion Bridge Company, Winnipeg, introduced the picture with a short historical paper. He traced the development of suspension bridge design from its early beginnings of about 140 years ago to the present. During the first fifty years of this period there were a number of failures by wind action. The behaviour of some of these failures bore a striking resemblance to the mode of failure of the Tacoma span.

These early bridges were light structures with plank deck built for horse-drawn vehicles. They did not have much in the way of stiffener trusses. About the end of this early period at the middle of the last century, Trautwine, of handbook fame, suggested that the danger arose " from action of strong winds striking below the floor either lifting the whole platform and letting it drop or imparting to it violent wave-like undulation ". He proposed that substantial trusses be used to dampen the undulation.

Coincident with this suggestion, the demands of the heavy live-load concentrations of railway and suburban trains made obvious the necessity of stiffener trusses to distribute these loads along the flexible cable. Following the use of a substantial stiffener truss, trouble from undulation ceased and there were no further failures from this cause until the present.

There seems to be some doubt whether the function of the stiffener truss to dampen undulations, as well as to distribute live-load concentrations, was generally understood at the time of its introduction. Probably it was thought, and understandably so considering the data available, that dead load heavy enough to resist wind uplift was sufficient for this purpose. We do know, however, that subsequently-developed methods of designing the stiffener truss did not directly consider the dampening function.

The modern trend to lighter girders was the direct result of the smaller live-load concentrations of automobile traffic. The Tacoma bridge girder was stiff enough to distribute this live-load but not to dampen the undulations. The low vertical stiffness combined with the narrow width resulted in insufficient torsional rigidity.

The heavy deck of the modern suspension could not be raised by direct wind uplift and when undulations appeared the aerodynamic origin became apparent. Looking back it appears likely that the failures of the early structures of a century ago were due to this same phenomenon. There had been, however, no evidence or analysis which would have lead to this conclusion until the present development. It has apparently taken the failure of a modern, hardly comparable, structure to fully explain the failures of those pioneer structures of one hundred years or more ago.

Mr. Trueman had a table summarizing some of the main characteristics of several long suspension bridges. The table showed how much more flexible vertically, horizontally and in torsion, the Tacoma bridge was, compared to other bridges of like span.

The picture followed and showed very graphically the extraordinary nature of the failure.

Following the showing of the picture there were numerous questions and considerable discussion which brought out some very interesting points as regards design and aerodynamic action. Mr. Trueman was quite confident that safe, adequate, light, long span bridges can be built with the present knowledge. He thought that research would probably make for economies in design.

ENGINEERING EXAMINERS SEEK BETTER LAW ADMINISTRATION

Means for improving the handling of applications for professional registration were the chief subjects of interest at the 22nd annual meeting of the National Council of State Boards of Engineering Examiners held in New York Oct. 27-30. Represented at the meeting were 35 of the 44 member boards of the council, the largest registration at any meeting of the council. In addition, members of the Engineers Council for Professional Development meeting concurrently in New York, took part in the discussion.

A recommendation from the secretary that the publication of a registered engineers national directory and handbook be undertaken if a satisfactory proposition for the publication of such a directory can be obtained was approved, provided that it involved no financial commitments on the part of the council.

Qualification

Wide divergence in the practices of the several registration boards with respect to the qualifications of applicants for registration were noted by the committee on qualifications for registration. The committee observed that some states lay principal stress on the knowledge of the fundamentals of engineering while others give much greater weight to practical experience. To aid in obtaining greater uniformity in qualifying applicants, the committee presented for adoption an outline of requirements basic to a determination of competence. It also presented for approval a set of general principles to be applied to interviews of applicants for registration, and a set of general requirements basic to all branches of engineering that should be applied in determining whether the four years of qualifying experience required under most registration acts are up to adequate standards. This latter general statement was supplemented by a detailed statement covering civil engineering. Following approval of the committee's report, it was instructed to prepare similar detailed statements for the other major fields. With respect to civil engineering, the report states " All four years should be of a calibre equivalent to that described under and classified as Grade 1 by the American Society of Civil Engineers' Committee on Salaries," as published in the February, 1939, issue of *Civil Engineering*.

Engineering Examinations

Prof. J. H. Dorroh, chairman of the New Mexico board, stated that the preparation of examinations and the grading of papers presented by applicants for registration had not generally reached a satisfactory status. This matter is less serious with the respect to examinations in fundamentals, he said, than with professional examinations. In the latter, there is a serious lack of information as to how to bring out satisfactorily the evidence of a man's ability to apply his fundamental knowledge. In discussion it was stated that the committee on qualifications for registration is collecting examination papers and making a study of them in the hope of improving practices in this line.

The committee reported that in about one-fourth of the states the qualifications for registration are substantially below those of the model law. This is especially true of the older laws. The committee urged the council to work more aggressively for improvement of these laws.

Professor C. C. Knipmeyer, the new president of the N.C.S.B.-E.E. (right) and the secretary, Mr. Keith Legaré (left).

Registration Laws

Wide divergence of views developed in discussion of the recommendation of the committee on qualifications that the national council ask the Engineers Council for Professional Development to make a study of engineering registration laws and of examining board procedures with the object of bringing out the weak points in the laws and in their administration. Some members of the council maintained that such a study should be a basic function of the council itself, not of an outside agency, while others held that an outside agency would have less hesitancy in pointing out defective laws or in their administration than would the council itself. Chairman Dorroh suggested that E.C.P.D. might accredit state licensing just as it accredits engineering schools, but Dean N. W. Dougherty of Tennessee took strong exception to this view on the basis that practices with respect to registration are matters of state law while the make-up of the curricula of engineering schools is not a matter of law but a matter that can be changed by the faculty of the school at will. Also, he said that he does not believe that divergence between states in the matter of licensing requirements and examination of applicants is as important as some people believe it to be.

Problems raised by efforts to promote reciprocal registration between states for the benefit of engineers who practice in several states were discussed by D. B. Steinman in a report by the committee on interstate registration. The committee stated that insistence on reciprocal registration is a form of coercion toward relaxing responsibility and lowering standards. It urged more general use of "registration by endorsement" under which registration is permissive rather than mandatory, decision in each case being left to the board as to whether it will grant registration to a registered applicant from another state on his record without re-examination.

Effect of Registration

Broader aspects of the registration movement were considered in a general discussion of the report of the committee on the effect of registration, presented by Prof. Charles F. Scott. Professor Scott recommended that the council ask E.C.P.D. to prepare a pamphlet for the use of engineering students and young engineering graduates to help them in rounding out their development in the period before they apply to the registration board for admission to practice. President Harry F. Rogers of Brooklyn Polytechnic Institute endorsed the views expressed by Professor Scott as to the desirability of doing more for the young engineers in their formative period and urged the council to co-operate with the professional groups in such work.

The desirability of requiring applicants for registration to give their endorsement to a code of professional ethics as part of their application for registration, as is now done in some states, was put forward as a desirable step in developing professional consciousness. A major obstacle to such practice is lack of a universally acceptable code of ethics for the engineering profession. Development of such a code by E.C.P.D. was recommended as an objective to be sought in the near future.

The question was raised by P. S. Callahan from California as to the legality of asking applicants to subscribe to a code of ethics, stating that in his opinion enforcement of codes of ethics was a function of the professional societies rather than of the registration board. Exception to that view was taken by F. E. Rightor, secretary of the Texas board, who pointed out that under the model law a license can be revoked for unprofessional conduct, and that lawyers look upon subscription to a code of ethics as the best way to define what is and what is not professional conduct.

A feature of the meeting was the annual dinner, attended by representatives of the major engineering societies both in this country and in Canada, at which Mayor La Guardia took a few minutes from his political campaign to talk to the group, urging them as engineers to take a more active part in the new era into which, in his view, we are entering.

C. C. Knipmeyer, professor of electrical engineering at Rose Polytechnic Institute, Terre Haute, Ind., was elected president to succeed Virgil M. Palmer of Rochester, N.Y., and J. H. Dorroh, dean of engineering at the University of New Mexico, was elected vice-president. New regional directors elected were George M. Shepard of St. Paul and F. W. Anderson of Lexington, Va. The next meeting is to be held in Indianapolis, Ind.

A.S.M.E. ANNUAL DINNER

President Looks Ahead to Post-war Period

Speaking at the annual dinner of the American Society of Mechanical Engineers at the Hotel Astor, New York, on December 3rd, William A. Hanley, president, called for " some realistic thinking and some definite planning " for the post-war period.

While pledging full support of the engineering profession to the task of carrying out our government's pledges and restoring peace to the earth, Mr. Hanley said that it was the job of every individual in the country to help prepare for the situation to be faced when the war ends.

Based on the estimate of the U.S. National Resources Planning Board that, if the war continues, nearly half of the country's 55,000,000 workers in 1944 will be either in defence projects or under arms, Mr. Hanley said that when the war ends the United States will have the colossal job of putting more than 26,000,000 workers back into peace-time employment.

Unless government is to put fifteen to twenty million on WPA work and in CCC camps, Mr. Hanley said, the alternative " is to prepare now to create jobs in private industry, and to plan to reduce government employees to a bare necessary number."

"If all the men and women in America will become interested in this post-war employment," he declared, " and will individually adopt a policy to help in the solution, we can solve the problem, and America can thrive as she did thrive from 1790 to 1930. The solution lies with individuals to a greater degree than it does with corporations, municipalities or other groups.

"As individuals, as corporations, as cities and states and as a nation we should reduce our peace-time expenditures now, so that we can accumulate money to spend, and then spend it, when the war is over. Accumulate needs and money now. Satisfy those needs and spend the money when the war ceases.

" If we could have ten million orders for new automobiles in the first two years after the war, it would be very helpful. If the majority of car owners will drive their cars twenty-four months longer than has been their custom, then we should have the ten million orders for automobiles. As a patriotic duty, to save this nation at home, to save our form of life for ourselves and our children, to avoid fascism, we should not only have this demand for ten million new automobiles but for great quantities of goods and commodities which must be produced by labour. We should accumulate the need for clothing, home furnishings, new equipment for homes and in addition accumulate the need for several million new homes.

" Millions of men can go back to work on these jobs alone, if this back-log is provided. There may be some personal inconvenience in such a programme of waiting, but surely the sacrifices will be greatly repaid in helping create a staple economic condition in America.

" In the same way the commercial organizations should have an accumulation of man-hour projects which have been postponed until the war is over and then should carry forward such projects fearlessly, to assist the job programme.

" The town and city should, where possible, postpone the paving of streets, building of bridges, municipal buildings, extension of utility services, etc. In like manner the respective states might well postpone as far as possible the paving of roads, and repairs and additions to state institutions. The churches, schools, hospitals and non-profit organizations can all contribute to this great effort of accumulation, and if we will all do our part the WPA and CCC can pass into history.

" Let us measure up to our responsibilities in not only winning the war," Mr. Hanley concluded, " but in winning the peace, and in so doing continue our way of life for ourselves and our children, as we received it from our parents and from those whose great sacrifices created it for us. This country has gone through many crises. Surely in this one, when we have the stewardship, we shall not fail."

Library Notes

Book notes, Additions to the Library of the Engineering Institute, Reviews of New Books and Publications

ADDITIONS TO THE LIBRARY

TRANSACTIONS, PROCEEDINGS

American Society of Civil Engineers:
Proceedings, November, 1941, v. 67.

The Royal Society of Canada, 1941:
Minutes of Proceedings, List of Officers and Members.

American Society of Mechanical Engineers:
Transactions, November, 1941, v. 63.

REPORTS

Canada Department of Mines and Resources:
Report of Soldier Settlement of Canada, for the fiscal year ended March 31, 1941, Ottawa. Price 50 cents.

Canada Department of Public Works:
Report of the Minister of Public Works on the works under his control for the fiscal year ended March 31, 1941. Ottawa, Price 50 cents.

Canada Department of Mines and Resources—Mines and Geology Branch:
Geological Survey, Memoir 229, Noranda District, Quebec, by M. E. Wilson. Price 50 cents.

TECHNICAL BOOKS

A.S.M.E. Mechanical Catalogue and Directory, 1942:
Thirty-first Annual Volume issued October, 1941.

Belt Conveyors and Belt Elevators:
By Frederic V. Hetzel and Russell K. Albright, 3d., revised and enlarged, John Wiley & Sons, Inc., 1941. 439 pp. 9¼ x 6 in., $6.00.

Bridge Railings—Their Design and Construction:
Booklet by F. H. Frankland, Director of Engineering, published by the American Institute of Steel Construction, New York. Copies are free to interested persons.

Godfrey's Structural Tables:
By Edward Godfrey, Structural Engineer, Pittsburgh, Pa. Published by the Author, 126 pp., 8¼ x 5¼ in. Price $1.25.
This book is a reprint of Godfrey's Tables first published in 1905 and carries readily available information which, in many cases, is not found in manufacturers' handbooks. Among other things will be found ways of solving skew and batter details as well as lever arms for truss members and other data. Tables are computed for designing girder and truss spans for Cooper's standard loading. The tables of properties of built sections should be useful in designing truss members. The book ends with a list of the author's contributions to various engineering publications.

Highway Curves:
By H. C. Ives, C.E., 3 ed., John Wiley & Sons, Inc., 1941. 380 pp., diagrs., maps, charts, tables, 7 x 4 in., cloth, $4.00.
A presentation of the theory and practice of highway curves as practiced in this country is presented in this manual, together with the mathematical tables required in road building. The new edition has been revised and four new chapters added, dealing with the Selection of a curve and spiral, Curbs, crowns and grades, traffic lanes and divided highways, and construction stakes.

Canadian Engineering Standards Association, Specification:
Standard specification for galvanized (zinc-coated) steel line wire. C3-1941. Ottawa, October, 1941. Price 50 cents.

Canadian Engineering Standards Association Specification:
Standard specification for vitrified clay sewer pipe. A60-1941. Ottawa, September, 1941. Price 50 cents

U.S. Department of the Interior-Bureau of Reclamation—Boulder Canyon Projects Final Reports, Part IV—Design and Construction:
Bulletin 1—General features, presents general descriptive information regarding all of the more important parts of the Boulder Canyon Project and the principal problems involved in their design and construction. Subjects treated separately in the various chapters include preliminary construction; construction plant; river diversion works; Boulder Dam; penstocks, outlets, and spillways; power plant; architectural features; Lake Mead; Imperial Dam and desilting works; and the All-American Canal system. Selected drawings and photographs illustrate the various construction activities as well as the completed structures. Paper-bound $1.50 per copy. Cloth-bound $2.00 per copy.
Bulletin 2—Boulder Dam, present detailed data and information regarding the design and construction of the dam, exclusive of the appurtenant works. Subjects covered by the different chapters include design of dam, excavation of foundation and abutments, foundation and abutment grouting, construction of dam, cooling mass concrete, and contraction joint grouting. Detail drawings and carefully chosen photographs are included to supplement the text and to illustrate the different features of the work. Paper-bound, $1.50 per copy. Cloth-bound, $2.00 per copy.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet the books are not in the Institute Library, but inquiries will be welcomed at headquarters, or may be sent direct to the publishers.

A.S.T.M. STANDARDS ON PETROLEUM PRODUCTS AND LUBRICANTS
Prepared by A.S.T.M. Committee D-2 on Petroleum Products and Lubricants. Methods of Testing, Specifications, Definitions, Charts and Tables. Sept., 1941. 400 pp., American Society for Testing Materials,

Phila., Pa., diagrs., charts, tables, 9 x 6 in., paper, $2.00.

This pamphlet brings together in convenient form the 1941 report of the A.S.T.M. committee on petroleum products and lubrication, over ninety standard and tentative methods of test and specifications pertaining to petroleum, and the regulations and personnel of the committee and subcommittees.

AERODYNAMICS OF THE AIRPLANE (Galcit Aeronautical Series)

By C. B. Millikan. John Wiley & Sons, New York, 1941, 171 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $2.50.

This volume presents a brief but rather intensive summary of those portions of the subject which every well-rounded aeronautical engineer should know. Fundamental fluid mechanical principles are first presented, followed by a discussion of certain of them to specific aerodynamic questions. Airplane performance, stability and control are then treated. The book is based upon lectures to graduate non-aeronautical engineers.

AEROPLANE CARBURETTORS (Part 2)

Edited by E. Molloy and E. W. Knott. Chemical Publishing Co., New York, 1940. 132 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $2.00.

This handbook describes in detail the dismantling, adjustment and re-assembling of aircraft carburettors of the Zenith, Rolls-Royce and Stromberg types. Chapters on Boost pressure control and mixture strength and on the Cambridge exhaust-gas analyzer are also included.

AIR PILOTING, Manual of Flight Instruction

By V. Simmons. Revised ed., Ronald Press Co., New York, 1941. 758 pp., illus., diagrs., charts, tables, 8½ x 5 in., cloth, $4.00.

The intention of this book is to illustrate and describe the best known means of developing pilot skill, and in addition to supply technical material, in text and question and answer form, which will definitely aid the applicant in passing the various written examinations. The present revision provides the currently approved techniques for the training and testing of pilots.

AIRCRAFT DESIGN SKETCH BOOK, compiled and published by Lockheed Aircraft Corporation, Burbank, Calif.

Aero Publishers, 120 North Central Ave., Glendale, Calif., 1940. Paged in eleven sections, illus., diagrs., tables, 11 x 8½ in., paper, $3.00.

Some hundreds of sketches of airplane parts and complete aircraft, both military and commercial, compose this book. Brief descriptive information is included in many cases. The purpose of the book is to give the designer a collection of ideas that will stimulate his own creative and inventive mind toward further development.

AIRCRAFT INSTRUMENTS

By G. E. Irvin. McGraw-Hill Book Co., New York and London, 1941. 506 pp., illus., diagrs., charts, maps, tables, 9½ x 6 in., cloth, $5.00.

This book aims to provide, in one volume, a complete course in the subject for all those concerned. The construction and operation of all types are described, and detailed instructions given for installing, using, testing, maintaining and repairing them.

AIRCRAFT LOFTING

By E. P. Grenier; published by Emile P. Grenier, 110 Highland Ave., Buffalo, N.Y., 1941. 202 pp., diagrs., charts, tables, 11 x 9 in., fabrikoid, looseleaf manifold copy, $3.00.

This textbook has been developed as a result of the application of lofting methods to mass production of aircraft. In addition to presenting a practical study of aircraft loft practice, it also includes sufficient information to give an understanding of the necessary mathematical, engineering and aerodynamical concepts. Full use is made of illustrative diagrams.

The AIRCRAFT YEAR BOOK FOR 1941, 23rd Annual Edition

Edited by H. Mingos. Aeronautical Chamber of Commerce of America, New York, 1941. 608 pp., illus., diagrs., maps, tables, 9 x 6 in., cloth, $5.00.

This annual records the developments of American aviation during the past year. Both civil and military activities are reported in considerable detail. Training and education, the growth of air lines and private flying and the increase in airports and airways are described. The expansion of manufacturing is presented. There are tables of aircraft and engine specifications and much statistical matter.

AIRSCREWS, Part 2. (Aeroplane Maintenance and Operation Series, Vol. 20)

Edited by E. Molloy and E. W. Knott. Chemical Publishing Co., New York, 1940. 100 pp., illus., diagrs., 9 x 6 in., cloth, $2.00.

Continuing the airplane maintenance and operation series, this second volume on airscrews deals with the Rotol, Curtiss, Hamilton and Hele-Shaw Beacham variable-pitch airscrews. A section of general notes on the operation, maintenance and inspection of fixed-pitch airscrews is included.

The BELL TELEPHONE SYSTEM

By A. W. Page. Harper & Brothers Publishers, New York and London, 1941. 248 pp., illus., diagrs., charts, maps, tables, 9 x 6 in., cloth, $2.00.

This is a description of the operating policies of the American Telephone and Telegraph Company and its constituent companies, written by the Vice-President in charge of public relations. Problems of research, technology, wages, rates and service, relations with the government, and finance are considered, and the methods and achievements of the organization set forth. Much hitherto scattered information is brought together in convenient form.

CHEMICAL ENGINEERS' HANDBOOK (Chemical Engineering Series)

Edited by J. H. Perry. 2 ed. McGraw-Hill Book Co., New York and London, 1941. 3,029 pp., illus., diagrs., charts, tables, 7 x 5 in., lea., $10.00.

The new edition of this valuable reference work has been thoroughly revised and largely rewritten to bring it abreast of current practice. New sections have been added on solvent extraction; on shotting, granulating and flaking, and sprays and spraying; on bulk packaging and on sublimation. Many new chapters have been added. The section on patents and patent law has been omitted, but the new edition nevertheless contains nearly four hundred pages more than the previous one. The work covers chemical engineering comprehensively.

The CHEMICAL FORMULARY, Vol. 5

Edited by H. Bennett. Chemical Publishing Co., Brooklyn, New York, 1941. 676 pp., diagrs., tables, charts, 9 x 5½ in., cloth, $6.00.

This latest volume of this series follows the form of preceding ones, but contains entirely new formulas. Receipts are given for preparing large numbers of adhesives, beverages, cosmetics, foods, inks, metal products, paints, etc. The formulas have been collected from many sources.

DESIGN OF PIPING SYSTEMS, EXPANSION STRESSES AND REACTIONS IN PIPING SYSTEMS

Published by M. W. Kellogg Company, Jersey City, N.J., 225 Broadway, New York, 1941. 97 pp., illus., diagrs., charts, tables, 11½ x 8½ in., cloth, $10.00.

The general method of analyzing pipe lines for flexibility presented in this manual is applicable to piping systems of almost any shape or configuration such as are needed in the power, oil refinery and chemical industries. The derivation and application of formulas for expansion stresses and reactions are presented in a detailed manner, design data are furnished, and there is a bibliography.

ELECTRICITY APPLIED TO MARINE ENGINEERING

By W. Laws. Institute of Marine Engineers, London; Engineers Book Shop, New York, 1940. 276 pp., diagrs., charts, tables, 7½ x 5 in., cloth, $2.00.

A clear, simple presentation of the fundamental principles of electricity, with special emphasis upon their application in ships. The text is intended for young engineers without much mathematical or technical background, who are preparing for British Board of Trade Certificate examinations, and is based upon articles published in the Transactions of the Institute of Marine Engineers.

ELECTRONICS

By J. Millman and S. Seely. McGraw-Hill Book Co., New York and London, 1941. 721 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $5.00.

The primary purpose of this textbook is to provide a development of basic electronic principles with applications to many problems in electrical engineering and physics. It co-ordinates the physical theory of electronics and the theory of operation of electronic devices, gives attention to material of present-day commercial importance, and includes both detailed illustrative problems and groups of problems to be worked.

FIRE SERVICE HYDRAULICS

By F. Sheppard. Case-Shepperd-Mann Publishing Corporation, New York, 1941. 254 pp., illus., diagrs., charts, tables, 8½ x 5½ in., lea., $3.00.

A presentation of the principles of hydraulics as applied to fire department work. Detailed instructions are given for calculating nozzle velocities and pressures, friction losses in hose and mains, engine pressures, fire streams, sprinkler systems and pump discharges, and are illustrated by many worked examples.

FUNDAMENTALS OF VACUUM TUBES

By A. V. Eastman. 2 ed. McGraw-Hill Book Co., New York and London, 1941. 583 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.50.

The aim in this work has been to combine in a single text the basic theory underlying the operation of all types of modern vacuum tubes with descriptions of their more common applications in communications and industry. Mathematical analyses are preceded by verbal descriptions of the phenomena under consideration. The new edition has been completely revised and entirely rearranged.

GLASS: THE MIRACLE MAKER Its History, Technology and Applications

By C. J. Phillips. Pitman Publishing Corp., New York and Chicago, 1941. 424 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.50.

This is a welcome addition to books on glass, for it provides an up-to-date, comprehensive and authoritative account of this important, widely used material. The manufacture, physical and chemical properties and uses of glass are all presented in sufficient detail for all ordinary purposes, and illustrated by a wealth of drawings and photographs. References accompany each chapter.

Great Britain, Board of Education and Ministry of Labour and National Service.
HANDBOOK OF WORKSHOP CALCULATIONS

His Majesty's Stationery Office, London; British Library of Information, New York, 1941. 40 pp., diagrs., tables, 7 x 5 in., paper, 3d (obtainable from British Library of Information, 30 Rockefeller Plaza, New York, 10c.).

This pamphlet is issued as a guide to students and workers in the engineering industry. The introductory exercises and the practical examples are nearly all solvable by simple arithmetic.

Great Britain, Dept. of Scientific and Industrial Research
BUILDING RESEARCH. WARTIME BUILDING BULLETIN No. 15A, Supplement to Bulletin No. 15.

His Majesty's Stationery Office, London, 1941. 14 pp., diagrs., charts, tables, 11 x 8½ in., paper, (obtainable from British Library of Information, 30 Rockefeller Plaza, New York, 15c.).

This bulletin supplements a previous one upon the design of one-storey war-industry factories, by describing modifications in the interest of camouflage treatment. It also presents a new reinforced concrete design, introduced for steel economy.

HANDBOOK OF AIRPLANE INSTRUMENTS

Kollsman Instrument Division of Square D Company, 80-08 45th Ave., Elmhurst, New York, 1940. Paged in sections, illus., diagrs., charts, maps, tables, 11½ x 9½ in., fabrikoid, $2.00.

This is a guide to the testing, repairing and adjustment of airplane instruments, with special attention to those made by the company which issues the book. The directions are full and explicit, and illustrated by many drawings.

HOW TO TRAIN SHOP WORKERS

By C. A. Prosser and P. S. Van Wyck. American Technical Society, Chicago, 1941. 126 pp., diagrs., charts, tables, 11 x 8 in., stiff paper, $1.25 manifold copy.

This shop training manual is for the use of foremen and instructors in training workers in production and service jobs. It is intended for both manufacturing plants and vocational schools, and covers the duties, responsibilities and characteristics of the efficient foreman, as well as practical training methods and suggestions.

MACHINE TOOL OPERATION. Pt. 1, The Lathe

By H. D. Burghardt. McGraw-Hill Book Co., New York, 1941. 420 pp., illus., diagrs., charts, tables, 7½ x 5 in., cloth, $2.25.

This text for apprentices and young machinists presents the fundamental principles of the construction and operation of all types of lathes, describes bench work done by hand, and discusses methods of soldering, hardening and tempering, and hand forging. The material added in this revised edition is chiefly on hand forging.

MATERIALS TESTING, Theory, Practice and Significance of Physical Tests on Engineering Materials

By H. J. Gilkey, G. Murphy and E. O. Bergman. McGraw-Hill Book Co., New York and London, 1941. 185 pp., illus., diagrs., charts, tables, 11½ x 8½ in., cloth, $2.75.

The field of materials testing work in colleges is covered comprehensively in this laboratory manual, from general observations on test procedures to suggestions upon the conduct of a course of instruction, and on typical final examinations. More material is included than is likely to be used in any one laboratory, in order to provide for wider use. Answers are given for the many supplementary questions, and there is an unusually complete subject index.

THE MICROSCOPE

By S. H. Gage. 17th ed. revised, Comstock Publishing Company, Ithaca, N.Y., 1941, 617 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.00.

In the new edition of this well-known and popular textbook, additions and modifications have been made to clarify the text and add new developments of the last five years. The book remains, as before, an admirable guide for beginning microscopists. The construction of the instrument, its limitations, and its possibilities for aiding one to arrive at truth are presented clearly and thoroughly.

MODERN MARINE ELECTRICITY

By P. de W. Smith. Cornell Maritime Press, New York, 1941. 279 pp., illus., diagrs., charts, tables, 7½ x 5 in., cloth, $2.50.

This handbook is intended to provide the operating marine electrician with a practical guide to the electrical equipment of the modern ship and to its maintenance.

MOLDING TECHNIC FOR BAKELITE AND VINYLITE PLASTICS

Bakelite Corporation, New York, 1941. 224 pp., illus., diagrs., charts, tables, 11½ x 8½ in., fabrikoid, $3.50.

The important phases of the molding processes and molding equipment employed generally in the commercial production of plastic parts are discussed. Materials, mold design, finishing processes, inspection and plant layout are among the topics covered. There is a glossary, including a list of terms not recommended.

MOTION STUDY

By H. C. Sampter. Pitman Publishing Co., New York and Chicago, 1941. 152 pp., illus., diagrs., charts, tables, 8½ x 5 in., cloth, $1.75.

The principles of motion study, as distinct from time study, are presented in a clear and simple manner. Motion symbols are explained, the basic laws and principles for motion economy are discussed, and flow process charts are emphasized to eliminate the study of superfluous operations in a series or complete process.

NUCLEAR PHYSICS. (University of Pennsylvania Bicentennial Conference)

By E. Fermi and others. University of Pennsylvania Press, Phila., 1941. 68 pp., diagrs., charts, tables, 9 x 6 in., paper, 75c.

This pamphlet contains six papers presented at a conference on nuclear physics held in connection with the bicentenary of the University of Pennsylvania.

PERFORMANCE OF PRESSURE-TYPE OIL BURNERS (Iowa Engineering Experiment Station Bulletin 151)

Iowa State College, Ames, Iowa, 1941. 32 pp., illus., diagrs., charts, tables, 9 x 6 in., paper, gratis.

An investigation of four high-pressure oil burners operated with various nozzles and cycling rates in both conversion and oil-designed boilers is reported in this bulletin. The apparatus and testing procedure are described and detailed results are given, including the effect of various characteristics upon efficiency.

PERSONNEL MANAGEMENT, Principles, Practices and Point of View

By W. D. Scott, R. C. Clothier, S. B. Mathewson and W. R. Spriegel. 3 ed., McGraw-Hill Book Co., New York, 1941. 589 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $4.00.

Completely revised and rearranged, the new edition of this text presents a comprehensive outline of up-to-date principles, practices and instruments in the important relationships of management, work and workers. The revision includes a discussion of modern personnel practices and procedures supported by a detailed survey of 231 companies employing more than 1,750,000 workers.

PRACTICAL SHIP PRODUCTION

By A. W. Carmichael. 2 ed. McGraw-Hill Book Co., New York and London, 1941. 283 pp., illus., diagrs., charts, maps, tables, 9½ x 6½ in., cloth, $3.00.

The present increased interest in shipbuilding is responsible for the revision of this text, which appeared originally in 1919. The book is intended particularly for engineers and technical men who are transferring their activities from other fields to those of the marine engineer and naval architect. The treatment is practical, rather than theoretical, and concerned with construction, rather than design. The new edition has been partly rewritten, especially the section on electric welding.

PROTECTIVE and DECORATIVE COATINGS, Paints, Varnishes, Lacquers and Inks: Vol. 1, Raw Materials for Varnishes and Vehicles

By J. J. Mattiello. John Wiley & Sons, New York; Chapman & Hall, London, 1941. 819 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $6.00.

This volume is the first of three which are intended to form a comprehensive treatise on the paint and varnish industry. The present instalment is devoted to the raw materials for varnishes and vehicles. Drying oils, resins, driers, thinners and solvents, natural minerals and ethers are discussed, each chapter being prepared by one or more specialists. An enormous amount of information upon the sources, properties and uses of these materials is summarized in this work, and numerous lists of references to original papers are included.

The RUNNING AND MAINTENANCE OF MARINE MACHINERY

Institute of Marine Engineers, London. 2 ed. Engineers Book Shop, New York, 1941. 164 pp., illus., diagrs., charts, tables, 10 x 7 in., cloth, $2.50.

A practical work, prepared for junior members of the Institute of Marine Engineers, intended as a guide for those entering upon a sea-going career. Steam reciprocating engines and turbines, boilers, diesel engines, electrical and refrigerating machinery, pumping arrangements and steering gears are discussed. A list of books is appended.

SANITARY ENGINEERING

By H. G. Payrow. International Textbook Co., Scranton, Pa., 1941. 483 pp., illus., diagrs., charts, tables, 8½ x 5 in., fabrikoid, $4.00.

In preparing this work the author has endeavoured to supply a concise textbook covering the general field of sanitary engineering for civil and chemical engineers. The fundamentals of water supply and purification and of sewerage and sewage treatment are comprehensively covered with the help of many tables and practical examples. Hydrology and other related topics, new types of equipment, and the application of recent developments such as air conditioning are included.

SHIP AND AIRCRAFT FAIRING AND DEVELOPMENT for Draftsmen and Loftsmen and Sheet Metal Workers

By S. S. Rabl. Cornell Maritime Press, New York, 1941. 90 pp., illus., diagrs., charts, tables, 12 x 8½ in., paper, $2.50.

This practical manual for draftsmen, loftsmen and sheet-metal workers presents the essentials of both ship and aircraft fairing and of the development of surfaces as necessary in sheet metal work. Descriptive plates are alternated with pages of explanatory text to facilitate the understanding and application of the principles described.

PRELIMINARY NOTICE

of Applications for Admission and for Transfer

November 25th, 1941.

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.–

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described at the January meeting.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science or engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of tbe Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of tbis age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

AUGER—GERARD J. B., of 65 Broadway, Shawinigan Falls, Que. Born at Ste-Croix-de-Lotbinière, Que., Aug. 29th, 1906; Educ.: 1930-33, School of Engrg., Milwaukee, Wis., Industrial Elec. Engr.; 1930-33, substation experience in a rotary station; 1933-37, elec. mtce. work for the Provincial Govt.; 1937-41, power plant supervision, North Shore Paper Co.; 1941, rectifier stn., Aluminum Company of Canada, Arvida, and at present, witb same company at Shawinigan Falls, i/c of new rectifier stn. being constructed and two D.C. power plants.

Employment Service Bureau

SITUATIONS VACANT

MECHANICAL DESIGNING DRAUGHTSMAN. Graduate preferred, urgently needed for work in Arvida for specification drawings for plate work, elevators, conveyors, etc., equipment layouts, pipe layouts and details. Apply to Box No. 2375-V.

REINFORCED CONCRETE DRAUGHTSMAN with one or more years experience on production of detailed drawings for reinforced concrete on general building plans, etc. Apply to Box 2401-V.

MECHANICAL GRADUATE ENGINEER with machine shop experience required for work in Mackenzie, British Guiana, on essential war work. Apply to Box No. 2441-V.

SALES ENGINEER with excellent technical or industrial qualifications, for work largely in the electrical industry. This is a splendid opportunity for a good man. Employment will be permanent. State training, experience and other qualifications. Apply Box No. 2451-V.

ENGINEERING DRAUGHTSMAN with experience in machine and structural design, proficient in steel design calculation, and having ability for estimating. We require a man with at least five years' industrial experience, preferably in the paper mill field. Position is permanent' State experience and give physical description. Include small photograph and a sample of draughtsmanship. Apply to Box No. 2458-V.

MECHANICAL DRAUGHTSMAN, experienced in making layouts for various installations, piping, etc., around a paper mill. Applicant must be a college graduate. State previous experience, wages expected, etc. Apply to Box No. 2461-V.

MECHANICAL DRAUGHTSMAN preferably with pulp and paper experience. Good salary and permanent position. Apply giving details of experience to Box No. 2480-V.

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.

GRADUATE MECHANICAL ENGINEER required for Mackenzie, B.G., immediately on work of plant and mining equipment maintenance. We are prepared to do necessary training which will give exceptional opportunity for experience. Apply to Box No. 2481-V.

MECHANICAL ENGINEER preferred with experience on diesels and tractors, for work in Mackenzie, B.G. Apply to Box No. 2482-V.

MECHANICAL DRAUGHTSMEN and engineers for pulp and paper mill work. Experienced men preferred. Good salary to qualified candidates. Apply to Box No. 2483-V.

SITUATIONS WANTED

CIVIL ENGINEER, B.A.SC., JR.E.I.C., age 29, married. Two years city engineer, five years experience in highway work, including surveying, location, construction, estimating and inspection. Apply Box No. 2409-W.

ELECTRICAL ENGINEER, B.E., in electrical engineering, McGill University, Age 24, married, available on two weeks notice. Undergraduate experience, cable testing and cathode ray oscillography. Since graduation, five months on construction of large and small electrical equipment in plant and sub-station. One year operating electrical engineer in medium size central steam station paralleled with large Hydro system. At present employed, but is interested in research or teaching. Associate member of the American Institute of Electrical Engineers. Apply to Box No. 2419-W.

CIVIL AND STRUCTURAL ENGINEER, M.E.I.C., R.P.E. (Ont.), M.I.Struct.E. Age 49. Married. Home in Toronto. Experience in Britain, Africa, Canada, Turkey. Chief engineer reinforced concrete design offices, steelworks construction. Resident engineer design and construction munitions plants, and general civil engineering work. Extensive surveys, draughting, harbour and municipal work. Location immaterial. Available now. Apply Box No. 2425-W.

ELECTRICAL, MECHANICAL ENGINEER, age 35. Dip. and Assoc. R.T.C., Glasgow, A.M.I.E.E., (Students Premium) G.I. Mech.E., M.E.I.C., Assoc. Am.I.E.E Married. Available after December 22nd. Seventeen years experience covering machine shop apprenticeship, A.C. and D.C. motors, transformers, steel and glass bulb arc rectifiers, design, testing and erection sectional electric news and fineprints paper machine drives, experience tap changers H.V., L.V. and marine switchgear. Apply to Box No. 2426-W.

MECHANICAL ENGINEER age 55 years. Married. Available at once. Thirty years experience in draughting and general machine shop and foundry work. Fifteen years as works manager. Considerable experience in pump work, including estimating and inspection. Apply to Box 2427-W.

PRELIMINARY NOTICE (*Continued from page 626*)

design & estimating high pressure water mains, stacks, coal bunkers, ore bins, etc., and at present, squad boss, dfting room.

AIR RAID SYRENS

A 4-page bulletin No. 4110, recently issued by Burlec Limited, Toronto, Ont., features the "Burlec-Carter" syrens, designed by Carters of Nelson, Lancashire, England and now built by "Burlec" in Canada. The salient features of these syrens are given.

C-G-E APPOINTMENT AT PETERBORO PLANT

H. A. Gadd, for the past seven years manager of Carboloy and Metals Products for Canadian General Electric Co., Limited, has been appointed assistant general superintendent of the company's gun carriage plant at Peterborough. Mr. Gadd's promotion to this responsible position comes after almost twenty years of experience with Canadian General Electric.

CENTRALIZED SYSTEM OF LUBRICATION

The Farval Corporation, Cleveland, Ohio, has issued an 8-page bulletin, Form No. 167 which, under the title "Why Farval," describes "Farval" centralized system of lubrication. After a brief comment on the importance of correct lubrication in maintaining high production schedules, the booklet deals with the simplicity of the "Farval" system, illustrates its component parts, and charts 12 distinct savings effected.

DRILLING MACHINES

Canadian Blower & Forge Co. Ltd., Kitchener, Ont., feature in their 8-page bulletin No. 2726-C, the "Buffalo" No. 14, high speed sensitive drilling machines, which are available in either bench or pedestal type models, in single or multiple spindle units. Illustrations, dimensional drawings and specifications are given.

CENTRAL OFFICE NOW IN TORONTO

Canadian Johns-Manville Co., Limited has moved its Canadian headquarters to 199 Bay Street, in downtown Toronto. This office was formerly located at Leaside where the Toronto district warehouse remains. The telephone number of the new offices is Adelaide 9431.

ELECTRICAL EQUIPMENT

In a 62-page looseleaf catalogue, E. W. Playford Limited, Montreal, Que., has incorporated information covering a wide range of electrical equipment produced by manufacturers for whom the company is sales representatives. Illustrations, specifications and other data are included.

ELECTRICAL INSULATION

Bulletin No. CG9.D, 20 pp., issued by Fiberglas Canada Limited, Oshawa, Ont., describes the method of production of "Fiberglas" and its application for electrical insulation. A section deals with the electrical properties of "Fiberglas" and is followed by sections on insulating tapes, cordage, braided sleeving, and varnished or impregnated materials with "Fiberglas" base. Illustrations, curves and specification tables are included.

HOISTING EQUIPMENT

The Yale & Towne Mfg. Co. Canadian Div., St. Catharines, Ont., are distributing a 44-page Catalogue dealing with hoisting equipment. Introduced by a comparison of the three types of chain hoists, and an outline on how to select the proper type of hoisting equipment, this catalogue is really a "text book" on the subject. It contains a large number of illustrations, tables and specifications with details of design and characteristics covering the four types of hoists—differential, spur-geared and screw-geared and various modified types, notably—clevis, trolley, rail hugger, twin hook and extended wheel.

REPRESENTATIVE FOR WINDSOR DISTRICT

Railway & Power Engineering Corporation Limited announce the appointment of E. S. Mitchell, President and General Manager of Windsor Brass Works Limited, as Representative in Windsor, Ont., district of Canadian Controllers Limited.

HEAVY DUTY PRODUCTION DRILL

"Buffalo" No. 15 heavy duty production drill; No. T-15 tapping machine; and accessories, are dealt with in the recently issued 8-page bulletin No. 2963-D of Canadian Blower & Forge Co. Ltd., Kitchener, Ont. Detailed descriptions, drawings and illustrations are given for each. The accessories include a slow speed attachment, straight shank adaptor and mortising attachment.

PRESIDENT OF B. F. GOODRICH

G. W. Sawin has been elected President of the B. F. Goodrich Rubber Company of Canada, Limited, which position was previously held by John L. Collyer who now becomes Chairman of the Canadian Company's Board of Directors in addition to being President of the B. F. Goodrich Company, Akron, U.S.A. Mr. Sawin has been with the company for over twenty-nine years and was Vice-President and General Manager for the past five years.

SWITCHGEAR

Catalogue No. 42, 250 pp., published by Canadian Line Materials Ltd., Scarboro Junction, Ont., presents well-illustrated details of Canadian Line Materials and Delta-Star products. This catalogue includes data on outdoor bus supports and fittings, switches and fuse mountings, high tension switching equipment, bus bar clamps, pipe structure fittings, spool insulator cable fittings, indoor bus supports and fittings, indoor switch and fuse mountings, and switchgear control accessories.

MANAGER CARBOLOY DIVISION OF C-G-E

Mr. Charles Neal has been appointed as manager of Carboloy and Metals Products Division of Canadian General Electric Co., Limited, succeeding Mr. H. A. Gadd. Mr. Neal was formerly in charge of sales of this product.

FREQUENCY CHANGER

As described in a folder issued by Milton-Thompson Electric, Toronto, Ont., the "M.T.E." induction frequency changer is designed to furnish 3-phase, 60-cycle current for fluorescent lighting, motor testing, X-ray, etc., where the primary source is 3-phase, 25-cycle. These frequency changers have been supplied in capacities from 1 to 150 Kv.a.

DOUBLING PLANT CAPACITY

Canada Illinois Tools Ltd., 177 Front St. East, Toronto, manufacturers of metal-cutting tools, hacksaws and gauges, are doubling their plant capacity to take better care of present business expansion. It is expected that the increased facilities will be in operation early in November.

TEMPERATURE AND PRESSURE CONTROLLERS

The 8-page catalogue No. 77-2 issued by Minneapolis-Honeywell Regulator Co. Ltd., Toronto, Ont., emphasizes the fact that "Automatic control stops wasteful hand regulations." This bulletin describes the company's line of "Brown" non-indicating air operated controllers for temperature and pressure. Illustrations, sectional and dimensional drawings, specifications and tables supply complete data regarding these instruments.

TUBE CLEANERS AND EXPANDERS

Affiliated Engineering Corps. Ltd., Montreal, Que., have issued a 16-page catalogue devoted to the products of the Airetool Mfg. Co. of Springfield, Ohio. This publication describes the "Airetool" tube cleaners, tube expanders and refinery specialties. Each type is thoroughly described and illustrated and is accompanied by a table of specifications.

WORM GEAR SPEED REDUCERS

Cleveland Worm & Gear Co., Cleveland, Ohio, has issued an 8-page bulletin designated as Form No. 150. Entitled "Background," this booklet reproduces quotations from a series of letters from manufacturers who began purchasing these drives 15 to 20 years ago. The conditions under which the worm gear driven machinery must operate in each industry are described.

Commenting on the telegram reproduced herewith, the President of the Company, Mr. W. F. Angus, said: "The credit goes to our employees. I am sure the Minister's telegram will spur us all on to even greater efforts. Right now the Plant is far ahead of original production schedules."
