The present work is not merely a reprinting of the preceding edition with the addition of extra chapters here and there, but is a completely rewritten production. The authors have been by no means restrained by the authority of standard specifications and regulations of technical bodies, but have boldly voiced dissenting views where these appeared well founded. Thus, a column formula different from that of the Joint Committee is recommended for spirally-reinforced columns—being the same in form as for rodded columns—and entirely different limiting proportions for columns are set forth. The portion on flat slab construction is particularly extended, doubtlessly by reason of the special interest of Mr. Smulski in this type of construction. While the S.M.I. system, of which Mr. Smulski was the inventor, is described in detail, the authors very properly refrain from comparing its economy with that of other flat slab systems.

Those who are already familiar with the earlier editions of this work will not care to be without the new and much extended edition. It is a treatise that everyone interested in reinforced concrete design or construction should have at his disposal.

C. R. Young, m.e.i.c.

Les Moteurs à Explosion

Par Edmond Marcotte. Librairie Armand Colin, Paris, 1926. Paper, 4½ in. x 7 in., 216 pp., illus., 7 fr.

This work presents in a condensed form the fundamental principles which underlie the construction and operation of internal combustion engines.

The author first studies those considerations which can be applied to the majority of explosion motors. He discusses successively the principle of operation and the general arrangement of the motors, their working cycles, their valve arrangements, power, efficiency, and methods of test. A description of the various parts of the engine is then given, classified according to their functions; carbonization, ignition, cooling, lubrication, exhaust, regulation and balancing.

The engines are then considered with respect to their particular applications. Two general classes are distinguished, turbines and piston motors, the latter being grouped according to the nature of the fuel used. The peculiarities, advantages and development of each type are well shown, and special attention is given to automobile and aviation motors. A concluding chapter gives general information on construction, operation and maintenance.

The book is remarkable for its systematic arrangement, and can be consulted with advantage by those wishing to acquire sound fundamental ideas on this branch of engineering.

Stainless Iron and Steel

By J. H. G. Monypenny, Chapman & Hall, London, 1926. Cloth, 6 x 10 in., 304 pp. illus., 21/-.

Stainless steel dates from just before the War and is therefore a recent development. Used at first for cutlery it has now many applications in engineering. Essentially it is a low-carbon steel containing about twelve per cent of chromium, which has received a suitable heat-treatment and mechanical finish. Permissible changes of composition as regards chromium, carbon and other elements make possible a considerable range of mechanical properties, so that stainless steel can be made suitable for a variety of uses; "Stainless Iron" is a very low-carbon variety of stainless steel. Mr. Monypenny gives a brief history of the development, the usual range of composition and method of making, working and treating the steel. He explains the influence of chromium on steel and shows how this is related to the composition, heat-treatment and non-corrodible nature of the steel. He describes the mechanical and physical properties, the resistance to corrosion and the applications of stainless steel.

The book is well written and illustrated, and gives in an easily assimilated form the essential information on a subject that must be increasingly important to engineers.

Alfred Stansfield, m.e.i.c.

The Elements of Automatic Telephony

Arthur Crotch. E. & F. N. Spon, London, 1924. Cloth, 5½ in. x 8¾ in., 74 pp., illus., 3/6 net.

Automatic telephony is a difficult subject to write on; it is particularly difficult to explain the manner by which these circuits perform these functions, also the number of different circuit arrangements in use in each system of automatic telephony is very large and there are several different systems in use. Nevertheless, the author has succeeded in giving a fairly good picture of the basic principles underlying the scheme of operation of three systems. The fundamental differences between these systems are explained very lucidly and a limited amount of descriptive matter is included.

The book is well illustrated with circuit diagrams, but some of these have been so much reduced in size that it is difficult to follow out the connections; apparently this was done in order to avoid folded pages.

J. L. Clarke, a.m.e.i.c.

The Ethics of Business

Edgar L. Heermance, Harper & Brothers, New York, 1926. Cloth, 5 x 8 in., 244 pp., $2.00.

This is a very complete record up-to-date of the history and progress of business associations in their efforts to standardize their trading ethics in much the same way as they have standardized their products—thus covering both service and product. The attempts made in the past are reviewed, such as the pool, the combination and the present popular trade associations.

The remarkable growth of this movement is well set forth, the striking results obtained being evident on all sides—it being only necessary to carry the mind back for thirty years to realize the real advancement that has been made in trading methods. While this volume cannot be considered as a text-book or work of reference for engineers, it is probably the most plainly written record of a new business development which has yet appeared, and the continual reference in it to well-known and successful trade associations gives it that social interest which might be lacking if pure ethics alone were under consideration.

R. A. Ross, M.E.I.C.

The Strength of Materials

Ewart S. Andrews, Chapman and Hall, London, 1925. Ed. 2, Cloth, 5½ x 8¾ in., 608 pp., illus., diagrs. 13/6.

This text-book is primarily for engineering students and particularly for those reading for the Assoc. M. Institute of C.E. examinations. It covers the usual ground, starting with simple stresses, etc. The title is a little misleading in that the text deals more with stresses in beams, joints, plates, etc., than with the materials used. I was particularly interested in the section on fixed and continuous beams, and the chapter on springs. The theoretical treatment is exhaustive and complete as would be expected of an overseas authority.

From the standpoint of the engineer trained in North America difference of notation makes the study of certain sections rather laborious, but members of the Institute should find this book a valuable supplement to the usual American texts.

E. O. Turner, A.M.E.I.C.

EMPLOYMENT BUREAU

Situations Wanted

Sales Engineer

Mechanical engineer, A.M.E.I.C., desires to hear from manufacturer or firm requiring the services of a capable representative in the Prairie Provinces and Eastern British Columbia. Sales and consulting experience in municipal, mining, contracting, and power plant equipment, also industrial specialties and supplies. At present engaged. Apply box No. 210-W.

Civil Engineer

Civil engineer, M.E.I.C., with varied experience in constructional and commercial field, and an extensive knowledge of the whole of Canada, except the Maritime Provinces, desires connection as representative or sales engineer for manufacturers dealing with engineers or the construction industries. Apply box No. 211-W.

Situations Vacant

Electrical Draughtsman

Electrical draughtsman wanted. Must have had experience in power plant or substation design. Apply stating experience and salary expected. Apply box No. 154-V.

Members' Exchange

Transit

Cooke-Canadian Transit $125.00; Foster Y Level $40.00 with tripods and boxes. Recently overhauled and in first class condition. $150.00 if taken together. Can be seen at Division Engineer's office, Tunnel Station, C.N.R., Montreal.

Back Numbers of Magazines

In order to complete the library records for The Institute the following magazines are required: Canadian Machinery, Vol. 31, No. 26, 1924, and Construction, Vol. 16, Nos. 2 and 9, 1923. Any member having spare copies of these will confer a favour by forwarding same to Headquarters.

Technical Book

An enquiry has been received for a copy of a book entitled "International Bridge over the Niagara River, Bridgeburg to Buffalo" by C. S. Gzowski. The enquirer wishes to purchase this volume and any member having a copy might communicate with Headquarters.

Recent Additions to the Library

Transactions, Proceedings, etc.

Presented by the Societies:
- Transactions and Year Book of the Toronto University Engineering Society, 1926.
- Year Book of the Franklin Institute of the State of Pennsylvania, 1925-26.
- Calendar of the University of Alberta, 1925-26.
- Annual Report of the Association of Professional Engineers of Nova Scotia, 1925.
- Calendar of the University of British Columbia, 1926-27.
- Engineering Index, 1925. American Society of Mechanical Engineers.

Technical Books

Presented by the National Municipal League:
- Depreciation in Public Utilities, by Delos F. Wilcox.

Presented by Librairie Armand Colin, Paris:
- Les Moteurs à Explosion, by E. Marcotte.

Presented by Chapman and Hall:
- Stainless Iron and Steel, by J. H. G. Monypenny.

Presented by Gauthier-Villars, Paris:
- Combustibles Inférieurs et de Remplacement, by P. Appell.

Presented by McGraw-Hill Book Company, Inc.:
- Bacteriology, by Stanley Thomas,
- Fuels and Their Combustion, by R. T. Haslam and R. P. Russell.

Presented by Harper & Bros.:
- The Ethics of Business by E. Heermance.

Reports, etc.

Presented by the Canadian Bureau of Statistics:
- Central Electric Stations in Canada, 1924.

Presented by the Department of Registration and Education of The State of Illinois:
- Bulletin 21 of the Illinois State Water Survey, 1925.

Presented by the American Association of Port Authorities:
- World Ports, 1926. A compendium of North American Ports.

American Society for Testing Materials

The American Society for Testing Materials has issued a provisional programme for their 29th Annual Meeting which will be held at the Chalfonte-Haddon Hall, Atlantic City, N.J., commencing Monday, June 21st, and continuing until Friday, June 25th.

As usual an extensive programme has been arranged, the first day being devoted to registration and meetings of committees, the latter continuing during the morning of the second day.

The afternoon session on Tuesday, June 22nd, is devoted to the consideration of wrought iron, cast iron and magnetic testing, while on the evening of the same day there will be presented the presidential address and the reports of administrative committees and testing.

On Wednesday, June 23rd, the morning session will include steel, and brick, tile, refractories and fire tests. During the afternoon the Edgar Marburg lecture will be delivered, while in the evening an informal dance and smoker will be held.

The sessions on Thursday, June 24th, will include corrosion and fatigue of metals; road materials, waterproofing, petroleum products and thermometers; non-ferrous metals and metallography; textiles, rubber, coal, timber, insulating materials and slate; a symposium on resin.

On the last day of the meeting, Friday, June 25th, consideration of the following subjects is planned: preservative coatings and naval stores; cement, lime, gypsum and nomenclature; and the final session will be devoted to concrete. Arrangements have been made for recreation on each day and on the last day plans include golf and tennis tournaments.

International Conference on Housing and Town Planning

The next international conference on housing and town planning will be held in Vienna, Austria, in September, 1926. The conference is being held under the auspices of the mayor and council of the city of Vienna and is being arranged by the International Federation for Town Planning and Garden Cities. Previous conferences were held in Paris, 1913; London, 1914; Brussels, 1919; London 1920 and 1922; Paris, 1922; Gothenburg, 1923; Amsterdam, 1924 and New York, 1925.

Map of the Red Lake District

A map of the Red Lake District in northern Ontario has been issued by the Topographical Survey Department of the Interior, Ottawa, in co-operation with the Royal Canadian Air Force. The map has been published on a scale of one inch to two miles and covers an area about forty miles by sixty miles in extent, approximately centred at Red Lake.

BRANCH NEWS

Halifax Branch

K. L. Dawson, A.M.E.I.C., Secretary-Treasurer.

At the regular monthly meeting of the Halifax Branch, Thursday, January 28th, 1926, vice-chairman W. A. Winfield, M.E.I.C., presided and Professor F. R. Faulkner, M.E.I.C., acted as secretary, in the absence of H. W. L. Doane, A.M.E.I.C., branch chairman, who was attending the annual meeting of the Institute at Toronto, and the secretary, who was ill. Twenty-six members partook of the dinner that preceded the meeting. This meeting of the branch fell on the same day and very nearly the same hour as the annual dinner of the Institute at Toronto. It was therefore thought fitting to send a telegram of greetings from the Halifax members at the branch meeting to the Institute members at the annual meeting.

Pulp and Paper Development at Corner Brook, Newfoundland

At the close of the regular business meeting, H. B. Pickings, A.M.E.I.C., and C. St. J. Wilson, A.M.E.I.C., spoke most interestingly on the Pulp and Paper Development at Corner Brook, Newfoundland. Mr. Pickings with the aid of a large number of photographs traced the construction work from its beginning in 1923 to its completion last fall. His talk was replete with facts and figures in development which included not only a town site but the hydro-electric plant and the pulp and paper mill. Mr. Wilson dealt specially with the problem of drainage and water supply at Corner Brook and traced the system installed on a large map, giving particular attention to the question of the pressure in the water mains.

The ensuing discussion brought out many more points of interest and Mr. Pickings gave in more detail the difficulty encountered in obtaining titles. There was considerable discussion on the cost of construction and the probable cost of operation compared with smaller plants in Canada and this brought out some interesting facts regarding labour conditions in Newfoundland.

At the conclusion of the discussion the presiding officers conveyed a hearty vote of thanks to Messrs. Pickings and Wilson.

Regular Meeting

At the meeting of the Halifax Branch on February 17th, 1926, a larger number than usual were present, about 50 in all, because of the local interest attached to the subject for discussion. During the regular supper there was music by an orchestra, of piano, violin and banjo, augmented by two banjos played by the students of the Nova Scotia Technical College for some special numbers.

Chairman's Report on his Visit to Institute Annual Meeting

Chairman, Major H. W. L. Doane, A.M.E.I.C., was in the chair. He reported that he had attended the annual meeting of the Institute in Toronto and that he had enjoyed himself immensely. Among the things that stuck in his mind concerning it were the following: The discussions of the papers were prepared beforehand; students were prominent in the discussions; there were over 400 couples at the dance; the telegram which was sent to the Institute dinner by the Halifax Branch was not read; and the Gzowsky medal was awarded to A. G. Tapley, A.M.E.I.C., of the Saint John Branch for his paper on "Concrete in Seawater." He was very much pleased with the entertainment provided by the Toronto members and he wished to record his appreciation of their efforts on his behalf.

The chairman introduced Mr. F. A. Gaylord, manager of the Albany Perforated Wax Pulp and Paper Company, Ltd., of Sheet Harbor, Nova Scotia.

Pulp and Paper Manufacture

Mr. Gaylord sketched the history of pulp and paper manufacturing in United States and Canada and described the different kinds of paper which were made from the different kinds of pulp. He also told of the kinds of wood which are preferred in the manufacture of each kind of pulp. All chemical pulp requires approximately two cords of wood to the ton of pulp. Mechanical pulp requires one cord of wood to the ton of pulp. Chemical pulp is 80 per cent of the total made. Of the chemical pulps sulphite pulp is the cheapest to manufacture. Large quantities of it are used in the Rayon industry which has grown from the one million pounds made in 1914 to the 85 million pounds made in 1926. The basis is highly refined sulphite pulp of which the cellulose is dissolved to a viscus transparent mass which is forced through a colander-like machine to form threads which drop into a second tank of chemicals and are there fixed. Rayon finds its application in artificial silk hosiery, ladies underwear and overwear, silk ties, etc.

In the manufacture of ground wood pulp, Mr. Gaylord said that three things were essential: abundance of material, power, and pure water. At his plant in Sheet Harbor, 2,000 gallons of fresh water per minute were used in addition to 1,800 gallons of previously used or "white water." This mill is electrically driven by power provided from the Nova Scotia Power Commission plant on East river. At present it is consuming at the rate of 4,500 h.p. and the new contract with the commission will call for 6,000 h.p. The wood from which pulp is manufactured at Sheet Harbor is bought in lengths 2, 4, 8 and 16 feet. In buying wood 12½ per cent on 16-foot lengths is allowed or shrinkage due to cutting. Spruce and balsam-fir are used entirely. Hemlock and pine, although present in the timber areas, are not used.

The A.P.W. Company controls 75,000 acres back of the mill on West river which is all good wood, and is not cut beyond the growth, which is the only sane policy About 75 per cent of their wood comes from the district between Country Harbor and Jeddore, N.S., and is transported by scows, schooners and even steamers, although ordinary barges are preferred because of the greater ease of loading and unloading. The cost of transportation is mainly in the handling of the wood. The old rossers are disappearing and are being replaced by the barking drum. The company has experienced difficulty in getting rid of the bark, and has tried burning it but without success. During the coming year it will be used for filling and subsequently three small barges will be used to dump it off-shore in deep water. The pulp is ground by grinders 27 inches wide, 54 to 60 inches diameter. About 70 h.p. are used per ton of pulp in grinding alone, and 8 stones are turning out up to 83 tons of air-dry pulp per day. Governors which keep the motors working at constant maximum steady load, increase the grinding output by 15 to 18 tons per day. After leaving the grinders the pulp contains 97 per cent of water. Bull screens take out splinters and slivers, while centrifugal screens take out practically all the remaining slivers, and Wesby screens reclaim the pulp from the slivers. In wages and the purchase of wood (the cost of wood is about 90 per cent. of the wages), the A.P.W. company spend $450,000 per year in Nova Scotia, and in the purchase of supplies in Halifax, $170,000 per year. Some 600 men are employed in the mill and in the woods.

The A.P.W. company has installed about 23 miles of telephone wires for forest protection, also two steel towers 80 feet high, at each of which a man is stationed continuously during the day. It is necessary to protect practically the whole country in order to protect their own property. Mr. Gaylord suggested that the province might well adopt a general system of fire protection. In Mr. Gaylord's opinion there is opportunity for two more good sized paper mills in Nova Scotia. He suggested that over-development in the manufacture of pulp should be guarded against. Regarding the embargo on pulp wood he believed that this would right itself as the paper industry was coming this way as fast as it could get here. He predicted that in the future the trend of the manufacture of paper will be towards South-eastern United States due to the fact that wood grows so prolifically in those districts. He did not think that this would happen immediately, and thought that it would be postponed by proper methods of reforestation in Canada. He suggested that because of the suitability of Nova Scotia woods and the comparative rapid growth that Nova Scotia was in a very favourable position to support plants manufacturing pulp and paper.

The discussion was opened by Major H. W. L. Doane, A.M.E.I.C., who described the mill foundation and the manufacture and construction which necessitated a coffer-dam sunk through sawdust and bog on the site of an old saw mill.

H. S. Johnston, M.E.I.C., complimented Mr. Gaylord on his concise review of so extensive a subject. He was very glad to hear Mr. Gaylord say that Nova Scotia could be made essentially a pulp and paper province. He agreed with Mr. Gaylord that there was room for not more than two more good-sized mills in the province, but he thought there might be some opportunity for manufacturing pulp at small mills. These mills could utilize the water-power available in many places in small quantities and could ship their pulp to a central paper mill. He suggested that Mr. Gaylord was very modest in his estimate of the good which his mill has been to the province. His mill has operated very efficiently.

C. H. Wright, M.E.I.C., said that the very life of New Brunswick depended on ground wood pulp. There used to be twelve saw mills on the Saint John river near Saint John. Owing to the competition of British Columbia woods in the eastern American market and in other markets to which Nova Scotia and New Brunswick timber was formerly shipped, these mills are now closed. The outlet for the wood which they used to manufacture is now through the pulp mills of New Brunswick. He mentioned that a good shipping point was a decided advantage, that the matter of reforestation is tremendously important, and the manufacture of rayon silk products is an excellent and growing outlet for pulp.

At the conclusion of the discussion a vote of thanks was moved by F. A. Bowman, M.E.I.C., and seconded by Professor F. R. Faulkner, M.E.I.C., and was extended to Mr. Gaylord by the chairman.

A number of splendid photographs were thrown on the screen from a reflectoscope and a motion picture illustrating the story of a newspaper from the cutting of the trees to the final product on sale by newsboys was exhibited through the courtesy of the Halifax Herald, Ltd.

Moncton Branch

M. J. Murphy, A.M.E.I.C., Secretary-Treasurer.
V. C. Blackett, A.M.E.I.C., Branch News Editor.

Forest Fire Prevention

Each spring, the New Brunswick government conducts a vigorous campaign of public education in the matter of the protection from fire of the most valued asset of the province, its forests. To co-operate with this movement and to further the activities of the Dominion-wide "Save the Forest" week, the branch was fortunate in securing H. P. Webb, M.Sc.F., professor of forestry of the University of New Brunswick, who gave a most interesting illustrated address on "Forest Fire Prevention" at a meeting held in the City Hall Council Chamber on the evening of April 22nd.

In addition to throwing the meeting open to the public, personal invitations to attend were sent to the teachers in the Moncton schools in order that the educational features of the address might be the more readily passed on to the youth of the city.

Professor Webb stressed the care that should be taken in the preservation of our forests. Canada is depleting her timber resources faster than any other nation in the world. The annual fire loss is in the neighborhood of $15,000,000, nearly ninety per cent of this is caused by human agency and so might be prevented.

Forest fire prevention may be divided into three parts, prevention, detection and suppression.

Prevention includes propaganda and the various legislative enactments such as control of slash burning and the travel permit system which compels the taking out of permits before entering the forests during the dangerous season.

The prompt detection of fires is made possible through the use of forest look-out towers. These are placed in commanding positions and during the dry season are manned by observers who are in telephonic communication with each other and with headquarters. It is customary to place each tower so that it may have at least one other tower in view, and, since the position of the towers is definitely fixed, it is possible on the outbreak of a fire to determine its exact location by triangulation. This information is at once phoned to headquarters and measures taken to meet the situation. Experiments have been made with airplane patrols but they are expensive.

The suppression of fires requires, first of all, adequate organization. Sufficient equipment is next in importance. This generally consists of portable gasoline pumps, weighing from 35 to 100 pounds and carried by from one to three men. Unfortunately the class of labour obtainable for fighting fires is often very inefficient. Through fear or laziness men are inclined to shirk their duty.

At the conclusion of Professor Webb's address, lantern slides were shown depicting forestry operations in various European countries and also in the maritime provinces and British Columbia.

Senator C. W. Robinson, former Minister of Crown Lands, was present and spoke briefly on the grave importance of saving the forests.

A vote of thanks for his excellent address was tendered the speaker by C. S. G. Rogers, A.M.E.I.C., chairman of the branch.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
Stanley A. Neilson, A.M.E.I.C., Branch News Editor.

The History of Science

On April 22nd, Dr. L. E. Pariseau, speaking before the Montreal Branch, outlined briefly the history of science up to the eighteenth century, running through the list of scientific philosophers from Thales of Miletus, of whom he spoke as being one of the first, to Galileo and others whose energies were devoted to elucidating and even refuting theories propounded by their forerunners.

The address was illustrated by a selection from the speaker's collection of books dating back from four to five hundred years.

The true men of science ante-date the commencement of the Christian era, Dr. Pariseau declared, other philosophers, coming after the birth of our Lord, having added to the store of knowledge and profited from the experience of their predecessors. There have been many halts in scientific research, he said, during periods when the world was being built up, but there has been a steady development in the scientific field throughout all ages, except during that nebulous period called "The Dark Ages."

Dr. Pariseau showed how many errors have arisen through too much authority having been placed on the pronouncements of the earlier philosophers, and later emphatically declared that authority does not exist in science.

The first philosophers of science, concluded Dr. Pariseau, were giants of genius, but many of their successors have been able to see farther than they, because they have sat on the giants' shoulders.

J. L. Busfield, M.E.I.C., was chairman at the meeting.

Tribute to General Sir Alexander Bertram, M.E.I.C.

The great loss sustained by The Engineering Institute of Canada through the death of Sir Alexander Bertram was given expression at the meeting of the Montreal Branch on April 29th, when members of the branch adopted a resolution setting forth their regret and paying tribute to his services to The Institute in particular and to Canada in general.

"The Montreal Branch of The Engineering Institute of Canada," the resolution read, "places on record the deep sense of loss sustained by the society in the death of General Sir Alexander Bertram, an honoured member of our profession, valued by his friends and business associates throughout Canada for his upright and honourable career; by the Department of Militia of this Dominion for his ready and successful response to his country's appeal in time of stress; by his fellow-citizens for his sympathetic advice and wise action in their philanthropic undertakings and, most of all, perhaps, by the engineering profession of Canada, which this Institute represents. Especially do those of us who were privileged to be associated with him on the council and special committee realize that the institute had in Sir Alexander Bertram a most loyal member who gave ungrudgingly an immense amount of time and talent for the benefit of the organization. As treasurer, he was a tower of strength, and succeeded in bringing the financial department to its present satisfactory condition. His ready assistance to, and sympathetic consideration for, those members who were less fortunate in their careers and had difficult problems to solve was well known, and he always assisted them, if possible, in the solutions.

"We of The Institute, as well as all others associated with engineering work throughout the Dominion, have every reason to be mindful of this attitude and to be grateful to him for his many generous actions, so modestly belittled by himself."

A copy of the resolution was ordered to be sent to Lady Bertram, with The Institute's expression of deepest sympathy.

Belgian State Railways

To the Montreal Branch on April 29th, Dr. Ferdinand Van Bruysell, former Belgian consul to Canada and a railway operation expert, read a paper on "Belgian State Railways." In this paper Dr. Van Bruysell outlined some of the difficulties to be encountered in operating a railroad owned by the state. "What can be done with a government-owned railway that does not pay?" he asked, and proceeded to detail the various replies generally given to the question, from turning it over to private capital to operation at a loss for the public convenience.

Without attempting, because of differing conditions of operation, to draw a comparison between the Canadian National Railways and the state-owned railways of Belgium, Dr. Van Bruysell gave facts and figures of operation of Belgian railways, outlined some of the difficulties brought about by post-war conditions, and told of the measures taken to overcome these difficulties and make the railways pay. He stressed the conclusion of a Belgian railway head who said that "a government-owned railway must have financial autonomy," as a solution of one of the chief difficulties of operation.

Mr. Arthur Surveyer, M.E.I.C., presided over the meeting and introduced the speaker. The meeting was the last to be held this season.

Excursion to the Saguenay District

As a result of invitations that have been received from the Duke-Price interests and the Aluminum Company of Canada, it is proposed to run an excursion to the Saguenay district. The programme as at present outlined is to leave Montreal on the evening of the 25th of June, spend the 26th in Arvida, go over to Isle Maligne to see the developments there, returning to Montreal the following evening.

The Branch executive are at present arranging the details and will communicate with the members in due course. Those who were fortunate enough to make the trip to Shawinigan Falls last year can be counted on again this year and those who did not go last year should not miss this opportunity.

Next Season's Meetings

The Papers and Meetings Committee are still looking for suggestions for next season's programme, particularly for the second term. Send in yours.

Amongst those who are at present on the list of speakers are the following:—

H. R. Wake, A.M.E.I.C., of the Aluminum Company of Canada.
Dr. Howard T. Barnes, M.E.I.C., the eminent ice engineer.
R. Witherspoon, Shawinigan Water and Power Co.
Messrs. Roast and Newell, the bronze experts.
H. E. Pawson, M.E.I.C., Ottawa-Montreal Power Co.
W. H. DeBlois, Mond Nickel Co.
G. P. Cole, M.E.I.C., Dominion Glass Co.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

At St. Catharines, on April 21st, a large and representative audience listened with close interest to J. L. Busfield's paper on the "Chicago Water Problem." Situated as this district is, on the main shipping highway between the Great Lakes and the sea, the effect of any disturbance to the lake levels is very keenly noted. Ships coming down the present Welland Canal have little margin to spare in draught, and a lowering of one to two inches will often force them to unload part of their cargo, or else delay until the normal level is regained. These stoppages and the consequent congestion have been frequent in the last year or so, and naturally the local press records each one. Such temporary irregularities in the levels as are directly attributable to the prevailing wind conditions on Lake Erie under ordinary circumstances would pass unnoticed, but due to a cycle of conditions which has made the last few years, years of unnaturally low levels, the problem has become acute, and Chicago has received its full share, or perhaps more than its share, of the blame.

Mr. Busfield's paper was particularly timely, and he gave statistics and engineering data which we, in Canada, should certainly be cognizant of before passing any final judgment.

Anyone who is interested in the question will be well-advised to read Mr. Busfield's paper in the May issue of the Engineering Journal.

Both Mayor Anderson of Welland and Mayor Smith of St. Catharines were extremely cordial in expressing their appreciation of Mr. Busfield's work, and intimated that it reflected great credit, not only upon his own initiative, but upon that quality of the engineering profession which bids its members leave no stone unturned in the search for the truth.

There was considerable discussion, and a number of questions asked at the close of the paper by various members. Norman Gibson, M.E.I.C., wished to know the date of Canada's first protest and also the extent of damage estimated, excluding future power loss. The answer to the first was "that Canada protested to the U.S. Secretary of War in February, 1912." The second question was more difficult to answer and had hardly been studied sufficiently as yet to yield any reliable data. D. A. Andrus, M.E.I.C., made a very pertinent remark to the effect that other large cities on the Great Lakes appeared to be able to handle their sewage and water supply problems without any diversion of lake waters. Mr. Busfield explained that Chicago could hardly be compared with any other such city, not only on account of her size but also because of her peculiar position at the southern extremity of Lake Michigan, where there is very little, if any, natural flow or current. Another member wished to know if Chicago was responsible for the scheme of diverting part of the Hudson Bay watershed into the Great Lakes. To this Mr. Busfield replied that the proposal had first appeared in the "Canadian Engineer"; it had been investigated by Chicago engineers but appeared to be impracticable on account of economic and physical features.

Chairman H. L. Bucke, M.E.I.C., in tendering a vote of thanks to Mr. Busfield also asked as to the effect of a lowering of lake levels upon harbours. Mr. Busfield explained that most vessels were loaded to the last inch of navigable draught and that therefore the slightest variation would mean decreased carrying capacity or else increased harbour dredging. Replying to the vote of thanks, Mr. Busfield committed, in this editor's opinion, the one faux pas of the evening, when he admitted that many of the meetings in headquarters at Montreal were not so well attended as this one at St. Catharines.

Annual Meeting

Annual Meeting and election of officers, May 12th, "The Inn," Niagara Falls. Speaker, Dr. Mackintosh Bell.

Retiring Officers

Chairman	H. L. Bucke, M.E.I.C.
Executive	J. B. McAndrew, A.M.E.I.C.
	T. V. McCarthy, A.M.E.I.C.

New Council

Chairman	Alex. Milne, A.M.E.I.C.
Vice-Chairman	T. S. Scott, M.E.I.C.
Secretary-Treasurer	R. W. Downie, A.M.E.I.C.
Executive	E. G. Cameron, A.M.E.I.C.
	J. C. Street, M.E.I.C.
	L. L. Gisborne, A.M.E.I.C.
	W. S. Orr, A.M.E.I.C.
(ex officio)	H. L. Bucke, M.E.I.C.

Mr. Bucke, in his retiring address, stated that this Branch had been formed mainly through the efforts of engineers employed in the construction of the Queenston-Chippawa power project and the Welland Ship Canal. Now these works were nearing completion and many members would be leaving for other parts within the next few years. He urged therefore, that a special effort be made to keep the Branch active and suggested that all engineers having more or less permanent positions with industrial plants should enter with greater zeal into the activities of the Branch.

Mr. Bucke expressed his thanks for the whole-hearted co-operation given during the last year by the vice-president, the executive, and particularly by Mr. Downie, the secretary-treasurer.

Mr. Milne then took the chair and in a few happy words expressed his appreciation for the honour conferred. He was most anxious that the Branch should continue, and thought that, if the members would co-operate, much interest might be aroused by getting papers from the local membership and assigning to certain other members the duty of preparing discussions on such papers.

E. G. Cameron, A.M.E.I.C., chief assistant engineer of the Welland Ship Canal, then moved that the professional meeting which was proposed for this year, be postponed for twelve months. He explained that certain features of the canal, such as the large steel lock gates and lift bridges would be at the most interesting stage of their construction during the summer of 1927.

Mr. R. Bond of the Victoria Park Commission seconded this motion, saying that certain of the main roads in the Park would be under heavy repairs this summer and that next year they would be in a much better position to show visitors around. Motion carried.

Vice-President T. S. Scott, M.E.I.C., introduced the speaker of the evening, Dr. Mackintosh Bell, as the Managing Director of the Canadian Lorrain, president of the Huronian Belt Mining Co., an eminent geologist and a member of the British Intelligence Staff during the war.

Dr. Bell gave a strictly non-technical but nevertheless highly interesting talk on travel in many lands. He took us with him to the Copper-mine River in the Northwest Territory, to Siberia, to Russian Turkestan, to Manchuria, to New Caledonia, and finally to New Zealand, where he had the unfortunate distinction of poking the Maori heir-apparent in the ribs under the impression that he—or she—was merely a common-or-garden baby.

H. G. Acres, M.E.I.C., expressed the feeling of the meeting when he said that Dr. Bell's address was one of the most interesting that had ever been delivered before this Branch. "A regular Cross Section out of Kipling's Works."

Quebec Branch

Louis Beaudry, S.E.I.C., Secretary-Treasurer.

The Port of Quebec

On Monday, April 26th, Brigadier-General T. L. Tremblay, C.M.G., D.S.O., A.M.E.I.C., chief engineer of the Quebec Harbour Commission, addressed the Quebec Branch on the subject of "The Port of Quebec," at a luncheon-meeting held at the Chateau Frontenac.

After being introduced by A. B. Normandin, A.M.E.I.C., chairman of the Branch, General Tremblay commenced his address by declaring that Quebec had long ago been recognized as one of the most important ports of America. In 1608, Champlain realized its strategic importance, and the Frenchmen chose a particularly beautiful and convenient spot at which to moor their ships, at the foot of Canoterie Hill, so called because it was there also that the Indians kept their canoes.

After the advent of the first French settlers the growth of the port proceeded in proportion to the requirements of increased trade, which in turn brought a greater number of larger vessels. At the outset the wharves were built by private interests without any general direction on the shores of the St. Lawrence and St. Charles rivers, on both sides of what is still known as the Pointe à Carcy.

In 1805, Trinity House, which was the first organization to administer the affairs of the port of Quebec, and which also had authority over the pilots of the district, was incorporated by an act of Parliament. The Corporation of the Harbour Commissioners of Quebec was formed in 1858. These two public bodies functioned together until 1876, when the affairs of Trinty House were taken over by the Harbour Commissioners. In 1912 the number of commissioners, which had been nine, was reduced to three, including the chairman, who was appointed by Order-in-Council and remained in office until he chose to resign. Since that date the chairmen who have headed the Commission have been : the late Sir William Price, Hon. Senator D. O. L'Esperance, the late Major-General Sir David Watson, and the present chairman, Hon. W. Gerard Power, M.L.C.

The limits of the port of Quebec were defined by act of Parliament in 1899 and have not been changed since. According to this act the port extends along both shores of the St. Lawrence river from Deschambault in the County of Portneuf to St. Barnabe Island, opposite Rimouski, a distance of 175 miles; while the Quebec Harbour comprises both shores of the St. Lawrence from Cap Rouge to an imaginary line starting at Montmorency Falls and passing opposite the church of St. Petronille, Island of Orleans, in the direction of the south shore.

The first period of important development of the port commenced a few years before the absorption of the Trinity House by the Harbour Commission, and a scheme of construction was worked out by Messrs. Kinniple and Morris, prominent English engineers. A general plan was developed, including all the wharves of the time, and also considerable enlargements at the estuary of the St. Charles river. These works were largely executed under the supervision of St. George J. Boswell, M.E.I.C., who has been the chief engineer of the Harbour Commission for forty-six years.

General Tremblay outlined the facilities which are now possessed by the port for the handling of ships and their cargoes. The increase in activity in the port during recent years justified the construction of the Wolfe's Cove terminal wharves, work upon which had commenced and would be continued as the need made itself felt.

A. R. Decary, M.E.I.C., honorary-president of the branch, thanked the speaker on behalf of the branch.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Addressing the Ottawa Branch at luncheon in the Chateau Laurier at noon April 29th, A. H. White, M.E.I.C., of New York, chief engineer of the International Paper Company, told his auditors of the power developments now under way by the company at Chelsea, Quebec.

Mr. White, an abstract of whose address appears elsewhere in this issue, gave some interesting facts and figures relating to the big development at the doors of the Capital.

Chicago Drainage Canal

An extremely interesting address was delivered May 7th, in the palm room of the Chateau Laurier, on the Chicago Drainage Canal, by J. L. Busfield, M.E.I.C., of the firm of Beaubien and Busfield, consulting engineers, Montreal. It was given before a fairly well attended gathering of the Ottawa Branch, Engineering Institute of Canada.

The lecture was plentifully illustrated with lantern slides, showing the many features of the famous canal. The lecturer did not touch so much on the international aspects of the canal, as on the engineering skill that was displayed in its construction.

Mr. Busfield devoted himself practically entirely to constructing a background for a clear understanding of the questions arising out of the Chicago diversion. He did not offer any opinions or advance any suggestions as to what the solution will or should be.

In view of the fact that the Joint Engineering Board has the matter under consideration, that was, of course, amply sufficient reason for confining the paper to an explanation of the problem.

Mr. Busfield's paper was published in full in the May issue of the Engineering Journal.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer

Photography in Science, Industry and Medicine

On April 21st, 1926, the members of the Saint John Branch were addressed by Professor E. L. Harvey, M.A., of the University of New Brunswick, Fredericton, on the subject of "Photography in Science, Industry and Medicine." The address was illustrated by a large number of lantern slides, and by means of blackboard demonstrations; the speaker also illustrated some fundamental principles to observe for obtaining good pictures. As this meeting was being held during the week when the annual Save-the-Forests campaign was in progress some slides describing the loss occasioned by forest fires were shown on the screen. A number of the citizens of Saint John, including some of the medical doctors, were present at this meeting. W. R. Pearce, M.E.I.C., chairman of the branch, presided and on the conclusion of Professor Harvey's address tendered him a vote of thanks on motion of Geoffrey Stead, M.E.I.C., and A. R. Crookshank, M.E.I.C.

Photography in addition to being a hobby of some persons has to-day been developed to such a state of perfection that it is now in general use in many industries and for a variety of purposes. As examples of the degree of refinement attained might be mentioned that photographs can be obtained with a ten-millionth part of a second's exposure; that the aeroplane surveyor can take photographs, through mist, of landscapes almost invisible to the eye; that a microbe, a twenty-five-thousandth of an inch long, can be magnified two hundred million times in area, and that its photograph produced in ultra-violet light will reveal its structure. The progress of photography has been largely due to the extension of the colour-sensitiveness of the photographic plate; the sensitiveness to light of silver bromide and its inclusion in an emulsion of gelatin has been used by the plate chemist to make it sensitive to all the colours of the spectrum, to invisible infra-red and ultra-violet rays, to X-rays, and the shortest wave motions produced by radium.

In pure science the use of photography has been the means whereby many experiments were successfully completed and results obtained which without its aid would have been impossible. The photographing of wave lengths of the ultra-violet has been used in experimental work on sugars and starches and other processes of vegetable life. Spectrum analysis by photography, of spectro photography, has disclosed the constitution of the sun and of stars and is used by astronomers to calculate the velocity of heavenly bodies.

The microscope has been used extensively in conjunction with photography during the past three or four years. This photo-micrography has discovered inherent defects in steel, such as troubles arising through bad ingot pouring, or possibly faults arising in the forging and stamping of steel. Within the past couple of years an apparatus has been designed which permits the magnifications of 25,000 diameters. A new process of seasoning wood in about nine days as against some months of air curing was photographed every ten minutes and the gradual chemical and physical changes recorded. Slow motion photographs of workers on piece work in industries has been the means of discovering lost motions and thus speeding up production.

Photographs have been recorded at the rate of 5,000 per second for scientific research, the actual exposure being that of a spark discharge in a Leyden jar. It has thus been possible to record the flight of bullets and of meteors.

One of the inventions of photographic recording is the sonometer, a machine in which a pencil of light is deflected by a diaphragm vibrated in accordance with the sounds impinging on it, and a fine spot of light makes its record upon a moving plate or band of sensitive paper. It is useful in recording musical and vocal sounds and is applied in engineering work for testing periodic errors in geared machinery.

Probably the most advanced work attained in photography to date has been its application to radio-active phenomena. The bombardment of the nucleus of an atom by an alpha particle of radium and the actual breaking off of a hydrogen atom has been shown. This transmutation of an element being photographed by an end-on collision was only obtained after 21,000 attempts.

The telegraphic transmission of pictures, inaugurated in 1907 and only occasionally used since on account of excessive cost, is gradually gaining ground in the newspaper world. In the early days of X-ray work back in 1896, the time necessary for an exposure was several minutes; it was used extensively during the South African War to locate bullets, and is now in general use in medicine and dentistry and has been so perfected that an exposure is practically instantaneous.

Photography has many practical uses in engineering. The photographing of a blue-print can now be successfully done, thereby ensuring an exact copy without any omissions as possibly might occur in re-tracing. It is also available for reducing or enlarging maps or other plans. Plans, prints or paintings which may have been hopelessly damaged through ink or other stains can be accurately reproduced in the original by having the stain neutralized when the photograph is being taken. The use of photographs of engineering works and in engineering reports is too well known to repeat their value.

Colour rendering or the taking of photographs in their natural colours without re-touching is one of the advances of photography along artistic lines. This work is used largely in photographs of landscapes and of sunsets.

Annual Meeting

Again the members of the Saint John Branch observed the completion of another successful season by a combined dinner and annual meeting. The affair was held on the evening of May 5th at the Admiral Beatty hotel and was presided over by W. R. Pearce, M.E.I.C., chairman of the branch during 1925-26. Guests included Honourable J. B. M. Baxter, N.L.A., premier of New Brunswick; Dr. W. W. White, mayor of Saint John; O. J. Fraser, C. F. Sanford, K.C., of Saint John; A. P. Theuerkauf, M.E.I.C., and E. L. Martheleur, M.E.I.C., of Sydney, N.S.

After disposing of a very fine meal an item of educational entertainment was provided by the screening of a picture showing the manufacture of carbide as produced by Canada Carbide Company.

The toast to the King was observed in the usual manner. Major W. J. Forbes-Mitchell, D.S.O., M.E.I.C., as a newcomer to the branch, proposed the toast to the Province of New Brunswick; this was replied to by Premier Baxter, who dwelt at considerable length on the proposed hydro-electric development of Grand Falls, N.B., to be done soon under an agreement with the International Paper Company. The toast to the City of Saint John was proposed by J. L. Feeney, A.M.E.I.C., and replied to by Mayor White. Dr. White was recently elected to office and had not previously made any announcement as to the policy he intended following in office; his remarks were closely followed as he mentioned a number of ways the engineer might assist in improving the city, including extensive harbour developments. The toast to Our Guests was introduced by J. N. Flood, A.M.E.I.C., and fittingly replied to by O. J. Fraser. The Press was proposed by A. A. Turnbull, A.M.E.I.C., as chairman of the Publicity Committee of the branch, and replied to by K. E. MacLaughlin, a press representative. Councillor A. G. Tapley, A.M.E.I.C., proposed The Engineering Institute of Canada, which was replied to by J. L. Holman, JR. E.I.C.

An innovation adopted by the chairman was his insistence that practically all speakers on the toast list be those who do not generally have much to say at branch meetings. All members took their parts well and received good practice in speaking in public. Someone said one time—don't know exactly what time or who said it—that "Engineers can't speak in public"; but anyone who says so should have been at this dinner in order to be convinced that this statement is wrong. Any engineer who does not speak well in public, does not speak well because he does not speak often enough—that's all.

The report of the auditors was submitted by E. J. Owens, A.M.E.I.C., and the report of the executive was read by the secretary.

Reports were submitted by the chairmen of various committees on the year's work as follows:—

Committee Report	*Submitted by*
Papers and Meetings	Geoffrey Stead, M.E.I.C.
Entertainment	E. A. Thomas, A.M.E.I.C.
Civic Building and By-Laws	C. C. Kirby, M.E.I.C.
Concrete in Sea Water	Alex. Gray, M.E.I.C.
Fuel	Prof. John Stephens, M.E.I.C.
Publicity	A. A. Turnbull, A.M.E.I.C.
Employment	J. A. W. Waring, A.M.E.I.C.

J. R. Freeman, M.E.I.C., on behalf of the scrutineers, reported the election of A. R. Crookshank, M.E.I.C., as chairman; S. R. Weston, M.E.I.C., as vice-chairman; J. D. Garey, A.M.E.I.C., as member of executive. The present secretary-treasurer was re-elected to office.

A vote of thanks was passed to the New Brunswick Telephone Company for having made available its assembly hall for holding branch meetings.

A. R. Crookshank, M.E.I.C., was escorted to the chair and briefly thanked the members for his election to office. The other members elected to office also spoke in reply to insistent demands from the members. All present voted the meeting as a very interesting and instructive affair and a suitable finish to a splendid season's programme.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

A regular meeting was held on April 30th, at the Y.W.C.A. rooms. Major Thompson and Major Clayton of the Provincial Forestry Department were the guests at the dinner.

C. H. Speer, M.E.I.C., chairman, called the meeting to order and dispensed with the regular business. The telegram announcing the death of Sir Alexander Bertram, M.E.I.C., the treasurer of the Institute, was read and received with an expression of regret by all the members present, also an expression of sympathy was extended to the family.

At 8 p.m., under the guidance of Major Thompson and Major Clayton, a visit was made to the local hangar of the Provincial Forestry Department, on Church street. The delegation consisting of about thirty-six were divided, with Majors Thompson and Clayton each acting as guide and instructor to a party.

The wood-working room, the paint room and all the various departments were visited in turn, and it was most interesting to see the different parts of the machines. After viewing the disassembled parts and noting carefully their lightness of construction, the members were much impressed with the stability of the fully assembled machines which were inspected next.

The two hours spent going through the hangar were very instructive as well as interesting, and the members of the executive wish to express their appreciation and thanks to Major Thompson and Major Clayton for the courtesy shown and the trouble taken by them to make the inspection a successful one.

Victoria Branch

E. G. Marriott, A.M.E.I.C., Secretary-Treasurer.

Launching of Drydock Caisson

On April 12th, on the invitation of N. A. Yarrow, A.M.E.I.C., a number of the members of the branch attended the launching of the second of the large drydock caissons constructed by Yarrows Limited. The lieut.-governor of the province, the Hon. R. R. Bruce, and Miss Helen Mackenzie were escorted to the launching barge by Piper-Major Wishart, playing "The Cock o' the North" on his pipes. Miss Helen Mackenzie, chatelaine at Government House, touched a button, a bell rang, and amidst the shrieks of factory and steamship whistles and sirens, the 720-ton drydock gate started slowly down the skidway, gaining increased speed as it neared the water, then with a graceful plunge it made its maiden dip, entering the water on its side at an angle of about 30 degrees. Following the launching, Miss Cynthia Yarrow, 5-year-old daughter of Norman A. Yarrow, presented Miss Mackenzie with a beautiful bouquet of flowers.

Some 700 invited spectators witnessed the launching ceremony, with an additional 200 interested onlookers who occupied vantage points in the surrounding neighbourhood.

The description of the two gates appears on another page of this issue of the Journal.

Building the Cariboo Road

On April 14th, P. Philip, M.E.I.C., deputy minister of public works of the province of British Columbia, spoke on the building of the new Cariboo road.

The description of Simon Fraser of the Fraser canyon was as follows:—

> "This country is a series of cascades, interrupted with rocks and bounded by precipices and mountains that seem to have no end, I scarcely ever saw anything so dreary and so dangerous. Whatever way I turn my eyes, mountains upon mountains, whose summits are capped with eternal snow, close the gloomy scene."

Further on he says:—

> "As for the road by land, we could scarcely make our way even with our guns. We had to pass where no human being should venture. Yet in those places there is a regular footpath impressed or rather indented upon the very rocks by frequent travelling. Besides this, steps which are formed like a ladder by poles hanging to one another crossed at certain distances with twigs, the whole suspended from the top, furnish a safe and convenient passage to the natives down these precipices, but we, who had not the advantage of their education and experience, were often in imminent danger when obliged to follow their example."

That was in 1808. Half a century later road building began in earnest. In 1862, the Cariboo road was started by the Royal Engineers north of Yale, and by 1863, in the month of June it had been completed to Cook's Ferry (Spence's Bridge), a distance of 80 miles.

The suspension bridge at Spuzzum was constructed by Joseph W. Trutch, and in February 1864, Thomas Spence replaced Cook's Ferry with a bridge that gave his name to this place.

In the early days construction looking toward a road connecting coast and interior was started along three routes, the Harrison, Hope-Princeton, and the Cariboo. The same three have been the object of much examination these last few years, and at length the government decided to relocate and rebuild along the old Cariboo route, the original road having been largely obliterated by the advent of the railway, which followed the old trail.

The location of the Old Cariboo road required 45 level crossings between Hope and Spence's Bridge, but by skilful relocation 33 of these were eliminated, and of the remainder it is probable that only six grade crossings will be necessary for the present. The proximity of the railway added greatly to the difficulty of carrying out the work in the canyon, as every precaution had to be taken to prevent rock falling on to the track, and also to prevent rock being dumped into the Fraser river to the detriment of the passage of salmon.

The new Cariboo road has a road-bed of 16 feet, widened to 18 to 20 feet on curves, and has a maximum grade of 8 per cent except at Jackass mountain.

The bridges, particularly those over Cisco and Stoyoma creeks, and Anderson river, will be of interest to motorists. These bridges cross canyons at an average height of 160 feet above the bed of the stream.

The new Alexandra suspension bridge has been designed with a view to preserving, as far as possible, the historic features of the old bridge at this point, but at the same time providing for modern traffic requirements.

Mr. Philip paid tribute to the engineers past and present who had carried out their work on the old and new roads, and also to the efficient and expeditious work of the present contractors, and urged all Institute members to visit the road not only for its scenic charms, which were unequalled, but that they might acquaint themselves with the outstanding engineering features of its construction.

A number of lantern slides were shown covering the construction of the road, and at the conclusion of Mr. Philip's talk he was accorded a very hearty vote of thanks.

Trade Publications

The selection and application of centrifugal pumps to mine pumping is the subject of a twenty-page leaflet distributed by the De Laval Steam Turbine Co. of Trenton, N.J. Instructions are given for the design of piping, and the calculation of friction head power required. Details of construction which should be looked into when selecting pumps for this service are also discussed at length. This publication should be useful not only to mine owners and engineers but to anyone using pumps for irrigation, general water supply, and similar service.

The Construction of the Gatineau River Power and the West Templeton Paper Mill

A. H. White, M.E.I.C., Chief Engineer, International Paper Company, New York.

Ottawa Branch, April 29th, 1926.

Mr. White said that soon after the Riordon properties were taken over by the Canadian International Paper Company, the president, Mr. A. R. Graustein, set in motion the establishment of power plants and a paper mill to make use of the lumber and powers which were part of the Riordon properties. In this development the Canadian International Paper Company is making use of Canadian talent, manufacturing facilities and labour to the greatest extent possible. The engineering designs for the power plant are being executed by Canadian engineers in Canada. The general engineering and construction work is being done by a Canadian company. In addition to this Canadian consulting engineers are being employed. Water wheels, generators, paper machines, etc., are bought in Canada. In short the company is making these developments Canadian.

Physical Features of the Gatineau River

The Gatineau river has a drainage area above Chelsea, Quebec, of 9,600 square miles. The high level of the lake to be formed by the construction of the Bitobee dam is 750 feet above the water. The water level below Farmers rapids, the lowest fall in the river, is at elevation 157, making a total fall of 393 feet in a distance of 120 miles. All this fall cannot be used. There are several points at which the fall is concentrated enough and the character of the country is such as to make developments feasible both from an engineering standpoint and commercially. The four principal points for development are: Maniwaki, Paugan falls, Chelsea and Farmers rapids; the two latter being now in the progress of development.

The storage dam to be built at Bitobee, a short distance below the mouth of the Gens de Terre, will impound 82,000,000,000 cubic feet of water, which, with the natural run-off below the storage dam, will give a regulated flow at Chelsea of from 8,000 to 10,000 cubic feet per second depending upon the precipitation in any given period. The fall at Paugan falls is 115 feet, Chelsea 95 feet and Farmers rapids 65 feet, a total of 275 feet.

Available Power

At 8,000 cubic feet per second and unity load factor, these three head will develop 220,000 h.p. on water wheel shafts. Higher flows will, of course, yield proportionately greater powers. Of course unity load factor never obtains and the developments will utilize more than the absolute minimum flow of 8,000 cubic feet per second. The average commercial load factor may be placed at 60 per, cent and this load factor will require a total installation at the points named above of 360,000 h.p. on water wheel shafts. Since the records show the average natural flow in the river to be 10,000 cubic feet per second most of the time, and as there are additional storage possibilities, developments will be made on the basis of at least 10,000 cubic feet per second regulated flow, which, at 60 per cent load factor, will require an ultimate installation of 450,000 h.p. If we allow 10 per cent for losses from water wheel shafts to the point of delivery of electric current, we will have 405,000 h.p. delivered for 60 per cent of the time. These statements apply to Chelsea, Farmers and Paugan sites.

In addition to the above, there are other heads capable of development which should bring the total of 60 per cent load factor delivered power up to the neighbourhood of 600,000 h.p.

Bitobee Storage Dam

At Bitobee a storage dam is to be built under the direction of the Quebec Streams Commission, of which O. O. Lefebvre, M.E.I.C., is chief engineer; the construction to be performed by the Foundation Company of Canada, Limited, of which F. E. Chadwick, M.E.I.C., is vice-president and general manager. The crest of this dam is to be at elevation 750, possibly 755. Three cut-off dams are necessary, at Castor lake, Lacroix creek and Philemon creek. Work has already commenced on this dam, cement and other necessary materials to the extent of some 10,000 tons having been taken in over the snow during last winter. The distance from the railway to Maniwaki is about 28 miles. It is intended and expected to have this work finished by January 1st, 1927, at a cost of approximately $3,000,000.

Numerous surveys and studies have been made on the development at Paugan falls, but the work there has not commenced.

Chelsea Power Development

At Chelsea, about eight miles above Ottawa, the construction of a dam and power house is well under way. The crest of the spillway at this point will be at elevation 315. Flashboards will hold the water at periods of low flow at elevation 318. This dam will set the water back about to the village of Wakefield and will necessitate moving to higher ground some six miles of tracks of Canadian Pacific Railway, and also of the highway. The power house will be between the island and the west shore of the river. The dam between the island and the east shore of the river is to contain flood gates and across the island will be the spillway before mentioned, carrying flashboards. The power house has been designed for five turbines of 34,000 h.p. each at 95-foot head, the turbines running at a speed of 100 r.p.m. The turbines will be of the Francis vertical type and will each drive a 36,000 Kv.a. Canadian Westinghouse generator. Turbines will be built by the Dominion Engineering Company of Montreal. Draft tubes are of the Moody type, and the tailrace will extend 1,200 feet from the power house through the channel between the island and the west shore. The generators will produce current at 6,600 volts which will be stepped up to 110,000 volts for transmission.

At Farmers rapids, about 7,000 feet below Chelsea dam, the company is building an hydro-electric plant to contain five turbines of 24,000 h.p. each, directly connected to generators to be built by the Canadian General Electric Company. On account of the short distance between the two plants the Chelsea and Farmers rapids plants will be run in synchronism, that is to say, each plant will use the same amount of water at the same time.

The Chelsea and Farmers rapids plants are being designed by the Fraser Brace Engineering Company, Ltd., in co-operation with the Power Engineering Company, Ltd., of Montreal. Construction at Chelsea, Farmers rapids and the paper mill is being executed by Fraser Brace Engineering Company, Ltd., Major James H. Brace, M.E.I.C., vice-president, being in direct charge.

While the matter has not yet been fully decided, it is quite likely that there will be both 60-cycle and 25-cycle units in both plants. Power from these plants will be used at the paper mill now building at West Templeton, about four miles below Ottawa on the Quebec side of the Ottawa river, and by others as the demand may require. It is planned to sell the 25-cycle current from these plants to the Hydro-Electric Power Commission of Ontario and also to develop Paugan falls at 25 cycles. This 25-cycle current from all three plants would be transmitted to the province of Ontario over a 220,000-volt transmission line.

The entire power and storage development will cost in the neighbourhood of $50,000,000.

Paper Mill at West Templeton

The paper mill building at West Templeton will be called the Gatineau mill. The first unit will contain four paper machines, capable of producing a sheet of newsprint paper 256 inches wide at a rate of 1,200 feet per minute. These machines will be the largest single producers so far installed in the world. The paper mill will require some 39,000 h.p. for grinding wood and for miscellaneous needs about the mill. In addition electric boilers will be installed to use surplus electrical energy until such time as the demand for such energy no longer warrants its use for making steam. The paper machines, wood pulp grinders, sulphite digesters and practically all other machinery used in the mill will be of Canadian manufacture. Paper machines will be furnished by the Dominion Engineering Works, Limited, the steel by the Dominion Bridge Company, Limited, and so on down the line, including brick and cement. It is intended to have the power plants and paper mill finished by the first of the year 1927, and by July 1st, 1927, to be producing upwards of 450 tons of newsprint each twenty-four hours, six days per week. The mill is being laid out so that its capacity can be doubled or trebled if conditions in the future warrant.

In conclusion, let me say that the ability and spirit of co-operation shown by all engaged in this vast amount of work and by the business men and others with whom we come in contact, are gratifying and surely conducive to economy and efficiency. Furthermore, the Provincial and Dominion authorities have shown us the utmost consideration, and we believe that these developments will prove of great benefit to both the province and the Dominion.

Quebec

An interesting and handsomely illustrated booklet, entitled "Quebec," has been issued by the Department of Roads, of the Province of Quebec. This booklet is intended for the use of tourists contemplating visiting the province. While it is not intended as a guide, it contains a great deal of very interesting information regarding the province.

Geological Formations of Manitoba

An interesting bulletin of the geological formations of Manitoba by R. C. Wallace, professor of geology and mineralogy of the University of Manitoba, has been issued by the Natural History Society of Manitoba. The bulletin contains a summary of the extensive information on the geological formations of the province and contains also a bibliography of literature on the subject.

Map of Calgary and District

Topographical Survey, Department of the Interior, has issued a new map of Calgary and district which covers an area of roughly sixty-five miles north and south by fifty-five miles east and west and is on the scale of one mile to three inches.

Preliminary Notice

of Applications for Admission and for Transfer

May 19th, 1926.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in June, 1926.

R. J. Durley, Secretary.

---

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council, shall be required to pass an examination before a board of examiners appointed by the council The candidate shall be examined on the theory and practice of engineering with special reference to the branch of engineering in which he has been engaged. This examination may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the first year in such a course, shall be required to pass an examination in the following subjects: geography, history (that of Canada in particular), arithmetic, geometry, euclid (books I, IV and VI), trigonometry, algebra up to and including quadratic equations.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed successfully an examination equivalent to the final examination of a high school or the matriculation of an arts or science course. He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination equal to that prescribed for admission to the grade of Junior in the foregoing section and he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BAILIE—EDWARD LEONARD, of Stellarton, N.S., Born at Bridgeport, Conn., May 24th, 1902; Educ., B.Sc. N.S. Tech. Coll. 1926; 1923-24 engrg. staff of Brit. Emp. Steel Corp. of Stellarton, as ch. of party on topographical survey, also drafting and blotting notes in connection with same dept.; June to Sept. 1925, asst. engr. on highway constrn with N.S. Highway Board.

Diesel Engines

Their Early History, Development and Present Application

E. V. Buchanan, M.E.I.C.

General Manager, Public Utilities Commission, London, Ont.

Paper presented before the London Branch of The Engineering Institute of Canada, December 9th, 1925

The Diesel oil engine, the original patents of which were taken out in the year 1892, is named after its inventor, Dr. Rudolph Diesel, who, with the engineering firms associated with him, spent the following three or four years on tests and experiments.

Early Development

The first engine was constructed without a water jacket, and coal dust was used as fuel, the temperature for the combustion of fuel being obtained by compressing air to a sufficiently high pressure in the cylinder before injecting the fuel. Mechanical difficulties were experienced and also troubles from ash and grit remaining as products of combustion. Various features of the original invention were abandoned and modifications of others adopted, until, about the end of the year 1896 satisfactory results were obtained from an engine using oil as fuel and a compression pressure of about 470 lbs. per square inch.

In 1897 the first British-made Diesel engine was constructed in Glasgow. This engine was also the third Diesel engine in the world, and is still operating. The original Diesel engines were of the four-cycle, air-injection type, and the name of the inventor is therefore only strictly applicable to this type. However, the term " Diesel engine " is usually used to cover the two-cycle, and the mechanical or solid injection and other recent modifications as well.

The four-cycle engine having air-injection of the fuel, that is, the oil is carried into the combustion chamber in a stream of highly compressed air, and thereby resulting in a fine state of atomization, is probably the most popular yet. However, both the two-cycle principle and the mechanical means of fuel injection have been rapidly gaining ground during the last few years. Strong arguments are entered by supporters of all these principles, and we are probably far from standardizing any one type.

The reasons behind this gradual change from the original Diesel engine are the large power units required now; the necessity for the conservation of space; and the limit in cylinder capacity; all of which account for the substitution of the two-cycle for the four-cycle engine. It will be readily seen that of two engines, one of each type, having similar dimensions and running at the same speed, that the engine having only one power stroke in four will not develop as much power as the engine having one power stroke in two. One of the difficulties in the design of a two-cycle engine is that, because there are more power strokes per revolution, more heat is generated per unit of area of cooling surface which results in higher stresses in the cylinders and cylinder covers. However, in favour of the two-cycle engine there is also the argument that for marine work and other uses, in which the engine must be reversible, the two-cycle engine can be made directly reversible with fewer cylinders than the four-cycle engine, which, to be directly reversible, must have at least six and preferably eight cylinders.

The mechanical injection of fuel owes its place to the desire to do away with air compressors, which are apt to be a source of trouble and also consume a considerable portion of the power developed. The supporters of air injection, however, say that compressors are required in any case for the purpose of starting the engine. The value of this argument has been reduced more or less by a lowering of the starting pressures required. A typical pressure in the cylinder of an engine using air injection is 480 lbs., whereas 600 lbs. is frequently exceeded when mechanical or solid injection is used. Consequently for a cylinder of any given dimension using solid injection, the working parts should be larger and stronger than for a Diesel engine.

The latest development is the double-acting engine. In the first engine mentioned, the four-cycle, a power stroke occurred only in every four. In the two-cycle engine a power stroke took place in every two, but in the two-cycle double-acting engine every stroke is a power stroke, just as in a steam engine. The principal advantages of this type are obvious. The material used in its construction

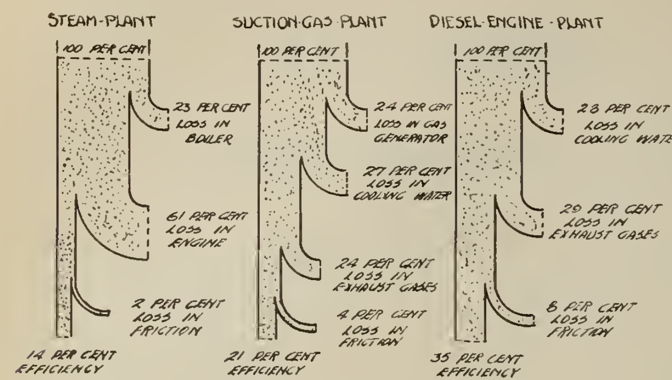

Figure No. 1—Comparison of the Thermal Efficiency of the Fuel for Steam, Suction-gas and Diesel Engine Plants.

is utilized to develop power more continuously than in other types, which reduces weight and first cost; two very vital matters. Another characteristic is that it may be made directly reversible with any number of cranks from two or three to eight, which enables any one size of unit to be adopted for a very wide range of powers, facilitating standardization and mass production to an extent much greater than has been previously possible with any type of marine prime mover. For example, a double-acting two-cycle cylinder developing 450 b.h.p. may be used in directly reversible engines of from 900 b.h.p. for a single screw to 7,200 b.h.p. for twin screws. The North British Diesel engine is of the two-cycle double-acting type. There are no piston rods and the cylinders reciprocate synchronously with the piston; the cylinder covers being stationary but separate from the cylinders.

Diesel engines are being made up to 12,000 h.p. There does not appear to be any practical limit. The power of the engine is dependent only on the size of the cylinders and the number of them.

Advantages of the Diesel Engine

In considering the advantages of the Diesel engine over other prime movers, the following points should be mentioned:—

1. No smoke.
2. No chimney.
3. Freedom from noise.
4. Small space occupied because of absence of boilers and other auxiliaries.
5. No deterioration of fuel such as occurs with soft coal or gasoline.
6. No carting of fuel or ashes.
7. Immediate starting from cold.
8. Neat and convenient storage of fuel.
9. Suitable for the most fluctuating loads.
10. Fire risks minimized, as only high flash point fuel used.
11. Absence of boilers or gas producers and their heavy up-keep.
12. No fuel consumed when engine standing by or not running.
13. No lamp, hot bulbs, sparking device, carburetor or vaporizer.
14. Fuel consumption controlled entirely by governor; does not depend upon skill of driver.
15. Contrary to the principle adopted in gas or oil engines of the ordinary type, the piston compresses pure air and not a mixture of air and fuel. This allows the use of a much higher compression as there is no danger of premature firing. The thermal efficiency of the engine increases in ratio with the compression; the Diesel engine, therefore, has a higher thermal efficiency than any other prime mover.

    The Diesel engine operates on a constant pressure system which means that when the fuel enters, instead of burning with explosive violence, as in the gasoline engine, it burns gradually and a constant pressure is maintained in the cylinder during that time. This means lower pressure and consequently lighter construction.

    Therefore the true province of the gasoline engine is in the lower powers, leaving the field of high power for the Diesel engine.

British manufacturers have not yet attempted a Diesel engine for the automobile. The various accessories to a Diesel engine such as compressors, starting bottles and piping, in addition to a fuel tank and cooling medium, would, no doubt, make this difficult.

A number of French and German manufacturers are working on it and recording satisfactory progress. Higher speeds than in the case of the aeroplane type are required and great flexibility in speed and power is essential. Speeds up to 2,500 r.p.m. have been attained and maintained for lengthy periods. The fact that fuel costs are reduced to one-sixth when using oil in place of gasoline, or as much as one-tenth on a light grade fuel oil, the advantages of an automobile type oil engine can be readily appreciated.

In the case of aeroplane engines, the use of non-volatile liquid is an important and most valuable asset. It makes this aspect of the problem of oil engine application particularly attractive. There are, however, many difficulties. The lowest possible weight, together with high engine speeds, does not introduce easy conditions under which the combustion of heavy oils is accomplished. Not much work has been done on this. There is one engine still in the experimental stage, which weighs three pounds per brake horse power for a total of 600 b.h.p., and operates at a speed of about 1,300 r.p.m. Some type of mechanical injection of the fuel is used.

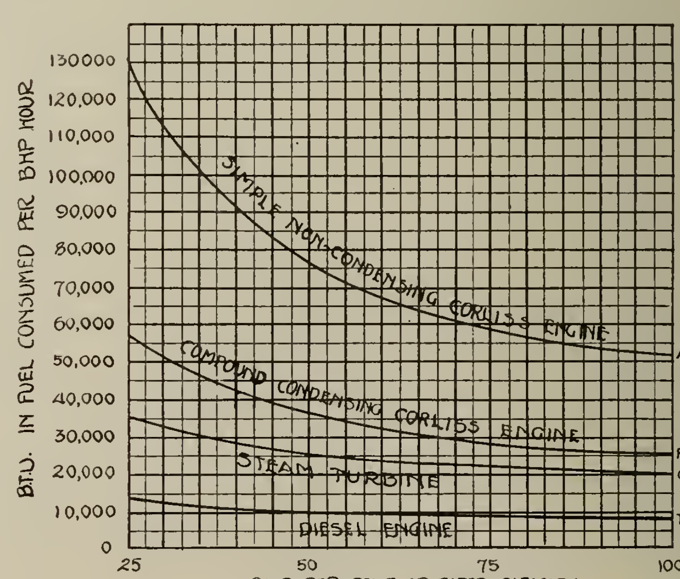

Figure No. 2—Average Consumption of Heat Units (neglecting stand-by losses.)

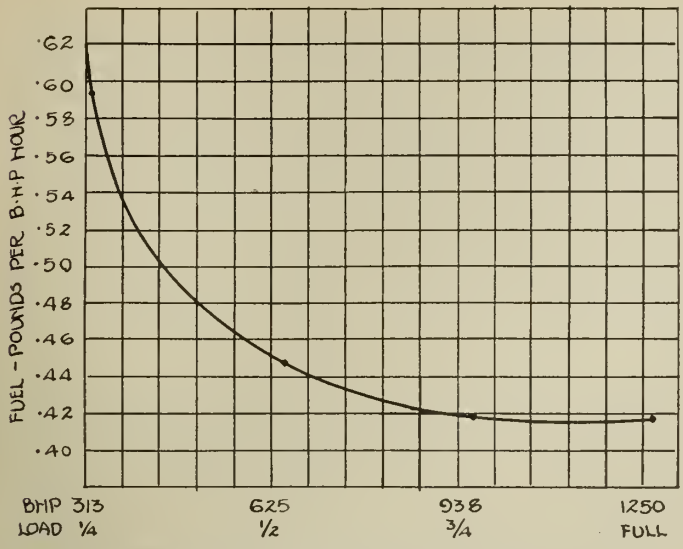

Figure No. 3—Curve showing Fuel Consumption— 1,250 B.H.P., 2-Cycle Marine Diesel.

The Diesel Electric Locomotive

In view of the recent activity of the Canadian National Railways with the Diesel electric locomotive, this function of the oil engine is particularly interesting at this time. The application of the oil engine to locomotive design is one of the few fields where, despite the promising scope, very little progress has been made so far, particularly in America. In Sweden, however, this type of locomotive has been used since 1913, and in 1923 there were twenty units up to 250 b.h.p. in service there. At that time it was calculated that, in proportion, the United States should have five hundred and sixty in service. British firms are devoting much time and money to experimental work. The starting torque embraces the crux of the matter for a successful and practical solution, and it has been suggested that a combination of oil and steam plant would further matters.

In the Canadian National Railways Diesel cars the difficulties of starting torque have been overcome by means of a Diesel engine electric drive. Two types of car are in use at the present time, one type a single car 60 feet long; the other type, called the " articulated type," consisting of two bodies on three trucks and 102 feet long. The engines used on these cars were manufactured by William Beardmore and Company, Ltd., of Glasgow. They conform to a modified Diesel cycle of the solid injection of four-stroke cycle type, and are arranged with four cylinders in line for the small unit, and eight in line for the large unit, and develop 185 b.h.p. at 700 r.p.m. in the small unit, and 340 b.h.p. at 650 r.p.m. in the large unit, with engine weights of 2,750 lbs. and 5,450 lbs. respectively.

One of the special features of this engine is its very low weight per horse power, which has been obtained entirely by a scientific use of materials. The thickness of the materials has been reduced to a minimum consistent with the required strength, using high tensile steels and special alloys throughout. The crank case is cast steel; the cylinder liners, forged steel; cylinder heads, cast aluminum; valve seats, alloy steel; pistons, forged aluminum; crank shaft, special forged alloy steel; sump cover, sheet steel; connecting rods, special forged steel. The aluminum pistons are fitted with six cast iron rings and one oil scraper ring. The exhaust from each cylinder enters a manifold on the side of the engine from which one exhaust pipe for every four cylinders is carried vertically up through the roof.

A centrifugal-type governor, driven off the crank shaft, is coupled to the fuel pump controls and so arranged as to increase or decrease the oil supply to the fuel distributing system. It is fitted with an emergency device to cut the fuel pumps out of action should the speed of the engine, for any reason, increase above that for which it is designed.

The electrical equipment on the two cars is quite different, and will, therefore, be described separately. That on the articulated car consists mainly of a 200-k.w., 600-volt, d.c., generator mounted on a common bedplate with the engine, and connected to it by a fast flexible coupling. The generator is differentially compound wound, the shunt field being excited from a 300-volt battery. The motors are railway type 548-C-8, 600-volt, 145 amperes (one hour rating), connected permanently in parallel and mounted two on each of the front and rear trucks and connected to the axles by helical gearing at a 24:65 ratio.

The engine is started by the generator driven as a motor from the 300-volt battery, this starting position being obtained from the controller by moving the operating handle contrary to its operating direction. The engine starting position is also the battery charging position when the car is standing. The 300-volt battery, by motoring the generator, brings the engine to a speed of about 200 r.p.m., at which speed it fires on the first compression, the starting current for about two seconds being a maximum of 480 down to 230 amperes at 150 volts. The battery voltage is applied to the generator through resistance steps, and at the same time the engine throttle is moved by an electrically controlled air cylinder to full fuel position.

Both cars have attained a speed on level track of approximately 60 miles per hour, and show a low fuel consumption. Both cars have sufficient power to handle a trailer over an average profile at a proportionally reduced speed.

Two world's records were broken on November 4th, 1925, when one of the new oil-electric cars of the Canadian National Railways completed a run from Montreal, Que., to Vancouver, B.C., a distance of 2,937 miles, in 67 hours. Not only was this the fastest run on record for such a distance, but it is the longest non-stop run in the history of rail transportation, as during the whole of the trip the engine of the car did not once stop running. From first to last the trip demonstrated the superiority and great possibilities of the oil-electric car, an entirely new type of transportation

Figure No. 5—Magnitude and Capacity of British Manufacturers—Marine Type Diesels.

Note:—Low-pressure engines include all types using no higher compression pressures than 150 lbs. per sq. inch.

Medium-pressure engines—all types using compression pressures from 150 lbs. to 300 lbs. per sq. inch.

High-pressure engines—all types using a higher compression pressure than 300 lbs. per sq. inch.

evolved by the motive power engineers of the Canadian National Railways to solve branch line problems and to meet bus line competition. Arranged primarily as an endurance test for the engine, not only did the run prove this point but it also showed the speed possibilities of the car over long distances which had not previously been proved. At one point in western Canada the car covered twenty-two miles in less than 22 minutes and one of the steepest grades in the Rocky Mountains was climbed at an average speed of 40 miles per hour. The average speed for the entire trip was slightly under 43½ miles per hour.

The only American locomotive development of note recently is a 1,000-h.p. Diesel locomotive which was built this year by the Baldwin Locomotive Works.

The Diesel Engine in Marine Service

The Diesel oil engine has shown to best advantage in marine service. As a result rapid progress has been made, and manufacturers, having realized the scope for the oil engine as the main propelling agent of a vessel, at once set to work and so developed a plant meeting the varied requirements of the mercantile marine. The screw propeller operates most efficiently at speeds of from 100 to 120 r.p.m., and for this reason a direct-connected oil engine is eminently suitable. One of the difficulties in connection with turbine engines for ships is that the turbine runs most efficiently at high speeds and, therefore, for direct connection a compromise has to be made between the efficient turbine speed and the efficient propeller speed.

It has been stated, on good authority, that oil fuel in the dearest ports for Diesel engines compares favourably with coal fuel in the cheapest ports for steam engines. Again, Diesel engine ships which have shown a speed of 13½ knots on trial runs have maintained higher average speeds on actual voyages than steam ships showing 15 knots on their trial runs. The higher average speed in the case of the oil engine being accounted for by the fact that there are no fires to clean. It is interesting to note the flexibility of these marine engines for the purpose of manoeuvring. Engines of 2,000 h.p. running at full speed ahead can be reversed in seven seconds. The saving in space and tonnage is demonstrated by the statement that in a 12,000-h.p. ship the weight of machinery and fuel for a twenty-day voyage, when equipped with an oil engine, is 2,840 tons, and for a coal-fired steam engine is 6,180 tons. Statistics published in June of this year show that 50 per cent of the horse power of ships under construction is represented by Diesel engines. It is also interesting that to date 50 per cent of the marine oil engines in use are of the four-cycle type.

Various Uses on Land

Diesel engines are serving under a great variety of conditions on land. They are used extensively in electrical power stations, not only on single generators, but also on machines in parallel, which requires a very fine degree of governing. They are also used in districts remote from the central station to build up load until such time as it becomes profitable to extend the transmission lines. Later they can be moved into another new district, or tied in with the extended lines from the main station. In some cases it is profitable to install a Diesel engine for use on "peak load" only.

A case of this kind is now being worked out for the Public Utilities Commission of the city of London, Ontario. The Public Utilities Department is purchasing power at $25.00 per h.p. per annum on a "peak load" basis, and supplying the city with light and power, and also supplying power for street railway and waterworks. By the installation of a 1,500 h.p. engine developing 1,000 k.w. it has been found, from examination of the load charts, that it is only necessary to operate 200 hours per year to reduce the "peak load" by 1,000 k.w. or 1,330 h.p. This would mean a net saving on the bill for the bulk power purchased of $33,000 per annum. It has been assumed that as the human element would enter materially into the operation of such a stand-by engine, that it would only be safe to

Figure No. 6—Magnitude and Capacity of British Manufacturers—Stationary Type Diesels.

figure a saving of half the above amount, or say $16,500. The cost of operating the engine for 200 hours a year, taking the operation costs at 1.35 cent per k.w.hr., would be only $2,700. Deducting this amount from $16,500 leaves an amount of $13,800, which is sufficient to pay the interest and depreciation charges on an investment of $150,000. The result of such an installation would be that the public utilities of this city, such as waterworks, street railway or street lighting, would be afforded a stand-by to the hydro-electric system at no additional cost.

For street railway service with heavy, variable loads and long hours, the Diesel engine is particularly suited, as the full benefit is obtained of the high fuel economy at light as well as heavy load.

Many oil engines are used to drive, by gears, a high pressure plunger pump on pipe line service. It is a very strong recommendation of the reliability of Diesel engines that so many of them have been chosen for this service where reliability is so essential. Two 1,500-b.h.p. engines are direct-connected to large fans used for ventilating the longest railway tunnel in North America. When no traffic is passing and the tunnel has been cleared of smoke, the fans are shut down, but it is very necessary that the fans can be put in service at any time at full power in a very few minutes. The Diesel engine is especially well suited for this work. A buzzer in the station signals when a train comes into the block at either end of the tunnel, and by the time the train reaches the tunnel, the engine-driven fans are in operation at full power. It is apparent that in such service there will be considerable periods between trains, when the fans will be shut down, and the fact that Diesel engines use no fuel whatever while not in operation was one of the important reasons for choosing this type of engine.

Diesel engines are often employed in cement mills. The making of cement is a continuous process and requires operation of the power plant continuously at practically full load. In this service the savings made by the oil engine, due to its superior fuel economy at this high load factor, are so pronounced as to seriously challenge any other kind of power.

The fact that the Diesel engine eliminates the usual boiler room with its accompanying soot and smoke, makes it a desirable prime mover for use in flour mills, both from the viewpoint of cleanliness and saving in space.

For an ice plant the compressors require a great deal of power continuously, and an interesting thing about such a plant is that it was in seeking to produce more efficiently the large amounts of power required for this service, that Dr. Diesel originated the principles on which the Diesel engine works.

The comparatively small space requirements of Diesel engines make it a desirable engine to drive a low lift centrifugal pump in an irrigating plant. As the suction lift of a centrifugal pump is limited, the whole unit in some cases has to be placed in a well and this engine allows the well to be of moderate size. These plants are often in out-of-the-way places, and the fact that the fuel transportation problem is simplified is important.

Among the other locations where the Diesel engine is working to advantage is the cotton seed oil mill, sugar plantation and mill, the quarry and the mine.

The Development of the Outside Plant of the Bell Telephone Company of Canada

Historical Facts, with a Review of the Development, Field Engineering, Construction and Maintenance

W. H. Winter,

Assistant to General Manager, Bell Telephone Company of Canada, Montreal, Que.

Paper read before the Montreal Branch of the Engineering Institute of Canada, February 25th, 1926

As a matter of historical interest, a reference in regard to the invention of the telephone may not be out of place.

We, as Canadians, are proud that a great deal of the constructive work leading up to the invention of the telephone was carried out in Canada prior to the result on March 10th, 1876, at Boston, when the first connected sentence was transmitted, thus enabling Professor Bell to file his patent papers. That Canada should be always linked with any statements made in regard to the invention of the telephone, is borne out by Professor Bell's father, who, in an address to a Canadian audience on the telephone in 1878, the original manuscript of which is in existence, said:—

> "It will not lessen your interest in the telephone to be informed that the birthplace of the invention is Canada. It was here that the theory of the instrument was explained and it was here that the first constructive experiments were made—the first public introduction of the completed telephone was made in the United States."

The statement made in 1878 was corroborated by the inventor, Professor Alexander Graham Bell, who, in his address at the unveiling of the Telephone Memorial at Brantford, Ont., in October, 1917, made the statement, "The telephone was conceived in Brantford, although born in the United States."

The first outside telephone plant in Canada was undoubtedly the wire erected on a fence from Professor Alexander Graham Bell's residence to the residence of a Mr. Henderson nearby, at Brantford, Ontario, in the summer of 1876 and used for constructive experiments in the transmission of speech.

Development of Outside Plant

Broadly speaking, "outside plant" as referred to in this paper comprises all structures, apparatus and appurtenances required to connect the central office with the subscribers' stations and to connect the various central offices with each other.

The outside plant is broadly divided into two main classifications, toll and exchange. Toll plant may be defined as that portion which is used for toll service, *i.e.*, service which carries a charge in addition to that covered by the contract for local service. Exchange plant consists of all plant used principally for exchange or local service.

A limited development of outside telephone plant took place between 1877 and 1880. In 1880, The Bell Telephone Company was organized and absorbed a number of small exchanges operating at various points in Ontario and Quebec. In subsequent years the company operated exchanges in the Maritime and Prairie provinces for a time;

now their field of operation is confined to the provinces of Ontario and Quebec. At the time of the organization of the company, and for a number of years later, there were no written methods or specifications for the construction of outside telephone plant. The only people who had experience in construction of wire lines were those who had been employed in the telegraph service, and it, therefore, naturally followed that the telephone outside plant was modelled after the ideals followed by the telegraph companies.

With the rapid increase in the use of the telephone, necessitating many wires, modifications of the telegraph practice had to be developed, such as increasing the size and capacity of crossarms to 8 wires, then to 10 wires. With the increasing demands for telephone service, it became very difficult to carry the large number of wires. Galvanized iron wire No. 12, New British Standard gauge, had been adopted as a suitable conductor for telephone service, and is still largely used for short lines where open wires can be maintained and other conditions are suitable.

With the ever-increasing number of wires, the number of crossarms on the poles necessitated very long poles, many being over 50 feet in height. To provide greater capacity per arm, insulators were attached under the crossarms which allowed the carrying of 16 wires on an eight-pin crossarm and 20 wires on a ten-pin crossarm. Iron wire, in addition to having a comparatively short life in cities on account of smoke and gas, was also found to be too heavy for the crossarms, which were at this time attached to the poles by 2 or 3 spikes. No. 16 steel was used extensively to reduce the weight, but as its life was unsatisfactory, No. 17 bronze wire was used in cities and gave excellent service. All lines were single with earth return. Where the lines were of short length and in open wire the crosstalk, though objectionable, was not serious, but as the number and length of lines increased, crosstalk also increased.

Difficulties arose as to supports for the wires, more particularly near the central offices, as many pole lines were now carrying from 10 to 18 arms, with 10 to 20 wires per arm, and in many sections of the cities roofs of buildings were used on which large frames were placed as supports, as poles could not be placed, particularly in narrow streets, such as in the business sections of Montreal. The solution of this problem was realized to be in the use of cable, but as the manufacturing of cable was in its infancy, it was difficult to obtain and this only in comparatively short lengths.

Among the first cables used in Canada were those made by The Bell Telephone Company, and were composed of No. 18 annunciator wire, wrapped together by hand and then drawn through an ordinary lead water pipe. It is needless to say that this type of cable did not improve the crosstalk situation.

Up to the time when the twin or twisted pair conductor cable was developed there were placed on the market by foreign manufacturers various types of cables with different so-called induction and anti-crosstalk killers; a favourite was tinfoil, spiralled outside of the jute or cotton insulation around each conductor. Someone had the theory that the voice would follow a spiral, but the induction would get whipped off by following the spiral. In some cases such cables were augmented by a large-sized bare conductor in the centre of the cable, which when grounded was supposed to overcome crosstalk.

During this period of development the cable terminal apparatus largely consisted of a plain wooden box with binding posts, consisting of wood screws or washers, brass binding posts, with a wooden screw, then wooden terminals and later iron terminals in which cable was ended and the terminal filled with hot paraffine. Protectors were gradually developed, the first in use followed the telegraph practice made up of saw tooth plates on line and ground.

With the installation of electric lighting, a serious noise problem developed on the telephone lines. Many telephones were practically useless during the time the electric light plant was in operation. Fortunately the lighting systems for some time were only operated at night.

The scheme of using a common return ground was developed and used extensively. This return consisted of a W.P. covered copper wire ranging from No. 9 to No. 4 B. & S., according to the number of telephone lines. This return was carried on a bracket with an insulator, and generally located as near as possible to the centre of the mass of telephone lines.

Each telephone was connected to the common return, the earth connection removed at the subscribers' station, and the return was connected to the ground at the central office.

This system gave considerable trouble, but was more or less satisfactory until the electrification of street railways. In Montreal this change in railway operation took place some time about 1892, after which there was no alternative but to convert all telephone lines to full metallic operation.

The first underground conduit system in Canada was installed in Toronto in 1889, when 63,360 feet of duct was laid, and which has now grown in that city to 4,695,504 feet. The construction of a conduit system in Montreal followed in 1890, and was laid on St. Catherine street, from Mountain to Bleury streets, and consisted of 75,191 duct feet; the system now has 4,817,736 duct feet. The first duct used was creosoted wood, and is still in use and apparently in as good condition as when laid. Vitrified clay duct has been almost exclusively used by The Bell Telephone Company of Canada, whose underground system in Ontario and Quebec, the territory in which it operates, now contains 3,042 miles of duct in 703 miles of subway.

The cables available for placing in the first underground ducts constructed in 1889 and 1890 were lead covered 50 wire No. 19 B. & S. gauge with cotton insulation boiled in paraffine.

During the subsequent years, continued development of cable was carried on by the American Bell Telephone Company and the Western Electric Company, and during this period dry core paper insulation was developed.

Step by step, gradually and steadily, the No. 22 and No. 24 B. & S. gauge cable development has progressed, and, as a result, cables with 400 pairs, 600 pairs and 900 pairs were successively designed, and to-day it is now possible to place in a single lead sheath, 2⅝ inches in diameter, as many as 1,200 separately insulated metallic circuits.

In 1902 the first telephone cable was manufactured in Canada by The Wire and Cable Company (now The Northern Electric Company), the largest size at that time was 100 pair and at the present day 1,200 pair.

There was a real demand for development in cables to carry more conductors. The first conduit system was built for cables carrying 50 lines, and estimates for growth were based on that capacity per duct, later on a duct capacity of 100 lines, then for a duct capacity of 400 lines.

During this period we built for the future better than we knew, as the development of cables with a larger number of conductors and approximately the same size of sheath has provided the possibility of replacing in an existing duct system the cables having a small number of wires by cables having a much greater number of wires, which has offered opportune solutions to many critical demands for more wire facilities without reopening the streets to add ducts.

To-day The Bell Telephone Company of Canada has 1,530 miles of cable in its exchange underground system, in which there are 1,115,093 miles of wire. Of this amount, Montreal has 481 miles of cable, containing 344,187 miles of wire, and Toronto has 505 miles of cable containing 425,409 miles of wire.

With the development of stranded steel messenger wire, cable clips and brackets, together with cable terminals to keep pace with the increasing size of cables, aerial units of cable up to 400 and 600 pairs can be economically erected and maintained. Types of terminals with distribution facilities, combined with splicing design of the underground cables, has increased the flexibility in use of the conductors, thus deferring at many points the necessity of constructing an expensive underground conduit system.

To-day The Bell Telephone Company has 3,260 miles of cable in its exchange aerial system, of which there are 424 miles in Montreal and 708 miles in Toronto.

The Bell Telephone Company of Canada use northern cedar poles exclusively, which are more or less plentiful in its territory. The company has 840,221 poles in its exchange and long distance system. From a survey, the supply of cedar timber within reasonable shipping distance will no doubt equal their demand for some years for the class of pole now largely used. The annual requirements heretofore for the class of poles used will not materially increase, although the system will continue to expand, for the following reasons:—

With the increased use of aerial cable, the average size of pole for telephone purposes has been considerably reduced; the trend for conservation of poles by public utility companies entering into agreements for joint use means the use of one pole in place of two, and also the efforts now being made to prolong the life of poles by butt treatment of those already in service and those to be placed in use will in time effect the requirements for annual replacements. As the source of the cedar supply becomes more distant, requiring higher freight rates, with the possible difficulty to obtain, the use of other classes of treated timber with a much longer estimated life, such as jack pine, particularly for lines in the country, will no doubt extensively replace the use of cedar in the future.

The close association and working agreement with The American Telephone and Telegraph Company gives The Bell Telephone Company the advantage of the extensive study and tests of materials by that company, and from the information obtained specifications and standards have been adopted for material and supplies required to make up the various component parts of the outside plant. The specifications and standards required by the various Canadian companies using pole line hardware unfortunately lacks uniformity, therefore the consumers do not obtain the advantage of mass production by the manufacturers. It is hoped that the work of the Canadian Engineering Standards Association, who have already issued standard specifications for galvanized wire for telegraph and telephone, steel wire strand, poles, etc., will be extended to include items of pole line hardware which will be satisfactory for all users.

Complete and comprehensive engineering specifications are now in the field covering the various standard requirements for construction, embracing the following:—Pole lines, aerial wire, guying, aerial cable, drop wires, cable terminals, block wires and cables, underground conduit, underground cable placing and cable splicing.

The specifications provide for various classes of construction suitable for the particular requirements of the service in any locality, that is to say, the standard to be used is controlled by the type and size of the units to be constructed immediately, as also the units and time of future or ultimate requirements. In the telephone industry the obligation is to be prepared to give service as required and deliver it when and as it is required. Furthermore, regardless of the remoteness of the territory or of the physical and climatic conditions involved, that a way be found as far as practicable to construct and maintain the plant and safeguard the service to the public.

To meet these exacting requirements calls for ingenuity and foresight in the design of the plant, and involves careful study of various plans for plant extensions and rearrangements with a view to the solution of the most economical and desirable plan.

Estimates of Future Requirements

It was early recognized that one of the most important engineering problems of The Bell Telephone Company was the formulation of estimates of expected future telephone business, both as to quantity and expected location, and the development from these estimates of basic plans of procedure, which plans must, of course, be flexible and capable of modification from time to time as changing conditions show them to be advisable.

The first step in determining the estimated future telephone requirements is to prepare a " commercial survey " covering the requirements 15 to 20 years ahead. These studies include an analysis of the existing market for telephone service, facts as to the present sale of telephone service, of classes of service and users and forecasts of the market for service at future date or dates. Consideration is also given to the growth and distribution of populations and assumptions of the amount of business that must be sold in each area on the future dates selected under assumed rate conditions. Having thus determined from the " commercial survey," the requirements for various parts of a city at the future date assumed, the next essential to develop is a comprehensive plan to serve as a basis for the layout of the plant to meet these requirements.

A so-called " fundamental plan " is made for the community covering the conditions as estimated 15 to 20 years hence. The importance of such a plan is obvious.

In laying out a plan for a city, the engineer might, as an extreme case, centre all the subscribers' lines at one building, which would give high efficiency in operation in some respects, as the switchboards would be grouped together, but outside plant costs would be abnormal and other disadvantages would be experienced. As the other extreme, the engineer might place many buildings throughout the city, thus placing the outside plant costs at a minimum, but increasing the difficulty and expense of operating so many centres.

Obviously there is some arrangement between the two extremes cited which would provide an economical and satisfactory layout of the plant. Therefore, several test plans must be set up, and those which in the judgment of the engineer seem promising are therefore studied and the most economical and satisfactory plan determined upon. In completed form, the " fundamental plans " furnish us with the following essential information upon which to proceed with the more detailed studies covering plant extensions:—

(a) The number of central office districts which will be required to provide the telephone service most economically and their boundaries.
(b) The number of subscribers' lines to be served by each central office.
(c) The proper location for the central office in each district to give service economically with regard to cost of outside plant, land, buildings and the economical number of switchboard units in each building.
(d) The proper streets in which to build underground conduit in order to result in a consistent and economical distributing system reaching every block to be served by underground cable.
(e) The most economical number of ducts to provide in each conduit run as it is built.

Experience has shown that fundamental plans reduce guesswork to a minimum by utilizing the experience of years in studying expected telephone growth in order to make careful forecasts. The fundamental plans, together with related studies, provide a general programme of plant extension to be followed throughout the period for each of our cities. Both the ultimate plan and programme must have flexibility to meet unforeseen requirements and must work in satisfactorily with the existing plant, meet immediate service requirements and permit advantage being taken of new developments in the telephone art.

Owing to the complexity of the problem of suitable advance planning for growth in the telephone plant, study and selection must generally be made between a choice of arrangements. It is usually necessary, therefore, that two or more practical plans or programmes for construction be prepared so that the most advantageous plan may be selected.

An important factor in the selection is a study of the relative economies of the different plans, that is to say, a comparative cost study. The cost study requires analysis and consideration of the cost and resulting annual charges for different amounts and types of plant, and also losses on plant removed included under each plan. This is important in assisting to reach a decision as to the most desirable plan, but requires, in addition to all the definite facts that can be brought to bear on the question, the exercise of sound judgment and experience in weighing the results of the study with all related factors bearing on the problem. Factors in these studies are often of a character which do not permit of expression as a direct charge against a given plan, but must be considered on a broader basis, such as the difference in quality or dependability of the service. Finally, throughout all the work of preparing fundamental plans and a construction programme, the fact to be kept foremost in mind is that the telephone system exists for the purpose of furnishing service to the public, and the results of the effort should insure a service which is satisfactory from the subscribers' viewpoint.

Development and Construction

The commercial survey, fundamental plan and construction programme having been developed by the general commercial and engineering departments covering a relatively long period picture of the situation, it then follows for the division plant engineer to keep in close touch with the growth of telephone lines and with all major building operations and developments of or changes in the character of the various areas of the city and undertake the preparation of construction plans as required, so as to keep at all times sufficient outside plant facilities to meet the demands of the public for service.

The specific or detailed plan for each major project of plant extension must be started early enough so that adequate time is allowed for completion of the construction work before the new facilities are required. The complete interval between starting on such a project and getting it into service can seldom be less than a year.

In the early days of the telephone business, when the plant consisted chiefly of a combination of aerial wires and poles, the problems were comparatively simple and there was no great need for pre-arranged plans and intensive engineering study. The rapidly growing complexity of the situation is, however, constantly introducing many difficult problems which can best be met, and, in fact, can be satisfactorily met, only if a broad plan, giving full consideration to the future possibilities in their relation to the existing plant, is developed and adhered to.

In designing the plant, the future extensions must always be considered, as if a cable is placed to-day in a conduit or a cable placed on a pole line, its design must be such that it can be adapted to meet future changing conditions with the minimum expenditure for changes. The detailed plans, which may comprise conduit, underground and aerial cable, block cable, pole lines and open wire necessary to meet the service requirements in an orderly and economical manner, presents a real problem in the process of fitting together the piecemeal extension into a homogeneous and well-balanced plant capable of providing satisfactory service and earning a reasonable return on the investment.

It might be of interest to discuss briefly some of the problems requiring cost studies which are encountered by those engineering the outside plant. We have a plant consisting of poles, wires, cable, conduit, etc. It must be expanded in some respects to meet service requirements for the immediate future; certain portions are deteriorating to some extent and others, because of improvements and changes in the art, are becoming more or less obsolete. It is estimated that it will be necessary to spend considerable money to be able to continue to meet promptly the public demands for service. How shall this money be spent? Shall the poles carrying cable and wire be replaced by conduit and underground cable, or would it be more economical to continue over a period of years, to bring the pole lines up to satisfactory strengths and reinforce the existing aerial cables?

Of course, there are numerous features to be considered in this problem, among which would be the transmission requirements involved, the future central office locations and possible changes in class of service, all of which would have a very direct and important bearing upon the design of the plant.

A problem might be cited where a particular cost study would involve the question of placing additional aerial cable to reinforce an existing one as against replacing the existing aerial cable with one of suitable size to meet the requirements for a given period. Such a study might indicate that it would be cheaper, both in point of new money required and in the present worth of annual charges over the period, to reinforce the existing cable. In consideration of the known facts and such assumptions as were made with regard to the probable growth, etc., this answer might theoretically be the correct one. However, before making a final decision, there are many pertinent questions to be answered with regard to numerous items which are difficult to evaluate and which surround practically all studies of this nature. In problems of this kind, intimate knowledge of the plant and the picture of potential possibilities tempered by past experience and the exercise of good judgment is required to design piecemeal additions to the plant, so that they will contribute towards making for an economically sound investment.

The work of design and development of the outside plant also involves, to a large extent, relations with other wire-using companies, more particularly with electric power and electric railway companies, as important problems of safety and of service arise due to the proximity between their electric circuits and the telephone circuits. These problems involve provision not only for the protection of the plant and employees against the danger of contact with the wires of other companies, but also include co-ordination of the two systems to prevent excessive inductive effects which often become important where electric power lines or electric railways and telephone lines run parallel to each other.

The electric companies and the telephone company often find it advantageous to enter into arrangements for the joint use of pole lines, which in general has, by long years of experience, been found to possess advantages and economies of great benefit to the wire-using utilities. If the principles and practices which have been developed to cover joint use of poles are adhered to, there is every reason to believe that safety, good service and economy will be insured and that the most efficient and economical use will be made of the poles required for distribution service in the plants of the power and telephone company.

Another problem in the design and development of the outside plant is the desire of municipalities to have the streets cleared of poles and wires. The Bell Telephone Company has always been sympathetic, and in the study and design of plant extensions this feature among the many discussed, is taken into serious consideration.

The company's relations with the municipal corporations of the various cities and towns of Quebec and Ontario bear out that every endeavour, when economically possible to do so, has been made to improve the appearance of the streets.

In the foregoing, some of the major considerations affecting the design of the exchange outside plant have been referred to, which also, to a more or less extent, applies to the design of the outside toll or long distance plant.

In 1925, The Bell Telephone Company of Canada spent $5,356,240 on outside plant, with estimated expenditures for the years 1926-1930 of $27,723,000, or an average of $5,544,000 per annum. The average of the two large cities, Toronto and Montreal, is about $1,000,000 each. Obviously, with a programme of this magnitude and of such diversity in the character of its related units, careful advance planning and careful designing is necessary to insure economical and satisfactory development and performance.

In the cable distribution plan it is important that the arrangement of the pairs of conductors at the several terminals be so ordered that the distribution may be as flexible as possible. Access to each wire in every cable is made possible by terminating the wires separately on the main distributing frame in the central office, from which point the cable is extended in the underground as a main cable, portions of which are then bridged for distribution as required. Provision is made for connection between the underground cable from the central office and the aerial cable, by means of a protecting lateral pipe from the manhole to the pole in which the cable is carried to a cross connecting terminal, containing fuse post chambers for the underground cable conductor termination and binding post chambers for the aerial cable conductors. This terminal provides electrical protection for the cable and central office equipment. The cross connecting feature between the underground and aerial conductors also makes for a high degree of flexibility. The plan for the main underground cable having provided for bridging at various points with pairs of wires multiplied at two or more underground and aerial junction terminals, a similar plan of multiplying conductors in two or more aerial cable terminals is also provided for, all of which gives flexibility and greater use of the cable plant. This is important, as even in the best designed telephone cable plants there is always a large percentage of copper conductors which cannot be used.

The cabling of the average city block may not appear to present features involving any great amount of study on the part of the engineer, yet it is rarely the case that requirements for any two blocks are sufficiently alike to apply the same plant layout. Generally speaking, each block must be given careful and individual engineering consideration in order that cable may be provided and the necessary terminals, etc., located as to care economically and properly for present and future developments.

Very closely associated with the features of design are those involving construction of the plant. To accomplish the best results, the design must be engineered to meet the limitations of current construction practice and methods and according to the various standard specifications which have already been mentioned.

Beyond the telephone instrument on the subscriber's premises, a very complex and extensive telephone plant is necessary with which the public in general are unfamiliar, and it is the construction of the outside portion of this plant which will now be briefly described.

From the protector placed in the subscriber's premises, except where cable is carried direct to a terminal inside a building, such as an office or apartment building, connection is made by what is known as a " drop wire " made up of twisted pair rubber insulated conductors to a cable terminal, or direct to open wire on the pole where open wire rather than cable is maintained as the feeder.

" Drop wire " connection with the cable plant is made by means of a distributing terminal mounted on the pole at a convenient location.

In closely built-up sections, both residence and business, where there would be a considerable number of wires involved, a block cable is often installed on the building walls and terminals placed at frequent intervals care for the distribution. In this type of construction, the cable is secured to the walls of the buildings by clamps. " Block wires," which are similar to drop wires, are used for entering the premises.

In aerial cable construction the placing of the steel supporting strand preparatory to installation of the aerial cable is a problem of considerable importance. For determining the proper tension in supporting strand, an ingenious method based upon the theory of the oscillating pendulum has been devised. This method for practical application has been reduced to a simple direct reading table from which the tensions under varying conditions of cable load can be predicted. It is important that the tension in the strand before placing the cable be predetermined, so that when the cable is in place the final tension in the strand and the sag of the cable will be within the allowable limits of safe construction. After the strand has been erected a lineman rides it and places the rings at proper intervals to support the cable. As the rings are placed a drag line is drawn through them to which, upon completion of a section, a pulling-in line is attached and drawn into the rings for use in connection with the actual installation of the cable.

The cable, having been made fast to the pulling-in line, is pulled through the rings usually by a winch-equipped truck which under ordinary conditions operates at about 200 feet of cable per minute.

The aerial cable when unnecessary to provide for local distribution can be placed in sections ranging from 600 to 1,500 feet, depending upon the size of the cable. It is then spliced and connected into the underground cross connecting terminal and to the various distributing terminals already mentioned. In placing underground cable in conduit the operation is quite simliar to that previously outlined for aerial cable, except that the speed of installation is considerably reduced. Underground cable is generally pulled in at a rate of not over 90 feet per minute, the speed largely depending upon the size of the cable, condition of the duct, number of bends in the run, length of section, etc.

The splicing of cables presents quite a complicated operation, as a very large number of joints have to be made and separately insulated by cotton sleeving in an extremely restricted space. For example, in a straight splice of a twelve hundred pair cable, twenty-four hundred joints are encased in a lead sleeve 4½ inches in diameter and 20 inches long. In addition, bridged splices of varying sizes are necessary for distribution purposes, also splices for connecting loading coils, which adds considerably to the complicated operation.

Under favourable conditions a maximum of 150 pairs of conductors per hour can be spliced. Each conductor splice is made by hand. Cable splices are boiled out with hot paraffine at intervals during the operation, and also when the splice is completed, after which the lead sleeve is drawn over the splice and the joints wiped.

In the larger central offices a cable vault is usually provided in the basement of the building into which the cables are extended from the nearest manhole. From the vault the cables are extended to the main distributing frame. In those cases where the main frame is located on the floor directly above the cable vault, lead covered silk and cotton insulated cables connect with the paper insulated cables in the vault and are extended to the main frame and terminated thereon. Where the main frame is not so well situated the paper cables are extended through conduits and connected at some convenient point with silk and cotton insulated cable for the termination at the main frame, on which access to each wire in every cable entering the office is made possible. The main distributing frames vary in capacity per terminating strip from 200 to 400 pairs. Where 300- or 400-pair frames are used a mezzanine floor is generally provided in order that it will be possible to reach any pair without the use of a ladder. The individual cables in such cases are terminated either all above or all below the mezzanine, in order that any pair of a cable will be available from that point.

There is another interesting phase of the telephone development: the outside plant of the toll or long distance system of the company.

In 1880, when The Bell Telephone Company of Canada was organized, there were only two places, Hamilton and Dundas, connected by telephone. In 1881 the development of the long distance system was initiated by the construction of lines between Hamilton and Toronto, Windsor and Amherstburg, Montreal and Lachine and a submarine cable connecting Windsor with Detroit, amounting to 70 miles of poles and wire. The system now consists of 122,326 miles of wire and 9,590 miles of poles.

In the early days of long distance communication, with only the tradition of the telegraph to emulate, the ground return iron wire circuit was used, but what worked well for telegraph was soon found to work poorly for the telephone on account of interference from telegraph and earth currents. It was also found that when more than one circuit was required that it was impossible to use them simultaneously. It was recognized that induction was the source of these troubles. It is strange, as we see it now, that the ground return was used, but the telegraph influence was strong. It took considerable courage to try the metallic circuit, and the successful solution of which it gave promise had to wait for the development of hard-drawn copper wire. Iron wires could support themselves on pole lines, but with them the metallic circuit still had limitations. With the coming of hard-drawn copper wire, the metallic circuit came into its own. There were still problems of crosstalk from neighbouring circuits, which was overcome by the use of wire transpositions. Crosstalk and other extraneous influences have always offered serious problems, and the success of a telephone circuit is not assured until these are solved.

Prior to and for some time after the above refinements were made in the telephone line the ground return iron wire circuit rendered fair service in a number of towns. With the early difficulties of the telephone circuit fairly well solved, lines were built here and there with ever-increasing public demand for more facilities and greater distance. These increasing demands presented important problems; more wires had to be provided and distance had to be increased. Furthermore the existing wire facilities had to be used more effectively.

The Phantom Circuit, Loading and Quadded Toll Cable

The problem of more communication channels without more wires brought about the development of the " phantom " circuit. The " phantoming " of circuits calls for one pair of wires to be used jointly as one wire together with another pair of wires used jointly as the other wire to form a third circuit and so three telephone conversations are carried by four wires. Where this system is applied to open wires, special transposition plans must be carried out in addition to the regular physical wire transpositions.

A considerable stride in increasing distance talking was brought about by the development of the " loading " coil for telephone circuits. By applying these coils to cable conductors and open wire lines of moderate size, transmission efficiencies even higher than those attained with large conductors could be secured and the heavy expenditure for large copper wires avoided.

The increasing use of long distance service between important points and the problem to provide for future growth with open wires has been met by the development of quadded toll cable. The toll cable development based on the use of repeaters, loading coils and many other technical improvements now make it possible to give satisfactory service for long distances over toll cable circuits of such small gauge conductors that about 300 circuits can be included in a sheath 2⅝ inches in diameter. The same number of circuits would require four or five heavily built pole lines of open wire.

This company placed in service its first long toll cable extending from Toronto to Hamilton, 40 miles, in 1924. The cable is carried underground at the Toronto and Hamilton ends and on poles for the balance of the distance and replaces three heavy pole lines of open wires. It may be of interest to state that in the designing of this toll cable provision has been made for the extension of a toll cable west and south of Hamilton at the time when the open wire facilities will have to be supplemented or replaced by cable.

Maintenance

Having followed the development and construction of the outside plant through various stages, perhaps a few words regarding maintenance would be of interest.

Maintenance may be divided into two main classes, corrective and preventative. The average unit of plant, regardless of how well it may have been designed and installed, is subject to wear damage or may develop defects during its period of usefulness. These defects, while they may not in themselves either seriously impair or affect the service life of the plant, will, if allowed to accumulate, result in a gradual lowering of the quality of the service and will in general tend to shorten the service life of the plant.

One of the very important elements in the giving of good service is to insure that the proper grade of transmission is maintained, first in the toll plant, and second in the exchange plant which also serves as the terminal for toll connections.

A high grade of maintenance is required on the outside plant to meet the demands for operation of the complex apparatus and equipment now used on telephone lines. Testing apparatus, routines, practices and records have been developed for periodic tests so that corrective or preventative measures may be applied which will give assurance that all the features which go to provide good telephone transmission are being maintained. Furthermore, testing equipment, records and efficient methods for quickly and accurately locating the various troubles to which a telephone plant is subject has been developed to a very high degree.

A few years ago if a break in a long distance circuit was located by the tester within a mile or so of where it actually was it would be considered good work. To-day with the modern toll test board equipment, a large percentage of interruptions are located by the tester within a few hundred feet. With the development of cable testing equipment at a central locating bureau in multi-office exchanges, efficient methods have been developed of quickly locating cable troubles. The bureau is connected by circuits extending to the various central offices within the bureau's operation and equipped with records of the cable plant, thus enabling the results of loop tests to be readily associated with the cable maps and diagrams to show the location of the troubles with respect to poles or manholes. Upon completion of the location, particulars are referred to the cable department and repairs are immediately undertaken. In this way cable troubles are cleared with a minimum of expense and so quickly after detection that a complete failure of a cable is unusual.

This paper gives some historical facts of the manner in which the outside plant has been developed. Also in a sketchy manner the various field engineering steps for present and future requirements, and the construction and maintenance of the outside plant.

In closing, it might be added that it is a tradition and has been the policy of The Bell Telephone Company from the beginning to have the best apparatus and methods for giving service and at the same time study, constantly, how to improve the service and to meet the telephone needs of the public and develop new means and methods for meeting the requirements. This policy has brought about a development, beginning with a few small isolated telephone exchanges with 2,100 stations in 1880, to an up-to-date telephone system second to none of 592,000 exchange stations and long distance facilities to interconnect with 17,000,000 telephones throughout Canada and the United States, an achievement of which any builder may be justly proud.

Influence of Personnel on Industry

The Necessity of Studying the Personnel in Industry and Possibility of Creating Better Relationship between Employer and Employee

R. A. C. Henry, M.E.I.C.

Director, Bureau of Economics, Canadian National Railways, Montreal, Que.

Paper read before the Montreal Branch of The Engineering Institute of Canada, January 14th, 1926

Generally speaking, the functions of the engineer group themselves into three categories:—(1) design of works; (2) development and construction of works; and (3) maintenance and operation of works. In all these contact is had with the human element, and to this extent it is important that the engineer should appreciate the importance of and study the question of personnel.

Apart altogether from this, however, there is a growing tendency in industry to recruit executives from the ranks of the engineering profession, and no executive is properly equipped to deal with the problems involved in the operation of the modern industrial structure who has not studied carefully this very important question.

Products of Industry

In preparing a budget intended to represent the estimated results of operation in any industry, from the cost side, one encounters in ordinary every-day business the following factors:

(1) Labour;

(2) Material; and

(3) Interest upon investment, including depreciation.

The purely operating costs consist of the first two, the third being an income charge. The proportion of the total operating expenses absorbed by labour and material respectively will undoubtedly vary considerably and depend upon the character of the particular industry under consideration.

In the transportation field it will generally be found that something in excess of fifty per cent of the operating expense consists of wages paid to employees.

"The Canada Year Book" for 1924, published by the Dominion Bureau of Statistics, shows that for the year 1922 the value added to materials in process of manufacture was

$1,159,316,000, of which $497,113,000, or 43 per cent, represented salaries and wages paid.

"The Commerce Year Book," published by the United States Department of Commerce, for the year 1924, shows that the value added to materials in the process of manufacture amounted to $25,867,000,000, and that of this amount $11,000,000,000, or 43 per cent, represented wages paid.

Material

If one were going to construct a building or a bridge, one would first prepare a plan showing the general layout and dimensions of the structure, and would next prepare detailed plans, descriptions and specifications covering every detail entering into the construction of the structure. The specifications would go into great detail as to the quality, chemical and physical characteristics of the various materials which are to be used, and would also prescribe the manner in which these materials would be inspected to insure that the specifications had been lined up to; all of which demonstrates the care which is exercised in making sure that the proper combination has been obtained for the purpose desired. After the structure is completed, great care is usually exercised in its maintenance during its economic life.

This is what is done in the case of the materials used in industry, which usually represent no greater percentage of the cost of the products of manufacture than labour.

Industrialism

What has been the situation with respect to labour? Let us consider the problem somewhat in retrospect.

A century ago there occurred what is known as the "Industrial Revolution." The development of the steam engine and the numerous other inventions which have followed one another with great rapidity since that time resulted in the development of industry on an entirely new scale and wrought miraculous changes in the processes of manufacture.

Previous to this time manufacture was greatly diversified and performed principally by the artisan in his own home assisted by members of his immediate family or apprentices indentured to the artisan for the purpose of learning the trade. This method had the advantage of developing an all-round artisan capable of performing all the processes necessary, from the laying out of the patterns to the final completion of the finished product. Naturally, this resulted in close contact between the master workman and his assistants, and a realization of community of interest amongst them all.

With the industrial revolution the individualistic character of the worker changed and he was drawn into the vortex of large industrial structures. The production of the individual was multiplied many times. The labourer found himself getting a larger share of the material things and, as a natural consequence, the industrial population increased enormously.

Yet, in spite of this increase in real wealth, the attitude of the worker towards his work was rapidly changing. The old interest in his work was decreasing and there was a positive and widespread unrest among employees generally, which in many cases showed itself in an absolutely direct hostility to the employees' own industry and especially to the management of that industry. Worse than that, there was growing up among employees an idea that they belonged to a class in industry entirely different from the class to which the management belonged. Industry was rapidly becoming a house divided against itself; harmony was disappearing.

This condition of affairs was due to the fact that in this period of the rapid development of machinery and the attendant improvement in processes, the management of industry had been devoting itself exclusively to the machinery and methods. In the course of time the management of industry began to realize that, notwithstanding the great progress made in machinery and processes, something was radically wrong with the industry as a whole, and when they began an intensive study of the situation, they found that the human factor had been neglected.

It developed that the owners, or the executive officers operating on behalf of the owners, had lost contact with the people actually doing the work; that there had been built up between the executive officers and the workers a line of intermediate supervision which had failed to interpret on the one hand the executives to the general forces, and on the other hand the general forces to the executives.

It was found that instead of there being only two human factors in industry as had been generally assumed, and as actually was the case prior to the industrial revolution—namely, the owners of the industry and the working forces; this new development had interjected four human factors into the problem of modern industry—namely, the owners or stockholders, the executive, the intermediate supervisory organization, and the general working force. The realization of this fact forced the executives to the conclusion that the time had come when the human element in industry required more careful study and intelligent attention. Hence we have the personnel problem.

Personnel Problem

If this problem be examined from the standpoint of the worker, it is found that, due to the lack of that contact and intimate relationship between employee and employer which was found to exist under the new industrial structure, that the employee naturally became disturbed by certain considerations affecting his personal relations with the industry in which he was engaged.

He had before him always the fear of the loss of his job, as it became evident that in the development of the industrial structure his services were actually becoming nothing more than a commodity which he had to sell, due to the fact that he often came in contact with arbitrary executives lacking in consideration for anything but their own conception of the immediate interests of the industry. As an individual employee selling his commodity and lacking the force necessary to bargain with a strong industrial institution, he felt forced to consider the joining of his interests with those of others with similar services to dispose of.

There was also the fact that he saw around him individuals in the same industry enjoying greater remuneration. He sometimes failed to realize the difference in the intellectual requirements or the relative value of services rendered. From his point of view, these others have leisure while he himself appears to be tied to unceasing labour, is the thought foremost in his mind, and the feeling was that his personal welfare, education and recreation were left largely to be provided by fortuitous circumstances. In an attempt to improve his condition he perforce became a member of an organization in which, as an individual, he had little or no control. It appeared a case of collective action and, for his self-preservation, he found himself forced to follow the dictates of his fellow-workmen.

It is not to be wondered at that considerations such as these often produce in the minds of men, whose opportunity for education has been limited, an unhealthy and mistaken view of the social relations as well as an antagonistic attitude towards not only their employers, but to their own duties in industry and even their own real good. One must remember that man is an active animal. He is not content to be simply passive; he desires to have some say in his destiny, or what he thinks is his destiny; he is suspicious of what he does not understand; and is skeptical of efforts for his well-being in which he has no directing part. He must be convinced that a real mutuality of interest exists between himself and his employers, and that he has some say in defining that interest. There will always be a problem, no final solution is possible; it is one of the necessities of life that this should be so, otherwise there would be stagnation and ultimate dissolution.

It is necessary that in a recognition of the mutuality of interest the employee be furnished with the facts of industry and kept informed of changes in them, and educated in the fundamentals of industrial issues, otherwise he will adopt fallacies apparently supporting the claims which he makes, or which are made for him.

"Open confession is good for the soul," and particularly good for the soul of the employer and employee. Suspicion of his foreman's and employer's policies is removed by the frankness of their attitude and treatment of the employee. Pay and any additional incentives appeal to him as fair and reasonable. Provision made for prompt and adequate communication of opinions and desires on matters pertaining to his status and conditions gives him a personal interest in the conduct of affairs.

The worker reserves the right to make his own mistakes, and no attempt should be made to dictate what he shall think or do in his own economic affairs. Paternalism, however well conceived or applied, is usually a cause for ultimate discontent. Safety, health, compensation, thrift inducements, educational opportunities are all beneficial, provided they are not regarded by the employer as things for which he may expect extra effort or consideration from the employee. These things will be approved by the employee only when his immediate personal interests are given proper consideration, and these latter are often surprisingly simple compared with the sociologist's anticipations. Industrial relations should be organized with the view primarily of giving serious study to all of the conditions and obtaining effective administration for any policies which may be adopted.

Industrial personnel may be defined then as the creation of the machinery necessary to give sufficient intensive attention to the human factors in industry, to make sure that the entire human element and man power in the industry is mobilized for attaining the proper objectives of that industry.

The engineer, as pointed out in the beginning, is vitally interested in this phase of the industrial relationship, and it should be one of the professional requisites that he familiarize himself with what results have been attained in the cultivation of more intelligent and less contentious relationships between the employees and employers in different large industrial concerns. The training which the engineer obtains should produce an analytical type of mind and peculiarly adapt him for the investigation and analysis of the elements entering into this problem, and by the application of the same methods which he uses in physical engineering works, add much toward a consistent and adaptable solution of these industrial relationships.

It may be interesting to the members of the Institute to know briefly what is being done on the Canadian National Railways looking towards a more sane and reasonable relationship with its employees.

Railway Employees' Relationship Organizations

The railroad labour organizations in Canada are largely international in scope, a vice-president generally being appointed to look after Canadian affairs. The agreements with our employees are made with a committee representing the employees, not directly with any labour organization, although we know that they are members of and operate under the constitution of the various labour organizations they represent. There are two exceptions to this practice,—one being with our shop crafts employees and the other with our maintenance-of-way and structures department employees,—these two agreements being made through the Railway Association of Canada at the request of the above-named organizations in 1918, in order to obtain uniform rates and working conditions throughout Canada in line with the national agreements made in the United States after the latter country took over the operations of the railways in that country on January 1st, 1918.

The employees have their respective periodical conventions, and each elects a General Grievance Committee as well as a general chairman for a defined territory (generally covering the same territory as the railway general manager), and local chairmen for local matters. All agreements are subject to revision or cancellation on thirty days' notice, except that for the maintenance-of-way and signal department employees which provides for a sixty days' notice. The elected general chairman acts as chairman of the General Grievance Committees as well as of committees handling negotiations with respect to wages and working conditions.

When an employee feels he has been unjustly treated or that he has a grievance in connection with wages or working conditions, he may take the matter up either directly or through his local chairman up to and including the superintendent of the division; if the matter cannot be adjusted with the superintendent, the local chairman may turn over the case to his general chairman, who, if he considers there is merit in the employee's contention, will appeal the case to the general superintendent, and, if necessary, to the general manager. When it is impossible for the general manager and the general chairman to agree, then, if it is a case of interpretation of the schedule, the general manager will refer the matter to the chief of wage bureau, Montreal, for an interpretation before definitely declining to adjust the dispute. If the general manager's contention is upheld, the general manager and the general chairman write up the case,—first agreeing and writing "a joint statement of facts",—after which the employees will set out their contentions, and the railway officer does the same. The dispute is then referred to the board or committee provided for in the agreement between the railway and the respective organization.

In the case of the following organizations, the case would be referred to the Canadian Railway Board of Adjustment No. 1,—created in August 1918 for the purpose of adjusting grievances:

Brotherhood of Locomotive Engineers
Brotherhood of Locomotive Firemen and Enginemen
Order of Railway Conductors
Brotherhood of Railroad Trainmen
Order of Railroad Telegraphers
United Brotherhood Maintenance-of-Way Employees and Railroad Shop Labourers.

This board is composed of twelve members, six being representatives of labour organizations,—generally vice-presidents,—and of six railway officers, a chairman and vice-chairman being elected from among the twelve members, such position alternating every six months between a railway officer and an officer of the labour organizations. The decisions of the board are final and binding upon both parties.

This board has done excellent work; there has never been occasion to call in an arbitrator since its existence. This board is considered one of the best mediums of disposing of grievances, and is very helpful in maintaining a harmonious relationship between employees and the railways.

In the case of shop crafts' employees, the joint write-up of the general manager and general chairman is sent to the Railway Association; the secretary of the association notifies the Sub-Committee on Wages and Working Conditions, and also advises the president and secretary of division No. 4, and a meeting is arranged, through a board consisting of ten members,—five being labour organization representatives and five being railway representatives.

In either case, whether the matter is referred to the Canadian Railway Board of Adjustment No. 1 or to the Railway Association of Canada's Sub-Committee, the parties to the dispute are advised of date the dispute will be heard. Both parties appear before the board of which they are a party, and, in addition to the written statements, submit oral arguments in support of their respective contentions. The board asks of each party such questions as, in its opinion, will help to clarify the points at issue, after which the parties to the dispute retire and the Board considers the case and arrives at a decision, which is made unanimous once adopted.

On the whole, the results obtained through this procedure have been very satisfactory indeed, as evidenced by our freedom from labour troubles.

The Canadian Brotherhood of Railroad Employees, which covers clerks, freight handlers, station, stores and shop laborers, has no international affiliations, and, while there is no obligation on their part to bring their grievances before the Board of Adjustment No. 1, their cases will be heard, provided they agree in writing beforehand that they will accept the decision of the board as final. It is expected, however, that within a short time, a separate board will be set up for these employees.

At the present time, the Canadian National Railways has in force in several of its shops what is known as the "Premium System," the essential features of which may be described as follows:

(1) A careful classification of the work to be done in the shop in question is made.

(2) Careful studies are made of the time required to perform the work under each classification.

(3) A complete system of cost accounting is installed.

(4) Employees are paid additional compensation in the form of a percentage allowance equivalent to the percentage improvement which they make over the standard time set in the time-studies for the class of work which is being done.

At these particular shops, meetings are held monthly at which shop superintendents, foremen, and charge hands exchange ideas, review the situation, offer suggestions and have a general discussion of the various problems from the standpoint of the company and the men. This system is working out very satisfactorily and results so far have been good.

Co-operation between standard organizations of railway shopmen and the railway management has long been the subject of discussion, and a tentative plan for co-operative management is being tried out on the Canadian National Railways.

Briefly, co-operation in management means the assumption of responsibility by the employees towards the major welfare of the railway enterprise as a whole. This finds expression in the work of joint shop committees, set up at each plant. The committees meet in co-operative conference for discussions and suggestions in such matters as:—

(1) Job analysis and standardization.
(2) Better tools and equipment.
(3) Care and distribution of tools.
(4) Proper storage, care and delivery of material.
(5) Economical use of supplies and materials.
(6) Re-arrangement of machine tools.
(7) Proper balancing of forces and work in shops.
(8) Co-ordinating and scheduling of work through shops.
(9) Improving quality of work.
(10) The introduction of output records.
(11) Condition of shops and shop grounds, especially in respect to heating, lighting, ventilation, safety, etc.
(12) Increasing effectiveness of shopmen's organizations.
(13) Securing new business for the railroad.
(14) Steps necessary to secure new work.
(15) Improvements in technical training of apprentices and others.
(16) Recruiting and building up of working force with competent responsible individuals.
(17) Local stabilization of employment.
(18) Improvement in physical working conditions.

Representatives of the employees and management are now engaged in setting up the necessary machinery. Obviously at this juncture, it is impossible to forecast the results.

The participation in, or "sharing fairly" the benefits of co-operation is one phase of the plan which probably presents a serious difficulty, for the reason that measurement of all of the work performed by the employees of the maintenance of equipment department in relation to man-hours is something which heretofore has not been accomplished. Time production in manufacturing is simple in comparison.

In several of the company's locomotive and car shops, a premium system is in effect, as previously stated, whereby work performed on time-schedules can be definitely measured. At some points, more than half of the shop activities are on a time-production basis, but these are confined to the Central Region, no extension of this method having so far been made to the plants located on the Atlantic and Western Regions.

A committee is now at work endeavouring to evolve a plan whereby a division may be made between employee and employer of such benefits as are expected to accrue from this new scheme of co-operation. It is realized that new and difficult ground must be broken, as the ascertainment of exact cost data in maintenance of railway equipment has never been vital to the existence of the mechanical department, with the result that reliable data is not obtainable through any existing accounting practices.

The indications are that in so far as the heavier work is concerned, a solution of the measurement difficulty lies in the complete application of the premium system already mentioned. Further study will develop to what extent this system can be applied to minor repairs in yards and at engine terminals, and also to the housing and caring for locomotives actually in transportation service.

Maritime General Professional Meeting

Preliminary arrangements have been completed and the final details are being planned for the Maritime General Professional Meeting which is to be held at Sydney, Nova Scotia, on Tuesday, Wednesday and Thursday, August 17th, 18th and 19th, 1926.

The provisional programme for this meeting provides for two technical papers with discussions. The first paper is on the "Development of the Humber Valley, Newfoundland," by H. C. Brown, A.M.E.I.C., electrical superintendent, Newfoundland Pulp and Paper Company, Limited. This paper should be of general interest. The plant of this company was opened less than a year ago, and is one of the largest and most modern equipped on the Continent. The second paper is on "Characteristics and Utilization of Nova Scotia Coals," by W. S. Wilson, A.M.E.I.C., assistant chief engineer, and M. W. Booth, A.M.E.I.C., steam engineer, Dominion Iron and Steel Company. While of vital interest to eastern members of The Institute, this paper is also of great interest to members throughout Canada.

The tentative programme, which is given below, provides for various other functions and entertainment. On Thursday, August 19th, following the meeting, arrangements have been made for a drive along Bras d'Or, through Baddeck and on to the Margaree Valley.

Tentative Programme

TUESDAY, AUGUST 17TH

9:30-10:30 a.m.—Registration.
10:30-11:00 a.m.—Address of Welcome — The Mayor of Sydney.
11:00-12:15 p.m.—Paper—"Development of the Humber Valley, Newfoundland," by H. C. Brown, A.M.E.I.C., electrical superintendent, Newfoundland Pulp and Paper Company.
12:15-12:45 p.m.—Photograph.
12:45- 2:00 p.m.—Lunch—Complimentary to visitors.
2:00- 5:00 p.m.—Visit to No. 1-B Colliery, Glace Bay; or Waterford Lake Power Plant; or sail on Harbour; or Golf.
5:30- 7:00 p.m.—Golf—Cards—Lingan Country Club.
8:00 p.m.—Informal dinner and dance, Lingan Country Club.

WEDNESDAY, AUGUST 18TH

9:30 a.m.—Business meeting.
10:00-12:00 noon—Paper—"Characteristics and Utilization of Nova Scotia Coals," by W. S. Wilson, A.M.E.I.C., assistant chief engineer, and M. W. Booth, A.M.E.I.C., steam engineer, Dominion Iron and Steel Company. Discussion.
12:00- 1:30 p.m.—Lunch—at individual choice.
2:00- 6:00 p.m.—Visit Steel Plant and Coke Ovens of Dominion Iron and Steel Company, Sydney, or drive to East Bay.
7:30 p.m.—Banquet — Prominent Speakers — Sing-song—Etc.

THURSDAY, AUGUST 19TH

9:00 a.m.—Leave Sydney for drive along Bras d'Or lakes, through Baddeck and on to the Margaree Valley—Fishing.

A special committee of the branch is arranging hotel accommodation for visiting members, and in order that all may be assured of such accommodation, it is important that all members planning to attend the meeting should notify the secretary of the Sydney Branch promptly.

Amendments to the By-Laws

Following the announcement which appeared on page 302 of the June issue of the Engineering Journal regarding the amendments to the By-laws, which became effective following the approval of the members by letter ballot returnable April 30th last, attention is directed to the changes given below:—

BY-LAWS SECTIONS NOS. 8, 9 AND 10

The changes under these sections refer particularly to the requirements for examination for admission to the grades of Student, Junior and Associate Member, and, with these changes in view, the Board of Examiners of The

Institute have prepared revised schedules of examinations, which together with sample examination papers are at present being printed and will shortly be available. These schedules are referred as follows:—

A—for admission as Student
B— " " " Junior
C— " " " Associate Member.

By-law Section 33

In accordance with the amendment to this By-law, which deals with the entrance fees, provision is made for the payment of the amount specified at the time of application for admission to The Institute. Accordingly, all applications for admission must be accompanied by a remittance covering the amount of entrance fee set forth in the By-laws for the grade of membership to which the applicant considers himself eligible.

By-law Section 35

This section deals with the schedule of annual fees payable by the various grades in The Institute and provides for an increase in these fees of one dollar in each case, which amount is deducted if the fees are paid on or before March 31st of the current year. In view of the fact that the ballot in connection with the amendments to the By-laws was not returnable until April 30th, the change in this By-law will not be made effective until January 1st, 1927.

Meetings of Council

Meeting of May 18th, 1926

A meeting of Council was held at eight p.m. on Tuesday, May 18th, Vice-President K. B. Thornton, M.E.I.C., in the chair and seven members of Council being present.

The report of the Finance Committee was approved, and its recommendations regarding twenty-seven cases of members in arrears of fees were approved.

F. P. Shearwood, M.E.I.C., was appointed treasurer of the Institute, succeeding the late Sir Alexander Bertram, and J. B. Challies, M.E.I.C., was appointed a member of the Finance Committee.

The report of the scrutineers, regarding the letter ballot on the Amendments to the By-laws proposed by Council at the Annual Meeting January 27th, 1926, was submitted, and the number of affirmative votes being in all cases greater than two-thirds the number of votes balloted, all the amendments were declared to be carried.

The question of the publication of Transactions was considered, and the secretary reported that over 290 members had signified their willingness to subscribe for the Transactions if published. It was considered that this response would justify the publication of a limited edition, say one thousand copies, and the Publications Committee was requested to submit a detailed plan for the proposed volume, for the approval of Council, at its next meeting if possible.

Discussion regarding the arrangements for the next Annual General Meeting took place, and the secretary was directed to confer with the Executive Committee of the Quebec Branch regarding this matter.

A letter was submitted from Mr. C. E. Skinner, chairman of the Tour Committee of the International Electrotechnical Commission, expressing appreciation of the arrangements made for the welcome and entertainment of that Commission during its Canadian tour.

The seventeen elections and fourteen transfers were effected as follows:—

Elections

Members	5
Associate Members	7
Juniors	3
Affiliates	2

Transfers

Associate Member to Member	4
Junior to Associate Member	1
Student to Associate Member	2
Student to Junior	7

Twenty applications for admission and transfer were scrutinized and classified for the ballot returnable June 15th.

The secretary reported that on May 18th, in accordance with Council's instructions, fifty-five names were removed from the list of members of the Institute for non-payment of fees, as follows:—

Members	4
Associate Members	41
Juniors	2
Students	8

The Council rose at 10.30 p.m.

Meeting of June 15th, 1926

A meeting of Council was held at eight p.m. on Tuesday, June 15th, Geo. R. MacLeod, M.E.I.C., in the chair, and six members of Council being present.

The monthly report and recommendations of the Finance Committee were approved and resignations of one Student and one Member were accepted. Five applications for re-instatement were considered.

The proposed programme for the Maritime Professional meeting to be held in Sydney, C.B., on August 17th and 18th was considered and discussed, and the preliminary programme for the Annual Meeting to be held in Quebec, Que., in February 1927, was also discussed.

A report was submitted from the chairman of the Publication Committee, stating that a preliminary list had been made of papers to be considered in connection with the proposed publication of volume of Transactions, these having been chosen from papers presented during the years 1923, 1924 and 1925. Arrangements were discussed for the further work in this connection.

The list of officers for the Quebec Branch for the year 1926-27 was submitted and approved.

The proposal from a member was considered outlining a scheme for group insurance for all members of The Institute, but, after discussion, it was not considered advisable to embark on such a scheme, such working falling more particularly within the activities of the various provincial associations of professional engineers.

The Board of Examiners presented a report containing the revised examination schedules and the sample examination papers, revised in accordance with sections 8, 9 and 10 of the by-laws as recently amended; these were approved for publication.

Prof. C. M. McKergow, M.E.I.C., was nominated to succeed the late Sir Alexander Bertram as one of the three nominees of The Institute of the Canadian Engineering Standards Association.

Further consideration was given to the request received from England to suggest a name for the next recipient for the Kelvin Medal.

The following elections and transfers were effected:—

Elections

Members	2
Associate Members	4
Juniors	3

Transfers

Associate Member to Member	4
Junior to Associate Member	1
Student to Associate Member	2
Student to Junior	4

Twenty applications for admission and transfer were scrutinized and classified for the ballot returnable September 21st.

Consideration was given to twelve special cases in connection with applications for admission.

The Council rose at 12:45 a.m.

OBITUARIES

Augustine V. Redmond, M.E.I.C.

It is with regret that we record the death of Augustine V. Redmond, M.E.I.C., which occurred on February 9th, 1926.

Mr. Redmond was born at Kingston, Ont., on May 16th, 1878, and graduated from Queen's University with the degree of B.Sc. in 1903. Since that date he had almost been continuously engaged on railway work, commencing as leveller and transitman on location with the Grand Trunk Railway and the National Transcontinental Railway in January 1904. For one year, from October 1908, he was resident engineer on construction of the National Transcontinental Railway. In October 1909 he was appointed division engineer on construction on the same railway, which position he occupied until May 1915. In June of the following year he was appointed resident engineer and acting division engineer with the Canadian Government Railways, and the following year was promoted to division engineer. In 1919 he became district engineer, Canadian National Railways, with headquarters at Winnipeg, Man. At the time of his death, the late Mr. Redmond was district engineer, Canadian National Railways, Winnipeg, Man.

The late Mr. Redmond was admitted to The Institute as Associate Member on January 8th, 1910, and transferred to Member on July 22nd, 1919.

David Frederic Maxwell, M.E.I.C.

It is with sincere regret that we record the death of David Frederic Maxwell, M.E.I.C., which occurred at his home in St. Stephen, N.B., on June 8th, 1926.

The late Mr. Maxwell was town engineer of St. Stephen, and had been active in his work until a few days prior to his death. He was a native of St. Stephen, having been born there on October 21st, 1848. Throughout his life he was greatly interested in railway matters, having devoted practically all his time to engineering work in connection with railways in the Maritime provinces.

As early as 1873 he was rodman and assistant engineer on the Chatham Branch of the Canada Eastern Railway. He was successively assistant engineer of the Kent Northern Railway in 1875; in New Brunswick Southern Railway in 1876; and in 1877 the New Brunswick Railway. In 1878 he became chief engineer of what was later part of the Washington County Railway in the state of Maine. From 1880-83 he was resident engineer of the St. Croix Cotton Mills and Gibson Cotton Mills, following which he was appointed chief engineer of the Canada Eastern Railway. From 1884-1888 he was engineer of railways for the government of New Brunswick, and for the next four years was engaged on railway surveys as division engineer. In 1894 he became chief engineer of the Calais, St. Stephen Electric Railway. In 1897 he entered private practice and during the next three years was engaged on reporting on water powers in connection with pulp mills.

In 1901 he became town engineer of North Sydney and from 1909-14 he was engaged as chief of location on the St. John and Quebec and on Fredericton and Grand Lake Railways in New Brunswick.

The late Mr. Maxwell was admitted to The Institute as Member on October 8th, 1903.

R. A. Hazlewood, M.E.I.C.

R. A. Hazlewood, M.E.I.C., formerly on maintenance and structures, Hudson's Bay Railway, with headquarters at The Pas, Man., died on February 23rd, 1926.

The late Mr. Hazlewood was born at Brockville, Ont., on June 26th, 1857. He commenced his engineering career with the Canadian Pacific Railway on surveys west of Port Arthur from 1875-78, and in 1878 was appointed, by that company, section engineer on the Thunder Bay division. In 1881 he was engaged on location work with the International Railway in Maine, U.S.A., and in 1882 he became engineer in charge of a section of the Ontario and Quebec Railway at Sharbot lake.

The following year he engaged in contracting for the Canadian Pacific Railway on the north shore of lake Superior. In 1884 he was with the same company in charge of a location party in the Eastern Townships, again returning to contracting in 1885 with the Minneapolis and Soo Railway. In 1886 he was divisional engineer, Canadian Pacific Railway, on the Windsor extension. Two years later he was engineer in charge and superintendent of construction of the Port Arthur, Duluth and Western Railway. For the following five years he was engaged in contracting work, returning to railway location in 1898 with the Rainy River Railway. For five years, commencing 1899, he was contract engineer on the Algoma and Hudson Bay Railway.

The late Mr. Hazlewood was elected Member of The Institute on April 23rd, 1903.

John Davis Barnett, M.E.I.C.

It is with regret that we record the death of one of the earliest members of The Institute, John Davis Barnett, LL.D., M.E.I.C., which occurred on March 21st, 1926.

The late Dr. Barnett's membership in The Institute dates back to January 20th, 1887, when he was admitted to The Canadian Society of Civil Engineers, some five months prior to its incorporation under Dominion charter.

Dr. Barnett was born in 1850, and at the age of fourteen he commenced his engineering studies as pupil in the shops and drawing office under the mechanical superintendent in the Great Western Railway at Wolverhampton, London and Swindon (England). In 1867 he continued his studies as pupil under the mechanical superintendent of the Grand Trunk Railway in Montreal. His subsequent rise was rapid and was successively junior draughtsman, chief draughtsman and assistant mechanical superintendent at Belleville, Ont., Montreal, Que., and Stratford, Ont. In 1883, he became mechanical superintendent of the Midland Railway of Canada, and in the following year was appointed divisional superintendent of Midland division, Grand Trunk Railway.

The late Dr. Barnett took a very active part in the affairs of The Canadian Society of Civil Engineers in its early days, and served on the Council of the Society for nine years, from 1889-1896 inclusive, and also in 1898. He was one of the Charter Members of the London Branch of The Institute.

Raoul Rinfret, M.E.I.C.

Sincere regret is expressed at the death of Raoul Rinfret, M.E.I.C., which occurred at Shawinigan Falls, Que., on May 8th, 1926.

The late Mr. Rinfret was born at St. Stanislas, Que., on July 16th, 1856. He received his degree of B.A.Sc. from McGill University in 1887, and was commissioned as a Dominion Land Surveyor and a Provincial Land Surveyor of Quebec. The year following his graduation, he was engaged on highway bridge construction and later, in 1893, he became engaged on railway location work. In 1907 he was appointed chief engineer for the town of Montcalm, a suburb of Quebec, and in 1909, chief engineer for Thetford Mines, Que., and at various times was engaged on:—the location of the transmission line for the Montreal Light, Heat and Power Consolidated, from Cedar Rapids to Lachine, Que.; estimates for the water-works for Ste. Therese, East Broughton, Matane and St. Jude, all in Quebec. He was later engaged in consulting practice, and at the time of his death was connected with the Shawinigan Engineering Company, Shawinigan Falls, Que.

The late Mr. Rinfret was admitted to The Institute as Associate Member on March 10th, 1908, and transferred to Member on October 13th, 1913.

PERSONALS

J. R. Bradfield, S.E.I.C., is with the Horne Copper Corporation at Rouyn, Que. Mr. Bradfield graduated from McGill University in 1922.

I. W. Boyd, S.E.I.C., who received the degree of M.Sc. (with honours) from Queen's University this spring, is at present on a tour in the Old Country.

Willard B. Fraser, S.E.I.C., who has just completed his third year in electrical engineering at McGill University, is with the Shawinigan Engineering Company, and is located at St. Narcisse, Que.

James Ferguson, A.M.E.I.C., formerly on the engineering staff of the Canadian National Railways, Montreal, Que., has been transferred by that company to Cochrane, Ont., where he is division engineer.

Ralph Allingham, A.M.E.I.C., has been appointed field engineer for the Semet-Solvay Company at Buffalo, N.Y., on the construction of a battery of sixty coke ovens and other additions to the company's plant.

J. J. Richardson, A.M.E.I.C., division engineer with the Canadian National Railways, Cochrane, Ont., has been transferred by that company to Montreal, where he is division engineer with headquarters at the Tunnel Station.

H. D. Cluff, S.E.I.C., who graduated from the University of Manitoba in 1924, is lieutenant with the Royal Canadian Corps of Signals, and is officer in charge of the North West Territories Radio-Telegraph station at Aklavik, North West Territories.

Darrel D. Steeves, Jr.E.I.C., who recently was with Messrs. C. O. Barton Company, of Detroit, Mich., has resigned and accepted the position of chief estimator of Messrs. Martin and Krausman, general contractors, Detroit, Mich.

Ernest Peden, A.M.E.I.C., who has for some time been with the Dominion Bridge Company at Lachine, Que., has joined the staff of Ross and Macdonald, architects, Montreal. Mr. Peden is a graduate of McGill University of the year 1912.

Frank L. Grindley, S.E.I.C., who received his degree of B.Sc. in civil engineering from the University of Alberta this spring, has been appointed instrumentman with the Canadian National Railways on the Cold lake survey in Alberta.

G. R. Adams, S.E.I.C., who this year completed his fourth year in civil engineering at Queen's University, is at present with Fraser Brace Engineering Company on work in connection with the development on the Gatineau river near Ottawa.

D. T. Welsh, S.E.I.C., who graduated from the University of Toronto in 1924, has resigned from the staff of the city engineer's department at Hamilton, Ont., and has joined the Fort William staff of the Department of Northern Development of the Ontario Government.

L. C. Prittie, A.M.E.I.C., who graduated from Queen's University with the degree of B.Sc. in 1912, and who for several years, subsequent to April 1920, was assistant patent examiner in the Patent and Copyright Office, Ottawa, Ont., is now patent attorney with the Canadian General Electric Company, Limited, Toronto, Ont.

A. G. Jeffreys, M.E.I.C., who through ill health was forced to discontinue active work for some time, has recently recovered sufficiently to return to his profession, and is at present with the Thunder Bay Paper Company, Limited, at Port Arthur, Ont., in charge of the engineering office in connection with the construction of the company's new paper mill.

Edward Hughes, A.M.E.I.C., who has been located at Camp Verde, Arizona, with the Western Chemicals, Incorporated, is going into the Dease lake country in northern British Columbia on Canadian Geological Survey work. Mr. Hughes has had considerable experience in railway, land and mine survey work, and was for a time with the Crow's Nest Pass Coal Company, Limited, as mine surveyor.

C. M. Walker, A.M.E.I.C., has been transferred from the Topographical Surveys Branch of the Department of the Interior to the engineering staff of the Canadian National Parks Branch. For the past thirteen years Mr. Walker has been engaged on Dominion land survey and subdivision work in the west and also did a large amount of townsite surveying in the western parks. His work with the Parks Branch will be in connection with highway location, and construction and municipal work.

R. M. Calvin, A.M.E.I.C., has rejoined the staff of H. S. Taylor, Limited, of Montreal. Mr. Calvin is a graduate of Queen's University, from which he received the degree of B.A. in 1911 and B.Sc. in 1914. Subsequent to graduation he served overseas with the Canadian Engineers. He was later for a short period with the Water Power Branch of the Department of the Interior, after which he joined the the staff of H. S. Taylor, Limited, where he remained until April 1923.

K. H. Smith, M.E.I.C., formerly chief engineer of the Nova Scotia Power Commission and district chief engineer of the Dominion Water Power and Reclamation Service of the Maritime Provinces, located at Halifax, N.S., is now employed by the Montreal Engineering Company, Limited, 164 St. James street, Montreal, Que., the engineering department of the Royal Securities Corporation. It is understood that Mr. Smith retains his connection with the Dominion Water Power and Reclamation Service in a consulting capacity.

S. Eastman Root, Jr.E.I.C., is construction engineer with the Wm. I. Bishop Limited on the extension to the Belgo plant of the St. Maurice Valley Corporation at Shawinigan Falls, Que. Mr. Root has had considerable construction experience, having been with the Thompson, Starrett Company on the construction of the mill for the St. Maurice Paper Mills, Limited, at Three Rivers, Que., and on construction at Donnacona, Que., with the Donnacona Paper Company. Previous to his present appointment he was on preliminary field work in connection with the new mill of the International Paper Company near Ottawa, Ont.

R. E. Butt, A.M.E.I.C., has accepted the position of mechanical engineer assisting the production manager with Messrs. General Motors New Zealand, Limited, at their new works at Petone, near Wellington, N.Z. Mr. Butt, in 1922, was chief engineer of Messrs. Kindred and Company of Wolverhampton, England, which company was a subsidiary of Messrs. Bostock and Hargrove Limited, and in 1924, due to trade depression, Mr. Butt was transferred to the parent company, which was engaged on the installation of power plants, pumping and filter plants. Early in 1925 Mr. Butt went to New Zealand, where he was engaged on various temporary work until his recent appointment.

J. G. MacLachlan, A.M.E.I.C., who has been division engineer, Kamloops-Kelowna-Lumby Line of the Canadian National Railways, has been transferred to The Pas, Man., and has been appointed division engineer, construction, operation and maintenance, Hudson Bay Railways, succeeding the late R. A. Hazlewood, M.E.I.C. Mr. MacLachlan has had extensive railway construction experience which dates back to the year 1906. For five years he was with the Canadian Northern Ontario Railway as resident engineer on various sections. He served overseas as company commander in the Canadian Railway Troops, and subsequent to the War he was division engineer on construction, Canadian National Railways, Okanagan Branch, at Kamloops, B.C., later being appointed to the position from which he has just been promoted.

J. B. Hamilton, A.M.E.I.C., receives Appointment

J. B. Hamilton, A.M.E.I.C., who for the past five years has been town engineer and superintendent of utilities of the town of Estevan, Sask., has recently resigned to undertake the management of a manufacturing organization in England, which controls certain patents on mechanical tools. Mr. Hamilton was born at Bellshill, Scotland, on March 31st, 1892. His technical education was received in the Old Country.

Prior to coming to Canada he was assistant plant manager with Messrs. Harland and Wolff, ship builders, Belfast, Ireland, and carried out the erection of that company's new shipyard on the Musgrave Channel, Belfast. Previous to that Mr. Hamilton was assistant inspector in the Aeronautical Inspection Directorate of Great Britain.

During his tenure of office in Estevan, he was particularly active in advancing the interests of the municipality, particularly in connection with its electrical and sewage works and in encouraging industries to locate in that town. During the past year, Mr. Hamilton was the unanimous choice of the Conservatives of Estevan to represent them as federal candidate for the constituency of Assiniboia in the recent election.

Major R. B. Jennings, A.M.E.I.C., appointed General Manager of Inspection Company

Major Robert Bernard Jennings, A.M.E.I.C., who has been appointed general manager of Robert W. Hunt and Company Limited, with headquarters at Montreal, was born at Paris, Ontario, June 29th, 1888. After receiving his education in Humberside Collegiate Institute, Toronto, and Faculty of Applied Science, University of Toronto, he engaged in railway location and construction, and was appointed resident engineer, Canadian Northern Ontario Railway, in 1909.

He served in this capacity on the various lines under construction until January 31st, 1916, when he enlisted in the Canadian Overseas Expeditionary Force. He was appointed Lieutenant, and promoted to Major in the 10th Battalion, Canadian Railway Troops, with active service in France and Belgium.

On his return to Canada, he was placed on the Reserve of Officers, and was on June 1st, 1919, appointed division engineer, Toronto Division, Canadian National Railways, Toronto, Ontario.

On February 22nd, 1921, he was appointed division engineer, Ottawa Division, Canadian National Railways, Ottawa, Ontario, and on May 1st, 1922, he was appointed division engineer, Montreal Division, Canadian National Railways, Montreal, which position he recently resigned to accept his present appointment.

Recent Graduates in Engineering

In addition to the list of Students of The Institute who have recently completed their courses at the various universities, as published in the June issue of the Journal, congratulations are also in order to the following, results of whose examinations were received too late for publishing with the main list last month:—

Nova Scotia Technical College

Special Prize

MacIntosh, Charles Alexander Daniel, North Earltown, N.S., The Alumni Medal.

Degree of B.Sc.

MacIntosh, Charles Alexander Daniel, B.Sc., (Mi.), North Earltown, N.S.

Pippy, George Alexander, B.Sc., (E .), Springhill, N.S.

McGill University

Honours in the Graduating Class, Medals, Certificates and Prizes

Arthur Caldwell Abbott, Montreal, Que., Honours in Electrical Engineering.

Douglas Orrin Bremner, Montreal, Que., Montreal, Light, Heat and Power Consolidated, Second Prize.

Herve Alfred Gauvin, Ottawa, Ont., Prize for Summer Essay.

Erceldoune Gray-Donald, Montreal, Que., Undergraduates' Society's Third Prize for Summer Essay.

Morris Katz, Montreal, Que., British Association Medal in Chemical Engineering, Honours in Chemical Engineering.

John Whiting Noyes, Montreal, Que., British Association

Medal in Metallurgical Engineering; Research Fellowship in Metallurgical Engineering.

George Hugh Pringle, Three Rivers, Que., British Association Medal in Mechanical Engineering; Honours in Mechanical Engineering.

Guy Raoul Rinfret, Montreal, Que., British Association Medal in Civil Engineering; Jenkins Bros., Limited, Scholarship; Honours in Civil Engineering.

Francis Edward Winter, Montreal, Que., British Association Medal in Electrical Engineering; Montreal, Light, Heat and Power Consolidated, First Prize; Honours in Electrical Engineering.

Degree of B.Sc.

Abbott, Arthur Caldwell, B.Sc., (El.), Montreal, Que.
Archambault, Jules, B.Sc., (El.), Montreal, Que.
Baxter, Gordon Bruce, B.Sc., (El.), Three Rivers, Que.
Bremner, Douglas Orrin, B.Sc., (El.), Montreal, Que.
Cooper, Donald Frederick, B.Sc., (Mi.), Montreal, Que.
Costigan, James Percival McDougall, B.Sc., (El.), Montreal, Que.
Crepeau, Louis, B.Sc., (Ci.), Montreal, Que.
Dion, J. Edgar, B.Sc., (Me.), Ottawa, Ont.
Gauvin, Herve Alfred, B.Sc., (Ci.), Ottawa, Ont.
Gilmour, William Alexander Turner, B.Sc., (El.), Hamilton, Ont.
Gray-Donald, Erceldoune, B.Sc., (El.), Montreal, Que.
Halpenny, Merle Benjamin, B.Sc., (Me.), Montreal, Que.
Henderson, Ian Gordon, B.Sc., (Ci.), Williamstown, Ont.
Herscovitch, Charles H., B.Sc., (Me.), Montreal, Que.
Hinchliffe, Joseph Edward, B.Sc., (Ci.), Victoria, B.C.
Hodina, Frank Albert, B.Sc., (Chem.), Montreal, Que.
Jubien, Ernest Burchell, B.Sc., (El.), North Sydney, N.S.
Katz, Morris, B.Sc., (Chem.), Montreal, Que.
Leitch, Hugh James, B.Sc., (Ci.), Montreal, Que.
Lister, Arthur, B.Sc., (El.), Montreal, Que.
McClung, Joseph Eldon, B.Sc., (El.), Montreal, Que.
Mills, Cecil Gordon, B.Sc., (El.), Montreal, Que.
Mulligan, Henry Iveson, B.Sc., (Ci.), Fort Coulonge, Que.
Nathanson, Max, B.Sc. (El.), Montreal, Que.
Norris, Herbert Bethel, B.Sc., (El.), Montreal, Que.
Noyes, John Whiting, B.Sc., (Met.), Montreal, Que.
Paterson, Alexander Pierce, B.Sc., (El.), St. John, N.B.
Pigot, Charles Hugh, B.Sc., (Ci.), Quebec, Que.
Pringle, George Hugh, B.Sc., (Me.), Three Rivers, Que.
Reid, Kenneth, B.Sc., (El.), Metchosin, B.C.
Rinfret, Guy Raoul, B.Sc., (Ci.), Montreal, Que.
Ross, William Thomas Dygnum, B.Sc., (Chem.), Pictou, N.S.
Rutherford, James Forest, B.Sc., (El.), Montreal, Que.
Salter, Frederick Cumberland, B.Sc., (Ci.), Montreal, Que.
Simon, Robert Carleton, B.Sc., (Me.), Montreal, Que.
Stewart, Donald, B.Sc., (El.), Lakeside, Que.
Stewart, William Franklin, B.Sc., (El.), Antigonish, N.S.
Vernot, George Edward, B.Sc., (El.), Montreal, Que.
Wallace, Reginald Henderson, B.Sc., (Me.), Halifax, N.S.
Webster, James Stewart, B.Sc., (El.), Ottawa, Ont.
Wilson, Valentine William Gibson, B.Sc.,(Mech.), Montreal, Que.
Winter, Francis Edward, B.Sc., (El.), Montreal, Que.

University of Manitoba

Special Prizes

Gauer, Edward—Joseph Doupe Gold Medal for highest aggregate in third and fourth year Civil Engineering.

Rodgers, Lawrence Aylmer—Gold Medal in Electrical Engineering.

Degree of B.Sc.

Antenbring, Clarence, B.Sc., (Ci.), Winnipeg, Man.
Carry, Charles William, B.Sc., (Ci.), Winnipeg, Man.
Gauer, Edward, B.Sc., (Ci.), Winnipeg, Man.
Hadden, Lyall Conley, B.Sc., (El.), Winnipeg, Man.
Hardy, A. Elvin, B.Sc., (Ci.), Winnipeg, Man.
Kellett, James Edward, B.Sc., (Ci.), Winnipeg, Man.
Kernaghan, Edward Benson, B.Sc., (El.), Winnipeg, Man.
Kennedy, James Mitchell, B.Sc., (Ci.), Winnipeg, Man.
O'Day, Martin, B.Sc., (Ci.), Winnipeg, Man.
Reekie, William George, B.Sc., (El.), Winnipeg, Man.
Rodger, Lawrence Aylmer, B.Sc., (El.), Winnipeg, Man.
Sumner, Joshua, B.Sc., (Ci.), Winnipeg, Man.
Treble, Harold Edison, B.Sc., (Ci.), Crystal City, Man.
Warkentin, Cornelius Paul, B.Sc., (Ci.), Winnipeg, Man.
Wilson, James Harvey, B.Sc., (El.), Qu'Appelle, Sask.

ELECTIONS AND TRANSFERS

At the meeting of Council held on June 15th, 1926, the following elections and transfers were effected:—

Members

BRYANT, Orville Frank, B.S., (New Hampshire Univ.), chemical engineer, Laurentide Co., Ltd., Grand'Mere, Que.

NICHOLS, David Andrew, B.Sc., (Queen's) M.A., (Columbia), engaged on research work for Ph.D. degree at Columbia Univ., Ottawa, Ont.

Associate Members

BROUGHTON, William Hamilton, Instructor in industrial mechanical engineering, the Provincial Inst. of Tech. and Art, Calgary, Alta.

HUTCHINSON, Eric Charles, C.E., (Ecole Polytechnique Fédérale Suisse), ch. of engrg. party at Farmers dev. on Gatineau river for Fraser Brace Engineering Co., Chelsea Falls, Que.

McLEOD, Neil, ch. elect. all coal mining operations, Brit. Empire Steel Corp., Glace Bay, N.S.

WHITE, Hans Grove, mining engineer, Glacier Creek Mining Co., Stewart, B.C.

Juniors

ADDIE, Donald Kyle, B.Sc., (McGill), mechanical engineer and at times night superintendent with Dominion Glass Co., Ltd., Montreal, Que.

McDONALD, James Alexander, B.Sc., (Univ. of Alta.), coke ovens dept. of Steel Co. of Canada, Hamilton, Ont.

PATTERSON, Thomas MacMillan, B.A.Sc., (Univ. of Toronto) with Dom. Water Power and Reclamation Service, Ottawa, Ont.

Transferred from class of Associate Member to that of Member

KELLY, Edward Arthur, asst. engineer on construction, C.P.R., Lethbridge, Alta.

MOODIE, Kenneth, B.A.Sc., (McGill), ch. engineer, P. Burns Co., Ltd., Calgary, Alta.

MORSE, John, E.E., (Chalmers Tech. Inst., Gottenburg, Sweden), gen. supt., Shawinigan Water & Power Co., Montreal, Que.

POLYBLANK, Kenneth Grahame, asst. ch. engineer, Rouyn Mines Rly., O'Brien, Que.

Transferred from class of Junior to that of Associate Member

BUCKMAN, Addison W., asst. to engineer in charge, Ottawa-Prescott Highway, Kemptville, Ont.

Transferred from class of Student to that of Associate Member

DAWSON, Heber William, B.Sc., (McGill), electrical and hydro-electric design, Shawinigan Engineering Co., Montreal, Que.

McLAGAN, Thomas Rodgie, B.Sc., (McGill), asst. supt., mechanical pulp mill, Laurentide Co., Grand'Mere, Que.

Transferred from class of Student to that of Junior

CAMPBELL, Amos John Gladson, B.Sc., (Queen's), sales engr., Riley Engineering & Supply Co., Ltd., Toronto, Ont.

DUNBAR, Prosper Gerald, B.A.Sc., (Univ. of Toronto), layout dftsman, mech'l dept., Smith Hinchman & Grylls, Detroit, Mich.

ELLIS, Franklin Alexander, B.A.Sc., (Univ. of Toronto), session demonstrator, i/c third year electrical lab., Univ. of Toronto, Toronto, Ont.

SMITH, George Westwood, B.A.Sc., (Univ. of Toronto), engr. with Lago Petroleum Corp., Maracaibo, Venezuela, S.A.

B.C. Professional Engineers Issue Year Book

The Association of Professional Engineers of British Columbia have issued a pamphlet containing the Engineering Act of the province of British Columbia and the by-laws, code of ethics, schedule of fees and membership list of the Association.

The Relation of the University to the Engineering Profession

R. W. Brock, M.A., LL.D., F.G.S., M.E.I.C.,
Dean of the Faculty of Applied Science, University of British Columbia, Vancouver, B.C.

Paper presented before a joint meeting of the members of the Vancouver Branch of the Engineering Institute of Canada, Vancouver members of the American Society of Electrical Engineers, and the Vancouver Engineers Registered under the Engineering Act of the province of British Columbia, on May 26th, 1926.

The address took the form of answers to questions which had been submitted to the Dean. The questions were, in part:—

1.* Should not all students of engineering be encouraged by the faculty, (or by the Dean), to register, on commencing their studies, with the Association of Professional Engineers ?

2. Should not the aims of the profession, as expressed in the "Engineering Act," the by-laws and regulations of the association, together with the terms of registration of pupils and engineers-in-training, be printed in the university calendar ?

3.† Should not professors of engineering seek registration under the "Engineering Act" ? Would the Dean use his influence thereto ?

As the notice of this meeting has advised you, I am going to answer a number of questions relating to the relationship of the university to the engineering profession, or to the Engineering Act. Before answering the questions, I desire to give as best I may some idea of my conception of what education is and to combat an erroneous conception held by many people.

Many people think that the schools—public, high, college or university—exist to supply students with information which will be useful to them in their business life, and that anything, or indeed everything useful should be included in the curriculum. Such a conception of the task of the university is manifestly erroneous. It is an impossible task.

It is true that the work of the public schools is to teach the three R's, but beyond this, I maintain the chief work of the schools is not to impart mere information, but to educate. If, of course, at the same time, students incidentally get information so much the better. I am developing grave doubts about some of our new education movements. All movements are not necessarily advancement. It may be retrograde, and I am beginning seriously to wonder if the system of the old Scottish dominie has not much in it to be recommended.

On one point at least I am clear,—the main task of school, college and university is to *educate and to turn out students*—students—those who know how and what to study. What is education ? It is from educare—to lead forth, and it embraces the development of the body, the spirit and the mind. I cannot do better than to quote to you Huxley's conception of a liberal education.

"That man I think has a liberal education who has been so trained in youth, that his body is the ready servant of his will and does with ease and pleasure all the work that as a mechanism it is capable of; whose intellect is a clear, cold, logic engine with *all* its parts of equal strength, and in smooth working order; ready like a steam engine to be turned to any kind of work and spin the gossamers as well as forge the anchors of the mind; whose mind is stored with a knowledge of the great and fundamental truths of nature and of the laws of her operations; one who, no stunted ascetic, is full of life and fire, but whose passions are trained to come to heel by a vigorous will, the servant of a tender conscience; who has learned to love all beauty, whether of nature or art, to hate all vileness and to respect others as himself. Such an one, and no other, I conceive has a liberal education, for he is, as completely as a man can be, in harmony with nature."

This conception of a liberal education is, in my opinion correct. The man so educated is the man of energy, background, broad vision and trained imagination, the man required for the big job, for leadership in all walks of life.

Unfortunately the time spent at university is all too short for such an education. Therefore much has to be deferred, to be acquired by the student after he leaves college. In deciding what shall be included in a college course, the determining factor should be not merely what is most useful or necessary, but rather what can one acquire at college that one cannot acquire so well, if at all, outside.

The student should develop his physical body. Without this he cannot have the healthy brain and energy necessary for the full accomplishment of which he would be capable in life. Too little attention is devoted to this phase of his education by most university authorities. He should have enough of the humanities to give him a liking for and an insight into them and to develop his taste and feeling. These are the subjects that develop the spiritual side of his nature.

He should have the basal sciences, not merely to know nature and her laws, not merely because man's life is a struggle to bring himself into harmony with them and secure the most from nature that is possible only by a knowledge of these laws and by conformity with them, but also because science is the great tool for educating the mind, and because the scientific method is the only technique by which material truth can be apprehended and established. It trains the observation, it trains in ordering and marshalling of facts so that they will tell their story. It trains in inductive reasoning, deductive reasoning and enables one to test these results. It subjects the mind to rigid discipline. That is, it trains the observation, the reasoning faculties, imagination and judgment. It trains one to recognize problems and to solve them. Science is peculiarly adapted to educating the mind. Since life consists of facing and solving problems, what other form of training can be more beneficial ?

Many facilities exist outside the university for education along humanitarian and spiritual lines. Provided one has developed a taste for them, has some knowledge of them, is a trained student and recognizes a lack of sufficient training in them, one can and will make good this deficiency after leaving the university.

The sciences require special facilities that are rarely to be found outside the halls of learning. In large part therefore they must be acquired at college if at all. For this reason they may be included in a sound educational course, even at the expense of further desirable training in the humanities. Incidentally I may observe that the reason classics rightly formed such an important place in the arts curriculum, was that the precision and rigidity of these languages afforded an excellent mental discipline such as none of the other humanities did, and at the same time they give one the historical background necessary for an appreciation of our civilization. No other of the older university studies served at one and the same time so many useful purposes.

In laying out the courses in the Faculty of Applied Science, of our provincial university, we have had the above principles in mind.

We require one year in Arts, to give the student his start in the humanities and to enable him to form the lasting college friendships with arts students from which he will, unconsciously perhaps, continue his education along humanitarian lines. In his first two years in applied science, his course is a general one covering mathematics and the basal sciences. When possible these classes are taken with students of other faculties for the broadening educational effects. At the end of his second year, applied science, or third year at college, he selects his more special course. In this time he has had a chance to learn something about the courses and their content, he has had the science or sciences on which each is largely based, and has learned his own tastes and aptitudes in the subjects. He is therefore in a position to make an intelligent choice. But even in the last two years these specialized courses are kept as general as possible, to give the broad training, so that the student, if he has made a mistake in his choice can still switch into another specialty.

---

*It was mentioned in support of this theory that some form of annual registration was, it was reported, practised at McGill.

†Any liability or legal need to registration by the professors had not been advanced, only the desirability thereof, and the help to the profession was advanced and emphasized.

Such an applied science course furnishes sound education for almost any industry or life of affairs.

We think it forms the best possible training for one who intends to become a professional engineer. No attempt is made to turn out the finished product. It would not be desirable even if it were possible. Some information necessary to the engineer has been omitted from the course, but that he can acquire outside. Indeed if it is necessary, he must, so we may safely trust to his doing so.

The success or otherwise of such a course will be shown by the success of our graduates. We are too young for decisive results to have appeared, but the indications so far may he said to be very favourable. For example, universities of world-wide renown are giving special recognition to our graduates.*

There is a conception abroad, and it seems to be held by some professional engineers, that the Faculty of Applied Science is an engineering school. From my introduction it should be evident that it is not. I do not want this body, the public, or the students, to think it merely and solely a professional school. It is the aim of the Faculty to give a broad education, useful in almost any life of affairs. So it is not a professional school, such as a law school, or what a medical school has now become. Not one-half of the present students will ever enter the engineering profession. I say to the students,—look into those industries, those walks of life where up to the present technically trained men have not been employed. There, your opportunity lies. These are openings in British Columbia for all we turn out. The best industry to get into is one that does not know it needs technically trained men. There is even room in the engineering profession. It will take the present graduates ten years to qualify as professional engineers, and what a tremendous expansion will have taken place by then! British Columbia will need them.

In the United States, such is the demand for technically educated men, that although the schools are turning out 485,000 men per annum, industry is exercised about its future supply.†

Two ways are open to ambitious youth, dissatisfied with his present prospects:—Leave the country or go to the university. The university is the one great stopper to emigration.

I repeat, gentlemen, not half of the science students will enter the field of engineering, so the university does not wish to give the Faculty of Applied Science a professional school label. It wishes to encourage all who can be induced to take this training, but it does not wish to push anyone into an engineering career, but to have this confined to those who cannot resist the call. I want you to remember your own attitude when you first became a free agent and authority tried to shove you where they had not the power to force you. The students today are just the same as when you arrived at college. It is thus, the work of the profession to interest those students who are thinking of becoming engineers. The initiative rests with the profession. The university wants the profession to take an interest in the students who are thinking of going into engineering, and in their welfare and training, and the university will co-operate heartily to this end.

Another question put to me was "Should engineering professors of the faculty be registered?" In other words. "A movement, such as the professional engineer movement, is judged by the world by the number of influential men supporting it." A number of the university faculty are not members, and it is suggested that I, as Dean, should urge them to register with the association.

Such influence or authority as I may have is academic and this is not an academic matter. It is bad policy to give an impression that one is using his academic influence in a matter entirely outside his academic jurisdiction. So I am the last man to be selected for such a task.

On account of the almost total absorption of the university staff in their work, there is a corresponding lack of initiative in outside interests. Members of the faculty who do outside work are naturally subject to the "Engineering Act" and thus are registered and are members of the Association of Professional Engineers. It is not surprising that those who do not do outside work are not registered and are not members of the association, nor is this uncomplimentary to the association. They are merely assuming that the professional engineers are competent to look after their own affairs without academic assistance. Speaking as a registered engineer, that is, as a member of the association, I say, if these professors would be of help to us, if their names and presence would be of value, how about making them honourary members,—honourary registration,—thereby, putting them under some obligation to the association? Then we would be free to call on them. Such an arrangement would be,—members of the university staff who practise, obtain registration in the ordinary way,—those who do not, receive honourary registration, but all are at your call for assistance and advice.

Now a word as to the relationship of the university to the engineering societies, and to the Association of Professional Engineers. The relationship is very close. To a limited extent the university can help the profession,—to an unlimited extent the engineers can help the university. University help is limited by the fact that no university savant has yet discovered how to get more than twenty-four hours into a day. No one outside of the university knows how completely the time of a conscientious professor is absorbed by his official duties. How little time there is for research, and without "research" teaching is work without inspiration.*

Further, every society with which our civilization abounds feels it has the right to call on the time and the interest of the professor. I suppose that upon no other class are so many demands made. There is a limit to the kind of appeal made to the church or to a service club, but there is not a mortal thing that any sport, or artist, or prophet, or fool ever conceived to be of any value, that the university man is not expected to support with his time and meagre allowance. For instance, I am severly criticized for lack of proper interest in societies for the advancement of science or engineering and complaint has been made to the president. As acting president, I have to jump on myself for this lack of interest. I am a convicted shirker, yet, Gentlemen, I do belong to some twenty of these Societies, and pay dues and am expected to take an interest in them and devote my time to them. Then there are the religious, military, cultural, social service, uplift societies ad infinitum et ad nauseandum.

The relationship between the engineering societies and the university I have said is very close; it can be made yet closer by the help of the profession. I have already referred to interesting the faculty and the students. Other avenues of help are:

1. Get the facts about the university and combat the stupid, ignorant criticism based on mere opinion and founded on imaginary facts,—the opposite of the truth. For example:

a. Students are spoiled as real workers.

b. Students are educated for the United States.

c. The province cannot afford higher education.

The province cannot afford not to have higher education. Our competitors are using technically trained men in every department. We cannot compete unless we also make use of knowledge and employ those who know.

d. Higher education costs too much.

e. Faculty of Agriculture useless and a loss.†

2. To create a demand for students by making industry and business see the possibilities in student labour.

3. To encourage donations for scholarships for research.

When graduates of applied science permeate industry then there will be a greater demand for professional engineers for they will realize how professional engineers may be employed and the value of their services. For instance, all mining is based on some geological theory. We give students a considerable amount of training in geology. Not that they may do their own geological work, for they cannot, but that they will know enough to employ geologists. And this is much needed, for notwithstanding that all mining is based on some sort of a geological conception, good or bad, of mining conditions, until two years ago there was not a trained geologist in the employment of a single mining company in Canada, while some United States companies were employing geological staffs stronger than most national geological surveys. Again, I know a man who has managed a specialty for thirty years. In this line, he will not risk one cent without technical advice, but in any other line, about which he knows nothing, he will risk any amount on his own uninformed "guess."

---

*At this point the Dean gave as illustrations the recognition afforded by the universities of Oxford, Princeton and Illinois, and then resumed.

†The Dean, here, showed that only eight per cent of university men in recent years left for the United States, and most of these for post graduate work.

*The Dean then outlined the value of research to the teacher, to the student and to the public, and added:

†The Dean here remarked that, "as he was not a member of the Faculty of Agriculture he was in the happy position of being able to refute such a stupid assertion." The Dean then gave many instances where the faculty saved to the province annually many times, over and over again, the cost of the faculty.

No, when technical men get into industry, it will be a brave day for engineers.

If we attract into professional engineering, only the students who are born with an engineering call, furnishing the students by a liberal education with abundant means to discover what is involved and with sufficient breadth to enable them to switch into some other pursuit if they find they are in the wrong field, we shall have done the most effective work possible for raising the status of the engineer. For it is the *men* who make the status of their calling. Laws do not accomplish, they merely register accomplishments. Those laws are laws that do enforce themselves.

Let us, as engineers, avoid that simple, pathetic faith in the efficacy of law that is making this continent ridiculous, and remember that no real results are yielded by legerdemain, but only by honest, patient, intelligent effort.

The "Engineering Act" will assist your work and your efforts; it cannot replace them.

CORRESPONDENCE

Why is the Educational Basis of the Engineering Profession Different to that of Law and Medicine?

The Editor, (*The Engineering Journal*)

Dear Sir:—

In connection with Dean R. W. Brock's address appearing in this issue, it is submitted that, although it is not within the province of the writer to question the views given from an educational aspect, yet, it is felt that interest in the profession warrants at least the following criticism, particularly in view of the importance of the questions arising therefrom.

The Dean is reported to have said:

> "The Faculty of the University object to the Department of Applied Science being labelled as an 'Engineering School,' as the law and medical schools are known."

Is it not then strange, this being the ruling principle, that degrees, or diplomas are given, not as Bachelors of Applied Science alone, but as Bachelors of Applied Science in civil or mining or electrical or mechanical engineering? Is not the addition of the words (Branch) engineering clearly a Professional label?

Does not the course as given in the calendar bear every indication of a professional label, when the courses are headed—"Courses in Civil Engineering—leading to a B.A.Sc. degree?"

Are not the courses popularly and rightly recognized as courses or instruction, not in applied science, but in engineering in all branches, and are not the graduates popularly and rightly recognized as chemical, civil, electrical, forestry, geological, mechanical, mining or structural engineers?

Why should not the engineering profession have its "Engineering Schools" in exactly the same way as theology, law and medicine?

CONDITIONS ARISING FROM THE OPERATION OF THIS PRINCIPLE

How would a lawyer or doctor regard the presence in the community of thousands of commercial men, salesmen, drug mixers, who were known and recognized as lawyers and doctors, who had received degrees—Bachelors of Science or Art—in law or in medicine, and popularly known as lawyers and doctors—where would be the professions (as known to-day)? Indeed the answer to this question seems to be that the professions of law and medicine would not exist as professions at all, but would be merely occupations.

Much more could be said on this subject. It is sufficient for the time and for the purpose, if this letter encourages the whole profession throughout the Dominion to study deeply the problem.

The writer begs to appeal to engineers more qualified than himself to speak on this subject, to give their views in future numbers of the Journal, and this appeal is made particularly to educationists who at heart and in heart feel the call for aid from every member of the profession.

Vancouver, B.C.

BOOK REVIEWS

Fuels and Their Combustion

By R. T. Haslam and R. P. Russel. McGraw-Hill, New York, 1926. Cloth, 6 x 9 in., 809 pp., illus., $7.50.

This book, just off the press, affords a most comprehensive review of present knowledge regarding the chemistry and engineering of the combustion of the standard commercial fuels. A certain portion of the given material is available elsewhere, but the present work presents within the covers of one book, a thorough treatment of the essentials of what is termed combustion engineering.

It is interesting to note, that in the chapter on combustion calculations, the authors present to their readers the concept of the pound-mol. This is the number of pounds of a substance numerically equal to the molecular weight. Therefore for all gases a pound-mol at 0° C. and pressure of 760 mm, will occupy 359 cu. ft. The use of the pound-mol is not as familiar to American engineers as its convenience warrants.

The authors present in logical order a description and a discussion on the origin and types of fuels, the extent of these resources, the fundamental chemistry of combustion, and the principles of combustion calculations. From this point they proceed to a discussion of the combustion of coal on grates and stokers, powdered fuel, the combustion of fuel oil, efficiencies, and gaseous fuels. A chapter on the carbonization of coal—obviously of profound importance for the future—closes the main portion of the work. It perhaps may be pointed out that this last chapter does not give sufficient prominence to the possibilities of low temperature carbonization, nor does it emphasize sufficiently the commercial results achieved at Fairmont by C. V. McIntire. Three valuable appendices are also included. These discuss flow of liquids, flow of heat, and the rate of heating. Much of the material in these three appendices has in the past been extremely difficult to obtain.

On the whole the present work is a valuable and very comprehensive addition to the library of fuel technologists.

LESSLIE R. THOMSON, M.E.I.C.

Combustibles Inferieurs et de Remplacement

By Pierre Appell. Gauthier-Villars, Paris, 1926. Paper, 5 x 8 in., 197 pp., illus., 20 fr.

A very complete review of the various fuels, such as wood, charcoal, coke, lignite, peat, coal, etc., commonly in use for domestic and power purposes in France. It contains tables and graphs of the quantities produced in France and in other countries, as also the characteristics of the fuels referred to. The production and uses of the various by-products are outlined and a number of interesting designs of furnaces, boilers, etc., are given as being adaptable for the different classes. It is a booklet well worthy of perusal by any one interested in the production and use of heat, not only in Europe but in America as well, for it refers to the fuels found in this country, as well as in Europe, and comparisons are drawn between the methods in vogue here and those in Europe. A useful bibliography is appended.

The Alouette Power and Storage Development in British Columbia

In the Vancouver Branch news appearing in this issue, there is a report of the visit of members of the Branch to the Alouette development of the British Columbia Electric Railway Limited. In view of the many interesting features of this development a brief outline of the entertainment is given below:—

Synopsis of Construction Features

The essential features in connection with the Alouette development are:

1. The Alouette dam, creating a storage reservoir, diverting the waters of the river into Stave lake.
2. The Alouette-Stave tunnel, leading from Alouette lake into Stave lake.
3. TheAlouette generating station, utilizing the fall between Alouette and Stave lakes.
4. A transmission line, connecting the generating station with the transmission system of the B.C. Electric Railway Company Limited, at Stave Falls.

All of these items have been completed with the exception of the generating station, which will be ready for operation in the fall of 1927.

The dam is an earth-fill structure built by the semi-hydraulic method. Clay excavated by steam shovel from the spillway channel was hauled on to the dam with standard-gauge railway equipment and dumped near the outer slopes of the dam. The dump piles were then attacked by the streams from hydraulic monitors which spread the clay in toward the centre of the dam, at the same time segregating out the finer material and washing this into the sluicing pond which was carried in the central portion of the dam. The fine suspended clay settling out of this pond forms the impervious core of the dam.

The tunnel is 3,485 feet long, with a section 12 feet wide by 16 feet high, excavated entirely in solid rock. It is unlined except near the entrance and exit, and for a short section where faulty rock was encountered.

The power house for the Alouette generating station will be a substantial building of reinforced concrete construction located on the shore of Stave lake. Extensive rock excavation will be required, extending 40 feet below high water level in Stave lake. There will be a single unit consisting of a 12,500 h.p. vertical reaction turbine, direct-connected to a 10,000 k.w. generator. The plant will be arranged for automatic operation with the starting and stopping controlled from the Stave Falls station.

The transmission line is 10½ miles in length and is of single pole construction with pin-type insulators carrying one circuit of No. O stranded copper designed for operation at 66,000 volts. The country traversed by the transmission line is very rough and most of the materials for construction had to be packed in on the backs of men.

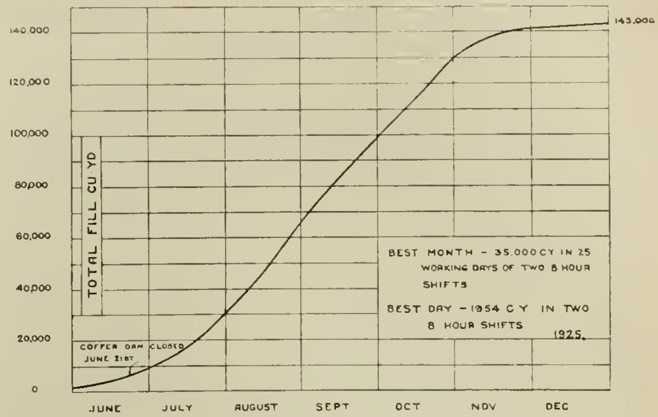

Figure No. 2—Chart of Progress in Placing Fill.

The record day in placing material in Alouette dam was when 1,954 cubic yards of material were washed into place in two 8-hour shifts, and the best month recorded a total of 35,000 cubic yards placed in 25 working days of two 8-hour shifts. In order to expedite the work, flood-lighting was used, which permitted uninterrupted progress.

Alouette Dam and Reservoir Statistics

Average annual precipitation at dam site	100 in.
Estimated drainage area	79 sq. mi.
Average runoff (133% based on precipitation at dam site)	779 c.f. s.
Design based on regulated draft of	700 c.f.s.
Elevation of natural lake level above sea-level	370 ft.
Difference between high and low reservoir levels	45 ft.
Storage capacity	170,000 ac. ft.
Average difference in elevation between Alouette and Stave lakes	138 ft.
Height of dam above stream bed	63 ft.
Length along crest	1,000 ft.
Width of crest	20 ft.
Upstream slope	3½:1 and 4:1
Downstream slope	2½:1 and 3:1

Yardage of fill:

Clay	108,000 cu. yd.	
Gravel facing	29,770 cu. yd.	
Rock paving	3,380 cu. yd.	
Cofferdam—enclosed	1,850 cu. yd.	
Total		143,000 cu. yd.
Total concrete		8,000 cu. yd.

Spillway:

Three stoney roller gates	18′ x 22′
Open weir—length on crest	348 ft.
Thirteen undersluice gates, 6′ x 7′, to augment low water discharge for log splashing.	
One logway bay, 10′ x 18′, for passing timber products	
Combined spilling capacity	30,000 c. f. s.

Figure No. 1—Compounding Water Fifty Feet above Former Lake Level.

Alouette dam is 1,000 feet long and 63 feet high, with a curved crest. The spillway is shown to the right. The width of the crest is 20 feet. The dam is of hydraulic fill construction, containing 143,000 cubic yards of material and 8,000 cubic yards of concrete.

Proposed Constitution for an International Standards Association

Following the announcement of the proposal to form an international body to develop and perfect industrial standards, which appears on page 307 of the June 1926 issue of the Engineering Journal, the following suggested constitution for this association will be of interest to the members of The Institute.

Section 1—*Title*. The name of the organization shall be the International Standards Association (I.S.A.).

Section 2—*Aims and Objects*. The aims and objects of the International Standards Association are:

(*a*) To lay the groundwork for international agreement upon standards by providing simple systematic means of interchanging information on the standardization work and activities in the different countries.

(*b*) To develop general guiding principles for the assistance of the national standardizing bodies.

(*c*) To promote uniformity among the standards of the various national bodies.

(*d*) It is the intention of the International Standards Association that its work shall include the approval of international standards, and the administrative machinery herein set up is so designed that it may be readily extended or modified to include the approval of such international standards when sufficient experience has been acquired.

Section 3—*Membership*. The International Standards Association shall be composed of the central National Standardizing Bodies existing in the different countries, one for each country, which have accepted this constitution.

Section 4—*Plenary Assembly*. (*a*) The chief executive body of the International Standards Association shall be the Plenary Assembly, composed of delegates nominated by the national bodies. The final authority rests with the national bodies.

(*b*) A Plenary Assembly can be called by the President, or in case of his inability to act, by two members of the Administrative Council. The Administrative Council shall call a meeting of the Plenary Assembly upon the request of—national bodies. The date and place of meeting shall be fixed by the Administrative Council. Six months' notice of a Plenary Assembly shall be given, except in the case of the first Assembly.

(*c*) The Plenary Assembly shall be presided over by the President of the National Standardizing Body in the country in which the Assembly is held.

(*d*) As a general rule, Plenary Assemblies will be convened once in three years.

Section 5—*Voting Power*. At a Plenary Assembly each National Standardizing Body shall be entitled to one vote only, either by person, by proxy, or by correspondence, whatever the number of delegates it may send to the meeting. All questions except those for which provision is made in this constitution shall be decided by a majority of the members voting.

Section 6—*Officers*. (*a*) The Plenary Assembly may confer the title of Honorary President on persons of distinction whose co-operation it is desired to enlist.

(*b*) The President shall be elected by the National Standardizing Bodies either in Plenary Assembly or by correspondence; he shall hold office for a period of three years and shall be ineligible for re-election until a further period of six years has elapsed.

(*c*) Each national body shall designate a Vice-President of the I.S.A.

(*d*) A General Secretary shall be appointed by the Plenary Assembly. He shall attend the meetings but without power to vote.

(*e*) The Officers of the International Standards Association shall retain office until their successors have been appointed.

Section 7—*Administrative Council*. (*a*) An Administrative Council shall be appointed by the Plenary Assembly and shall be composed of the President of the I.S.A. and four other members on nomination by selected National Standardizing Bodies, with a power for the President to call other persons to attend, but without vote. In the case of death or inability of the member to serve on the Administrative Council, the National Standardizing Body concerned may nominate one of its members to act in his place.

(*b*) Provision shall be made in by-laws for rotation in office.

(*c*) The Administrative Council shall call such meetings and take such steps as it may think desirable to facilitate the progress of the work. It can agree by correspondence.

(*d*) The Administrative Council shall be responsible for all financial matters.

(*e*) The Administrative Council shall take no technical decisions.

(*f*) The reports of the meetings of the Administrative Council shall be circulated to all member National Standardizing Bodies without delay.

(*g*) The travelling expenses of the members of the Administrative Council shall be paid by the respective National Standardizing Bodies.

(*h*) The Administrative Council shall meet at least once each year.

Section 8—*Central Office*. (*a*) The Plenary Assembly shall decide on the locality of the seat of the International Standards Association and the Central Office of the Association shall be established in accordance with this decision.

(*b*) The Central Office shall be under the supervision of the General Secretary acting in accordance with the instructions of the Plenary Assembly and of the Administrative Council.

(*c*) It shall be the business of the Central Office to circulate among the members all information available as to standardization matters of importance to the work of the Association and in every way to further international agreement on such matters.

(*d*) Formal business of the International Standards Association shall be conducted by correspondence between the Central Office and the National Standardizing Bodies.

Section 9—*Technical Committees*. (*a*) Technical Committees are committees appointed for the purpose of studying technical subjects having an official status in the Association, as provided in Section 10 (*a*) and (*b*).

(*b*) Each technical committee shall consist of one official delegate from each of those National Standardizing Bodies desiring to take part in the work of the Committee. Additional unofficial delegates may be appointed.

Section 10—*General Procedure*. (*a*) On receipt of a request from one or more Member Bodies to study a technical subject, the Central Office shall at once inform all Member Bodies, asking whether they are in favour of a Technical Committee being formed to study the subject, and, if so, whether they wish to nominate a delegate, should a Technical Committee be formed. The Central Office shall then place the matter before the Administrative Council, together with the replies received.

(*b*) If the majority (not being less than three) of the members voting are in favor of a Technical Committee being appointed, then such committee shall be appointed by the Administrative Council. [See Section 10 (*j*)].

(*c*) Before a Technical Committee is organized, the scope of the work, or terms of reference, shall be clearly outlined, and no Technical Committee shall go beyond the work outlined for it.

(*d*) The Administrative Council, in consultation with the Technical Committee concerned, shall appoint either the Central Office or one of the National Standardizing Bodies to act as Secretariat for that Technical Committee. The Secretary so appointed shall be responsible to the Administrative Council for the work, including all correspondence.

(*e*) Meetings of Technical Committees shall be arranged in consultation with the delegates, either by the Central Office or by the National Standardizing Body appointed to act as Secretariat for the subject in hand.

(*f*) The General Secretary ex-officio shall have the right to attend all meetings of the Technical Committees and take part in the discussions, but without the power to vote.

(*g*) A report of each Technical Committee meeting shall be sent to the members of that Committee and to the General Office.

(*h*) The Administrative Council shall be authorized on behalf of the Association to instruct the Central Office to keep all national bodies in touch with all subjects having official status, by reports and memoranda. This is a general rule, action not being required in individual cases.

(*i*) The Secretary of any Technical Committee shall submit the proposals of that Technical Committee to the National Standardizing Bodies appointing delegates. When the Technical Committee has reached agreement, its proposals shall be sent to the Central Office to be dealt with in accordance with Section 10 (*h*).

(*j*) If a request has been received from one or more bodies for a Technical Committee, but it has been decided not to appoint such a Committee, then the group of national bodies interested in the

---

Unanimously agreed upon by the Third International Conference on Standardization, New York, April, 1926.

subject shall be encouraged to come to agreement with regard to them. Such an agreement shall not be considered as a decision of the Association.

SECTION 11—*Units Employed.* English and metric measures shall be used in the published recommendations of the International Standards Association. Conversions shall always be given unless otherwise decided by the Administrative Council.

SECTION 12—*Funds.* (*a*) The financial support of the central office shall be divided into three parts:

1. A sum amounting to 25 per cent of the total budget divided equally among the national bodies.
2. A sum amounting to 50 per cent of the total annual budget divided in proportion to the average total foreign trade of each country during the preceding three years.
3. A sum amounting to 25 per cent of the total annual budget divided in proportion to the population of each country.

NOTE: Assuming a first budget of £2000 per year, these amounts would be:

1. Fixed sum for each national body....................£25
2. For every hundred million pounds total foreign trade..£12 10s.
3. For each million inhabitants...........................£1

Increases in these amounts in subsequent budgets shall be subject to the approval of the national bodies.

(*b*) Each National Standardizing Body joining in the work of the Commission shall agree to contribute to the expenses of the Commission for three years and shall give not less than one year's notice if they desire to retire

(*c*) In the event of the expenses in any one year being less than the amount contributed, the Administrative Council shall establish a Reserve Fund, and fix the maximum, after which any sum unexpended shall be deducted from the contributions due from the National Committees for the subsequent year pro rata.

SECTION 13—*Accounts.* The accounts of the Central Office, which shall be made up annually to the 31st December, shall be submitted to the Administrative Council before the 31st March in each year and shall be signed by the President and by the General Secretary. In the case of the inability of the President to do so, they shall be signed by one of the other members of the Administrative Council on his behalf. The report of a professional auditor shall be accepted as proof of the correctness of the accounts.

SECTION 14—*Alteration of Statutes.* Any future alteration to these Statutes can only be effected by a vote of four-fifths of the participating National Standardizing Bodies and after ratification by a Plenary Assembly.

SECTION 15—*Liquidation.* In case of the International Standards Association being dissolved, the Administrative Council shall decide upon the disposal of the remaining funds.

Agreement Reached Looking to Preservation of Niagara Falls

In a statement issued to the Press, the Honourable Charles Stewart, minister of the Interior, announces that an agreement has been reached with the United States looking to a study of the problem of preserving the scenic beauty of the Niagara falls.

Mr. Stewart stated that it has been a matter of common knowledge that the Horseshoe falls are progressively receding upstream in a manner which materially alters the general appearance of the falls from year to year. Periodic surveys of this crest line have been made from the year 1764 to date. These surveys show that the average recession of the escarpment in that period has been some 650 feet, or an average of 4 feet per year. While the recession has been widespread along the crest, the maximum rate has taken place in the bend of the Horseshoe and has totalled in the same period to 820 feet. During the period 1917 to 1925 this maximum rate of recession has proceeded at the rate of seven and a half feet per annum.

It is the judgment of close observers of the falls that the rate of recession in the notch of the Horseshoe will progressively increase since more and more of the total flow is being continuously concentrated at this point, and this in turn is resulting in a faster and faster rate of recession. This has frequently been referred to as the "suicide of Niagara Falls."

The recession of the notch of the Horseshoe has had the effect of withdrawing water at an ever-increasing rate from the escarpment forming the ends of the Horseshoe on either side of the river, leaving these sections at times and in places totally without flowing water. The withdrawal of water under treaty provisions for power purposes has in some quarters been credited with laying bare of the borders of the Horseshoe falls. Some observers, however, consider that a greater effect arises from the natural process referred to in the foregoing and that the withdrawal of water for power purposes, by reducing the total volume, has to some extent at least, been instrumental in retarding the rate of recession in the notch of the Horseshoe and to this extent has been beneficial.

While the investigation which has been agreed upon by the two governments has primarily in view the study of the conditions which have been and are adversely affecting the scenic beauty of the falls, with a view to designing such remedial works as are feasible for the protection of the falls from further erosion and for the preservation of their scenic beauty, the study will also include an investigation into the total amount of water which, in conjunction with the installation of remedial works and consistent with the restoration and maintenance of the scenic beauty of the falls, could be released for the development of power. The board will not consider the question of allocation as between Canada and the United States, of any additional water which it may find could be made available. This is a matter reserved for subsequent negotiation.

The investigation will be carried out by an International Niagara Board of which J. T. Johnston, M.E.I.C., director of water power and reclamation, and Dr. Charles Camsell, deputy minister of mines, are the Canadian members, and Major D. C. Jones, of the United States Corps of Engineers at Buffalo, and J. Horace McFarland, former president of the American Civic Association, are the United States representatives. The board's report will be submitted to the two governments for their respective consideration.

Survey Parties engaged in Mapping Canada

The following members of the Engineering Institute are engaged on topographical, control, and aerial surveys this season:—

TOPOGRAPHICAL SURVEYS

Topographical survey parties are engaged in various districts across Canada mapping on different scales and by different methods.

C. H. Taggart, A.M.E.I.C., is using photo-topographic methods in completing the mapping of an area surrounding Kamloops, B.C.

W. Christie, M.E.I.C., and F. H. Wrong, A.M.E.I.C., are revising the Victoria Sheet of the Sectional Map, on a scale of one inch to three miles, and G. C. Cowper, A.M.E.I.C., the Battleford sheet.

P. E. Palmer, A.M.E.I.C., is finishing the field work for Sheet M 13 N of the one millionth international map of the world.

In Quebec, C. Rinfret, A.M.E.I.C., is making plane table surveys of the Shawinigan area.

In Nova Scotia, A. L. Cumming and G. A. Bennett, A.M.E.I.C., are similarly mapping the Windsor area.

CONTROL AND AERIAL SURVEYS

G. H. Blanchet, A.M.E.I.C., is continuing explorations and lines of control surveys in the Northwest Territories. During the season he is to explore the Wood Buffalo reserve and report on its possibilities for supporting the present number of buffalo and any future increase in the herds.

C. S. Macdonald, A.M.E.I.C., in Northern Saskatchewan, S. D. Fawcett, A.M.E.I.C., in New Ontario, and L. Brenot, A.M.E.I.C., in northern Quebec are obtaining sufficient ground control to enable plotting aerial photographs of these areas.

J. Carroll, A.M.E.I.C., and C. B. C. Donnelly are acting as navigational officers with the sea planes of the Royal Canadian Air Force.

B. W. Waugh, M.E.I.C., is obtaining horizontal and vertical control for the Fredericton sheet, New Brunswick, and P. M. H. LeBlanc, A.M.E.I.C., is doing the same for the Shawinigan area in Quebec.

Map of Kootenay Park, B.C.

Another new map just off the presses of the Topographical Survey, Department of the Interior, is of Kootenay park in British Columbia and shows a portion of the route of the Banff-Windermere highway, nearly sixty miles of which lies through the centre of this park. The map was printed for the Canadian National Parks Branch, Department of the Interior, Ottawa, and will be distributed by that organization.

The Application of Engineering Methods of Analysis to Financial Investigations

W. W. Colpitts, B.Sc., M.Sc., LL.D., M.E.I.C.
Consulting Engineer, New York, N.Y.

Address before the McGill Chapter of the Society of the Sigma XI, Montreal, March 23rd, 1926

It is not so long ago as to be almost within the memory of men now living that most of our industries were owned either by individuals or by a small group, and financial transactions involved little more than taking money into the till and paying it out again. The amount taken in, in a year, less the amount paid out, measured the year's profit. Accounting was just about as simple as that.

But as our industries grew, and more particularly in the building of our railroads, large amounts of capital were required, and to secure this capital it was necessary to devise different types of securities to suit the widely different views of investors. Before an investor of one class would venture his savings in the enterprise he wanted to know for a certainty that his interest would be paid to him regularly and his principal returned when due. He was not gambling or speculating, he was investing. The mortgage bond suited him.

Another wanted security, but like most of us he liked the idea of participating in the profits as well. For him preferred stock was invented.

Another wanted to rise or fall with the enterprise and the common stock was the class of security that appealed to him.

If you think back you will realize that comparatively few of the business enterprises of the country have been complete failures but a very large number have been failures in one degree or another. That is to say there are all sorts and degrees of failure and the measure of failure may be said to be the extent of the company's inability to meet the bed rock expectations of its promoters as expressed by the fixed interest requirements of its debts.

A fixed interest requirement, when it represents a considerable part of a company's net earnings, has done more, in my opinion, to cause the failure of sound business enterprises than any other agency for which man is responsible and I would like to take the time to tell you why I think so.

Let us take an extreme case for purposes of illustration. Assume that two companies doing the same class of business and of about the same volume are started off at the same time. One secured its funds to a large extent by the sale of bonds and to a small extent by the sale of stock; the other wholly by the sale of stock.

We will say that for several years each pays about the same return to its security holders.

As is inevitably the case in every business, these two companies run into a period of hard times. The first is obliged to pay its interest to keep solvent, but its officers firmly believe better times are just around the corner. Usually, however, their optimistic hopes are not realized and business gets worse instead of better and to meet the interest payments they reduce the inventory, suspend payment of bills, sell any marketable securities the company may own, perhaps make short time loans from banks or individuals and thus pile up a large floating debt in addition to the mortgage debt. During such a period the company almost invariably fails to maintain its property adequately. It is no time to put in new machinery that would tend to improve the product or reduce its operating cost, and finally, if this condition continues long enough, the company is unable to pay the next installment of interest and a receiver is appointed. It has failed.

Now what of the other company ? Its owners, in my opinion, were better gamblers to begin with, and I use the word gambler in the best business sense as men with nerve and foresight, men who are willing to take their chance with the business and to forego profits when times were such that the company could not earn them.

In the period of hard times that we have just brought into the lives of these two companies, the second immediately reduced its dividend. When times became harder still, the company suspended dividends altogether. But each year there was a surplus which was devoted to the improvement of the plant and product. When times got better this company was able to expand, in all likelihood absorb a considerable part of the business of the first company, and resume dividends at perhaps a higher rate than formerly.

Now in point of fact, did the man who invested in the first company actually make his investment more secure by buying bonds instead of stock? What he really did, and what in fact very many men have actually done, was to buy the right to strangle the company when it most needed relief, and for this right he paid a higher price than did the man in the second company who bought stock. Of course, as I said in the beginning, this is an extreme case, but it has been made so purposely to illustrate the point.

Now let us look at this matter from the standpoint of the ability of large industrial concerns, over a long period of years, to earn a fair return on their investment, which fair return we ordinarily regard as 6 per cent. Of course, we all know of instances where much larger returns than 6 per cent are made on invested capital. Many sound industries make very much more for short periods and sometimes even for long periods, but as a percentage of the capital invested in all of the industries of the country, they are relatively few and do not appreciably affect the long time average.

I believe very few people realize how low the average earnings of money invested in business enterprises really are. It is said that the island of Manhattan was bought from the Indians for $24.00 a few hundred years ago, which seems cheap enough, but the astonishing fact about this purchase is that this $24.00 if invested at 7 per cent compound interest for the period since the purchase was made would amount to several times the total assessed value of Manhattan island realty to-day; and yet in all probability the increment of increase in value of Manhattan island has been greater than that of any other real estate in the world.

This is only another way of saying that average earnings over a long period are not nearly as large as we are accustomed to think they are, and when we erect a financial structure that makes it obligatory upon a company to pay out in interest charges year by year an amount that represents what we normally regard as a reasonable return on the actual investment, we are likely to lay up trouble for the future.

This, in fact, is the very difficulty that is facing many financiers to-day. The ease with which money can be gotten by the sale of bonds rather than stock is a temptation to mortgage a property for its full value. Cases have been cited where the interest charges on the bonds amount to more than any reasonable expectation of earnings of the property, and yet you and I buy bonds of this character thinking we have security merely because we have a mortgage.

In the early days of railroad construction in the United States most of the different classes of railroad securities were invented that are in use today. But in many cases the bonds alone represented real money. The stock was largely given to the bondholders as a bonus and to the promoters for their services. Even in such cases the bonds were often sold at a discount. As a result, the face value of the bonds was often greater than the actual amount of cash invested in the enterprise. Many of these companies flourished for a time until from without, the inexorable laws of competition and the hand of regulation, and from within the even more inexorable law of depreciation, began to make themselves felt. These companies could not in a few years, notwithstanding their great size and strength, raise the level of the average return on invested capital and as a result a very large part of the railroad mileage in the United States has at one time or another been in the hands of receivers. Many companies have suffered this experience a number of times and in some cases the old bonds are now, through one reorganization after another, wholly represented by stock.

There are over twenty billions of dollars invested in the railroads of the United States and railroad investment is normally regarded as profitable, yet the Transportation Act of 1920 provides that rates shall be fixed, as nearly as may be, so that the annual net earnings in the aggregate shall equal 5.75 per cent of the value of the railroad property. As a matter of fact in not a single year since the act was passed, except 1925, have the earnings nearly equalled that rate. The 1925 earnings were nearly that amount based upon the Interstate Commerce Commission's valuation, but this valuation is regarded by railroad officers as entirely too low.

If then, the average earnings of money over a long period of time are less than 6 per cent it is apparent that when a large percentage of these earnings is committed to fixed interest requirements, often at a rate considerably higher than 6 per cent, the margin of safety for lean years may be nothing, or less than nothing.

To my notion therefore, the adjustment of a company's capital, particularly its fixed interest bearing capital, to its earning power is one of the most important matters to which financiers should give consideration. Most of the failures to which my attention has been drawn have been due to inability to pay interest during periods of depression, and as our companies are managed by boards of directors, elected by the stockholders, it is only human that a board will view the company's prospects from the standpoint of the stockholders, and in the effort to avoid a receivership and the consequent depression in the value of the stock, and a lowering of the company's credit will allow the property to run down and otherwise curtail expenditures, and the inevitable result of such a procedure is to depreciate also the security behind the bonds.

Now, I want to say that I am not in the least opposed to corporations borrowing money whether on bonds or notes. What I want to emphasize is that, from the point of view of investors, many corporations borrow too much money. Over-borrowing usually takes place in good times, when there are no clouds on the business horizon, when everybody is feeling optimistic, even the banker who arranges the loan, and bankers are supposed to be proverbially pessimistic.

It is not the low average return on investment that bothers business concerns, or the rates that bankers must charge for the use of money, but rather the failure to realize and provide against the wide fluctuations in earnings in connection with the amount of the loans, and the fact that interest must be paid each year whether earned or not. When the capital raised by borrowing is a large percentage of the total capital of the company and bad times come, as come they always have and probably always will, whether due to a general business depression, inherent peculiarities of the business, competition, new inventions which render processes obsolete, or what not, and the leeway between interest and earnings disappears altogether or even becomes a minus quantity, then there is real trouble ahead for everybody, whether stockholders or bondholders.

The railroads of the United States are perhaps as stable business enterprises as we have, yet the fluctuations in the railroad business are sometimes very wide both in individual cases and as a whole. The average percentage of bonds to total capitalization is somewhat over 60, and this being an average, there are, of course, many roads whose bonds bear a much higher proportion than this to the total securities outstanding.

My own feeling is that the man whose inclination would be to invest only in high grade securities, (and that usually means bonds), would often be better secured, if the capital of the company in which he was an investor were represented only by stock and he a stockholder, instead of a bondholder; and recently in the reorganization of a railroad company in which we had a voice, our views in this respect prevailed to the extent that no bonds whatever were issued, and I might add that the company has since prospered beyond our expectations; but I might also say that when it again needed money it issued bonds.

As a matter of fact the reorganization which follows the bankruptcy of a company is usually in its rough essentials merely the process of converting the senior bonds into junior bonds and the junior bonds into preferred or common stock. In other words, if the financial structure had been designed in the first place with a larger percentage of stock to bonds or entirely without bonds, the stockholders would have had to forego dividends during the period of the company's rehabilitation but the company would not have become bankrupt and in due course would have recovered.

The most a bondholder can hope for is that his interest will be paid promptly and his principal returned when due. But the dollar returned is not usually worth nearly as much in buying power as the dollar he loaned, or at least such has been the tendency for many years. For my part I would rather be a stockholder in a going concern with an interest in a property that is steadily appreciating in value than a bondholder whose best prospect is to be paid in a depreciated dollar.

I said a moment ago there were perhaps two reasons which might be stretched to the point of justifying my appearance before a scientific society, the first was some slight connection with the great invention—interest; the second is in the field of discovery.

It seems to me that throughout my career as a consultant on corporation business, I am constantly rediscovering an old truth, and that is that things are not always as they seem.

I think this is best exemplified in the case of the most recent railroad financial disaster, that of the Chicago, Milwaukee and St. Paul. So prone are people to take appearances at face value that there are a great many very influential people in the United States to-day who do not believe that the receivership of the St. Paul was necessary.

The circumstances that led to the St. Paul receivership are now under investigation by the Interstate Commerce Commission and I do not wish to appear to prejudge the question at issue; but it is a subject that I want to talk to you about for a moment because in several of its aspects it illustrates the points I have just made, and the lessons to be drawn from the experience of the St. Paul are of the greatest importance.

The St. Paul was before the receivership and is to-day a magnificent railroad of 11,000 miles, one of the largest in the world.

Just now it is commonly referred to as the biggest financial failure in history. But it did not completely fail by any means, it merely found itself in a position where it was unable to meet all of its obligations.

As a matter of fact, while the difficulties of the St. Paul culminated in 1925, they really began with the construction of the Puget Sound Extension which was commenced in 1906, and opened in 1909. Prior to that time the company was in a strong position with a financial structure that was amply able to supply the needs of its growing business. Its preferred stock was selling at 170 and its common at 110. It was therefore able to meet all of its requirements for additional funds by the sale of preferred and common stock. In connection with what I have just said in relation to fixed interest obligations an important fact to bear in mind, as measuring its ability to weather the storms of business depression, was that at that time only one-third of its outstanding capital was represented by fixed interest bearing securities and two-thirds by capital stock, whereas these ratios at the date of receivership, March 17th, 1925, were exactly reversed, that is two-thirds of its capital was represented by bonds and one-third by stock. At the earlier date the percentage of bonds to total capital was much lower than that of the average of all of the roads in the United States, at the later date it was much higher. Had it been possible to have maintained the ratio of bonds to stock of the earlier date throughout the subsequent period the railroad would not be in the hands of receivers to-day and I think it is safe to say that a large part, at least, of the depreciation in the market value of the company's securities as a result of the receivership would not have occurred.

But to state the facts in this way is merely to state effects rather than causes, or in engineering terms to compare the cross-section of the company's affairs as of 1909 with that of 1925. The causes which led to the change in its situation and the cure were not so easy to ascertain or to state. Were they easy, my firm would not have been engaged to make an investigation of the company's affairs and I personally, upon whom the work devolved, would have been spared a lot of trouble and worry and misrepresentation.

The purpose of the investigation for which we were engaged was to determine the best course to pursue in the interest of all security holders in view of the pending maturity of about $75,000,000 of bonds of which $48,000,000 were due in 1925, $3,000,000 in 1926 and $25,000,000 in 1927.

I might say that when I began to look into the affairs of the company I had no thought that the ultimate outcome would be a receivership. The resources of the company were generally thought to be so large, its pre-war record so good, its gross earnings so enormous that I shared the optimistic views of the officers and directors that some course could be devised to tide the company over its difficulties.

It occurs to me that perhaps the methods used in examining the company may be of interest to you.

As a preliminary to the real work of the investigation I made a trip of inspection over the company's main line from Chicago to Seattle. An inspection of the physical property is an important part of an examination of a railroad company's financial status. It is necessary to know the condition of the property, (including roadway, track, buildings, machinery, equipment and all other physical elements), both for the purpose of ascertaining the amount of money that must be expended upon it for maintenance and rehabilitation, to determine its adequacy for the work demanded of it, and to be in a position to estimate the requirements of the future. But this inspection trip was not wholly as its name implies for the purpose of observing the physical condition of the property, but was also planned as a means of bringing all of the officers together under one roof, as it were, for discussion of the company's problems, free from interruption so that each officer, irrespective of rank, could be interrogated and given an opportunity to express his independent views concerning those matters with which he was personally familiar.

The story of what happened to the St. Paul is rather a long one, because so many things happened to it, but I will try and condense it into a few words.

As I stated a few moments ago its troubles began with the construction of the Coast Extension which was completed in 1909. If any of you Canadians should be tempted to build another line to the Pacific coast and feel that your own experiences do not furnish sufficient warning not to do so, I suggest that you meditate on St. Paul.

To those who are inclined to criticize the St. Paul management for building the Coast Extension, let it be said in the first place that our hind sight is better than our foresight. At that time trade was booming with the Orient; the lumber industry was growing rapidly; important mining developments were under way; gold had been discovered in Alaska; federal, state and private irrigation projects were being built and as a result the Northern Pacific and Great Northern railroads were doing a heavy business. To participate in this rapidly growing traffic the St. Paul directors decided to build to the coast. Unfortunately, no sooner had the line been completed than the building boom in the Northwest subsided. The lumber industry has remained practically stationary ever since. To make matters worse, the development of the Northwest has been retarded by restrictive immigration laws and immigrants who had been brought over at the expense of the Canadian Government could no longer, in such numbers, at least, be induced to move across the line.

As a result, the St. Paul's Pacific Coast Extension, which includes 3,000 miles of line and cost $252,000,000, in the best year of its history, 1924, earned but 6/10 of one per cent on this investment, notwithstanding the fact that it was supported at its eastern end by 8,000 miles of railroad comprising the balance of the St. Paul system and situated in the heart of the agricultural section of the country.

But this was only one of the St. Paul's difficulties. In recent years not only has the competition of the older established lines been keener but new transportation agencies have come into the field which have affected all railroads alike. Your newer Canadian transcontinental lines, the Canadian Northern and Grand Trunk Pacific, have not been an inconsiderable factor in contributing to the troubles of the St. Paul. Knowing something of the history of the Canadian National lines, I have no doubt you feel you have railroad troubles enough of your own without shouldering any part of the responsibility for the troubles of lines on the other side of the border; and I think, as a Canadian born, I should be inclined to share that view with you and will not pursue the subject further.

As a matter of fact, though, in respect of competition, the new agencies that have most adversely affected the company have not been other railroads at all but the Panama canal in freight transportation, and the motor vehicle in passenger transportation.

I feel certain that if the effect of Panama canal competition could have been foreseen the St. Paul's Coast Extension would never have been built. The extent to which the canal route has grown in popularity with shippers may be judged from the fact that freight transported through the canal increased from 5,000,000 tons in 1915 to 27,000,000 tons in 1924. Of the traffic of the later year, eliminating 16,000,000 tons of California oil and other tonnage that would not in any case have moved across the continent by rail, there remain 11,000,000 tons in which the transcontinental lines would have participated had the canal not been built. And it seems to me that with improved refrigeration on ships, larger and better vessels and a reduction in operating costs, that the canal route will continue to grow in favour and that this prospect must be frankly faced by the transcontinental lines.

Now let us see what this 11,000,000 tons would have meant to the railroads had the canal not been built. There are ten transcontinental lines by which this traffic might have been moved, and if we assume that the St. Paul would have moved one-tenth of the tonnage this would be equivalent in transportation units to 2,200,000,000 ton-miles, or just one-fifth of the total ton-mileage of the St. Paul for the year 1924. This traffic could have been moved at much below the company's average operating ratio since a great many items of expense would not have been affected by it. It is probable that this traffic would have added about $8,000,000 a year to the net revenue of the company, which would have been much more than sufficient to have offset the deficit; and that portion of this revenue accruing to the Pacific Coast Extension would have raised the return on the investment of $252,000,000 in that property from 6/10 of one per cent to 2.5 per cent, which, though still a low rate of return, would easily have saved the company from default. One of the major considerations in building the Pacific Coast Extension was to participate in the movement of this traffic, and it will be seen from what I have said that the heavy loss of revenue entailed in the diversion of this traffic to the canal has been a great disappointment to those who promoted the building of the extension.

I do not know a better ocular demonstration of unrealized hopes than is to be found in the docks and warehouses at Tacoma and Seattle built by the company to accommodate transcontinental and trans-Pacific traffic that unfortunately never materialized. At the time of my inspection not a vessel was at the docks and the freight in the warehouses would scarcely have filled an ordinary room. The sense of desolation about these enormous works was oppressive, yet there are those who contend that the Panama canal has not adversely affected the traffic of the transcontinental lines.

I mentioned a moment ago the disastrous effect of motor vehicle competition in passenger transportation. This is an item which cannot be accurately measured. We know this, however, that notwithstanding improved service the St. Paul's passenger revenues declined from $31,000,000 in 1920 to $21,700,000 in 1924, a loss of $9,300,000, or 30 per cent in only four years. We know also that the registrations of motor vehicles in this territory doubled during this period and that the business of the Northwest expanded, and but for motor vehicles the passenger business of the line would undoubtedly have increased. It is apparent, therefore, that the loss from this source is even greater than that indicated by the figure I have just mentioned. The saddest phase of this story is that this loss is wholly a net loss because the company performed more passenger service in 1924 than in 1920.

I firmly believe that but for these two sources of loss the St. Paul would be a prosperous road to-day and that rate reductions of considerable proportions would have been possible in the western territory where the farmers are in greatest need of such relief. I think it could be said also that the inability of the railroads to reduce rates in the Northwest because of canal competition, has placed a burden upon the people of that territory that they should not be required to bear. The lower rates of the canal route benefit the country as a whole but the effect of canal competition upon the railroads is borne in large measure by the people of the Northwest, and these people, because of the unfavourable agricultural situation of the past few years, have been less able to sustain that burden than the people of any other section of the country.

So far I have spoken only of some of the occurrences which contributed to the inability of the St. Paul to meet its obligations. Now these troubles did not all fall upon the company at once. Instead they came in series—one following another. And throughout the long period since its difficulties began the officers and directors believed, (until shortly before the receivership), that better times for the company were not far off. So prone are business men, and I think more particularly American business men, to view the concerns in which they are interested through rosy spectacles that when drastic action is required to restore sound condition in a company's affairs it is almost inevitably too long delayed. And such was the case with the St. Paul.

We found for example that through pressure to meet its various obligations its position with respect to current assets and current liabilities had reached a condition that was embarrassing to the management. At the time of our examination there was a net deficit in current position of over $13,000,000.

A brief résumé of the company's financial transactions for the four years ended December 31st, 1924, is illuminating in this connection, one result of which was the deficit in current position.

The deficit in earnings after payment of interest was	$20,700,000
Additions to road and equipment amounted to	26,700,000
The increase in advances to subsidiaries was	3,100,000
And various small investments amounted to	1,500,000
A total of	$52,000,000

Now, what was the source of this money, a large part of which it will be noted, was required to meet interest obligations?

Bonds were issued which netted	$29,500,000
Materials and supplies were liquidated to the extent of	6,900,000
Net current assets were reduced	5,800,000
A bank credit was supplied of	2,300,000
Investments were sold amounting to	1,500,000
Various other items netted	6,000,000
An equal total of	$52,000,000

In other words, the company during this period had to a large extent been living on its assets.

Let us now consider the matter for a moment from the standpoint of what was to be done in those circumstances.

A careful estimate of probable future earnings was made in which all factors having a bearing on the subject were taken into consideration and numerous sources of information were consulted. This estimate showed that it would be several years before the company could earn the fixed charges on its present capital, not to mention interest on the new money which must be invested in the property from year to year to enable it to meet its obligations as a common carrier in adequately serving the public. Without these annual expenditures for new equipment, for roadway improvements and the numerous purposes for which funds must be provided, no railroad can hope to maintain a position against the competition of other lines. I might add that the actual results of operation show that our estimate for the first year was a fairly accurate forecast.

The conclusion reached in this connection was, of course, only one measure of the credit position of the company. Its inability to earn its interest charges over a period extending even to several years would not of itself have brought about a receivership, providing the company possessed other resources from which the deficiency might be made good until such time as its net earnings equalled or exceeded its interest charges, but as might naturally be expected under these circumstances we found in making a survey of what may be termed its treasury resources, that the company was in an unusually weak position because of the fact that it had from time to time, in past years, used up practically all of its resources of this nature that might now be available as new financing media. The only assets possessed by the company that could be considered as in any sense available for raising money were $9,000,000 General Mortgage Bonds, selling at a considerable discount, $44,000,000 General and Refunding Bonds, saleable only at a very heavy discount, and a small amount of capital stock, also selling at a very great discount, and the stock of the Milwaukee Land Company owned by the railroad company.

The Milwaukee Land Company owns large tracts of timber lands in the west and was organized to furnish traffic to the railroad. While its holdings will ultimately be of considerable value, they are not such as to be quickly realizable except at a great sacrifice, and after a careful examination it was found that their value for borrowing purposes was surprisingly small.

Briefly then, to sum up, we found the company in this position:

1. Its earnings for years past had been quite insufficient to meet its interest charges.
2. Its position with respect to current assets as against current liabilities was decidedly weak.
3. For several years the company had been obliged to resort to the measure of depleting its treasury assets in order to meet its current obligations.
4. The estimates of earnings offered no prospect of relief in the immediate future.
5. The company possessed no current or convertible assets that could be considered as at all adequate in the circumstances to employ in the formulation of new financial plans, except such as would only postpone the evil day, and its financial structure was so designed that it was not possible to issue and sell additional securities in sufficient amounts to provide the new money to meet its large maturities and for new capital requirements.

Notwithstanding our regret that such should be the outcome of our investigation we could see no other course in the interest of all concerned than a readjustment of the capital structure, and that was our recommendation.

This recommendation necessarily involved a receivership and the process of readjusting the securities is now being carried out through a plan of reorganization formulated by Kuhn, Loeb and Company and the National City Bank of New York.

If as a student in engineering at McGill I had listened to a talk such as I have just made I would have said, "This may be interesting to others but what has it to do with me—an engineering student ?" I would like to take a moment to answer that question, because it seems to me that the answer possesses points of great interest to students of engineering.

I believe the scope of the engineer is broadening far beyond our realization, not only in technical work but along the lines of practical everyday business. It is not so long ago that engineers were regarded as being wholly without business sense—and that feeling was expressed in the facetious definition of an engineer, that he was a man who could do anything except earn a living for his family.

I do not know whether engineers have taken that characterization to heart, or whether it never was true, but the fact remains that engineering advice is coming to be more and more sought upon subjects that wholly concern the business phases of industry. After all it is as much the job of the engineer as the business man to make a dollar earn the largest return. There is perhaps not the romance in the business phases of an enterprise that there is in technical engineering work but it is quite astonishing to those of us who have been on both sides to find how much adventure lurks in the problem of setting a new dollar to work or of stirring up an old one. I believe that engineering is the greatest of all professions, and I also think that its pleasantest phases are to be found in construction work. But the fact is that there is no more delightful indoor sport than spending other people's money, and particularly when in doing so one can build a monument to himself. This sort of sport, however, is not always healthful from the standpoint of the stockholders of the company. And it is the desire to build too well for the purpose, to build ahead of the times and having to wait too long for a return, that has been the cause of many business failures. We have had an example of it before us for many years in the case of the old Grand Trunk Railway. We have had it in many other railways—some of which should never have been built at all. We have had it in the case of irrigation projects where it should have been foreseen in the beginning that the outgo would exceed the income for many years to come.

In fact we have these examples of unwarranted expenditures before us all the time but we go right ahead creating new ones. Now why is this ? I think there are several reasons for it. It is easier to explain the mistakes of the past than to foretell the mistakes of the future. It is due to over enthusiasm for the project both on the part of the promoter and the engineer and the failure to gather the evidence against the project as well as for it, and to give each its proper weight. I think we all naturally revert from discussions of the possibility of a mistake and dwell more often on the pleasanter subject of rosy prospects.

The reason I speak of these things is because I believe the man with an engineering training is splendidly equipped to solve business problems, particularly if he has the knack of the diagnostician. While engineering is not an exact science it is more nearly so perhaps than any other. In technical practice the engineer deals with the forces of nature which operate with exactness and his mistakes come home to him at once. He cannot be half right and get results. He must be all right. Therefore in his college training and later in his practice he learns to weigh all sides of a question. He must be careful, methodical, accurate and above all things he must be without bias. Now when he applies this training and habit of thought to a business proposition it is to be expected that he will reach sound conclusions.

And so we find that the engineering profession is not only broadening its scope in the technical branches but an entirely new field is opening up—that of business engineering. I am not sure which is the more important, the technical or the business branch, and it is not necessary to know. This much is to be said, however, that the technical engineer does not need to know a great deal about the business side of his problems, but the business engineer must know a great deal about the technical phases, and for that reason I suppose the business engineer is almost invariably a graduate from the technical branch.

The difficulty we now face, as I see it, is due to the fact that the business engineer does not begin early enough in acquiring a knowledge of the fundamentals of business. Whether the student intends to confine himself strictly to technical work or whether, as is usually the case, he has no well defined ideas on the subject, it seems to me he should have a grounding in practical business procedure such as would enable him to understand financial operations, the meaning of the items on a balance sheet and income statement and generally the manner in which corporation business is transacted. The graduates of a technical school have no feeling about the fact that not since graduation have they directly applied many of the subjects taught them as students. They were broadened by these studies and they were an indispensable prelude to other work. But as I see the profession advancing into the field of business I often ask myself the question—are the students recognizing this movement and are the colleges preparing men for a business engineering career after they have served an apprenticeship in technical work ? Even should the graduate never apply the knowledge thus gained in professional practice I am sure he would benefit greatly in the management of his personal investments.

But the thought behind this suggestion and which impels me to speak of it now is that business men, and particularly bankers, are beginning to look with increasing confidence to the engineering profession for advice in the management of industrial concerns in which they are interested, and the men who are pioneers in this field, among whom may be included the members of my own firm, have long felt that the preliminary training for such work should be organized and directed by the colleges just as in the technical branches of the profession.

And so if I may, I would like to convey to students of engineering my own impression that there is an immense new field opening up for the engineer of the future that will not only tax his ability and knowledge of matters pertaining to technical practice but will require of him training and experience in the solution of business problems of the greatest importance; and to those who are engaged in moulding the minds of the students I should like to express the hope that recognition be given of this new development.

BRANCH NEWS

Halifax Branch

K. L. Dawson, A.M.E.I.C., Secretary-Treasurer.

At the regular monthly meeting of the Halifax Branch on March 3rd, 1926, J. W. MacDonald, JR.E.I.C., mechanical superintendent of the Oil Refinery at Imperoyal, gave an account of the investigation to date into the bursting of a steel tank 115 feet in diameter and 35 feet high which was used for the storage of water and which failed suddenly a few days before. This tank was not insulated and there was ice at the sides and bottom as well as on the top. A vent was always maintained through the ice on the top. The overflow pipe was located inside the tank and near the north side. The tank split from the top to the bottom on the north side opposite the overflow pipe and the cause of the failure is not known. Mr. MacDonald described the construction of the tank, referred to thickness of plates, size of rivets, location of I-beams, roof and overflow pipe.

The Toronto-Hamilton Highway

H. S. VanScoyoc, M.E.I.C., consulting engineer, service and promotion department, Canada Cement Company, who was visiting the branches of the Institute in the Maritime provinces at the request of the branches, was then introduced by the chairman. Mr. VanScoyoc described the construction of the concrete highway between Toronto and Hamilton and also the manufacture of cement. Each of these descriptions was illustrated by means of motion picture films. At the close of his address a discussion was opened by R. W. McCulloch, A.M.E.I.C., chief engineer of the Nova Scotia Highway Board, and participated in by a number of the members present.

Some of the points which were brought out in the discussion were very interesting. It appears that the concrete road between Hamilton and Toronto was laid on the natural soil without any special preparation of the subgrade and the cost of maintenance has been low, about $70.00 per mile per year. The cases of subsidence were very few and of minor importance. Perhaps the most interesting things which were mentioned were the rise of property value along the road and the very great increase of the vehicular traffic which followed the completion of the road.

Mr. VanScoyoc said that the values of property along the highway had increased by six millions dollars. The significance of this increase is seen in the following. The road passes through fourteen townships or municipalities exclusive of the cities of Toronto and Hamilton, each of which was required to share in the expense of building the road, the cities of Hamilton and Toronto and the provincial government absorbing the balance of the cost. It was thought that this would mean an increase in the rate of taxation in these townships and the people at a distance from the road did not see why they should be taxed for the benefit of the people near it. However, with the increase in property values along the road it was found that the rates actually went lower and that the people living at a distance from the road, the value of whose properties did not increase as much, were paying less taxes than before the construction of the road.

In 1914 the highest traffic-count was 526 vehicles per day. Since the completion of the highway the highest traffic-count has risen to 20,000 vehicles per day.

Truck traffic at the present time is greater than the total original traffic. The average number of vehicles per day-period for the maximum week is 7,000.

In connection with the manufacture of cement, Mr. VanScoyoc referred to a piece of road which had been constructed by the Canada Cement Company for test purposes which did not fail under a 2,000-pound per square inch test at the end of twenty-four hours. The quick setting of the cement in this road was obtained by mixing calcium chloride with the cement in the proportion of one part in fifty. At the close of his address the vote of thanks was tendered Mr. VanScoyoc, which was moved by C. A. Fowler, M.E.I.C., and seconded by C. B. Blanchard, M.E.I.C.

George D. MacDougall, M.E.I.C., vice-president of the Institute for the Maritime provinces, was present and spoke briefly. He expressed his thanks to the Institute in the Maritime province for the honour which they had conferred upon him and asserted his desire to be of the greatest help to the Institute during his period of office.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

The final supper-meeting of the year was held at the Barker House on the evening of June 6th. C. S. G. Rogers, A.M.E.I.C., chairman of the branch, presided. During the course of the supper hour several banjo duets were rendered by Messrs. Leverett Hutchinson and Bob Selig. Vocal solos were also given by Mr. Fred Wilkins.

At the conclusion of the repast the annual financial statement was read and the names of officers elected for the ensuing year announced. Only the required number were nominated at the meeting held for the purpose on April 30th, consequently an election was unnecessary.

The following are the officers for 1926-27:

Chairman	A. S. Gunn, A.M.E.I.C.
Vice-Chairman	G. C. Torrens, A.M.E.I.C.
Secretary-Treasurer	V. C. Blackett, A.M.E.I.C.
Executive Committee	Prof. F. L. West, A.M.E.I.C.
	Jas. Pullar, A.M.E.I.C.
	G. E. Smith, A.M.E.I.C.

In addition to the above, the members of the Executive Committee are:—A. F. Stewart, M.E.I.C., J. D. McBeath, M.E.I.C., J. R. Freeman, A.M.E.I.C., F. O. Condon, M.E.I.C., (ex-officio), C. S. G. Rogers, A.M.E.I.C., (ex-officio), M. J. Murphy, A.M.E.I.C., (ex-officio).

A. S. Gunn, A.M.E.I.C., the incoming chairman, in moving a vote of thanks to the retiring secretary-treasurer, M. J. Murphy, A.M.E.I.C., referred in high terms to the untiring efforts of Mr. Murphy in furthering the work of the local branch during the six years he had been in office.

After the business of the meeting had been disposed of, a very interesting display of coloured slides and motion pictures was shown, depicting Canada from coast to coast, along the Canadian National Railways. The views were greatly enjoyed by the gathering and thanks are due the advertising department of the Atlantic Region, Canadian National Railways, for the courtesy shown the Moncton Branch on this occasion.

Saulte Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

A regular meeting of the branch was held at the Y.W.C.A. rooms on June 1st. Twenty-seven members and guests attended the dinner held previous to the meeting.

C. H. Speer, M.E.I.C., chairman, called the meeting to order and the business was quickly attended to. The secretary read an article by B. E. Barnhill, M.E.I.C., one of our members who is at present on railroad location work in Florida. Mr. Barnhill's description of the troubles of a locating engineer in that district was good. They have their amusing as well as their serious problems to contend with. If it is not rain, flies, etc., it is the realtors that help worry them. The land values in that section of the country could increase more in twenty-four hours along the right-of-way than the tide of the Atlantic.

Mr. Speer then introduced Mr. G. C. Bateman, secretary of the Ontario Mining Association and Mr. T. F. Sutherland, chief inspector of mines for the province of Ontario.

The Mining Situation in South Africa

Mr. Sutherland, who visited South Africa in 1924 to study safety work in deep shaft sinking and deep mining, gave a most vivid description of the mining situation in South Africa. Mr. Bateman handled the slides which Mr. Sutherland had taken while in the African mining districts.

Mr. Sutherland pictured the country in all its rugged splendours. As he took you from Cape Town up through the country you could almost see the existing conditions as he found them. He pictured in vivid fashion, the mineral wealth of the Union dealing with the Rand section and the newer discoveries in Rhodesia and also telling of a visit to the Belgian Congo.

The following minerals are being mined in South Africa: diamonds, gold, cobalt, asbestos, copper, mica, zinc, lead and platinum at the present time.

In comparing the accident death rate with that of Ontario, he showed that in 1924 the Ontario rate had been 3.24 fatalities to one thousand employed while the South African rate had been 2.45 per thousand. The three main reasons he claimed for this, were,—

1. More government inspectors than in Ontario and the strict enforcement of the laws against foreign labour.
2. The educational work done by the Chamber of Mines who spend $25,000 per year in accident prevention work.

3. The license system in force, that is, all responsible men, such as mine managers, surveyors, electricians, foremen, stationary engineers, etc., must have certificates issued by a board of examiners.

The Ontario output in comparison to total accidents, however, had been 170, as against 70 tons in South Africa.

On the Rand in 1924 there were over 180,000 men employed, of whom 15,000 were white bosses, he said, and the remainder blacks. That year the Rand had mined 28,500,000 tons of gold ore, as compared to 4,500,000 tons in Ontario. The Rand ore had yielded 9,500,000 ounces of gold. These mines have not reached their maximum output, Mr. Sutherland said. There are 700,000,000 tons of ore running from $3.00 to $4.00 per ton blocked out and it is only a question of further reducing the cost of operation before that will be available. At present there is an agreement that not more than nine blacks will be employed for each white man, but he did not think that this agreement would last as black labour was much cheaper than white. The farther he went into the interior, the poorer the class of labour becomes. In the Belgian Congo, they pay $2.50 to $3.00 per month and feed the men and their families. Here the natives are housed in villages and not in corralls as in the Rand section. The Belgian Congo district is only 13 degrees south of the equator, hence it is not a white man's country.

In the Rand section, he pointed out that most of the mining was now below the 3,000 feet level, some of the mines reaching an actual depth of 7,000 feet, although the shaft to reach this level is 9,500 feet long. At this depth the rock temperature is 95 degrees and the air temperature is 88 degrees, although artificial ventilation is maintained. One of the greatest troubles met with is from silicosis, a disease which results from the clogging up of the lungs by fine dust particles from the crushing of the quartz. Medical inspection to insure the soundness of the lungs, proper ventilation and the plentiful use of moisture are employed to lessen the danger, although it is estimated that 20,000 had died from silicosis in the mines. As this district has been in operation since 1886, there are vast areas opened up underground which causes earth tremours and rock bursts, which are other difficulties to contend with.

Mr. Sutherland gave an interesting description of the Morensky Reef in Rhodesia where platinum has been recently discovered. This is the largest known deposit in the world and controls the world's market. He touched also on the copper deposits farther north in Katonga district, which is also a very large area.

The description of the diamond mining was most interesting. The Premium diamond mine has an area of 80 acres and a depth of 400 feet. This mine is operating at one-third capacity due to the demand and to keep the prices up. The diamonds are found in rock-like formation and this is crushed and the diamonds are taken out by a process of screening.

Many interesting points were brought out by the speaker. In nearly all the mines the machinery was the latest that could be bought. Wood is the main fuel for the boilers, while steam shovels were few as labour is so cheap. In the Belgian Congo reforestation is being extensively carried out to keep the fuel supply up. His address was touched with a quiet humour that made it doubly entertaining and the numerous slides shown brought out forcibly the fine points of his address, especially the last slide.

R. S. McCormick, M.E.I.C., moved a hearty vote of thanks to Mr. Sutherland for his splendid and instructive address; Wm. Seymour, M.E.I.C., on behalf of the members and Mr. J. E. Irving on behalf of the guests seconded the motion.

Vancouver Branch

E. A. Wheatley, A.M.E.I.C., Secretary-Treasurer.

Meetings of the Branch Executive

Meetings were held on May 5th, 14th, and 28th.

The resignation of P. H. Buchan, A.M.E.I.C., as secretary of the branch, was accepted with great regret. He was offered a seat as a member of the executive of the branch, as a small token of appreciation for his services, and a letter to this effect was requested to be sent by the secretary, E. A. Wheatley, A.M.E.I.C. Mr. Wheatley was appointed to succeed Mr. Buchan as secretary of the branch.

Other routine business was discussed and methods of improving the attendance and membership of the branch agreed upon.

The invitation of E. E. Carpenter, M.E.I.C., on behalf of the B.C. Electric Railway Company to visit the Alouette lake development was accepted.

Joint Meetings

A luncheon-meeting under the auspices of the branch, the Vancouver Section of the American Institute of Electrical Engineers and the Vancouver members of the Association of Professional Engineers, was held on May 26th.

The Relation of the University to the Engineering Profession

An address under this heading was given by Dean R. W. Brock, M.A., LL.D., F.C.S, M.E.I.C., Dean of the Faculty of Applied Science, University of British Columbia, on May 26th, 1926, to members of the Vancouver Branch of the Institute,—Vancouver members of the American Association of Electrical Engineers and the Vancouver engineers registered under the "Engineering Act" of the province. The meeting was arranged by and held under the auspices of the Association of Professional Engineers of B.C. J. P. Hodgson, M.E.I.C., was in the chair, and Major Geo. A. Walkem, M.E.I.C., President of the Institute, was present. A report of Dean Brock's address appears on another page of this issue.

The Dean was awarded an ovation and the chairman, J. P. Hodgson, M.E.I.C., conveyed the enthusiastic thanks of the meeting to him.

It is the hope of the engineering societies in Vancouver that many addresses on this, and allied subjects, will be given during the fortcoming months in the hope that the profession will educate itself to a realization of the problems facing them.

Inspection Trip to Alouette Dam of the B.C. Electric Railway, Limited

On a day of glorious sunshine, this beautiful trip was enjoyed by one hundred and fifty visitors composed of the engineers, their wives and friends, who were received by E. E. Carpenter, M.E.I.C., and Mrs. Carpenter.

The members motored from Vancouver some thirty-five miles to Port Haney, where a special train, consisting of two flat cars suitably equipped with special benches and hauled by a logging locomotive, was provided through the courtesy of the Abernethy-Lougheed Logging Company. Nine miles of the trip were thus taken through a beautiful, original forest to the dam.

The technical features of this gravel dam have been explained elsewhere, but even the ladies were interested to learn that both the dam and the concrete work surrounding the sluice-gates were set on a bed of clay and that borings had proved that there was no rock for over one hundred feet.

A luncheon was tendered the party by the B.C. Electric Railway Company in the now deserted construction camp adjoining the Lodge.

W. H. Powell, M.E.I.C., as chairman of the Vancouver Branch, was in the chair. After the toast of the King was given by the chairman, the president of the Institute, Major Geo. A. Walkem, M.E.I.C., referred to the early history of the B.C. Electric Railway Company; the success of the company under the management of Mr. Geo. Kidd, and the great development occurring at the moment under the control of E. E. Carpenter, M.E.I.C. He referred to the well-known hospitality of the company and three rousing cheers were given showing the appreciation of the members.

Mr. Carpenter responded on behalf of the B.C. Electric Railway Company.

A. E. Foreman, M.E.I.C., proposed the toast to the Ladies. Mr. Foreman's very witty remarks on behalf of the ladies met with enthusiastic applause and Mrs. E. E. Carpenter responded in a most charming and piquant manner on their behalf.

A scow, properly fitted with tarpaulins and benches, was supplied as the means of travelling up ten miles of Alouette lake, surrounded by the most beautiful scenery, to the mouth of the intake to the tunnels which carry the water from Alouette lake to Stave lake.

Specially printed programmes giving bird's-eye or aeroplane photographs were provided by the railway company and enabled every one of the party to realize the tremendous work done.

The party returned at seven o'clock and all agreed that the most enjoyable trip within the knowledge of the branch had taken place.

The Generation of Steam at Critical Temperatures

On Tuesday, June 8th, one hundred and twenty-five members of the Engineering Institute of Canada and the American Institute of Electrical Engineers and other engineering societies, gathered to hear an address by Dr. Mark Benson, F.R.G.S., on "The Generation of Steam at Critical Temperatures." An abstract of Dr. Benson's address will appear in the August issue of the Journal.

The lecture, which was followed with close attention by the large attendance, created great interest, and was followed by a number of questions from the members present which were dealt with somewhat at length by Dr. Benson. Following a hearty vote of thanks the meeting then adjourned.

Victoria Branch

E. G. Marriott, A.M.E.I.C., Secretary-Treasurer.

Visit to B.C. Cement Company's Plant

On Friday, April 16th, the Victoria Branch visited the Bamberton plant of the British Columbia Cement Company, Limited, leaving Victoria at about one o'clock and going by motors to Butchart's Gardens and thence by the company's boat to Bamberton, arriving at Bamberton about 3 p.m.

Mr. Edwin Tomlin, manager of the Cement Company, acted as host to the men of the party and Mrs. Tomlin as hostess to the ladies, who only went as far as Butchart's Gardens and remained for tea in Mr. Butchart's house, joining the party on their return from the plant.

About thirty men and an equal number of ladies comprised the party.

Upon arriving at Bamberton each member of the party was given a very attractive programme, each programme being marked with the member's name for whom it was intended. This programme, in addition to giving the times of arrival, etc., at the different points, showed a complete "flow sheet" and gave various other information about the plant.

Description of Plant

The site of this plant is on a steep side hill, and all shipments from and to the plant are made by water and the company has a private dock at this point. Complete repair shops are located at the lower level and power is obtained from the British Columbia Electric Railway Company and transmitted at 60,000 volts and stepped down to 550 volts in the sub-station.

The wet system entirely is used and the wet mill consists of 5 ball mills and 5 tube mills in series. Closed circuit grinding is practised, 2 trix separators being placed in the circuit between the ball and tube mills. Two sets of slurry pumps elevate the product 98 feet to the slurry mixers. The final product from the wet mills contains about 32 per cent moisture, and about 7 per cent (dry) is retained on a 180 by 180 screen.

Slack coal is delivered on scows and unloaded by a bucket elevator and conveyed to the coal store. The coal is then dried until the product contains only about 1 per cent moisture and then ground to a fineness of about 95 per cent through a 100 by 100 mesh screen, and is then blown up 80 feet to two cyclones and elevated again and conveyed to the kiln storage bins.

The quarry is worked in two benches by means of two electric and one steam shovels and about 800 tons of rock are quarried per day. The product from the quarry is used exactly as it comes out and, with the exception of gypsum, forms the entire raw product for the cement.

The amount of lime content is controlled by maintaining a higher content in some of the mixers than the others, and when drawing off the material just before going to the kilns the product is taken from the high and low content lime mixers as required, so that the final slurry will have exactly the amount of lime desired. The slurry is pumped from the mixers and fed in at the back end of the kilns and powdered coal blown in at the front end. There are three kilns 185 feet long each having a capacity of 1,000 barrels per day. The temperature in the burning zone is about 2,800° F.

There is a cooler in conjunction with each kiln and the air used for cooling being thus heated is later used for combustion in the kilns.

The dry mill consists of 4 ball and 4 tube mills and the amount of gypsum necessary to retard the time of setting is fed to the ball mills along with the clinker and steam is added in the tube mills to hydrate any free lime and to insure a sound product.

About 100,000 barrels of storage room is available and the cement is drawn from the storage bins as required and sacked in bags of 87½ lbs. nett, the bag loading machines automatically filling the bags and weighing in the proper amount of cement.

There is a complete physical and chemical testing laboratory.

On arriving at the cement plant the party was divided into small groups, each taken charge of by one of the officials of the company acting under instructions from Mr. Anderson, the manager of the plant, so that each individual member of the party was able to get personal attention from an official who knew all the details.

The Cement Company has a raw material at this point which gives them a very quick hardening cement. It is pointed out, of course, that quick hardening and quick setting must not be confused as having the same meaning, as a quick setting cement is not desirable under any practical conditions as it causes trouble in the mixers, chutes, wheelbarrows or other means of conveying the concrete from the mixers to the work, but a quick hardening cement will make concrete that does not lose its fluidity until deposited in its final position and then hardens very quickly.

This raw material, without the addition of gypsum, would form a very quick setting cement and one that could not be used under practical conditions, but the addition of the gypsum changes the product from a quick setting cement to a quick hardening cement with the result that very rarely indeed is any trouble occasioned by the quick setting properties of the raw material, this trouble only occurring when there is a stoppage in the gypsum feed and this danger has now been entirely overcome, but occasionally when the plant first started up there was some such trouble experienced with the result that it was almost impossible to get concrete out of the mixers before it set.

After going over the whole plant the party assembled in the store room for tea and were there also addressed by Mr. Tomlin and Mr. Anderson, returning later by the company's boat to Mr. Butchart's Gardens, rejoining the ladies and returning to Victoria by motor.

One of the ladies of the party has kindly supplied the following item in regard to the trip,—

After the men left for the cement works, the ladies, led by Mrs. Tomlin, proceeded to the sunken gardens, which were as beautiful as ever; though it was too late for the daffodils, there were many glorious colours, which were gorgeous in the bright sunshine.

After viewing the gardens, it was delightful to walk through the charming house, hear the wonderful organ and enjoy a rest on the cool verandah in comfortable lounges and chairs.

A very tempting tea was served which was thoroughly enjoyed and appreciated by all. After tea, while waiting for the men to return, the time was pleasantly spent reading some of the numerous magazines, or strolling in the garden, and resting on one of the many garden seats which are so tastefully placed in the arbours covered with climbing roses.

Many thanks are due to Mrs. Butchart for her kind hospitality, and also to Mrs. Tomlin, who made a most charming hostess.

Quebec Branch

Louis Beaudry, S.E.I.C., Secretary-Treasurer.

The eighteenth annual meeting of the Quebec Branch was held at the City Hall, Quebec, on Tuesday evening, May 25th, 1926.

At this meeting, A. B. Normandin, A.M.E.I.C., presided, and following the reading of the minutes of the previous annual meeting, Z. Langlais, A.M.E.I.C., and Robert Sauvage, JR.E.I.C., were appointed Scrutineers for the election of officers for the ensuing year.

The secretary-treasurer then presented the financial statement for the year 1925-26.

Receipts	
Balance in bank, 6/29/25	$119.71
Rebates from headquarters	219.21
Bank interest	.65
	$339.57
Expenditures	
Luncheons and meetings	$ 55.00
Printing	41.02
Postal box	6.00
Secretary's expenses, 1925/26	100.00
Postage, etc	5.00
	$207.02
Surplus on May 25th, 1926	132.55
	$339.57

Following this, Hector Cimon, A.M.E.I.C., Alex. Lariviere, A.M.E.I.C., and T. J. F. King, A.M.E.I.C., were appointed members of the Nomination Committee for the ensuing year, and Hector Cimon, Alex. Lariviere and F. X. Ahern, A.M.E.I.C., were appointed members of the Legislation Committee.

A vote of thanks was tendered to his Worship, the Mayor of Quebec for making available quarters for the meetings of the branch.

The report of the Secretary showed the election of the following officers for the year 1926-27:—

Chairman	A. B. Normandin, A.M.E.I.C.
Vice-Chairman	S. L. deCarteret, A.M.E.I.C.
Secretary-Treasurer	Louis Beaudry, S.E.I.C.
Committeemen	T. E. Rousseau, M.E.I.C.
	Hector Cimon, A.M.E.I.C.
	L. C. Dupuis*, A.M.E.I.C.
*In Office for another year.	Alex. Lariviere*, A.M.E.I.C.

It was motioned by A. R. Decary, M.E.I.C., and seconded by F. X. Ahern, A.M.E.I.C., that a vote of thanks be tendered to the retiring officers, following which Mr. Normandin thanked the members for the honour in re-electing him chairman of the Branch.

The Humber Development of Newfoundland Power and Paper Company, Limited

A Description of the Power Development and the Power Equipment and its Installation in the Paper Mill

H. C. Brown, A.M.E.I.C.

Manager, Power Development, Newfoundland Power and Paper Co. Ltd.

Paper to be presented before the Maritime General Professional Meeting of The Engineering Institute of Canada, at Sydney, N.S., August 17th, 1926.

It appears that hydro-electric power development on the Humber has been considered at different periods for the past twenty-five years. The British government, under the Trade Facilities Act, and the Newfoundland government assumed certain guarantees to assist in the building of a 100,000-h.p. power development and a 400-ton newsprint paper mill. Actual construction on the present development commenced in June, 1923, by the general contractors, the Sir W. G. Armstrong, Whitworth and Company, Limited, London, England, and paper was actually produced in July, 1925. This covers very little over two years from the inception of construction to production of the manufactured product.

Several schemes were considered, and it was finally decided to locate the power house at Deer Lake and the mill at Corner Brook. The locating of the mill at Corner Brook, rather than at Deer Lake, close to the power house, was deemed advisable owing to excellent water shipping facilities at Corner Brook which allows the paper to be conveyed from the mill direct to the steamers, saving the loading and unloading of railway cars with consequent freight and handling charges. This change necessitated the use of high-voltage transmission lines between Deer Lake and Corner Brook, a distance of 32 miles.

Water Storage

Water storage is necessary owing to the great seasonal variations and the run-off from the watershed falling short of the rate of consumption at certain periods of the year.

Grand lake, with an area of 215 square miles, makes an ideal regulating storage reservoir. The Grand lake catch-

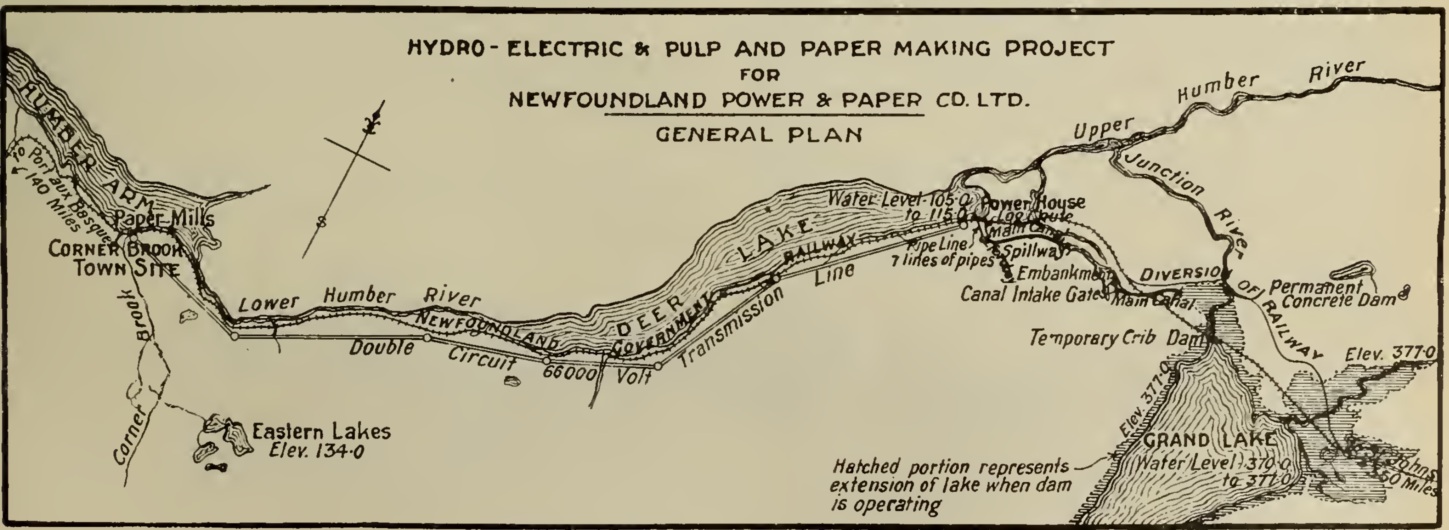

Figure No. 1.—General Plan.

ment area is about 1,650 square miles, having an average yearly run-off of about three cubic feet per second per square mile, giving an approximate average flow of about 5,000 cubic feet per second.

The storage capacity of reservoir is about 30,000 mill. cu. ft.; this, properly regulated, will, even during periods of greatest recorded drought, guarantee continuous full load output throughout the year.

Grand lake level has been raised about 30 feet by a dam placed across Junction river, which was the original outlet of Grand lake to Deer lake via the Upper Humber river. The operating difference in elevation between Grand lake (elev. 377) and Deer lake (elev. 107) is 270 feet.

Investigation of Precipitation and Flood Conditions

To carefully check the rain and snow precipitation four gauge stations have been installed. However, it was found extremely difficult to obtain accurate snow depth measurements during the past winter owing to wind conditions causing a very unequal depth of snow.

For the purpose of measuring the depth of snow, a light copper tube was made up in three sections having bayonet joints and with special shaped auger to cut through the layers of hard crust. A small spring balance scale was used to weigh the snow and tube, and the weights were converted to inches of rain precipitation by using a paper scale pasted to the spring balance. This method allowed a large number of samples to be taken in a short period of time. Prior to commencing this work the method was carefully checked. The survey party consisted of two men with dog teams, and samples were taken on selected clearings free from snow drifts and protected from the wind. The average of a number of samples was taken and it was found that snow depths were very consistent, varying over the territory covered from 48 to 52 inches.

The spring run-off from the uncontrolled watershed covering the Upper Humber river, Junction river and Deer lake must be taken care of at a different period than Grand lake excess storage discharge. This prevents excessive high tail-race water levels at Deer lake which would cut down the output of the power house and also affect logging operations in the Lower Humber river, as large quantities of logs are stored in the Lower Humber during the winter months.

High water levels in Deer lake would greatly increase the flow in the Lower Humber and there would be great danger of ice and log jams breaking the log booms, causing heavy monetary loss. Once the ice is clear in Deer lake and the Lower Humber river, this danger disappears.

Main Dam Across Junction River

A hollow reinforced concrete Ambursen type dam about 800 feet long, with a maximum height of 75 feet, was constructed across Junction river at a point now known as "Main Dam." This dam has a spillway with a capacity of 26,000 cubic feet per second for the purpose of discharging the occasional heavy floods that occur or when the lake level rises above the normal operating level.

The spillway consists of eighteen gate-controlled openings each 15 feet wide. Two special portable motor-driven lifting cranes, running on wide gauge rails, are used for lifting the gates. Three-phase, 550-volt power is available from weather-proof plug receptacles spaced across the dam for operating the lifting mechanism.

Power is supplied to the transformers for light and power to the dam and woods department depot buildings located at Main Dam, at 6,000 volts, 3-phase.

Provision has been made for the installation of heating elements in the gate guides for thawing ice between guides and gates if necessary. A small motor-driven low-pressure air compressor supplies air to the front of the gates to agitate the water and prevent freezing in of the gates. For purposes of economy the operation of gates is handled by the staff of the woods department, located at Main Dam, on instructions from the hydro-electric department.

Figure No. 2.—Panoramic View of Corner Brook showing New Mill.

Main dam contains 29,000 cubic yards of concrete, and to accomplish its construction 19,000 cubic yards of excavation was necessary, form work aggregating 600,000 square feet was constructed, 400 tons of reinforcing steel were placed, and it was necessary to build a rather large crib dam.

Due to the increased level of Grand lake, which is raised some 30 feet by this dam, a diversion of the railway was necessary and it is carried over Junction river on the dam.

Canal

To convey the water from Grand lake to the forebay near the power house, a canal approximately seven miles long was constructed. This canal is divided into two sections by Glide Brook lake, which is artificially formed by two earth embankments, one 4,400 feet long with a maximum height of 35 feet, and the other 950 feet long with a maximum height of 75 feet. By the formation of this lake the total length of canal excavation was shortened by 2½ miles.

Glide brook, with an average flow of about 200 cubic feet per second, discharges into the canal via the lake.

Figure No. 3.—Crib Dam—some Stop-Logs Removed.

During construction its normal course was maintained by means of sluices at the bottom of the longer of the two embankments. These sluices are built of concrete and form part of the permanent canal works. The peak spring run-off from Glide brook is taken care of by cutting down the normal water supply to the canal from Grand lake.

The excavation and construction of the canal involved the moving of approximately five million yards of earth.

Canal Intake Works

To regulate the water flow in the canal, an intake works, consisting of five gate openings each 20 feet wide by 15 feet high, is placed at the downstream end of the eastern section of the canal, so that the water level of Grand lake is maintained in this section.

These gates have individual electrically-operated lifting gear, with necessary electrical limit switches to prevent over-travel. Remote control push button contactor type of motor starters are used.

Power for motors, heating and lighting is taken through necessary switchgear and transformers from a 6,000-volt power line. A small motor-driven blower and electric heater supply heat in winter to the intake building, which consists of a small wood frame building covered by galvanized corrugated iron.

Two travelling gantry cranes used on the construction of the steel penstocks at the power house and operating on wide gauge rails outside the building are available for placing the heavy stop-logs on both sides of the gates.

The roof of the intake house is designed for removal in sections for lifting of heavy equipment. Slots for stop-logs are located outside the building and the stop-logs can be lifted without affecting the building roof.

All gate openings have curtain walls to prevent trouble from ice and logs affecting operation of gates. A sluice for logs is provided to allow logs to be sluiced from Grand lake to the western section of the canal.

One man is stationed at the canal intake to take care of its operation and look after the logging operations during the summer months.

Forebay

The arrangement of the forebay at the downstream end of the canal is such that the gate house is parallel to the canal banks on the Deer lake side of the canal with the seven penstocks to the power house running at right angles to the canal.

Figure No. 4.—Main Dam during Construction.

Across the end of the canal is a spillway 160 feet wide, the top of which is at elevation 369, and two automatic Stauwerke gates and an ice chute, all of which empty into the spillway channel running into Deer lake.

A log flume is located between the gate house and the ice chute. It has an electrically-operated gate with provi-

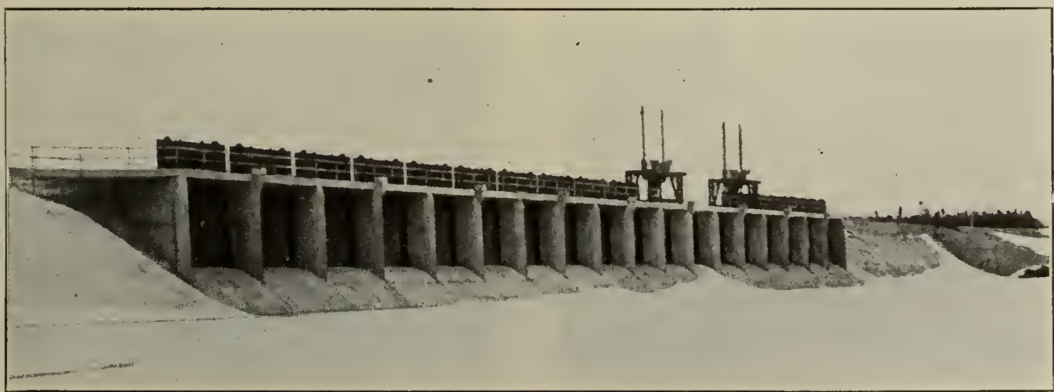

Figure No. 5.—Main Dam.

Figure No. 6.—The Canal.

Figure No. 7.—The Intake.

sion for stop-logs and guide booms attached to it for guiding the logs into the chute. The log flume is made of rivetted steel plate in the form of the letter " U " and runs parallel to the penstocks. It is supported on wooden framework and is provided with necessary expansion joints. Only a small quantity of water is used in sluicing the logs from the canal into Deer lake, where they are boomed and towed to the Lower Humber river, from which point they float down to the booms at Humbermouth and are towed to the slasher mill.

The gate house is a reinforced concrete building 138 by 34 feet, covering the requirements of the present development. A light end wall allows provision for future extensions. Seven gate openings, 11 feet 10 inches by 11 feet 10½ inches, are utilized at present and two spare openings blocked with stop-logs provide for future additions to the power house. Trash racks are built on heavy removable steel framework having 2 inch by ¼ inch flat iron on edge on 1¼ inch centres bolted together with spacers. The spacing used with these trash racks has proven very satisfactory with operations experienced to date from woods department logging operations and material brought down from flooded areas. Comparatively little trouble has been experienced from foreign material clogging racks, compared with experiences of power houses which operate on log driving streams.

The seven gates have individual electric hoisting mechanism somewhat similar to mechanism used at Main dam and canal intake house. Push button contactor type starters are used and electrical starting arrangement is such that an inching button allows the gates to be opened one inch when the current is tripped off. This allows penstocks to fill gradually. When penstocks are full the regular " running " button can be operated to open gates.

A multiple conductor aerial cable is run from the power house switchboard which allows the power house operator to close the gate and shut off water from the penstocks, in case of emergency, on all seven gates. Velocity trips are also provided on all penstocks so that in case of an accident occurring allowing velocity of water to reach an abnormal speed, the velocity trip, through an electrical contact, will close the particular penstock gate. Air vents for penstocks are provided in rear of all gates.

The design of the gate entrances and trash racks is such that there is no noticeable loss of head under normal operation with an approximate water velocity of 1.7 foot per second at the gate entrance.

The gate house is supplied with a heating system to prevent formation of ice at the trash racks. Heating ducts are run under the floor and allow hot air to be blown down on the water and trash racks. An electric heating unit with a maximum capacity of 200 k.w. is supplied with a motor-driven blower. Knife switches allow a wide range of this heating capacity to be used. It is interesting to note that no ice troubles of any kind occurred during the first winter's operation, and it is not anticipated there will be any trouble from frazil ice as there are no rapids or points where water is agitated or affected by wind to cause formation of frazil.

A 10-ton electric crane, hand-operated from the floor, is supplied for operating work and repairs.

Necessary transformers and switchgear for forebay power, lighting and heating are arranged for connection to two sources of 6,000-volt power. One line is direct from the power house to the forebay and is the one normally used. The auxiliary line is a short branch line from the 6,000-volt line going to the canal intake and Main dam.

Two automatic Stauwerke gates are used in addition to the spillway for taking care of abnormal rises in canal

Figure No. 8.—Forebay, Deer Lake.

Figure No. 9.—Pipe Line, Deer Lake.

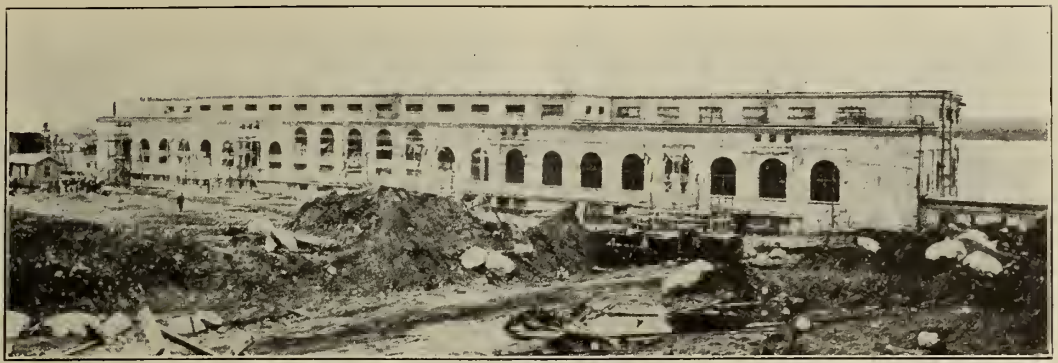

Figure No. 10.—Power House, Deer Lake.

water level, such as would occur with the sudden shutting down of the power house or sudden excess discharges from Glide brook which empties into the canal. This type of automatic gate is used considerably in European practice, but not to any great extent in America.

Electric heating units are supplied in the concrete walls adjacent to the gates to prevent the gates freezing to the walls during the winter. Hot air is also blown into the gate chamber and siphon chamber to prevent formation of ice. A total heating capacity of 75 k.w. is supplied for this purpose.

The elevation of the top of the Stauwerke gate in its normal closed position is elevation 369, and the elevation when fully opened approximately 359.0. Each gate is 25 feet wide and has two openings each 11 feet wide giving an approximate discharge when fully opened and water elevation slightly above 369.0 of 2,400 cubic feet per second.

Pipe Line

From the forebay the water is carried to the power house by seven penstocks, each approximately 4,000 feet long.

For the upper 2,500 feet these consist of wood stave pipes with an internal diameter of 9 feet 6 inches, while rivetted steel pipes 9 feet 6 inches in diameter at the top and 8 feet 6 inches at the bottom are employed for the lower 1,500 feet.

The wood stave pipes which are carried down to a head of 170 feet required about 150,000 cubic feet of timber. British Columbia fir was mostly used, together with a small quantity of pine, spruce and fir supplied from Newfoundland. About 2,000 tons of steel bands were supplied for the wood stave pipe, while the rivetted steel pipes weigh nearly 4,000 tons.

Two expansion joints are provided in each steel penstock to take up any expansion or contraction which might occur. The steel pipes were laid on the ground and covered with earth to about three feet over the top. The wood stave pipe is supported on concrete saddles clear of the ground. The pipe lines fan out at each end when entering the power house and forebay. Individual inspection chambers with penstock manholes allow entrance to each penstock near the power house, forebay and at a third point in the steel penstocks.

A special wood planer, manufactured in Norway, cut the special tongue and groove and gave the timber the proper curvature, all in one operation. Slots for 1/16-inch steel plates between ends of timbers required a second operation. Compressed air wrenches were used to tighten up the nuts on the steel bands, and this greatly assisted in the speedy erection of the wood pipe line.

An outside erecting yard was used for erection of the steel penstocks. Two electric gantry cranes and heavy automatic compressed air rivetters, as used in large boiler and railway shops, greatly assisted in speeding up the fabrication of the steel plates. These gantry cranes, as mentioned previously, were transferred after erection of the penstocks to the canal intake for permanent use in lifting the heavy stop-logs.

Power House

The power house is located at Deer Lake Town and is a reinforced concrete structure on a structural steel framework. The building is 193 by 62 feet and is divided into a generator section having a width of 34 feet and a transformer and switchgear section of 24 feet in width.

The generator units consist of seven 14,000-h.p., 375 r.p.m., horizontal type Francis turbines, and each direct-connected to a 10,250-kv.a., 95 per cent power factor, 50-cycle, 6,000-volt alternator with direct-connected 110-volt exciter.

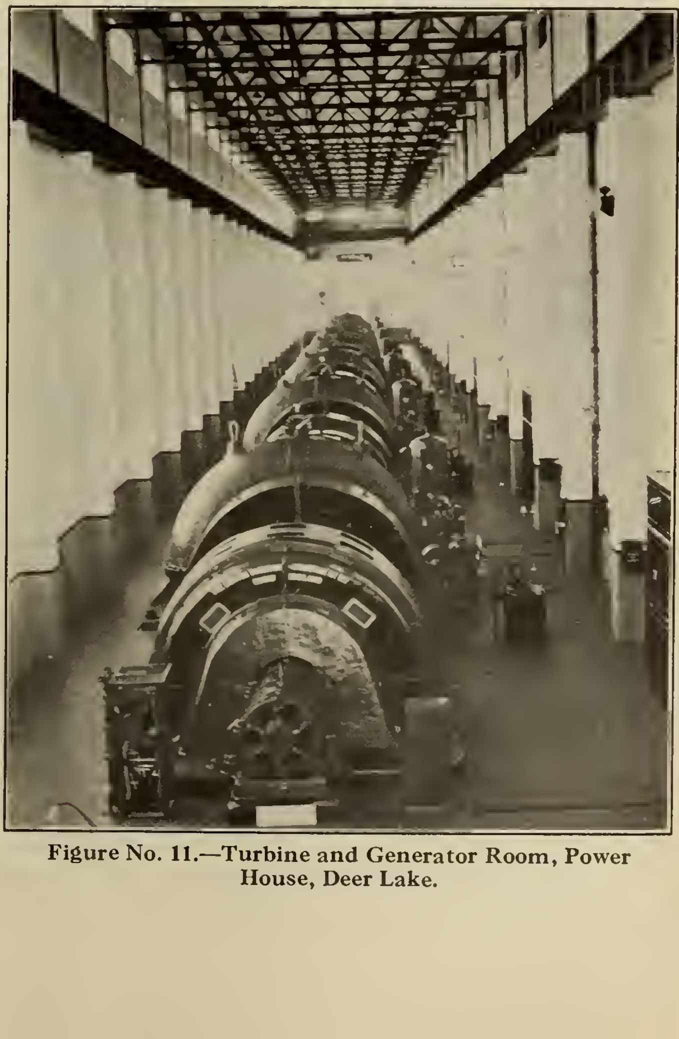

Figure No. 11.—Turbine and Generator Room, Power House, Deer Lake.

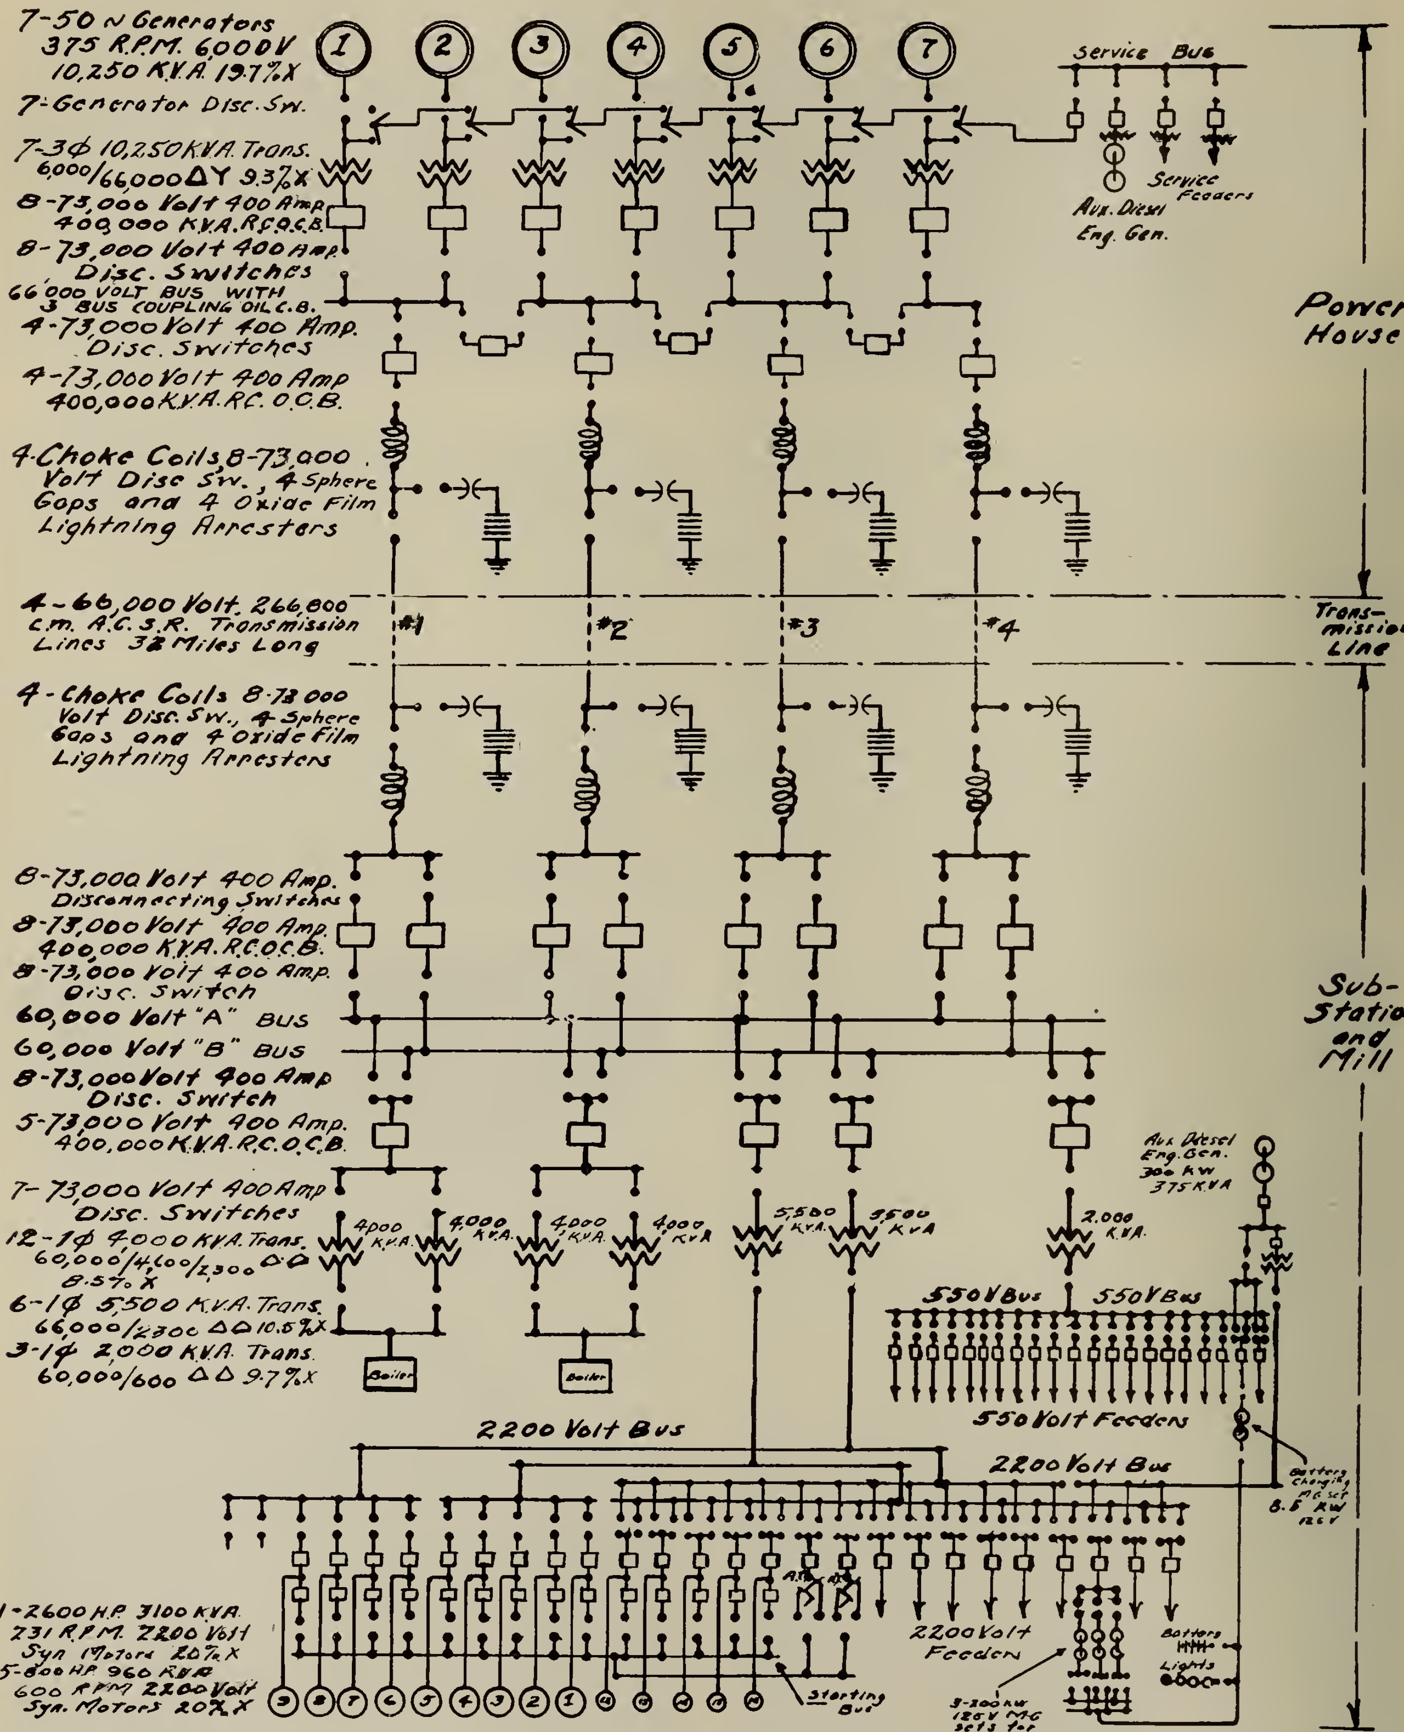

Figure No. 12.—Single Line Diagram of Newfoundland Power and Paper Company's Power System.

A 20-ton flywheel, 12 feet in diameter, is inserted between the turbine and the alternator. This flywheel is required for proper speed regulation owing to the lack of required flywheel effect in the generator rotor. Each generator is directly connected with heavy lead-covered cables to a 10,250-kv.a., 3-phase, 6000/66,000-volt, oil insulated, water-cooled transformer. These transformers as well as the oil breakers are installed in fireproof cubicles. A generator and transformer combine to make an individual unit supplying current direct to the 66,000-volt high-tension bus through an oil circuit breaker.

The high-tension 66,000-volt bus consists of stranded copper cable mounted on post type insulators consisting of two 44,000-volt insulators forming one insulator unit. The high-tension bus is divided into four sections by three circuit breakers which allows the isolation of bus sections. Four transmission line oil breakers supply the four outgoing lines. Where the conductors go through the power house wall, 110,000-volt compound filled wall bushings are used. Four outdoor type 72,000-volt oxide film lightning arresters connect directly to transmission lines just outside the power house. All lightning arresters are provided with the necessary isolating disconnecting switches. No spare or auxiliary excitation system is used for the generators as the exciter on the end of a generator is so designed that an armature or whole exciter can be very quickly changed, the extension of the generator shaft supporting the exciter armature which has no end bearings.

Electrical controls connected to the switchboard are provided in order that the operator can properly control the loads and also shut down a unit from the control room by tripping the butterfly valve mechanism. Each turbine is equipped with butterfly valve and necessary relief valves to take care of the excess pressure in the penstocks under sudden load changes, as no surge tank is used in connection with the penstocks.

The switchboard consists of twenty-five panels controlling the generators and oil circuit breakers for the operation of the plant. These switchboard panels are equipped with an extra panel mounted above the ordinary panel, electrically indicating when an oil breaker or a disconnecting switch is closed or open.

The relay system at the power house consists of differential and overload relay protection on the generators and transformers as a unit, as well as earth leakage relays on generators and transmission lines. The transmission lines

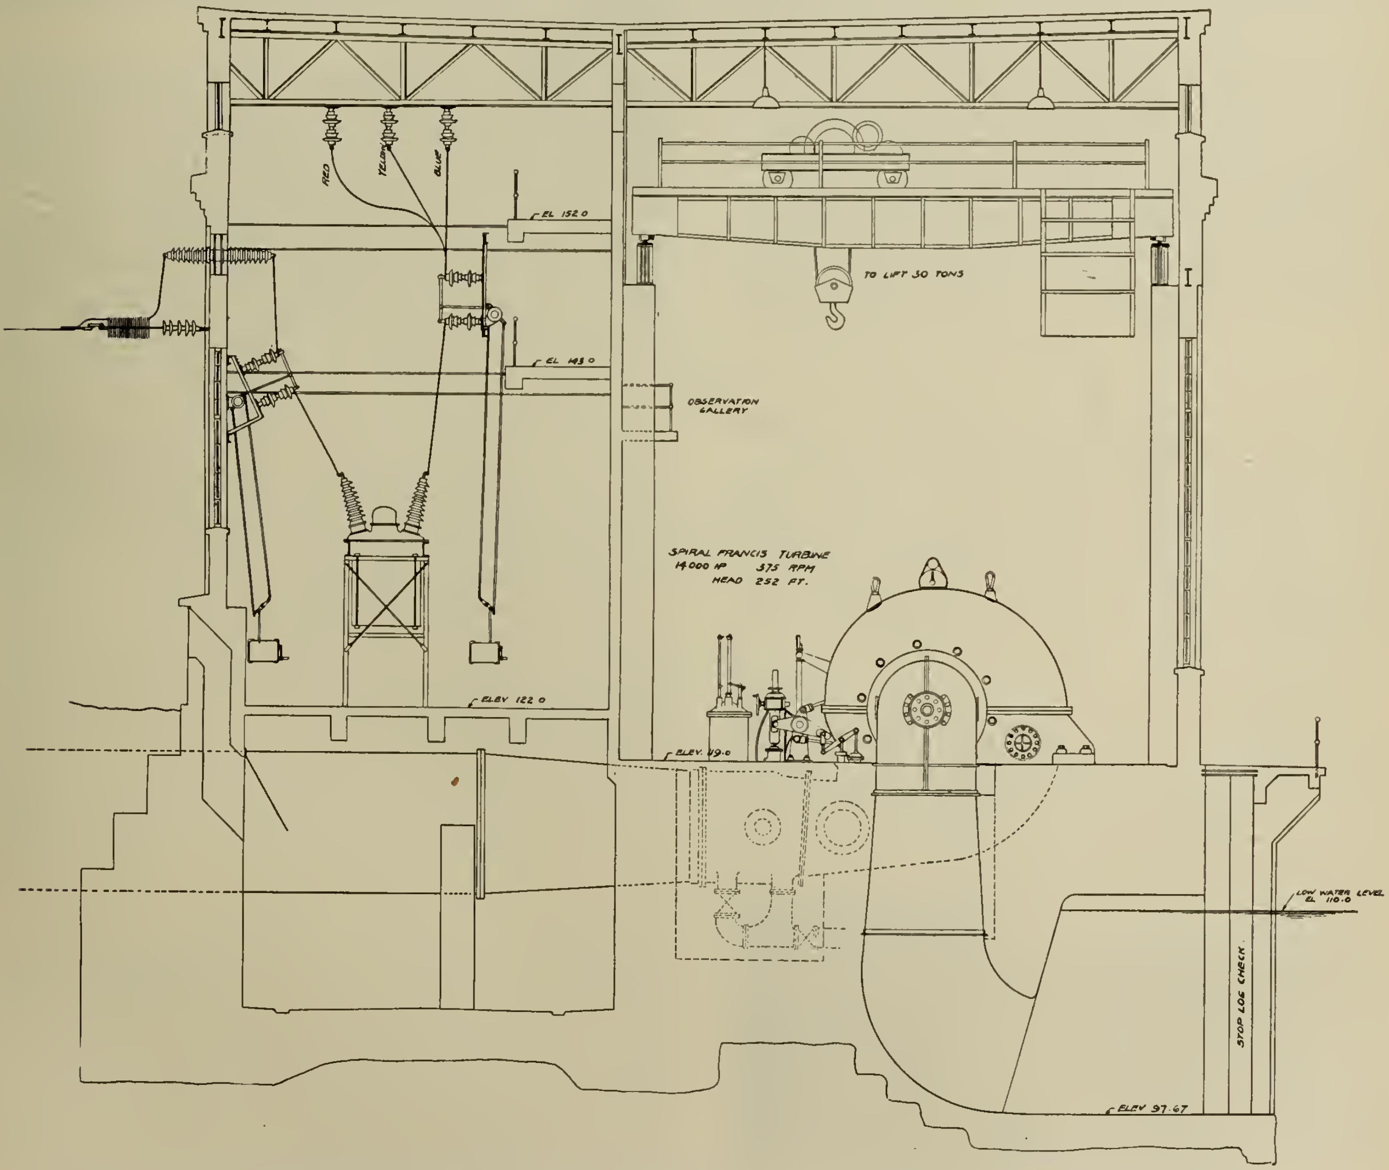

Figure No. 13.—Cross Section through Power House showing No. 4 Turbine and No. 2 Outgoing Transmission Line.

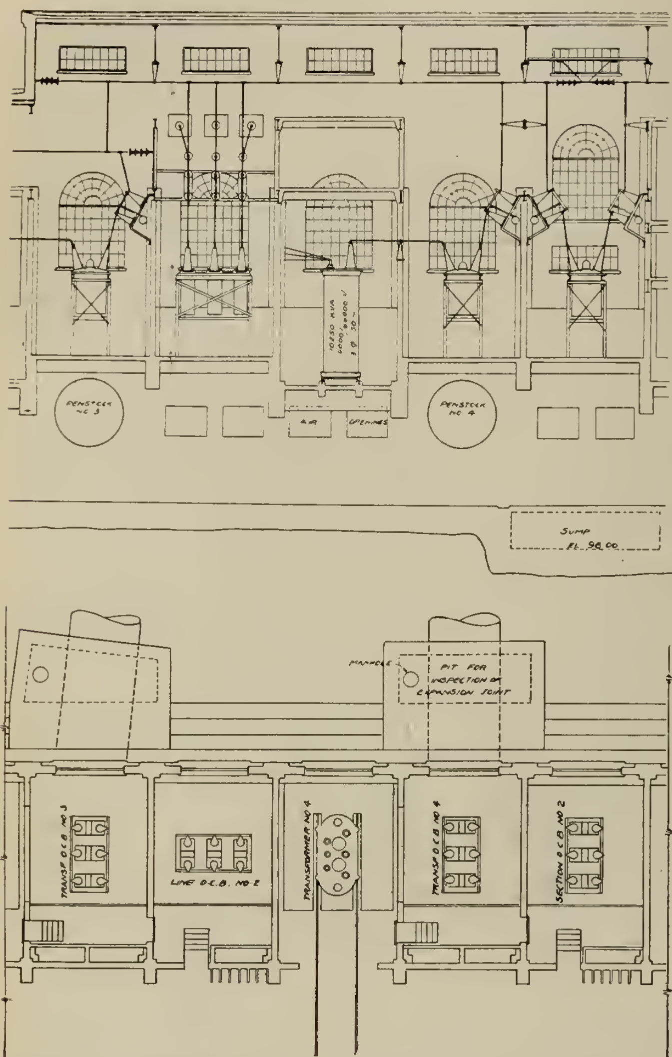

Figure No. 14.—Typical Plan View and Elevation showing part of Switchhouse.

are also provided with overload relays. The 6,000-volt bus coupler oil breakers are arranged with overload relays to take care of bus shorts only. All auxiliary power feeders are supplied with overload and earth leakage relays. Transformers are connected delta star with the star connection on the high-tension side. Generators are connected star and have their " Y " points earthed through a resistance.

The 6,000-volt auxiliary power supply is arranged to be taken from each of the seven generators, which are grouped into two sections, four being in one section and three in the other section. One generator on each section normally feeds approximately 50 per cent of the auxiliary power load. The bus coupler circuit breaker is installed between the two low-tension sections so that in case the generator, feeding one section, should be tripped off, this bus coupler is automatically thrown over too quickly for the motors to be tripped by the " no-volt " releases on their starters. Each generator in each section has a set of disconnecting switches which are so interlocked that it is impossible to open them under load and also impossible to parallel any two generators on one section through these disconnecting switches or to parallel generators in two sections. This system of low-tension auxiliary power supply has proved very satisfactory to date, considering that it is somewhat different from American design of stations where a small-sized high-tension transformer or small generator units supply auxiliary power. Power at 6,000 volts is supplied to an outgoing line to the Main dam and intake and a second line to the forebay. It also supplies low-tension transformers 6000/550 volts for station, auxiliary power and townsite distribution which is at 550 volts, 3-phase.

A separate 280-k.w., 550-volt, 3-phase Diesel engine generator set is arranged to supply through the transformers 6,000-volt power, and directly to the 550-volt bus. This Diesel engine generator set was purchased to be utilized during construction and later serve as an auxiliary to the power house.

The pressure oil system for the turbines and generators, which have water-cooled oil bearings, has the oil tanks located on the high-tension floor gallery so as to obtain the necessary head for proper circulation. The oil filter and oil storage tanks are located in the basement and the oil pumps are driven by two small motors and a small spare turbine-driven oil pump. Each of the three units is capable of supplying oil required for the whole system, and in case of failure of one pump, sufficient storage is provided in the tank on the high-tension gallery to run several hours, while the necessary repairs are being made to the oil system equipment, without interfering with the operation of the turbines or generators.

Necessary water sump pumps and an ejector are supplied to take care of any accumulation of water which might occur in the basement. A small motor-driven air compressor supplies the necessary air for blowing out generators, operation of air drills required for repair work, etc.

The air supply for the generators is taken direct into the basement through adjustable air openings. This allows a direct supply of air from the outside, across the short passage, direct to the generators, and assures a good continuous supply of clean dry air. The ground outside of the power house is grassed for a considerable distance in order to eliminate the dust.

The heating of the power house in winter is accomplished by using the heat from the generators. A circulating air system, through openings at the top of the building in the walls between the transformer section and the generator section, keeps the building comfortably warm. These large openings allow the air to pass down through the transformer and circuit breaker rooms, and through properly-guarded openings in the floor of the latter room the air passes into the basement where it is drawn into the machines, thus making a circulating system between the generator room and the transformer rooms. This system of heating of the power house has proved satisfactory during the past winter.

The power house is supplied with two 30-ton electric cranes, and provision is made for the insertion of a special wood mat between the rotor and the stator of the generator, in case it is necessary to lift the stator of the generator, so that the complete unit can be lifted by the two cranes. This arrangement is necessary owing to the fact that the stator was supplied in one piece.

The station lighting consists of overhead lights so adjusted as to be clear of the cranes when they are travelling, and are such as to give a six foot candle intensity on the power house floor. The lighting units are arranged in such a manner that there are no shadows. Flood lights are installed on the roof of the power house to illuminate the lightning arresters and transmission towers in the vicinity of the power house. They are also arranged on the tailrace side of the building to assist in night operation of the tugs which tow wood to the Humber river.

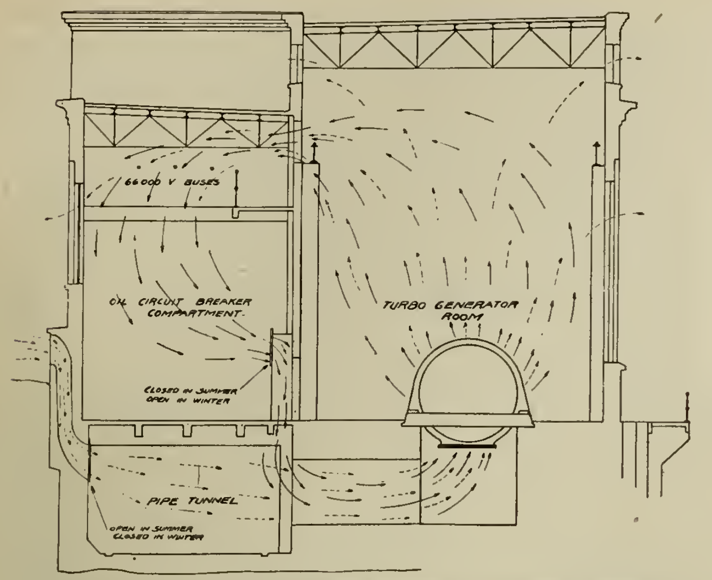

Figure No. 15.—Cross Section of Power House showing Air Circulation.
——+ Winter Circulation - - - - - -+ Summer Circulation

Transmission Lines

The transmission line consists of four separate 3-phase, 66,000-volt lines, covering a distance of 32 miles between Deer Lake and Corner Brook, composed of standard-size 266,800 CM. aluminum steel reinforced cable. The towers are of steel and the standard towers and strain towers are a duplicate of those used by the Shawinigan Water and Power Company on their Quebec lines. This also is true in regard to the concrete foundations which are used for supporting the towers. Insulators are of the pin type, except on the strain towers. There are 966 towers spaced approximately 350 to 400 feet apart. This transmission line has withstood the wind storms of two winters, and to date no failures have occurred on the steel towers. Wooden oak pins are used to support the insulators. Part of the transmission line is over a very rugged mountainous section and considerable difficulty was experienced in the erection of this portion of the line. Two special strain towers, having a height of 92 feet, provide proper clearance for the long span required to cross the railway tracks and give clearance to the buildings between the towers and the substation.

Telephone lines between Corner Brook and Deer Lake are run on wooden poles adjacent to the railway and were installed during the early construction period. Practically no induction trouble of the transmission line has been experienced on telephone lines, as they are a considerable distance from the power lines. Provision is made for instrument connection along the telephone line for the convenience of the patrol men. Telephone lines extend from Deer Lake to Howley for woods department operations.

Substation

Four transmission lines from Deer Lake enter the substation through 110,000-volt wall bushings, connect directly through disconnecting switches to four oxide film lightning arresters, duplicate to those outside the power house at Deer Lake, and connect through choke coils, and four 3-pole electrically-operated disconnecting switches, which are also designed for hand operation, to the high-tension volt busses. A double bus system is used for the 60,000-volt busses, two oil breakers being used on each incoming line. This arrangement permits the splitting of the load so as to take advantage of the best governing units at the power house in case trouble is caused by speed variation on the synchronous motors operating the paper machine electric drives, which are very sensitive to frequency changes. Single-circuit breakers are supplied with each transformer bank and provision is made with disconnecting switches to allow any circuit breaker to be connected to either of the two busses. Pin type insulators, the same as used on the transmission line, are used with a steel pin and an adjustable base to facilitate the alignment of the busses on the insulators. Standard metal caps are used on the top of the insulators for holding the copper tubes. The insulators are mounted on the latticed steel girders provided for the high-tension busses and the top metal cap allows for special clamps on the roof steel to take care of the connections between busses. This arrangement of the insulator and fittings provides a very simple and cheap scheme for high-tension busses for ceiling or ordinary mounting as parts are interchangeable, as against the more expensive post type insulators.

The high-tension room contains the 60,000-volt oil breakers and lightning arresters and has the steel work arranged specially for the busbar equipment. Circuit breakers and lightning arresters are supplied with light fireproof partitions in the form of cubicles up to a height just above the top of the oil breakers and metal-covered doors with wired glass openings are provided. Red and green indicating lamps, similar to those used on the switchboard, are supplied directly under the disconnecting switches located over the oil breakers to assist the operator in switching operations, so that a disconnecting switch will not be pulled under load as the lights indicate when an oil breaker is closed or open. This prevents the necessity of the operator going into the cubicle to see if the breaker is open, as the design of the top mechanism of the breakers is such that it is necessary to look at a small indicator on the breaker to know whether it is open or closed.

About one mile of ¾-inch iron pipe size copper tubing was used on the 60,000-volt bus work in the high-tension room and in that over the transformers.

Three different radii bends were adopted and a home-made bender was constructed which permitted accurate and quick bending of copper tubing and made the bending of the copper bus symmetrical. This scheme saved a large amount of labour and made possible the very quick erection of the copper tubing. All short ends of this copper tubing were saved and used on the low-tension circuit breakers, so that practically 100 per cent of the copper ordered was used.

Figure No. 16.—Transmission Line.

All tap connectors were drilled and pinned after the plant had been in operation approximately three months. This was done after all connectors were tightened up and had become set to their normal position. A small drill was used and the whole high-tension bus structure was completed during a single Sunday.

From the high-tension room to the short 60,000-volt busses directly over the transformers 110,000-volt floor bushings were used. A small concrete curb is provided around these bushings to prevent any possibility of burning oil running into the transformer rooms. Oil drains are also provided in all oil breaker cubicles, as well as under all transformers, to provide quick disposal of burning oil in case of trouble. Oil piping is provided in each oil circuit breaker cubicle so that the oil can be changed from the oil breakers directly from the oil tanks located in the oil storage room in the basement.

The substation is so designed that one side of the building accommodates the low-tension oil breakers on one floor and the switchboard room on the floor above, which has for its ceiling the floor of the higher-tension room. The other side of the building is so arranged that there is only one dividing floor between the transformer room and the high-tension room.

There are seven banks of transformers located in the transformer room, consisting of twelve 4,000-kv.a., single-phase, 60,000/4,600-2,300-volt, step-down transformers used for the two electric boilers, each taking two banks of three transformers or 24,000 kv.a.; six 5,500-kv.a., single-phase, 60,000/2,300-volt transformers for 2,200-volt motors and Corner Brook townsite power, and three 2,000-kv.a., single-phase 60,000/600-volt step-down transformers for 550-volt motors. The 4,000-kv.a. transformers have their secondaries designed for quick connection to 2,300 volts in case it is desired to use these transformers for power purposes, other than electric steam generators, at a future date. One transformer of 5,500-kv.a. capacity is utilized as a spare for both the 4,000-kv.a. 4,600-volt and the 5,500 kv.a. 2,300-volt transformers. The impedence of this transformer is so designed by the manufacturer that the transformer will operate correctly with either the 4,600-volt or 2,300-volt transformer banks. One spare 2,000-kv.a. transformer is available for 600-volt service.

The electric boiler transformers are grouped along the outside wall of the building and are connected through disconnecting switches to short 60,000-volt busses directly overhead. The low-tension terminals lead through disconnecting switches to 4,600-volt busbars located on the walls behind the transformers. These busbars run direct to the electric boilers located in a room separated from the trans-

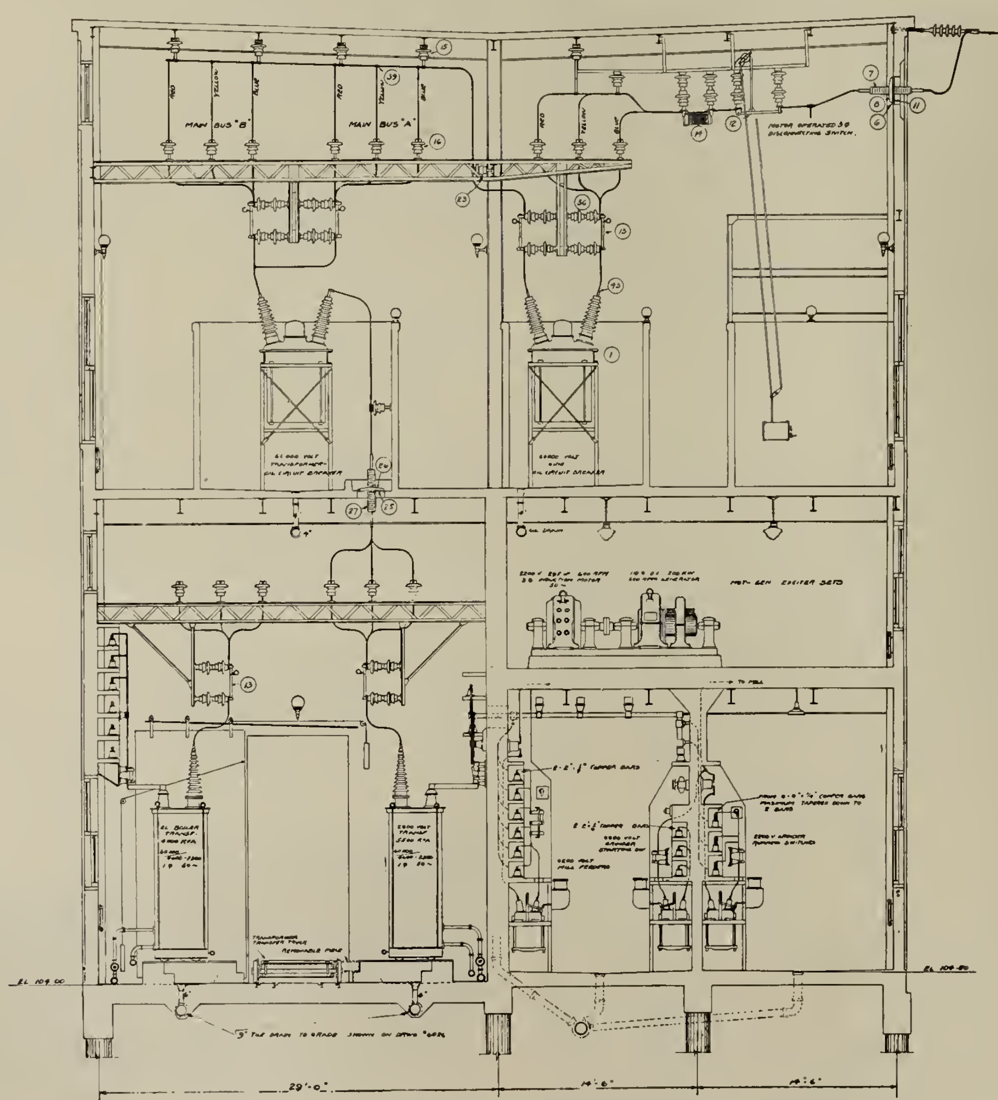

Figure No. 17.—Cross Diagram of Substation, Section A-A.

former room by a concrete wall. Insulator bushings are used on the 4,600-volt busses through the wall and are packed with oakum to prevent leakage of steam through the bushings into the transformer room. Owing to the long run of copper to the transformer banks farthest from the electric boilers, it was found necessary to provide expansion joints on these busbars. Also, all busbar clamps had their faces vaselined and were clamped up to a neat fit, but still allowed movement of busbars through them to take care of the contraction and expansion. Expansion joints were not considered necessary on the busbars having short runs to the electric boiler as expansion could be taken up by the flexibility of the fittings. Rubber washers were installed under all these busbar clamps to prevent breakage of any insulators in case one should seize the busbar and tend to move along with it. Experience to date has shown this scheme to be successful as not a single case of a broken insulator has been reported. All substation busbars are designed against short circuit stresses and bars are mounted in vertical position to take advantage of greater current capacity. Reinforcing rods in concrete bus structures were carefully arranged to avoid any possible short circuited loops.

The 2,300-volt and 600-volt transformers, as well as one spare transformer bay, make up the other side of the transformer room. The transformers are connected through disconnecting switches to the short 60,000-volt busbar sections located directly over the transformers. Low-tension power is taken from the transformers through the disconnecting switches directly through the wall on to the low-tension busbars. This arrangement provides for the shortest possible run from the transformers to the power busbars and gives in the same way as the electric boiler arrangement the minimum length of busbar required. All transformers are oil-insulated, water-cooled and the cooling water floor drains are arranged in such a way that any burning oil which might occur from trouble on the transformers will be drained away without spreading to other sections. All transformers are mounted on low concrete runways, open at the back, forming a pit under the transformers. Small concrete steps provide a passageway between the transformers. A transfer truck having removable sides provides facilities for moving the transformers. These sides can be quickly shimmed up to the exact level of the transformer rail, reducing the time element and the hard labour necessary to remove transformers when the height of the transfer truck rail and the transformer rail are not the same. The support for this side piece is made in the form of a step having a channel iron on top with the flanges embedded in the concrete. This and all other equipment has been designed from the operating point of view in order to arrange for speed and a small amount of labour when making changes. Eyebolts are provided in rear of transformers for pulling them into place. All water and oil piping is run in the rear of the transformers and all temperature indicators are located on the front of the transformers in easy view of the operator.

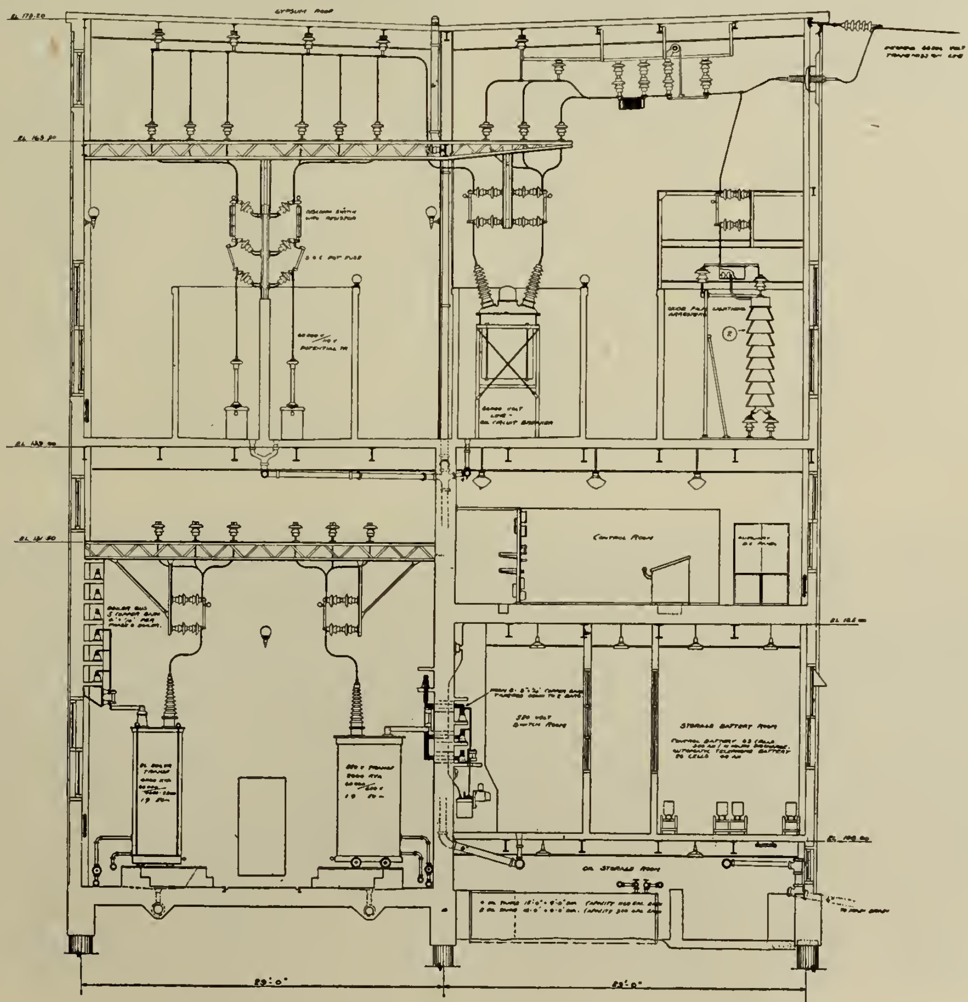

Figure No. 18.—Cross Diagram of Substation, Section B-B.

The transformers are connected delta on both high- and low-tension sides. This arrangement allows for operation of plant without appreciable delay in case trouble should develop on any single transformer. In paper mill operation it is very essential that all delays be cut to a minimum owing to the excessive expense of any appreciable delay, as the whole production of the Corner Brook mill is tied up in four units or paper machines and anything affecting any one unit affects very largely the total production output of the plant. It is always possible to carry on operations with slightly decreased load on the two remaining transformers of a delta-delta bank and necessary reductions of non-essential plant load until a spare transformer can be put into place.

Safety fire doors and light fireproof partitions are installed between all transformer banks, this arrangement being necessary in order that the plant could be passed by the fire underwriters who insured the whole mill property.

The low-tension leads from the two 2,200-volt transformer banks lead directly through the wall to the busses for the 2,200-volt feeder breakers. The twenty-two oil breakers on the starting and running positions of the eleven 2,200-volt synchronous grinder motors are located back to back in the centre portion of the low-tension switch room. Busbars for the running switches of these motors are divided into two sections, one section supplying five motors and the other section supplying six motors. The ends of these busbars are on the same busbar shelves and about 18 inches apart, and small busbar jumpers are available in case of emergency so that any grinder motor can be operated from either transformer bank under emergency conditions allowing for most efficient use of the equipment. Small light busbars are run over the starting switches for the grinder motors and receive power from two special auto-transformers which are used for starting all synchronous motors, one transformer being used as a stand-by. These auto-transformers are designed to start with one minute intermission between starts, eleven 3,100-kv.a. synchronous grinder motors and four 720-kv.a. synchronous motors for the paper machine drives, making a total of fifteen motors.

The starting circuit breakers for the grinder motors have disconnecting switches connected to them which tap directly through cable on to the running cables of the synchronous motors. By opening these disconnecting switches it is possible to work on any starting breaker at any time. The other side of the breaker is connected directly to the starting busbar and no disconnecting switches are necessary as the starting auto-transformer is only used during the starting period and can be taken off at any time, so that there is no possibility of danger to workmen working on circuit breakers.

The five starting switches for the smaller 720-kv.a. (800-h.p.) synchronous motors for the paper machine drives, of which one synchronous motor operates a spare generator set, are arranged directly behind the starting transformers. The running oil breakers are adjacent to the 2,200-volt feeder switches. This arrangement locates all starting synchronous motor oil breakers, starting transformers and running breakers for the grinders in one section so that no space is lost.

The 2,200-volt feeder oil breakers, as well as the paper machine running breakers, are designed to operate on the busbars connected to either of the 2,200-volt transformer banks. This is done simply with a double throw disconnecting switch and allows the balancing of loads on these two transformer banks.

In connection with the synchronous motors, it is interesting to note that all synchronous motors are started by push button signals located close to the motors, but that all starting operations are done by the substation switchboard operator, thus concentrating all necessary equipment in the smallest available space and saving large expense in starting equipment, cables, etc. The same auto-transformer as used for starting the 3,100-kv.a. synchronous grinder motors is also used for starting the 720 kv.a. synchronous paper machine drive motors, and these smaller motors are properly protected in starting through current transformers located in the starting busbar at such a point that they protect the paper machine motors only. These current transformers connect to relays which operate the circuit breaker controlling the auto-transformer. That is, two sets of current transformers (with different ratios), and two sets of relays, are used in the operation of the auto-transformer oil breakers and are arranged so that no matter which starting transformer is in service, its circuit breaker will be tripped out. At each synchronous motor a stop button signal is provided as well as an emergency trip button which is connected both to the motor and the starting auto-transformer relays. This provides protection to the motor by the person signalling the starting of same, in that he can trip the motor whether it is in a starting or running position. The substation switchboard has an ammeter located on the top of the board in such a way that it is visible to the operator when starting any synchronous motor

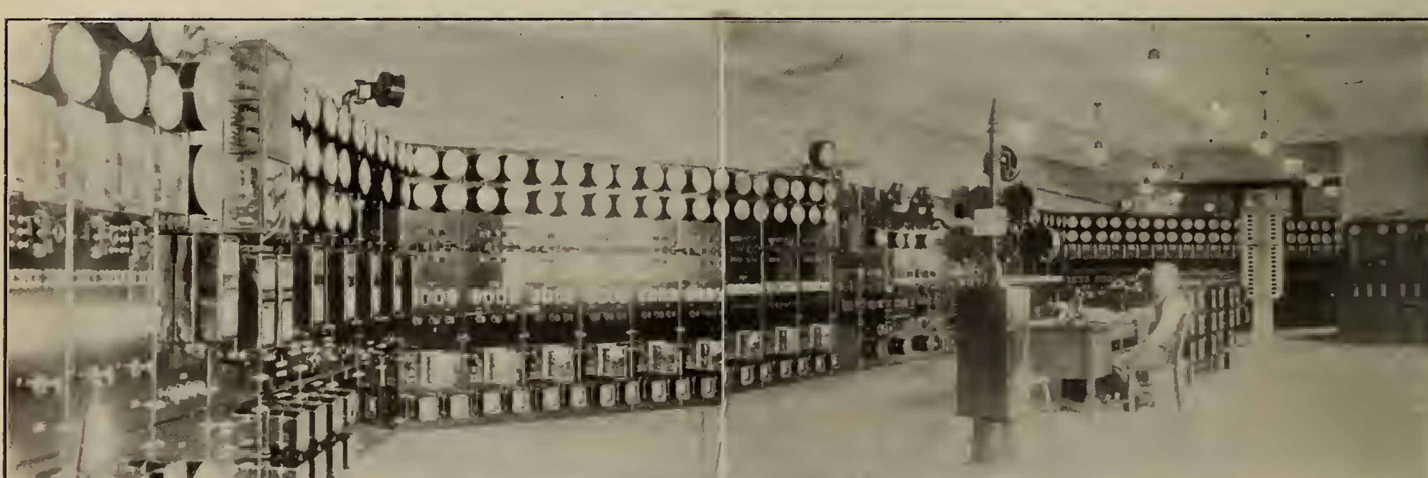

Figure No. 19.—Main Switchboard in Control Room.

Figure No. 20.—Part of Townsite showing Hotel.

so that he knows exactly the starting current and can see when it is time to go from the starting to the running position of the oil breaker.

Grinder running switches are of 1,500-ampere capacity and starting switches are of 900-ampere capacity, this lower capacity being entirely satisfactory owing to the short time in which they are in service. The current for these breakers depends on whether 50 per cent, 65 per cent or 80 per cent current taps on the two auto-transformers are used; one transformer is connected to 50 per cent and 65 per cent taps with double throw switches and the other transformer to 65 per cent and 80 per cent. These higher taps are only for use in emergency cases when the plant is suddenly shut down through interruption of power and the start may be exceptionally difficult.

The secondary leads from the 550-volt transformers go through disconnecting switches to the busbars located directly on the other side of the partition wall in the rear of the transformers. Three-pole single-throw disconnecting switches on one base are provided over each 550-volt feeder circuit breaker. The lower terminals on the disconnecting switches and the oil breaker terminals were supplied to take a ¾-inch iron pipe size copper tubing which is insulated by a split fibre tube extending between the disconnecting switch and the oil breaker. This allowed small ends of copper left over from the high-tension bus work to be utilized. Flat copper busbars connect the disconnecting switches to the main busbars.

There are twenty 550-volt oil circuit breakers of 900-ampere capacity for the numerous 550-volt circuits which are arranged to supply power to individual departments, so that the power consumption for the month for each department can be measured.

The eleven 2,200-volt feeder circuit breakers are all of 300-ampere capacity, which is also the capacity of the running and starting switches for the synchronous motors for the paper machine drives. This arrangement of circuit breakers allowed the minimum number of different capacities to be utilized so as to minimize the high expense of spare parts, which must be kept in stock in a plant such as this, which is isolated at times during the winter through lack of proper train accommodation.

Switchboard Room

The main switchboard consists of forty-six panels and is understood to be the largest switchboard shipped at one time from the British Isles. The slate panels have a baked enamel finish, with all control switches, test links and meters having nickel finish. Switchboards were purchased completely wired, with terminal boards and a colour scheme of wiring so that connection could be made by other than highly-skilled electricians. The eleven synchronous grinder motors and the five paper machine drive motors have each their own panel and the d.c. supply panels for these motors are situated approximately in the centre of the motor panels in order to be near the load centre and use a minimum quantity of copper bus. All other feeder panels carry meters, control switch, relays, etc., for two feeders, thus making the whole switchboard as compact as possible. The switchboard is in the form of an open " U " with the legs at an angle of 45°. This arrangement, owing to the size of the board, allows the operator the best possible view of all meters. A free standing signal pedestal, with red and green lamps, is used for all synchronous motors and has a bell attached to attract the operator's attention when it is desired to start any particular synchronous motor. Bells are provided near the synchronous motors and allow the switchboard operator to signal back the instant he is ready to close the starting breaker after he has put in his disconnecting switches. A white indicating lamp is also located on each synchronous motor panel so the operator has simply to go to the panel on which the white frosted light is shown, thus preventing him making a mistake in numbers after looking at a number on the signal post.

All essential a.c. and d.c. voltmeters are mounted on an instrument pedestal in close proximity to the operator's desk. Two small battery charging panels are located at one side of the main switchboard close to an entrance which leads into the substation control room. The substation is also provided with two 8½-k.w. motor generator sets and control battery for all control circuits.

The relay system provides for overload and reverse power on transmission line breakers, overload and differential relays on transformer banks and overload relays on all low-tension feeders.

A red tiled floor is supplied in the switchboard room.

The switchboard pit runs behind the switchboard and is arranged so that all conduits to the terminal boards are located directly under terminal boards. This pit was originally made larger than necessary so that it could be filled in after the switchboard was erected and the conduits correctly placed. This saved considerable time and trouble in trying to have conduits, which are located in the concrete, come directly in position and give a neat appearance. All conduits are fibre for 2-inch and larger and galvanized iron for the smaller sizes. Provision is made as far as possible for any future developments.

Owing to the fact that the substation and the whole mill are built on piles on filled ground, over which the tide originally flowed, two overhead passageways are used to

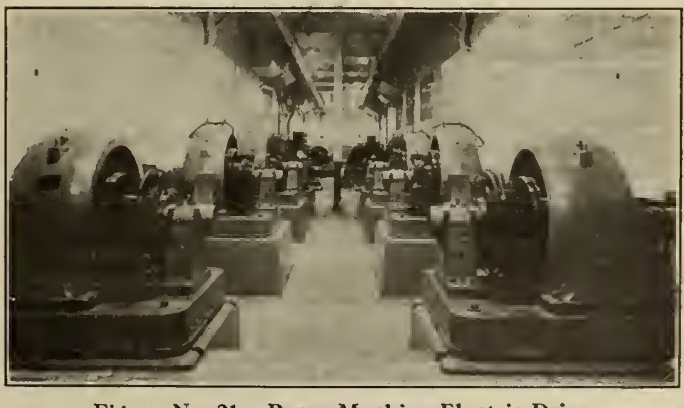

Figure No. 21.—Paper Machine Electric Drive.

conduct the power cables to the mill. The transformer station is located as nearly as possible to the load centre for the whole plant, that is, the whole plant is practically built around the substation, which was one of the first buildings designed. This arrangement reduces losses and installation cost to a minimum.

An automatic telephone exchange of 200-line capacity is located in close proximity to the switchboard in a special room so that the operator is available for correcting any troubles.

Conduit System

The mill and substation conduit system was laid out with the purpose of using fibre conduit as much as possible, in particular for the main feeders. All fibre conduits were embedded in concrete, utilizing air ducts and building walls wherever possible, so that the total amount of concrete required for such fibre conduits was kept to a minimum. It is interesting to note that there is no lead-covered cable in the mill and substation other than the paper-insulated telephone cables. A careful study was made for the design of the cable layout which allowed this arrangement to be made, as it was originally intended to use lead-covered cables in the grinder room, owing to the wet conditions in the vicinity of the floors, but by utilizing the walls of air ducts in the rear of the grinder motors, it was possible to do this work without using lead-covered cables. All duct sections are narrow so that they do not have more than two ducts together, thus giving high current capacity for all the cables in any duct section. Large-sized junction boxes were utilized throughout, giving easy access for pulling cables in order to cut down labour costs and also to ensure the cables from being damaged during installation. All conduit work throughout the mill and substation is entirely concealed, and no trouble has been experienced after one year's operation to indicate that the scheme of not using lead-covered cable is not entirely satisfactory. Only one case of a ground on a varnished cambric cable has occurred, and this was due to a steam pipe fitting breaking directly in front of a junction box which had its cover open as all cables had not been pulled in. Moisture getting into the cable duct gave a low resistance reading on the cable and immediate steps were taken to correct the trouble.

All lighting conduits, and wherever possible all other conduits, were made up in advance so that as soon as the form work was completed, the conduit was installed in the shortest possible time. A small portable motor-driven threading machine, threading conduit up to 2 inches and having a special cutter for conduit, was used to make up a large amount of small lengths of conduit. The steel work in the mill is such that the centre distances between columns are very nearly uniform so that a large number of lighting conduits could be made up in advance, as the lighting units were spaced at equal distances apart. Conduits were made up complete with locknuts and bushings and this saved time and reduced the cost of installation greatly, as unskilled help was able to install this conduit without any trouble.

Wire and Cable

Rubber-covered wire was used for all motor installations, except for large 2,200-volt size, and all cables were purchased in line with current capacity and insulation. That is, rubber-covered wire was ordered to certain sizes, which was found cheaper and more advisable to use, and over this point in current, varnished cambric cable was found to be much cheaper than rubber-covered wire and was used on all feeders. This gave the minimum cost for all cables installed in the mill and substation. Load centres were located throughout the mill for all departments, and distribution panels consisting of safety switch boxes were installed accordingly and feeders were run direct from the substation to the distribution panels.

The system of having the men move around their work as little as possible was utilized to a very large extent by having a special crew of men looking after the placing of all equipment on the spot so that electricians or skilled helpers were not sent to do any work until practically all required equipment was available for them. This allowed the most efficient use of skilled as well as unskilled help and resulted in a considerable saving as well as proper handling and responsibility being placed for breakage of any equipment.

The following are some interesting figures regarding electrical equipment in the mill and substation:—Over 120 miles of wire and cable are installed; over 23 tons of low-tension copper busbar ranging from 6 to 2 inches by ¼ inch; over 500 low-tension insulators; over 300 60,000-volt insulators; nearly 15 miles of fibre conduit ranging in size from 2 to 4 inches; over 40 miles of metal conduit of ½ to 2 inches; the number of lighting outlets is approximately 2,000; the number of lighting panel boxes 53; the number of motor safety switch boxes 298; the number of 550-volt distribution panels 41; the number of 2,200-volt power distribution centres 7; the number of switchboard panels, including substation, electric drives and grinder motor governor panels 120; 71 low-tension oil breakers; 13 high-tension oil breakers; 133 high-tension disconnecting switches and 213 low-tension disconnecting switches; the total number of connected motors 430 varying in size from ⅛ h.p. to 4,000 h.p. with necessary starting equipment.

These figures give a rough idea of the large amount of work required for the installation of this equipment, which, at the time, was the largest paper mill erected at one time.

The Characteristics and Utilization of Nova Scotia Coals

The extent of the Coalfields, the outstanding characteristics of the Coals, and a discussion of their Utilization.

W. S. Wilson, A.M.E.I.C., Assistant Chief Engineer, and *M. W. Booth, A.M.E.I.C., Steam Engineer,*
Dominion Iron and Steel Company, Limited, Sydney, N.S.

Paper to be presented before the Maritime General Professional Meeting of The Engineering Institute of Canada, at Sydney, N.S., August 18th, 1926.

Nova Scotia Coalfields

The principal coalfields of the province of Nova Scotia are the Sydney, Pictou, Cumberland and Inverness, although there are others of much smaller extent.

Sydney Field

The coal areas of the Sydney field dip under the sea. The land areas are in the shape of a segment of a circle; the chord, along the coast line, being about 30 miles and the greatest depth inland about 9 miles, comprising an area of some 200 square miles. The extent of the field seawards is unknown, although it has been proven for an area of 70 square miles submarine by workings which extend 2¼ miles offshore and indications are that it extends much further.

There are nine seams of 3 feet and over in thickness, totalling 42 feet of coal, although only three of them are being worked at present. Quite 80 per cent of the coal produced is won from submarine areas, and this percentage will keep increasing. In the proximity of 130 million tons have been extracted, and it has been estimated that there are yet in this field 2½ billion tons of available coal within an economic mining distance. The daily output, with present openings and equipment, approaches 25,000 tons. This, of course, could be, in time, increased on demand.

It may be mentioned here that the Nova Scotia fields are the only coal deposits on the Atlantic seaboard, and of these the Sydney field is the largest. Shipping facilities are excellent at three ports, Sydney, North Sydney and Louisburg.

The mining methods in vogue are in accordance with best present-day practice. Both the room and pillar and the longwall systems are followed, depending upon local conditions.

Though by far the greater part of the area worked is submarine, very little water is made over that area, the water to be contended with all being made through the old land workings.

Pictou Field

This field is located some 9 miles inland from the Northumberland straits and in its centre is the town of New Glasgow. It is small in area, being only 30 square miles in extent, but is of great economic value, due to the number and thickness of its seams; one of which reaches 40 feet in height.

The field is rather complicated by reason of its geological contortions and numerous faults, and is usually divided into three series, the upper having five seams with a total thickness of 21 feet of coal, the middle having twelve seams with a total thickness of 193 feet, and the lowest four seams totalling 42 feet in thickness.

For reasons mentioned above, it is most difficult to estimate the amount of available coal in this field, but a figure of 200 million tons might be offered. This figure is conservative and further development may show much greater reserves capable of being recovered. Shipping facilities are provided for at Pictou.

Cumberland Field

This field consists of a basin-shaped strip of coal, measures 12 miles in width by 25 miles long, and stretches from the bay of Fundy to the town of Springhill. In this field, to date, there are only three proven areas—(*a*) at Joggins, (*b*) River Hebert district, (*c*) at Springhill, and of these the Springhill area is much the greatest, both in extent and as to thickness of coal. There are here some five seams proven, of a total thickness of 37 feet. These seams dip very steeply,—at about 30°,—and depth of cover will probably prove the limiting factor to the area possible to be mined. The total tonnage available from seams proved to date, within a limiting depth of 4,000 feet, would probably be in the neighbourhood of 70 millions. The daily output at present is about 2,000 tons. Shipping facilities for this field are provided at Parrsboro.

Inverness and Other Fields

Practically all along the northwestern coast of Cape Breton island can be found outcroppings of coal seams, varying in thickness from a few inches to as much as 13 feet. These have been located in four basins, the Chimney Corner-St. Rose, the Inverness, the Mabou and the Port Hood basins. Very limited attempts have been made to work the Chimney Corner-St. Rose basin. Openings of some importance were worked in both the Mabou and Port Hood basins, but these were unfortunately lost some years ago, due to an inflow of water. The Inverness field shows a number of seams rapidly dipping seawards, of which five show a total thickness of over 30 feet, including the 13-foot seam abovementioned; the extent being approximately 5 square miles. This is the only field in the group being worked to-day.

General Characteristics

The coals of Nova Scotia, with few exceptions, are of the first rank bituminous, (high volatile), with high calorific value, low moisture and ash content, possessing coking properties and are suitable for all general purposes, viz., steam raising, (hand, mechanical stoker or pulverized fuel installations and bunker), metallurgical by-product coking and gas.

While all Nova Scotia coals with the exception of Inverness coal possess coking properties, they are not caking coals. " Caking coals " is the name given to those that, when burned in the furnace, swell and fuse together, forming a spongy mass that may cover the whole surface of the grate. When these coals are burned, this mass must be frequently broken up with the slice bar in order to admit air needed for its combustion. " Free burning coal " is a class

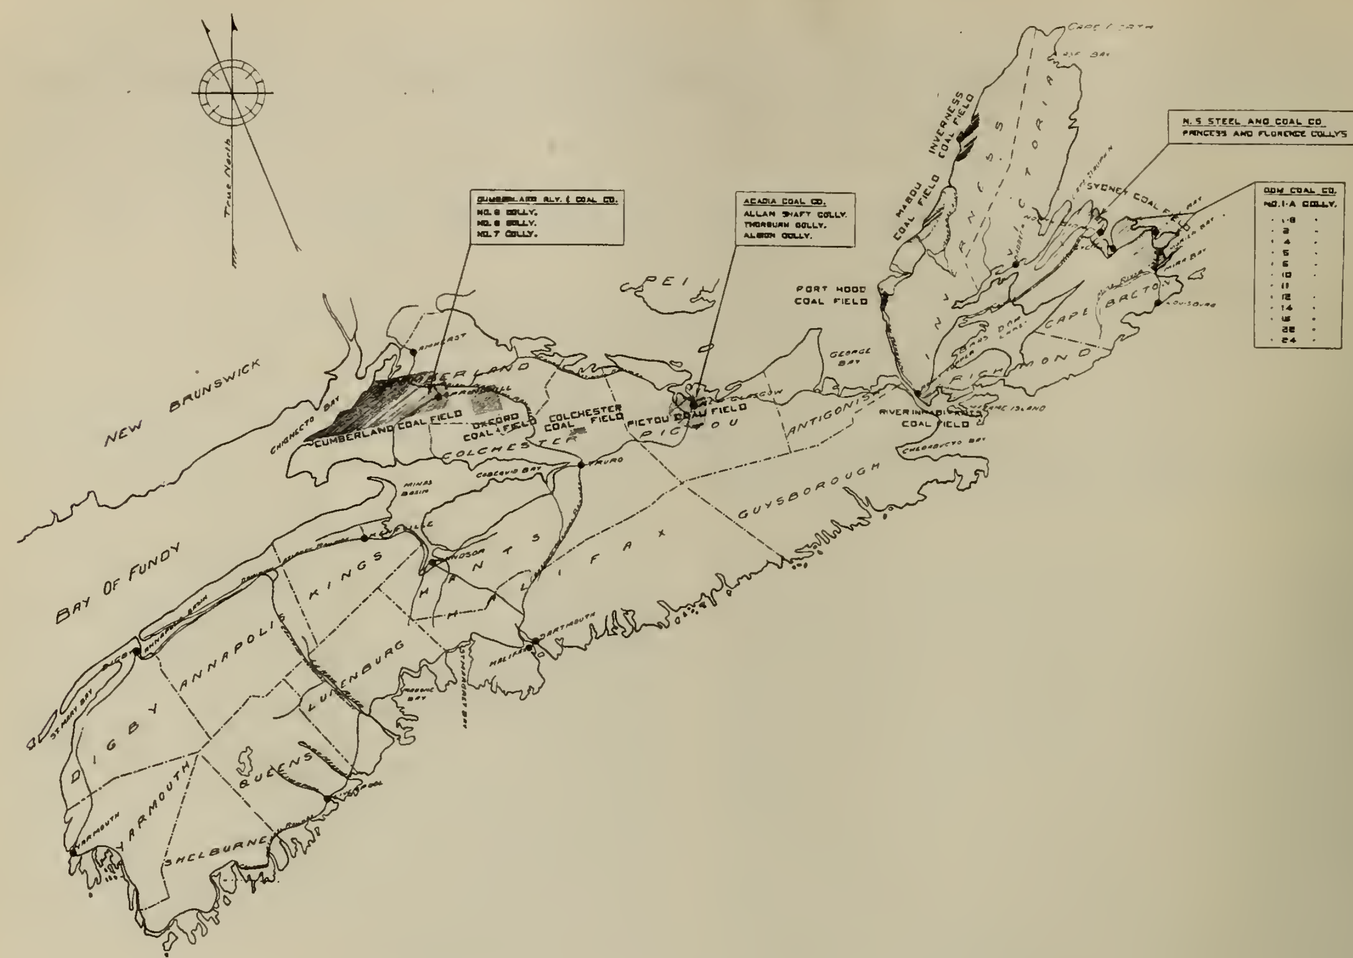

Figure No. 1.—Province of Nova Scotia showing Principal Coal Fields.

of bituminous coal that is often called non-caking from the fact that there is little tendency to fuse together when burned in a furnace at high temperatures. Nova Scotia coals shrink in the process of burning, and while they do fuse in a more or less marked degree, it is not necessary to agitate the fuel bed in order to admit air for its combustion. Recognition of this fact and handling of fires accordingly will go a long way towards removal of some complaints regarding Nova Scotia coals, as compared with some competing American bituminous coals. The fuel bed must be disturbed as little as possible,—it is not required.

The fact that a coal has coking properties does not mean that it will cake together in the furnace. (Domestic furnaces with low fire temperatures producing an oven effect are not included in this statement.) There are coals from the Pictou field which are very free burning and which do not fuse, and yet they possess excellent coking properties when distilled in coke ovens.

All of the Nova Scotia coals possess a high volatile content, up to 39 per cent, with a percentage of fixed carbon up to 60 per cent, and with a generally low percentage of ash. It is this high volatile content that provides such a large yield of by-products in coking, for which Nova Scotia coals are famed.

In burning these coals means must be provided for insuring combustion of the voluminous gases which are evolved. If this is not accomplished, black smoke may be seen issuing from the stack, which is not desirable, especially in cities that possess smoke ordinances. Smokeless combustion, however, is not necessarily an indication of efficiency, as the loss from visible smoke rarely exceeds 2 per cent. Dark smoke should be considered as visible evidence of incomplete combustion rather than as a loss in itself.

Ash

It is often stated that Nova Scotia coals contain a high percentage of ash. This is quite a mistaken idea, as study of the analyses will disclose. (See Table No. 1 for comparative analyses.)

Eliminating moisture, ash is the inorganic substance in coal and is that portion of the mineral substances in the coal which remains after the combustible has been burnt. It is valueless, a nuisance and represents a dead loss to the consumer, as it does not produce but actually absorbs heat units in reaching the temperature of the fire. Its removal, generally in a heated state, from the grates, together with a certain amount of unburnt fuel, is attendant with loss detracting in no small way from the efficiency of the furnace, especially if the ash content is high.

There are two kinds of ash, that which is inherent or fixed in the coal and the extraneous ash which can be removed on the picking belts or by mechanical cleaning. The latter kind has really nothing to do with the character of the coal as it is entirely foreign and represents pieces of shale or sandstone from the roof and bottom of the coal seams, which come down in the mining operations and which have escaped detection on the picking belts. There are, however, in some particular seams of the Nova Scotia coalfields, bands of " bone " or " bony " coal which are intimately associated with the purer substance, tending to make, on

*The Sulphur content is variable ranging from 2.25 to 4.6% according to location.

Note:—Above analyses represent average analysis of coal taken from working faces of mines. Delivered car samples will generally show some increase in percentages of ash and surface moisture.

the whole, a higher ash coal. This "bony" coal presents a somewhat duller appearance, and although it might be classed as a semi-impurity, it has a beneficial effect upon the clinkering properties of these coals when burnt in mechanical stokers.

Sulphur

Another statement made is that Nova Scotia coals are high in sulphur, which element is often looked upon as sufficient, if in quantity, to seriously impair the quality of the coal. Nova Scotia coals are as a whole relatively high in sulphur. There are, however, both low and high sulphur coals in the province. The metallurgical coals are higher in sulphur than most coals of this continent, and washing to remove some of the sulphur must be resorted to. This practice is the rule in Europe.

In many cases, the statement "high sulphur" coals, (whether used correctly or not in the case under consideration), is made and even adjudicated upon without true knowledge of what it really means. A better way to state the case is as follows:—

> The greater percentage of Nova Scotia coals contain sulphur in excess of 1.5 per cent, but not so as to be materially detrimental to their value except in certain cases, such as metallurgical and domestic gas purposes.

That part of the sulphur content which is organic is combustible and that which is in combination with iron, calcium, etc., and which does not burn, remains in the ash. It is this latter part which has more to do with the ash characteristics as affecting the clinkering properties of the coal than the total sulphur content, as will be shown later.

The uncontroversial points in connection with the sulphur content are:—

(1) That which is incombustible is a loss.

(2) That which is combustible burns, but with lower B.t.u. emission than carbon, namely, 4050:14,540.

The above statements do not militate against use of Nova Scotia coals in general, except the two cases cited which are outside the general run. What, then, are the popular ideas regarding,—to use the popular phrase,—a "high" sulphur content?

(*a*) It is a widely accepted idea that it is the cause of spontaneous combustion. This is a very important matter because of the necessity of winter storage both at the mines and points of usage.

Now, the most that can be truthfully said about sulphur and spontaneous combustion, or firing of the coal pile, is that there is a possibility of sulphur being a *contributory* cause, but most certainly not the main one. That sulphur is the cause of this trouble is an old belief, and it has been definitely discarded by the highest authorities of to-day. This is what the Fuel Committee of the National Electric Light Association have to say upon this matter:—

> *"Several companies have requested that consideration be given to specifications of sulphur content in coal. These companies seemed to believe that sulphur content determined the suitability or unsuitability of coal for storage. For a long time there has been a general impression that the sulphur content had everything to do with the difficulties encountered in storage of coal. This is a vestige of an old belief. It is known, for example, that Texas lignite, having a sulphur content of 0.75 to 1 per cent, gives a great deal of trouble in storage, indicating that the sulphur content cannot be held entirely responsible for the difficulty in storing, but rather that the nature of the vegetable compounds or size of fuel may be more properly considered the troublesome factor. In addition, it is known that as the percentage of fixed carbon increases and that of volatile matter decreases, less trouble is generally en-

Figure No. 2.—Relation of Total Sulphur Content in Coal to Softening Point of Ash.

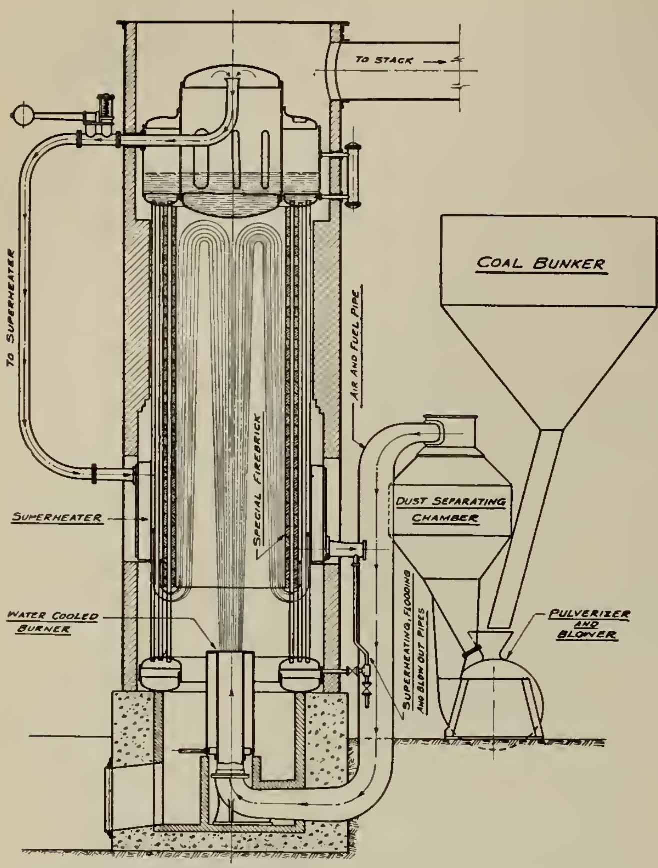

Figure No. 3.—Sectional View of Bettington Boiler, Waterford Lake Power Plant—Dominion Coal Co. Ltd.

countered in storage. Therefore the importance of specifying the sulphur content as being the sole important factor in determining the suitability of a fuel for storage is evidently questionable."

The Dominion Coal Company Ltd. have found from experience, (they have banked quantities up to 400,000 tons in one pile for periods up to eleven months without being lifted), that of all their coals, two of the highest sulphur coals, (one of which is not now worked), closely followed by a low sulphur coal, gave the most trouble. Their No. 6 mine, referred to as not now working, tested exceptionally high in sulphur, 5 per cent, and is therefore an extreme condition, and yet Mr. J. Mullins, the superintendent of the banking stations, states that from his extensive experience with banking coals:—

"We believe that fineness of coal is a bigger factor than its chemical constituents as a cause of fire, and might say, with past experience in mind, that we would prefer banking screened No. 6 coal to run-of-mine from any colliery in this district, even though No. 6 is our most dangerous coal."

It is not the intention to go any further than this here, but to deal with this subject more fully under the heading "storage," except to venture the opinion that the conditions under which the coal is stored and its physical qualities bear more relation to its liability to fire in the pile, than the sulphur content, which indeed plays a minor part in this matter.

(*b*) Another prevalent and erroneous idea is that the clinkering characteristics of a coal may be judged from analyses indicating the total amount of sulphur in that coal. Before enlarging upon this, let us consider the term "clinkering." Clinker is ash that has fused together. What tendency the ash has to form clinker and what kind of clinker it forms can only really be determined in one manner, and that is by burning that coal under the actual working conditions. Its tendency to clinker or otherwise may be minimized from knowledge of its peculiarities, and troubles in very aggravated form avoided, but nevertheless the determination of the clinkering characteristics of Nova Scotia coals can only be carried out as stated above. This is important.

Consideration of the softening or fusion point of ash is used by many authorities. Naturally, those coals having a high ash softening temperature are termed non-clinkering. It has been established that coals whose ash fused at temperatures over 2400°F., (1316°C), produce no objectionable clinkers. Below this point the formation of clinkers in more or less troublesome form may be anticipated. These rules are of immense importance to us because we have only one mine which produces a coal with an ash fusion point well over 2400°F., (1316°C.). Nevertheless, it is known by experience that there are several mines in Nova Scotia producing coals which do not form objectionable clinker, that is, clinker which adheres to the grates or brickwork and which is difficult to remove. This brings us back to the statement that actual trial is the only method by which Nova Scotia coals may be judged.

Dealing with these various points, the relation of total sulphur content in the coal to the ash fusion point will be considered. Figures gathered by the United States Bureau of Mines do not prove there is any direct relation. For instance, a coal was analysed having a sulphur content of 5.4 per cent, yet the ash fusion point was 2980°F.; another analysed 0.33 per cent sulphur and the fusion point of ash was 1990°F. This does not bear out the feeling that a high sulphur content means a low ash fusion point or vice versa. If reference is made to Figure No. 2, it will be seen that there is really no direct relation between the sulphur content and ash fusion point for Nova Scotia coals. In some cases, as the chart shows, the fusion point is lowered with the sulphur and again the opposite occurs, which emphasizes the futility of regarding the ash fusion point as bearing a direct relation to the sulphur content of the coal.

There is another point this chart reveals, and that is, with two exceptions, there is no great difference between the ash fusion point, and all of them except one fall under 2400°F., (1316°C.). Yet the best steam coals, and those which can be forced on mechanical stokers without trouble, are coals D, E, K & L. The ash fusion point is about the average of all of the coals shown. What is the reason for this? Why should these coals in particular, which are not low in sulphur and whose ash fusion point is in the clinkering region, act in this manner? Analyses of the ash reveals features which stand out consistently, and that is:—

These coals, namely, D, E, K & L on Figure No. 2, show *ash* analyses varying from 0.66 to 2.90 per cent lime and 0.14 to 0.60 per cent sulphur, while the other coals in the same field, while of a lower ash content and of better appearance, show an average ash analyses of 7.0 per cent lime and 2.25 per cent sulphur.

Generally speaking, the silica and alumina are a little higher and the ferric oxide a little lower, but the line of demarcation is not nearly so distinct as in the case of lime and sulphur.

These coals which are in the Sydney coalfield have a dull lustre and are not as good in appearance as others from the same field.

The foregoing are the only distinctive properties which might account for these coals being non-clinkering and against the generally accepted order of things.

In closing this matter it should be noted that even with the coals that clinker, no real trouble will ensue if the fires are not forced and intelligently handled, also that mixing of these different coals has had the effect of minimizing clinker trouble.

The foregoing emphasizes the fact that Nova Scotia coals have their own distinct peculiarities which must be recognized and prepared for. In some places, these coals have received a bad name simply because the conditions under which they were used were not suitable. In all but a few instances, where a supervised test was permitted and proper allowance made for these characteristics, Nova Scotia coals have proven equal if not superior to the same class of American coals previously in use.

Storing

This section deals with large storage of coal which is necessary in many plants on account of transportation requirements and other reasons. It is not intended to cover systems of storing, i.e., by drag scraper, conveyors, etc., which are purely mechanical features, but rather, to deal with those facts concerning the physical nature of the pile which should be considered, especially as affecting Nova Scotia coals.

Spontaneous combustion of coal in the pile is a very serious matter and the consequential loss from the pile firing may be large. In this connection, modern storage plants are designed with a view to preventing rather than combating this evil. All coals are subject to spontaneous combustion, some more than others and anthracite least of all. There has been much research work in this matter, and it will be sufficient to say in this paper that the main cause is considered to be absorption of oxygen from the air by the coal without sufficient means for carrying off the heat thus produced. It cannot be absolutely prevented, except by under-water storage. There are only a few plants that have this type of storage, and then it is generally in the nature of a reserve supply, such as provided for navies. In this climate it would not be very successful for industrial plants, and no doubt the reclaiming costs of coal stored in this manner would offset losses resultant from fires in the pile.

The experience gained by mine operators in Nova Scotia, where very large stocks are carried or " banked " in the winter months, should be of benefit to consumers, and some very instructive information is given in the following statement, which deals with the banking of coals in the Sydney field, by the Dominion Coal Company, Ltd.:—

"' Prior to the war, the coal stored consisted almost entirely of screened coal,—the quantity of run-of-mine was almost negligible. No attempt was made at systematic ventilation and no trouble arose from heating. Since the war, run-of-mine coal has been stored, and it is with this class of coal and slack that most difficulty is experienced due to heating. It was found that, generally speaking, no heat develops until after the coal has been stored for three months, and, further, that if no heat trouble occurs within five months, it is quite probable that the pile will remain indefinitely without heating, although it is doubtful if any run-of-mine coal can be stored to-day without ventilation and not heat after three months. In banking run-of-mine coal, it is essential to keep adding to the pile on a defined face slope and not in spots. In this way the coal naturally grades itself by gravity, the larger lumps going to the bottom, practically all the fines being confined to the topmost third. When banked in this manner, it is found that the heat, if any, develops at from 12 to 15 feet from the top of a 39-foot pile and rises slightly, but does not come to the surface, nor does it follow the larger coal to the bottom. Heat has never been found at a greater depth than 20 feet below the top of such a pile. At no time have we stored coal at a greater height than 39 feet. In storing slack coal, it has been found that it started heating practically at the bottom of the pile.

" It is evident from the above and from the known fact that a pile of screened coal does not heat, that immunity from fire in the base of a bank of run-of-mine coal is due to the larger coal being segregated at that section, thus affording better ventilation. This was demonstrated particularly in a pile at the Sydney steel plant made in recent years. In jacking up the track on this pile for one season, run-of-mine coal was used, each lift being about 20 inches to a total height of 34 feet. Heat developed throughout the whole section underneath the track. In the following year nothing but screened coal was used in jacking and there was complete freedom from heating under the track.

" Although no attempt is made at systematic ventilation to prevent heating, it has been the habit for the past ten years to ventilate once heating was discovered. It is quite an established fact that initially the pile does not heat throughout as a mass, but that heat occurs only in comparatively small isolated spots. Occasionally these spots are detected in the early morning by gases rising from them, but the practice to-day is to prospect the pile by test rods, after it has been in place for three months. These test rods are forced into the pile to a depth of 20 feet, left in place from 10 to 15 minutes and then withdrawn and the degree of heat judged by touch. When a hot spot is met, numerous test holes are made in the neighbourhood until its location is definitely fixed, both as to height and extent, and then it is ventilated in the following manner:—

" Pointed pipes, 1 to 1¼ inch in diameter, are

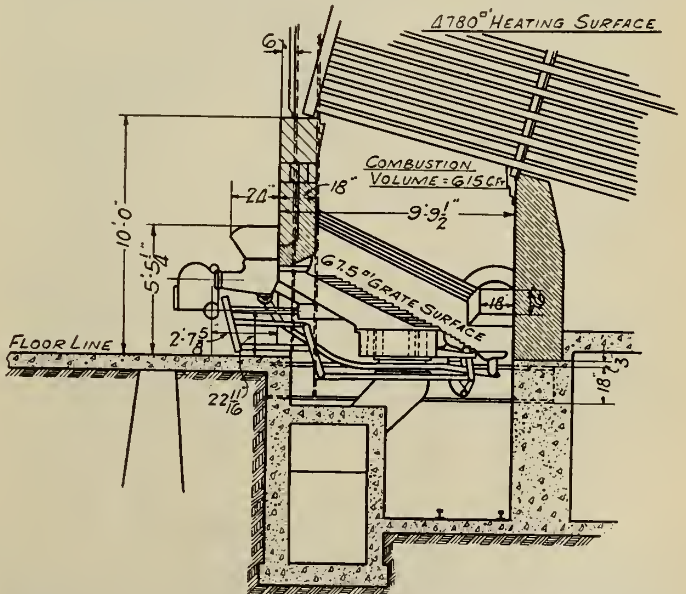

Figure No. 4.—Waterford Lake Power Plant—Dominion Coal Co. Ltd. Installation of Taylor Stokers under Babcock and Wilcox Boilers—Installed in 1912.

forced into the pile at 18- to 24-inch centres and below the known depth of the heat. These pipes are turned by a wrench so as to form a wall to the hole in the pile and a cone, of such material as ruberoid, is placed at the top of the hole to act as a casing and the pipe withdrawn.

"After an area has been so ventilated it usually begins to cool within 7 days and generally it has become quite cool in 10 days. Only occasionally is this followed by a second heating in the same spot, but it is thought that this, when it does occur, is due to the collapse of the holes and the consequent obstruction of the ventilation. It should be noted that water is not used for cooling.

"Perhaps the most serious objection to segregating into piles of slack and screened is that the screened pile might need re-screening when lifted, resulting in a greater ultimate percentage of slack.

"Our experience would lead us to recommend that only screened coal be stored, and we consider such coal could be banked to a height of 36 feet as a maximum without danger. Run-of-mine should not exceed 25 feet in height and slack piles not more than 14 feet. The largest stock ever stored by us amounted to 400,000 tons, mostly screened, with a height varying from 22 to 39 feet, and the longest period over which coal was stored without lifting was eleven months."

Very few complaints have been received on account of fires in ships' bunkers, resulting from spontaneous combustion, although 250,000 tons of bunker coal from Nova Scotia are used each year. The S.S. Wabana, 7,000 tons, took on sufficient bunker (2,158 G. tons) at Sydney to go to Vancouver through the Panama canal and back to New York. The round trip lasted three months, and there was not the slightest trouble from heating of the coal.

Apart from spontaneous combustion, coals suffer somewhat from "weathering," which is caused by oxidation of organic matter in the coal. The loss in heating value from this source, if any, has not been determined with respect to Nova Scotia coals. Experience shows, however, that "banked" coal becomes slower burning and therefore more adapted for use in furnaces not designed especially for Nova Scotia coals. Boiler operators have shown a decided preference for weathered Nova Scotia coals rather than freshly-mined coal, claiming equal efficiencies and better maintenance costs. This is borne out to some extent by tests made by the University of Illinois and published in their Bulletin No. 97. These tests show practically equal efficiencies and boiler ratings with weathered coals, after six years' storage, as compared with freshly-mined coal of the same class. Illinois coals are, however, inferior to those of Nova Scotia, being higher in moisture and ash and lower in fixed carbon and B.t.u. value.

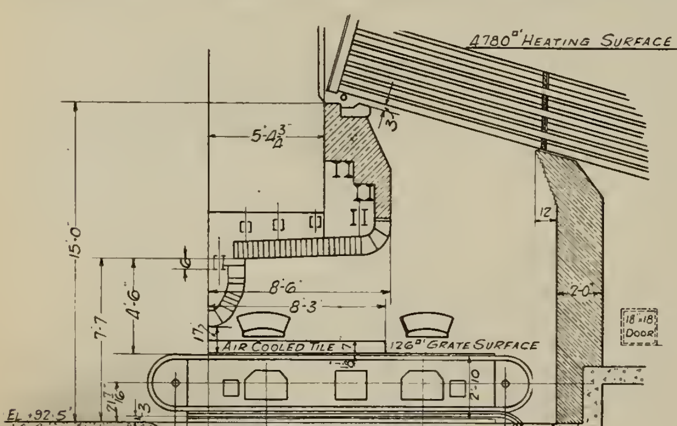

Figure No. 5.—Waterford Lake Power Plant—Dominion Coal Co. Ltd. Original Installation of Coxe Stokers under Babcock and Wilcox Boilers—Installed in 1924.

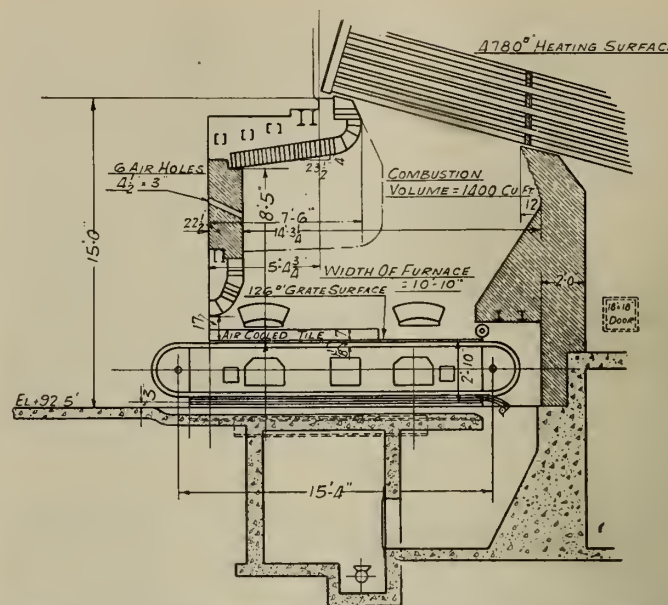

Figure No. 6.—Waterford Lake Power Plant—Dominion Coal Co. Ltd. Changes made to Setting for Coxe Stokers under Babcock and Wilcox Boilers.

It has also been found that weathered coal, if stored, is not so liable to fire in the pile as freshly-mined.

Utilization

Outstanding methods in which Nova Scotia coals are used and their adaptability will be touched upon in the order of relative importance, namely, by-product coking, steam raising by mechanical stokers and pulverized fuel.

Coke By-Products

The coking properties of the coals of Nova Scotia together with their high yield of by-products render them invaluable to the country. That by-product coke, as made from these coals, is a satisfactory but by no means an inferior substitute for imported anthracite for household fuel, is now generally accepted. The by-products obtained in distillation, such as gas, tar, motor fuel, sulphate of ammonia, etc., go a long way towards making a coking proposition commercially successful, and production of these materials would make us less reliant upon other countries for these necessary products.

For instance, a coking plant situated in Montreal, producing 385,000 tons of coke per year and replacing approximately half of the anthracite used in Montreal per year, would be the means of improving the trade balance of Canada by almost $10,000,000 per annum, represented by increased employment and increased production of valuable materials in Canada.

What is known as the regenerative by-product coke oven provides the means for producing coke most economically. The individual oven is a long narrow brick retort and is arranged in batteries with heating flues between each oven. Those at the Sydney coke plant are 37 feet 6 inches long, 17 inches mean width, 8 feet 7 inches from floor to top of coal. The coal charge is 11.25 net tons per oven. The volatiles are collected in mains and the gas is then stripped of its condensates and by-products extracted before being distributed. About 40 per cent of the total gas, or about 9 per cent of the total heating value of the coal charged, is used for heating the ovens and the remaining 60 per cent is available for other purposes.

The time taken in distilling the coal depends chiefly upon the temperature carried in the flues and the width of oven. At Sydney a minimum coking time of 16 hours is reached with an average temperature of 2600°F. in the flues. With an oven 14 inches wide, coking times of 12 hours may be reached with the same flue temperatures. This system is known as high temperature carbonization.

Low temperature carbonization is a different process altogether. When bituminous coals are carbonized at a temperature of 850°F. to 900°F., they undergo chemical and physical changes which are distinctly different to those brought about by the high temperature process. There is a lower gas and sulphate yield, but the tar yield is 100 per cent higher and the coke, which is in the form of soft semi-coke, contains about 10 per cent volatile. This semi-coke burns very readily and is smokeless. It requires briquetting for household fuel. This is done in Europe, but in America it is used in one or two places for pulverized fuel, for which it is very suitable. The tars are lighter and much more valuable than those obtained from the high temperature process, but how much so has not yet been ascertained. There are many operating difficulties to be overcome in this method of coking before it can be made successful, and after that, creation of a market for its products. As yet, there have been no investigations or experiments made with Nova Scotia coals along this line, although if this process is finally perfected it is only reasonable that these coals with their high volatile content will be very suitable. Mr. Henry Ford has built three coking plants, one of which is at Walkerville, Ont. It is understood that the Detroit plant is being dismantled to make room for a high temperature by-product coke plant.

The uses of coke are principally:—

(1) For metallurgical purposes, such as blast furnace and foundry.
(2) As a domestic fuel, replacing hard coal or anthracite.

Also in a lesser degree:—

(3) As a steam boiler fuel,—chiefly in the finer forms, such as coke breeze.
(4) In gas plants for making water gas, etc.
(5) In the manufacture of calcium carbide.

Only the first two, being the most important, will be considered here. The choice of coals for these cokes must be carefully made, and a policy of selection is necessary. For instance, all Nova Scotia coals with the exception of an Inverness seam are good coking coals. The best coking coals, that is, those producing coke with the best physical structure together with good yields, are those which test high in sulphur. Some of the low sulphur mines produce a poor coke physically. By blending various grades, different cokes may be obtained. Assuming that a certain coal or mixture of coals gives a satisfactory physical coke, the features that are the deciding factors are:—

(1) Percentage of ash in coal.
(2) Percentage of sulphur both in the coal and in the surplus gas.
(3) Yields obtainable.

The percentage of ash in coke for metallurgical purposes should be as low as possible. The ash percentage in the coke used at the Sydney blast furnaces averages around 7 per cent. The standard for comparison in the United States is Connellsville Beehive coke, which contains 11.5 per cent ash. The percentage of ash in domestic coke is not so important, provided the coke will burn well and the consumer pays on a proportionate B.t.u. basis. A high ash content will present many cleavage lines in the coke, producing too much fines, so that a higher ash content than 13 per cent should be avoided.

Sulphur is a very undesirable element in all metallurgical operations, especially in steel products. Injection of this element into the product by way of fuel must, therefore, be avoided. Metallurgical coke used at Sydney contains 1.8 per cent sulphur. A higher sulphur content than this in domestic coke is not at all objectionable in itself, but when it comes to the utilization of the surplus gas, the sulphur question comes up. If this gas is used purely for industrial purposes, such as firing boilers, etc., there is no practical limit to the sulphur contained in the gas. It is very objectionable in gas used for domestic purposes on account of the fumes that arise from its combustion. They are very obnoxious and smelly, and silverware tarnishes very readily if subjected to these fumes.

The volatile sulphur is driven off with the gas. The amount is variable, but is generally around 40 per cent of

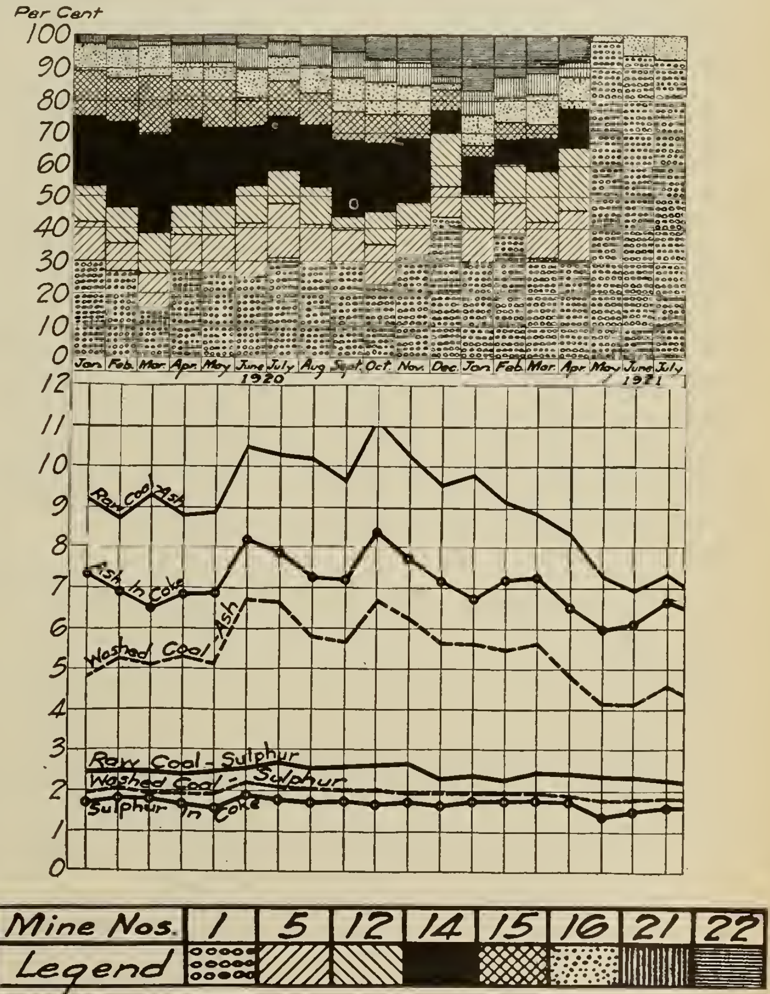

Figure No. 7.—Proportion of Coal by Collieries with Ash and Sulphur Contents of same, used monthly at Dominion Iron and Steel Company's Coke Ovens.

Note:—From above table, and taking mine No. 1 for example, rejection of 7% of total coal in washer removes 31.7% of total sulphur and 54.5% of total ash in coal.

the total amount of sulphur in the coal. This sulphur is contained in the gas in two forms, namely, sulphuretted hydrogen, (H_2S), and organic sulphur. For domestic uses the former must be eliminated and the latter kept down within 35 grains per 100 cubic feet of gas. H_2S is taken out in two ways. One is absorption by means of oxide of iron in the form of bog-ore. When the ore becomes " spent " or inactive, it is removed from the purifier and exposed to the air, when the sulphides are oxidized and the material is " revivified " for further use. The purifiers are simply cast iron boxes with trays or grids upon which the oxide is laid in layers eight inches or more deep.

Another process which is used is known as the liquefaction process. The gas is " washed " in towers by a solution of soda ash, later subjecting this to a process of revivification.

It is not known how to remove organic sulphur from the gases at the present time on a commercial basis, but it is found that when benzol towers were employed, i.e., towers in which the benzols are absorbed from the gas through the medium of absorbing oils, the organic sulphur is reduced by approximately 25 per cent. From tests made with Nova Scotia coals, it has been found that if the organic sulphur in the gas has to be kept within 35 gr. per 100 cubic feet, then the total sulphur in the coal as charged should not exceed 2.0 per cent, or if the benzol absorption towers are used, and they undoubtedly would be in a large plant, the total sulphur in the coal should not exceed 2.5 per cent. This refers strictly to production of domestic gas.

In order to meet these conditions, it is evident that selection of coals is necessary, depending upon the utilization of both the coke and the gas. If sulphur is the main consideration, then the coal must either be,—

(1) Selected from low sulphur mines, or
(2) Washed to remove excess sulphur, or
(3) Mixed with low sulphur coals.

Nova Scotia coals, owing to their variety, can meet condition (1), only being limited by the outputs from the low sulphur mines. However, taking the general run or mixture of different mines, as shipped from the Cape Breton fields, washing is necessary in order to meet the more rigid conditions. There are three coal-washing plants in the Sydney district. Washed coal for blast furnace coke-making has amply proven its desirability, and the economic advantages thus derived far outreach the cost of washing.

Washing processes are all based upon the fact that impurities such as stone, pyrites, etc., are heavier than the pure coal and the gravitation principle is employed. Washing is very effective in removing impurities foreign to the coal, as they are usually heavier. That part of the ash and sulphur which is integral with the coal may be removed, the percentage depending upon the rejects allowable. Table No. 2 gives examples of rejections necessary from different coals to give a product with the required sulphur content. In some European plants the washer rejects are used in gas producers for making the fuel gas for the ovens, also for low grade boiler fuel. Figure No. 7 is a record of the ash and sulphur analyses of the coals and coke as taken from

Remarks:—Test No. 6 shows relative small proportion of American coal required to be mixed with high sulphur coals in order to produce gas containing less than 35 grains organic sulphur per 100 cu. ft.

the operating files of the Sydney coke plant. The uniform quality of blast furnace coke produced from mixed coals may be noted.

As regards mixing the high and low sulphur coals, this may be accomplished either by mixing with our low sulphur coals or else by addition of low sulphur American coals. It has been found by actual test that even our higher sulphur coals in an unwashed state can be successfully employed in this manner with a relatively small proportion of American coal. This is illustrated in table No. 3.

The yields that are realized at the Sydney coke plant from one net ton of coal are exceptionally high, and are as follows:—

Coke	1,360	lbs., of which approx. 7.5% is coke breeze.
Gas	11,250	cu. ft., of which 6,920 is surplus gas, 585 B.t.u. per cu. ft.
Tar	10.5	Imp. gallons.
Sulphate of Ammonia.	28	lbs.
*Motor Fuel	2	Imp. gallons (equiv. to total homologue yield of 3.0 Imp. gallons).

The works of the Dominion Iron and Steel Company, Ltd., furnish an excellent example of various methods of utilization of Nova Scotia coals. The coals used in this plant are all taken at the present time from the southern Sydney fields, and are utilized in the following manner:—

(1) Slack coal after washing and crushing is coked, producing the following fuels:—
- *(*a*) Coke ....Blast furnace, foundry and domestic.
- (*b*) Coke breeze...Boiler fuel and recarburizing purposes.
- (*c*) Gas (585 B.t.u. per cu. ft.)....Heating ovens, steel-melting and reheating furnaces, ladle drying, steam raising.
- (*d*) Tar ....For further distillation, also used for boiler fuel and steel furnaces.
- (*e*) Benzols ....Motor fuel, etc.

(2) Screened coal is used in "Duff" gas producers giving gas 150 to 180 B.t.u. per cu. ft.; 75 per cent of heat value of coal is obtained in this process. This gas is used for steel-melting and reheating furnaces.

(3) Slack coal is used for steam raising in hand-fired boilers with undergrate blowers, also chain grate stokers with natural draft.

Use of Nova Scotia Coal for Steam-Raising on Mechanical Stokers

According to statistics given elsewhere in this paper, there are about a million tons of coal burnt annually among the larger industrial power plants throughout eastern Canada every year, at least 75 per cent of this being burnt mechanically. Of this amount, 20 per cent is or will be shortly burned in powdered fuel furnaces, the balance on mechanical stokers of the underfeed, overfeed or chain grate types, (see table No. 4).

By far the larger number of these plants have been installed within the last fifteen years, indicating a vast change in the complexion of the market that has now to be catered to by the coal emanating from Nova Scotia.

It is a significant fact also that about 40 per cent of the plants included in the list given are at the present moment using imported American coal.

The present condition, however, is that while eastern Canada is potentially a market for Nova Scotia coals, there is a disposition with American equipment through custom, habit or inclination, to burn American coal.

At one time, of course, before the War, the proportion of Nova Scotia coal used was much greater as regards the sum total used, but at the time when the incursion of the mechanically-equipped plant began to make itself felt, the troubles in burning coal from Nova Scotia on this new equipment were such as to have created a prejudice against the coal that persists to the present time.

The popular demand, however, from a national and economic standpoint for Canadian coal for Canadian industries, and the increased dependence of the producing companies upon the home market has led to a good deal of attention being focussed upon this question from both directions.

Table No. 4:—Summarized List of Principal Stokers and Pulverized Fuel Operated Boiler Plants in Eastern Canada, Including Newfoundland, Classified as to Type of Stoker and Boiler (Plants of Coal Producing Companies Not Included) as at June, 1926.

*Note:—This is a water-white liquid consisting of 80% benzol, 12% toluol and 8% naphtha, having specific gravity of 0.873 and entirely distilling between 80° and 145°C.

*Of the coke used in the blast furnaces, which amounts to 2,200 lbs. per net ton of pig iron, 60 per cent of this is recovered in the form of gas having a calorific value of 110 B.t.u. per cu. ft. This gas is used for preheating the air blast and raising steam for power and blowing apparatus.

Investigation by operating companies revealed:—

(1) Prevalence of equipment designed in the United States to burn United States coal.

(2) A feeling that Nova Scotia coal could not give the same general all around satisfaction in operation on this particular equipment as the United States coal.

(3) Presence of a ready supply of United States coal at highly competitive prices.

(4) General lack of any authoritative information, both technical and practical, in regard to Nova Scotia coal.

(5) Lack of consideration of the nature of Nova Scotia coal, both on the part of the producer and the consumer, and also the manufacturers of stoker equipment in meeting the new conditions.

A good deal has already been done towards overcoming many of the above points, but considering the rapidity with which the art of steam generation is advancing at the present time, a good deal more yet remains to be done.

While United States designed equipment is still much to the front in this market, the tendency of design in this equipment is for it to become better adapted towards burning Nova Scotia coals. The Canadian manufacturers are making special studies of this subject and interesting developments are expected.

The problem of boiler plant design and operation resolves itself into possibly four factors:—(1) the coal; (2) the boiler; (3) the stoker; and (4) the furnace.

Each of these items will be briefly discussed upon the experience that has been gained this last two or three years in extensive visits to plants in the district reached by Nova Scotia coal.

The Coal

The characteristics of the coal available for the present purpose has been described elsewhere in this paper.

The coal as a whole, as distributed throughout Nova Scotia, varies widely in its characteristics, but it is the coal from Cape Breton that enters mostly into the consideration of this subject, being for the most part the coal that is shipped to the St. Lawrence district. This coal also, generally speaking, contains the highest heat content of all coals in Nova Scotia, but at the same time offers most difficulty in operating successfully on mechanical stokers.

However, the characteristics of this coal in itself vary widely, and by a policy of elimination and selection a coal is now offered of a high grade that is eminently suitable for mechanical stoker or general steam-raising purposes. This coal may be described, generally, as " a full bituminous coal of 34 per cent volatile matter, with low ash and low moisture characteristics, with a heat value of an average of 13,500 B.t.u. as mined." A general analysis would approximate as follows " as mined ":—

Moisture	2.0	per cent
Volatile matter	34.0	" "
Fixed carbon	58.0	" "
Ash	8.0	" "
Sulphur	3.0	" "
Calorific value	13,500	B.t.u.
Fusion point of ash	2100°F.	

The coal is a coking coal, non-caking, and shrinks in process of burning. (See coals in Table No. 1.)

The question of the influence of banked coal on the operation of mechanical stokers is one that can very well be discussed in this section.

Discussion with engineers at various plants shows the general experience to be that Nova Scotia coal that has been banked for any considerable period operates to much better advantage than freshly-mined coal. The coal is used in the slack form in any case, so that the question of size does not enter into the question.

Figure No. 8.—Coal Pile (250,000 tons) at No. 2 Colliery,

In storage the coal seems to lose some of the most highly volatile of its constituents, or they are in some way merged into the less volatile constituents by the action of the atmosphere and moisture, which apparently makes a hardly detectable difference in the calorific value of the coal, but in operation the flame in the fire is less intense, a better fuel bed is formed, less fuel is lost in the form of dust blown by forced draft into the rear passes of the boiler, there is less slagging of the tubes and in general consequence the heat efficiency of the coal is thereby raised.

The question of spontaneous combustion in the coal pile also enters largely into this question. It is a fact that banked coal in second storage seldom heats in the pile. This in itself is an important factor when considering Nova Scotia coal in general.

The Boiler

Turning to the second of the items entering into boiler plant operation and design, the boiler itself at the present time offers the least number of problems in obtaining the desired results. Gradually increasing pressures and size are the two main features that are to be taken care of in the design for new plants.

As regards size, the question of allowable ratings in boilers should be briefly discussed. When boiler rating is mentioned the term usually refers to the rating obtained by the complete unit, nevertheless the point should not be overlooked that the basis of these ratings is the number of square feet of heating surface in the boiler. This is usually taken as 10 square feet of heating surface per boiler horse power, which may be an arbitrary figure, but a convenient one.

The boiler itself is rarely the limiting feature in attaining high ratings, and it is not here that the difficulty lies. The boiler is the driven and the coal, the stoker and the furnace, the driver. In discussion of boiler ratings, it is very important to bear this in mind, because an understokered boiler should not be expected to give high ratings or an over-worked stoker and furnace to obtain good results with the coal.

It is noteworthy that the average boiler ratings carried on the boiler plants in the district under consideration seldom run more than 150 per cent of normal, in spite of the fact that many were originally designed to give higher ratings. Where this has been exceeded, no trouble appears to have been met with as regards the boiler. It is evident then that the fuel burning equipment of a boiler should in mum consumption of coal per square foot of grate per hour for any type should not exceed 35 pounds. This will decide the rating obtained from the boiler unit as a whole, and will indicate the point to which the stoker may be operated to give least trouble in operation and maintenance.

It is recommended that the following details in design should be followed where Nova Scotia coal is to be used:—

Underfeed:—Provision of *side wall air backs* to prevent adhesion of clinker and erosion on side walls.

Front wall cooling by Bernitz blocks or other devices.

Design of air tuyere that will leave no projection on which clinkers may lodge or adhere, the air space being large and so designed as to sweep the entire surface of the tuyere and yet avoid any blow torch action.

Design of ram extensions in same way to avoid adhesion of clinker and blow torch action where air-cooled.

Steam dumps and deep ash pits have proven a great help in the burning of this class of coal.

Overfeed:—Low bridge wall and large combustion chamber beyond with flat arch design over grate in some cases have overcome the chief objection to the operation of this class of coal on this type of stoker.

Dominion Coal Company, Limited, Glace Bay, N.S.

the first place be liberally designed to meet expected ratings, as the combustion rate of coal is not so flexible as the steam generating properties of a boiler. For example, there is a plant in New Brunswick which was re-designed to take care of increased plant operations, in which the stoker part only was increased in size. A continuous average rating of 200 per cent for the full boiler house is maintained, with peaks exceeding 275 per cent, and yet the boiler is the last thing to be heard of when considering repairs and maintenance.

The Stoker

As has been pointed out above, the question of boiler operation at the present time revolves generally around the stoker.

The question is often asked, in reference to Nova Scotia coals, as to the correct type of stoker to be recommended for burning these coals. The answer is that all types of stokers, including underfeed, overfeed and chain grate, are successfully burning Dominion coal.

The question is a matter of design of details in almost every case, coupled with the limits as imposed by size or grate area. The correct size of grate to specify for this coal is generally difficult to give, but as a general rule the maxi-

Steam jets under clinker grinders and lower end of grates prevent clinker trouble.

Ash pit doors open continuously where natural draft is used.

Chain Grate:—Natural draft chain grates generally operate without difficulty. Provision has been required in cases in side walls above grate to prevent clinker adhesion by provision of air or water cooling, or by special brick.

Provision is required for rear dump plates or waterback to prevent large proportion of combustible in the ash.

An instance is given of a change in a make of stoker where the addition of a waterback helped considerably in this respect. Figures Nos. 3 and 4 show this stoker installation at the Waterford Lake power plant of the Dominion Coal Company. The benefits obtained by the change were:—

(1) Longer life of arch.
(2) Less combustible in ash pit.
(3) Distribution of fire over entire grate surface.
(4) Inrush of cold air prevented at ash pit cleaning times.

Furnace and Setting Design

It is upon correct furnace design that most attention is being focussed at the present time. The problem of high rating at high efficiencies, with consequent higher furnace temperatures, has gradually forced the conclusion that the refractory materials used in furnace construction up to the present are not equal to the task unaided.

Increasing the size of combustion chamber to correct proportions for obtaining complete combustion of the furnace gases, has to a certain extent helped the brickwork situation, but has not solved it. Water-cooling, either by an independent water supply or by making the furnace walls part of the circulating system of the boiler, either water or steam, is the solution offered at the present time.

Undoubtedly the trend in this direction will be the gradual enveloping of the furnace entirely in the boiler construction. But for the present, considering existing plants and present plant design, the brick furnace offers the cheapest and simplest construction at the present time.

Correct volume for the combustion of the gases before reaching the cooling surface of the boiler, and proper provision for mixing of the gases to ensure this complete combustion are the two vital features. Considering the nature of the coal in question, large furnace volumes are essential, not less than one cubic foot for every 3 pounds of coal burned on the grate per hour for maximum rating.

Correct mixing of the gases is something not yet attained in the majority of plants. For underfeed stokers, with no provision for an arch, this is particularly difficult, especially in the larger sizes. For chain grate stokers, the arch should be expressly designed with the mixing of gases in view, as an arch as a means of ignition for Nova Scotia coal is not necessary except in a very small degree. For overfeed stokers the design of arch is very much a question

of maintenance, the question of mixing of gases being taken care of in the combustion chamber, which, as stated above, should be of large proportions.

With regard to furnace settings, one point only needs to be emphasized, and that is the question of baffling as affecting draft. Instances have occurred where there has been a draft loss through the boiler of as much as 1½ inch W.G. High ratings are impossible in this plant if pressures in the furnace are to be avoided.

Instruments

In the operation of a boiler plant, nothing tends to better efficiency and general satisfactory operation so much as the provision of gauges and instruments for the guidance of the operators.

Draft gauges, CO_2 recorders and flow meters are indispensable adjuncts to the operation of a plant under modern conditions. These instruments now are fairly well standardized, and no difficulty should be experienced in selecting equipment that will give the necessary information and at the same time require little attention to keep them in proper working order.

One point only requires to be mentioned in this respect, having regard to CO_2 recorders with this particular coal, and that is the provision of a substantial filter for purifying the gas before it enters the registering apparatus.

A 6-inch pipe about 15 inches long partly filled with water, through which the gas bubbles, has been found very satisfactory in this respect. The gases from this coal are apt to contain excessive quantities of sulphur which readily attacks parts of any instrument with which it may come into contact. The water filter will remove most of this.

Pulverized Fuel

This is becoming a very popular method of firing boilers in the larger sizes, and the number of new installations has doubled itself each year for the past five years in the United States and Canada. Its novelty, coupled with its adoption in a number of the large super-power plants has given it a somewhat disproportionate place in the public eye, but there is no doubt it is here to stay.

It is by no means a new system. As a matter of fact, the first patent recorded was granted to one John Dawes, an ironmaster of the Black country, England, as early as 1831. This was contemplated for smelting iron. Pulverized coal was used successfully in the rotary kilns of the cement industry for ten years before the first really successful pulverized coal fired boiler was brought out. This particular boiler was designed by Mr. J. H. Bettington about 1907, and was successful in burning a variety of fuels with a degree of efficiency then unknown. Thermal efficiencies as high as 80 per cent with 20 per cent ash coal were recorded.

In 1912, an installation of these boilers, (four in number), was made at the Waterford Lake power station of the Dominion Coal Company, Ltd. This is now the principal generating station of this company. (For sectional view of one of these boilers, see figure No. 3.)

Compared with modern installations and practice in powdered fuel systems, it is interesting to note that:—

(1) The boilers are very small, 200 b.h.p. each, (1,966 square feet heating surface).

*(2) The combustion space or furnace volume is 424 cubic feet, or 2.12 cubic feet per rated boiler horse power. This is in contrast to other furnaces in use at the present time, which are mostly of large volume, the range being from 4 to 10 cubic feet per rated boiler horse power, with the majority between the limits of 6.5 and 8.5 cubic feet.

(3) There is no drying equipment. The coal is disintegrated in a pulverizer which is both crusher and blower combined. The pulverizer is driven by a 30 h.p. steam turbine, the exhaust from which is utilized in the feed water heater. There is a spare pulverizer for each two boilers driven by a 35 h.p. direct-connected motor.

(4) The flame is blown, not "fogged," directly upwards and thence it falls down and around the bottom of the brick baffle, having a "mushroom" effect. The flame travel is 35 feet.

These conditions are in general contradiction to the tendency of modern design, yet in one point Bettington was ahead of his time in that he built the boiler around the furnace, which is now the fundamental principle of the latest powdered fuel boiler installations.

In spite of deficiencies in the design of the boiler itself, which after all could only be expected in such a radical departure as this was, and after overcoming usual infantile troubles and others which were extraneous to the method of firing, these boilers have been in operation since 1912, and at the present are on the line giving excellent satisfaction. Ratings up to 300 per cent with corresponding thermal efficiency of 73.4 per cent have been obtained, and this without the aid of air preheaters or economizers. Lack of stack draft prevented even higher ratings being attained.

Slack from the adjacent collieries of the Dominion Coal Company is used. The characteristics of this coal, and they are in keeping generally with others in the Sydney coal field, make it admirably suited for powdered fuel firing. It possesses 14,000 B.t.u. per pound on the dry basis, it is readily pulverized and the action of the fused ash upon the brickwork of the combustion chamber is beneficial. This ash has a much lower fusion point than the brick, 2000°F. against 2900°F., and it forms a thin slag which first closes the interstices in the brickwork, and then, after giving the brickwork a protective coating of slag, it trickles down, and, cooling, falls into the ash pit below in small pieces from which it is easily removed.

Besides this installation of Bettington boilers at the Waterford Lake plant, there are—

Two Babcock & Wilcox boilers, 4,780 square feet heating surface each, fitted with Coxe chain grate stokers, (see figures Nos. 5 and 6), 126 square feet grate surface each. In operation since 1924.

Four Babcock & Wilcox boilers, 4,780 square feet heating surface each, fitted with "Taylor" type A.A.-4 stokers having active grate surface of 67.5 square feet each. In operation since 1912. (See figure No. 4.)

This plant provides an excellent demonstration of the adaptability of Nova Scotia coals to different systems of fuel-burning equipment.

The reasons why the coals of Nova Scotia are superior for pulverized fuel are:—

(1) High B.t.u. content,—less coal to pulverize.
(2) Low ash content.
(3) They are easily pulverized.
(4) The ash characteristics are suitable for this system of firing.

---

*Note that at maximum ratings, (300 per cent), for these boilers there are 5 pounds of coal burned per hour per cubic foot of combustion space, whereas in the ultra-modern underfeed stoker plant at Hell Gate 3 pounds of coal is burnt on the grates per cubic foot combustion space per hour to give a boiler rating of 450 per cent. The average rating carried is high, (250 per cent), corresponding to 500 b.h.p. output.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME IX AUGUST 1926 No. 8

Maritime General Professional Meeting

Sydney, N.S., August 17th, 18th and 19th, 1926

A general outline of the arrangements for the Maritime General Professional Meeting, which is scheduled to be held in Sydney, N.S., on Tuesday, Wednesday and Thursday, August 17th, 18th and 19th, 1926, appears on the editorial page of the July issue of the Journal.

The details for the meeting are now practically complete, and the programme as it now stands does not contain any material change from the tentative programme published in the last issue.

The technical sessions provide for the presentation of two papers: "The Humber Development of the Newfoundland Power and Paper Company, Ltd.," by H. C. Brown, A.M.E.I.C., manager of power development for the company, and "Characteristics and Utilization of Nova Scotia Coals," by W. S. Wilson, A.M.E.I.C., assistant chief engineer, and M. W. Booth, A.M.E.I.C., steam engineer of the Dominion Iron and Steel Company, Limited. Both of these papers appear in full in this issue of the Journal, and arrangements have been made for a thorough discussion of each.

The committee of the branch which is in charge of the arrangements for this meeting have spared nothing in their efforts to prepare a programme combining the various features which are so essential to the success of such a meeting, and all members who can possibly be in Sydney at the time of the meeting will find not only interesting and instructive technical discussions, but also arrangements for visiting the main points of interest in the Cape Breton district and ample provision for their entertainment.

Institute By-laws

There has recently been mailed to all members of The Institute, a copy of the revised By-laws of The Institute incorporating the amendments adopted by letter ballot on April 30th, 1926.

The booklet contains, in addition to the By-laws, a copy of the Charter and Code of Ethics of The Institute.

In past years, this information has formed part of the Year Book, containing, in addition, an alphabetically and geographically arranged list of members. This year it was decided to publish the By-laws separately from the list of members in order that the former might be available at an earlier date. The list of members is at present in the course of preparation, and will be ready for distribution early in the Fall.

Annual General and General Professional Meeting

Quebec City, February 15th, 16th and 17th, 1927

The Annual General and General Professional Meeting of The Institute will be held under the auspices of the Quebec Branch at Quebec city on Tuesday, Wednesday and Thursday, February 15th, 16th and 17th, 1927.

In accordance with the By-laws, the Annual Meeting will be convened at Headquarters in Montreal, and will be adjourned and re-convened at Quebec on the date mentioned above.

An active committee of the Quebec Branch has been at work for the past two months on the details of the programme, and it is expected that these arrangements will be available for publication in the September issue of the Journal.

The technical sessions and discussions will centre around the recent large hydro-electric power developments of Canada and the problem of the conservation and utilization of Canada's forest resources. A series of papers on both these subjects have been arranged, and will be available in advance proof form in order that thorough discussions may be prepared.

The city of Quebec offers exceptional facilities for the holding of such a meeting, and it is anticipated that there will be a very large attendance. All members are urged to make a special note of the date of this meeting, and plan well in advance to be present.

List of Members

The work of compiling the revised list of members of The Institute has been commenced, and as it requires a matter of about eight weeks before the list is ready for the printers, members still have opportunity to see that their names and addresses and official positions are properly recorded at The Institute Headquarters, so that they may appear in the Year Book as desired.

Members are therefore requested to forward to the secretary, as soon as possible, any changes they may wish made in this connection.

OBITUARIES

Henri Paul Lefebvre, M.E.I.C.

News of the death of Henri Paul Lefebvre, M.E.I.C., which occurred in Montreal, Que., after a long illness, on June 23rd, 1926, has been received with sincere regret.

The late Mr. Lefebvre, who received his education and diploma of "Ingenieur des Arts et Manufactures," Ecole Centrale de Paris, France, joined The Institute in the days of the Canadian Society of Civil Engineers, when he was elected Member on April 17th, 1909. He was born at Rouen, France, on October 3rd, 1854. After completing his academic studies in August, 1877, he was engaged on various works in France until the early part of 1882. The following year he spent in England studying the English language and railway conditions in that country. Subsequently in 1884 he opened an office at Elbeuf, France, as consulting civil engineer.

In 1885 he visited Canada; the following year he closed his office in France and returned to Canada, where, during the next seventeen years, he was employed in the vicinity of Cheneville and St. Andre-Avellin, principally on water works and telephone and telegraph construction. In 1909 he received his diploma as Quebec Land Surveyor.

For four years following 1906 he was engaged on investigation and study for the proposed lines of the Little Nation River Railway Company. In 1913 he joined the engineering staff of the city of Montreal, and was engaged on sewer work and later on reinforced concrete construction.

In addition to the diploma mentioned above, Mr. Lefebvre was awarded in 1874 the diploma of "Bachelier-es-Science" by the Academy of Caen, France. From 1898-1908 he was mayor of Cheneville, and in 1898 was appointed justice of the peace for the district of Ottawa.

George Walker Winckler, M.E.I.C.

George Walker Winckler, M.E.I.C., died at St. Michael's Hospital, Toronto, on June 30th, 1926.

The late Mr. Winckler was born at Cochin, India, in 1844, and received his degree of C.E. from Calcutta University in 1865. Continuing his studies, he attended the Sanitary Institute of Great Britain in 1870.

Mr. Winckler's early engineering work was as assistant engineer on the Great Indian Peninsula Railway, first on surveys, then on construction. He then served in the Public Works Department of the Indian Civil Service as assistant engineer, for eight years, on state railways, and later as executive engineer in charge of a division of the state railways then under construction. Subsequently he was transferred to the roads and buildings branch of the department in executive charge of the Chittledroog district. During the second Afghan War he was transferred to the Bolan Pass on railway surveys to Quetta. At the conclusion of the war, he was again transferred to Assam in executive charge of roads and buildings. He later returned to state railway surveys, and, following a short leave in Europe, returned to take charge of canal irrigation and conservation in the Mysore Province. His last work in India was in executive charge of roads and railways in the Assam Sylhet district, following which he retired from the service in 1893.

In the same year he came to Canada, taking up his residence in Winnipeg. Eight years later he moved to Collingwood, Ontario, and in 1916 he moved to Toronto, where he continued in his profession as civil engineer.

The late Mr. Winckler was elected Member of The Institute on January 30th, 1919.

Gilbert Tweedie Livingstone, A.M.E.I.C.

Gilbert Tweedie Livingstone, A.M.E.I.C., died at St. Paul's Hospital, Vancouver, B.C., on June 3rd, 1926, following an illness of some months.

The late Mr. Livingstone was born at Dresden, Ontario, on April 28th, 1881. His early education was received at the public school of Seattle, Wash., U.S.A., and at the Seattle High School. In 1906 he graduated from the University of Washington with the degree of B.Sc. in mining engineering.

Prior to graduation he was engaged in railway location and construction, general civil, mining and hydraulic engineering, principally in Alaska, and the following year opened an office as civil, mining and hydraulic engineer at Seattle, Wash. In 1910 he was appointed superintendent and engineer on the irrigation plant for the Columbia River Orchards Company, Wahluke, Wash., in connection with which he was engaged on the construction of one of the company's pumping stations. From 1911 to 1914 he was chief engineer for Uplands, Limited, Victoria, B.C., and in 1914 became interested in the preparation of irrigation and townsite development for the Barriere Land Company, Ltd., Barriere, B.C. Prior to his death he was with the Pacific Great Eastern Railway at Squamish, B.C.

The late Mr. Livingstone joined The Institute as an Associate Member on November 16th, 1915.

Thomas Franklin Bastedo, S.E.I.C.

It is with regret that we record the death of Thomas Franklin Bastedo, S.E.I.C., which occurred on May 30th, 1926.

The late Mr. Bastedo was born at Beachville, Ont., on November 24th, 1901, and joined The Institute as a Student member on February 3rd, 1922, while still attending Queen's University.

Alfred George Guscott, S.E.I.C.

Alfred George Guscott, S.E.I.C., of Toronto, Ont., died on February 18th, 1926, in the Toronto General Hospital, following a short illness.

The late Mr. Guscott was born in Toronto on September 5th, 1897, and graduated from the Faculty of Applied Science of the University of Toronto in 1922, since which date he had had considerable experience, having been engaged on the Queenston-Chippawa power development; on the staff of the location and construction department of the Canadian National Railways; on the valuation of the Toronto Street Railway, and on municipal work for the township of Etobicoke and county of York.

At the time of his death, the late Mr. Guscott was on the staff of the Faculty of Applied Science of the University of Toronto. He was admitted to The Institute as Student on November 23rd, 1921.

PERSONALS

H. V. Ellegett, S.E.I.C., is at present with the Goldie Construction Company, Limited, Toronto, Ont., on the construction of the Danforth Park Sewage Disposal Plant, for the township of East York.

Frank L. Grindley, S.E.I.C., who graduated from the University of Alberta with the degree of B.Sc. in civil engineering this year, is with the Canadian National Railways as transitman on location at St. Paul, Alta.

W. H. Stuart, A.M.E.I.C., formerly resident engineer on hydraulics, Western region, Canadian National Railways, has been appointed by the company supervisor of hotel, grounds and buildings with headquarters at Montreal.

Howard J. Williams, A.M.E.I.C., formerly assistant engineer on the design of the new Scituate reservoir for the water supply for the city of Providence, R.I., has joined the staff of Fay, Spofford and Thorndike, consulting engineers, Boston, Mass.

Edward Peal, S.E.I.C., formerly of the Bailey Meter Company, Limited, Montreal, has been appointed to the engineering staff of the Canada Sugar Refining Company, Limited. Mr. Peal graduated from Queen's University with the degree of B.Sc. in 1924.

M. N. Hay, Jr.E.I.C., who has been on the engineering staff of the Aluminum Company of Canada at Shawinigan Falls, Que., has been transferred to the staff of the United States Aluminum Co., Massena, N.Y. Mr. Hay graduated from Queen's University in 1923.

Charles F. Gray, A.M.E.I.C., who has since 1912 been practising as consulting engineer in Winnipeg, Man., is at present located at Miami, Fla., where he has opened an office, and gives his temporary change of address as 701 Realty Board Building, Miami, Florida.

Professor C. R. Young, M.E.I.C., of the University of Toronto, has been appointed consulting engineer on the design and construction of the bridge over the Don river between Leaside and Todmorden, near Toronto. Frank Barber, M.E.I.C., is the engineer in charge of the project.

Hugh J. Leitch, S.E.I.C., of Westmount, Que., who graduated from McGill University with the degree of B.Sc. in civil engineering this year, has been appointed to the staff of the Steel Gates Company, Limited, at Hamilton, Ont. This company is at present working on a contract for lock gates for the Welland ship canal.

H. H. James, A.M.E.I.C., has accepted a position on the engineering staff of the American Steel and Wire Company at Donora, Pa. Mr. James was for a number of years with the Montreal Locomotive Works as engineering draughtsman in the office of the maintenance engineer, and for the past year has been located at Worcester, Mass.

W. D. Lee, A.M.E.I.C., who was formerly resident engineer on the construction of the transprovincial highway for the Department of Public Works of British Columbia, Spuzzum, B.C., is now located at Squamish as maintenance-of-way engineer with the Pacific Great Eastern Railway. Mr. Lee was for a number of years resident engineer on the staff of the construction department of the Canadian Pacific Railway.

L. R. Brown, A.M.E.I.C., who has been in Sault Ste. Marie, Ontario, for the past ten years, having been associated with the Toronto Chemical Company; the Algoma Steel Corporation; the Dominion Tar and Chemical Company as road engineer; and city engineer since 1921, has resigned as city engineer to accept a position with the Newfoundland Power and Paper Company, at Corner Brook, Newfoundland.

F. E. Winter, S.E.I.C., who graduated with the degree of B.Sc. with honours in electrical engineering from McGill University this year, and who was awarded the British Association Medal and the first prize of the Montreal Light, Heat and Power Consolidated, is now located with the General Electric Company at Schenectady, N.Y., where he is taking the student course in the company's school for graduate engineers.

A. C. D. Blanchard, M.E.I.C., is resident engineer on the construction of the power development for the Saint John River Power Company at Grand Falls, N.B., having severed his connections with the New Brunswick Electric Power Commission to accept his new position. Prior to his appointment to the New Brunswick Electric Power Commission as hydraulic engineer in September, 1924, he was for several years engaged as chief field engineer in charge of surveys, field engineering and inspection on the Queenston-Chippawa power development.

CLARENCE V. CHRISTIE, M.E.I.C.

T. V. McCarthy, A.M.E.I.C., has moved from Toronto, Ont., to Grand Falls, N.B., and is with Messrs. H. G. Acres and Company, Limited, who are consulting engineers for the Saint John River Power Company on the Grand Falls development. Mr. McCarthy was some years ago assistant laboratory engineer for the Hydro-Electric Power Commission of Ontario.

W. A. Bucke, M.E.I.C., manager of the apparatus sales department, Canadian General Electric Company, Limited, spent two weeks of last month on a tour of the Maritime Provinces. During his stay in Halifax he visited the Nova Scotia Power Commission and others interested in the electrical industry. At Bathurst he was the guest of the Bathurst Company, Limited; at Sydney, Mr. Bucke conferred with the engineers of the Coal Company and Steel Company, and at St. John, N.B., visited the engineers of the New Brunswick Power Commission.

Professor C. V. Christie, M.A., B.Sc., M.E.I.C., Heads Electrical Engineering Department of McGill University

Professor C. V. Christie, M.E.I.C., associate professor of electrical engineering at McGill University, has been appointed Macdonald professor of electrical engineering and head of the department, succeeding the late Dr. L. A. Herdt, M.E.I.C.

Professor Christie was born at Couva, Trinidad, B.W.I., and in 1902 received his degree of B.A. at Dalhousie University and the following year was awarded his degree of M.A. from the same university. In 1906 he graduated from McGill University with the degree of B.Sc. Immediately following graduation, he was appointed lecturer at McGill, and in 1908 became assistant professor and in 1913 associate professor in the department of electrical engineering.

For the past eight years he has acted as consulting engineer for the Shawinigan Water and Power Company. Professor Christie is an authority on electrical engineering, and his text book on that subject has been widely used by students in both the universities in Canada and the United States. He has taken an active interest in the affairs of The Institute, and is at present vice-chairman of the Montreal Branch.

G. GORDON GALE, M.E.I.C.

General Manager, Gatineau Power Company

G. Gordon Gale, M.E.I.C., vice-president and general manager of the Hull Electric Company, has been appointed general manager of the Gatineau Power Company, and while assuming his new duties, retains his former position as head of the Hull Electric Company.

Mr. Gale is a graduate of McGill University in mining engineering in 1903, and electrical engineering in 1904, receiving the degree of B.Sc. in each case, and in the year 1905 he received the degree of M.Sc. from the same university.

From 1904 to 1906 he was assistant engineer with the Canada Rubber Company, and in 1907 he was resident engineer at Deschenes, Que., for Messrs. Ross and Holgate. The same year he was appointed superintendent of power with the Hull Electric Company. In 1909 he was promoted to acting general superintendent, and the following year was made general superintendent. In 1914 he became general manager of the Hull Electric Company, and since 1917 he has been vice-president and general manager of the company.

Mr. Gale was chairman of the Ottawa Branch of The Institute in 1918, and a member of Council during the years 1919, 1920 and 1921. He was president of the Canadian Electric Railway Association during the year 1921-22, and president of the Rotary Club of Hull in 1922.

Addresses Wanted

A revised list of members is being prepared for publication in the form of the Year Book, and it is desired to have this list as complete as possible. The following is a list of members for whom there is no address on file at headquarters. The Secretary would appreciate any information as to the present address of any of these members.

Members

A. Angstrom	J. H. Gray	A. E. Johnson
J. R. Barlow	J. F. Guay	H. Longley
T. B. Campbell	E. F. T. Handy	A. H. Smith

Associate Members

W. A. G. Adams	H. B. Fisk	F. W. Pearson
P. I. Baker	J. L. Franzen	G. M. Ponton
A. N. Ball	J. S. Galbraith	H. H. Robertson
W. L. Ball	W. H. Jones	C. R. Scott
W. H. Blanchet	L. W. Lester	C. F. Szammers
D. M. Bright	H. Lindsay	W. E. Tidy
G. A. Emslie	H. Macneil	T. W. Webb
J. Erskine	C. W. McCarthy	J. L. Wilson
R. J. Fisher	W. M. Miller	W. G. Wilson

Juniors

G. N. Allen	T. Clarke	J. A. M. Penrose
J. S. Arbuckle	J. H. Hewson	L. A. Perry
F. D. Austin	C. Mackay	J. H. Ryan
E. Bryant	R. G. MacKenzie	
R. A. Campbell	C. A. McConville	

Students

Members' Exchange

Back Numbers of The Engineering Journal

The Secretary will be pleased to receive spare copies of the May, June, July, August, September, October, November and December, 1918, May and December, 1919, January, February, March, April, May, June, July and September, 1920, issues of the Journal to complete library sets.

ABSTRACT OF PAPER

The Generation of Steam at Critical Temperatures

Dr. Mark Benson, F.R.G.S.
Vancouver Branch, June 8th, 1926.

Dr. Benson proceeded to give the results of five years of intensive study and experiment directed towards the improvement of the overall efficiencies of steam generating power plants. He first went back over the history of steam generation, tracing its commencement from about one hundred and twenty-five years ago to the present time, and stated that the best efficiency obtainable in even the most modern plants, approximated 12 per cent from fuel to bus bar, and also stated that were it possible under present conditions to maintain this as an average efficiency it would be considered very satisfactory indeed.

It would appear that this condition was forcibly brought to his attention some years ago and that he then formed the determination that it was time this was changed and a more efficient use made of the fuel in steam generating plants, and he stated that to-day, after five years of study—average overall efficiencies of between 30 and 50 per cent are definitely in sight. He stated also that the day of the Diesel engine is also definitely past, although that is at the present time the most efficient means of generating power from fuel.

Dr. Benson's address was divided into several parts and was profusely illustrated with lantern slides showing charts and the calculations upon which his high temperature-pressure system of steam generation is based, and he stated that his plans for such extremely high efficiencies as are now promised are based upon the use of steam at a pressure of 3,200 pounds per square inch and at a critical temperature between 700 and 800 degrees Fahrenheit. For practical reasons, however, it would be necessary to superheat the steam to approximately 1,200 degrees Fahrenheit. The principle involved is that generating steam under these conditions involves no latent gradual vaporization, the vaporization, or in other words, transition from water into steam being instantaneous and involving practically no losses, as there is no latent heat of vaporization at this point. The acceptance of the general principle, however, brings forward a very large field for study in the development of the practical features involved in the use of steam at such high temperatures and pressure. It is claimed, however, that the plant is greatly simplified and in spite of the high pressure the risk of explosion is greatly decreased, due to the fact that there is no storage of energy in the form of large bodies of steam or water. Only a few pounds of water at any one time being actually under the temperature-pressure condition proposed.

A great deal of work has been necessary in the development of a suitable steel for tubes and at the present day suitable metal is only made at the Krupp plant in Essen, Germany. It is anticipated, however, that a number of the larger steel plants will recognize the opportunity that lies for them in this system in the immediate future.

Another section of Dr. Benson's address dealt with the experimental work that has been already done and referred to the plant which has been built and is operating on this system at Rugby. Numerous variations of arrangement were shown graphically dealing with various conditions to be met with in steam plant design and operation and included problems of feed pump installation; various arrangements for superheating and re-superheating the steam in the various stages of its use and also showed the possibility of translating existing steam plants, adding to them the critical cycle and re-arranging the part for use under the new conditions without fundamental or expensive alterations.

Reference was also made to the possibility of using the system in connection with locomotives, and while it was admitted that it cannot be as readily applied to reciprocating engines as to turbines, possible arrangements were shown and described and particular reference was made to the development of a metal for pistons and cylinders in which the steam itself would act as a lubricant, thus doing away with the principal inherent defect of high pressure steam in cylinders under high temperature conditions.

In conclusion, and with particular reference to a large power plant which is being designed for the California Edison Company, Dr. Benson stated that wherever at present 400 kilowatt can be developed per barrel of oil fuel, it is now confidently expected to be able to develop 900 kilowatt to the barrel.

BRANCH NEWS

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

Visit to Alberta Wood Preserving Plant

On June 19th a party of members of the Calgary Branch gathered at the plant of the Alberta Wood Preserving Company, in West Calgary. Despite the inclement weather, the visit through the works proved of considerable interest. Following the inspection of the process of preservation from the untreated lumber to the finished article, Manager J. H. Dixon gave a short instructive address, in which he related the history of the lumber treating business from its origin in 1837.

Mr. Bethel was the discoverer of the effect of creosote on timber in England. While his process was crude, it is fundamentally the same in standard use throughout the world today. The method of application differs, however, on account of the advancement in mechanical apparatus. A Mr. Burnett, in 1838, made the first use of zinc chloride as a preservative of wood. This method is also in use at this plant and a 50 per cent solution is forced under pressure in a similar manner to the creosote through the wood cells. In this up-to-date plant, air is forced through these cells when the lumber is stacked in large tubular airtight compartments, and is afterwards extracted, leaving a slight vacuum, which is replaced by the preservative solution, also under pressure.

Mr. Dixon explained carefully the cell formation of various timbers, the pine variety, as an instance, having open cells running lengthwise of the tree, whereas those in the hardwoods, such as white oak, are plugged. He stated that preserved sapwood is today considered just as good, if not better, than the hardwood varieties.

Lodge pole pine was practically not in general use five years ago. Today this is a splendid lasting timber when treated, and as telegraph poles should last 75 years, at a cost of only 15 per cent increase for the treatment. He went on to say that there is really no such thing as dry rot in this country at least, as moisture and warmth must be present to cause fungus growth. Zinc chloride is soluble in water, whereas creosote is not, and therefore timber treated in each manner has its particular uses. He stated the fact that a Louisiana railroad trestle bridge, six miles long, was built in 1882 of preserved yellow pine, and is in use today under main line traffic. Referring to untreated ties, he gave the lives of various kinds of timber used.

Following the address, J. H. Ross, A.M.E.I.C., chairman of the branch, thanked the speaker and staff, and stated that, in his opinion, this branch had never spent a more instructive and interesting afternoon on any of their visits to various industries in Calgary.

Dinner in Honour of General Secretary R. J. Durley, M.E.I.C.

Members of the branch showed their pleasure at meeting general secretary R. J. Durley, M.E.I.C., by turning out in full force at a dinner in his honour on June 24th. A very enjoyable evening was spent, the dinner being followed by a varied entertainment. Mr. Durley spoke on matters of considerable interest concerning the internal affairs of the Institute as a whole and also had a few words of commendation for the activities of the Calgary Branch. During the evening short speeches were delivered by Chairman J. H. Ross, A.M.E.I.C., B. L. Thorne, M.E.I.C., A. L. Ford, M.E.I.C., and R. S. Trowsdale, A.M.E.I.C.

Community singing and solos were enjoyed and a comical sketch along the style of Shakespeare's "Henry IV" was put on, the parts being taken by C. C. Richards, M.E.I.C., W. B. Trotter, A.M.E.I.C., and W. St. J. Miller, A.M.E.I.C., and amusing references were made throughout to members present.

Mr. Durley met the executive of the branch prior to the dinner and exchanged views on Institute matters, explaining many points of importance hitherto not clear.

News Items

A hole-in-one episode was recently pulled off in local golf circles, when our worthy late secretary, G. P. F. Boese, A.M.E.I.C., achieved distinction in this respect, having neatly done the trick.

The reconstruction of and additions to the Alberta Flour Mills Plant in East Calgary is progressing rapidly. This mill has been taken over by Messrs. Spillers (Canadian) Ltd., who are sparing neither pains nor money to make it an up-to-date plant in every respect.

Vancouver Branch

E. A. Wheatley, A.M.E.I.C., Secretary-Treasurer.

Executive Meeting

A regular meeting of the Executive Committee was held at the University Club on June the 29th, when the meeting took the form of a dinner to general secretary R. J. Durley, M.E.I.C. After dinner the regular meeting was held.

In the absence of the chairman, F. W. Alexander, M.E.I.C., took the chair and the president of the Institute, Major Geo. A. Walkem, M.E.I.C. was present.

The Library Committee reported that the joint library maintained by the branch and the professional engineers was now installed in the University Club building and was proving of great value to the members.

The secretary reported that the Association of Professional Engineers had submitted, by letter, the details and extent of their participation in the maintenance and development of the library. The offer of the Association was accepted and the secretary instructed to take whatever steps he deemed necessary to complete the indexing of the library.

The presence of Mr. Durley was taken advantage of by having an intimate discussion on various topics of engineering work. Mr Durley was of great assistance to the executive and from the discussion held, improvements of the Branch Executive are looked for.

The Walter Moberly Memorial Prize.

The second recipient of this prize which was granted to commemorate the life and work of Walter Moberly was obtained by Francis Gilbert Aubrey Tarr, for his essay on "The Stave Falls Hydro-Electric Development of the B.C. Electric Railway Company."

The Executive meeting then adjourned and the regular meeting of the branch was held in the rooms of the auditorium of the Board of Trade.

Address by Mr. Durley

W. H. Powell, M.E.I.C., the chairman, introduced the speaker and guest of the evening, the general secretary of the Institute, R. J. Durley, M.E.I.C., and referred to the fact that as there was no business there would be ample time to have, not only a long address from Mr. Durley, but a discussion on Institute affairs.

Mr. Durley, who was received with great applause, gave an account of a number of activities of the internal administration of the Institute and touched on the fact that a number of members had recently been dropped from the Institute and he submitted that this actually made for greater strength. There was a reduction in paper strength, but an improvement in the actual strength of the Institute. He referred to the fact that the Institute organization was not only decentralized, but was of a very flexible nature. He showed that the branches were practically autonomous. The difficulties that existed were generally geographical difficulties. He stated it was his opinion and the opinion of many other engineers that another difficulty was that the requirements for admission by examination to the Institute are higher than for admission into many of the American societies and thus American societies found it easier even in Canada to form organizations where the Institute found it impossible. He showed that the existing number of members of the Institute, 4,500, of a population of 9,000,000, compared favourably with American societies who had a membership of some 50,000 of a population of 120,000,000. He invited members who were impressed with the technical value of certain American societies' magazines to take advantage of the reciprocal arrangements and thus to purchase the magazines in question. He pointed out that the Institute fee, together with the cost of the American magazine, was less than the cost of the American society fee.

Mr. Durley referred in terms of sorrow to the death of the treasurer of the Institute, General Bertram, and in terms of appreciation to his work. He mentioned the appointment of F. P. Shearwood, M.E.I.C., to this position.

Mr. Durley stated that while the transactions of the Institute have not been published since 1917 he had happiness in announcing the republication this year; the work of the volume would cover some 300 pages and would contain selections from papers given in the last three years, and would cost $3.00 per volume. He advised that a satisfactory number of applications for the volume had been received and urged further subscriptions.

Mr. Durley paid tribute to the work of Fraser S. Keith, M.E.I.C., and spoke in terms of admiration of the staff and organization that Mr. Keith had developed. He referred to the devotion and self-sacrifice of the staff at headquarters.

Mr. Durley referred to the inadequate way all application forms are filled in and he urged that members sponsoring applications and the Membership Committee see that the requirements as printed on the application forms are carried out by the applicants.

The president, P. H. Buchan, A.M.E.I.C., H. B. Muckleston, A.M.E.I.C., F. W. Alexander, M.E.I.C., J. F. Frew, M.E.I.C., S. F. Ricketts, A.M.E.I.C., and A. C. R. Yuill, A.M.E.I.C., all took part in a discussion of Institute affairs and made a number of suggestions for the improvement of the branch work.

E. A. Wheatley, A.M.E.I.C., addressed the meeting on his appointment as secretary and moved a vote of thanks and appreciation, which was seconded by Mr. Walkem, to his predecessor, P. H. Buchan, A.M.E.I.C. Mr. Wheatley implored the active support of the membership.

A very hearty vote of thanks was extended to Mr. Durley for his most interesting address.

The three new students of the Institute, Messrs. K. W. Hicks, Steed and Timmleck, were introduced to the members, and Mr. Hicks replied briefly.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

A regular meeting was held on June 25th, 1926 at the Y.W.C.A. rooms at 8 p.m. C. H. Speer, M.E.I.C., chairman, called the meeting to order and disposed of the regular business. General satisfaction was expressed by the members when it was announced that R. J. Durley, M.E.I.C., the general secretary of the Institute, would be in the Soo on July 16th. A discussion led by C. H. E. Rounthwaite, A.M.E.I.C., on the recent sad drowning accident in St. Mary's river on June 20th, resulted in the following resolution.

> "That the Sault Ste. Marie Branch of the Engineering Institute of Canada wishes to express its desire that a thorough investigation be made into the causes and circumstances surrounding the sad drowning accident in the St. Mary's river, Sunday, June 20th, and that every precaution be taken to prevent a recurrence of such an accident and that the advisability of placing rescue apparatus at various places along the water front be investigated."

The Operation of Fish Hatcheries

Mr. C. Hartman, superintendent of the Provincial Fish Hatchery, addressed the meeting. He outlined the different methods used in gathering the spawn and the hatching of it for the various species of fish.

Speckled trout eggs, he said, are collected from brood fish, kept at the hatcheries having ponds. The fish spawn in the fall and great care must be taken not to injure the female fish; the male fish being more hardy may be handled with more safety. In ordinary spring water the eggs hatch in about six weeks. A three-pound female trout will give between 3,000 and 3,500 eggs and under ordinary conditions 75 per cent of these were a good hatch and the growth to fingerlings a little less, due to disease, parasites, etc. One point that he stressed was that the troughs must be thoroughly cleaned to prevent disease and fungus by washing with salty water.

The rainbow trout which were planted in the waters around the Soo by the Michigan State Fish Hatchery do not drive the speckled trout from the streams, according to Mr. Hartman's belief. The increase of the number of rainbow trout was due, he thought, to spring spawning when the water was warmer and better hatching conditions prevailed. A five-pound rainbow trout will give about 3,000 eggs, and these are hatched in troughs in the same manner as speckled trout. The rainbow are harder to handle while taking spawn than are the speckled owing to their strength and the consequent danger of injury to the fish and spawn.

The salmon trout or grey trout, from which the spawn is taken, are caught in gill nets and the percentage of the eggs which hatch is low owing to the action of the nets upon the parent fish. They hatch in troughs also, and the fry must be released earlier than the young of the other trout owing to earlier feeding habits.

Pickerel are hatched in jars insted of troughs and about 55 per cent of the eggs hatch. The hatchery at Sault Ste. Marie, Ont., this year had about 3,000,000 pickerel spawn. The eggs run about 175,000 to the Imperial quart. He said that the pickerel fry have to be planted earlier than the trout fry owing to the fact that they start to feed as soon as hatched and would feed on the weaker fry.

The jar system of hatching is also used for white fish and the eggs are taken from fish captured in pond nets. About 35,000,000 fry were handled at the Sault Hatchery this year according to Mr. Hartman.

There is only one bass hatchery in Ontario, he said, and that was at Mount Pleasant. The bass hatch in nets in gravel prepared by themselves. The fry must be planted early owing to their cannibalistic tendencies.

Regarding 'lunge,' the fish have to be netted and are hard to handle as they are so large and strong. It is hard to keep from injuring them during the operation.

A lengthy discussion followed and some of the points brought out by Mr. Hartman were that a wounded fish, unless its gills are torn, will go to the bottom and roll itself in the mud which keeps the fungus off and helps the healing.

As it is almost impossible to handle small trout without killing them, he advised the anglers when they strike an area frequented by small fish to leave it alone and find the large ones elsewhere.

L. R. Brown, A.M.E.I.C., moved a hearty vote of thanks to Mr. Hartman for his address on a subject that is most interesting to Algoma residents and W. J. Fuller, A.M.E.I.C., seconded it.

London Branch

Francis C. Ball, A.M.E.I.C., Secretary-Treasurer.

Regular Meeting and Motor Trip

Motor trip to Woodstock and meeting held at Hotel Oxford, Saturday, May 15th, 1926, in connection with which the programme was arranged by the Woodstock members.

The party from London left the London city hall at 2 p.m., and met the other members at Hotel Oxford at 3.30 p.m. The party left for the plant of the Independent Concrete Pipe Company, being conducted through the plant by Mr. Carnwath. The Woodstock sewage disposal plant was visited and the details of operation of this activated sludge plant were described by W. G. Ure, A.M.E.I.C. Under the guidance of Mr. Archibald, the members motored to the waterworks pumping plant and to the springs from which Woodstock gets its water supply. On the return of the party, dinner was served at Hotel Oxford.

Meeting opened with W. P. Near, M.E.I.C., in the chair. His Worship Mayor Parker, of Woodstock, was introduced by W. G. Ure, A.M.E.I.C., and expressed his pleasure in meeting with the members of the London Branch.

Engineering and Public Health

Jas. A. Vance, A.M.E.I.C., introduced the speaker of the evening, Wm. Storrie, M.E.I.C., of the firm of Gore, Nasmith and Storrie, of Toronto. Mr. Storrie's subject was "Engineering and Public Health." He emphasized the importance of the engineer's work in regard to public health, and explained the relation of the work of the biologist to that of the engineer. To safeguard public health, it is the duty of the engineer to impress on a municipality the danger of drawing its water supply from a polluted source without purification.

On the subject of sewage disposal, Mr. Storrie said that for large municipalities it is generally agreed that the activated sludge method is best, but such a plant should be installed only where constant supervision and an uninterrupted power supply are available. The great difficulty with this system is in the disposal of the sludge. The vast expense of preparing sludge for fertilizer was so far not justified by the results as obtained in Milwaukee. The activated sludge system, with some separate form of sludge digestion, is a desirable method. Sludge does not digest when its temperature gets below a certain point. In temperate climates, this lower temperature may obtain during seven or eight months of the year, necessitating tanks of large capacity for the storage of sludge. To allow of the use of smaller tanks, the sludge may be heated during the winter months, thus providing continuous digestion through the whole year.

Where a municipality is faced with the problem of treating either its water supply or its sewage, it is advisable to first purify the water, because this method removes the possibility of pollution from sources other than the sewage effluent of the municipality under consideration.

Contrary to the common belief that water and milk obtained in the country are purer than are obtainable in the city, it has been found that the smaller towns and villages have more disease traceable to these two sources than the larger cities. It is known that rural municipalities often get milk from a source of supply that has been condemned by the veterinary inspectors of an urban municipality.

The present generation is devoting its energies to the treatment of water supplies and sewage. The next generation must attempt to clean up atmospheric conditions as they now exist in our large cities. As a matter of preventive engineering, more attention must be given to ventilation. To carry out his duty to the public, the engineer should give more thought to the development of public speaking, and should use this means, along with others, to educate the public to the inauguration and use of engineering services for the promotion of better health.

In the discussion on the treatment of sewage by the activated sludge method, F. J. Ure, A.M.E.I.C., spoke of the satisfactory results obtained from the plant at Woodstock, making special reference to the ease in disposing of the sludge from such a plant in a small city. Mr. Veitch spoke of the desirability of providing daily scientific supervision for an activated sludge plant.

The chairman tendered to Mr. Storrie and the Woodstock members a vote of thanks moved by E. V. Buchanan, M.E.I.C., and seconded by F. M. Brickenden, A.M.E.I.C.

On motion by W. M. Veitch, A.M.E.I.C., and J. R. Rostron, A.M.E.I.C., the secretary was instructed to advise the reception committee for the London Centennial Celebration of the willingness of the London Branch of The Institute to co-operate with the Centennial Committee in entertaining visitors belonging to the engineering profession.

Meeting of April 22nd

A regular meeting of the branch was held Thursday, April 22nd, at 6.15 p.m. The branch had the pleasure of a visit from general secretary, R. J. Durley, M.E.I.C., on Thursday, April 22nd. He explained to the members of the branch various points in connection with administration methods as carried out at headquarters which proved most interesting to those present.

W. E. Piper, of The Dorr Company, engineers, New York City, gave a short talk on the principle and performance of the paracycle pump and paracycle compressor.

The application of paracyclic motion to a pumping machine was invented by Lieutenant-Commander C. H. Varley, of the British Navy.

The Dorr Company has taken up Canadian and United States patent rights, and is developing the machine as an air compressor as well as a pump.

London, Ontario, has the first commercially-built compressor. Toronto has the second. Both are for aerating sewage in activated sludge plants. London's machine has a guaranteed output of 450 cubic feet per minute of air with a 15-h.p. motor. It has delivered 590 cubic feet per minute at maximum motor speed, direct-connected to a 15-h.p., 1,445 r.p.m. motor.

The pump shows correspondingly high efficiencies, a 100-gallons per minute pump giving better than 80 per cent overall efficiencies through a wide range of pressures.

The paracycle is a positive displacement blower or pump, its output varying but little with the pressure, like a reciprocating pump. It has a rotary shaft which permits of direct motor coupling where the speeds are appropriate, like a centrifugal pump, but its capacity and pressure are not interdependent like the latter.

Its unique motion principle of operation, variant forms, and points of expected superiority were illustrated by a "chalk-talk" at the blackboard.

Victoria Branch

E. G. Marriott, A.M.E.I.C., Secretary-Treasurer.

On June 30th, general secretary, R. J. Durley, M.E.I.C., visited Victoria, and after calling on several of the local members of The Institute during the morning, addressed the branch at a luncheon presided over by the chairman, J. N. Anderson, A.M.E.I.C.

The progress and present standing of The Institute generally were dealt with, together with the relationship of The Institute to the various provincial associations of professional engineers, and special emphasis laid on the large amount of work done and time given for the benefit of the profession by the members of council.

In the discussion that followed, the question of remuneration arose; it was suggested that The Institute could do more than has been done in this regard, but some felt that while The Institute might be able to be of assistance in any particularly flagrant case of unfair remuneration, it was a matter that depended mainly on the members themselves.

Other points of view expressed were that engineers as a rule were not in touch with the financial and commercial interests, and did not therefore obtain the recognition they might otherwise have, that generally speaking engineers are inclined to underrate their capabilities and value to the community; that whereas a commercial man feels satisfied that if one job turns out unsuccessful, he can soon succeed elsewhere, an engineer often loses advancement through the fear of losing his position.

In a specific case of a municipality requiring an engineer, it was pointed out that the range of salary asked for by applicants varied from $120 per month to $300; it appeared that there was a willingness to pay $200 per month to a qualified engineer, and it was suggested that if engineers would co-operate, (and the British Columbia Act makes such co-operation possible), to the extent of agreeing as to what would be reasonable remuneration for such positions when they became vacant, the standing of the profession would be materially bettered.

After a visit to the city hall and a chat with the city engineer, F. M. Preston, A.M.E.I.C., Mr. Durley enjoyed some of the beauties of Victoria under the aegis of the branch chairman, and in the evening met the past and present secretaries of the branch.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
Stanley A. Neilson, A.M.E.I.C., Branch News Editor.

Visit to the Saguenay District

Over the week-end of June 25th to 27th, some fifty-eight members and friends of the Montreal Branch visited the large industrial developments in the Lake St. John district at the head of the Saguenay river.

The visit was the occasion of the annual summer excursion of the Montreal Branch, and by those who have followed the development of the district visited, it will be readily appreciated that from the standpoint of general interest to engineers it would be difficult to find a more interesting district for such an excursion. While for many years this district has been the centre of a great pulp and paper and lumber industry, the recent developments, particularly the hydro-electric plant at Isle Maligne, the new pulp and paper mill at River Bend, the enlargement of existing mills, and, lastly, the establishment of the Aluminum works and the construction of the new town of Arvida in connection with these works, has created an intensive industrial activity in the district.

The party left Montreal on Friday evening, June 25th, and, through the courtesy of the officials of the Canadian National Railways, three special cars, attached to the regular train to Chicoutimi, were provided for accommodation. The party arrived at Chicoutimi about 9 a.m. on Saturday, and were met by Councillor E. Lavoie, M.E.I.C., officials of the Saguenay Branch, and Mayor Desbiens, of Chicoutimi., and after partaking of breakfast the members were conveyed in automobiles to the plant of the Port Alfred Pulp and Paper Company, where they were received by R. C. McCully, A.M.E.I.C., superintendent of the plant, and were afforded an opportunity of inspecting the new plant.

From Port Alfred, the party were motored to the new Portage des Roches dam of the Quebec Streams Commission, which controls the outlet of lake Kenogami. This dam, which was entirely designed by members of The Institute under the direction of O. O. Lefebvre, M.E.I.C., is an example of the excellent engineering work being carried on by the Commission.

The party then returned to Chicoutimi for lunch, following which the members were taken by automobiles to the new townsite of Arvida, where the Aluminum Company of Canada have under construction their new plant and town. Upon arrival, the members were welcomed on behalf of the company by R. E. Parks and H. R. Wake, A.M.E.I.C., and were conducted in groups by various members of the staff on a tour of inspection of the new plant, which is rapidly nearing completion.

To describe the extent of this development would require much more space than is available in Branch News, and it is expected that the branch will be favoured with a paper describing this work during the coming fall. Such a paper, no doubt, will give a general idea of the development which is being undertaken by this company, but a true conception of the extent of this work can only be secured by a visit to the site.

From Arvida, the party were motored to Isle Maligne, arriving about 5 p.m., where a reception was tendered by officials of the Quebec Development Company. At 7 p.m., the members of the party were the guests of the Quebec Development Company at a dinner and dance at the Staff House. At the conclusion of the dinner, F. H. Cothran, vice-president of the Quebec Development Company, welcomed the members on behalf of the company, and, in reply, O. O. Lefebvre, M.E.I.C., on behalf of The Institute, and Professor C. V. Christie, M.E.I.C., on behalf of the Montreal Branch, expressed the thanks of the members for the very hearty reception they had received.

During the afternoon, the special cars which had been placed at the disposal of the party for the entire trip were moved from Chicoutimi to Isle Maligne, and were available for the accommodation of the members.

On Sunday morning, the party were afforded an opportunity of inspecting the Isle Maligne power plant of the Duke-Price Power Company, Limited, which is another work that must be seen to be appreciated. This plant embodies the latest features of design, and many favourable comments were made on the superior type of construction evident throughout the plant. Through the courtesy of the Quebec Development Company, the party then were conveyed by rail to No. 4 dam, where the final closure was made in connection with the Isle Maligne development. This trip afforded an opportunity of securing a general idea of the complete development, and to appreciate further the vast undertaking which has been achieved by the engineers of this district.

The members were again the guests of the Quebec Development Company at luncheon at the Staff House at Isle Maligne, following which they journeyed by train to the River Bend mill of Price Brothers and Company, Limited, where they were welcomed by C. N. Shanly, A.M.E.I.C., chairman of the Saguenay Branch of The Institute, and where, through the courtesy of the company and the kindness of the manager of the mill, they were taken on a tour of inspection of this modern and up-to-date paper mill.

Following the inspection tour, the party was entertained at dinner at the Staff House at River Bend as the guests of the company, and during the course of the meal Mr. Shanly extended a welcome to the visiting members, and very briefly reviewed the extensive developments which have taken place in the Saguenay district over the period of the last fifteen years. Following Mr. Shanly's remarks, the secretary of the Montreal Branch expressed the appreciation of the members for the reception and hospitality they had received. The party then returned to the train, which left River Bend at 9 p.m., arriving in Montreal on Monday morning.

The trip was acclaimed most enjoyable and most instructive, and will long be remembered by all members who were fortunate enough to be present.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

Joint Meeting with Sections of Canadian Institute of Mining and Metallurgy and the American Institute of Electrical Engineers, at Estevan, Sask.

The annual summer meeting of the Saskatchewan Branch took the form of a joint meeting with the Saskatchewan Section of the American Institute of Electrical Engineers and the Southern Saskatchewan Section of The Canadian Institute of Mining and Metallurgy, and was held at Estevan, Sask., on July 8th, 9th and 10th.

The members attending, many of them accompanied by ladies and children, were accommodated under canvas at River Park, an ideal camp site on the banks of the Souris river about two miles south of the town and opposite the Prairie Nurseries.

Here such conveniences as electric light, running water, swimming pool and a large dancing pavilion were placed at the disposal of the visitors. Electric lights were installed in each tent, and the members and their friends availed themselves of the swimming, boating, golfing and dancing when not otherwise engaged on the programme provided.

The majority of the Saskatchewan members motored from Regina and other points in the province, and were joined by the visitors from Alberta, Manitoba and eastern Canada. Despite the fact that heavy rains set in on Wednesday afternoon, July 7th, the majority of those who had signified their intention of attending the meeting commenced their journey. Some arrived Wednesday evening, some in the wee small hours of the following morning and some later in the day. Recollections of the enjoyable summer meeting held at this point some three years ago spurred the motorists on over roads almost impassable on account of mud and water, and the inhospitable nature of the elements was not allowed in any way to dampen the spirits of the inner man. The total adult registration numbered fifty-five, and to this must be added about ten children.

On Thursday the party visited points of local interest, including the Souris Creamery, Estevan Bottling Works, International Clay Products Company's plant and the Estevan power station.

On Thursday evening the members were guests of the Town of Estevan at a banquet given in River Park pavilion. The guests at the banquet numbered approximately one hundred and twenty-five, and included a number of Estevan's prominent citizens.

D. Bannatyne, who worked unceasingly to make the meeting a success, was chairman. Mayor A. M. Taisey gave an address of welcome which was responded to by R. N. Blackburn, M.E.I.C. He expressed his great belief in the future of Estevan.

E. J. Campbell, president of the Estevan Board of Trade, proposed the toast to the guests, and traced the progress made by the Engineering Institute since its inception in keeping pace with the requirements of the country. E. W. Bull spoke in response, and assured the committee in charge of arrangements that everything had been done for the guests' enjoyment.

D. W. Houston, A.M.E.I.C., outlined the great possibilities of the town in a toast to Estevan which was replied to by Councillor Norman McLeod.

The toast to the ladies was proposed by Councillor J. H. McFadden and responded to by W. T. Hunt.

In addressing the convention, S. R. Parker, A.M.E.I.C., chairman of the Saskatchewan Section of the A.I.E.E., made the prediction that the town of Estevan would one day rise to be one of the great industrial cities of the prairie provinces. The subject of his address was, "Electrical Development of Southern Saskatchewan."

Mr. Parker traced first the development of steam power and afterwards the gradual change to electrical power which is now proceeding, without which the present very intensive development of industries in the twentieth century, which is without doubt the *electrical era,* would not have been possible. A number of figures were then quoted showing the horse power employed in different industries and the percentage of each which have been electrified in the north central states of the United States. Although these percentages run up as high as 88.5 per cent, Mr. Parker stated that the only reason they are not higher is because of the lack of available power, due to the phenomenal demand for electricity exceeding the available output.

"Coming now to the local situation," said Mr. Parker, "as it affects southern Saskatchewan, a survey of industrial history shows that all great industrial developments have taken place on the coal fields if and where they are near a constant supply of good water. On a cursory survey of the situation, this location must be within a very limited radius of the town of Estevan."

Mr. Parker then outlined the designing of a power plant, stressing lower cost and pointing to the feasibility of establishing a power distributing plant at the mine head, Estevan. With such a plant, manufacturing would be developed and periods of depression in agriculture would be obviated. At the outset, owing to small population, losses might occur, but in the end it would be the solution of economic development.

W. H. Greene, M.E.I.C., acting city engineer of Moose Jaw, Sask., and chairman of the Saskatchewan Branch of the Engineering Institute of Canada, gave an address on "Industrial Development of Southern Saskatchewan."

Agriculture, thought Mr. Greene, would continue to be our chief industry, but he saw the time within a few years when the United States would cease to be a grain exporting country, which will mean increasing markets for Canada.

Clay products he saw as being exploited but moderately at present. "Our climate requires well-built houses," he said, "and there should be a good market for brick if the price can be lowered through the use of cheaper local coal. Again, lumber prices are steadily increasing, and the spread between a brick building and a frame one will gradually decrease. Clays suitable for the making of pottery and some classes of china at least exist and are beginning to be used. China clays are very scarce in Canada, so these deposits may on development prove valuable."

He described Saskatchewan's water power, estimated at 1,800,000 horse power, "as wholly undeveloped," but thought it would prove a valuable aid and standby to any scheme of central station electric production utilizing our large coal resources. "The transmission of electric power throughout the province would be of great benefit to the rural community," he said. "The hand labour required for carrying on much of the work incident to diversified agriculture can be largely abolished by systematic use of appliances operated by electric power. It is pretty well established that cheap power is necessary to and will attract industries to a locality that would otherwise be passed up. Certainly we in this province need industries to stabilize year-round employment.

"This lignite can be successfully used throughout the province, and mass production will help solve its preparation for export, partly because ample funds will be provided for research and experimental work. Its solution in the near future is important because an Eastern market will soon be open. Ontario and Quebec together import over 13,000,000 tons of coal annually from the United States. Already there is, in the States, a strong and growing sentiment against the further export of coal.

"The migration of industries to sources of cheap and abundant power has already begun. With such a beginning, and realizing our enormous coal reserves, why should we not expect the building of industries in the vicinity of the coal fields, or, if a central power scheme is developed, then throughout the whole province?"

Following the banquet, many of those attending joined in the dancing at the Pavilion, the numbers being considerably augmented by the younger set of the town.

Visit to Columbus, N.D.

On Friday the members, accompanied by the ladies and the mayor of Estevan and other local citizens, motored to Columbus, North Dakota, and visited the Truax mines. There they inspected the open pit mining or stripping of the lignite, which operation is being performed by steam shovel. A 4½-yard shovel with an 85-foot crane similar to those used on construction of the Panama canal was seen in operation. On this field the coal is located at an average depth of 25 feet below the surface and the thickness of the seam averages about 9½ feet. A movable tipple with special loader, which is placed in the box car for this purpose, enables a car to be loaded in 8 minutes. Maximum daily production is 2,500 tons, with an average yearly production of 200,000 tons. Following this inspection, the party were entertained at luncheon given by the owners of the mines.

The visitors then returned to Estevan, via North Portal, and gathered in the evening at a banquet given by the institutes in River Park pavilion.

Mining Problems in Saskatchewan

Dr. Charles Camsell, of the Department of Mines, Ottawa, delivered a short address in which he discussed various problems confronting the people of Saskatchewan and how the Department of Mines is assisting in the solving of the problems. The road problem might be solved by the working of oil possibilities in the province, and Dr. Camsell stated that two parties of investigators are at present working along the border between Alberta and Saskatchewan developing oil claims. He had recently seen samples in Regina of oil found in the Carrot River country and Lake of Rivers. A detailed study of the secrets of the rocks, their structure and character was essential to the discovery of oil. Although the water supply in this district was not a very acute problem, Dr. Camsell believed that before very long Regina and Moose Jaw would soon be faced with a shortage, and in this work the Department of Mines was conducting researches in underground water supply.

Preservation of Wood

R. D. Prettie, of the Alberta Wood Preserving Company, of Calgary, spoke at length on the preservation of wood. Wood preservation was the art of protecting wood from decay. The speaker outlined the history of this art, which dated from the days of the Egyptians. Its importance was shown by the fact that there are now 162 wood preservation plants in the United States. In 1924, in Canada 2,086,180 telephone, telegraph and power line poles were treated to save them from the ravages of the fungi.

Describing the fungi and their activities, Mr. Prettie said he had often heard telephone engineers remark that the poles now do not last like the poles they used to get. These engineers have not taken into consideration the fact that the new poles were set in soil permeated with the mycelia of wood-destroying fungi. Creosote was the treatment most successfully used for the preservation of wood, although zinc chloride was also very successfully used.

Visit to Mines Near Estevan

On Saturday the party visited some of the more important mines in the Estevan field. Trips were made to the Crescent collieries, where a new shaft is being sunk. The party then divided into two groups, headed by R. J. Lee, Dominion inspector of mines, and E. Pierce, provincial inspector of mines. The former visited the Manitoba and Saskatchewan collieries at Bienfait and the latter the Western Dominion collieries at Taylorton. Both groups descended the mines and inspected the various operations underground. Much interest centred around the electrically-driven cutting machine and mechanical box car loading equipment. The coal seams at both of these mines average about 12 feet in thickness and are located about 80 feet below ground. The coal is considered of a better grade than in the Truax mines of North Dakota, the selling price of each being the same at tipple, viz.: $2.50 per ton for best lump.

Luncheon was given by the M. & S. and Dominion collieries in the community hall of the former company, where slides illustrating the mining operations were shown by Mr. Galloway, manager of the M. & S. collieries.

The return trip to Estevan was made via Roche Percée. Here the party inspected the pierced rocks, a peculiar geological formation caused by the weathering of the sandstone rocks, from which the village obtained its name. On some of the protected faces of these rocks ancient Indian drawings are to be seen.

Later a visit was paid to the Prairie nurseries, the largest nursery in western Canada, comprising over 700 acres. Many of the plots were inspected under the direction of Mr. Torgeson, president of the nurseries. The guests finally assembled at the nursery headquarters, where they enjoyed a sumptuous repast. Each lady was presented with a bouquet of white peonies taken from the nursery plot, where 40,000 of this species of flower alone were in bloom.

Some of the party left for their homes on Saturday, while others remained in camp over Sunday. All voted the meeting a great success, despite the inclemency of the weather and consequent condition of the roads. The citizens of Estevan spared nothing in catering to the success of the gathering.

Preliminary Notice

of Applications for Admission and for Transfer

July 19th, 1926.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in September, 1926.

R. J. DURLEY, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BRUCE—WILLIAM JOSEPH, of Maniwaki, Que., Born at Gamebridge, Ont., Jan. 6th, 1888; Educ., C.E., Univ. of Toronto, 1907; during undergrad. course constrn. and location as chainman, rodman, instrman and topographer with C.N.R.; 1908, mining claim surveys, Haileybury, Ont.; 1910, asst. engr., Dom. Land Survey, Peace River; 1911, res. engr. C.N.R., Cobourg to Deseronto. Ont.; 1912, asst. engr., city surveys and bridges and docks dept., Toronto; 1913-19, asst. engr., Dept. of P. W., Sault Ste. Marie, Ont.; 1919-21, asst. engr. i/c dredging and constrn. for Great Lakes Power Co., Sault Ste. Marie; 1921-23, dist. engr., Northern Devel. Branch, Swastika, Ont.; 1924, topographical survey, Watabeag Lake area; 1924-25, engr. and supt., Chisholm Constrn. Co., Cornwall, Ont.; at present, engr. i/c surveys for Foundation Co. of Can. Ltd.

The Stability of Masonry Dams

A Review of Theories of Stresses in Dams, the Results Obtained in the Investigation of Stresses by Various Methods, the Factor of Safety and the Necessity of Further Investigations and Research

C. L. Cate, A.M.E.I.C., Consulting Engineer, Montreal, Que.

Paper read before the Montreal Branch of the Engineering Institute of Canada, October 9th, 1924

The principles underlying the design of dams will be readily admitted to be of great importance, and particularly so in Canada and to Canadian engineers, because no other country has the construction of as many dams to look forward to as has Canada, and it is to be hoped and expected that these Canadian dams will be designed and built by Canadian engineers. This paper has been written in the hope of stimulating investigation and research in regard to these principles, with particular reference to conditions encountered in this country.

Practically the whole theory of dam design, in so far as internal stresses are concerned, has been developed by French and English engineers, and Canadian dams are of a class distinct from Europe in that, generally speaking, European dams are high dams on small streams and generally impound water for municipal supply or for the operation of canals, whereas it might be said that there is not a single high dam in Canada, and the great bulk of the important dams are from thirty to sixty feet high, and are built on streams of heavy discharge for power purposes.

There is perhaps no definition of the dividing line between high and low dams, but it might conveniently be considered as the point at which in a solid, purely gravity section it becomes necessary to flatten the downstream slope in order to keep the compressive stresses within the limits set. The exact height at which this would occur would vary with the characteristics of the profile as well as with the compressive stresses allowed, but would generally be about 150 feet.

The fact that Canadian dams are usually well below this height alters the problem from the European one of limiting the compressive stresses at the faces to safe values, to one where safety against overturning is the principal consideration.

The fact that there are many low dams in Europe on streams of considerable discharge is not here overlooked, nor is the fact that high dams must also be safe against overturning, but a study of European writings on the subject makes it evident that the limiting of compressive stresses has received greater attention there.

Review of Theories of Stress in Dams

The scientific investigation of stresses in masonry dams without reinforcement was begun by DeSazilly, Delocre and Bouvier in France, and Rankine in England between 1853 and 1875, and, so far as any tangible effect on the conception of stresses as affecting the design of dams is concerned, it might almost be said to have ended there.

DeSazilly introduced the "profile of equal resistance," and produced general differential equations for this profile. He was, however, unable to integrate these equations.

Delocre refined the profile and introduced the method of basing calculations on a slice of dam of unit thickness. He produced formulæ which were workable, although involved.

Rankine enunciated the middle-third rule, and pointed out that the maximum vertical pressure on horizontal planes is not the maximum compressive stress encountered.

Bouvier, basing his reasoning on LeBlanc's earlier work on the stress in arch rings, derived an expression for the maximum compressive stress, which he found to be the maximum vertical stress on the horizontal plane divided by the square of the cosine of the inclination of the resultant to the vertical.

The great bulk of the work which has been done in later years has been devoted to attempting to find general formulæ for facilitating design and to the consideration of external forces, such as uplift and ice pressure, and to the development of the various types of hollow and arched dams.

The exception to this statement is found in the work of Atcherley and Pearson, Sir Benjamin Baker, Ottley and Brightmore, Wilson and Gore, Unwin and Cains. This was done between 1905 and 1908. It dealt both theoretically and experimentally with the internal stresses in solid dams, and, although it seems to have had no practical effect on dam design, it might very well have done so.

The first experiments in this series were those of L. W. Atcherley, carried out at University College, London, " with some assistance from Prof. Karl Pearson." Two models were made to scale from the dimensions of a dam actually built. They were of wood, one being laminated horizontally and the other vertically. Weights were applied to each to represent water pressure, and it was found that the vertically laminated model failed at a lower pressure than the horizontally laminated model. From this fact, and from the fact that the vertically laminated model, in failing, first opened up cracks at the downstream toe, Atcherley and Pearson were led to the conclusion that tension would exist in actual dams on vertical planes before, or rather than, on horizontal planes.

Proceeding to verify this conclusion theoretically, the authors commenced with the rather bold statement that as the trapezoidal law was generally assumed, " it might with almost equal validity be assumed " that the shear on horizontal planes varied as the ordinates to a parabola. The expression *trapezoidal law* refers to the assumption of uniformly varying normal stress on horizontal planes which makes the stress diagram a trapezoid.

In an appendix to the memoir, in which the authors further elaborate their reasons for the assumption of parabolic distribution of shear, the following appears,—

> " If it be asked why is our parabolic distribution of shear on the base any more justifiable than the linear, the answer must be three-fold,—
>
> "(1) We have not confined our attention to a parabolic distribution, but considered also a linear distribution as another extreme;
>
> "(2) Both lead to a sensible tension in the tail;
>
> "(3) If the dam were built with vertical tail, it would show shear on the vertical line at the junction with the foundation."

The term *base*, as used above, appears to have been intended to cover all horizontal planes. This answer is not conclusive, and seems to have been widely criticized at the time. It must be understood in this connection that once the trapezoidal law is accepted and a shear distribution is assumed, the whole state of stress at any point in the dam is virtually determined. The total shear on a horizontal plane is not a matter of conjecture; it must equal the total force imposed by the water pressure down to that plane, and, a parabolic distribution of this shear being assumed, the value at any point is determined, and the excessive tensions on vertical planes at the tail found by Atcherley and Pearson follow at once.

The results obtained attracted wide attention, particularly in Europe. The remarks made by Sir Benjamin Baker, in the course of discussion at the Institution of Civil Engineers, indicate that the proposal to increase the height of the Assuan dam was postponed on this account, and Mr. E. Mattern stated that important works were in contemplation at the time in Germany, and doubt arose whether they could be economically carried out on the sections indicated as necessary by the Atcherley experiments.

Sir Benjamin Baker also made models, which were much more impromptu affairs than those of Atcherley and Pearson. They were made of ordinary jelly and the experiments covered only a few hours. No attempt was made to obtain quantitative results, the idea being to demonstrate the general nature of the distortion of an elastic mass when subjected to forces similar to those which act upon a dam.

Sir Benjamin commented very favourably on the work of Atcherley and Pearson, in so far as it had drawn attention to phases of the relationship of stresses in dams which required further investigation. He did not, however, agree with the conclusions as to tension on vertical planes.

At a meeting of the Institution of Civil Engineers in January, 1908, a paper was read by Sir James Ottley and A. W. Brightmore, and another by J. C. Wilson and Wm. Gore. These described further experiments with model dams. They represented a great deal of work, Ottley and Brightmore's researches having occupied some fourteen months.

The model used by Ottley was made of plasticene, a substance whose chief characteristic is its plasticity, but which was found to be elastic beyond the point to which it was stressed in the experiments. The model was of considerable size and weighed over 100 pounds. Water pressure was applied by means of a rubber bag filled with water. The cross-sectional face of the model was ruled off into squares, and, after water pressure had been applied, the distortion was measured. In this way, from an assumed stress-strain relationship, the stresses were obtained.

The experiments of Wilson and Gore were carried out with a model of India rubber blocks. It was comparatively small and forces representing weight and water pressure were applied externally. The construction of the model was carried out with great care. Each block had a hole drilled through its centroid. This hole was fitted with a bronze liner through which in turn was passed a steel rod to the extremities of which the weight for increasing the weight of the model was attached by cords. There were about 180 weights attached to the model, including those representing water pressure.

A careful set of observations was made to establish the stress-strain characteristics of the India rubber used, and the anticipated distortion calculated. The model was then built in such a form that when the weights were applied it would arrive at the form desired, which was a scale model of a dam already built. The cross-sectional face of the model was marked off into squares, and photographs of the cross-section were taken with and without the weights representing the forces acting. The differences between the two sets of photographs were measured to give the distortion. Measurements were made to the 1/1000th of an inch, and great care was taken in all the details of the experiments. It will be noted that these experiments, as well as those of Ottley and Brightmore, gave quantitative results and assigned values to the stresses, as distinguished from those of Atcherley and Baker, which only attempted to discover their nature.

The result of the experiments of Ottley and Brightmore, and Wilson and Gore, and the calculations made by their authors and by others at about the same time, notably Maurice Levy, E. P. Hill and Prof. Unwin, was to reverse the finding of Atcherley as to the existence of tension on vertical planes at the downstream toe of a dam designed so as to place the resultant pressure with reservoir full at the extremity of the middle-third of the horizontal plane.

All the calculations made at this time assumed the trapezoidal law to be practically true, (this being also in accord with the measured results obtained with elastic models), and, as indicated above, the whole question of the nature and amount of the internal stresses then reduces itself to one of shear distribution. The action of the models

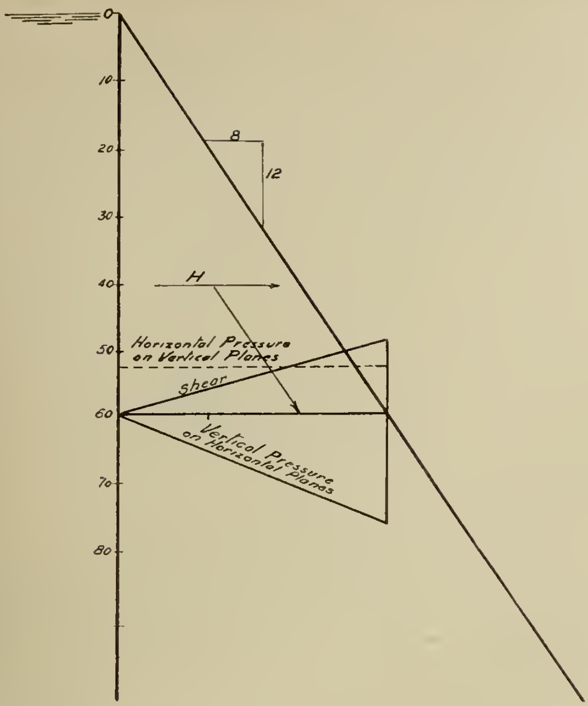

Figure No. 1

showed a triangular distribution of shear for triangular dam sections, except at elevations sufficiently near the foundation to be affected by the abrupt change of section.

Calculations made by Prof. Unwin, and by Hill and Cains, (and previously and independently by Levy in France), bear out this triangular shear distribution. The method of Cains* is perhaps the most easily worked.

Figure No. 1 indicates the distribution of vertical pressure on horizontal planes, shear, and horizontal pressure on vertical planes, as outlined above.

Relative Value of Compression and Shear

As methods of deriving the shear distribution and thence the complete state of stress at any point in the section have been given elsewhere, it is not the intention to recite them at length here. Cains' method, applied to a purely triangular profile with vertical face and water level with the top, and with the resultant at the extremity of the middle-third, gives the results tabulated in table No. 1, the stresses being in masonry units.

A purely triangular section has been used because, with this section and with water level with the top, all stresses vary proportionately to the distance from the top, and a solution on one plane can be transferred to another by using a suitable factor. Also, the higher powers which appear in the equations for more complicated profiles are not encountered. Much labour is thus saved and the results, from a theoretical standpoint, are not altered.

The corresponding ellipses of stress are shown in figure No. 2, along with some intermediate ellipses derived from them. It will be noted that the ellipse at the downstream face is a straight line, as it must of necessity be because there would be nothing but atmospheric pressure to resist any normal pressure. Also, if the general method of deriving inclined stresses from ellipse of stress be followed with regard to the principal stress at the downstream face, then the vertical pressure on the horizontal plane is $\frac{86.67}{1\times\tan^2\Theta}=60$. It will be noted that Bouvier's expression for the maximum compressive stress would be $86.67\times\cos^2 33°40'=60$. This exact agreement would only appear in a triangular section and at the downstream face. The vertical stresses obtained from the trapezoidal law do not represent the vertical component of the maximum compressive stress. They represent the vertical component of the total stress on the horizontal plane, which is quite a different matter.

Table No. 1:—Distribution of Stress Obtained Through Application of Cains' Method, as Applied to a Purely Triangular Profile with Vertical Face and Water Level with Top, and with Resultant at Extremity of Middle-Third.

60	40.	60.	26.67	.40	86.67	.0	33°40'

h=distance of joint from top of dam and water level.
x=horizontal distance from upstream face.
p=intensity of vertical pressure on the horizontal plane.
s=intensity of horizontal pressure on vertical plane.
q=intensity of shear on horizontal or vertical plane.
f=maximum principal stress=major axis of ellipse of stress.
f'=minimum principal stress=minor axis of ellipse of stress.
Θ=inclination of f to the vertical.

It will also be observed that the shear intensity $q=p\tan\Theta$, and as, at the downstream face, Θ must equal ϕ, where ϕ represents the inclination of the downstream face to the vertical, it follows that at the downstream face the shear equals the vertical stress on the horizontal planes multiplied by the tangent of the angle of inclination of that face. This gives a larger intensity of shear than is usually allowed for. After citing the shear thus obtained, one author neglects it on the ground that there is disagreement as to the correctness of the theory.

It may be true that there is disagreement, but it is as well to examine where the disagreement lies. It must be admitted that shear on the horizontal plane exists, and that it must be distributed. The question then narrows to one of the manner in which the distribution shall be made, leaving a choice between the parabolic distribution of Atcherley and Pearson and the triangular distribution. The former gives excessive tensions on vertical planes, and the latter high shear values. The fact that there is disagreement as to which of these two should be provided for, does not seem a sufficient reason for not providing for either of them.

One feature of the stress relationship derived from the Wilson and Gore experiments, which appears significant but which seems to have escaped notice at the time, is the value and arrangement of the minor axes of the stress ellipses. It will be seen in figure No. 2 that a line (yz) on which the normal stress is only about one-third of the hydrostatic pressure, runs into the profile. The effect of this, in the event

*Transactions of the American Society of Civil Engineers, Vol. LXIV, p. 208.

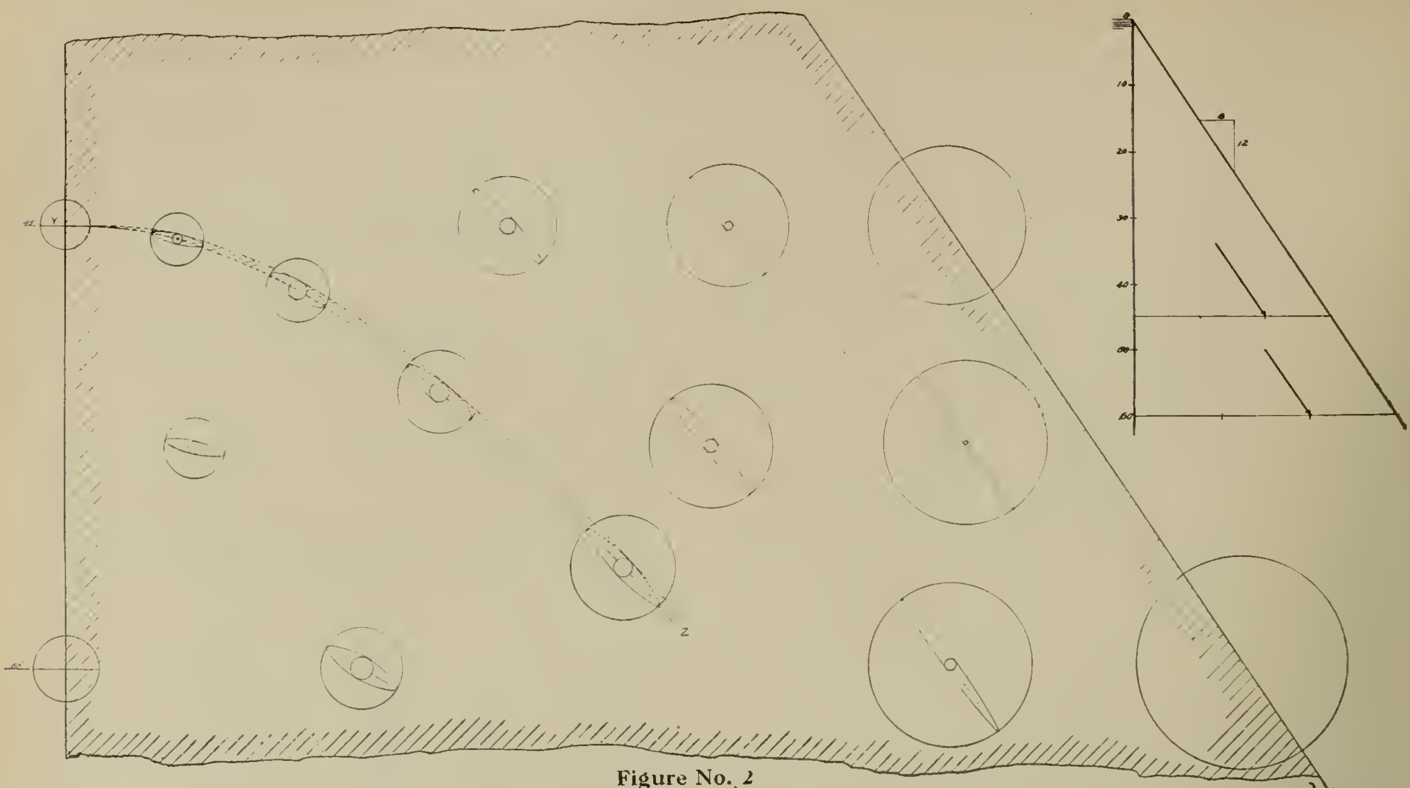

Figure No. 2

of water pressure entering a faulty construction joint, might conceivably be serious.

Factor of Safety in Dams

There is no point in connection with dam design about which there is more confusion, or at any rate conflicting opinions, than the factor of safety. A general survey of text books would perhaps lead to the conclusion that with the resultant at the extremity of the middle-third, there is a factor of two against overturning, plus an unknown but considerable value due to the tension strength of concrete, and minus the overturning effect of water entering horizontal cracks where the concrete has failed in tension.

It is obvious that the assistance due to tension strength and the additional overturning due to increased uplift will not in general be coincident, so that the factor would be 2± a considerable value. The first item is always disregarded in the calculations, but its value as a reserve of strength is probably counted upon more than it should be.

The second item is also usually disregarded in considering the factor of safety, but until we have more information as to whether tension cracks actually occur while the resultant remains within the profile and, if so, whether they are sufficiently large to permit water to enter, the stability should properly be considered with full head to the point where tension ceases.

It is not a difficult matter to integrate the compressive stress on the downstream face, and in connection with the stress-strain relationship obtain the contraction of this face, and a corresponding value for the increase of length of the upstream face, (which increase would be extremely small), but there might be a small number of relatively large cracks or a large number of relatively small ones. The total extension of the upstream face of a triangular dam 60 feet high with a 40-foot base with the water pressure increased so as to bring the resultant half way between the middle-third point and the downstream face would be of the order of 1/500th of an inch.

Apart from considerations of the possible effect of additional uplift in reducing the factor of safety, let us examine the effect upon the stress of multiplying the overturning moment by 2.

Let figure No. 3 represent the cross-section of a triangular dam in which the resultant cuts the base at the extremity of the middle-third of all horizontal planes. It follows from the fact that the section is triangular that the

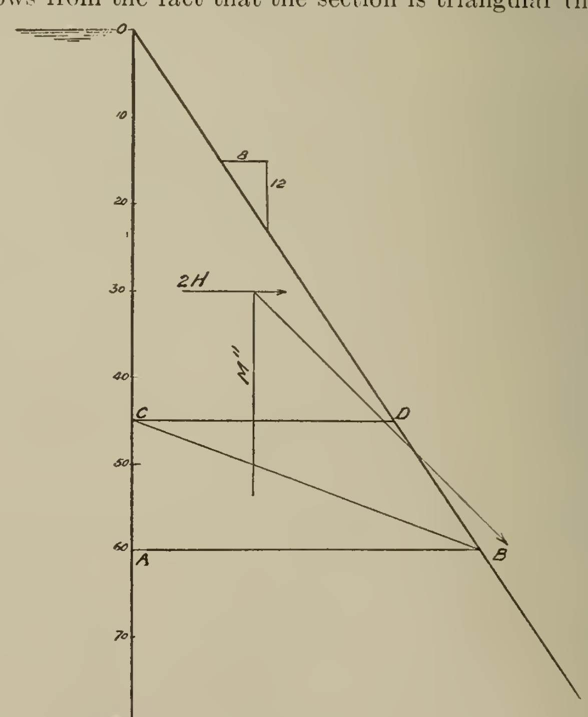

Figure No. 3

resultants of forces from above each horizontal plane will be parallel to the downstream face. If then the water pressure and hence the overturning moment be multiplied by 2, the resultants will cut each horizontal plane at its extremity. For simplicity in calculation, let it be assumed that the specific gravity of the masonry is such that a batter of 2:3 satisfies the condition that the resultant cut the base at the extremity of the middle-third, under ordinary water pressure.

Thus for a plane 60 feet from the top,—

OA = 60

AB = 40

M = weight of the section above AB = 1,200 (masonry units),

—the resisting moment = 32,000,

—the ordinary water pressure

$$H = \frac{Wh^2}{2} = \frac{.444 \times 60 \times 60}{2} = 800 \text{ masonry units}$$

and the overturning moment = 16,000.

Thus the factor against overturning = 2.

If now the water pressure be multiplied by two, the overturning moment = 32,000, and the factor against overturning will be 1.

Let CD represent a horizontal plane 45 feet from the top,—

OC = 45

CD = 30

M′ = weight of the section above CD = 675

—the resisting moment = 13,500

—the ordinary water pressure

$$H = \frac{Wh^2}{2} = \frac{.444 \times 45 \times 45}{2} = 450$$

and the overturning moment = 6,750.

If, as before, the water pressure be multiplied by two, the overturning moment = 900 × 15 = 13,500, and the factor is again 1.

Now consider the stability of the section above CB against overturning about B with water pressure × 2.

M′ = weight of the section above CD	= 675	
weight of triangle BCD	= 225	
M″ = weight of section above CB	= 900	
and the resisting moment = 675 × 30		= 20,250
225 × 16.66		= 3,750
		24,000
The overturning moment = 900 × 30		27,000

Evidently under ordinary water pressure the factor of safety of the section above BC against overturning about B is less than 2.

It can be shown that this result, obtained entirely from external forces, agrees with the results obtained from internal stresses.

From the definition of stability, if the resultant of the external forces acting on the section, (including its own weight but neglecting the supporting forces), cuts the base, then the section is stable and the moment of the resultant about the side of the base nearest it is a measure of the stability.

Similarly, if the moments of the external forces be taken about the side of the base nearest the resultant, their sum, (or difference), must be a measure of the stability.

Also, in figure No. 3, if the plane *AB* be considered as the base, the difference between overturning and resisting moments is a measure of the stability, and if the diagram of vertical stress on the plane *AB* be drawn, its moment about B is a measure of the stability, whether the diagram be drawn with or without tension.

Thus with ordinary water pressure and the resultant cutting the extremity of the middle-third, the difference of moments is 16,000 in foot-masonry units as given above, and if the vertical stress diagram be drawn, its area is 1,200 acting at 13.3333 from B or 16,000 foot-masonry units.

With water pressure multiplied by 2 and resultant cutting base at B, the difference of moments is zero, and if tension be disregarded the moment of the stress diagram is also zero, for the load would be concentrated at B.

Also, if tension be included we have,—

$$\text{Pressure at A} = \frac{M}{AB}\frac{(1-3\,AB)}{AB} = -\frac{2M}{AB} = -\frac{2400}{40} = -60,$$

$$\text{and at B} = \frac{M}{AB}\frac{(1+3\,AB)}{AB} = \frac{4M}{AB} = \frac{4800}{40} = 120,$$

and the moment of the tension diagram about

$$B = \frac{60 \times 13.333}{2} \times 35.55555 = 14{,}222,$$

and the moment of the compression diagram about

$$B = \frac{120 \times 26.666}{2} \times 8.88888 = 14{,}222,$$

The difference being zero, the moment of the stress diagram, whether tension is included or not, agrees with the moments of external forces.

Figure No. 4 represents the normal stress on the plane BC of figure No. 3. The ellipses from which the stresses are obtained are also drawn in figure No. 4, and the stresses tabulated in table No. 2.

The moment of the tension portion of the diagram = 9,950, and that of the compression portion = 7,000, leaving an unbalanced moment of 2,950, which agrees substantially with the results obtained from the moments of the external forces.

Note:—See foot of table No. 1, for explanation of signs.

If now the same conditions as before are assumed as to batter and location of resultant under ordinary water pressure, i.e., a factor of safety of two against overturning on horizontal planes, and if the water pressure and hence the overturning moment be multiplied by 1.5, the resultant will cut the base half way between the extremity of the middle-third and the downstream face. That is ED (figure No. 5) = CD ÷ 6.

Overturning moment = 450 × 1.5 × 15	= 10,125
and the resisting moment as above	= 13,500
Stability	= 3,375
Factor of safety = 1.333	

and this relationship will be true on any horizontal plane.

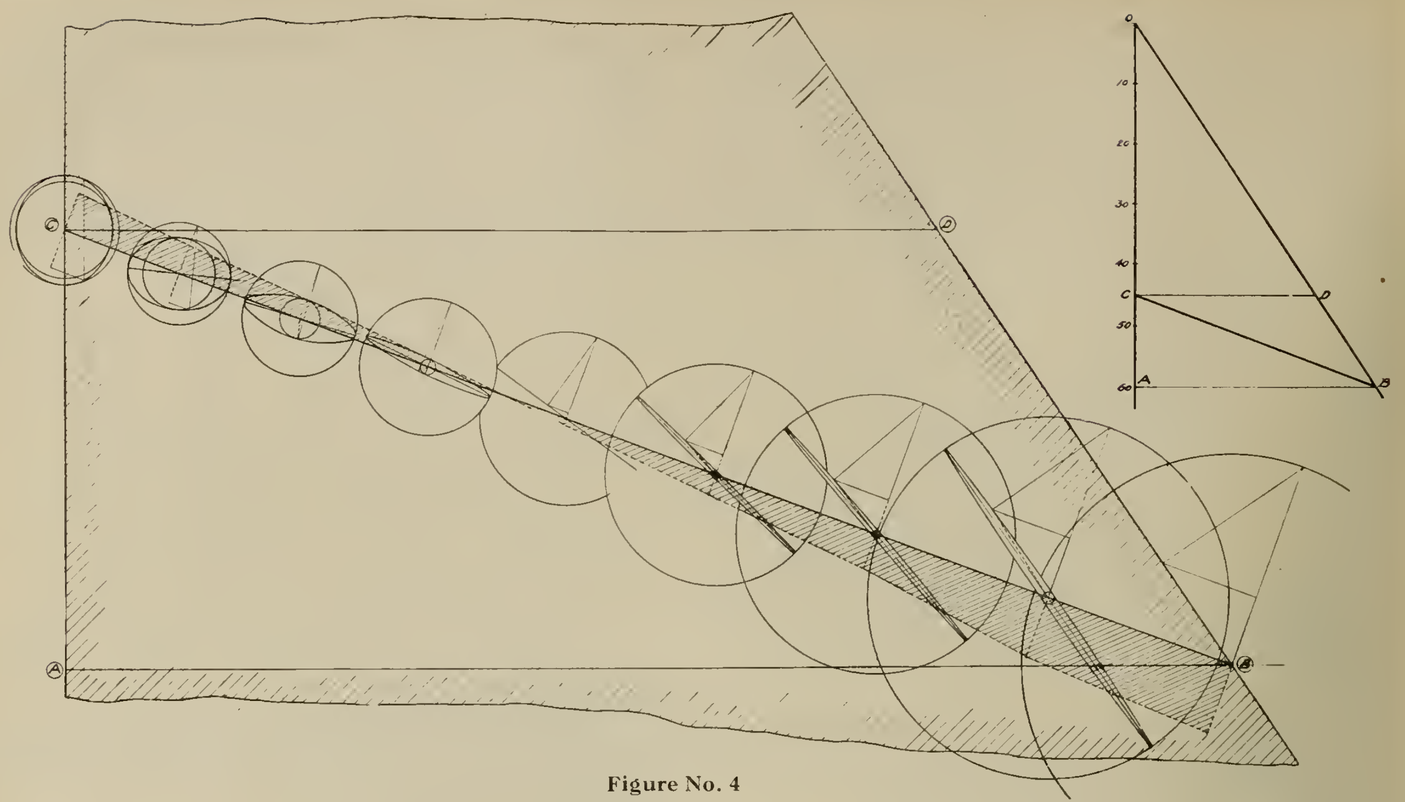

Figure No. 4

But if AB be the horizontal plane 70 feet from the top, consider the stability of the section above CEB.

M′ = the weight of the section above CD	=	675.
the weight of the triangle BED	=	62.5
M″ = the weight of the section above CEB	=	737.5
and the resisting moment = 675 × 36.66	=	24,750
62.5 × 13.77	=	850
		25,600
The overturning moment = 675 × 40		27,000

The section is therefore unstable with the overturning moment multiplied by 1.5. Hence, while the factor of safety against overturning on horizontal planes is 2, it is something less than 1.5 on CEB.

The stress diagram verifying this result is shown in figure No. 6, which also shows the stress ellipses. Stresses are given in table No. 3. It will be noted, however, that the stress diagram is drawn with B at the extremity of a plane 60 instead of 70 feet from the top, at which point the section is just stable. The moment of the tension portion of the diagram =3,620, that of the compression portion =3,813, and stability=183, and from the external forces the stability evidently equals the moment of the weight of the triangle BED=37.5 × 8.33=310, (because the line EB is the continuation of the resultant of the external forces above the plane CD and it passes through B), which result agrees substantially with the moment obtained from the stress diagram.

It may seem on first inspection that CEB is an unlikely line for a fracture to follow, but it coincides essentially with the line of fracture of the Bouzey dam. The result would not be greatly altered if ED were slightly increased, and the fracture might leave the profile anywhere between the intersection of the resultant with the downstream face and the point B.

So far as the author is aware, no dam has ever been known to fail on a horizontal plane, (other than its foundation), and if dams, when they fail, do not do so on horizontal planes, this in itself would seem an excellent reason for investigating other planes of weakness.

In connection with the above method of considering stability against rotation, about points on the downstream face at the extremity of downward inclined planes, it may be pointed out that the fracture can never cross the resultant. In triangular dam sections its application is limited to the examination of the factor of safety, because in a triangular section the resultants, (if they cut the horizontal planes at or inside the middle-third), will not, if produced, cut the downstream face. Sometimes, however, this method will show instability in headworks or the piers of stop-log dams, even when the resultants on horizontal planes are within the middle-third. Such cases are indicated in figures Nos. 7 and 8, which are self-explanatory.

The method does not lead directly to quantitative values for the stresses induced, but where the overturning moment exceeds the moment of resistance, stability must depend upon the tensional strength of the concrete, and the structure is evidently in a dangerous condition.

If the overturning effect of water entering cracks in the upstream face due to tension be allowed for, the factor of safety which has been shown to be less than 1.5 will be further reduced. It may almost be said that the factor of safety with the resultant at the extremity of the middle-third is 1.

One of three methods may be adopted for providing an increased factor,—

1. The resultant may be kept a sufficient distance inside the middle-third to give the desired margin.

2. The factor may be applied to the estimates of probable forces acting against the structure and the resultant kept at the middle-third with the increased forces.

3. The dam may be sufficiently reinforced on the upstream face to provide for tension resulting from multiplying the overturning forces by the factor.

Table No. 3:—Distribution of Stress with Water Pressure Multiplied by 1.5.

60	40	+90.	40	60.	130.	0.	33°40′

Note:—See foot of table No. 1, for explanation of signs.

The first two methods may seem at first to be the same, but consider the case of a non-overflow section designed to resist water pressure with water level with the top.

Neglecting considerations of uplift and ice pressure, a factor of 2 by the first method would bring the resultant to the edge of the middle-third at the horizontal plane 60 feet from the top with 20 feet of water flowing over the top, at the horizontal plane 30 feet from the top with 10 feet of water flowing over the top, and so on, whereas the second method would assume a constant super-elevation of water for all planes. It will be seen that the section required would be quite different under the two assumptions.

A dam, or at any rate a dam under 100 feet high, would seem to demand different treatment as regards its factor of safety from other structures. In designing steel structures, for instances, the steel is stressed up to a point giving a definite factor on its elastic limit, but in a low dam the compressive stress is always so far below the elastic limit

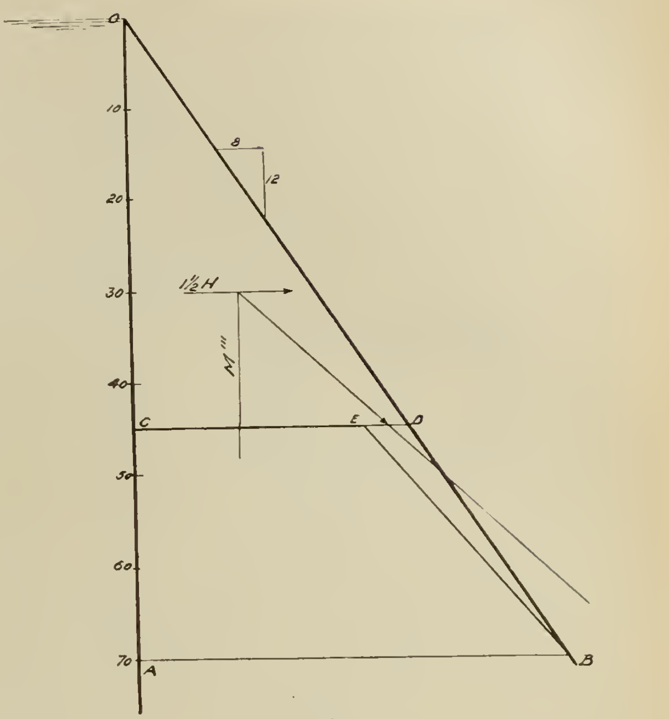

Figure No. 5

that a factor applied to it would have no practical meaning. The basis of design for low dams is really tension, and, as the tension stress allowed is zero, a factor cannot be applied to it. The factor must then be applied to overturning forces. These consist of the horizontal component of the water pressure, the uplift and ice pressure. The latter is something to which we are not now able to attach even an approximate numerical value, and it is quite likely that we shall never be able to do so. In these circumstances, a

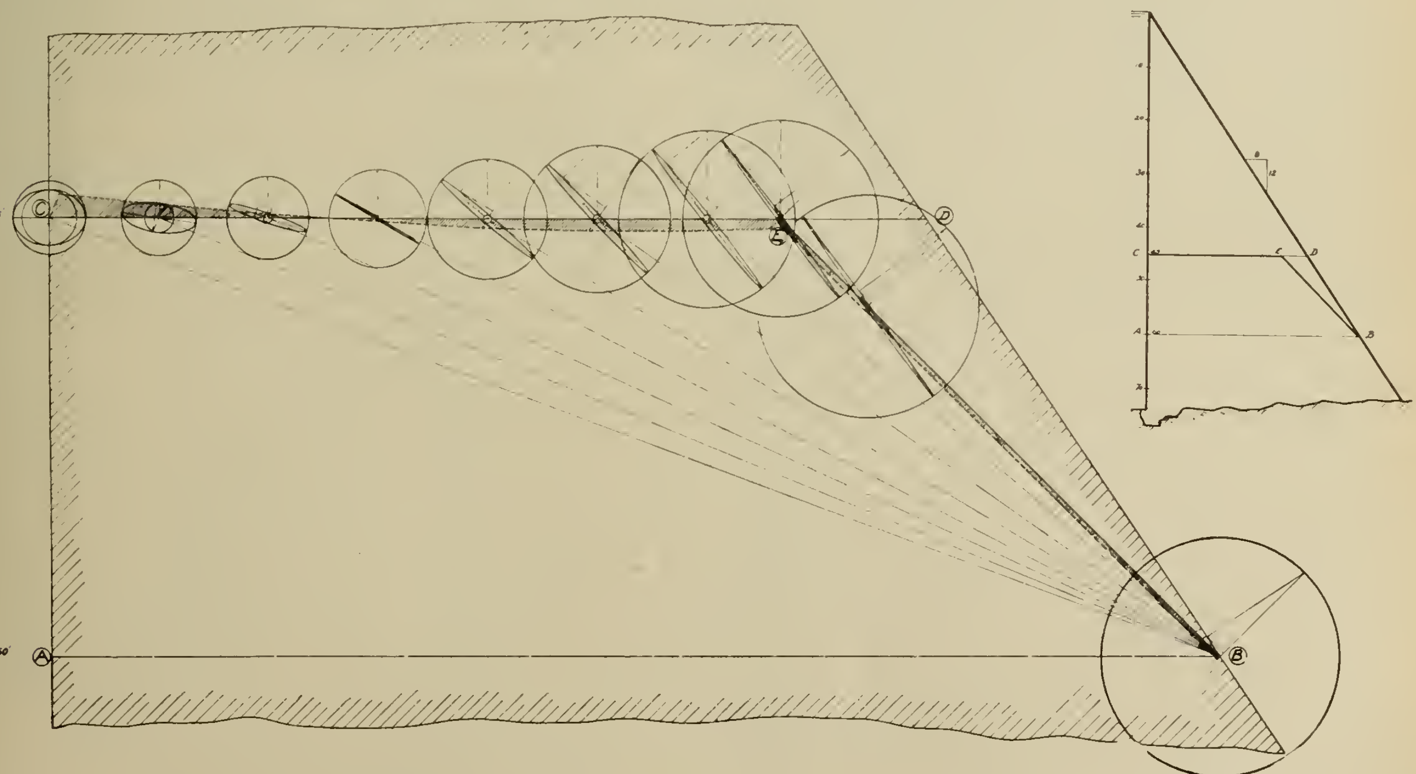

Figure No. 6

factor of safety is without significance; the ice pressure allowance might as well be assumed once and for all at the start. Both the uplift and the water pressure increase with the head, so that in increasing the head used in calculation, a more rational margin of safety is provided than by applying a factor to the overturning moment at each section. The latter method is really applying a margin of safety against increase in the specific gravity of the water.

An important advantage in the method of increasing the head calculated for, so as to provide the margin of safety, lies in the fact that in this way the upper portions of the dams are made proportionately stronger, and as most of the events which can be imagined as occurring to draw upon the factor of safety would impose stresses near the top, this seems desirable. It is not the intention here to go into the question of numerical values suitable for a factor to be used in this way. Any margin provided, however, must, if it is to be understood as corresponding at all to the meaning usually associated with the term *factor of safety,* represents an additional elevation of the water above anything that can be expected to occur. Merely to provide for an elevation that may be expected in the course of a few years to occur is to provide a factor of safety of one. It may be legitimate, however, not to consider the ice pressure as acting co-incidentally with the additional elevation of water in cases where co-incident action is manifestly impossible.

The third method mentioned, that of providing a factor of safety by vertical reinforcement of the upstream face, has already been advanced, but has been condemned, although reinforcement is generally used in the upper portion to provide for ice pressure and also in spillway crests. Two principal points were advanced against the general reinforcement of the upstream face,—first, a doubt as to the permanency of reinforcement imbedded in concrete near the face where it is constantly saturated with water, and, second, the difficulty of continuing the reinforcement into the base.

Data on the first of these objections should soon be available, if it is not already so, because it should be possible to judge from the changes in steel similarly imbedded for twenty or twenty-five years what change could be anticipated over the much longer periods which a dam is supposed to stand. In any case, all reinforced hollow dams are subject to this same action.

The second difficulty would be greatly reduced by the use of large bars at considerable intervals, the size of the bars being determined by the depth to which it is considered necessary to imbed them, from considerations of the physical structure and condition of the rock foundation. The deeper the hole, the larger the rod upon which the necessary bond strength can be developed. The holes in the foundation would in certain circumstances be a valuable source of information as to the condition of the rock.

The procedure would be to design the section to bring the resultant to the middle-third under the anticipated external forces. The section would then be fixed. The desired factor would then be applied to these forces, (or the water level increased as outlined above under the second method), and the steel required calculated under the method given for " flexure and direct stress " in various text books. The cost of providing a factor of two by this method for a sixty-foot dam would be about 10 per cent of the concrete cost, as compared with 40 per cent by method one. These percentages are, of course, not general. They are intended to indicate the difference in the cost of providing a factor of safety of two, (over and above any factor which is present when the resultant cuts the base at the middle-third), for a triangular dam section 60 feet high under water pressure only. They would represent the starting point of an investigation, not the end of one.

It may be remarked that French engineers, in their specification for high dams, allow a factor of safety of one, provided there is no chance of the assumed overturning forces being exceeded.

Here another, and perhaps the most important, difference between the high dam in the small drainage basin and the low dam on the large basin appears. To adequately estimate the overturning forces is not difficult in the first case, but it is extremely so in the second.

As an example, consider the effect upon the overturning moment at a plane 150 feet from the top of a dam 1,000 feet long on a river having a basin of 316 square miles of increasing the run-off from 20 c.f.s per square miles to 40 c.f.s. per square mile. This would mean an increase of about 3 per cent in the overturning moment at the 150-foot plane. (It is assumed that the additional run-off is discharged by spilling over the total length of 1,000 feet.)

Compare this with the effect upon a dam 50 feet high and 700 feet long with a 3,500-mile basin of making the same increase in the run-off. Here the overturning moment at the 50-foot plane is increased some 60 per cent.

Thus in the high dam, (which will in the nature of things generally be longer than a low one), on a small stream, the effect of even a great variation in the run-off is negligible, while in the low dam cited the effect is tremendous, and variation of flow and consequently of head is one of the principal factors which can be imagined as operating to cause the assumed overturning forces to be exceeded.

An examination of figures of run-off for floods of rare occurrence and of formulæ deduced from them, and a comparison of the flows thus obtained with those actually recorded in the few years of available observations on our Canadian rivers, will make it evident that the possibility of

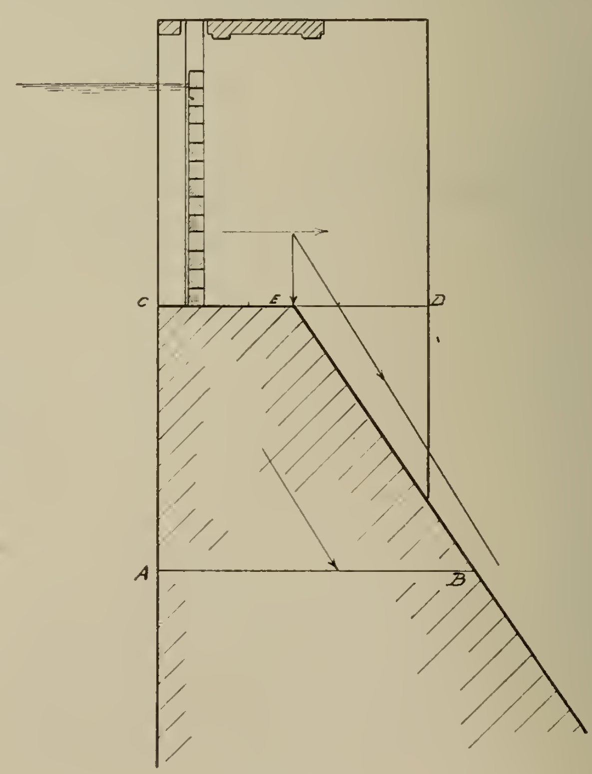

Figure No. 7

a maximum flow assumed for design being exceeded is not remote.*

To design the dam so that with the greatest even remotely possible flow the resultant still remains within the middle-third, is to provide a factor of safety under method two.

Need of Further Investigations

Any careful study of the theory of dam design as it stands to-day must lead to the conclusion that it is incomplete, if not actually erroneous, in some of its phases, and this is all the more significant as research in this direction appears to be at a standstill. We are left, for further information on this important subject, to the teachings of experience.

It is often said that experience is the best teacher, but it is always an expensive teacher, and, in the case of dams, the fee has often run into hundreds of lives and millions of dollars per lesson; and, in spite of the cost, or perhaps partly because of it, the results from an educational standpoint are very disappointing.

The Bouzey dam failed in 1895, and Prof. Unwin, speaking before the Institution of Civil Engineers on the report of the investigating engineers, said that there were, according to the report, so many reasons why the Bouzey dam should have failed that the world was left to wonder why it had ever stood up for a single day.

The case of the Gleno dam, which failed in December, 1923, is no better. This dam was a reinforced concrete multiple arch structure resting in the central portion on a solid masonry substructure. Judging from the articles which appeared in the American technical press, (which included a summary of the official investigation), one is led to believe that the materials and workmanship in the superstructure were bad, but the laboratory report shows the concrete to have had ample strength for the stresses it had to withstand, and although the failure occurred in the superstructure, the investigators are forced to the conclusion that the failure was due to the settlement of the masonry substructure under the central portions.

This block of masonry seems to have remained intact, however, and, in view of the fact that it is designated as the immediate cause of failure and of the criticisms made as to its stability and the quality of the work, it seems remarkable that no data is given supporting the supposition that settlement occurred in it, and that no tests were made on the strength of the masonry of this portion of the work.

Apparently tension existed at the upstream face of the superstructure, but we are told that the piers were reinforced, and, as no plans of the reinforcement have been published, either in the official government report or in the engineering papers, it is impossible to judge of the ability of the structure to withstand this tension.

So that, the lesson which cost humanity the lives of over 500 Italians and enormous property loss, is not of great value from a technical standpoint as it stands to-day. About the only conclusion we can draw is that people should not be allowed to build dams without adequate inspection of design, material and workmanship.

What we learn in this matter of the stresses in dams from experience must be learned from failures, because the fact that a dam designed according to certain assumptions

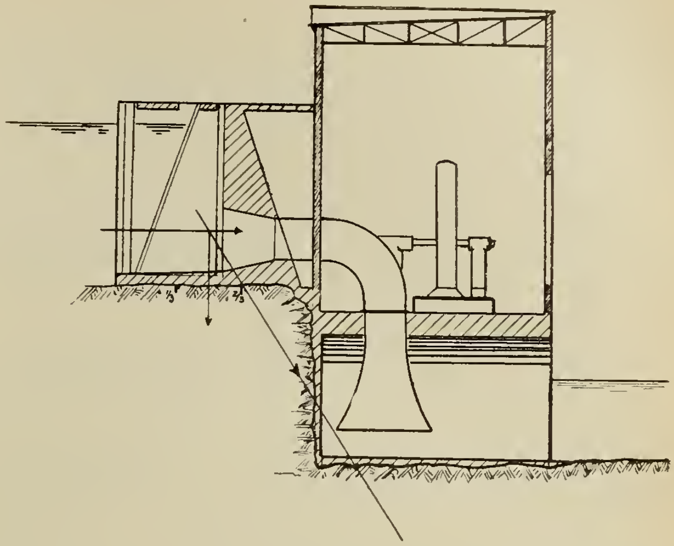

Figure No. 8

has not failed cannot logically be taken as proof that the assumptions used in design were correct.

It is not the intention of this paper to indicate that present ideas of design are all wrong, and that some day we shall see things entirely differently, nor is it the intention to picture the majority of existing dams as unsafe; but if it is admitted that our knowledge of the stresses acting in dams is incomplete, then it is evidently our duty to try to complete our theories so that we may get the maximum effect out of every yard of masonry placed and every dollar spent.

Much has been learned from dams that have failed, but a great deal remains to be learned. It might be said that we have a choice as to whether we shall wait for further lessons from experience or whether we shall attempt to get new information in some other way.

There is material before the profession which has not been digested. The data and theories resulting from experiments on elastic model dams in England referred to in the early part of this paper should be carefully considered, and there should be an authoritative expression of opinion as to whether the shear stresses deduced should or should not be accepted, and, if accepted, their effect upon design.

The fundamental basis of the whole system of dam design, the assumption that a masonry dam acts as a perfectly elastic homogeneous body, has not itself been verified. The English experiments indicated quite clearly that if a dam acts as an elastic body, then the trapezoidal law of uniformly varying perpendicular stress on a horizontal plane is true, but there was never any real doubt as to that. There is, however, a doubt as to the truth of the elastic assumption itself, which it would seem can only be verified by experiment.

If it were a question of building a test section 150 feet high, the case would no doubt be hopeless, but if it be accepted that our dams are generally from 40 to 60 feet high, and that information as to the action of a structure of that height would go a long way towards filling our needs, the matter is not so difficult. Concrete retains a characteristic stress-strain relationship over a considerable range of proportions of aggregate, and if concrete of lower strength than that used in dams, but of otherwise similar characteristics, were used, the same results might be expected from a proportionately smaller section. Cinder concrete is not very reliable in its performance, but this is in large part due to lack of uniformity in the cinders themselves, and if a uniform quality of cinders or some similar material were used, the

*Shortly after this paper was written floods have occurred along the north shore of the St. Lawrence river, and great surprise was expressed at the discharge recorded in some of the rivers in the area. These discharges, however, will be found to be lower than those indicated by the various formulæ for flood flow.

strength would be further reduced. It is possible that a model 20 feet high could be made in this way to indicate the action of a 40- or 50-foot dam. The weight of the section might also be controlled to such an extent that in loading with water the effect of doubling the overturning moment could be established.

A study of such a model should go far towards clearing up definitely the question as to whether or not, in an actual structure, vertical pressures on horizontal planes vary uniformly from face to face, i.e., whether the universal acceptance of the trapezoidal law is justified.

It should teach us many other things, and, if successfully carried out, should leave the profession in a much more comfortable frame of mind as to the soundness of assumptions used in design.

The question of uplift on sections above the base is one which presents no great difficulty for experimental investigation, and on which information is badly needed. It is sometimes said that as the foundation is where uplift principally occurs it might as well be included all the way up the section, but this is not altogether true. If, for instance, uplift were reduced in the upper section where the effect of ice pressure is most felt, it would have a distinct effect on the design.

Of a similar character and similarly comparatively simple would be experiments on the overturning effect of water entering minute tension cracks. The occurrence of such cracks is also a matter of great interest.

The action of reinforcement against ice pressure may also need to be more fully established. It is usual to design this reinforcement by the method used for "flexure and direct stress." It is perhaps not certain that with the extremely low percentage of steel usually used in dams the action is the same as with higher percentages.

There is also the question of provision for shear. Shear distribution is not referred to here, as that is something which could probably be demonstrated only with the large model previously suggested, but the total shear of any plane is something the amount of which is known, and there is a question as to how to treat it. The method usually used is to take the total shear, (or force acting to cause shear), and deduct from it the friction developed and term the remainder residual shear. It is perhaps not perfectly evident that this is a proper procedure. We might say that the friction and the shear are likely to act together or even that they probably do so, but before we can say that they certainly do we should have some experimental demonstration of the fact.

A similar, though perhaps not a parallel case, is that of rivetted lap joints in tension; here we recognize the presence of friction, but assume that it disappears before the shearing strength acts fully and the rivets are designed to carry the full load as shear. It is doubtful whether the cases can be considered as parallel, but in any event it should not be difficult to determine experimentally what actually does happen in a dam.

The form of the lower nappe has never been determined for any but very low heads. The form of spillway sections is determined by the shape of the nappe. In fact the nappe, rather than considerations of stability, will in some cases rule the whole design, yet our data on the nappe are based upon a set of experiments carried out in 1888, in which the maximum head used was about one foot. This certainly seems an inadequate foundation upon which to base deductions for the shape of a spillway to carry perhaps 10 or 12 feet of water. There are many dams where experiments at the higher heads could be conveniently and cheaply carried out, but such work is outside the province of the individual engineer.

Canada has been wonderfully fortunate in the matter of dam failures. That we have so far had no disasters should, unless our methods of design or construction are better than those followed in other countries, be a matter for thankfulness rather than for self-congratulation.

This Institute is as a whole more vitally interested in dams than any other similar body. That is to say, the proportion of our members who are more or less directly concerned with dams is greater than that of any other national engineering society. It is possible that the sum involved in the building of dams under construction in Canada today, (1924), or that have been completed within the past year, is in excess of the cost of all the existing dams in England. Yet the contribution of Canadian engineers to the knowledge of the subject is negligible compared with that of English engineers.

It would be a very desirable thing for the Canadian universities and other interests, who are in a position to do so, to carry on some of the much needed research in this connection, and there is an opportunity for The Institute to be of great assistance to the practising engineer by accumulating information and obtaining an authoritative opinion on the subject of the proper general assumptions for dam design. There are many matters in connection with each individual scheme which will always make the final choice of a section a matter of individual judgment, but the formulation of a generally-accepted basis of design would be helpful, and the Engineering Institute of Canada should be in a position to formulate that basis.

Partial Government Control Desirable

The author wishes to make a suggestion which has particular reference to the province of Quebec.

That a disaster may some day occur to a Canadian dam is quite conceivable. Such a disaster would probably result in hasty and perhaps unwise legislation regulating construction. Would it not be better to proceed in an orderly fashion to the framing of carefully thought-out regulations which might also make the possibility of disaster more remote?

There is in France an official standard specification for the investigation of dam sections. Would it not be to the advantage of the profession, and of the public generally, to have such a standard in the province of Quebec? Could not such a standard be drawn up by a committee of The Institute and approved by the government of the province, and could not the government be induced to establish an authority to which designs would be submitted as regards their safety before construction is started?

To carry the proposal to its logical conclusion, would it not be well for the government, in addition to passing upon the safety of the design, to appoint inspectors to examine the foundations upon which dams are to be built and inspect the materials and workmanship of the dam itself?

It is not the intention to go at length into the respective advantages to be derived by the public and the profession, but that the public could not lose seems evident. They would be provided with a double safeguard. The fact that the government authority would be intimately familiar with each stream and with *all* the dams and similar works built upon it, deserves notice. There would be, for instance, a very evident and important advantage in having the discharge capacity of all dams on a given river designed on the same basis.

Such an arrangement might be made to bring at least one advantage to the engineer or contractor. There is, as you are aware, a law peculiar to the province of Quebec, (and the French Republic), under which engineers and contractors are jointly and severally responsible for the safety of their work for a period of ten years after completion. Without going into the working of this article of the code, it will be admitted that there is a considerable feeling of dissatisfaction among engineers with regard to it.

With a practical scheme of government inspection of design and construction, any need or justification which now exists for this liability law would be removed and the article could well be amended to exempt dams and similar structures from its provisions.

This proposal is not made with the idea of exempting either the contractor or the engineer from his proper responsibility, but to the end that the contractor and engineer, having properly and skilfully carried out their several functions, they should be free of fear of future litigation due perhaps to no fault of their own. In other words, to put engineers and contractors on the same footing here as they are in other parts of the world.

Richibucto Cape Breakwater

A Description of One of a Number of Similar Necessary Public Works along the Coast of the Maritime Provinces

Geoffrey Stead, M.E.I.C.
District Engineer, Department of Public Works, Canada, St. John, N.B.

Paper read before the St. John Branch of the Engineering Institute of Canada, November 16th, 1922

Richibucto Cape is a fishing settlement on the northeastern coast of New Brunswick, in the county of Kent, and 5 to 7 miles south of Richibucto Harbour. Richibucto village lies 2 miles inland and the town of Richibucto about 12 miles north by road. The population of the cape, village and vicinity is about 1,000.

Richibucto Cape is one of the nearest points of the New Brunswick coast to Prince Edward Island, the distance across the Northumberland strait at this point being only 14½ miles, and was examined by Professor Kirkpatrick, when making his report on the car ferry service to the island, which has since been established between Cape Tormentine and Carleton Point, a shorter and more convenient crossing.

The preliminary survey for proposed works at the cape for the protection of the fishing boats was made in January and February, 1905. The first report is dated 17th February, 1905.

Probably since the first settlement of the locality fishing has been the chief means of livelihood, and in 1905 about 40 large boats were employed and the value of the fisheries was about $25,000 to $30,000 per year. However, there was no natural shelter, and in the previous five years 19 boats had been lost in storms.

In October and December of 1906, a survey was made extending over about 1½ mile of the shore with soundings out to a depth of about 15 feet at low water, and the site was chosen near the northern end of the cape, where deep water was closer to the shore than to the southward, the southern section being skirted with wide reefs and sand bars.

Construction Commenced

In 1908, an appropriation having become available, a right-of-way and site containing 1¼ acre was purchased for $175 and work was begun on September 8th by day labour. The site finally adopted was about 775 feet south of the one above mentioned, since the depths were practically the same and this position was more central for the lobster factories. The first work consisted of grading a roadway to the shore and opening stone quarries.

The shore section of the breakwater, which was begun in 1908, consisted of a stone embankment. This was extended in 1909 to a total length of 241 feet, where, reaching deeper water and the action of heavier waves, it suffered damage in several storms, and therefore at the outer end a timber crib 29 feet long by 20 feet wide was built as a core for the embankment.

Cribwork was adopted for the larger work of the pierhead and outer section of the approach, and, after tenders had been asked and only one, and that a very high offer, had been received, authority was given to proceed with the work by day labour at an estimated cost for those sections of $29,000.

During the construction of the approach from the shore a bank of sand had gathered on the site of the pierhead and southwards of the approach. The contract plans called for the removal by dredging of about 1,500 cubic yards of sand for the foundation of the pierhead, and, while the amount was not large, the danger to a dredging plant at this site and expense of towage made this part of the work difficult to tender on.

Successive surveys showed continued shoaling and advantage was taken of the facility for changes in the plan afforded by the day labour method and authority was obtained to build the pierhead first as a detached breakwater, further from the shore and thus in deeper water. This arrangement, by allowing the shore currents to pass between the approach and the breakwater, might naturally keep the harbour clear, and if not it was proposed to build a connection between breakwater and approach on the north side, from which the drift was coming, and a southern pier leaving a narrow entrance to the south through which the sand drift would necessarily be small, and afterwards to keep the harbour clear by a moderate amount of dredging, which plan has finally been carried out.

The change was of advantage in allowing additional room inside the pierhead, and the number of boats has so largely increased as a result of the construction of the breakwater that the extra harbour area now available, and which can be made so by further dredging, is valuable.

The pierhead cribs were built, and, taking advantage of the privileges of the day labour method, instead of dredging for the foundations, sank them in the sand and gave them a full year for settlement before completing the superstructure. They gradually settled practically to the rock, and the superstructure, except at one corner, has since remained exactly level.

Instead of passing behind the pierhead, the sand lodged in its shelter and therefore a connecting block was built between the end of the original approach and the north end of the pierhead. Thus the work was completed in the form shown on the contract plan, except that the pierhead was 73 feet further from the shore and there was a correspondingly greater length of approach. This change also increased the depth of the pierhead by about 4 feet when it had settled to the solid or rock bottom. The cost of this by day labour was about $33,800, but labourers' wages in 1912 went up 10 per cent, i.e., from $1.35 to $1.50 per day, and the cost of lumber was slightly higher towards the end of the work, increasing from about $15 per m.b.m. to $16 for square hemlock.

The changes in the work involved the construction of additional cribwork amounting to approximately 67,500 cubic feet, which at 11½ cents per cubic foot, the rate allowed in the estimate for the day labour work, would cost $7,762.50.

However, another change was made from the work as shown on the contract plan which saved probably $2,000 to $3,000. A reinforced concrete wave-break was called for, but from our experience with concrete at Cape Bauld, N.B., we considered that a timber wave-break would be equally serviceable and lasting, and the continued settlement of the blocks would most probably have caused serious cracks in the concrete wall. Therefore a timber wave-break was adopted. It was built of six tiers of 10- by 12-inch timbers laid close on the flat with long fenders outside and 10- by 10-inch posts inside, screw-bolted through from fenders to posts, and diagonal braces of 10- by 10-inch timber were placed inside, notched into the posts and into the stringers of the breakwater. The whole making a very strong wave-break.

Where the timber is almost continually wet with salt spray it lasts a long time, and after twelve years no signs of decay are apparent.

In 1911 two cribs each 64 feet long by 33 feet wide at the bottom were sunk in place for the pierhead and built to half-tide level. In 1912 two cribs of a total length of 100 feet for the remainder of the pierhead were built to half-tide level and additional timbers were placed on the last year's cribs. Cribs 86 and 85 feet long and 25 feet wide at bottom were built and sunk for the connection with the approach. The second of these cribs, when under construction, was carried away by a storm and grounded on a sand bar, but was raised with empty barrels and a scow, replaced and ballasted in position. In 1913 the corner crib, 55 by 30 feet, connecting the approach with the pierhead was sunk in place, the upper tiers, stringers, covering and cap were laid on the pierhead and approach, and the wave-break 330 feet long and about 5 feet high was built along the outer face.

In 1914 the remainder of the covering and cap timbers were laid. The corner crib, which was built last and which was not left as long as the other cribs, is the only one, as mentioned above, which after completion has not remained level, having settled about one foot on the northern side.

The greater part of the lumber was towed in rafts from Richibucto river and about five miles through the open straits, fortunately without loss though at times occasioning delay in the work.

As mentioned above, when constructing the cribs of the pierhead the sand lodged inside. The bank thus formed reached to about half-tide level, and therefore the connection with the shore approach was at once proceeded with. After the connection was made the bank levelled down somewhat, but the harbour was then practically filled to within one foot below low water level, except a narrow deeper strip close to the pierhead, and the outlook was apparently very blue for its future usefulness.

Southern Pier

The only course remaining was to proceed with the construction of the southern pier, leaving a narrow entrance, and maintain the harbour by dredging.

Work on the southern pier was commenced in 1914, building a 30- by 30-foot close-faced block of square timbers which was intended to be the end block or head of the pier and also a length of 60 feet of the approach from the shore, 10 feet wide on top, of round timber in open-faced work. The end block was left to settle and was not finally completed until 1920.

In the following year the approach was extended to a total length of 326 feet, and then there remained gaps of 160 feet between the approach and the 30-foot square block, and 100 feet between the latter and the end of the original pierhead of the breakwater.

The 30-foot square block was sunk somewhat further to the south than originally intended and it was noticed that waves striking the outer face of the block, instead of dissipating throughout the harbour, rebounded from the face and took a direction parallel to and slightly inside the pierhead, i.e., where all the boats lay. Though their force was diminished, it was still sufficient to seriously disturb the boats even when lying at the inner corner of the harbour. The fishermen naturally complained of this, and it was suggested that the outer gap be closed and the entrance established inside the 30-foot square block, which also had the advantage of giving a considerable area of perfect shelter inside the pierhead and proposed works.

As decided shoaling was occurring even beyond the pierhead by the withdrawal of the entrance within the outer line of the latter, the danger of a sand bank forming which would close the entrance was increased. However, the outer face of the proposed connecting block is parallel to the heaviest winds and seas, those from the northeast, and it was believed that these would tend to carry the sand along this face and sufficiently past the entrance.

Also, in the position that the smaller block was then placed there was a decided risk of the sand moving along the outer face of the pierhead being carried into the harbour through the first gap instead of beyond the block, and in general with works of this kind the windward pier, represented by the main breakwater, should overlap the leeward work which was in this case represented by the southern pier.

What appeared the lesser risk was taken, and so far has been justified, and again the harbour area was advantageously increased.

During 1916 a quantity of lumber and stone was purchased, and early in 1917 a block 100 feet long, connecting the 30-foot square block with the original pierhead, was built in place on the ice.

After the block was ballasted and the ice cut it settled as expected, and even after last year when covering was temporarily laid it settled about one foot in the centre and has since been finally levelled and covered.

The block was constructed of round timber in open cribwork and was sheathed with hardwood plank on the outside face and with spruce on the inside. It proved a great protection in the spring when the ice was driven heavily towards the shore, since it deflected the ice and none went into the harbour where all the boats were lying, whereas in the previous spring the ice returning filled the harbour.

About two months after this block was built it parted

Figure No. 1.—Richibucto Breakwater.

above the upper ballast floor during a storm, the superstructure being lifted about one-half foot on the inner face and floating up an additional 1½ foot at high tide. Heavy iron bars were then hooked under the lower face timbers, passing through the projections of the upper cross-ties and, the upper ends of the bars being threaded, they were secured to the upper timbers with nuts and washers. When, however, additional timbers were placed in 1919 to level the block and it was fully ballasted it went back into place and most of the hooked bolts were withdrawn as unnecessary.

At that time the number of boats in use was increasing and since most of the boats were aground when inside the harbour at low tide, and since the harbour was then fairly well inclosed, only one opening of 160 feet remaining where it was not likely to admit much sand, authority was obtained to have a section of the harbour dredged, which was done during July, August and September, 1917. A small clamshell gasoline power dredge was employed, at a rental of $21 per day, including wages of the operator and cost of gasoline, oil and repairs, and did the work by day labour.

About 5,171 cubic yards of sand were removed at a cost of 29 cents per cubic yard barge measurement and the depth given was 2½ to 4 feet at low water, where the previous depths varied from 1 foot above to 1 foot below low water, the range of spring tides being 5 feet.

The place measurement, quantity allowing for filling-in which occurred, the entrance channel being twice dredged, was 4,300 cubic yards, giving an expansion factor of 20 per cent.

In 1917 the first section, about 43 feet long, of an end block for the southern pier was also built.

In the fiscal year 1918-19 there was no appropriation, but in 1919 general work was done in levelling up the southern pier and the new blocks at the south end of the breakwater, and a number of piles were driven to strengthen the outer face of the pierhead where in one section the square-face timbers had been carried away.

In square timber work it was formerly the custom to carry the cross-ties through the face with well-made and close-fitting dovetails and to depend on the dovetails for holding the face timbers, and no bolts were driven through the dovetails for fear of splitting them. It has been found that the dovetails in time work loose, and the outer face timbers are then liable to be carried away. Therefore in late specifications bolting through the dovetails is allowed, holes being first carefully bored, and also, when the work is at all exposed, vertical posts inside the face screw-bolted through the face timbers to the fenders outside are called for, which makes a very strong construction, the inner posts being also bolted to the cross-ties.

On the Richibucto Cape pierhead, however, one of the blocks went about 2 feet out of line when placed, and the superstructure overhung somewhat to bring the top in line. Therefore the face timbers did not have a full bearing and the fenders did not overlap properly, and the damage was most probably due to these causes. Posts were used inside the face in at least part of the pierhead.

In 1920 the remaining crib was built to complete the pierhead of the southern pier, narrowing the entrance to 85 feet. The sides of the pier were sheathed with plank and filled and the approach was surfaced with brush, stone and gravel. Other work during the year included repairs, levelling and sheathing on the breakwater.

The last crib was built on a brush mattress, 3 feet thick, as a foundation, although doubts were expressed as to whether the sand under the mattress would not scour out and cause the same settlement as occurred when sinking the former cribs. This has not occurred so far, and apparently a considerable amount of cribwork has been saved by using the mattress. The block was completed in 1921 when no appreciable settlement was observed.

With the blocks of the pierhead, which are exposed to very heavy seas and where heavy scouring was liable to occur and has occurred, as shown in our latest survey, a mattress foundation would scarcely be safe and these blocks have now a solid foundation on hard or rock bottom, but, at the end of the southern pier, where there was a considerable depth of sand which was not likely to scour to any extent, the mattress was very suitable.

The accompanying illustration, figure No. 1, gives a general view of the harbour and works during 1920.

The Problem of the Action of the Sand

With reference to the action of the sand, which is the most difficult and interesting problem in connection with this work, it would be interesting to present some definite conclusions which would be of value as a guide to other works, but since the last block of the pierhead was built only during 1920 it is not possible to tell just what will be the final condition when a state of equilibrium has been reached, if such a state is ever reached on this shore.

It would appear from general observations that the heavy sand movements occur in cycles during perhaps a season of heavy storms when large bars form, remain perhaps for several years and again disappear or move along the coast. Undoubtedly there is a continual drift along the shore and continual changes in the outer bars, but it hardly seems possible that the great changes which have been seen during the construction of certain of our works are due wholly at least to the comparatively insignificant works themselves.

At Point Sapin a breakwater was built on a rock foundation over which there were only a few inches of sand or mud, and there was no evidence of heavy sand drift on the shore. It seems possible that a large submerged bar, lying out to sea about one-third of a mile to the northeast of the work, which had been there as far as is known for many years, moved bodily southwards and towards the shore, and thus caused the difficulty experienced in connection with that work. Certainly the boats formerly had some shelter between this bar and the shore, but since the change their shelter is gone.

At Richibucto Cape a series of surveys have been made covering the years from 1906 to the present, and these indicate the changes which have occurred and to a certain extent their causes and what appears to be the present trend. All along this coast the littoral drift is evidently from the north. The river entrances are deflected to the south in each case and the channels are continually moving south until they reach a stage in which they break through the bars to the north and again begin the southward progression.

There are several features, however, in the last survey which point to somewhat better conditions in the future.

These are, (1st)—The High Water line runs straight northwards from about the centre of the north side of the breakwater, and while it is now some 200 feet further from the shore than before, its straight course is an indication of its having reached a stable form, for if very heavy drift were still occurring the High Water line would curve outwards towards the northeast corner of the breakwater. Also, the extensive area of sand beach between the new High Water line and the original shore will give storage room for large quantities of sand carried shorewards by winds and waves.

(2nd),—The last survey, in comparison with the others, shows that the scour around the northeast corner of the breakwater has increased and that it is extending along the whole outer face of the breakwater. If this continues there may still be a bar outside the entrance, but there is likely to be a channel with sufficient water to either side of it.

(3rd),—The bar which formed in the spring of 1918 to such an extent as to prevent the boats from entering at low tide went away naturally, and the last survey showed better water across this bar than was found in the surveys of May and July, 1917. The water deepened somewhat in 1920 in the entrance after the construction of the last block and it was then deepening along the south side of the southern pier.

It is certainly to be hoped that the harbour can be maintained within reasonable expense, since the shelter it has provided, the encouragement given to the fisheries and the resulting extension of this industry have been very satisfactory.

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

VOLUME IX SEPTEMBER 1926 No. 9

Secretary Visits Western Branches

On returning to Headquarters from his journey to the West, the Secretary wishes to thank the officers and members of the various branches for the uniform kindness and hospitality shown to him.

A journey of this kind affords an opportunity, not only for the formation of many pleasant acquaintanceships, but also for a survey of the activities and work of The Institute in the West.

The general impression gained is one of healthy life and activity, and it is interesting to note how the various branches follow lines of individual development, while at the same time working in unity with the other branches of The Institute, and showing loyalty to the objects which it has in view. It was especially pleasing to note the cordial relations existing between the various branches of The Institute and the several Provincial Associations of Professional Engineers. The Institute and the Professional Associations, while essentially different in their functions, are working along parallel lines, and the objects of each will be furthered by the spirit of co-operation which is manifested.

The results of the informal exchange of views which took place at so many of the branch meetings at which the Secretary was present will be presented to Council in due course, and Council will in this way be put in possession of the ideas of many individual members, as well as those of the Executive Committees, in a way which would not otherwise be possible.

Discussions of this kind are of even greater benefit to the functioning of The Institute as a whole than the discussions of Institute affairs which quite rightly take place at the Annual General Meeting, and cannot fail to be of assistance to the Council in its deliberations.

It was a pleasure to note the steady growth in numbers of nearly all the branches.

The Secretary was glad to have the privilege of attending the joint meeting at Estevan held under the auspices of the Saskatchewan Branch of The Engineering Institute of Canada, the Southern Saskatchewan Section of the Canadian Institute of Mining and Metallurgy, and the Saskatchewan Section of the American Institute of Electrical Engineers, for meetings of this kind do much to emphasize the friendly relations which exist between these important technical bodies.

Announcement Regarding Honour Roll

The final checking of the list of names to appear on the Honour Roll of The Institute is being undertaken at Headquarters. In accordance with the decision of the Committee under whose direction this work is being carried out, the list is to contain the names of those members of The Institute who served outside of Canada and the United States with the Allied land, air or naval forces.

With a view to assisting in the checking of this list, a letter is being addressed to all members of The Institute whose names are at present on The Institute's War Service list, with the request that certain information be supplied regarding their service overseas.

The letter referred to above is reproduced herewith, together with the headings under which information is desired, in order that any member who through one reason or another has not received a copy of the letter, may be made acquainted with the nature of the information required and forward the same to Headquarters without delay.

LETTER ADDRESSED TO MEMBERS

Dear Sir:—

The final list for the Honour Roll is now being prepared and checked, and in accordance with the directions of the Committee, is to contain the names of those members of the Institute who served, outside of Canada and the United States, with the Allied land, air or naval forces.

In order to ensure accuracy, I am sending this letter to all members of the Institute for whom we have a record of war service, and would ask you to fill in, tear off and return the enclosed slip at once.

Yours very truly,

R. J. DURLEY, Secretary.

Maritime Professional Meeting

Not quite twelve months after the Maritime meeting of 1925, a very successful professional meeting has been held at Sydney, Nova Scotia, under the auspices of the Cape Breton, Halifax, Moncton and St. John branches. Few engineering societies have their membership more widely scattered than The Engineering Institute, and it is a matter for congratulation that so many of our members were able to attend, coming to the meeting by rail, or over the excellent main roads of Nova Scotia, or, in some cases, by sea. This meeting was the sixth professional meeting held by The Institute in the Maritime Provinces.

The Sydney members had been engaged for weeks on the preliminary work of organization, and on Tuesday morning, August 17th, after the usual formalities of registration, issue of badges, and so on, had been completed, the first technical session was called to order by Councillor W. C. Risley, M.E.I.C., at ten-thirty o'clock. The Mayor of Sydney, Mr. James MacConnell, gave the members a hearty welcome to the city. His Worship touched on the part played by the engineer in the development of the industries on which Sydney depended, and hoped that the city would again be selected, at no distant date, for a similar convention of The Institute.

Paper on the Humber Development in Newfoundland

The first business was the paper by H. C. Brown, A.M.E.I.C., on the Humber Development of the Newfoundland Pulp and Paper Company at Corner Brook. This has already been published in the August number of the Journal, and Mr. Brown read an abstract, in which he outlined the methods adopted in solving the various problems arising in the design and construction of the plant at Corner Brook, particularly with respect to the electrical equipment.

An active discussion followed, during which a number of details connected with transformers, cables, transmission line and pipe line were dealt with by Messrs. C. H. Wright, M.E.I.C., F. A. Bowman, M.E.I.C., E. L. Martheleur, M.E.I.C., D. W. Robb, M.E.I.C., F. W. W. Doane, M.E.I.C., W. M. Bristol, A.M.E.I.C., and others. After the author's reply, a hearty vote of thanks was unanimously accorded him, and the meeting adjourned for lunch at the St. Andrews Hall.

Luncheon, Visits to Local Plants, Dinner and Dance

The meal was enlivened by several bursts of community singing, and at its conclusion members and ladies were conveyed to the Waterford Lake power station of the Dominion Coal Company and to No. 1-B colliery at Glace Bay. The arrangements made for guidance and information at both places were greatly appreciated.

In the evening a dinner and dance at the Lingan Country Club terminated a very enjoyable day.

Characteristics and Utilization of Nova Scotia Coals

The sessions were resumed at 10 a.m. on Wednesday the 18th, Vice-President G. D. Macdougall, M.E.I.C., in the chair. The paper presented was by W. S. Wilson, A.M.E.I.C., and M. W. Booth, M.E.I.C., on the Characteristics and Utilization of Nova Scotia Coals, and was given in abstract by Mr. Booth, having already been published in the August Journal. It contains much valuable information not hitherto available on this important subject. Written discussions were presented from F. W. Gray, M.E.I.C., Lesslie R. Thomson,M.E.I.C., R. L. Weldon, A.M.E.I.C., F. Williams, A.M.E.I.C., W. Herd, M.E.I.C., Dr. W. A. Bell, Prof. D. W. Munn, A.M.E.I.C., and J. D. Garey, A.M.E.I.C. These discussions dealt with such points as the effect of storage on the quality of the coal, liability to heating in the storage pile, the effect of the low melting point of ash, comparative tests of Nova Scotia and other coals, the suitability of Nova Scotia coal for locomotive use, the importance of coking and briquetting, the geological occurrence of the various types of coal, the measures taken by consumers to modify their equipment so as to burn Nova Scotia coal efficiently, and the desirability of further experimental investigation in this connection. As a result of the discussion, the following resolution, moved by C. H. Wright, M.E.I.C., seconded by D. W. Robb, M.E.I.C., was carried unanimously,—

> "In view of the fundamental importance of the coal industry in the Province of Nova Scotia and the need of a more thorough knowledge of the properties and characteristics of our coals when selling in a highly competitive market, the present meeting of the Engineering Institute of Canada, convened at Sydney, formally commended to the provincial government of Nova Scotia the appointment of a continuing Board to carry on additional investigations of Nova Scotia coal.
>
> "It is further suggested that a definite regular annual grant of money be authorized to defray the expenses of such a Board."

The secretary was requested to send copies of the resolution to the Premier and to the Minister of Mines of Nova Scotia and to the Premier and Minister of Lands and Mines of New Brunswick.

The authors having replied to the discussion, a cordial vote of thanks was passed to them, the sense of the members present being that their paper was very timely and of importance to the industries of the province.

The secretary was requested to convey the thanks of the meeting to those whose efforts and kindness had contributed so greatly to the success of the meeting, particularly to:—

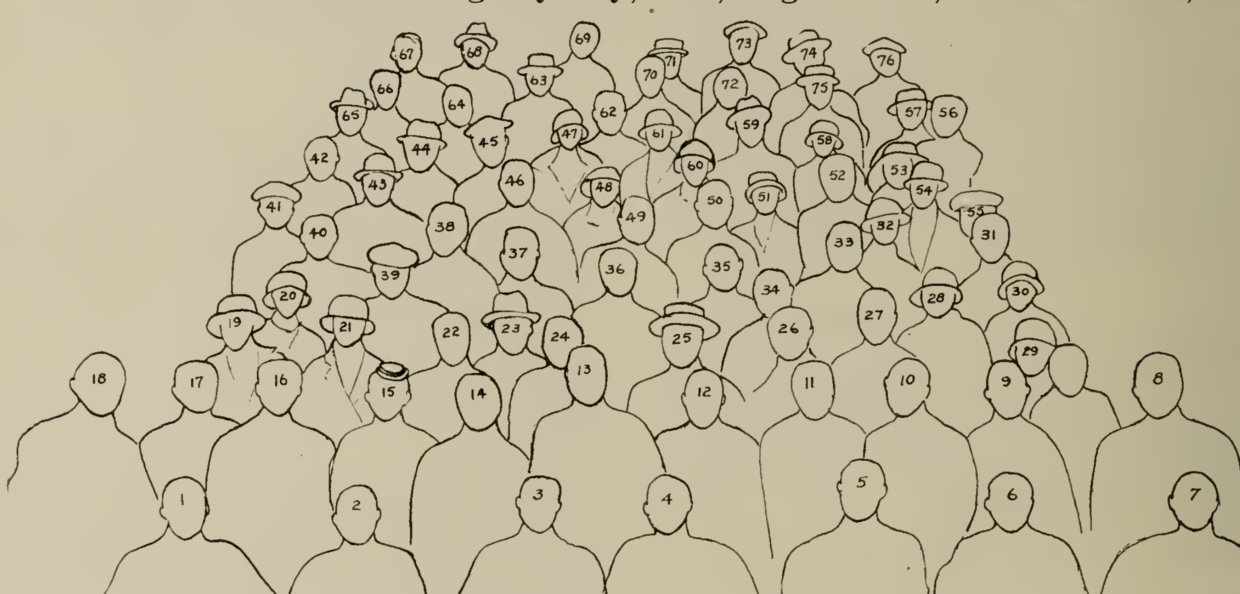
> His Worship the Mayor of Sydney, Mr. J. E. McLurg, Vice-President, British Empire Steel Corporation; the Commodore, Royal Cape Breton Yacht Club; the Manager, No. 1-B colliery, Dominion Coal Company; the Superintendent, Waterford Lake power station, and the ladies and gentlemen of the committees of the Cape Breton Branch who carried out the very successful arrangements for the meeting.

The afternoon of Wednesday was spent in an inspection of the steel plant and coke ovens of the Dominion Iron and Steel Company, and in the evening a very enjoyable dinner took place at the Lingan Country Club, Councillor W. C. Risley, M.E.I.C., chairman of the Cape Breton Branch, presiding.

The speaker of the evening was Mr. J. E. McLurg, who took for his subject The Engineer in Industry, and gave from his experience many instances showing the manner in which the engineering department of a great industrial enterprise is called upon to assist and advise the officers in charge of the operation of the plant. He referred also to the growing list of technically-trained men who are occupying executive positions, and drew attention to the openings for young engineers who desire to follow this line.

The toast of The Institute was proposed by Senator J. S. McLennan, and replied to by Vice-President G. D. Macdougall, M.E.I.C., and the Secretary. The Hon. G. S. Harrington, M.E.I.C., Minister of Mines in the Nova Scotia Government, in replying to the toast to Cape Breton, proposed in a happy speech by C. H. Wright, M.E.I.C., took the opportunity of referring to the resolution passed at the morning

Maritime Professional Meeting—Sydney, N.S., August 17th, 18th and 19th, 1926



1. D. W. J. Brown
2. F. A. Bowman
3. W. C. Risley
4. The Mayor of Sydney, Mr. Jas. McConnell
5. R. J. Durley
6. C. H. Wright
7. A. R. Crookshank
8. S. C. Mifflen
9. A. G. Tapley
10. J. R. Freeman
11. Major H. W. L. Doane
12. E. L. Ganter
13. J. P. Cotter
14. A. L. Hay
15. K. L. Dawson
16. E. L. Martheleur
17. J. D. Stewart
18. A. P. Theuerkauf
19. Mrs. W. C. Risley
21. Mrs. E. L. Ganter
22. W. J. Johnston
23. J. Kalbhenn
24. J. L. Clarke
25. G. W. H. Perley
26. J. G. H. Purves
27. D. H. McDonald
28. Mrs. J. R. Morrison
29. Mrs. G. S. Stairs
30. Mrs. C. M. Smythe
31. C. M. Smythe
32. Mrs. W. M. Bristol
33. G. S. Stairs
34. Col. F. W. W. Doane
35. J. R. Morrison
36. G. Stead
37. A. W. Fildes
38. P. Hiseler
39. J. A. Fraser
40. H. C. M. Gordon
41. A. Barlow
42. R. L. Nixon
43. A. T. Jewitt
44. Prof. F. L. West
45. W. A. Winfield
46. F. S. B. Heward
47. Mrs. K. L. Dawson
48. Mrs. McDonald
49. W. E. Hyndman
50. A. Gray
51. Mme. E. L. Martheleur
52. W. E. Clarke
53. Mrs. F. W. W. Doane
54. Mrs. W. E. Clarke
55. Y. C. Barrington
56. G. G. Murdoch
57. W. M. Bristol
58. Mrs. H. W. L. Doane
59. H. F. Bennett
60. Mrs. C. H. Wright
61. Mrs. H. F. Bennett
62. Prof. D. W. Munn
63. H. C. Brown
64. H. C. Hatfield
65. R. R. Moffatt
66. M. W. Booth
67. W. S. Wilson
68. H. Arthur
69. N. McLeod
70. B. Corlander
71. G. T. Medforth
72. A. D. Jost
73. J. J. McDougall
74. J. K. McKay
75. H. T. Doran
76. R. M. McKinnon

session, and was able to inform The Institute that measures had already been taken to give effect to their suggestions. A programme of experimental work on Nova Scotia coal had been drawn up and would be carried out at the Nova Scotia Technical College, Halifax, as soon as the necessary new equipment and changes in the existing boiler plant had been made. He was glad to say that the legislature had appropriated the necessary funds, and believed that great benefit would accrue to the Maritime Provinces from the action taken. Other speakers were W. Herd, M.E.I.C., A. P. Theuerkauf, M.E.I.C., and the visiting chairmen of the other branches of The Institute in the Maritime Provinces.

The dinner afforded a very pleasant opportunity for renewing and cementing acquaintanceships under the happiest conditions, and brought the official functions of the meeting to a close.

The Cape Breton branch was congratulated by all the visiting members on the very effective arrangements made and the entire success of the meeting, both from a professional and social viewpoint. The visiting ladies were particularly well looked after, a special programme of visits and social entertainments having been arranged.

The committee in charge of the general arrangements, Finance and Papers consisted of,—W. C. Risley, M.E.I.C., Chairman; W. S. Wilson, A.M.E.I.C., Vice-Chairman; D. W. J. Brown, Jr.E.I.C., Sec.-Treasurer; W. E. Clarke, M.E.I.C., J. R. Morrison, A.M.E.I.C., J. J. McDougall, M.E.I.C., S. C. Mifflen, A.M.E.I.C.

Other Committees in charge of arrangements were,—

Colliery Tour,—J. R. Morrison, A.M.E.I.C., A. L. Hay, M.E.I.C., H. C. M. Gordon, Jr.E.I.C.

Inspection Steel Plant and Coke Ovens,—A. P. Theuerkauf, M.E.I.C., W. Bown, G. Beaton, A.M.E.I.C.

Transportation,—W. E. Clarke, M.E.I.C., J. P. Cotter, A.M.E.I.C., N. McLeod.

Luncheon and Banquet,—W. S. Wilson, A.M.E.I.C., C. B. Ross, W. J. Ripley, A.M.E.I.C.

Publicity,—S. C. Mifflen, A.M.E.I.C., E. L. Ganter, A.M.E.I.C., M. Dwyer, A.M.E.I.C.

Reception and Housing,—D. W. J. Brown, Jr.E.I.C., R. M. McKinnon, A.M.E.I.C., C. M. Smyth, A.M.E.I.C.

Golf and Dinner Dance,—W. C. Risley, M.E.I.C., W. Herd, M.E.I.C., C. B. Ross.

Ladies' Entertainment,—Mrs. W. C. Risley, Mrs. W. E. Clarke, Mrs. E. L. Martheleur, Mrs. E. L. Ganter, Mrs. H. B. Gillis.

OBITUARY

John Seabury O'Dwyer, M.E.I.C.

The death of John Seabury O'Dwyer, B.A.SC., D.L.S., M.E.I.C., right-of-way engineer of the Canadian National Railways, Atlantic Region, occurred on July 9th at Shediac Cape, where he had gone to spend a few weeks, accompanied by Mrs. O'Dwyer. He was driving in an automobile with his wife and was stricken while returning to his cottage. Death was practically instantaneous.

The late Mr. O'Dwyer was in his sixty-ninth year and had resided in Moncton for the last twenty-five years. He was born at Abbotsford, Que., on September 28th, 1857, and received his early education at Bishop's College, Lennoxville, Que., later going to McGill University, where he graduated with honours as Bachelor of Applied Science in Civil Engineering in 1880, and was awarded the Lorne Medal. He was employed for a number of years by the Canadian Pacific Railway, later becoming a member of the Federal Department of Railways and Canals at Ottawa. He was construction engineer of the White Pass and Yukon Railways and, later, of the Midland line of the Dominion Atlantic Railway between Truro and Windsor. He also worked on the construction of the Intercolonial Railway from Campbellton to St. Leonards. In 1901 he came to Moncton as construction engineer of the Intercolonial Railway under W. B. MacKenzie, who at that time was chief engineer.

Mr. O'Dwyer was admitted to The Institute in the year of its incorporation as the Canadian Society of Civil Engineers when on June 25th, 1887, he was elected Associate Member. Eight years later, on May 23rd, 1895, he was transferred to Member.

During the past few years, his failing health occasioned anxiety to his friends, but, following two operations, improvement was so apparent that anxiety was allayed, and his sudden death was a great shock to his many friends and acquaintances.

By his death, the engineering profession, and the community in which he lived, suffer great loss; for, with a high ideal of duty and unflinching devotion to it, Mr. O'Dwyer always gave his best to his work, and his best was of a very high order. Fully equipped by knowledge, training and experience for the work in which he was engaged, he never failed to exercise diligence, conscientious care and sound judgment in every detail of it, allowing no personal consideration to interfere with his duty in full accordance with his own high standard of honour.

THE ANNUAL GENERAL

AND

GENERAL PROFESSIONAL MEETING

of THE INSTITUTE *for* 1927

WILL BE HELD AT

QUEBEC CITY

TUESDAY, WEDNESDAY AND THURSDAY
FEBRUARY 15th, 16th and 17th, 1927

Make a special note of the date.

Make your plans now, to attend.

PERSONALS

J. P. Freeman, A.M.E.I.C., formerly of Sydney, N.S., has joined the engineering staff of the Abitibi Power and Paper Company, Iroquois Falls, Ont.

J. H. Ings, S.E.I.C., of Toronto, Ont., is now with Messrs. Morrow and Beatty, Limited, at Kapuskasing in charge of residency No. 7 at Smoky Falls, Ont.

H. Aldous, Jr.E.I.C., is estimator and designer with W. H. Cooper, contractor, Hamilton, Ont. Some months prior to this Mr. Cooper was employed as temporary engineer on pulp and paper mill extension at Powell River, B.C.

J. B. Barnum, A.M.E.I.C., who for the past six months has been with the Riordon Pulp Corporation, Montreal, has joined the staff of the Foundation Company of Canada and is located at Maniwaki, Que.

Karl E. Buchmann, Jr.E.I.C., who graduated from the University of Toronto in 1925, is now located at Deloro, Ont., as assistant to the chief engineer of the Deloro Smelting and Refining Company.

E. R. Complin, S.E.I.C., who graduated from the University of Toronto with the degree of B.A.Sc. this year, has accepted a position in the safety department of the Ford Motor Company of Canada, Limited, Ford, Ont.

Angus D. M. Curry, M.E.I.C., of the Department of National Defence, Ottawa, has been promoted from the rank of Engineer Lieutenant-Commander to Engineer Commander, Royal Canadian Navy.

G. Vibert Douglas, A.M.E.I.C., is at present in Spain engaged in making a geological examination of property for the Rio-Tinto Company, Limited, and will be located at 23 Bella Vista, Minas de Rio-Tinto, Province of Huelva, Spain.

E. B. Hubbard, S.E.I.C., who has been for some time on the engineering staff of the Hydro-Electric Power Commission of Ontario, has severed his connection with the Commission and is leaving for California, where he expects to be engaged in hydro-electric work.

H. J. Edwards, S.E.I.C., formerly with the Employees' Relations Department of the Hydro-Electric Power Commission of Ontario, Toronto, Ont., is now superintendent, Simcoe R.P.D. of the Hydro-Electric Power Commission at Simcoe, Ont. Mr. Edwards graduated from Queen's University with the degree of B.Sc. in 1924.

J. B. Gough, A.M.E.I.C., who has been with the Newfoundland Power and Paper Company at Corner Brook, Nfld., is now with the engineering department of Price Brothers and Company, Limited, Quebec, P.Q. Mr. Gough was for several years chief draughtsman with the Laurentide Company, Ltd., at Grand'Mere, Que.

R. B. Young, M.E.I.C., senior assistant laboratory engineer of the engineering materials laboratory of the Hydro-Electric Power Commission of Ontario, and A. C. Tagge, M.E.I.C., vice-president of the Canada Cement Company, Montreal, were elected vice-chairmen of Committee C-1 on Cement at a meeting of the American Society for Testing Materials.

J. William Bain, A.M.E.I.C., has resigned from the position of assistant professor of electrical engineering at Queen's University, Kingston, Ont., and has been appointed electrical engineer in the Radio Branch of the Department of Marine and Fisheries, with headquarters at Ottawa. Mr. Bain, who is a graduate of McGill, went to Queen's as a lecturer in 1922 and was appointed assistant professor in 1924.

Gordon Kribs, M.E.I.C., who was for some time with the New Brunswick Power Commission at St. John, N.B., is now located at Niagara Falls, Ont., with Messrs. H. G. Acres and Company. Mr. Kribs graduated from the University of Toronto in 1905, and, prior to going with the New Brunswick Electric Power Commission in 1923, he had been with the Hydro-Electric Power Commission of Ontario since 1915 as assistant engineer in charge of the eastern district.

Hubert G. Welsford, A.M.E.I.C., Receives Promotion

Hubert G. Welsford, A.M.E.I.C., has been appointed to the position of general manager of the Dominion Engineering Works, Limited, to fill the vacancy caused by the death of Mr. John Overn, Jr. Mr. Welsford has been for some time assistant general manager of the company and has been closely identified with its development and expansion. Prior to the war he was connected with the Winnipeg office of the Dominion Bridge Company, having become connected with that company's staff in 1911. From August, 1916, and until the end of the war he was engineer officer in the Royal Air Force.

HUBERT G. WELSFORD, A.M.E.I.C.

Canadian Good Roads Convention

The thirteenth annual convention of the Canadian Good Roads Association will be held at Edmonton, Alta., on September 28th, 29th and 30th, 1926, with headquarters at the Macdonald hotel.

The past conventions of the association have proved of great interest, and the programme for the forthcoming meeting promises sessions of even greater interest than on past occasions. Important basic factors dealing with road building in all its phases will be discussed during the convention.

Included in the programme will be the subjects of earth roads, gravel roads, sand-clay roads, and the so-called permanent types of sidewalks, dust layers, equitable taxation, traffic regulations, federal aid, etc.

A general exchange of knowledge and experience in connection with road building will be afforded delegates attending the meeting, and there will be ample opportunity to bring up for discussion matters or problems of an educational or technical nature.

EMPLOYMENT BUREAU

Situations Wanted

Electrical Engineer

Canadian university graduate, twenty-nine years of age and single, with four years' experience in the design and construction of hydro-electric power stations, desires work in Canada. Last three years with the largest and most up-to-date engineering firm in the United States. Position with a progressive engineering firm, operating company or public utility acceptable. At present employed. Address replies to Box No. 211-W, Engineering Journal.

Experienced Mechanical Engineer

Experienced mechanical engineer, fifty-four years of age, at present located in England, desires to form a connection in Canada. Experience includes charge of construction and installation of equipment in a number of large industrial plants, and also general maintenance, ability to investigate and report on the engineering requirements of industrial plants. Can speak Spanish and Portuguese fluently. Address replies to Box No. 212-W, Engineering Journal.

Situations Vacant

A number of requests for recent graduates for temporary employment on surveys, draughting and construction work have been received. Members available for such positions should forward a statement of experience on file at Headquarters for consideration.

Draughtsmen

One or two draughtsmen for general paper mill work. Good opportunity to learn paper mill engineering. Unmarried men only. College graduates with one to three years' general draughting experience preferred. Address replies to Box No. 155-V, Engineering Journal.

Electrical Superintendent

Engineering electrical superintendent with four or five years' practical experience. Personal qualities will be considered to a great extent, especially ability to handle men under his direction. A thorough knowledge of alternating current motors and control is essential, also D.C. experience in sectionalized paper machine drives. Age about thirty or thirty-five years. Salary, $3,000 a year. Address replies to Box 156-V, Engineering Journal.

Chemical Engineer

Chemist familiar especially with newsprint manufacture who can set up and maintain a technical control system on groundwood, sulphite and newsprint, and be responsible for the quality of the individual constituents as well as the qualities of the final product. Personality equally important. Address replies to Box No. 157-V, Engineering Journal.

Civil Service Positions

List No. 320

The Civil Service Commission announces an open competitive examination for the following position:

Senior Assistant Engineer

A Senior Assistant Engineer, for the Department of Railways and Canals, Ottawa, at an initial salary of $2,700 per annum, which will be increased upon recommendation for efficient service at the rate of $120 per annum until a maximum of $3,180 is reached.

Duties.—To assist the Engineer in Charge in carrying out hydraulic or other engineering work.

Qualifications Required.—Education equivalent to high school graduation; either graduation in engineering from a school of applied science of recognized standing with three years of experience in engineering (preferably hydraulic) design, estimate, and construction work, two years of which shall have been in a position of professional responsibility, or five years of practical experience in engineering (preferably hydraulic) design, estimate, and construction work, two years of which shall have been in a position of professional responsibility; ability to complete and make ready for publication the results of investigations and surveys, or other pertinent data; tact and good judgment. Preference will be given to applicants who have had experience in the operation and maintenance of navigation canals and have specialized in hydraulic work. While a definite age limit has not been fixed, age may be a determining factor when a selection is being made.

Nature of Examination.—A rating on Education and Experience will be given from the sworn statements, supporting documents and other evidence submitted by applicants with their application forms. An oral examination may be given if considered necessary in the opinion of the Commission.

An eligible list, valid for one year, may be established.

General Directions.—Application forms properly filled in must be filed with the Civil Service Commission, Ottawa, **not later than September 9, 1926.** Application forms may be obtained from the offices of the Employment Service of Canada, from the Postmasters at Prince Rupert, Vancouver, Victoria, Edmonton, Calgary, Regina, Saskatoon, Winnipeg, Quebec, Fredericton, St. John, Charlottetown, and Halifax, or from the Secretary of the Civil Service Commission.

WM. FORAN,
Secretary.

Ottawa, August 16, 1926.

5. Approved for publication
6. Published

The letter R following the number of stage of progress indicates that the respective specification is under revision.

BRANCH NEWS

Calgary Branch

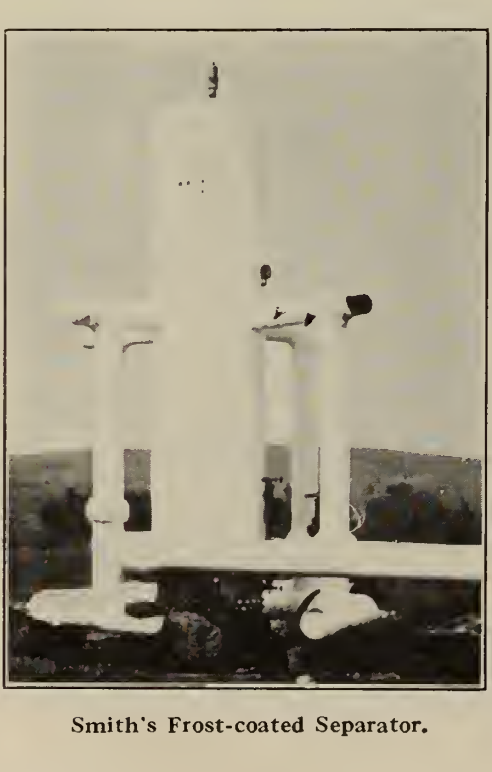
H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

Visit to Turner Valley Oil Field

On Saturday afternoon, July 24th, the branch members, together with a number of ladies and other visitors, made a trip by automobile to the Turner Valley oil field. As is well known considerable activity is in evidence in this area, and consequently over eighty persons availed themselves of the opportunity to join the party.

G. S. Coultis, A.M.E.I.C., local superintendent of the Royalite Oil Company, was on hand and took particular pains, and apparently pleasure also, in showing all around the plant of his company. This was the principal feature of the visit, which was primarily undertaken at the instigation of the Royalite Company. It was a big party to handle, but Mr. Coultis proved himself both painstaking and interesting, and the weather was extremely warm at that. The process of gasoline extraction at this plant whilst apparently simple to the uninitiated, is somewhat complex and any detailed description would require an expert in this line.

The first thing of interest to the visitor is the frost-coated Smith's separators, together with the frosted inlet and outlet pipes. These are coated with some four or five inches of solid frost which glistens in the hottest weather. It is here that the gas from the Royalite No. 4 well drips its gasoline content at 73 degrees Baume. This is conveyed to the treating plant nearby which consists of absorption, scrubbing, and compression departments. Gas is delivered from the Royalite No. 4 well at the rate of eighteen million cubic feet per day and at some twenty degrees below zero, and has to be raised to a suitable temperature for treating, in a special department. Then there are the necessary storage tanks and the pumping apparatus to enable the gasoline to reach Calgary some forty-five miles distant, through a four-inch main. Gas is conveyed for domestic use in Calgary through a ten-inch main. The huge roaring mass of flame projected over the river bank was a source of wonder to all. It is by this means that the excess gas is disposed of; a very wasteful method, but unavoidable. The disposal of this natural gas which is additional to the requirements of the district is a problem that will have to be faced and solved before very long. At present there is no alternative other than blowing it off and igniting it. The reflection in the sky of the flame from this one well is visible for fifty miles around.



Smith's Frost-coated Separator.

A visit to the Macleod No. 2 well, which has recently become a producer with some seventeen million cubic feet of gas, and the Royalite No. 4 and other wells in the vicinity, brought a most enjoyable trip to an end all too soon. The return trip was made through delightful scenery, luncheon being enjoyed on the banks of the Sheep river.

Edmonton Branch

A. Ritchie, A.M.E.I.C., Secretary-Treasurer.

The Edmonton Branch recently held its annual meeting which resulted in the election of the following officers for the branch year 1926-27:—

Chairman	T. W. White, A.M.E.I.C.
Vice-Chairman	A. I. Payne, M.E.I.C.
Secretary-Treasurer	A. Ritchie, A.M.E.I.C.
Committeemen	W. R. Mount, A.M.E.I.C.
	R. W. Boyle, M.E.I.C.
	W. J. Cunningham, A.M.E.I.C.
	S. R. Lamb, A.M.E.I.C.
(Ex-Officio)	A. G. Stewart, A.M.E.I.C.
(Councillor)	A. W. Haddow, A.M.E.I.C.

Lethbridge Branch

N. H. Bradley, A.M.E.I.C., Secretary-Treasurer.

Meeting in Honour of Mr. Durley

The general secretary, R. J. Durley, M.E.I.C., met the Lethbridge Branch on July 7th, in the course of his tour of the western branches. Summer is not an ideal season to bring members together for a meeting, but a fairly large number turned out to the dinner given in Mr. Durley's honour in the evening.

A feature of Mr. Durley's visit was a trip over the Lethbridge Northern Irrigation Project. The headgates at the intake were inspected and a stop was made at various other points of engineering interest, including the big metal flume 3,300 feet long and 15 feet wide; the two great wood stave siphons, one of which is 3,000 feet long with a diameter of 10½ feet, and the other 950 feet long.

Although the trip was taken by car, it might have been negotiated in a canoe for a distance of 80 miles through main ditches and canals. At any rate, the trip afforded an excellent illustration of a phase of engineering that is closely interwoven with agriculture. This is a particular instance where the engineer and the farmer meet on common ground.

Discussion of Institute Affairs

After dinner, Mr. Durley talked of Institute affairs and gave the members a general idea of the work of Council and the many angles of the year's activities. Among the topics taken up was that of The Journal and, in a humorous vein, Mr. Durley described his work as editor and called for suggestions as to methods by which The Journal could be improved. The Journal comes closer home to the average engineer than possibly any other detail of the organization and among the suggestions offered was a *Question Box* where questions of general interest could be answered. Another suggestion was for an editorial page, but this was turned into a general laugh when Mr. Durley stated very gravely that there was already a page devoted to editorials.

Another suggestion that aroused some discussion was one relating to propaganda designed to establish a better knowledge of the engineer and his work among the lay public, the idea being that popular mediums be utilized for articles on engineering to be written by writers of reputation who make a profession of feature stories. It was felt that while articles of a technical nature in the Journal were interesting and intelligible to engineers, few if any of them could be considered interesting to the public at large. Many of these, however, contained information that could be used for popular consumption if it were redrafted.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

On August 13th, the branch was favoured with a visit from R. J. Durley, M.E.I.C., general secretary of The Institute, who stopped off at Moncton on his way to the Maritime Professional Meeting at Sydney.

In the evening, Mr. Durley was entertained at a smoker held at the Riverdale Golf Club. Quite a goodly number of members journeyed over by car from the city, and listened with interest to the secretary's remarks on Institute affairs and progress made by the various branches. Following a general discussion, light refreshments were served. G. C. Torrens, A.M.E.I.C., vice-chairman of the branch, presided.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

Visit of General Secretary R. J. Durley

A special meeting was held at the Y.W.C.A., Queen Street, E., on July 15th, 1926, following a dinner at which we had as guests, R. J Durley, M.E.I.C., general secretary of the Institute, and R. O. Wynne-Roberts, M.E.I.C., past-president of the Toronto Branch.

C. H. Speer, M.E.I.C., called the meeting to order and introduced some of the local talent, who gave a fine programme of music and entertainment which was much appreciated by all. The programme was,—

Miss Doris Knight, piano selection.
Mr. A. McColl, vocal selection.
Mr. J. H. Jenkinson, A.M.E.I.C., a sketch from the Originals.
Miss Treva Richardson, piano selection.

Mr. Speer gave an outline of the activities of L. R. Brown, A.M.E.I.C., during the past twelve years that he had been in the Sault. Every position, and in fact everything, even to fishing, that Mr. Brown had taken on, had been carried through and he had made good. Mr. Brown is taking a position with the Newfoundland Power and Paper Company at Corner Brook and carries with him the best wishes of the Sault Branch.

Mr. Durley read the following letter and presented Mr. Brown with a fly book on behalf of the members of this branch.

July 5th, 1926.

L. R. Brown, Esq., A.M.E.I.C.,
City Engineer,
Sault Ste. Marie, Canada.

Dear Sir:—

The members of the Sault Ste. Marie Branch of the Engineering Institute express their regret at your leaving this city. Your great activity in matters pertaining to the general welfare of this community while it has met with that amount of opposition which goes with all endeavour, has made you dear to all. Your particular work in connection with the formation of the branch and during its early life has been, and will always be, appreciated by the members. Now that you are leaving they most sincerely hope that you will be greatly successful in your new field and wish you to make many new friends while not forgetting those you leave behind. As a token of this appreciation, will you accept this slight memento of your sojourn here.

On behalf of the Sault Ste. Marie Branch of the Engineering Institute, we beg to remain.

Yours sincerely,
(Sgd) J. W. LeB. Ross, M.E.I.C.
(Sgd) C. H. E. Rounthwaite, A.M.E.I.C.

Mr. Brown expressed his thanks and said that he felt sure that the Sault Branch would prosper and that he was proud to have been associated with it during his residence in the city.

Mr. Speer then called upon Mr. Durley who had just returned from visiting the western branches. He said that all the western branches showed good prosperity and were very active and congratulated the Sault Branch on its activity during the past year. He outlined the efforts being made to unite all the different engineering associations into a stronger body, and in referring to the general conditions of engineering in the west, he commended the work of the engineers on the Caribou highway construction through the mountains.

Speaking of the advantage of being a member of the Institute, he said it broadened our knowledge of other sections besides the one in which each member was particularly interested. Members should take an active part in the general discussion and interchange of views and should also make a determined effort to get to the meetings. In speaking of the work at headquarters, Mr. Durley complimented the staff on their efficiency, willingness and loyalty. A good many people think that headquarters is the Institute, but the headquarters staff existed solely for the purpose of carrying on the routine work and the Institute was the twenty-five branches from Halifax to Vancouver.

Mr. Durley touched upon the several duties of a general secretary, and the members fully appreciated what he and his efficient staff are doing to help The Institute carry on. It is a pleasure to have Mr. Durley make his annual visit to the Sault and the members are all looking forward to his next visit.

R. O. Wynne-Roberts, M.E.I.C., said that engineers should have more publicity than they get and that the public did not appreciate the work an engineer did and the benefit his work is to mankind. "We, in Canada," said Mr. Wynne-Roberts, "possess more engineering achievements than any country in the world, but there is nothing said about it. It is taken for granted."

Mr. Speer expressed his appreciation to the speakers and he felt sure that the Sault Branch had received many helpful suggestions from Mr. Durley. He pointed out that the attendance in this branch for 1926 was slightly over 50 per cent of the resident members.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

"We must make this an annual affair." This statement made by members present, describes the feeling of satisfaction of the members of the Saint John Branch who attended the *Branch Outing.* The affair was held at Belyea's Point, on the Saint John river, some sixteen miles from the city of Saint John. The party, twenty-nine in number, made the trip by automobiles, leaving the city from 5.30 to 6.00 p.m. on August 12th, 1926. On arriving at Belyea's Inn, the members found supper awaiting them on tables set outdoors in the orchard.

After supper the members went to the beach, where a branch meeting was held. It was truly a wonderful setting for a meeting. Forming a half-circle, the members sat on logs or stretched out on the beach; a perfectly calm night, people loafed along the shore in canoes, while farther off shore motor boats passed up and down the river. A. R. Crookshank, M.E.I.C., chairman of the branch, called the members to order and introduced R. J. Durley, M.E.I.C., general secretary of The Institute. Mr. Durley gave an impromptu address, and dealt with several features of his recent trip to the Pacific coast on his visit to the western branches of The Institute. Other phases of Institute work, including its financial condition, were dealt with. In particular, Mr. Durley laid stress on the important part taken by the branches in the work of The Institute, and of the satisfactory co-operation between headquarters and the branches. After Mr. Durley's address, the members asked many questions about The Institute, and it was evident all wanted to obtain information. In the variety of questions asked, a genuine interest in The Institute was evident amongst the members. Mr. Crookshank tendered a vote of thanks to Mr. Durley at the conclusion of his address.

After the meeting, soft-ball and volley ball was played until darkness stopped the game. Some of the members took advantage of the opportunity and had a swim. About 11.00 p.m. the members arrived back in the city, after a very pleasant evening.

Thanks to Cape Breton Branch, E.I.C.

Those members of Saint John Branch who were fortunate enough to attend the Maritime Professional Meeting held at Sydney, N.S., August 17th to 19th, 1926, are delighted with the trip, with the Cape Breton scenery and with the meeting itself. The meeting was in every way up to the high standard of previous Maritime Professional Meetings, and had the added attraction that Sydney and vicinity, with its coal and steel industries, has much to offer of interest to the engineer. The committees in charge of the various arrangements for the meeting are deserving of much praise. Good work, Cape Breton Branch!

Recent Additions to the Library

Transactions, Proceedings, Etc.

Presented by the Societies:

- Transactions of the Liverpool Engineering Society, Volume 46, 1925.
- Transactions of the Canadian Institute of Mining and Metallurgy and of the Mining Society of Nova Scotia, Volume 28, 1925.

Wind Measurement and the Protection of Coal and Ore Bridges

A Discussion of Existing Wind Recording Instruments and Special Designs for use as a Protective Measure on Coal and Ore Bridges and a Study of Wind Action on such Bridges

C. Stenbol, M.E.I.C.

Mechanical Superintendent, Algoma Steel Corporation, Limited, Sault Ste. Marie, Ont.

Paper read before the Sault Ste. Marie Branch of the Engineering Institute of Canada, March 26th, 1926

When a structure is designed, certain allowances are made for wind load, and, generally speaking, ample allowance is made. Occasionally, a house, a bridge, or a smoke stack blows down, particularly a bridge of the type known as a coal or ore bridge, which are structures on wheels, and can be moved along a track. This bridge travel is the weakest point, and forms the basis of the discussion in this paper.

Records Show Great Variation

To approach a subject a common and as well known as the *wind*, for the purpose of analyzing its behaviour, may seem to many, in our time of advanced science, as treading on rather beaten ground, and may, in fact, seem out of place. Every known force and phenomenon is safely bound by laws, expressed in formulas, the truth of which would be a serious matter to question. The wind is no exception. It is measured and expressed in recognized terms. The only trouble is that these terms vary. By comparing data compiled from various sources, we may come within 25 per cent of the truth, but should we be in the least careless a variation of 100 per cent is possible. The effects of such variations, when referring to specific measurements, are, to say the least, ridiculous, and convey ideas more erratic than the old nautical terms of *fresh wind, high wind, gale, storm, hurricane,* etc.

Students of travel and exploration, particularly in the Arctic and the Antarctic, will find that explorers are much concerned about the winds. By comparing their records, cases of variation of measurement seem very apparent. Using for comparison Captain Scott's South Pole expedition, 1910-1912, and Sir Douglas Mawson's Antarctic expedition, 1911-1914, and referring to the book written by Mr. H. G. Ponting, entitled "The Great White South," (Ponting was on Captain Scott's scientific staff), on page 126, he describes fully the Dines anemometer, which instrument they christened *the blizzometer.* On page 147, in describing one of the worst storms they had, he concludes by saying, "And the blizzard which followed on Atkinson's adventure attained a wind velocity of 60 miles per hour with a temperature of —35 degrees Fahr. On venturing outside, I was blown off my feet and completely lost in the smothering drift and pitch darkness. . . ."

Dr. Simpson, (of Scott's staff), reports of the same storm and describes it as the worst blizzard ever experienced. On July 8th, 1911, he records it as —31 degrees Fahr. and 63 miles per hour, and on July 12th, 1911, 66 miles per hour, with gusts as high as 80 miles per hour. Captain Scott wrote on July 10th, 1911, "We have had the worst gales I have ever known in these regions, and have not yet done with it. The wind reached an average of 60 miles per hour for one hour on Saturday. The gusts at this time exceeding 70 miles per hour."

Now, turning to Sir Douglas Mawson's records in his book, *The Home of the Blizzard*, vol. 1 and 2, he makes frequent and very interesting references to the wind and its behaviour, only a few of which will be mentioned. He writes, on page 114, vol. 1, "The classification of the winds here stated is that known as the 'Beaufort Scale.' The corresponding velocities in each case are those measured by the Robinson patent anemometer, our instrument being of a similar pattern." (Here follows the Beaufort scale in which hurricane is quoted as 77 miles per hour, equals 14.4 pounds per square foot.) "Beyond the limits of this scale, the pressure exerted rises very rapidly. A wind recorded as blowing at a rate of 100 miles per hour exerts a pressure of about 23 pounds per square foot of surface exposed to it. The mileage registered by our anemometer were the mean for a whole hour, neglecting individual gusts, whose velocity much exceeded the average, and which were always the potent factor in destructive work."

On page 119, he describes the art of walking against high winds, by using spiked boots and leaning forward on the wind. He illustrates this by several photographs, one of which shows a man, posing for the camera, with his feet together leaning forward at an angle of 31 degrees.

On page 121, he says, "Hodgeman was lost while visiting the anemometer. After two hours, search parties were sent out. The wind was blowing 80 miles per hour." On page 133, he says, "On May 15th, 1912, the wind blew at an average of 90 miles per hour for twenty-four hours. On the evening of May 24th, 1912, the hurricane came with a series of herculean gusts. As we afterwards learned, the momentary velocity of these doubtless approached 200 miles per hour." Again, on page 134, he says, "Frost bites that day were excusable enough, for the wind was blowing between 95 and 100 miles per hour. There was dense drifting snow and a temperature of —28 degrees Fahr."

There are numerous incidents in Mawson's records that his staff went about their usual work in winds above 90 miles per hour, whereas Scott's men had equal or more difficulty with winds of 60 miles per hour. It is rather difficult to account for this difference, but it becomes more apparent if the velocities are converted into actual force of pounds per square foot, using Eiffel's formula P equals $.0032V^2$, a wind of 60 miles per hour equals 11.52 pounds per square foot, and 90 miles per hour equals 25.92 pounds per square foot. The general condition of the two parties were somewhat similar or equal. They both had their bases on the South Polar continent, with the sea to the north and high glacial land to the south. They both had drifting snow with high winds. Captain Scott had 7 degrees lower temperature than Sir Douglas Mawson at incidents referred to, yet Mawson's men went about with greater ease than Scott's men, in winds of more than double the force.

Characteristics of Existing Anemometers

It is obvious that we cannot entertain any thought of the inequalities of the men, or that the records were incorrectly kept, consequently there is only one item open to question, namely, the correctness of their instruments. As before stated, Captain Scott used the Dines instrument. It is known as a *recording pressure tube anemometer*. Quoting the makers' further description, they say, "This instrument is constructed on the principle invented by Mr. W. H. Dines, F.R.S., in which the pressure and suction effects of the wind, acting upon a float, gives a perfectly true record of the action of the wind. The two tubes necessary to eliminate casual alterations of pressure in the room where the recorder is placed." Mr. Ponting makes many references to the Dines anemometer. Thus, on page 132, he says, "Another, and often less pleasant obligation of the watchman was to keep a heedful eye upon the blizzometer. When blizzards raged, the nozzle of this instrument sometimes becomes clogged with snow, thereby shutting off all pressure on the floating drum, and causing the pen to fall lifeless to the bottom of the chart."

Sir Douglas Mawson states that their instrument was of a similar pattern to the Robinson anemometer, and this instrument is described by the makers as follows: "In the well-known Standard Robinson cup anemometer, now in universal use throughout the world, for the determination of wind velocity, four hollow hemispherical cups are mounted upon crossarms at right angles to each other, with the open sections vertical, and facing the same way around the circumference. The centre of the cups moves with a velocity about one-third that of the wind which sets them in motion." The revolutions of these cups are recorded in several ways, which constitute various styles of instruments, but unlike the Dines instrument, it does not record sharp peaks or puffs of wind. Mawson writes on page 121, "The anemometer gave the greatest trouble, and before Correll had finished with it, most of the working parts had been replaced in stronger metal."

This will give an idea of the instruments, and shows that they were by no means reliable, yet there is nothing to show that the records were incorrect, except, assuming that Mawson tried to secure photographs showing men leaning against the wind, and it is natural to expect that the photographs giving the greatest angle were selected, making a rough calculation of the wind force required to support a man leaning 31 degrees forward, we get 14 pounds per square foot or 66 miles per hour, which is quite reasonable, as they would not be able to take pictures in the worst wind experienced, with dense drifting snow. But applying the same reasoning to Scott's men, they would not have been able to secure photographs in anything approaching even a 50-mile wind, which is hardly so, as we all have experienced greater winds; therefore, the only answer is that Captain Scott's instrument was reading low and Sir Douglas Mawson's instrument was reading high.

The reason for making this deduction is based on Mawson's quotation, "A wind recorded as blowing at a rate of 100 miles per hour exerts a pressure of about 23 pounds per square foot," which corresponds to the formula P equals $.0023V^2$, therefore 90 miles per hour equals 18.63 pounds per square foot, and if by chance Scott's instrument was calibrated to, say, old Smeaton's formula of P equals $.005V^2$, Scott's 60 miles per hour would equal 18 pounds per square foot, making the conditions and difficulties experienced by the two parties equal, instead of a difference of more than 100 per cent, as recorded. When we turn to our common engineering reference books, the various formulæ run from P equals $.005V^2$ to P equals $.0029V^2$.

The most recent information obtainable is from prominent instrument makers. Those of the United States appear to use P equals $.004V^2$ and those of Great Britain use P equals $.003V^2$, a difference of 25 per cent.

Turning back to our discussion of safeguarding moving structures from wind damage, we may differ 100 per cent,

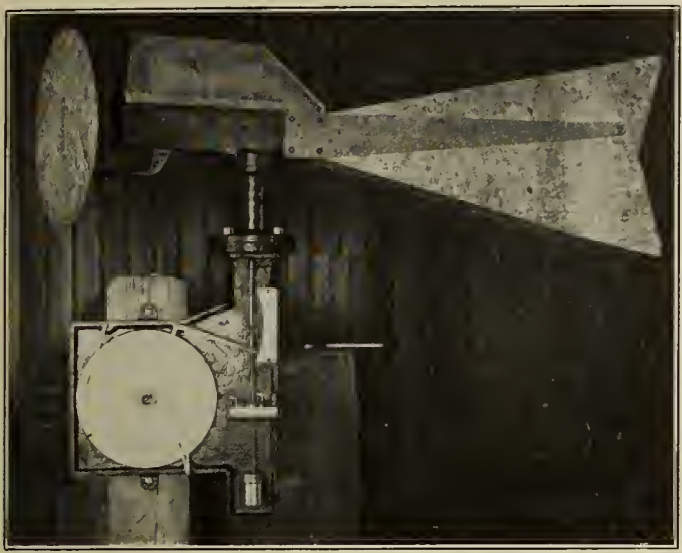

Figure No. 1.—Recording Gauge.

which, from an engineering point of view, is not permissible, and it is this difference which lead to the work described below.

Several years ago, the company with which the writer is associated was unfortunate enough to have two bridges blown down. This led to a vigorous campaign of safeguarding against similar accidents. Much was learned, and much had been done by the companies that carry tornado insurance. In their regulations as to bridge operators they stipulated that bridges must be fastened to track, at all times, except when moving, and must not travel in a *wind greater than 35 miles per hour.* This was accepted by the company and many others as a good safe rule, but it was not long afterwards that this rule was put to a test.

The blast furnaces needed ore, and the bridges were tied up on account of wind blowing at an estimated velocity greater than 35 miles per hour. The furnace superintendent naturally considered the superintendent in charge of bridges over-cautious, with the result that the mechanical superintendent was ordered by the manager to take the necessary precautions and move one bridge. To the writer, therefore, fell this unpleasant task.

Although, on the ground, the wind did not seem bad, on the top of bridge gusts of a force to indicate a 50-mile wind were experienced. The bridge was to move against the wind. The rails were wet and icy. The bridge had 100 per cent drive and good brakes. Men with wooden wedges were stationed behind each wheel, with instructions to follow up the wheel with the wedge as the bridge moved along. By watching the wheels it was noticed on two occasions that the wheels slipped on the rails when heavy gusts struck the bridge, showing that it would have been anything but safe to travel with the wind.

This incident led to the procuring of a wind gauge. Various instruments were considered, but none could quite meet the requirements. All that was required was to know accurately when the wind recorded 35 miles per hour; that is, 35 miles per hour here had to be 35 miles per hour anywhere else. The gauge had to be durable; it had to work in dust and snow; and, if out of working order, it must be easily repaired and calibrated again. As none of the instruments procurable seemed to meet such specifications, it was necessary to make one.

Two Types of Gauges Specially Designed for Bridge Use

Without describing the various models made, it will be sufficient to consider only two distinct types, as these are the final results of experiments carried out over a period of several years. The pendulum type, which is being mounted on all bridges, is simply an oblong plate hanging by a hinge from a yoke and faced square with the wind by a tail-plate. The whole instrument swings horizontally on a pivot, and as the wind increases the plate swings out, and when, say, 35 miles per hour is reached its lower end makes an electric contact on a stop fastened to the tail-plate. This is in turn wired in the usual way to the operator's cab, where a light, a bell, or both, call the operator's attention to the fact that the wind has reached the allowable limit. There is nothing about this gauge to go out of order, and when once calibrated it is fixed for all time. It does not need any other attention than that given by the regular men about the bridges. This wind-limit gauge is being manufactured, and, up to the present time, it has been installed on some 30 or 40 bridges.

The other type is also a pressure plate model, in which the plate is squared to the wind by a suitable tail-plate. The whole apparatus swings horizontally on a pivot, but, unlike the pendulum type, the pressure plate remains vertical and

Figure No. 2.—Recording Gauge Mounted and in Operation.

travels horizontally away from the wind. This motion is transferred through suitable levers, all mounted on ball bearings, to a vertical rod passing through centre of pivot.

The whole instrument is properly weatherproofed and mounted on a pipe, which in turn is supported by a mast. The rod passes down through the pipe to the recording instrument, which is located, in this case, in the dock office.

The recording instrument is a clock with a standard 12-inch chart. As the wind acts on pressure plate, it raises the rod, which is connected to a pen, which in turn marks the chart. It also records the wind direction on the same chart through the rod which turns with the gauge. The lower end of rod rotates a disc which through a cam-motion operates the wind-direction recording pen. It makes a complete 24-hour chart, giving at a glance the exact behaviour of the wind.

These, briefly, are the results of the experiments. The recording gauge described above is the fourth and final model. The second of these has been in operation for three years, and is still recording the characteristics of the wind.

The greatest difficulty to be overcome in the work was the calibration, or rather the determination of the ratio between pressure and velocity. The conflicting data, already referred to in this paper, left no definite base from which to start the work. By writing firms dealing in wind instruments their catalogues were secured, but in reply to inquiries as to upkeep and calibration, they politely replied that their guarantee went with the instrument, etc. From a British maker, however, a reply was received, part of which is as follows: "The indications are translated from pressure in pounds per square inch (should be pounds per square foot) to miles per hour by the formula P equals $.003V^2$. The actual calibration of the instrument is done by comparison with water tube gauge, using the formula W equals $.000731V^2$, where W has the pressure difference measured in inches of water, and V is the speed in miles per hour. The Robinson anemometers are constructed from calculations and corrected by comparison with standard instruments in a wind channel."

This indicates that the formula P equals $.003V^2$ is used in Great Britain, against an equally reputable one by United States, giving P equal to $.004V^2$, a difference of 25 per cent.

Our recording gauge is easily enough calibrated by dead weight, in the same manner as any weighing scale is tested. A pressure plate of one square foot and one pound acting horizontally against its centre, must be equal to a wind of the same force. It is, however, stated by various authorities that the unit pressure of the wind varies with the size of obstruction, and also with the shape of the object. This latter is clearly shown in the cups of the Robinson anemometers. Therefore, as a basis, one square foot flat surface and pound weights were used, and a series of tests were run to check the relation between pressure and velocity.

The wind is air passing a stationary object, and must be equal to an object passing stationary air. An automobile driving along a smooth level road on a calm day is about the handiest and most satisfactory means of carrying on such tests, as the speed can be varied and read directly on the speedometer. Several pressure plate models suitable for this work were made and mounted on a plank projecting four feet outside of the car. The top and wind shield of the cars were taken off. The speedometer was calibrated prior to the tests by timing between mile posts. Incidentally on this test it was found that mile posts varied from 1.2 to 0.8 mile. Tests were run from 20 to 40 miles per hour. The driver keeping constant speed by watching the speedometer, and the other man observing the pressure plate. Each test was run both ways several times, and on different days. Tests were run on July 24th, 1925, with pressure plate 6 by 6 inches or ¼ square foot, giving the following results as the average of several tests:

(1)	Speed of car	20	m.p.h. reading of gauge	0.4 × 4	equals	1.6	lbs.
(2)	" " "	25	" " " "	0.55 × 4	"	2.2	"
(3)	" " "	30	" " " "	0.75 × 4	"	3.0	"
(4)	" " "	35	" " " "	1.05 × 4	"	4.2	"
(5)	" " "	40	" " " "	1.2 × 4	"	4.8	"

P equals XV^2, V equals $\frac{P}{X}$ and X equals $\frac{P}{V^2}$, therefore, X from above tests worked out to:

$$\text{Test (1) } X \ldots\ldots = \frac{1.6}{20^2} = 0.0040$$

$$\text{Test (2) } X \ldots\ldots = \frac{2.2}{25^2} = 0.0035$$

$$\text{Test (3) } X \ldots\ldots = \frac{3}{30^2} = 0.0033$$

$$\text{Test (4) } X \ldots\ldots = \frac{4.2}{35^2} = 0.0034$$

$$\text{Test (5) } X \ldots\ldots = \frac{4.8}{40^2} = 0.0030$$

$$\text{The average of the five tests..} = \frac{0.0172}{5} = 0.0034$$

Similar tests were run with the pendulum type pressure plate, which gave an ascending scale with increases in the speed, the greater the coefficient X, apparently increasing with the angle of the plate.

(1)	Speed	20	m.p.h. angle with vertical	23°	coefficient,	X=0.003
(2)	"	25	" " " "	41°	"	X=0.0048
(3)	"	30	" " " "	46°	"	X=0.0045
(4)	"	35	" " " "	56°	"	X=0.0056
(5)	"	40	" " " "	60°	"	X=0.0058

The pressure plate in this case was 6 by 24 inches suspended lengthwise, the same as used for the wind limit gauges. This same plate has been checked with our recording gauge, by being mounted on same mast, with the contact stop at various angles, and the alarm compared with recording gauge in actual wind.

In conclusion, it may be said, although the experiments were not carried out over a sufficiently wide range, they indicate that there should not be any doubt as to a given wind. It should be measured and expressed in like terms everywhere. The research laboratories no doubt will in time take this question up, and, in doing so, it may be found that the wind pressure will be the logical unit to use. The velocity is then easily determined by a constant formula for a given temperature, barometric pressure, and rain, snow or dust carried with wind. Knowing this, a storm in any part of the globe can be compared with any other storm. For convenience, a pressure- and direction-recording gauge should be erected 50 feet from ground, or 20 feet above high buildings, with pressure plate one square foot, as such an instrument is large enough to be sensitive when heavily constructed.

Our experience showed that nothing of a flimsy or delicate nature will stand up to the continuous racking of the wind, the action of moisture, dust and snow. Sir Douglas Mawson emphasizes the destructive work of gusts or wind peaks. The writer has made many observations, and will mention an example watching the behaviour of the wind from the cab of one of the bridges. It was plainly noticeable (the wind peaks were just touching the 35-mile mark), that the gusts at times were coming with equal regularity, just as if they were trying to time the sway of the bridge. Once or twice it was done to such a nicety that it appeared that the sway of the bridge was sounding the alarm rather than the wind.

In guarding structures against wind damage, the maximum peaks must be considered, as they are really more destructive than a steady wind of equal velocity. Thus in the case cited above, the gusts added to the momentum, and each time put greater stress on the swaying structure until, fortunately, the timing of peaks changed and normal loading was again established. The action is probably best seen if watching exposed tall trees in a storm. They sway back and forth, and sometimes they sway back apparently beyond their normal position, and if the wind catches them again at that moment, it seems that it forces them with doubled power towards destruction. Another action of the wind is, *momentary peaks* at long intervals. It has been noticed, particularly in an abating wind, that the velocity of the wind sometimes increases after 20 to 30 minutes, with one or two peaks equal to its original force; therefore, it has been found advisable not to travel bridges until 30 minutes after last alarm.

This brings us up to very recent ideas in safeguarding travelling bridges against wind damage. The *Iron Age* of January 28th, 1926, in an article describing a modern manufacturing plant in which bridges were part of the equipment, says, referring to a coal bridge: " In addition to the usual safety appliances, is provided an anemometer which automatically cuts off the power and sets the clamps when the wind reaches a certain predetermined velocity." Again in a letter to the writer, the manager of one of the Tornado Insurance Companies, dated February 20th, 1926, says among other things: " The insurance companies and some superintendents think it adds to the safety of the bridge to have the travelling power cut off when the wind reaches a predetermined velocity." Referring to a certain manufacturer of bridge safety appliances, he goes on to say: " and he is now working out a plan whereby such cut-off would be effective only on a side wind, allowing the bridge to be moved with an end wind at a higher velocity."

In dealing with the idea of the wind cutting off the power and setting the clamps, the extreme conditions under which this will happen must be borne in mind. The bridge is travelling away from wind at its maximum speed. The wind reaches the danger peak and cuts off the power, and automatic clamps, together with the brakes, are applied. The nature of the automatic clamps is such that they jam tight to rail. In other words, the bridge is clamped to track suddenly, with the result that you have the momentum of the huge structure plus the force of the wind. The impact, when stopped suddenly, will be tremendous.* Would it not be safer, when the operator receives the wind alarm, to stop his motors, apply the brakes and, if necessary, plug the motors until the bridge is stopped, and then put on clamps? The above question was considered last December, and the suggestion it contained seemed to have some merit. All parties interested in the operation of our bridges were called in to discuss it. The operators considered themselves absolutely helpless and in great danger to their personal safety if the power was cut off the bridge while travelling. The question also arose as to whether bridge can travel with safety in greater end wind than side wind.

If the behaviour of the wind direction is studied it will be found that, like the velocity, it is by no means steady. One of the two bridges lost some years ago was from a *momentary gust, and from the opposite direction to the original wind, and it came after everybody thought the storm was over.* This was probably an exception, but it is really these exceptions which have to be guarded against. It is, therefore, hard to determine just when an end wind is safe. Also, considering that the side wind is probably not exerting its greatest force when it blows at right angles to the bridge. Compare it with a two-masted ship or sail boat. Wind dead astern does not drive it as fast as abeam, because when dead astern, only one sail is driving, whereas, when abeam, both sails are in the wind. The same is true in the case of the bridge. Any other wind, except a right angle wind, will blow through and *catch both sides of bridge,* and the vertical members offer greater surface when placed converse than when square with the wind.

Another factor to be considered is, when the wind strikes a surface other than at right angles, the co-efficient X in formula $P=XV_2$ increases as the angle increases; so that when the wind swings around to the end of the bridge, the side surface decreases, but the force of the wind per projected area of surface increases. This behaviour of the wind is plainly demonstrated when sailing *close hauled.* A good boat will lay four points off the wind, equalling 45°. Assuming half of this is the angle of wind to sail, and knowing that the same velocity wind will drive the boat faster at this angle than when squared to sail, it is almost reasonable to assume that the wind action on bridge members would be similar, so therefore a safe end wind would be only some of what lays inside of 45°, half of which comes on each side of bridge. If you examine a wind direction record, you will find that ordinarily it varies that much, and if of a gusty nature, fluctuates a great deal more.

The safeguarding of bridges from wind damage is, and probably will have to be, taken care of by the human element, and in this the operator plays an important part. When he is given the proper appliances and instructions, there is no excuse for bridge being subjected to undue hazards, but in order to establish standard appliances and coordinate the operator's duties with these and conditions under which he works, legislation similar to that governing steam boiler operation might be found useful. It will guard against unsafe structures, inadequate equipment, and radical methods, as well as assure the owners that only competent men, carrying the necessary qualifications, and having proven themselves reliable and efficient, are in charge of such structures.

*This statement has been discussed since this article was written, and advocates of letting the wind cut off the travelling current and set the automatic clamps say that " The clamp sets slow." That is, it requires several seconds for the clamps to set, which is generally true, but it will be found that this time is used up while clamp is travelling through its clearance space. Accordingly, the actual gripping of clamp allows for little or no braking power.

Electrical Development of Southern Saskatchewan

A Review of Existing Conditions and the Advantages of a Comprehensive Scheme for the Development of the Power Resources of the Province

Samuel R. Parker, A.M.E.I.C.
Plant Engineer, Department of Telephones, Regina, Sask.

Paper read before the Joint Meeting of the Saskatchewan Branch of the Engineering Institute of Canada, the Saskatchewan Section of the American Institute of Electrical Engineers and the Southern Saskatchewan Section of the Canadian Institute of Mining and Metallurgy, at Estevan, Sask., July 8th—10th, 1926

The electrical development of Southern Saskatchewan is rather a comprehensive subject, and it is proposed to deal with only two or three of the salient features in this connection.

In order to obtain a thorough grasp of the subject, it is almost necessary to delve into ancient history. While steam and its attributes were more or less thoroughly understood at an early date, it remained for George Watts, in 1769, to harness this potential power for the benefit of mankind, and from this period on to the end of the nineteenth century may very suitably be designated as the *Steam Age,* which was the main factor that rendered possible the very rapid industrial development of the old world nations.

While it relieved the drudgery and hardship of human toil, and thus increased production, it was not a serious contributing factor to the elevation of the living conditions of the worker. Approximately one hundred years after George Watts' epoch-making discoveries, Siemens and Gramme, in the years 1866 to 1868, invented and perfected the electric generator which rendered possible the harnessing of electricity for industrial purposes. The initial research work of Faraday, the proof of this research work by mathematical calculation by Maxwell, the development of the necessary measuring instruments by Lord Kelvin and the pioneer training in the electrical field by Thompson have rendered possible the inauguration of the *Electrical Era* in the twentieth century, which has enabled the very vast developments of the new world under ideal conditions without having to go through the transition stages from the manual to the steam to the electrical development, which transition states have to a certain extent handicapped the industrial growth of the old world.

In a recent paper read before the Saskatchewan Branch of the Engineering Institute of Canada on "Industrial Development in Saskatchewan," the following table was used to show that the importance of cheap power is often exaggerated in the minds of the public:—

	Wages, Taxes, etc., per cent	Raw Material per cent	Fuel and Power per cent
The average of all manufacturing industries	20.4	77.5	2.1
Iron and steam industries	19.6	86.2	1.4
Food products	12.4	63.1	1.4
Textiles	35.5	62.6	5.4
Paper	32.0	77.5	2.1

If the above figures are allowed to stand at their face value, there is very little object in wasting any further time discussing the subject matter of this paper. While it is conceded that the actual cost of the power used in manufacturing processes is only a bagatelle of the production value of the article, it is very easy to prove, from an engineering and economic standpoint, that without the savings which have been effected in large and small industrial plants due to the labour-saving made available and the increased production rendered possible, which, it will very readily be seen, affects both the value of the raw material to the manufacturer and the wage item, which are the two major factors in all industrial production, the present very intensive development of industries in the twentieth century would not have been possible. This is conclusively proved by the following table showing the percentage of industries electrified in the industrial communities of the north central states of the United States:—

Industry	Total Horse Power Used	Percentage Electrified
Iron and steel	2,898,036	53.0
Food	1,562,360	62.0
Machinery	1,024,273	88.5
Transportation	968,311	85.9
Paper and printing	850,586	56.0
Steam, clay and glass	762,081	51.6
Chemical	724,930	77.6

The reason that a greater percentage of these industries are not electrified can be attributed to the lack of available power at a cheap rate, due to the phenomenal demand for electricity exceeding the available output. The present investment in the electrical industry exceeds seven billion dollars and new capital at a rate of over one billion dollars per year is being invested in this industry without any appreciable prospect of meeting the demand, and an extraordinary thing about all power development schemes is that even where developments have been started presumably well ahead of any prospective demand, immediately the power developed has become available it has been absorbed by the industrial development of the country.

Without further stressing the engineering and economic importance of electrical development, there is one other factor that is worthy of very great consideration in this connection, and, as far as the author is aware, has never received due recognition from engineers and executives in considering electrical industrial development schemes. This factor, which has a vital bearing, is the viewpoint of the worker, which cannot be shown better than by quoting the remarks of Mr. Wm. Green, president of the American Federation of Labour, the mouthpiece of undoubtedly the world's largest organization of labour. " The workers have learned from experience that electrically-driven machinery has lightened the burden of employment and relieved them of the drudgery and hardship of human toil. They now do with the machine what at one time required the strength and vigour of their bodies. Work has been made easier, life has been made more tolerable, living conditions have improved and the workers have been permitted to enjoy the blessings and benefits of modern life. The marvellous development of electrical power has resulted in increasing the efficiency and productivity of the individual worker. In proportion, as he has been supplied with additional horse power, the worker has made strides forward in increasing in capability and enlarging his usefulness. The United States Government statistics show that within the last two decades the productivity of the individual worker has been increased from twenty-five to fifty per cent; this showing could not have been made except for the broad and general use to which electricity has been adapted."

Further, Secretary of Labour Davis, of the United States, in a recent speech before the National Electric Light Association, gave as his considered opinion that the same degree of electrical development applied to industries in Great Britain as exists at the present time in the United States would very possibly have obviated the recent general strike, which has without doubt retarded the industrial development of the Old Country, and is still continuing in the mining industries. That this viewpoint is known and thoroughly shared by the British Government is, in the author's opinion, amply borne out by the Electricity Bill which is at present before the British Parliament and is the tangible result of the creation of the electricity commission some years ago.

The benefit of living in a new country is that we need not go through the throes of the evolutionary and development stages that were necessary in the older settlements, but can take advantage of the lessons learned by them and apply them to our own conditions. For this reason, the salient features of this Electricity Bill are of considerable interest to us who are on the threshold of the possible electrical development of this province. The fundamental features of this bill, and what it involves, were very concisely stated by the Right Hon. Neville Chamberlain, member of the British Cabinet, who was the speaker of the evening at the recent annual dinner of the Institution of Electrical Engineers, which is the largest and most influential technical society in Europe. The following is quoted from his address:—

> " I do not know what you think of it, but the first sketch of the proposals has been welcomed by the public with an unanimity which has rather alarmed me. The only thing that concerns me is that the bill is praised quite as much for what it does not do as for what it does do. To begin with, there is no subsidy and there is to be no nationalization, there is to be in fact as little state interference as is compatible with the purposes we have in view. I think I may, from a layman's point of view, express our purpose as being threefold, to provide for a concentration of production, for the pooling of power reserves and for the standardization of equipment. I believe that if we can achieve these three things, we may hope to see throughout the country a considerable cheapening of electricity and certainly a very much more available supply. I hope it will be agreed that aims of that kind are worth a serious effort. We cannot, of course, make such changes without interfering with local and personal interests; certain stations will have to be closed, thereby causing a certain amount of dislocation and change and possibly the abolition of existing offices. What we desire, however, are changes which we believe to be in the national interest and of benefit to the community as a whole, and what is of benefit to the community as a whole must sooner or later percolate right through to every individual part of it."

The last portion of these remarks are of very vital interest in considering any development scheme in a new country, as it will readily be seen that by initiating the development before instead of after the local demand forces the building of small isolated plants will be cheaper in the long run for the community, even although the scheme does not initially produce dividends, as it will obviate the necessity, at some later date, of having to buy and close the plants that will not dovetail into a comprehensive scheme. From information available, it would appear as if the five hundred and eighty odd local plants throughout the British Isles will be reduced, under this Electricity Bill, to less than sixty, situated at logical distributing centres selected on account of their facilities for the production and transmission of power at the cheapest possible rate.

The Situation in Southern Saskatchewan

Coming now to the local situation as it affects Southern Saskatchewan, a survey of industrial history will show that all great industrial developments have taken place on the coal fields if and where they are within easy access of a constant supply of good water. A survey of Southern Saskatchewan, in the vicinity of the coal fields, shows heavy alkali ground waters in the western portion of the field, with the Souris river as the only logical body of water draining an area where the alkali deposits are not so prominent as in the western section, and with its course so situated as to render the creation of a very large reservoir of water economically feasible without serious damage to arable land in the vicinity, storing sufficient water for both a very large electrical generating station and for all industrial undertakings which might be established in the vicinity of such a station due to its ideal location.

On a cursory survey of the situation, this location must be within a very limited radius of the town of Estevan.

The question of the possibilities of economical distribution from a plant so located has often been raised, a study of the Shannon river development scheme in Ireland, with an initial development of 75,000 horse power, will, to a certain extent, adequately answer this question. As this scheme is proposed to be a state-wide scheme, and if we consider that they propose to leave out the industrial area of Northern Ireland from this scheme, it will be seen that the conditions are very similar to those governing in Southern Saskatchewan, and by placing a map of Ireland over Southern Saskatchewan, with the development site near Limerick on Estevan, it will be seen that the territory to be covered is very similar. If further proof is required of the feasibility of such a scheme, a study of the Australian scheme for the supplying of power to South Eastern Australia from the lignite fields in the vicinity of Victoria, N.S.W., boundary, and the development scheme in the area of the Golpa open pit mines in Germany, are a further indication of the possibility of generating at pit heads. Mining in both areas is very similar to the conditions which would govern in Southern Saskatchewan.

Two very interesting features of this 160,000-horse power German plant which have a bearing on the possibility of development at Estevan are that, due to the high ash and sand content of the raw lignite, the steaming capacity of the boilers was very unsatisfactory, and this difficulty has been obviated by blowing dry pulverized fuel into the furnace, increasing the boiler ratings from 30 to 50 per cent. A further factor is that a well-designed lignite power plant taking advantage of all data available at the present time can be superior from the point of view of utilization of space, compared with the best bituminous coal plant possible, thus rendering the first cost of construction of the plant considerably cheaper, and this saving can be utilized toward a reduction of rate or an increase in the distances of economical transmission, thus increasing the scope of pit head generation on the lignite fields, as against local generating systems.

From the above, it will be readily agreed that the establishment of a large generating plant for Southern Saskatchewan at the pit heads is, from the engineering and economical standpoint, possible. The next point to be considered is, is it justifiable under present conditions? A reference to Mr. Chamberlain's speech referred to above will bring out one phase of this situation, namely, the necessity for the elimination of the uneconomical small plants which are bound to spring up if a general development scheme is not undertaken in the near future.

The second factor of considerable importance to a farming, as differentiated from an industrial, community is the prospect, becoming more possible every year, of serious inroads being made into the foreign markets for our farm produce by countries who previous to the World War held those markets, and who will within a very short time possibly be again serious contenders on these markets, with everything in their favour. Even if they fail to make serious inroads into our present export market, the competition introduced is bound to seriously affect the price obtainable for our produce, making possibly production, under present agricultural methods, unprofitable. Considering the above possibility, until new markets can be found for our surplus products or until our methods of agricultural production can be adjusted to conform to the new conditions which are bound to arise, serious depression is almost bound to result unless an industrial development of our natural resources can be started to tide us over this adjustment period. Such industrial developments are unquestionably bound to be hastened by any comprehensive electrical development scheme which may be inaugurated.

On account of the sparse population and the lack of present large industrial centres, an electrical development scheme is bound to incur serious losses during the first few years of operation unless the resources available in the vicinity of the proposed plants are utilized at their maximum efficiency. This can never be done economically by the individual development of small companies, and the only scheme that is apparently at present feasible is the creation of a large holding company for the establishment of the necessary water reserves for power and industrial purposes and the adequate conservation and use of all products of such a development scheme to the maximum extent. This is only possible under unified control with subsidiary companies, thus reducing the engineering and sales organizations and expenses to an absolute minimum.

It is generally recognized that coal cannot be considered as just a fuel, but is a valuable and complex mineral resource to be conserved to the best of our ability. The report of the British Coal Commission, considered to be a masterpiece and the most comprehensive report yet drawn up on this industry, contains the following significant paragraph:—" The question of the most profitable use of coal is not the co-ordination, as is often supposed, of two industries, coal and electricity, but of several, coal, electricity, gas, oil, chemical products, etc."

A comprehensive scheme for the utilization of all by-products of Saskatchewan lignite has been very thoroughly outlined as an economic issue in the eastern financial press, and some of the salient engineering features have been touched upon recently in the technical press. Any discussion of electrical development under existing conditions in Southern Saskatchewan must of necessity touch on the economic and engineering details of industrial development as well as rural electrification, which subjects it is not intended to touch upon in this paper, except to state that the Southern Saskatchewan scheme can be elaborated and reproduced at other centres into a provincial-wide scheme, and the logical centres that suggest themselves for further initial industrial electrical development points are Regina, Saskatoon, Prince Albert and the coal fields of the north, eventually linking up with the hydro-electric developments possible on the Churchill and Nelson rivers.

The two largest steam-boiler plants within reasonable freight haulage of the lignite fields are at Regina and Winnipeg, and both of these have found it more economical to use the Alberta semi-bituminous coals in preference to lignite, partly due to the inherent defects of lignite, such as inability to store high moisture and ash content, low calorific value and low fusing point of the ash. These, however, as pointed out, can and have been overcome in the German plant mentioned, and there is no inherent difficulty in utilizing the Saskatchewan lignites in properly-designed plants, but from the results conducted so far it would appear that it is up to the people of Southern Saskatchewan, and particularly Estevan, to work out their own salvation in the matter of the utilization of the natural resources so prolifically situated at their thresholds. If this is done, quoting from Mr. Chamberlain again, " The community is bound to benefit as a whole, and what is a benefit to the community as a whole must sooner or later percolate right through to every individual part of it." Such development, however, is not possible unless local and personal interests are waived and comprehensive plans are involved for the future, and continually brought up to date as more engineering information on developments becomes available. In a survey of the industrial and scientific development of the last hundred and fifty years, it will be found that the visionary dreams of the individual electrical community or state, oftentimes considered absurd and impossible when first suggested, have by perseverence become established facts and have resulted in some of the greatest benefits to mankind, and it seems safe to state that the above applies most forcibly to the growth and development of the technical industry in its broadest aspect.

Rural Electrification in Western Canada

A Compendium of Some of the Problems Encountered in Venturing into a New Market for Power, with Particular Reference to Rural Distribution

C. A. Clendening, A.M.E.I.C.
Commissioner, Manitoba Power Commission, Winnipeg, Man.

Paper read before the Joint Meeting of the Saskatchewan Branch of the Engineering Institute of Canada, the Saskatchewan Section of the American Institute of Electrical Engineers, and the Southern Saskatchewan Section of the Canadian Institute of Mining and Metallurgy at Estevan, Sask., July 8th—10th, 1926

General

It is difficult to define rural distribution or to describe a rural line. In most localities a *rural line* is taken to mean one that serves farmers only. This limits the field too closely, for there are many lines serving hamlets and even villages, as well as farmers, that might comprehensively be described as rural lines; so, for the purposes of this paper, rural distribution will mean service to hamlets and villages as well as to farmers.

It is only within the present decade that any nation-wide attempt has been made to study and meet the rural demand on this continent. Perhaps the Great War may be given the credit or cited as the cause which gave an impetus to this movement. Previous to the war there were, of course, many transmission and distribution systems all over the continent, linking up great and small cities and serving en route towns and even villages where there was sufficient manufacturing load to bear the cost of a substation and local distribution system. But the feasibility of serving the hamlet and the farmer had not been determined. It is true that there were many distributing companies, composed largely of consumers, who purchased energy en bloc from an operating company for distribution to themselves. They assumed all the risks.

The scarcity of labour and its high cost; the movement of great bodies of rural population and consequent widening of knowledge of and demand for modern conveniences; the release of capital diverted temporarily into war channels; the prosperity of sections of the farming community; an increasing diffusion of knowledge of the utility to rural people; and the increasing density of population have all been causes contributing to the movement. To these should be added the perception by the management of the utilities that the great mass of the rural population must be served electrically, otherwise they would serve themselves. Whatever the cause, there is at the present time a very widespread endeavour on the part of operating companies to study and develop the rural field. In 1923, the National Electric Light Association, collaborating with the United States Department of Agriculture, the American Society of Agricultural Engineers and the National Farm Bureau Federation, appointed a committee of experienced engineers to study the problem, and, under their guidance, in seventeen of the United States, experimental lines have been constructed and the results of the operation are being closely analyzed.

In Canada we have the outstanding development of the Ontario Hydro-Electric Power Commission, who, since 1911, have been working on this problem, and at present are serving over 20,000 rural consumers. In one year alone, 1920, this commission caused personal visits to be made to 22,000 farmers, to determine the feasibility of giving them electrical service. In the Prairie Provinces, a beginning has been made along these lines in Manitoba by the Manitoba Power Commission, but this system is in its early development state, and no conclusive data may be expected from it for a year or two. The Commission is now actively engaged in the study of the farm problem. During the past year approximately forty miles of rural lines have been built. Many petitions for service have been received and are now under investigation.

The Market

All will agree that there must be a nucleus of demand or potential market before a development of this nature may take place. One illustration of this will suffice. In the northern parts of Manitoba and Saskatchewan are the Nelson and Churchill rivers, with five or six million potential horse power. Why are they not developed? Because there is apparently no convenient market. There are no large consumers of power, no large centres of population close enough to the power sites to carry the tremendous annual charges on the cost of development of the sites and the building of transmission lines. There must, therefore, be a ready market for the sale of power or a market capable of development.

The potential rural market has long been overlooked or neglected. There are isolated examples to the contrary, as in Ontario, in California among the irrigated farms, and in some of the states where small cities and towns, all containing manufacturing plants, and thickly scattered over the countryside, form centres of distribution from which rural communities are served, but, generally speaking, it has not been considered sufficiently profitable to merit development.

The urban demand in many localities has made it unnecessary to sell electricity; it has sold itself; but rural districts are now demanding service, and the industry is busy trying to satisfy this demand. In most cases, however, great difficulties are encountered; returns on capital are small, and, compared with urban distribution, the capital invested per consumer is large, load factor is low and demand irregular. Low density of population and small consumption of energy per capita contribute largely to the difficulties of the problem.

There are many points of difference between rural and urban distribution; in the design of the lines, in the load demand, in the consumption, in the methods of service and in the general aspect of the subject.

To-day we hear engineers speaking of customer miles, of kilowatt miles, instead of kilowatts per thousand feet of line or per hundred square feet. We hear such things as yearly service charge per farm instead of minimum monthly charge; kilowatt-hour per pound of butter instead of per ton of steel, and so on; power costs per bushel of grain threshed, per ton of ensilage cut, etc. A new nomenclature has come into the engineer's language, and those who are dealing with such matters have had to revise their tables, alter their constants and make new curves and graphs to depict the condition and results.

It is evident that new methods of obtaining revenue, of increasing consumption, must be developed if rural lines are to show a profit or even be self-supporting. The market, therefore, must be developed along the lines of showing the consumer value for his money, and once this point is demonstrated the saturation point will be easier to approach.

In the Ontario Hydro-Electric Power Commission, three farmers or hamlet consumers, or 15 kilowatts per mile, is set as the minimum requirement at the published rates for the extension of a rural line from a village or town. In Manitoba, if two farm services per mile between villages cannot be obtained, the service charge becomes so large as to prohibit, in many cases, the extension. In some of the states the requirement is that the farmer shall make a definite investment in wiring and current-consuming devices to the value of over $500. In other states the farmers are required to finance the building of the line from the centre of distribution.

In western Canada, our problem differs from that in eastern Canada or from that in the eastern or middle states. Here we have a lower density of population. In Saskatchewan, for instance, of a total area of 161 million acres, with 44 million acres occupied as farm land, the total population, 1921 census, is 757,510, including a rural population of 538,552. Taking the area of assessed land as a basis, the rural population per square mile is approximately eight.

On the same basis, the rural population of Manitoba is approximately fifteen. In Ontario, on the same basis, the rural population is thirty-five per square mile. These figures should not be taken as a measure of the prospective market for power, but only as a comparison of the relative densities of rural population. In western Canada towns are infrequent, and there is little or no manufacturing. The farmers have heretofore been largely grain growers, and except in the cultivating of the fields are not large consumers of power. In eastern localities, every small town has a manufacturing plant of some kind which uses power. The farmer raises more stock, more dairy products, and has a greater use for power in a confined area, which is a great essential to low unit cost. There is, therefore, more consumption per dollar of capital invested in construction. Rates can be lower and greater encouragement given to the market, resulting in profit. As the soil becomes impoverished in western Canada, and no longer responds to mining methods but requires diversity of product, and, as the population becomes denser, then the problem of cost will become simpler. It will be seen that conditions here are even more difficult than in the east.

Here in our own country we have reached the point at which the future of the Dominion is in our own hands. It is in our power to develop into a great nation,—the biggest link in the British Empire. The prime essential would seem to be an increase in population, not necessarily in the present urban centres, but most certainly in the rural areas, because for a long time agriculture must remain our basic industry. We require the best class of immigrant it is possible to obtain, preferably the experienced and intelligent farmer. We must strive to attract and welcome the best settlers only, and, when we get them, keep them on the land. Many of the present-day farmers do not consider the farm their permanent abode. They think of it as a means whereby they may accumulate sufficient capital to enable them to retire to some comfortable urban centre to enjoy life according to their tastes. Agriculture is the most essential industry in any nation. In the older communities, families occupy the same land generation after generation. In this newer land, the majority of childhood scorn the farm and at the first opportunity desert the land and swarm to the bright lights.

Farming in this country must not only be profitable, but also the farmer and his family must be comfortable and contented. They must enjoy being agriculturists. Chief amongst present-day comforts and conveniences is electricity. If we can serve the farmer with electricity and teach him its proper uses, then it will indeed become a factor, and a great factor, towards settling the land problem.

Now, are we to sit back and wait and hope for a dense population to serve at an assured profit? Or will we place this incomparable servant and convenience at the farm door now, to the limit of our ability and resources, and thus assist in attracting the population so necessary to our future prosperity?

The Source of Power

Power may be developed by any of the methods in common use,—steam, fuel-oil, natural gas, producer gas, water falls, wind power.

In Manitoba there is the Winnipeg river, which can serve practically all of the settled portion of the province. In Saskatchewan there are the Souris coal fields but no large water power within easy transmission distance of the farming communities. In Alberta there are many water powers and coal fields and wells of natural gas.

Power may be developed in one large central station or in a number of stations of greater or smaller size, either connected or isolated, as the case may be. This paper does not deal with the central station problem, but the power may be generated, and its cost at the bus-bar is a very important factor.

In small systems, where the farthest point of transmission does not lie beyond, say, 25 miles from the point of generation, the cost may go beyond 3 cents per kilowatt hour at the bus-bar. But beyond this distance it should be below 3 cents, and as the distance goes beyond 100 miles it should drop below one cent. The reason these limits are chosen is that power losses in transmission and distribution of from 20 to 70 per cent are experienced, and even 70 per cent may be exceeded. If, then, the cost at the consumer's meter is beyond 5 or 6 cents, and in addition there are the fixed and operating charges service on the line, the total cost of the kilowatt hour becomes so high as to make its use prohibitive.

The voltage of generation is not a very weighty factor in the general case. It is assumed that only a.c. is being considered, and it is readily increased in pressure. At present, 3-phase, 60-cycle current is the most common; 60-cycle current creates higher transmission losses than 25-cycle, but there are compensating advantages, such as lower cost of apparatus per unit of capacity, which make it desirable.

The Method of Distribution

The first step in rural electrification is to obtain a supply of energy at a centre of distribution. The centre of distribution may be the generating station or a point in a link of a transmission system. Let us assume that energy is available at this point at a suitable voltage and a market is waiting for service. The load may be purely farm load, village load or combination of both.

The size of the load and the distance transmitted determine the voltage and type of line to be built. Experience gained formerly in transmitting large blocks of power long distances at stated voltages is not necessarily a true standard by which to design rural lines, because on the latter the load demands are much smaller and consequently the distance of transmission may be greater. Voltage regulation determines the distance of transmission on rural lines. The present market may not be the ultimate market, and in the future the line may require to be extended far beyond the original terminus. Consequently, before deciding on the voltage and type of line, the whole area capable of being served from that centre of distribution should be investigated.

It would appear that 11,000-volt star connection is the limiting voltage from which farm and village loads may be economically tapped off the same line, and 30 miles might be taken arbitrarily as the limit of transmitting distance at that voltage. From this line farmers may be served single-phase with 6,600-volt transformers at a cost not greatly in excess of the usual 2,200-volt type. For distances up to 15 miles, 4,000-volt star connection is a very useful voltage to use, as all equipment is standard, easy to obtain from stock, and protective equipment is low in price. With the same size of pole and conductor, there is little difference between the cost of an 11,000-volt line and a 4,000-volt line.

In the majority of systems at present operating, transmission between generating stations and large cities and towns is affected by 66-kv. or 110-kv. lines. From these towns 40-kv. or 22-kv. lines link up other small towns and villages, and from the latter 4,000-volt, 6,600-volt, 11-kv. or 13-kv., 3-phase lines radiate. From these mains single-phase lines are taken off to serve consumers located in the surrounding territory.

In one of the northwestern states there is a 40-kv. loop 250 miles in perimeter, fed at two points, the longest leg being 150 miles. This seems to be a considerable distance to transmit energy effectively at 40-kv. In Manitoba, there is a 2,200-volt line serving two small villages and some farmers which is 15 miles long and is giving good service. These distances are cited to show the nature of the load demand and the danger of using the usual standards in designing or estimating rural lines.

A 3-phase, 22-kv. line can be built for under $1,500 per mile, using 35-foot butt-treated poles, triangular spacing steel pole tops, No. 3 copper or equivalent, normal pole spacing 250 feet, guyed at road crossings and at the half-mile.

A 4,000-volt or 2,200-volt, 3-phase line, using the same type of construction, will cost about $1,400 per mile. Using No. 6 copper, 30-foot poles, 200-foot spacing, it can be built for about $1,120 per mile. Single-phase, 2,200-volt or 6,600-volt lines with 30-foot poles, 150-foot to 200-foot spacing and No. 6 copper cost from $650 to $800 per mile, depending on local conditions and the amount of *sand papering* which the line receives.

These are lines of substantial construction for their purpose, and, with reasonable maintenance, will last from 15 to 25 or 30 years. None of them include ground wires or right-of-way.

Cost of farm services vary; a 3-kw. service directly off the line to the buildings costs approximately $85; the half-mile-long service of 15-kw. or 20-kw. costs $1,000 to $1,500.

It seems reasonable to assume that there will not be required, for a long time, in the Prairie Provinces any greater voltage than 4,000-volt to serve the farm load. The choice of voltage at the beginning of this development of farm service is important. Complications will arise and costs increase if more than one voltage is chosen, since apparatus of the various voltages will have to be carried in stock. Unfortunately, sufficient test data have not been collected on the Manitoba Power Commission's system to furnish tables of demand and consumption. However, curves can be obtained from other operating utilities.

The Rate Structure

The fixing of rates for village or farm service is a very contentious matter. It may be stated that in villages and small towns, 20 cents per kilowatt hour for lighting and 5 cents per kilowatt hour for power are the maximum rates that can be set and still obtain a fair consumption. This is a point for argument, but experience has shown that consumers are very careful of the use of power at these rates and will not use it freely.

At these rates, in villages and towns where there no street lights, consumptions lower than 50 kilowatt hours per capita per annum occur. With street lighting it goes as high as 170 kilowatt hours. With rates of 15 cents and 4 cents, respectively, it ranges from 150 to 200 kilowatt hours per capita per annum.

These consumptions are obtained without any intensive selling of appliances. With careful education and energetic sale of appliances, there is no reason to doubt that these consumptions will go as high as 350 kilowatt hours per capita per annum, even at 15 cents and 4 cents, without greatly increasing the peak demand.

When farm rates are considered, a new factor is encountered, but perhaps it would be well to revert at this point to a short study of any rate structure, considering only transmission and distribution costs. There is first the cost of power. In the transmission end of the rate this may be a rate per horse power or per kilowatt year or a kilowatt hour rate. In rural distribution it is usually a kilowatt hour rate, for the reason that the load factor at present is not definitely determined, and diversity factor on a kilowatt year rate might approach 100. Whatever unit is used, the rate should cover interest, sinking fund, replacement reserve or insurance on the capital cost of construction, taxes, maintenance and operation, and in addition the cost of power at the receiving end. It will be readily seen how the cost of the kilowatt at the receiving end decreases with the increase in the load factor up to the point where the capacity of the line is reached. These are bare costs, to which may be added profits or dividends. Then in a village there are the same charges on the distribution system, and, when all these items are added, the cost of the kilowatt hour to the consumer is obtained.

These are the items of cost, but they are treated in various ways. The treatment varies, whether the utility is financed by private or public capital. In Ontario, the Hydro-Electric Power Commission may suspend for five years certain of the fixed charges. In some private companies this section of the utility is operated at a loss for a time until increasing consumption and revenue overtakes the accumulated losses.

The rate to the village is applied in many ways. Some companies put the same rates into effect in all small towns and villages over a large area. In other localities each section of the transmission system is self-supporting, that is, each new town taken on carries the yearly cost of the extension of line necessary to reach it. The Ontario Commission arrive at the wholesale rate by a system of mileage and demand. These comments apply to a transmission system; where there is an isolated plant, the town or village carries all of the yearly costs unless the operating company is absorbing a loss in one town by spreading it over other towns operating at a profit.

Coming back to the farmer's rate, it is becoming a recognized principle that the farmer must carry the fixed charges on the line from the centre of distribution and pay an energy charge in addition. The fixed charges and maintenance on a farm line may be taken as 12 to 15 per cent per annum. Operation costs vary with the mileage patrolled by one man, for this is practically the only operating cost.

One mile of line costs, say $1,120, this being the main trunk through the district.

The fixed and maintenance charges, at 15 per cent per annum are	$168.00
Cost of patrolling	15.00
Total annual costs	$183.00
With 3 farmers per mile, each share will be	$61.00
Taking the capital cost of a 5-kw. farm service at $200, with an annual charge of	30.00
Service charge per farm per annum will be	$91.00

In addition, there will be the cost of energy, which should not exceed 8 cents per kilowatt at the meter. It is quite evident that the costs of construction must be kept to the absolute minimum, otherwise the cost of service becomes prohibitive.

The Ontario Hydro-Electric Power Commission base their rates on the cost of the kilowatt mile. All consumers within a certain zone are charged the same rate for the same class of service. The zones have no geographical or political boundaries.

Other utilities use different systems. The Adirondack Power Company establish a rate for the first consumer outside the village. If another farmer farther out desires service, estimates are made of the cost of extension. If the average rate for these two farmers does not exceed the first farmer's rate, both have the same rate. If it exceeds the first rate, the latter remains the same, number two farmer paying the excess, and so on as new extensions are made.

In some localities the utility finances and constructs the line and services, recovering its costs in the yearly service charge. In others the farmers finance and the utility constructs the line, or the farmers also do the construction and the utility sells energy at the centre of distribution. There seems to be a trend towards the utility both financing and constructing the line, thereby controlling more effectively the design and operation and making it easier for the farmers to finance.

The rate must be reduced to its simplest terms before quoting to the farmer. He cannot be expected to understand the complicated process by which it is constructed. He is first of all interested in the cost in dollars and cents of the classes of service offered. The value received for expenditure made must be demonstrated.

Experience gained in localities where farm service has been given a trial, where a demonstration of the great variety of uses has been made, shows that he becomes a satisfied and even enthusiastic consumer. Even though his rates are higher, he would not be without the service at much higher cost. Much of the time formerly expended in tedious chores is released for more profitable work. The quantity and quality of produce is increased, and he finds that electrical power is not only a convenience but a money-maker as well.

Whatever the rate, or however it may be apportioned, there must be an intelligent and continued effort on the part of the utility or some directing body to develop the greater use of electrical energy. Its use for lighting is the first, but should not be the last to which it is put. By lighting the buildings efficiently and cheerfully, and by taking the drudgery out of the chores, farm life can be made comfortable and attractive, and these improvements will go a long way in retaining for agriculture its position as the basic industry of our country.

Here is a problem that challenges the best thought and skill of the engineer.

Conclusion

1. Much experimental and constructive work has been done in rural electrification and valuable data on the result are available.
2. At the first glance, the market in the Prairie Provinces does not appear capable of development, owing to low density of population and long distances between consumers.
3. A closer study reveals certain localities that are capable of immediate development.
4. Development of a market attracts and makes feasible adjoining markets.
5. Standards set and results obtained in other localities should be used with caution when applied to conditions in the Prairie Provinces.
6. The electrification of the rural field must be accompanied by an intelligent direction and demonstration of the varied uses to which electricity may be put.
7. Costs must be kept low and construction simplified.
8. Rates must be simple.
9. In the initial stages of development, large returns cannot be expected on the capital invested.
10. The benefits derived from rural electrification cannot be fully estimated; its dividends are cumulative.

The writer is indebted, for a great part of the information from which this paper has been written, to the officials of the Ontario Hydro-Electric Power Commission, the Northern States Power Company, the Otter Tail Power Company, and to articles that have appeared from time to time in technical periodicals.

Mining North of The Pas, Manitoba

Notes on Mining Claims and Mineral Prospects in the Mineral Belt North of The Pas, Manitoba

W. T. Thompson, M.E.I.C.
The Pas, Man.

Paper read before the Joint Meeting of the Saskatchewan Branch of The Engineering Institute of Canada, The Saskatchewan Section of The American Institute of Electrical Engineers and The Southern Saskatchewan Section of The Canadian Institute of Mining and Metallurgy, at Estevan, Sask., July 8th-10th, 1926

The recent discovery of valuable copper-zinc-gold deposits in granite gneiss in connection with pegmatite dykes at Kiss-iss-ing or Cold lake, and other points to the east and west, indicates that the mineralized region is much more extensive than had been supposed, and, from present information, includes the area within the hatched line on the accompanying map.

Toronto interests having taken an option on the Sherritt-Madole claims, indicated at "A," a diamond drill was brought in last fall, and drilling was completed for the present a few weeks ago, and although no definite information is yet available, information brought down by reliable parties is to the effect that the ore is of the same type as that of Flin-Flon, but of much higher grade. Its development will be dependent upon that of Flin-Flon, and if the value and extent of the ore body are as represented, it is probable that the projected railway to Flin-Flon will be extended to Cold lake, and that a transmission line for electric power may be constructed to the Bloodstone falls, on the Churchill river, about 35 miles further north, (see map), where 35,000 continuous 24-hour horse power are available, and it is probable that with small additional expenditure the possible power output could be increased to 60,000 horse power. (See page 22 of Dr. E. L. Bruce's Report on the Amisk-Athapapuskow Lake District, 1918, Memoir 105, Department of Mines, Ottawa.)

Referring now to the great Flin-Flon copper sulphide ore deposit, which is situated at Flin-Flon lake on the boundary between Manitoba and Saskatchewan, but lies mostly in the former province, and is now in process of development by New York interests and the Mining Corporation of Canada, a railway charter from mile 7 on the Hudson Bay Railway to Flin-Flon, via Cranberry Portage, has recently been granted by the Manitoba government, and bonds for construction guaranteed to the extent of $3,500,000. Surveys for this line were made several years ago, and the approximate location is shown on the accompanying map. The distance from mile 7 to Cranberry Portage over the flat lying dolomite is about 48 miles, and reported easy of construction, and when that point is reached water transportation will be available through lake Athapapuskow to the head of Schist lake, thus giving access to the Mandy mine, and, by a 4-mile wagon road, to Flin-Flon during the summer season. This route could be utilized pending the construction of the remaining 37 miles through the rugged Pre-Cambrian to the terminus, and in the rock cuts on the latter portion it is highly probable that, in the same way as at Cobalt and other points in the construction of the National Transcontinental Railway, valuable mineral discoveries will be made, for the region is well mineralized, there being numerous surface indications of copper, zinc, gold and silver.

The gross value of the 16,000,000 tons of ore at the mine is stated by Mr. Watson, president of the Mining Corporation of Canada, to be approximately $242,000,000, viz.:—

Zinc.....	$79,000,000	Copper.....	$76,000,000
Silver....	62,000,000	Gold.......	25,000,000

Mr. Phelan, chief engineer of the corporation, states, in connection with the application for the railway charter referred to, in which the corporation is interested, "*The Flin-Flon is the largest known ore deposit on the North American continent.* The ore deposit is commonly called complex, which is generally considered to mean an ore containing not only gold, silver and copper, but also zinc. Due to the scarcity of new mines and the high price of zinc in the last five years, an intensive study has been made of such ores in an attempt to treat them successfully. One of the successful methods, which is in extensive use, is the so-called 'preferential oil flotation' process. Harry Whitney's mineral department, in 1919, secured patents covering another process designed to treat such ores. This method is called the 'sulphating process,' and a large amount of money has been spent in its perfection and its adaption to complex ores in general, and the ore from the Flin-Flon mines in particular." Mr. Phelan said that it would be some time before the tests now being made at Denver would be completed, but that reports from that city express extreme satisfaction in the progress being made thus far. Eighty tons of ore and one hundred gallons of Flin-Flon Lake water were shipped to Denver a few days ago, the object being to determine the chemical action of the water. In connection with these tests, Messrs. Watson and Clark, officers of the Mining Corporation, in an interview at Winnipeg in April, stated that the present option on the property would positively be taken up and that there was no question about the discovery of a satisfactory process for handling the ore whereby values in zinc would be realized, thereby increasing the total value of the ore by about $6.00 per ton. Present value of this ore being from $7.00 to $10.00 per ton, it would thus be worth from $13.00 to $16.00 per ton.

When the tests are completed, it is then intended to erect a pilot smelter costing from $600,000 to $700,000 for the purpose of working out further details of the process on the ground, and after this has been operated so as to determine any modification that may be necessary, the regular smelter to handle the full output will be installed, and Mr. Watson stated that the Mining Corporation would expend approximately $12,000,000 in initial expense within eighteen months of the time the railway reaches the mine.

The construction of a smelter and mining operations at Flin-Flon will afford employment for a large number of men, so that on the border between Manitoba and Saskatchewan there is now reasonable assurance that a large mining town will soon be established.

The Mandy mine of high-grade chalcopyrite, from which over two million dollars worth of ore has been shipped to the Trail smelter, is situated about six miles south of Flin-Flon, and there is still a large amount of valuable ore to be taken out. A detailed description of this remarkably rich ore body will be found on pages 72 to 77 of Dr. Bruce's report previously referred to, also in the report of Dr. Alcock, pages 1 to 36, in Summary Report, 1922, part G, of the Department of Mines, Ottawa.

The Mandy was prospected, drilled and developed under the direction of Mr. J. E. Spurr, geologist to the Tonopah Mining Company and now editor of The Engineering and Mining Journal. In his book on the ore magmas published in 1923 he describes the ore as follows:—"The ore deposit is a sulphide lens in green schistose rocks, which are probably of tufaceous origin. The only difference between the foot wall and the hanging wall is that the latter is slightly more schistose. The ore occurs in a narrow especially schistose zone lying in more massive greenstone schist. Three-quarters of a mile from the mine is a large granite intrusion. . . . The length of the lens is about 200 feet, with a well sustained width of about 40 feet, it wedges out with depth, and in about 200 feet, more or less, practically comes to a point or becomes inconspicuous. Inasmuch, however, as the construction indicates that a large part of the vertical extent of the lens has been removed by erosion, it is evident that originally the ore body had much greater vertical dimensions; it must have been a body at least 400 feet high by about 200 feet long, and 30 to 40 feet wide at the centre, tapering above and below.

"The lens consists of practically solid sulphides, with

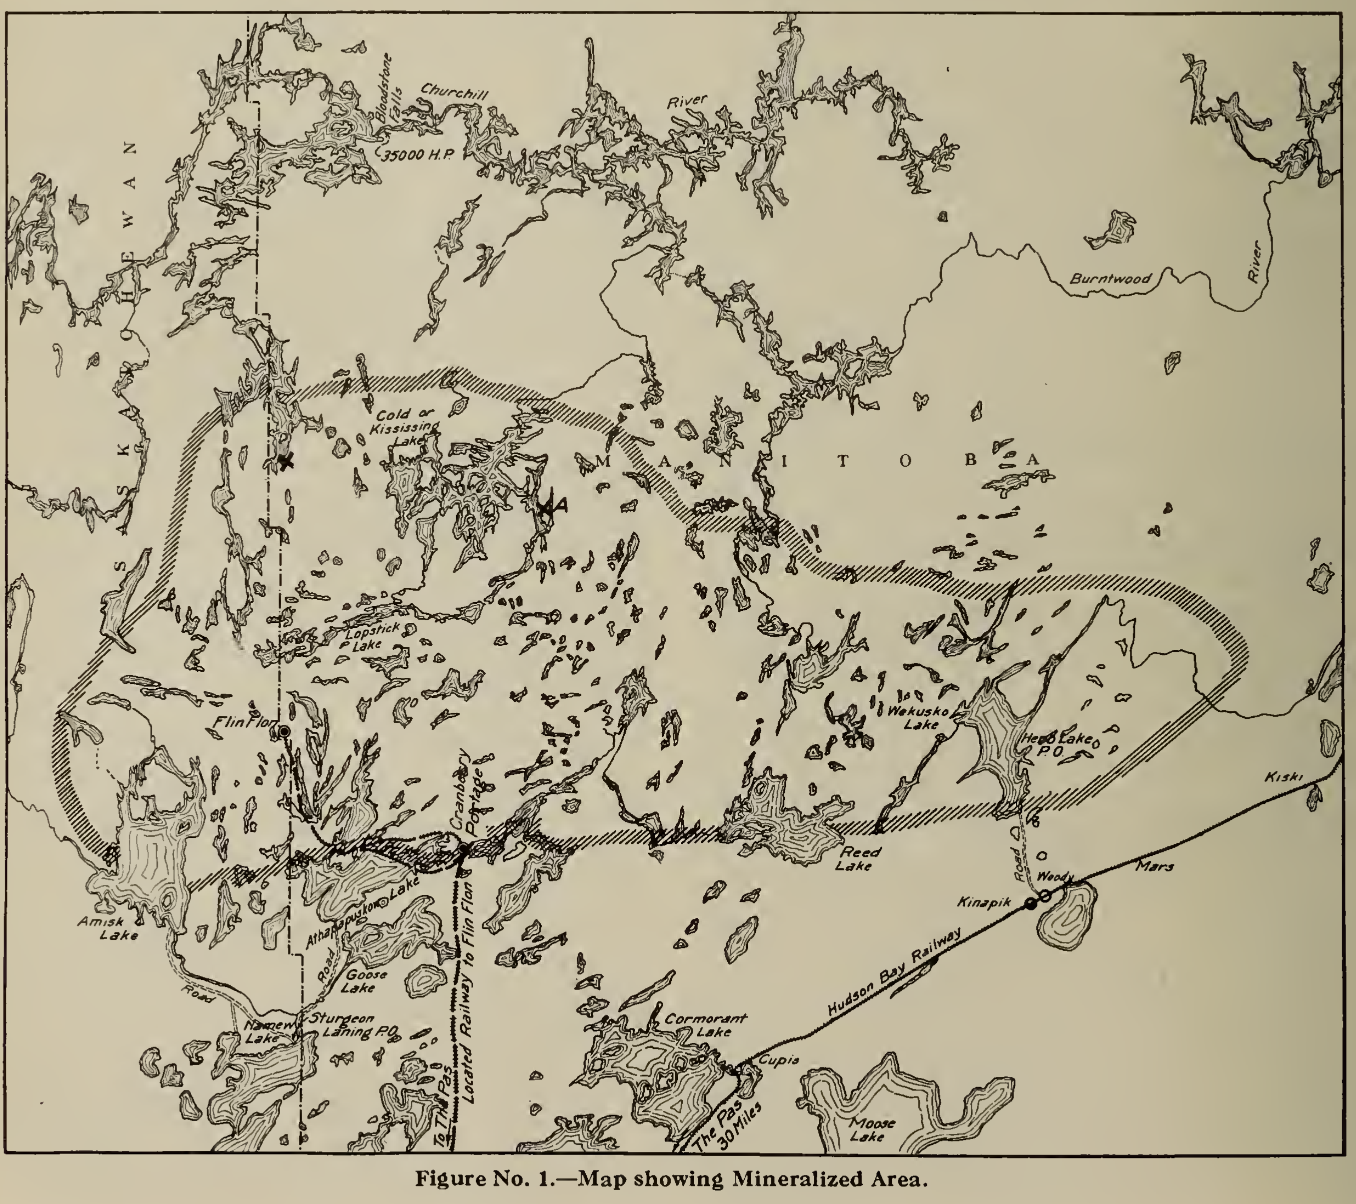

Figure No. 1.—Map showing Mineralized Area.

very little visible quartz. Massive chalcopyrite and zinc blende are the most conspicuous elements, and, though often occurring mixed and interlaminated, occur mainly in separate portions of the lens, so that it has been possible to mine the high-grade chalcopyrite separately and ship it to the smelter.

"(1) The earliest vein or vein-like formation consisted of a very unimportant amount of white quartz veinlets, and veinlets of coarse pyrite.

"(2) Massive fine-grained blende, dark red, dense and homogeneous throughout as to grain and colour, was introduced. It formed a lens, with a vertical cross-section double that of the horizontal. This lens locally contains many streaks and bands of cupriferous pyrite intimately drawn out and interstreaked with blende in such a way as could only have been done by flow. This shows that the blende and cupriferous pyrite was in a plastic form or stiff paste. This zinc ore carries up to around 30 per cent zinc when sampled in five-foot cuts.

"(3) The blende ore was split open, and high-grade chalcopyrite introduced a little diagonal to that of the cupriferous blende lens. This chalcopyrite is massive and homogeneous throughout as to texture and colour, except for streaks and bands of blende, like No. 2. This ore assays up to around 25 per cent copper when sampled in five-foot cuts. Thousands of tons mined and shipped averaged around 18 per cent copper. . . . The fine lines and bands of blende are so intimately interstreaked with the chalcopyrite, and the streaks are drawn out in such perfect parallelism, that the conclusion is that the structure is the result of flow, and that the ore could have been introduced in no other way than in a plastic form as an intrusive mass. Therefore both main periods of one deposition, first of blende and later of chalcopyrite, were intrusions of plastic sulphides. Certainly the intrusions were stiffer than is usually the case in most igneous rocks, which are introduced as solutions and crystallize after intrusion. . . ."

In a footnote, page 120 of *The Ore Magmas*, Mr. Spurr differs from the view expressed by Dr. Bruce in an article on Economic Geology, viz.:—That the banding of the chalcopyrite-blende ores was due to an original schistose structure which the sulphides have replaced. "I cannot accept this theory for which no evidence is offered. The form of the ore body is believed to be possibly due to the replacement of a drag fold in the schist. The distribution of the chalcopyrite, whose later diagonal intrusion furnishes the extensions of the ore body, which led Dr. Bruce to this conclusion, quite negatives it. Dr. Bruce agrees with my conclusions that the ore is genetically connected with the granite intrusion."

As far as is known, the Mandy lens has no duplicate elsewhere, and the views of such able geologists as Dr. Bruce and Mr. Spurr regarding the formation of this unique and remarkably rich ore body may be of interest.

It is also interesting to note the great change in the view of geologists regarding the granitic rocks of the Laurentian plateau or Pre-Cambrian shield, nearly all of which were supposed to be our most ancient rocks, and that the greenstone lavas had been poured out over them, whereas further investigation has shown that most of the greenstones or Keewatin lavas and sediments are more ancient, and that in many areas both these rocks, as well as the older granites, have been intruded by younger granites and granite gneiss, and it is in connection with these later intrusions, and especially where pegmatite dykes occur, that ore deposits may be looked for with some hope of success. When it is considered that in the vast area of the Pre-Cambrian shield, covering as it does about 2,000,000 square miles, little more than the margin of this area has yet been prospected, and yet valuable mines have been discovered, we may reasonably expect further exploration to greatly add to the number, and it is probable that the mineral resources of the Northland will be found in time to greatly exceed in value the agricultural resources of the West.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

VOLUME IX OCTOBER 1926 No. 10

Secretary's Eastern Visit

The Secretary has just returned from a journey to the Maritime Provinces and Newfoundland, during which he attended the Maritime Professional Meeting held in Sydney on August 17th and the following days, the report of which has already appeared in the Journal.

At St. John, N.B., Moncton, Sydney and Halifax the members' hospitality was much enjoyed, and the round table discussions which took place on matters of Institute affairs were most helpful. It is evident that the Sydney meeting, like the five other Professional meetings which have been held in the Maritime Provinces, has been of benefit to The Institute at large, for such meetings have greatly enhanced the prestige of The Institute in the Maritime Provinces, particularly by drawing public attention to technical questions of the greatest importance to the community. As an example of this may be taken the important programme of experimental work on Nova Scotia coals which was announced at the Sydney meeting by the Minister of Mines, and is now being put in hand by the Provincial Government. This investigation results directly from the discussions on methods of coal utilization which took place at the Halifax Professional Meeting last year and the Sydney meeting this year.

After the Sydney meeting, a number of our members took the opportunity of paying a visit to Corner Brook, Newfoundland, where we were most kindly received and entertained by the officers of the Newfoundland Power and Paper Company and the local members of The Institute. The party was able to form a very clear impression of the construction and operation of all parts of the important enterprise which is being carried out at Corner Brook and Deer Lake.

The Secretary afterwards proceeded to St. John's, where a considerable number of our members are located, many of them being engaged on the public works, highways or mining activities of the Colony. Discussion turned upon the desirability of forming some representative organization for the engineers of Newfoundland, whether as a branch of The Institute, or possibly a separate affiliated Association, and a committee was formed to consider and study this question. There is at present no corporate body of engineers in Newfoundland available for consultation or co-operation in regard to matters affecting the engineering profession, or engineering work on which public money is expended.

The last few years have seen most interesting developments in Newfoundland, not only in connection with the utilization of the natural resources of the country, but also as regards improvement in the means of communication both by land and sea.

Members of all grades of The Institute in Canada will join in wishing success to the engineers in Newfoundland in the work which they are carrying out in Britain's oldest colony.

Institute Transactions being Published

Early this year consideration was given to the question of publishing a volume of Transactions by The Institute, and in March a circular was addressed to all members of The Institute calling attention to the matter and requesting members to advise the secretary on a printed form as to their willingness to subscribe to a copy of these Transactions if issued. The subscription price per copy was set at a sum not to exceed three dollars ($3.00). The response to this circular was such as to justify the publication of a limited edition, and accordingly Council issued instructions that the work be proceeded with. Preliminary work in connection with the manuscripts is already completed and the volume will shortly be going to press.

In view of the importance of this volume, containing as it will the most valuable papers published in the Journal during the years 1923, 1924 and 1925, it is considered that a further opportunity should be given to members who desire to subscribe but who failed to so notify the secretary when the original circular was sent out. Accordingly, subscriptions will be received, and copies reserved for the subscribers, if these are in the hands of the secretary not later than November 15th, 1926.

Discussions of Papers Published in Journal

With the resumption of the publication of Transactions of The Institute, as outlined in the above announcement, the attention of the members is drawn to the opportunity afforded to submit written discussions on papers which have appeared or will in future appear in the Engineering Journal. The papers published in the Journal are read at either professional meetings or branch meetings of the Institute and these may be discussed by any member. Such written discussions should be forwarded to Headquarters as soon as prepared in order that they may be available for consideration when future volumes of Transactions are being prepared.

Annual General and General Professional Meeting

On page 386 of the August issue of the Journal there appears an announcement regarding the Annual General and General Professional Meeting of The Institute which is to be convened, in accordance with the By-laws, at Headquarters, 176 Mansfield Street, Montreal, on Tuesday, January 28th, 1927, at 8 p.m., where, after the transaction of formal business, the meeting will be adjourned to reconvene at Quebec City on Tuesday, February 15th, and will be continued during the two succeeding days. This announcement points out that the technical sessions and discussions will centre around the subjects of conservation and utilization of Canada's forest resources and the recent development of hydro-electric power in Canada. Other subjects will be discussed, and it is expected that in the November issue of the Journal there will appear a tentative programme of the meeting. This meeting promises to be one of the most interesting gatherings held under the auspices of The Institute, and members are urged to make a special note of the dates and to plan to attend this meeting.

Meeting of Council

MEETING OF SEPTEMBER 21st, 1926

A meeting of Council was held at Headquarters at 8 p.m. on Tuesday, September 21st, 1926, Past-President A. Surveyer in the chair, six members of Council being present.

The financial statement and monthly report of the Finance Committee were presented and approved, and the Committee's recommendation in regard to twenty-eight special cases were adopted. Five applications for reinstatement were considered.

Attention was drawn to the cases of a number of students who are over age for Student membership, but who have not applied for transfer, and the Secretary was directed to communicate with the various branches to which they belong, asking them to look into these cases.

Discussion took place regarding the expenditure of Institute funds available for Students' and other prizes, and a small committee was appointed in order to study the situation with a view of making recommendations as to the policy to be adopted and the best method of expending the funds available for this purpose.

With regard to the approval of Branch By-laws, the Chairman of the Legislation and By-laws Committee stated that his committee would shortly be prepared to submit a report on the divergencies which at present exist between the various Branch By-laws and those of The Institute.

The cases of two members eligible for Life Membership under Section 38 of the By-laws were considered, and Life Membership granted.

Lists of officers of the Winnipeg and Edmonton Branches were submitted and approved.

The Secretary's reports on his journeys to the Western and Maritime Branches were submitted and received.

Council noted with pleasure that the President will be able to visit Headquarters during October, at which time he also expects to visit a number of branches in the east.

A draft programme for the Annual General and General Professional Meeting to be held in Montreal and Quebec in January and February, 1927, was submitted and discussed, and approved by Council, subject to any further minor changes which may be found desirable.

Elections and Transfers were effected as follows:—

Elections	
Members	6
Associate Members	3
Juniors	2
Affiliate	1
Students	12
Transfers	
Associate Member to Member	4
Junior to Associate Member	2
Junior to Affiliate	1
Student to Junior	5

Twenty-five applications for admission and transfer were considered and classified for the ballot returnable October 15th.

Consideration was given to nine special cases in connection with applications for admission.

Council rose at twelve-fifty a.m.

The Honour Roll

An announcement regarding the checking of the list of names to appear on the Honour Roll of The Institute was published on page 414 of the September issue of the Journal, and at the foot of this announcement was reproduced the circular letter addressed to members of The Institute whose names at present appear on this war service list, with the request that any members who have failed to receive the circular should notify the secretary at once giving, on the form printed in the Journal, the information asked for regarding their service. This letter, together with the headings under which the information is desired, is again reproduced below and members are urged to forward this information to the secretary immediately, as this is the last opportunity they will have of doing so.

LETTER ADDRESSED TO MEMBERS

Dear Sir:—

The final list for the Honour Roll is now being prepared and checked, and in accordance with the directions of the Committee, is to contain the names of those members of the Institute who served, outside of Canada and the United States, with the Allied land, air or naval forces.

In order to ensure accuracy, I am sending this letter to all members of the Institute for whom we have a record of war service, and would ask you to fill in, tear off and return the enclosed slip at once.

Yours very truly,

R. J. DURLEY, Secretary.

Date...

OBITUARIES

Colonel Georges Roy, M.E.I.C.

The death of Col. Georges Roy, M.E.I.C., occurred with tragic suddenness on July 6th, 1926. Born on August 5th, 1878, he commenced his military career at the early age of seventeen, being commissioned as 2nd Lieutenant in the 1st Field Battery at Quebec on June 15th, 1895. In 1902 he proceeded to South Africa with the 4th Canadian Mounted Rifles, returning within a few months owing to the declaration of peace. Resigning his appointment, with which he then held the rank of Captain, he entered the Permanent Force as a Lieutenant in the Royal Canadian Artillery on August 13th, 1903. He was promoted to Captain on November 19th, 1906; Major on May 28th, 1915; substantive Lieutenant-Colonel on April 1st, 1920; and Colonel on January 12th, 1922. Appointments which he held included

COLONEL GEORGES ROY, M.E.I.C.

those of Officer Commanding the Royal Canadian Artillery; Commandant, Royal School of Artillery; Chief Instructor of Artillery; Inspector of Artillery (Horse, Field and Heavy); Officer Administering Royal Canadian Artillery (later changed to Colonel Commanding, R.C.A.), and Staff Officer for Artillery, National Defence Headquarters. In addition, he was at the time of his death a member of the Mobilization Committee and Chairman of the Standing Arms Committee.

On May 23rd of this year Colonel Roy assumed the acting command of Military District No. 5, with Headquarters at Quebec, his old home and birthplace. On July 6th he was appointed to command the district in succession to the late Major-General J. P. Landry, and it is one of the ironies of fate that he should have died so soon after attaining one of his life's ambitions. There is no doubt but that had he lived he would have proved a very acceptable and able commander of this essentially French-Canadian district.

Colonel Roy possessed scientific and academic qualifications which are not usually found in an officer of a regular army, being a graduate of Laval University of the year 1901 and a qualified civil engineer, with the degree of Bachelor of Science. After graduation, he studied Law at the same institution and completed the full course, although owing to proceeding on active service to South Africa he did not take the examinations.

On the outbreak of war in August, 1914, fate, combined with his own efficiency and the necessity of retaining in Canada some senior qualified officers for instructional purposes, again stepped in, and for over two years he was prevented from seeing service at the front. He never, however, for a moment permitted his keen disappointment to overcome his high sense of duty, but threw himself wholeheartedly into the tasks that lay before him. As Inspector of Artillery; O.C. Royal Canadian Artillery; Commandant, Royal School of Artillery, and Chief Instructor of Artillery,—appointments, which under the exceptional circumstances, he held simultaneously,—he was the man chiefly responsible for the artillery training in Canada of the reinforcements for the Canadian Expeditionary Force. The gunnery courses at Petawawa during the early years of the War were planned and conducted almost entirely by Colonel Roy, and the character of his training was reflected in the efficiency of the units and drafts which reinforced the Canadian Artillery in England and France.

In April, 1917, Colonel Roy achieved his ambition when he was at last permitted to proceed overseas. There being at the moment no vacancy in the Canadian Artillery, he was offered and accepted the command of the 38th Siege Battery, 63rd (Mobile) Brigade, R.G.A. With this Battery he served in the field for fifteen months, was mentioned twice in Despatches and was reported on by the Imperial authorities in the highest terms. Early in April, 1918, he was acting in command of the Brigade during the severe fighting which followed the successful German attack on the Portuguese Division, which was holding a sector of the line on the Lys. At the time of the Armistice, arrangements were in hand to recall Lieutenant-Colonel Roy to the Canadian Corps, where he was to have been given command of the new Brigade of Heavy Artillery then forming.

For over twenty years Colonel Roy was a member of the Canadian Artillery Association and for some years previous to his death was also, as Staff Officer for Artillery, an ex-officio member of the Executive Committee. His work brought him into almost daily touch with the officers of the association, and it is a real tribute to his tact and administrative ability that he succeeded during the difficult period of the post-war years in evolving artillery programmes which it was possible for the department to carry out in spite of severe financial limitations, and which were at the same time satisfactory to the non-permanent members of the association.

Colonel Roy was an exceptonially efficient soldier, who made artillery tactics and training a life-long study. His greatest asset, perhaps, was an inexhaustible fund of sound common sense. His education as a civil engineer and a lawyer was of great service to him and enabled him to bring to the problems with which he was faced a logical and trained scientific mind. He was a good disciplinarian who knew how to win the confidence as well as the ready obedience of those serving under him. He always took the keenest interest in moulding the characters of young officers, encouraging them both by precept and example to realize their responsibilities. There are many officers in the Canadian Militia who gratefully admit that they are better for their training under Colonel Roy, a man who watched over them with a fatherly eye and sought always to instill the principles of honour and an abiding sense of duty.

Although the very antithesis of a militarist, Colonel Roy was an ardent advocate of preparedness for war. He wrote occasional articles for publication and was as much at home with the English language as he was with the French tongue. Two articles from his pen appeared in early numbers of the *Canadian Defence Quarterly*. Colonel Roy was elected Member of the Engineering Institute of Canada on June 24th, 1924, and was active in the promotion of closer co-operation between the Institute and the Canadian Military and Air Services.

Colonel Colin Worthington Pope Ramsey C.M.G., M.E.I.C.

News of the untimely death of Colonel Colin Worthington Pope Ramsey, C.M.G., M.E.I.C., which occurred as a result of an automobile accident on September 11th, 1926, has been received with great regret by his many friends in the engineering profession and in public life throughout Canada. Colonel Ramsey was returning to Montreal in his car after visiting an estate at Bedford, Que., which he purchased early this year, when he suffered the injuries which caused his death.

The late Colonel Ramsey was born at Bury, Que., on January 15th, 1883, and received his early education in his native town. In 1901 he joined the engineering staff of the Canadian Pacific Railway and during the next four years occupied successively the positions of rodman, draughtsman, transitman and resident engineer. In 1905 he was appointed assistant engineer in charge of the location of various lines and two years later occupied the same position in charge of the construction of various lines. In 1910 he became division engineer of construction and the following year engineer of construction and subsequently chief engineer of construction.

Colonel Ramsay entered the militia while a young man, becoming Adjutant of the 7th Hussars. Early in 1915 he joined the Canadian Expeditionary Forces as Lieutenant-Colonel, Canadian Engineers. He formed a battalion of engineers under the name of the Canadian Overseas Construction Corps, being promoted to Colonel in April 1917. As a result of his work in France, he had conferred upon him the distinction of Companion of St. Michael and St. George and the Distinguished Service Order. At the end of the war he returned to the Canadian Pacific Railway as superintendent. In March, 1920, he entered the firm of Dominion Construction Company and Ramsey, engineers and contractors, and the following year he became a director of the Grenville Crushed Rock Company, engaged at the same time in consulting engineering.

The late Colonel Ramsey was admitted to the Institute as Student on October 8th, 1903, and was transferred to Associate Member on October 8th, 1908, and to Member on April 11th, 1914.

Allan Gordon McLerie, A.M.E.I.C.

Through the death of Allan Gordon McLerie, A.M.E.I.C., general manager of the Fairfield Aerial Surveys Company (of Canada), Limited, which occurred while on duty at Kenora, Ont., on August 4th, 1926, commercial aviation in Canada has lost one of its early pioneers and staunch supporters, and to those who have had the pleasure of knowing him the news of his death has come as a great shock.

The late Mr. McLerie was born at Windsor, Ont., on December 7th, 1888, and following completion of his public and high school education he carried on his studies through an engineering course with the International Correspondence Schools. From 1907 until the beginning of 1911 he was engaged in junior engineering work on the National Transcontinental Railway, successively occupying the positions of rodman, draughtsman and instrumentman. In March, 1911, he was appointed resident engineer on this work at Winnipeg, Man. In April, 1913, he became resident engineer on the Banff-Windermere road, British Columbia, and in March of the following year was appointed in the same capacity in connection with the work of the Greater Winnipeg Water District, subsequently being appointed assistant division engineer on the same work.

In December, 1916, Mr. McLerie joined the staff of the Walbridge Aldinger Company, at Detroit, Mich., as superintendent of construction. In March, 1918, he joined the Royal Air Force as cadet and lieutenant and acted as field instructor at Camp Borden, Ont. Following the Armistice he carried out the trial of a mail route between Toronto and Camp Borden for six months and, flying through all weather conditions, he demonstrated the feasibility of commercial aviation in Canada. He then returned to the Canadian Air Force at Camp Borden and remained there until he joined the Fairchild Aerial Surveys Company at Grand'-Mere, Que., in 1923, as manager of the mapping division. In the spring of 1926 he was appointed general manager of the company and held this position until his death.

Mr. McLerie was admitted to The Institute as Student on October 14th, 1911, and was transferred to the class of Junior on June 22nd, 1912, and to that of Associate Member on July 22nd, 1919. He was also a member of the Detroit Engineering Society and the Automotive Engineering Society.

Addresses Wanted

A revised list of members is being prepared for publication in the form of the Year Book, and it is desired to have this list as complete as possible. The following is a list of members for whom there is no address on file at headquarters. The Secretary would appreciate any information as to the present address of any of these members.

Members

A. Angstron	J. F. Guay	H. Longley
J. R. Barlow	A. E. Johnson	A. H. Smith
T. B. Campbell		

Associate Members

W. A. G. Adams	W. E. Janney	G. M. Ponton
P. I. Baker	W. H. Jones	H. H. Robertson
W. L. Ball	L. W. Lester	P. Oakley Spicer
A. R. Black	H. Lindsay	M. S. Sutherland
W. H. Blanchet	H. Macneil	C. F. Szammers
D. M. Bright	J. C. Meade	W. E. Tidy
J. Erskine	W. M. Miller	T. W. Webb
R. J. Fisher	C. N. Mitchell	J. L. Wilson
J. L. Franzen	F. W. Pearson	W. G. Wilson
J. Hole		

Juniors

G. N. Allen	G. A. Emslie	J. A. M. Penrose
F. D. Austin	J. H. Hewson	L. A. Perry
E. Bryant	R. G. MacKenzie	J. H. Ryan
T. Clarke	C. A. McConville	

Students

W. W. Abernethy	W. J. Evans	T. W. Kennedy
J. M. Allen	J. W. Fagan	W. J. Lewis
A. G. Anderson	R. W. Farmer	R. E. Lindsay
M. Balfour	R. H. Foss	R. St. C. Low
P. E. Bauman	J. M. Fraser	E. M. O'Brien
A. Benjamin	C. H. Frid	J. H. Oliver
C. M. Bowyer	L. Gareau	R. J. Rainnie
G. F. Bryant	A. J. Grant	L. L. Roquet
E. W. R. Butler	J. H. Halliday	L. J. Scott
H. Carignan	S. B. Hansuld	R. C. Shanly
J. A. Circe	R. A. H. Hayes	T. G. Sillers
F. L. Code	D. A. Henderson	W. L. Simpson
H. Crutchfield	R. M. Hueston	S. W. Williams
W. V. Delaney	C. B. Jandrew	F. E. Wilson
C. D. Evans		

PERSONALS

J. Grant MacGregor, M.E.I.C., formerly of Red Deer, Alta., is at present municipal engineer with the Manitoba Department of Provincial Highways and is located at Killarney, Man.

J. E. Letson, A.M.E.I.C., is at present with the Imperial Pipe Line Company, Limited, at Wayne, Mich. Mr. Letson was for a number of years resident engineer, Imperial Oil Refineries, Limited, Montreal East.

G. L. Bockus, A.M.E.I.C., who for some time has been with the Shawinigan Engineering Company, Limited, Montreal, is now with the Canadian Celanese Limited, Drummondville, Que. Mr. Bockus was for a time superintendent of power, city of Sherbrooke, Que.

Norman D. Wilson, M.E.I.C., of Wilson, Bunnell and Borgstrom, consulting engineers and town planning engineers, of Toronto, is shortly leaving for Mexico on business in connection with the tramways in Mexico City. Mr. Wilson has recently returned from Brazil.

J. B. Barnum, A.M.E.I.C., who was reported in last month's Journal as being with the Foundation Company of Canada, Limited, is on the staff of the Canadian International Paper Company, representing them on the construction of the Gatineau storage dams.

Frederick H. Palmer, A.M.E.I.C., has been appointed to the post of Canadian Trade Commissioner in Milan, Italy, his present address being via Manzoni 5, Milano 2, Italy. Mr. Palmer is a graduate of Nova Scotia Technical College of the year 1913.

E. M. Van Koughnet, S.E.I.C., has accepted an appointment to the staff of the Shawinigan Engineering Company, Limited, and is at present engaged on power line work for the company. Mr. Van Koughnet received his diploma of graduation from the Royal Military College in 1922, and subsequently attended McGill University.

W. B. Crombie, A.M.E.I.C., formerly construction engineer with the Abitibi Power and Paper Company, is now resident engineer for the Spruce Falls Company, Limited, in charge of the construction of the company's new mill at Kapuskasing, Ont., and the hydro-electric power development at Smoky Falls.

Major C. A. Doherty, A.M.E.I.C., formerly superintending engineer, North Eastern District, Department of Works and Buildings, Air Ministry, Bedfordshire, England, has been transferred to the Air Ministry Headquarters to take charge of the Designs Branch (Works). His present address is Alexander House, London, W.C. 16, England.

J. M. Duncan, A.M.E.I.C., has severed his connection with the Hydro-Electric Power Commission of Ontario to accept an important position with the Atmospheric Nitrogen Corporation, Syracuse, N.Y. Mr. Duncan was previously engaged as consulting engineer specializing in steam power plants, central and district heating plants and fuel economy, with headquarters in Toronto, Ont.

Horace L. Seymour, M.E.I.C., consulting engineer, of Toronto, and vice-president of the Town Planning Institute of Canada, will spend the greater part of the next three years in the city of Vancouver, where he is being retained as resident engineer on the city plan, with consultant privileges. A. G. Dalzell, M.E.I.C., consulting engineer of Toronto, who is associated with Mr. Seymour in some phases of his town planning work, has just left for St. John's, Newfoundland, and a preliminary report, in collaboration with Mr. Seymour, is being prepared along town planning lines. For the convenience of clients, a consulting office will be maintained in Toronto under the name of Horace L. Seymour and Associates.

E. G. Richards, A.M.E.I.C., who has been on leave of absence in England, is returning to the Gold Coast, British West Africa, towards the end of October. In a recent letter to Headquarters, Mr. Richards outlines the work in which he was engaged with Major L. E. Silcox, D.S.O., M.E.I.C., when last in Africa. At that time they completed 350 miles of a close preliminary survey for a new railway commencing at Kumasi and ending at Navorongo, following the Eastern frontier of the Gold Coast Northern territories. The work to which Mr. Richards is returning will be in connection with an alternative route from the same points but along the Western frontier. He estimates that it will take until the end of 1929 before the final location is completed. Their staff on this work consists of eight Europeans and about 250 natives, and they have been successful in training several young educated natives as instrumentmen and draughtsmen.

Paul A. Beique, A.M.E.I.C., Appointed Member of Montreal Tramways Commission

Paul A. Beique, A.M.E.I.C., according to a recent announcement, has been appointed a member of the Montreal Tramways Commission by the Quebec government, succeeding the late P. E. Mercier, who had been appointed to fill the vacancy following the death of the late Dr. L. A. Herdt, M.E.I.C.

Mr. Beique is a native of Montreal and received his early education at St. Mary's College and St. Charles College, Baltimore. He later undertook his engineering studies at the Ecole Polytechnique, Montreal, from which he received the degrees of Civil Engineer and Bachelor of Applied Science. His first work was with a firm of engineers and architects. Subsequently he accepted the position of draughtsman with the Quebec, Montreal and Southern Railway.

In 1907, Mr. Beique joined the staff of Messrs. O'Brien and Mullarkey, railway contractors, in the capacity of inspector, and in the following year was appointed superintendent for the same company on construction of the Quebec, Montreal and Southern Railway. In 1909, he became associated with a firm of civil engineers and land surveyors who were engaged in private practice. In 1913 he entered consulting work, and in addition to his general practice was acting town engineer for the town of Lasalle, Que., and was a member of the Consulting Board of the Metropolitan Commission of Montreal.

J. J. Macdonald, M.E.I.C., Appointed Chief Engineer.

J. J. Macdonald, M.E.I.C., has been appointed chief engineer of The Foundation Company of Canada, Limited, with headquarters in Montreal. He was formerly located in London, England, occupying the position of construction engineer for The Consolidated Construction Company, Limited, and J. G. White and Company, Limited, and returned to Canada early this year.

Mr. Macdonald is a graduate of McGill University of the year 1911, when he received his degree of B.Sc. Following graduation he took a post-graduate course at McGill in the advanced theory of structures. Prior to and during his engineering course he had several years' experience in railway location. After graduation he entered the employ of Messrs. Waddell and Harrington, consulting bridge engineers, Kansas City, Mo., and specialized in structural design and construction, covering the work in all departments of bridge engineering. During his work he was engaged on some of the largest installations of vertical lift and other moveable bridges and also on reinforced concrete arch bridges and other structures.

Mr. Macdonald was next appointed office engineer on the staff of The Halifax Ocean Terminals project. In this capacity he had charge of structural design in connection with the harbour works, bridges, transit sheds, sewer and water systems, etc., and acted on the valuation in respect of the expropriation of property, including exchequer court work. During this period he did notable work in connection with development of the mobile pneumatic caisson method of preparing deep water foundations for quay walls and in the design of long span reinforced concrete arch bridges. He next served as resident engineer on the construction of sections of above work and spent some time at the head offices of the Canadian Government Railways at Moncton, N.B., in charge of preparation of plans and specifications for work going to tender.

Early in 1919, Mr. Macdonald accepted an offer to join a firm of British engineers and contractors with a view to introducing Canadian or American methods of design and construction in connection with reconstruction work in Great Britain and France. He rapidly advanced to the position of chief engineer and had charge of the design and construction of important works, notably the extension of the Royal Edward Docks at Avonmouth, and large grain elevators for the same port, besides a great variety of factory, warehouse and general work.

In 1923, Mr. Macdonald accepted the position of construction engineer with J. G. White and Company, Limited, of London, England. He had charge of the construction of the super-steam-electric power station for the London Counties at Barking, under their subsidiary The Consolidated Construction Company, and was connected with important foundation, tunnel, and water works contracts. He also directed extensive sanitation and harbour work in South America for J. G. White and Company, Limited, and work in connection with a number of important hydro-electric projects.

In 1925 Mr. Macdonald prepared construction layouts and estimates for the difficult foundation work for the great new bridge across the Tyne river, at Newcastle, under Sir Douglas Fox and partners for Dorman Long and Company, Limited, who secured the contract for the work. He also had charge of important road and pavement contracts.

Catalogue of Publications

The Natural Resources Intelligence Service of the Department of the Interior, Ottawa, Canada, has issued a new catalogue of the Service's publications. The function of the Service is to supply authentic information on the natural resources of Canada to all who are interested in them and in the problems associated with their development. The recently issued catalogue of publications lists the numerous reports, maps and charts which have been issued to date, and will prove of considerable assistance to those interested in making applications and enabling them to state clearly their requirements. Copies of this booklet and also any maps or reports referred to in it will be gladly supplied to any members upon application to the Director, Natural Resources Intelligence Service, Department of the Interior, Ottawa, Canada.

ELECTIONS AND TRANSFERS

At the meeting of Council held on September 21st, 1926, the following elections and transfers were effected:—

Members

BAIRD, John Ainslie, B.A.Sc., (Univ. of Toronto), engaged on sub-divisions and municipal drainage, Sarnia, Ont.

COTHRAN, Frank Harrison, gen. supt. of constrn. for Aluminum Co. of Canada, Ltd., Isle Maligne, Que.

COX, Leonard Martin, consulting engineer, San Francisco, Cal.

DEBLOIS, William Howard, B.Sc., (McGill Univ.), mgr. chem. div. Mond Nickel Co., Ltd., Coniston, Ont.

SILLCOX, Lewis Ketcham, M.E. and E.E., (Univ. of Brussels), gen. supt. motive power, Chicago, Milwaukee & St. Paul Ry Co., Riverside, Ill.

SUTHERLAND, Luther Holton Dunbar, B.Sc., (McGill Univ.), engr. i/c various bldg. contracts, E. G. M. Cape & Co., Ltd., Montreal, Que.

Associate Members

COX, Archibald, town engr. and supt. of utilities, Estevan, Sask.

SWITZER, James Everett, dist. hydrometric and irrig. inspecting engineer, Dept. of Interior, Calgary, Alta.

WOODSIDE, James, B.A.I., (Dublin Univ.), on hydro-electric development with Can. International Paper Co., Montreal, Que.

Juniors

BUTCHART, Harold Tremayne, B.Sc., (Univ. of Alta.), fuel engr., Wilson Coal & Coke Co., Ltd., Calgary, Alta.

MURPHY, George Arnold, ch. clerk, office of the gen. supt., Montreal Tramways Co., Montreal, Que.

Affiliate

VERDON, Joseph Benjamin, boiler inspector, Prov. Gov. of Quebec, Dept. of Public Works and Labour, Montreal, Que.

Transferred from the class of Associate Member to that of Member

JENNINGS, Robert Bernard, div. engr. C.N.R., Montreal div., Montreal, Que.

KESTER, Fred. Henry, contracting engineer, Walkerville, Ont.

McCRORY, James Alexander, B.S., (Pennsylvania State College), off. engr., Power Engineering Co., Montreal, Que.

MIDGLEY, Frank Harold, C.E., (Associate, Royal Tech. Coll.), engr. Lake Erie & Northern & Grand River Rys., (subs. of C.P.R.), i/c mtce. and constrn., Galt, Ont.

Transferred from the class of Junior to that of Associate Member

MOONEY, Frank Melbourne, Jr., B.Sc., (McGill Univ.), asst. engr. timber mechs., Forest Products Research Labs., South Farnborough, England.

STAVERT, Reuben Ewart, B.Sc., (McGill Univ.), gen. mgr., Brit. Metal Corp., Ltd., Montreal, Que.

Transferred from class of Junior to that of Affiliate

IRVING, George Fleming, B.Sc., (Armour Inst.), Imperial Oil Limited, Winnipeg, Man.

Transferred from class of Student to that of Junior

BISSELL, Harold Rudolph, B.Sc. '22, M.Sc. '23, (McGill Univ.), divisional engr., Copper Queen Branch, Phelps Dodge Corporation, Bisbee, Arizona, U.S.A.

BUDDEN, Arthur Napier, B.Sc., (McGill Univ.), gen. engrg., Gen. Electric Co., Mexico.

HUMPHREY, Harold William, B.Sc., (N.S. Tech. Coll.), with Public Service Electric & Gas Co., Newark, N.J.

ROSS, Malcolm Vaughan, B.Sc., (McGill Univ.), asst. elect'l engr., Brown Corp. sulphite pulp mill, La Tuque, Que.

WOOLWARD, Charles Desmond, B.Sc., (McGill Univ.), engrg. dftsman., Foundation Co. of Canada, Montreal, Que.

Publications of Other Engineering Societies

An exchange arrangement exists between the Engineering Institute of Canada and the American Institute of Electrical Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Civil Engineers and the American Society of Mechanical Engineers.

Subscriptions may be sent either directly to New York or through Headquarters. The following list of rates gives in the first column the amounts payable by members of the Engineering Institute for the various publications:—

	Rate to Members	Rate to Non-Members
American Institute of Electrical Engineers		
Journal, single copies	$0.50	$ 1.00
" per year	5.50	10.50
Transactions, per year, paper	5.00	10.00
" " " cloth	5.00	10.00
Year Book	1.00	2.00
Pamphlets	.25	.50
American Institute of Mining and Metallurgical Engineers		
Magazine, single copies	0.50	1.00
" per year	5.00	10.00
Transactions, per volume, with pamphlets, paper	2.50	5.00
(Other publications, same rate E.I.C. members as to A.I.M.M.E. members.)		
American Society of Civil Engineers		
Proceedings, single copies	0.50	1.00
" per year	4.00	8.00*
Transactions, " "	6.00	12.00†
Year Book	1.00	2.00
(Other publications 50 per cent reduction on catalogue price to E.I.C. members.)		
**If subscription is received before January 1st, otherwise $10.00.*		
†If received before February 1st, otherwise price $16.00.		
American Society of Mechanical Engineers		
Journal, single copies	0.50	0.60
" per year	4.00	5.00
Transactions, per year	6.00	8.00
Year Book	1.00	2.00
(Other publications, same rate to E.I.C. members as to A.S.M.E. members.)		

Recent Additions to the Library

Proceedings, Transactions, Etc.

Presented by the Societies:

Transactions of the Institution of Civil Engineers of Ireland, vol. 51, 1926.

Reports, Etc.

Presented by the Sewerage and Water Board of New Orleans, Louisiana:

Semi-Annual Report, 1925.

Presented by the Department of Trade and Commerce, Canada:

Sixth Census of Canada, 1921, vol. 2.

Technical Books

Presented by Professor E. A. Allcut:

Materials and Their Application to Engineering Design, by E. A. Allcut and E. Miller.

Engineering Inspection, by E. A. Allcut and C. J. King.

Presented by D. Van Nostrand Company:

Elementary Steam Engineering, by E. V. Lallier.

Presented by the Harvard University Press:

Mathematical and Physical Papers, 1903-13, by B. O. Pierce.

EMPLOYMENT BUREAU

Situations Wanted

Civil Engineer

Canadian, civil engineer, university graduate with experience in road works, construction and maintenance, desires position with engineering firm where advancement may be won on recommendation of efficient service. Business experience, age 25, single, in excellent health, speaking both languages. Best of references. B.A.Sc. At present employed, but available on short notice. Personal interview sought. Address replies to Box 213-W, Engineering Journal.

Construction Engineer

Recent graduate of University of New Brunswick, with experience in field surveys and draughting, desires position, preferably with a structural or hydro-electric organization where there is possibility of advancement. Address replies to Box 214-W, Engineering Journal.

Electrical Engineer

McGill '23, age 27, single, three years' drafting experience on the construction of substations and power stations. Eight months' test with the Canadian General Electric Co. Four months' mining and electrical maintenance in Northern Ontario. Two and half years' general commercial experience. Position in or around Montreal preferred. At present employed in New York City. Address replies to Box 215-W, Engineering Journal.

Situations Vacant

Draughtsmen

Two draughtsmen for Welland Ship Canal. Salary $150 per month. Apply, stating qualifications, experience, etc., to Alex. J. Grant, engineer-in-charge, Welland Ship Canal, St. Catharines, Ont., not later than October 7, 1926.

BRANCH NEWS

Victoria Branch

E. G. Marriott, A.M.E.I.C., Secretary-Treasurer.

On Friday, August 13th, the members of the Victoria Branch, and local members of the Association of Professional Engineers of British Columbia, through the courtesy of P. Philip, M.E.I.C., deputy minister of Public Works, were able to attend an exhibition of moving and other pictures that gave glimpses of the main highways of the province, of its scenery, and its industrial developments.

There was a large number of engineers and their friends present, a musical programme giving added enjoyment.

The location of the various views was well indicated by an arrow moving across a map of the province, and stopping at the point at which each picture was taken. Along the various routes from Victoria to the Mainland were gathered illustrations of the beautiful scenery among the islands passed. A splendid portrait was shown of the great explorer Simon Fraser, who gave to the public so much of the early information regarding this province. In the Fraser Valley, pictures of the New Westminster bridge across the Fraser river, and of Harrison lake and Hot Springs were included.

The progress in transportation was well indicated by photographs of mule teams hauling gold and supplies along the old Cariboo road in 1860, followed by views of the Canadian Pacific Railway and Canadian National Railways freight trains, and of motor stages and trucks. The old Alexandra bridge was shown in comparison with the new structure of the suspension type that has recently been completed. Actual construction work was shown in progress, the shovel on caterpillar treads attracting much comment on account of the ease with which it could be handled in awkward places. The timber cribbing along the road near Jackass mountain was an excellent example of this class of work.

Pictures taken along the various main roads of the interior, such as Kamloops to Vernon, and Vernon to Kelowna, were used to illustrate the development of these farming and orchard sections.

Photographs of the Southern Okanagan irrigation project at Oliver showed details of the well-constructed main canal, flumes, pipes, and other outstanding features of this work, which was inaugurated by the provincial government in the interests of returned men.

The magnificent Bonnington falls on the Kootenay river near Nelson came in for recognition, including the power developments of the city of Nelson and the West Kootenay Power and Light Company, which supply municipal and mining requirements to a very large area.

Transportation of logs by flume was strikingly illustrated by pictures from the works of a logging company near Cranbrook, the main flume being some thirteen miles long, served by several branch flumes from which the logs are received automatically. The excellent character of the British Columbia roads, the resulting advantage to industrial and farming development, and the variety of interest that awaits the tourist to this province were well emphasized by the pictures shown; and the thanks of the branch are due Mr. Philip for his invitation.

Vancouver Branch

E. A. Wheatley, A.M.E.I.C., Secretary-Treasurer.

Executive Meeting of August 17th

A meeting of the branch executive was held in the offices of the branch on August 17th. Further consideration was given to the subject of the relation of the Public Works Department of the Dominion to the Provincial Professional Engineering Acts. The secretary was instructed to forward to the Council of the Institute full information on this subject.

The following nominating committee for 1926-27 was appointed: Chairman, C. Brakenridge, M.E.I.C.,; members, J. Muirhead, M.E.I.C., W. O. Marble, M.E.I.C., F. P. V. Cowley, A.M.E.I.C., and Tom McElhanney, A.M.E.I.C.

Additional bookcases were ordered to be purchased for the development of the Branch Library at the University Club.

Executive Meeting of August 24th

A meeting of the branch executive was held on August 24th.

The president of the Institute, Major Geo. A. Walkem, M.E.I.C., was present, together with J. L. Rannie, M.E.I.C., past-chairman of the Ottawa Branch.

A blue print of the proposed tablet to be erected by the Institute and the Association of Professional Engineers of British Columbia, jointly, was submitted and considered. The wording adopted was:

"In commemoration of the Engineering Achievement of the two Companies of Her Majesty's Royal Engineers, who, in 1858, were responsible for the construction of the Cariboo Road.

"This Tablet is erected by the Engineering Institute of Canada and the Association of Professional Engineers of British Columbia."

The following committees were appointed, their duty being to obtain speakers for the forthcoming fall and winter sessions:

Committee No. 1—On Engineering Education

Prof. Duckering, L. F. Merrylees, A.M.E.I.C., and the Secretary.

Committee No. 2—Subjects of Mining Interest

Geo. A. Walkem, M.E.I.C., W. H. Powell, M.E.I.C., R. W. Brock, M.E.I.C.

Committee No. 3—On Electrical and Mechanical Subjects

J. Muirhead, M.E.I.C., and J. F. Frew, M.E.I.C.

Committee No. 4—On Civil Engineering Subjects

W. B. Greig, A.M.E.I.C., Chas. Brakenridge, M.E.I.C., A. S. Wootton, M.E.I.C.

A discussion was held, in which Mr. Rannie participated, on the problem of dealing with such contentious matters as the appointment of American engineers on Canadian works, and whether it was within the scope of the work of the Institute to deal with such contentious problems. It was agreed that the most satisfactory way of dealing with such problems was by very close co-operation beween the Institute and the provincial associations of professional engineers.

Branch Entertains United States Engineers

On August 28th a number of engineers and ladies from Bellingham, Wash., U.S.A., were entertained by the branch. The entertainment took the form of a trip around Vancouver harbour. This was made possible by the courtesy of the Vancouver Harbour Commissioners, who placed at the disposal of the branch the V.H.C. "Fispa."

The day being bright and warm, one of the most pleasant and interesting trips was enjoyed. Opportunity was provided to note the new work going on in the harbour, and the development of the summer resorts around the margin of the inlet. The head of the inlet, Indian river, was visited, and on the return trip an opportunity was given to see the work of the new terminal railroads being carried out by the Vancouver Harbour Commissioners.

The party landed at the new B.C. pier of the Canadian Pacific Railway, and were conducted around the pier by Sydney E. Junkins, M.E.I.C.

The day was concluded by a dinner given in honour of the engineers of Bellingham at the Hotel Vancouver, where votes of thanks were tendered, both to the Vancouver Harbour Commissioners and to Mr. Junkins.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

The members of the Papers and Meetings Committee of the branch have been working hard to arrange an interesting programme for the fall. As a result of their endeavours, the following programme has been arranged, and it is felt that a record attendance and keen interest should result:—

Date	Subject	Author
Oct. 7	—Arvida Townsite	H. R. Wake, A.M.E.I.C.
" 14	—Engineering Features of Breaking the Alleghany Ice Gorge with Thermit	Dr. H. T. Barnes, M.E.I.C.
" 21	—Manufacture of Carbide	Mr. Witherspoon
" 28	—Bearing Metal Bronzes	Messrs. Roast and F. Newell, M.E.I.C.
Nov. 4	—The American Railway Engineering Association	J. E. Armstrong, A.M.E.I.C.
" 11	—Student Papers.	
" 18	—Vacuum Process for Drying Paper	Mr. Ogden Minton
" 25	—Bryson Development	H. E. Pawson, M.E.I.C.
Dec. 2	—Railway Supplies	L. C. Thompson
" 9	—Municipal Symposium	H. A. Terrault, M.E.I.C. P. E. Jarman, M.E.I.C.
" 16	—Annual meeting.	

The chairman of the Papers and Meetings Committee would like to remind the branch that the success of the meetings is not dependent only upon the securing of good speakers, but requires a good attendance of the branch members and a lively discussion. Special endeavours are being made to increase the discussion this year, and every member is asked to do his part.

If there are any suggestions which members have for speakers for the second term, please send them to the secretary.

Trade Publications

Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa., have recently issued a publication entitled "Registers of Revenue" describing special features of the watt meter. The publication number is C-1753. The company has also issued revised leaflets Nos. L-3549-B, L-20135-A, and L-20011-A covering their types CA, CL, and CN circuit breakers and types F-11 and F-22 oil circuit breakers. These publications may be obtained from any of the district offices of the company.

The Dominion Insulator and Manufacturing Company, Niagara Falls, Ont., are now distributing a new general catalogue, No. 20 O-B. This book of 945 pages includes complete listing of all O-B porcelain insulators, trolley and line materials, rail bonds, car equipment and mining materials. It is logically divided and thumb-indexed for the well-defined classes of products of this company. In addition to descriptive and listing information, there are many helpful suggestions for the man concerned with the installation of these products. All of the material pertaining to porcelain insulators and hardware, and other pertinent data, 472 pages, is also being distributed in a separate binding, known as the Insulator Section. This special binding is for the convenience of those interested in the high tension materials only. The books are carefully indexed and convenient cross references are plentiful.

THE CHATEAU FRONTENAC, QUEBEC CITY

THE HEADQUARTERS *of the*

FORTY-FIRST ANNUAL GENERAL

AND

GENERAL PROFESSIONAL MEETING

of THE ENGINEERING INSTITUTE OF CANADA

The Annual Meeting will be convened in Montreal at the Institute Headquarters (in accordance with the By-Laws) on Thursday, January 27th, 1927, at 8.00 p.m., and will be adjourned to reconvene at

QUEBEC CITY

FEBRUARY 15th, 16th and 17th, 1927

Preliminary Notice

of Applications for Admission and for Transfer

September 19th, 1926.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in October, 1926.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

COLE—ARTHUR WM. WILLOUGHBY, of Ottawa. Ont., Born at Glasgow, Scotland, Aug. 30th, 1898; Educ., prel. D.L.S. 1915, final D.L.S. 1926; 1923 (June to Dec.), 1924 (Apr. to Sept.), instrumentman, Geodetic Survey of Can.; Oct. 1924 to Feb. 1925, instrumentman, Dept. of Rys. and Canals; Apr. to Sept. 1925, instrumentman. Geodetic Survey of Can.; Oct. 1925 to Jan. 1926, dftsman., Can. Int. Paper Co.; 1926 to date, instrumentman with same Co. 1916-19, overseas.

TREASURER
F. P. SHEARWOOD, Montreal.

SECRETARY
R. J. DURLEY, Montreal.

OFFICERS OF BRANCHES

HALIFAX
Chairman, H. W. L. DOANE
Vice-Chair., W. A. WINFIELD
Sec.-Treas., K. L. DAWSON, 115 Morris Street Halifax, N.S.
Executive, W. F. McKNIGHT, H. S. JOHNSTON, W. P. COPP, J. S. MISENER, R. R. MURRAY, J. G. W. CAMPBELL, H. F. BENNETT, D. W. MUNN, W. A. WINFIELD, C. W. ARCHIBALD, H. C. BURCHELL
(Ex-Officio) C. H. WRIGHT

CAPE BRETON
Chairman, W. C. RISLEY
Vice-Chair., W. S. WILSON
Sec.-Treas., D. W. J. BROWN, Bank of Commerce Bldg., Sydney, N.S.
Executive, J. J. McDOUGALL, W. E. CLARKE, J. R. MORRISON
(Ex-Officio) S. C. MIFFLEN, GEO. D. MACDOUGALL

ST. JOHN
Chairman, A. R. CROOKSHANK
Vice-Chair., S. R. WESTON
Sec.-Treas., W. J. JOHNSTON, Box 1417, St. John, N.B.
Executive, A. G. TAPLEY, J. D. GAREY, W. R. PEARCE, H. F. MORRISEY, E. A. THOMAS

MONCTON
Chairman, A. S. GUNN
Vice-Chair., G. C. TORRENS
Sec.-Treas., V. C. BLACKETT, Eng. Dept., C.N.R., Moncton, N.B.
Executive, F. L. WEST, J. PULLAR, G. E. SMITH, A. F. STEWART, J. D. McBEATH, J. R. FREEMAN
(Ex-Officio) F. O. CONDON, C. S. G. ROGERS, M. J. MURPHY

SAGUENAY
Chairman, C. N. SHANLY
Vice-Chair., G. E. LAMOTHE
Sec.-Treas., BURROUGHS PELLETIER, Box 181, Chicoutimi, Que.
Executive E. LAVOIE, J. E. A. McCONVILLE, J. L. DELISLE, A. A. MacDIARMID

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, A. B. NORMANDIN
Vice-Chair., S. L. deCARTERET
Sec.-Treas., LOUIS BEAUDRY, P.O. Box 115, Quebec, Que.
Executive, T. E. ROUSSEAU, H. CIMON
(Ex-Officio) A. LARIVIERE, L. C. DUPUIS, W. G. MITCHELL

MONTREAL
Chairman, C. J. DESBAILLETS
Vice-Chair., C. V. CHRISTIE
Sec.-Treas., C. K. McLEOD, 318 Lagauchetiere St. W., Montreal, Que.
Executive, A. DUPERRON, A. R. KETTERSON, J. A. McCRORY, P. L. PRATLEY, JAS. ROBERTSON, F. C. LABERGE
(Ex-Officio) C. M. McKERGOW, J. M. R. FAIRBAIRN, GEO. R. MacLEOD, K. B. THORNTON, ARTHUR SURVEYER, O. O. LEFEBVRE, J. T. FARMER, J. H. HUNTER, J. L. BUSFIELD

OTTAWA
Chairman J. D. CRAIG
Sec.-Treas., F. C. C. LYNCH, Nat. Resources Intelligence Br., Dept. of the Interior, Ottawa, Ont.
Executive, A. E. DUBUC, J. ALBERT EWART, S. J. FISHER, W. A. RUSH, A. K. HAY
(Ex-Officio) J. L. RANNIE, A. F. MACALLUM, O. S. FINNIE

PETERBOROUGH
Chairman, B. L. BARNS
Secretary, W. E. ROSS, 787 Water St., Peterborough, Ont.
Treasurer, A. B. GATES
Executive, A. E. CADDY, W. M. CRUTHERS, R. C. FLITTON, J. A. S. GOULET, P. MANNING
(Ex-Officio) A. L. KILLALY, R. L. DOBBIN

KINGSTON
Chairman, R. J. McCLELLAND
Vice-Chair., L. T. RUTLEDGE
Sec.-Treas., G. J. SMITH, 266 Albert St., Kingston, Ont.
Executive, D. S. ELLIS, D. M. JEMMETT, J. M. CAMPBELL
(Ex-Officio) L. F. GRANT, L. M. ARKLEY

TORONTO
Chairman, J. G. R. WAINWRIGHT
Vice-Chair., R. B. YOUNG
Sec.-Treas., J. W. FALKNER, H. E. P. C., 190 University Ave., Toronto, Ont.
Executive, A. E. K. BUNNELL, H. W. TATE, L. W. WYNNE-ROBERTS, A. T. C. McMASTER, I. H. NEVITT, J. KNIGHT
(Ex-Officio) T. R. LOUDON, C. B. FERRIS, E. G. HEWSON, H. K. WICKSTEED, J. M. OXLEY

HAMILTON
Chairman, C. J. NICHOLSON
Vice-Chair., F. P. ADAMS
Sec.-Treas., H. B. STUART, Hamilton Bridge Works, Hamilton, Ont.
Executive, H. LUMSDEN, W. L. McFAUL, L. W. GILL
Emeritus, J. J. MACKAY
(Ex-Officio) W. F. McLAREN

LONDON
Chairman, W. P. NEAR
Vice-Chair., J. R. ROSTRON
Sec.-Treas., F. C. BALL, City Engineer's Office, London, Ont.
Executive, H. A. McKAY, F. A. BELL, W. M. VEITCH, H. A. BRAZIER, R. ANGUS
(Ex-Officio) W. C. MILLER, E. V. BUCHANAN

NIAGARA PENINSULA
Chairman, A. MILNE
Vice-Chair., T. S. SCOTT
Sec.-Treas., R. W. DOWNIE, Box 1163, Thorold, Ont.
Executive, E. G. CAMERON, J. C. STREET, L. L. GISBORNE, W. S. ORR
(Ex-Officio) H. L. BUCKE

BORDER CITIES
Chairman, A. J. M. BOWMAN
Vice-Chair., L. McGILL ALLAN
Sec.-Treas., W. H. BALTZELL, Canadian Steel Corp. Ltd., Ojibway, Ont.
Executive, HARVEY THORNE, J. J. NEWMAN, A. E. WEST
(Ex-Officio) J. CLARK KEITH, F. JAS. BRIDGES, J. E. PORTER

SAULT STE. MARIE
Chairman, C. H. SPEER
Vice-Chair., G. H. KOHL
Sec.-Treas., A. H. RUSSELL, Engr's Office, City Hall, Sault Ste. Marie, Ont.
Executive, W. S. WILSON, A. E. PICKERING, C. R. MURDOCK, C. V. CORLESS
(Ex-Officio) C. H. E. ROUNTHWAITE, WM. SEYMOUR

LAKEHEAD
Chairman, C. B. SYMES
Vice-Chair., D. G. CALVERT
Sec.-Treas., GEO. P. BROPHY, P.O. Box 86, Port Arthur, Ont.
Executive, D. C. CHISHOLM, J. C. MEADER, W. H. SOUBA, G. R. DUNCAN
Ex-Officio H. S. HANCOCK, G. H. BURBIDGE

WINNIPEG

Engineering Features in Breaking the Allegheny Ice Gorge

Conditions Prior to the Commencement of the Work, Methods of Attack and the Results Obtained

Howard T. Barnes, D.Sc., F.R.S., M.E.I.C.
Professor of Physics, McGill University, Montreal, Que.

Paper read before the Montreal Branch of The Engineering Institute of Canada, October 14th, 1926

Description of the Gorge

Early in February 1926, the surface ice on the Allegheny river broke and moved down over a distance of some 50 miles above Oil City and Franklin, Pennsylvania. The restriction of the river at Brandon, 14 miles below Franklin, caused the ice to stop and jam in such a way that the entire mass above filled the gorge to that city, causing the river to rise, but not enough to cause apprehension. The character of the river is typical of these mid-state streams, and winds for miles between high cliffs with shallows, islands and deep hollows interspersed. The normal flow is in the neighborhood of 3,000 second-feet, but in the rainy season or with a sudden storm the level rises 20 feet or more in a few hours.

Towards the end of February a large quantity of ice came down from Kinzau, and quickly jammed into the pack which held below Franklin without dislodging or moving it. This caused the river to become packed from Franklin to Oil City, a distance of 8 miles, with a rapid rise of water level, higher than had ever been experienced by these communities. So serious was the situation with the flooding of Oil City and Franklin that the entire water works was put out of commission and Oil City was left without water or lights for several hours. The Pennsylvania Railroad put its locomotives to work supplying steam for the pumps, and the city fire apparatus was used to assist in the same work. The two cities were in very grave danger, apart from the uncomfortable condition in which the lower streets were from the high water and floating ice.

This second run of ice blocked the river up to Oil City, and left a solid ice gorge for 20 miles. In a few days more ice came down and blocked for 5 miles above Oil City, making a solid and almost dry ice jam 25 miles in extent.

Grave fear was evinced by the citizens over the situation, as it would have been impossible to cope with a heavy rain, and the normal run-off from such rain would have very materially increased the flood condition.

On the first of March a telegram was sent to the writer from the Mayor of Oil City asking for aid, and on the same day the writer left for New York, where he got in telephone communication with Oil City. In the meantime, the United States army engineer at Pittsburgh had been in communication with the Mayor of Oil City and had dissuaded him from seeking aid from the writer. From New York, the writer explained over the telephone that his methods were unknown to most engineers, and that he felt certain the flood level could be relieved, as had been done elsewhere. Later on in the day a message was received from the Oil City Chamber of Commerce by the secretary, Mr. L. H. Gavin, to come out to the Allegheny valley to look over the situation. Accordingly, the writer arrived in Oil City at noon on the third of March and at once met the combined Chambers of Commerce of Oil City and Franklin. After describing the principles of the method of ice control, which the writer had worked out during many years of study and experiment on the St. Lawrence, it was unanimously decided by the Chambers of Commerce to finance the work, and that same afternoon a special train was put on by the Pennsylvania Railroad, whose tracks followed the gorge for the entire length, and during the afternoon the writer inspected every part of the gorge. In the evening the writer again met the members of the Chambers of Commerce, when the method of attack was outlined and the various committees of co-operation were organized. A special Ice Gorge Committee was formed, and at the writer's request met every evening in the Chamber of Commerce at Oil City and at Franklin on alternate evenings. Reports of committees were received each evening, and the work laid out for the following day.

The writer realized that such a large jam could not be moved easily with no water to float the ice, and indeed, during the first week, the weather was so cold that it was useless to send large masses of ice down the river, as they merely jammed lower down. The river was free of ice below Brandon, and when the writer arrived the Pennsylvania

Figure No. 1.—Allegheny Ice Gorge from a Hill Overlooking Venango.

Railroad had been using dynamite in an effort to break out the foot of the jam.

The remaining story of the work will be given as the various steps are described. What has already been written brings the story up to the time the writer took charge of all operations, and received the loyal and hearty support of the citizens of Oil City and Franklin.

Methods of Attack

As explained to the Chambers of Commerce, every known method of attack known to the writer would be used in forcing a passage for the water through the gorge. In the writer's experience, thermit had proved the most powerful tool, and while other agencies were employed they were all of small value compared to that.

The various committees formed were:—

Thermit, under the personal direction of the writer.
Dynamite, under the direction of Mr. J. T. Ridgley, supervisor of the Pennsylvania Railroad, Allegheny Division.
Calcium Chloride, under Mr. T. C. Frame.
Ash, Sand and Gravel, under Mr. L. O. Bouquin.
Sulphuric Acid, under Mr. F. B. Hall.
Water Levels, under Mr. W. S. Wilson.
Weather Reports, under Mr. H. G. Johnson.
Field Inspection, by Boy Scouts, under Mr. L. S. Culbertson and Captain Ziegler.

Figure No. 2.—Street Scene in Oil City During the Early Flood when the Second Gorge Came Down.

Until March 5th, the writer was engaged in gathering material on the nature of the ice, plotting the findings on the government maps of the river, and planning the best method for the attack. The containers for the thermit were being constructed and filled with the first ton ordered from New York. Up to this time the dynamiting alone had been carried out, and a small channel had been opened through the lower end of the gorge with its use.

In a broad general way the use of the heat units at first was for the purpose of opening up the channels under the ice and weakening the surface before taking the ice out in order to bring down enough water to float the ice and afford relief to the high water at Franklin and Oil City. As soon as the weather moderated the various sections of the gorge were treated, and large patches opened, but when the warm weather set in the final removal of the sections was effected with large charges of thermit.

The use of dynamite was continued to free as much of the restricted area below Brandon as possible in preparation for the final removal of the pack. As a matter of fact, the dynamiting had to be discontinued shortly after the thermit was applied on account of the excessive bleeding of the ice running under the gorge and coming out at the lower end.

The calcium chloride was used to open channels in the surface ice near the bridges, and was found quite effective.

The mixture of sand and gravel was used for the same purpose, and was spread on the surface so as to gather the sun's heat to melt the ice faster. It was remarkable to see the rapidity with which the gravel sank into the ice, and at these treated points patches of water opened when the weather moderated.

Sulphuric acid was never used, although it was kept in reserve, there being a considerable supply of crude acid in the neighbourhood.

Water levels were carefully observed at Franklin and Oil City and at points higher up, and the writer was kept constantly informed of these. At the same time, weather reports were received during the day from various stations along the river as well as from the Weather Bureau at Washington.

The Boy Scouts were organized into groups for observation at the various bridges near Oil City and Franklin to report on the fluctuations of levels and the surges from hour to hour. The entire river during the first ten days was constantly surging and pulsating, due, no doubt, to the high head of water seeking channels through the ice in the lower pack. The boys also ran lines of stakes across the river at two points near the railroad bridges at Oil City and Franklin. These stakes were capped with red, and were accurately placed in alignment so that the slightest movement in the upper pack could be at once detected. Long before the ice was moved out the whole gorge was slowly moving down stream like a glacier, and the stakes gave the writer the first sign of this movement.

Dynamite Operations

The whole progress of the dynamiting operations is recorded in the minutes of the daily reports put in by the head of the Dynamite Committee. The operations which had been begun by the Pennsylvania Railroad, before the writer took charge of the work, had been discontinued pending the writer's initial work of reorganization. They were resumed, however, by the writer as soon as possible, as it was doing effective work in "biting off" the foot of the pack. On March fifth it was reported that in the lower end of the gorge a channel 1,000 feet long and 80 feet wide had been successfully opened with the use of 500 pounds of dynamite through ice in some places 8 to 11 feet thick.

The report of the sixth stated that in the morning they made fifteen holes 50 feet apart, and used 1,200 pounds of dynamite. In the first seven shots they used 100 pounds each, and for the other shots 50 pounds. They took out 50-foot sections, 75 feet wide, and approximately 1,700 feet of a channel was made. The first ice encountered was 6½ feet thick, while at some spots it was as much as 11 feet. Subsequently, shots were put off at regular intervals of ten minutes.

On March 8th, it was reported that 500 feet more of a channel had been opened up, but that most of the time during the day had been spent in making holes, so that the next day considerable progress could be made as most of the holes were completed and more time could be devoted to dynamiting.

On the following day it was reported that fourteen shots had been used and from 1,600 to 1,700 feet of ice taken out. The last shot made a 500-foot channel 100 feet wide. It was put off just above the first holes where the thermit had been used. In this part the spacing of the shots was increased and 100-foot sections were taken out, showing weakening effect of the thermit action under the ice. Ice taken out in this last section was 11 feet thick.

It was reported that the ice sent down by the operations of the previous day had jammed lower down the river at the railway signal tower. Efforts were made to dislodge this, using eight boxes of dynamite. The attempt was unsuccessful, and forty new holes were made for use the following day.

On March 11th, most of the day was spent in dislodging the lower gorge and making sixty-five new holes, and the report of the 13th was to the effect that 100 feet of the ice in the new gorge had been shot away, but that a block of ice 75 feet long had come down and was causing more trouble. It was decided to use smaller shots of dynamite in future operations.

Shortly after this date it was decided to discontinue the dynamiting, as little was accomplished compared to the amount used, and it was thought better, in view of the rapid work progressing with the thermit in weakening the lower gorge, to reserve the remaining stock of dynamite for any emergency that might arise. The bleeding of the ice hindered the men from making the holes for the dynamite.

Calcium Chloride Treatment

As much salt as possible was gathered from the road

Figure No. 4.—Railroad Tracks Flooded at Oil City in the First Flood.

department, and it was decided to open up 3-inch channels under the Big Rock bridge.

On the 6th, Mr. Frame reported that 1,600 pounds of calcium chloride had been put in the channel under the bridge, making lines 2,000 feet long.

No further use was made of calcium chloride, pending the decision to order a fresh supply. The action of the material already laid was watched with much interest, and it was expected that the weakening of the ice under the bridge would help to relieve the pressure on the piers.

Ash, Sand and Gravel

On March 5th, it was reported that one carload of cinders would be spread at places along the channel as would be suggested by the writer. On March eighth, one carload of cinders was unloaded at East Sandy, 300 yards being laid along the channel at that time. Arrangements were made with the Atlantic Refining Company, of Franklin, for a car load of ashes to be taken by the New York Central and dumped off the bridge at East Sandy on the ice. The Atlantic Refining Company donating the ashes and the New York Central their train service.

The report on March 9th showed that the carload of ashes was dumped on the ice at 9.30 a.m. They were spread 50 yards up the river and 350 yards below Camel Hump to a width of 15 yards. The action was noticed to make slush ice by drawing the heat of the sun.

Report on March 10th that seven men were employed in spreading ashes, 275 yards were spread up the river and 25 yards down. Around both piers of the bridge cinders

Figure No. 3.—Reno Traction Bridge at Oil City Lifted 18 inches above its Piers by the Ice.

Figure No. 5.—Reno Traction Bridge Put Back Without Damage on to its Piers with the Removal of the Ice by the Thermit Treatment.

Figure No. 7.—Looking Down Stream from Big Rock Bridge Showing One Span Carried along on the Moving Ice.

were placed 12 feet. The ice was found not stuck on the east side of the west pier. Cinders spread the day before had penetrated the ice from a half inch to one inch.

On March 11th, the men employed in spreading gravel were used in assisting the dynamiting operations, as after this date no further ashes or gravel were used, and it was found the ice covered by the gravel gradually showed water on the surface. No further application of gravel was made, as the thermit was producing such great effects.

The Thermit Operations

The writer will now try to give some idea of the way in which the general attack on the gorge was carried out with the use of the thermit heat units.

Some experimenting had to be done during the first few days on the writer's arrival. Special containers were constructed by Mr. J. P. Coffman, superintendent of the National Transit Pump and Machinery Company, of Oil City. Arrangements were kindly made by Mr. Coffman to have the containers loaded at the shops. Before the containers were finished, some charges were prepared in 10-gallon oil barrels.

After a careful survey of the gorge, the writer laid out the points of greatest resistance in the old jam below Franklin which had resisted the onslaught of the second gorge. These points were about five to six miles apart, beginning at the foot of the pack. No attempt was made to treat the upper pack from Franklin to Oil City, because this was being weakened by the effect of the open water above Oil City at the head of the jam. The sun's heat was being carried into the pack, and the greatest danger lay in this upper ice under high water shoving down on the older pack, still hard and solid, and causing great damage to the city of Franklin, situated in the jaws of the mass.

The water, when it reached the lower pack, had had its heat all taken out of it by passing through the upper pack, and hence its melting action was reduced to a small amount. The entire gorge was divided into two parts. The lower, represented by the older gorge, which was dry and grounded with the water forcing its way around through side channels, and the newer gorge, lifted high on flood waters accumulating above Franklin. The object of the first thermit treatment was not to dislodge the ice, as the dynamiting operations had shown the uselessness of this while the cold weather lasted, but to open channels under the surface. The water had to be brought down into the old pack and by its presence do two things; relieve the flood level above, and afford water enough to lift the lower ice and get it ready to be passed on down the river without gorging and causing more floods.

With this in view, all work was concentrated on the heavy packs and the thermit containers fired as low down in the ice masses as possible. The liberation of this great heat had the effect of burning out great areas under the ice, and the force of the explosions, which resulted from the heated metal in contact with the ice and water, caused cracks and disruption which allowed the water to force its way through these places under a high head and gradually work its way down, clearing and melting a channel much larger than was evident to the eye at the time.

In the accompanying curve figure No. 8, it will be seen how the levels of water at Franklin and Oil City dropped after the thermit was applied. Each charge was noticed to produce its effect in reducing the flood water.

With the fall of water in the upper pack there was a rise of level in the lower end, and care had to be taken not to let the water down too fast so as to avoid flooding the Pennsylvania Railroad tracks at the lower part of the gorge.

All of the time up to March 18th was taken up with intelligent use of the thermit at the critical points and the operations regulated by the writer from the daily watch of the flood levels. The drop in level occurred simultaneously with the thermit treatment. (See Appendix A.)

From the 10th to the 20th, when the weather turned very mild, the gorge was held in control in this way, and the whole pack was observed to move very slowly down-

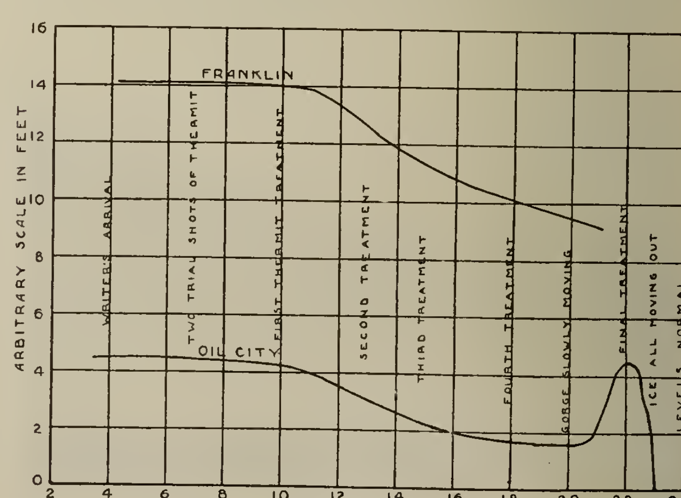

Figure No. 8.—Diagram showing Fall of Water Levels due to Thermit Heat Units.

ward as the water was brought down. From this glacial-like movement much valuable information was obtained as to the hardest and most resistant points. By the 20th, great areas had opened up, and it was found desirable to begin the final attack to remove the gorge. The writer was criticized for not taking the ice out at once, but this was unwise, for reasons already given. The whole situation was under control and the river levels held down until such time as nature could aid in the removal of the ice.

On the afternoon of the 20th, the upper pack began to move under the weakening action of the sun. This was a little sooner than the writer had expected, and in consequence new tactics had to be adopted. Everyone thought that the entire gorge would move out, but so strong was the ice still holding between Oil City and Franklin that it gorged into the ice at that point under a high head of water without moving beyond Reno. The citizens had a taste of what might have occurred to them in a much worse way had not the lower gorge been opened and the previous flood waters taken away. A considerable flood ensued at Oil City, although Franklin did not experience this flood in the least.

The same night the waters began to rise, and early the following day Oil City was in flood, with rain falling. The Reno traction bridge was in grave danger, and stood 18 inches off its piers, resting on the ice, while the power house was partially submerged and in grave danger also.

On Monday, March 21st, two heavy charges of thermit were set off at the two points in the new jam at Reno where the pack was greatest, and these were effective in relieving the flood in Oil City, and were so gauged as to put the Reno bridge safely back on its piers without damage of any kind. (See comparative photographs.)

On that day, March 21st, more thermit was rushed from Pittsburgh by motor truck and special train, and all night long the men worked heroically to fill containers for the morning.

On Tuesday, additional charges were inserted in the pack to bring the ice level down to a safe distance below the bridge, and then a concentrated attack was made on the gorge to remove it entirely.

Two thermit crews were sent out, one below Franklin at Indian Bend, the last remaining point of resistance, and the other to loosen the pack holding between Oil City and Franklin.

The men in charge of the work, Messrs. Geo. L. Bannon and Fred. Wenner, deserve the greatest praise for the courageous way in which they went at the attack in the rain and bad weather. The ice was none too firm to go on to place the charges, and frequently planks had to be used to effect a safe passage.

Under the terrific action of these thermit charges, the gorge was shaken loose in great patches and sent down the river safely, the lower pack giving just ahead of the upper, thus avoiding any flooding except for a short time at Indian Bend, where some of the track embankment was washed out. This was from the great rush of water from the upper pack meeting the resistance of the slowly-moving ice below. Very little damage was done, however, and by 6.30 o'clock in the evening the ice was all moving on down easily, and by late evening the river levels at both Oil City and Franklin were back to normal.

The United States Army engineers at Pittsburgh, who never at any time understood the function of the thermit treatment, had predicted the worst flood in the history of Oil City, with the rain and warm weather. This prediction, like their earlier ones, was not fulfilled. Had the gorge been left to nature, as they had urged, then their predictions would have doubtless come true, but under the scientific treatment accorded the ice in the gorge was removed without damage.

On Sunday night, March 21st, two spans of the Big Rock bridge were taken out by the ice movement, but this could not have been prevented as the understructure, which had been condemned as unsafe, was a prey to the slowly-moving ice and the flood waters above. It was a matter of great satisfaction to the writer that no loss of life or injury resulted from the whole operation, and the property damage was comparatively small, compared with what it might have been.

Comments on the Work

It is but fair to review some of the comments of the engineers and others who were in close touch with the whole fight.

General Manager V. A. Redfield, of the Traction Company, stated to the press that " Credit for saving the Reno bridge and for diverting the ice pack to the opposite side of the river, saving the switching equipment and preventing tremendous loss of property, resulting in interruption of service of a far more serious nature, is given to Dr. Howard T. Barnes. It is quite evident that the wall of water backing up on Monday evening was not great enough to move the big jam, which could only be placed in motion by a still greater head of flood. The thermit crew, in charge of the Montreal Scientist, devoted practically all of their efforts on Monday to attacking the ice below Reno on the opposite side of the river from the West End power house. This caused a gradual weakening of the pack below the surface of the ice, with the result that the field moved out on the opposite side of the river, avoiding the transformer yard

Figure No. 10.—Lowering Water Level. Shot No. 2.—Black Powder, 25 lbs., Thermit, 160 lbs.

Figure No. 11.—Pennsylvania Express No. 900 to Pittsburgh shown Racing the Moving Ice to Get Through First.

and its intricate network of switches and other protective equipment and sparing Oil City and Franklin a far more serious interruption of electric service. As it was, the first movement of the ice resulted in a sudden movement which sheared off one of the big steel towers at the power house, carrying away the 11,000-volt supply lines to Franklin."

Another comment in the Pennsylvania News, and written by Mr. Shingledecker, of the Pennsylvania Railroad: "We can now review a bit. People will never forget the gruelling experiences of those three days, beginning Sunday morning, March 21st, and ending Tuesday night, March 23rd, only after Dr. Barnes had shaken and virtually burned the packs to pieces with heat mines. Thermit was rushed to Oil City over the Pennsylvania Railroad, arriving at 9 p.m. on March 22nd. All night a force worked to prepare the containers for a desperate attack on the two gorges the following day. With organized crews, Dr. Barnes launched a desperate effort against the great mass of ice. Fifteen shots were placed in the Oil City gorge during the day and four in the Brandon pack. Hour after hour the crews risked their lives to place *heat mines*. The Brandon pack broke at 5.40 p.m. and the Oil City gorge followed at 6.35 p.m., an hour after the thermit crews were driven to shore. With the aid of thermit, the gorges moved ahead of a wall of water three feet lower than the great volume the day before."

Superintendent J. J. Rhoads, of the Pennsylvania Railroad, issued the following statement on March 22nd: "I attribute the 31-inch drop in the river at Oil City to the use of thermit in the vicinity of Reno."

The following day, after conferring with Division Engineer W. S. Wilson and Supervisor J. T. Ridgley, Superintendent Rhoads issued another statement, as follows: "That the Allegheny Division's loss is not much greater, we attribute to Dr. Barnes' work, and in each case where the *heat mines* were used, the river level dropped within twelve hours. The entire community of Oil City and Franklin, as well as the Allegheny Division, were fortunate in having at their disposal the services of Dr. Barnes."

It might be well to add that the work was not carried on without many difficulties, and as the people of both cities were not familiar with the scientific method of doing such work it was not easy to have them understand what the writer was really going to do to help the situation. One question was raised as to whether the thermit would poison the water and the fish, so the medical health officer of Pennsylvania rushed there to have an interview with the writer, and, if necessary, to stop the work.

Engineers did not realize that there were not one or two ice packs, but a number of packs, and that the key to each of these separate jams had to be treated to have the work carried on successfully.

The whole cost of the operations was under six thousand dollars, which was insignificant compared to the value of the property saved. The saving of the Reno bridge alone was sufficient to justify the expenditure.

Report to the United States Government

The Ordnance Department of the United States Army appointed Reserve Officer Major H. B. Faber to make an official inspection of the writer's operations in removing the ice gorge. Accordingly, Major Faber came out to Oil City, and was present during the last two days of the work. He witnessed the final removal of the ice. His report was sent in to Washington and is on file as an official document of the War Office.

The report is of an entirely favourable character, as he was very much impressed by the whole procedure, characterizing it as "amazing."

Even after the gorge had gone out, the United States Army engineers at Pittsburgh sent out a bulletin to the effect that the ice had gone out under the pressure of high water, without giving any credit to the thermit operations. This, as will be apparent by reading the text of this paper, was not true, for the gorge withstood the highest water in the history of Oil City without moving for nearly 18 hours, and it was only when the flood level had been reduced to a safe point with thermit treatment that the ice was moved out. Then the movement was effected from the lower gorge first, which quite reverses the way these accumulations usually move. Had the lower gorge been left to nature, there is no knowing when it would have moved, since it was gathering no heat from the waters above except a little from French creek at Franklin. But it is well not to speculate on what would have happened to the city of Franklin under these conditions, as it was just at the meeting-place of the old and new gorges. It must be pointed out in comparison that the Kinzua gorge, 60 miles above Oil City, which was feared would come down any time, never moved out at all, but melted in place, the water making new channels around it.

At the beginning of the work, the writer paid a visit to Kinzua, and after a careful inspection gave it as his opinion that there was no danger from it moving down, so securely

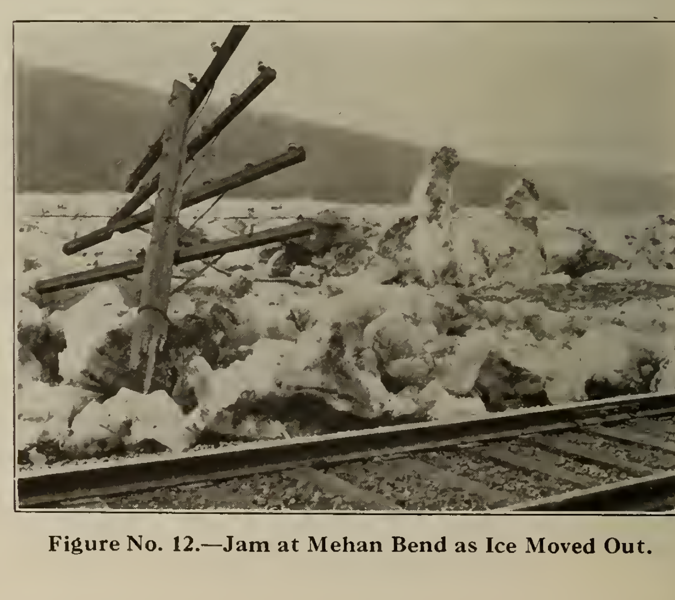

Figure No. 12.—Jam at Mehan Bend as Ice Moved Out.

wedged was it between islands and the main shore in a bend of the river.

The whole thermit work puzzled many prominent engineers all over the country, who had not been aware of the writer's recent work. Those who honoured the writer by coming to see the work and study the plans which he had worked out, all expressed astonishment at what could be accomplished, and went away favourably impressed with the work.

It is not to be expected that those who did not see the work could feel confident of success, since nothing like this had ever been attempted before.

The best evidence that the thermit accomplished the task is given from the enthusiasm of the thermit crews who daily went out in the cold and wind to place the charges and risked their lives in the work. Had they not known the effectiveness of the operations, it is not likely that these men would have been so willing to do so. No other incentive actuated them but one for the general good of the communities.

APPENDIX A.

Report of Thermit Operations to Reduce Flood Levels

Wednesday, March 10th, 1926

Shot No. 1. The first shot was placed 300 or 400 yards north of Brandon station in a swift-moving channel. The container was of the double-lined type. The thickness of the ice at this point was 6 feet, and the depth of water was 10 to 12 feet. The charge was fired at 10:55 a.m. and the reaction was not as noticeable as in the case of the shots fired in the single-lined containers the day before. There were no flames shooting high into the air or the deep rumbling and rolling motion of the ice as noted by the single-lined container. The only part of this container left was one handle which appeared to have been blown off.

Shot No. 2. The second charge was placed at the mouth of Sandy creek in 12 feet of water, and the thickness of ice was 8 feet with a quantity of slush ice underneath. This shot was fired at 11:51 a.m. and lasted for fully one minute, during this period there were two very pronounced reports. Water boiled up through the ice at a distance of 8 feet from the hole for a period of 10 minutes, and cracks radiated from the hole for a distance of 75 yards. The ice from shore to shore was shaken by a loud crumbling and rolling action. There seemed to be more of an equal distribution of energy. All reaction from this container seemed to take place underneath the ice.

Shot No. 3. The third charge was placed at Indian God Rock at 12:45 noon. The thickness of ice was 8 feet and the depth of water over 14 feet. This shot was placed at the edge of a pressure ridge between two large cracks in the ice. It also was successful, there being two very loud reports, (similar to those in the case of shot No. 2), and a few sheets of flame shot into the air to a height of 6 to 8 feet. Upon examining the hole after the shot was fired we found that it had been enlarged to 10 feet in diameter. Five minutes later the boiling action appeared very noticeable at the surface. The river at this point was about 500 feet wide and the ice shook considerably from shore to shore. This container was also lowered about 4½ feet underneath the surface of the water.

Figure No. 13.—Carrying Large Heat Unit out on the Ice.

Figure No. 14.—Placing One of the First Heat Units under the Writer's Direction.

Shot No. 4. This shot was placed at the lower end of Fosters ripples at 1:45 p.m. The thickness of ice was 4 feet, and the depth of water in the channel over 14 feet. This container was lowered 5 feet under the surface of the water. There were three loud reports and one less distinct at 3 or 4-second intervals. Balls of fire shot out of the hole at each report, and upon examining the spot we found that the container sides were not destroyed, the top and bottom only being missing. There was no violent upheaval as noted before, and although the shot did some good it was not as satisfactory as the other three.

Shot No. 5. Charge No. 5 was placed at the upper end of Fosters ripples at 2:30 p.m. The thickness of ice was 5 feet and the depth of water over 12 feet. There was a pulsation of 3 inches at this spot and this appeared to be very violent at times. This was also a successful shot, heaving the ice up 6 inches accompanied by a violent boiling action about 25 or 30 feet down river from the hole, which lasted for ten minutes.

Shot No. 6. This charge was placed at Foster station in the middle of the channel at 3:05 p.m. The thickness of ice was 6 feet and the depth of water over 12 feet. After the shot was fired a deep rolling motion took place and a series of short sharp reports, accompanied by a boiling action. The shot was very satisfactory.

Shot No. 7. This shot was placed at the mouth of Big Sandy creek, 275 yards north of East Sandy bridge, at about the middle of the river. The thickness of ice was about 11 inches with a quantity of slush ice underneath, and the depth of the water over 12 feet. This shot was fired at 4:15 p.m. and was accompanied by two loud reports and a deep rumbling and rolling motion of the ice for a radius of 300 feet, while a boiling action was also noticed.

Shot No. 8. This charge was a small double-lined container and was fired about 60 feet nearer the shore than shot No. 7. It was fired at 4:25 p.m. and it seemed to take longer for the reaction than in the case of the single-lined containers. Ice shot up into the air to a height of 75 feet, and small sheets of flame were noticed above the hole and it seemed as if too much energy was lost in this case. There was also a slight rumbling and rolling motion of the ice but not as pronounced as in the other cases.

Thursday, March 11th, 1926

Shot No. 1. This charge was placed on the lower end of ice jam 300 yards south of the railroad tower. This ice was projecting into the open water for perhaps 50 feet from the main pack. After the shot was fired there was a reaction lasting for fully one minute. Sheets of flame and black smoke rolled out of the hole and a series of low deep rumblings took place, then a loud report was heard and ice and part of the container were thrown 200 feet into the air. Examination of the hole afterwards showed that it had been enlarged 30 feet in diameter and huge cakes of ice, 18 to 24 inches, were all jumbled and tossed about. The ice at this point was 11 feet thick

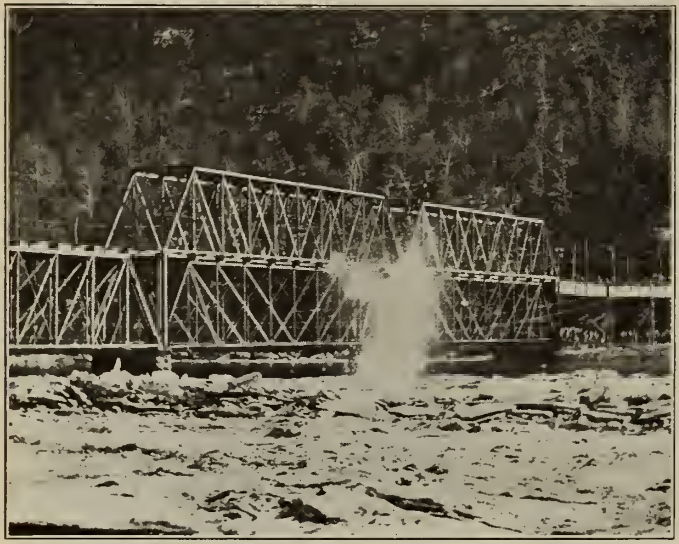

Figure No. 15.—A Thermit Heat Unit fired at Big Rock Bridge.

and resting on the river bed. A slight settling movement was noted five minutes after the shot was fired.

Shot No. 2. Was lost under the ice, and it was impossible to retrieve it.

Shot No. 3. This shot was placed at the edge of the main pack and the new jam and was of the special ice thermit. There was nothing unusual about this shot apart from the rumbling and short flames which shot out of the hole. This thermit was packed in a transit container, no iron pot being ready.

Shot No. 4. Was placed 250 feet north of shot No. 3, with a charge of dynamite 50 feet away and both fired together. A section of ice 200 feet long was moved down stream.

(Signed) *G. L. BANNON.*

MONDAY, MARCH 15TH

Shot No. 1 was fired at 11 a.m., ¼-mile below Brandon about 300 feet from shore. It shook the ice for about 500 feet and fire shot into the air for about 25 feet. Two explosions occurred and water boiled for about five minutes. There was 18 inches of ice, and a single container was used.

Shot No. 2 was fired at 11:20 a.m., ¼-mile above Brandon, a double-lined container was used and fire came out of the hole and shot about 25 feet into the air. The container came out of the hole and water boiled out for about five minutes. The thickness of the ice was about 2 feet.

Shot No. 3 was fired at 12 a.m., 500 feet below Sandy creek, where there was a thickness of 2 feet of solid ice with slush ice underneath. This shot shook the ice off the bank along the shore, and shook the ice from shore to shore. There was not much of an explosion and not much change in the hole. An iron container was used.

Shot No. 4 was fired at 12:30 p.m., 500 feet above Sandy creek. An iron container was used. The thickness of the ice was 2 feet, solid, with slush ice underneath. Fire came out of hole to a height of about 25 feet, but there was not much change in hole.

Shot No. 5 was fired at 12:50 p.m., ½-mile above Sandy creek, where there were 2½ feet of solid ice with slush ice underneath. The shot shook the ice from shore to shore, with two explosions, and left a hole about 15 feet in diameter. An iron container was used.

Shot No. 6 was fired at 1:25 p.m., ¼-mile above Indian God rock, with 3 feet of solid ice and slush ice underneath. This shook the ice from shore to shore, boiled at the hole for about five minutes, but did not make much change in the hole. An iron container was used.

Shot No. 7 was fired at 12:45 p.m., ½-mile above Foster station, where there was solid ice 18 inches thick, with slush ice underneath. This shot shook the ice from shore to shore; fire came out of the hole to a height of about 5 feet, but did not make much change in hole. An iron container was used.

Shot No. 8 was fired at 3:50 p.m., about 500 feet below the railroad bridge at Sandy. It shook the ice for about 200 feet, but not much fire came out of the hole. There was solid ice about 12 inches thick with slush underneath. There was not much change in the hole. An iron container was used.

Shot No. 9 was fired at 4:00 p.m. but did not result in much of an explosion, although water boiled at hole for about five minutes, without much change in hole. An iron container was used.

THURSDAY, MARCH 18TH

Shot No. 1 was placed 200 yards south of Big Rock bridge in the deep channel at 2:40 p.m. There was one deep report and a small quantity of black smoke. Water shot up around middle pier of bridge, covering the ice to a depth of three to four inches. It also gave the ice a good shaking. The ice was from 3 to 4 feet thick, with plenty of water.

Shot No. 2 was placed 60 feet north of No. 1. There was one loud report and flames and molten metal were hurled high into the air. This shot also gave the ice a good shaking.

Shot No. 3 was placed 200 feet north of Big Rock bridge. The ice was in layers of 18 to 24 inches in thickness to a depth of over 8 feet. There was a series of short sharp explosions, then one loud report. Water spurted out of the ice at a distance of 150 feet from where shot was fired. It also tore a hole in the ice about 30 feet in diameter.

Shot No. 4 was placed 60 feet away from No. 3, toward the west shore line, in layers of ice 18 to 24 inches thick, to a depth of over 8 feet. There were two reports and flame shot out of the hole to a height of 6 feet. It tore a hole 15 feet in diameter in the ice. There was also a small part of the container left.

SUMMARY

In all, four containers were taken to Big Rock bridge and the four were discharged without any trouble. The ice was shaken loose from the two middle piers and settled so that water covered the ice to a depth of 3 inches or more.

FRED. WENNER.

APPENDIX B

NATURE OF THE THERMIT-ICE REACTION

The thermit heat units as developed by the writer for use in ice accumulations contain ordinary welding thermit manufactured by the Metal and Thermit Corporation of New York and Toronto.

It consists of a mixture of metallic aluminum and iron oxide in such proportions that the combustion of the aluminum results in the reduction of the oxide of iron forming metallic iron according to the relation:—

$$3\ Fe_3\ O_4 + 8\ Al = 4\ Al_2\ O_3 + 9\ Fe$$

The heat of formation of the Alumina, which is generated by the reaction, raises the mass to 5000° Fahr. Heat from a body at such a temperature is radiated in the form of light and heat waves with a maximum of energy in the heat spectrum.

Water and ice are partially transparent to these short rays, as is evident to anyone who observes the rays of the

Figure No. 16.—Erie Railroad Bridge Held Down by a Heavy Coal Train.

sun penetrating water. The absorption is gradual as the rays proceed, and thus the energy can be distributed over a wide area.

To loosen the ice crystals comprising a mass of ice, only a very small amount of actual heat is necessary. The amount absorbed from a beam of sunlight, or from a charge of thermit is quite sufficient to do this.

When heat is applied in the form of steam or hot water the action is only local, as no rays are sent out from a body at that temperature which can pass through water. A small amount of energy at a high temperature is a much more effective agent in disintegrating ice than a large quantity of heat at the temperature of steam.

In addition to this, when heat is shot into ice at the high temperature of thermit the energy input causes the ice to rupture and the molten iron dissociates the ice, forming iron oxide again, and liberates hydrogen which burns with the oxygen of the air. It is well-known how hydrogen can be prepared by passing steam over red hot iron, but at the thermit temperature the dissociation is more rapid and gives rise to sudden generation of hydrogen as well as steam. This results in a slow explosion resembling a heave upwards, which is ideal in loosening ice masses. Then the activity of the explosion comes from the ice itself, which literally causes the ice to blast itself. Dynamite can in no way be compared, as the shattering effect comes from the blow delivered by the explosive.

One very important feature of the thermit-ice reaction is that it is not in any way harmful to concrete structures or earth works. Large charges have been repeatedly set off alongside of bridge piers and embankments without any effect on them.

Large masses of ice have been moved near concrete walls with no other effect than the lifting of the ice several feet in great fields with consequent large surges spreading out as a number of waves through the ice.

To fire thermit to the best advantage it is confined in a water-tight container, with lined walls, of a size suitable to the work it is designed to do. The standard unit in this work contained 160 pounds of thermit.

A central fire ignitor is inserted in the top and operated by a hot-shot battery, blasting machine or fuse. The reaction takes place in from 5 to 8 seconds, causing the thermit to be converted into a mass of molten iron which is held long enough by the thickness of the walls to burn completely to the bottom. The bottom is made of thinner metal, through which the molten metal drops by melting it. It is thus suddenly thrown into the ice or water with the evolution of the radiant beam, followed after a few seconds by the explosion which loosens the ice and burns out the channels under the ice. Ignition has to begin from the top, as the thermit will not burn upwards. The result of a thermit shot in an ice mass is to start a point of weakness which gradually grows by the infiltration of the water currents. The action in an immense pack is like the spreading of infection from a wound. The effectiveness of thermit was first tried out by the writer in the ice jams on the St. Lawrence in the winter of 1924-25. At this time, two large jams were removed by a few charges judiciously placed in the key positions. In the one at Waddington, a quarter of a million tons were taken out by three charges of 90 pounds each, while at Chimney island, a few weeks later, over a million tons were moved down the river by two charges of the same size.

Building the City of Arvida

The General Planning, Construction Methods, and Details of Materials and Equipment Used

H. R. Wake, A.M.E.I.C.
Aluminum Company of Canada, Ltd., Arvida, Que.

In August 1925, the Aluminum Company of Canada, Limited, purchased property in the vicinity of Ha Ha Bay Junction, on the Canadian National Railways between Jonquiere and Chicoutimi in the Saguenay-Lake St. John district, and work was immediately started on the construction of an aluminum plant about three and one-half miles from Jonquiere and five miles from Chicoutimi. It was started in the midst of a field of oats, potatoes and pasture. There were no roads leading to it and no living accommodations. Temporary living accommodations were provided

The future City of Arvida in Present Stage of Development.

by a construction camp, which allowed time for planning the town development and permitted starting the plant construction immediately.

For plant and town purposes the company purchased about 6,000 acres in a block about three miles square. It slopes gradually from the main Jonquiere-Chicoutimi highway on the south to the bluff along the Saguenay river on the north. Between the top of the bluff and the river there are two terraces which will make excellent house locations when the natural growth of the city reaches that section.

Running in a south to north direction between the main road and the bluffs are a number of deep ravines. There are several rock outcrops at different points within the area.

In planning the town, the principal problem was not the layout of the section to be built in 1926. It was first necessary to visualize a city of from thirty to forty thousand people built on this site. From the topography, it was possible to block out the several areas which are suitable for housing purposes. It was then possible to consider the location of these several areas with reference to the plant and railroad, and select an area for the main business section of the completely developed city. In each of the housing areas it was necessary to provide for small neighbourhood stores, as many of these areas are too far to permit the people to do all of their marketing in the main business section.

With this picture, it was possible to lay out the main arteries of transportation so as to provide proper connections between the housing and business areas, and also with the neighbouring towns of Chicoutimi, Kenogami and Jonquiere.

The next step was to lay out the streets and blocks in each housing area and make additional connections between these areas where possible and advisable.

Having the general layout, it was possible to select a housing area for development in 1926. The area selected is adjacent to and northwest of the portion of the plant now under construction. It is also adjacent to and just northeast of the business section, and is about a mile from the railroad station. With this layout, the stores where the people will trade are at the edge of the residential area, but that is the only arrangement which could be made to fit in with the ultimate development. With such a general layout, each housing area can be built as conditions demand and will require only such minor changes in the areas as may be dictated at the time they are built.

After a careful study of the operating organization required for the plant which is being constructed, it was decided that two hundred and seventy houses would be sufficient; two hundred for workmen, fifty for foremen and clerical men and twenty for superintendents and department heads.

A study and inspection was made of houses in the adjoining towns and opinions were obtained from the owners regarding the types of construction best suited to this climate. Many favoured filling the walls and above the ceiling with sawdust. Others were very much opposed to this as being unsatisfactory and affording a place for the collection of vermin, rats, etc.

It was finally decided to build frame houses one and one-half and two stories in height, with full concrete basement. One hundred of these are typical Quebec houses with the flared eaves and with one large room across one-half of the house serving as a living room, dining room and kitchen. The remainder have different styles of roofs so as to provide variation in the appearance of the houses.

Of these houses,	143	have floor dimensions	20 x 26 feet
	80	" " "	24 x 24 "
	12	" " "	26 x 26 "
	24	" " "	$24\frac{1}{3}$ x $27\frac{1}{3}$ "

while the floor dimensions of the balance of the superintendents' houses vary.

There are	18	houses with	4 rooms
	8	" "	5 "
	204	" "	6 "
	41	" "	7 "

The basement walls are ten inches thick at the top with a one-half-inch batter on the outside, making them fourteen inches thick at the bottom. The basement floors are three inches thick. The frame construction is siding on paper on sheathing on the outside of the framing and plaster board and plaster on the inside. Care has been taken to fill all cracks around the doors and windows.

First and second floors are double with building paper between. The roofs are sheathed and covered with paper and asbestos shingles. Eight-inch brick chimneys are built from the basement. Each house has a large front porch and small back porch.

Except in the case of twenty houses, the windows are nine and twelve light with the upper sash stationary. In twenty houses the lower sash is a single glass instead of six light. There are three basement sash in each basement. Each house will have storm windows and storm doors.

Each house has a bathroom with bath, toilet and lavatory, and in the kitchen a sink and drain board. Two hundred and fifty are to be heated by stoves, although there is a flue connection for a furnace in the basement, should it be found desirable to install a furnace at a later date.

The plumbing is placed either in the inside walls or inside the rooms. It has been the aim to purchase plumbing materials and fixtures which are substantial and which will require a minimum of repair and maintenance.

The workmen's houses have two drop lights in the living room and one in each of the other rooms, the front porch and the basement. Water and light service will be metered. The interior trim is stained a medium dark fumed oak and the floors are sanded and filled. The walls are left white, and will be painted later as occasion demands.

The lumber for these houses is B. C. fir and Western red cedar siding. Four and one-half million feet (230 carloads) were brought around in one boat. The doors also are of B. C. fir, but the windows are of white pine and were made in Ontario. The best parafined paper is used in the walls and floors, which is expected to give much better service than the usual building paper.

Both straight and diagonal asbestos shingles are used on the roofs. They vary in colour, but there is only one colour of shingle on each roof.

The painting schedule has been carefully worked out but will be revised in light of the experience in the first two blocks that have been painted. It will only be possible to prime most of the houses this year as it is too late for finished painting.

There is the town—on paper—and that is exactly where it was on June fifteenth, at which date there were only the floor plans for four of the thirty types of houses to be built. It can be imagined how hard the draftsmen have had to work in order to get out plans ahead of the workmen. It will be said that such plans should have been drawn during the winter so that they should have been ready for the spring. They were, but those plans were all discarded—and rightly so—around the middle of May and the new designs were much more acceptable.

Having selected the types of houses to be constructed it was necessary to select a site for them. The section chosen for development this year is located in open land forming two benches of about twenty feet difference in elevation and bounded on the east and west sides by deep ravines which form natural drainage for storm water and acceptable locations for the sanitary sewer mains.

For the most part the soil is a twelve to fifteen-inch layer of loam over a very fine blue clay or rock dust. There are two small outcrops of rock but these have not materially interfered with the work this year.

The first basement excavations were started on June fifteenth with two Insley excavators. The soil was found to be saturated and the water soon filled the excavations. Accordingly work was immediately started on laying the sanitary sewers and it has been possible to keep them ahead of the excavations except in the first two blocks. This has greatly aided in draining the sections as the work progressed. Later a Keystone shovel was added and all except four of the basements have been excavated by these machines. Two hundred and seventy basements, containing about thirty-seven thousand six hundred cubic yards, were excavated in one hundred and thirty-six shovel days, during part of which time the shovels worked at night.

Prior to June first built-up forms for each type of house were prepared at the planing mill and as the dimensions of the basements were not changed they were available for use. Altogether seventeen sets of these forms were built and this number has been sufficient for the work. Several sets of forms were built for each type of house and these were stripped and moved forward as rapidly as possible as the work progressed.

Simultaneously with the starting of excavating gangs were organized for form erection and pouring concrete. The first difficulty arose when materials could not be delivered to the job fast enough. The ground was so soft that teams could hardly pull an empty wagon. One five-ton Holt tractor was on the work and another was immediately purchased. Heavy sleds were built and practically all of the materials have been delivered on sleds hauled by tractor. In addition, it was also necessary to build a railroad siding into each section, affording a closer delivery of materials to the tractors, and these tracks have been so placed that the concrete mixers could be set alongside and the sand, rock and cement delivered right at the mixers. This saved handling immense quantities of these materials, and it was not difficult or expensive to pour the concrete by using buggies and movable runways. These sidings were built down the centre of proposed streets so the ballast would later be available for street use.

As soon as the forms were stripped from the first foundations the framing crews commenced work. At the planing mill, a crew of six men and a swing saw cut all of the framing for these houses. The length of each piece was marked thereon. A bill of material showed the number of each length for each type of house and only the required number were delivered at each house. These fitted so nicely that house after house was put up without a saw being used on the framing. This greatly increased the speed of erection and reduced the lumber waste to small blocks seldom more than six inches long.

As soon as the frames were started, the sheathing gangs were organized and followed the framing crews. The plumbing and chimney contractors started at the same time. These were followed by the plaster gang, which was augmented on rainy days by men from the framing crews. In the meantime, the roofing, siding and exterior finishing crews had started and the plasterers followed as soon as the roof was covered, (sometimes before). Aluminum flashing and ridge roll were used throughout. A week after the plasterers had finished the interior trim gang took possession, to be followed by the flooring crew, the men installing the plumbing fixtures, and the painters finishing the woodwork. Meanwhile grading had been done around the houses and the exterior painted so that they were all ready for occupancy.

Of course, it does not go as smoothly as it sounds. First the plumbers would get behind, and it would take a week or two to get them back to the scheduled rate. Then the plasterers were held up because the roofers were not working fast enough. If one group slows down it invariably affects the whole job, so that it is necessary to keep pushing all the time, for, after all, *time* is the principal factor in any construction work in this climate.

That finished the houses, but it does not bring water to the basement connection, give protection in case of fire, provide for sewage disposal, make the lights shine at the turn of a switch, permit calling central by lifting a receiver, or keep people out of the mud when going about.

Provision still has to be made for streets, schools, churches, a passenger station, freight station, post office, banks, grocery and meat stores, merchandise and furniture stores, barber shop, drug store, pool hall, bowling alley, movies, dance hall, gas stations and innumerable other accommodations which are needed daily and which in most places have been supplied in the general development of the town and are consequently accepted without any thought on the part of the user. These are expected to be immediately available by the occupants of houses in a new industrial town and are being provided at Arvida as quickly as possible.

Because of the late start, it is probable that all the houses will not be completed before December first, but at least two hundred and fifty of them will be completed by November first. That will mean two hundred and fifty completed in one hundred and thirty-five days or two hundred and seventy in one hundred and sixty-five days, making no allowance for bad weather.

In the house construction, there will be used about seventy-five thousand bags of cement; four thousand eight hundred barrels of lime; six thousand yards of sand; twelve thousand yards of gravel; two million four hundred thousand feet of framing; one million six hundred thousand feet of sheathing; three hundred and sixty-three thousand feet of flooring; two thousand seven hundred and fifty squares of shingles; nine thousand two hundred and fifty squares of paper; four thousand one hundred and fifty windows; eight hundred and fifty basement sash; five thousand same for storm windows, doors and sash; one thousand and ninety-six sinks, tubs, lavatories, toilets; one million one hundred and sixteen thousand square feet of plaster board, and one thousand six hundred kegs of nails.

When fully organized, six basements were excavated per day,—two with each shovel. An average of four basements were poured per day over the entire period, but six per day were poured under favourable conditions. Eight basement floors are now being poured per day. The rate of chimney construction by contract was six per day and plumbing four per day. Shingles are put on five houses per day. There was an average of two hundred and fifty men in June; seven hundred in July; and eight hundred in August and September.

As in all work, labour was the governing feature. Very good progress was made with the water and sewer line construction, and the work was not held up by the form erectors, the concrete men or the frame erectors. Trouble was experienced in getting enough good inside and outside finishers; men who knew their work and would do good work.

The workmen's houses will be heated by stoves. The others by hot water. The walls and second floor ceilings of some houses will be filled or covered with sawdust, others will have Insulex for additional insulation. The heating of the houses will be studied this winter in order to find out whether the houses, without additional insulation, are too cold. They are, however, built better than the houses in that section, and it is believed they will prove to be warmer.

There has been some criticism to the effect that they are too small for the ordinary French-Canadian family. That may be true if you think only of the old French-Canadian with twelve to twenty children, but it is not expected that there will be many of those, as the work appeals more to the younger man who has only four or five children. As conditions require larger houses, they will be built, but we do want as much as possible to keep away from having two and three families in one house.

The streets are fifty feet, sixty feet, eighty feet and one hundred and six feet between lot lines. On the narrower streets the houses are set back not less than twenty-five feet. This makes a wide street, along both sides of which walks will be laid and trees planted. The only poles on the street will be for street lights. Light and telephone lines will all run down the rear of the lots in the centre of each block, and entrance will be at the back of each house. This will reduce the wires and poles on the streets to a minimum.

The water mains are located on one side of the street between the curb and property line. A three-quarter inch tap supplies two houses. The three-quarter inch line extends from the main to within one foot of the property line, where it divides into one-half inch service lines for each house. A curb box and cut-off is placed on each house service just outside the property line. The three-quarter inch pipe is copper, but the service lines are one-half inch galvanized iron. The street mains in this section are six inches and eight inches, supplied by two twelve-inch mains at the east and west sides.

An Austin trenching machine excavated all water line trenches at a rate of about one thousand feet per day, and the trenches were backfilled by an Austin backfiller. The trenching machine and backfiller were also used in constructing the sewer system. Sewer pipe was laid as closely behind the trencher as possible and partly backfilled at once. At least eighty per cent of the trenches for sewer and water connections to the houses were excavated by the trenching machine.

The mechanical equipment for the job consisted of two Holt tractors; three Insley excavating machines, equipped with ditcher, skimmer and crane attachments; three Austin backfillers, (one of which assisted greatly by handling twelve-inch to eighteen-inch water line pipe into the trenches; four one-half yard concrete mixers, electric-driven; a heavy street grader with the usual dump wagons, etc. These machines certainly aided in getting the work done speedily and economically.

There is the picture of the construction of the section of the city of Arvida, which has been carefully planned by men experienced in industrial housing with the hope that its inhabitants will enjoy every advantage from well-constructed houses, pleasant surroundings, sanitary, fire and police protection, social, educational and religious advantages. There have been no serious obstacles to overcome and no great engineering feats have been accomplished.

Underground Mapping of Oil, Gas and Water Horizons

Procedure Followed, Information Secured and Interpretation of this Information with Particular Reference to Operation in the Turner Valley Oil Field

Stanley J. Davies, A.M.E.I.C.
Petroleum Engineer, Department of the Interior, Calgary, Alta.

Paper read before The Calgary Branch of The Engineering Institute of Canada, February 18th, 1926

The correlation of underground rocks is at all times an interesting process, and this is particularly true during the early stages of development in an oil field. For the purpose of introducing this paper it is the intention to describe in some detail the various rocks encountered in Turner valley, and it is hoped that the description of the rocks of Turner valley will lead to a better understanding of the fundamental principles governing the production of oil and gas. In this way the interests of the legitimate operator will be furthered and the oil industry, as such, will benefit by the knowledge gained from the study of underground formations.

While this paper has some reference to geology, as such, yet in the main it is an engineering problem that faces us in underground mapping.

Securing Samples

In order that the basis of the work may be outlined in a clear manner, the methods by which information is secured will be reviewed. When a well is commenced, the drillers proceed to drill a hole into the ground, and, as each four or five feet is drilled with cable tools, it is necessary to remove, with a bailer, the mud from the bottom of the hole. In this mud are small portions of the formation that have been pounded up. The drillers have this mud washed out and the cuttings washed clean. These are then dried and placed in small bags provided for the purpose and a tag is then tied to the bag giving the number of the well and the depth at which the sample was secured.

The tools keep going down, and as each ten feet is drilled a sample is collected and placed in a bag. The samples from all wells drilled with cable tools are obtained in this manner.

Diamond drills furnish us with cores of the formation penetrated. Actually 2-inch cores are secured, and these are placed in long boxes, and are carefully labelled and later examined.

Wells drilled with the rotary have a different system. The circulating mud carries out with it cuttings from the bottom of the hole. These cuttings are collected at frequent intervals and placed in bags. In addition, it is the practice to take cores at all important points, so that an actual sample of the formation of any particular depth is secured. These cores are placed in suitable boxes, labelled and forwarded for examination.

Examination of Samples

Samples are arranged in order and are carefully examined both with the naked eye and microscopically. In addition, all samples are tested for their particular chemical composition. This is a matter that requires special training and special equipment, and is a long, tedious task.

The question is often asked—What do you see in a sample? In answer to this question, it is intended to outline briefly what has been found in the work of examining samples during the past eight months and further, so as to give some idea of the value to be attached to such information.

In the first place, examination determines just what the sample consists of, whether shale, sandstone, limestone or a mixture of all three or any two.

This examination may bring out the fact that a sample is wholly a sandstone. Sandstones have voids or spaces between the grains, and as such these beds may then contain gas, oil or water. Limestones, also, may have crevices or pore spaces, and so may contain oil, gas or water, as these limestones are usually formed from the remains of animal life, and this animal life provides us with a probable source of oil and gas. Shales are muds pressed together, and in many shallow seas there is abundant animal and plant life which may form oil.

From an examination, it may be concluded that a sample contains a shale with, say, 10 per cent sand or a sandstone with 20 per cent lime content.

The next step is to determine the colour, since in this country there are blue, green, light grey, red and brown and black shales, and there is a history connected with each colour.

Further, a search is made for evidence of marine life, whether animal or plant remains. This is important so that the age of the rocks may be determined accurately, as the ages of our various sedimentary rocks are determined from the plant and animal life.

In October, 1924, at a depth of 3,740 feet, Royalite No. 4 was *brought in* by the Royalite Oil Company, and production was secured which, in 1925, amounted to approximately 160,000 barrels 73° Be., along with some 18,000,000 cubic feet of gas per day. Just what is the significance of this well?

Rock Formation in Turner Valley

Starting at the top of a hypothetical well, drilled in Turner valley, here is what is found from the samples.

Drilling commenced in a blue black shale. This shale is called Benton shale, being upper cretaceous in age. The Benton shale does not produce any quantities of oil in Turner valley, the main reason being that probably the lack of a suitable porous horizon in which oil or gas might collect, and a second reason being that the Benton rocks are well exposed and oil or gas would have a chance to escape. The Benton contains sand lenses near its base, and these lenses contain small amounts of oil and gas.

It is a matter of importance in oil geology to be able to secure a proper seal of any oil-bearing strata, and this is the main purpose served by the Benton shale in western Canada, which acts as a blanket over the lower producing oil and gas horizons.

The Benton shales are some 2,000 feet thick, and are unmistakeable in appearance. Below these shales we find a light green, grey and maroon shale. This shale, which is called the Dakota and is of the Upper Cretaceous age, is bright green or light chocolate when wet and dries out to a light green or dark red.

Interbedded with the shales are numerous sandstone beds which are porous and which in Turner valley contain oil and gas. These sandstones are lenticular, and because of this the production varies from well to well and the sands found in one well may be absent in another, and so the oil varies in gravity, depending upon where it is found in the sand lense.

The thickness of the Dakota beds is from 500 to 660 feet in Turner valley. Further west these beds are no doubt very much thicker, and they contain a conglomeratic sandstone which has formed many of our foothill ridges running from Bow river south to the Crowsnest.

Below these light green and red shales we find a coal-bearing formation which has been named Kootenay. The coal seams at the top of this formation have been found in as widely-separated areas as Turner valley, Medicine Hat and Wainwright.

Below the coal seams are found deep red, dark green, and interbedded green, chocolate and deep purple shales. The Kootenay formation contains certain markers which have been called the Red Beds. The colouring is very distinct. This formation, also, contains sand near its base, and the sand is light greyish-green in colour with dark specks in it. Some call this sand a pepper and salt sand, as it very much resembles a mixture of pepper and salt. White quartz being the salt and black chert being the pepper. Several wells in Turner valley have secured both oil and gas from the Kootenay sands. The Kootenay formation is from 300 to 450 feet thick.

Below the Kootenay sandstones are to be found a black slatey shale with pyrites and near the base hard brown sandstones. This shale is called Fernie shale of Jurassic age, and is 90 to 110 feet thick.

Gradually our well is getting deeper, and more interesting as we go. A new formation is entered after we have passed through the Fernie shales, which is now called the Calcareous shales, and it properly belongs with the underlying Triassic formation.

The shales are black in colour, having very frequent bands of brown limey sandstone, and become more calcareous until finally, after penetrating about 450 feet of these shales, we secure hard dolomitic limestone. This limestone has more content and more pore space due to increasing $MgCO_3$ as we drill deeper into it. Royalite No. 4 went into it 300 feet, and it has been fittingly named the Royalite Dolomite. Dr. Hopkins, of the Imperial Oil Company, has, in the writer's opinion, correctly placed this limestone as Triassic dolomite.

It will now be easy to review the formation, starting at the productive horizon and coming back to the surface.

300	feet	Royalite Dolomite
450	"	Calcareous shales
110	"	Fernie shales
400	"	Kootenay
600	"	Dakota
2,000	"	Benton

Actually, Royalite No. 4 had 1,900 feet of Benton, 100 feet being eroded, so that the depth of the well would be 3,740 feet. I am going to spend a few moments in order to outline the results secured from a series of wells in Turner valley; assume that there are seven wells, and each secures the Dakota shales at the following depths, 1,600, 1,700, 1,600, 1,800, 2,400, 2,800, 3,000 feet. Some are high and some are low, and the result is that the surface of a hill or hump underground has been outlined, and in the hump there can be looked for, at the top, oil below the gas, and water below the oil.

The information secured is then used to set casing where it will be of the greatest use. It is important that water should not flow into an oil sand, or a high-pressure oil or gas into a low-pressure horizon, and this result is secured by setting casing and cementing it into the proper formations.

Again, water in a well makes drilling difficult in the Benton shales, and all surface water is shut off at the top of the hole so that it will not impede the progress of drilling by causing the hole to cave. As gas or oil is drawn from any area, water follows it up the structure, so that all oil and gas fields gradually come to an end. By careful mapping, new wells can be located on areas where the maximum production can be secured without the well going to water.

There is in Turner valley, and other foothill folds, the question of thrust faults and small folds. Turner valley is believed to be a faulted structure, and this faulting sometimes brings the productive formations nearer the surface. At other times it makes a well repeat whole formations, and consequently it is a failure.

By carefully examining samples and cores, it is possible to determine just what is happening in any well, and by this means the operators may be saved considerable expense and effort.

There is very considerable excitement over oil and gas in Calgary today, and it is of interest to note that from the above description it will be apparent that wells which start in the Benton shales have approximately 4,000 feet to go before reaching the Royalite Dolomite. Now, above the Benton shales is the Belly river sandstone, which is from 1,300 to 1,800 feet thick. This added to the 4,000 feet mentioned above gives a well from 5,300 to 5,800 feet deep, if it is begun at the top of the Belly river standstone.

While what is believed to be the normal thickness of the strata in Turner valley has been given above, it is very important to note that if the beds are tilted to an angle of 45° you are adding roughly two-fifths of their thickness to these formations, and a vertical hole will then have to be 5,600 feet deep in order to reach to the Royalite Dolomite productive horizon.

The following figures as to the cost of drilling wells in the foothills will be of interest. A well 4,000 feet deep costs from $120,000 to $150,000; a well 5,000 feet deep from $150,000 to $180,000; and a well over 5,000 feet requires in the neighbourhood of $200,000.

What is wanted in the oil industry is development, but it must be sane development, which, to the writer, means:—

1. A structure where the age of the rocks is such that oil may have been produced in the past and where now the oil and gas may be imprisoned in a porous horizon.

2. A location where a well may penetrate the rocks containing oil at a depth not exceeding 6,000 feet.

3. A first-class board of directors who know enough to employ good men, buy good materials and tools and let them alone to carry out the work the drillers are engaged to do.

4. Sufficient cash in the bank, or arranged for, before drilling starts to complete the project.

Information published recently shows that Royalite No. 4 produced approximately 20,000 barrels of crude naphtha during January 1926. However, 2,000 barrels of this was produced in December 1925.

Suppose that this crude is worth, on a gravity calculation, $6.00 a barrel, this represents $120,000 revenue in one month, or at $4.00 a barrel it is $80,000 in the month of January. This does not include the gas sales.

You may look at these figures and say to yourself, Wonderful! but consider the question of how many failures did the Imperial Oil Company have before they secured Royalite No. 4, and, again, how much money did they spend to just handle its production?

Those who first worked in Turner valley, Wm. Pearce, A. E. Cross, W. S. Herron, A. W. Dingman and others, and the Imperial Oil Company, have discovered a great possibility, but it is not yet a proven oil field. The extent is not known, and many failures may be expected.

Development is wanted in this country, but every well drilled is a gamble, and a big gamble, and there is no room in this country for the promoter who has the "get rich quick" fever.

Should it be desired to gamble in oil stocks, it will help the industry if the fullest possible information is secured by all concerned before stock is purchased. There are many good structures to test without wasting money on areas where there is not a chance of securing oil.

When considering the oilfields of the world, it is well to remember that, while there are countries producing six to seven million barrels a year, from ten to twenty oil pools, where the oil pools are each less than one hundred acres in extent, Signal Hill is about 1,000 acres in extent.

This paper but introduces the whole subject, and as yet it has not been possible to make an underground map of Turner valley.

Much valuable information has been accumulated with the assistance of oil operators in Turner valley, and by co-operating in the matter of supplying information it will help to create a new industry in Alberta, but a boom is not desirable at the present time.

Problems of Engineering Education

Professor W. E. Duckering, A.B., B.S., C.E.
Dean of the Department of Civil Engineering, University of British Columbia.

Paper read before the Vancouver Branch of The Engineering Institute of Canada, October 6th, 1926

It has fallen to my lot to endeavour to set forth some of the most obvious problems which are confronting the profession of engineering in general and engineering educators in particular.

This is an engineering age, and yet there are people (among them practising engineers) who question the wisdom of expending funds for the training of more engineers. Many educators, observing the fact that over two-thirds of those who enter engineering courses fail to complete them, are earnestly seeking means of reducing this terrible academic mortality; and others are studying possible changes in curricula and in methods of instruction to determine whether or not engineering education can be made more efficient. Professional engineers are raising the question of the teaching personnel of colleges, and teachers and practising engineers alike are endeavouring to find means of establishing a closer co-ordination between the entire field of engineering education and practice, and successful citizenship.

It has been said that the more liberal courses in Arts and Science teach men " How to live "; while the more specialized courses in Applied Science and Engineering merely teach " How to earn a living." When one considers the services which engineers have rendered to civilization during the past half century alone, one is likely to doubt the truth of the statement that engineers have learned only the art of earning a living.

We are hardly inclined to be carried away by the rhetoric even of Mr. H. G. Wells when he calmly consigns universities to the scrap heaps of the future. Self-made business men there undoubtedly are; self-made journalists and novelists, one is led to suspect; but self-made engineers are as rare as genius itself. We are repeatedly confronted with the statement that the engineer is either unwilling or unable to take his proper place in the community, and that part at least of this is due to the fact that his narrow engineering curriculum provides insufficient training in the so-called humanities and classics. May we not seek the proof of the pudding in the eating, or perhaps in the digesting?

It is over twenty-five years since I began my intimate acquaintanceship with colleges and college men. Over one-half of that time I have been actively engaged in teaching within university walls; yet I am not at all convinced that the average engineer falls below the average medical man, lawyer, business man or politician in the unfoldment and practical daily demonstration of a sound philosophy of life; nor has the participation in many hundred faculty meetings, conferences and committee meetings with my colleagues of the liberal faculties led me to believe that doctors of philosophy are less prone to be childish, unreasonable and selfish than are their less fortunate brothers who have merely been trained to do things instead of talk about them.

In some manner or other engineers as a class seem to have learned something of the art of doing a great deal of hard work honestly and effectively without interfering in the affairs of other men. It may be that this lack of interference is due to a disinclination to act parts that have not been assigned; or it may be simply a matter of indifference. In either case, the complexities of modern civilization may, in the cause of good citizenship, demand that the engineer exhibit a more active interest in community affairs.

It is not the province of this address to draw comparisons in favour of the engineer; but rather to discuss whether or not he is playing as creditably as he can the part he should play in the life of the community, the nation and humanity. Correct answers to this question deeply concern the engineering student, his instructor, the practising engineer and the public in general.

The Society for the Promotion of Engineering Education has recently undertaken a most important educational research in its effort to make a study of the objects of engineering education and the fitness of the present day curricula. To indicate the exhaustive nature of this effort, I will quote from the January 1925 issue of " The Journal of Engineering Education." A mere enumeration of the specific objectives of the investigation will make its scope and importance clear. They have been outlined as follows:—

I. To clarify the educational functions and responsibilities of the colleges of engineering.

II. To establish guiding principles for the content and arrangement of curricula and the improvement of teaching.

III. To consider in what ways problems relating to engineering students, graduates and teachers may be dealt with more effectively.

IV. To examine the practicability and possible benefits of closer group relationship among the colleges and with the professional organizations of engineers.

V. To make an analytical comparison of the organization and practice of engineering education in Europe and America.

Each of these main topics has been subdivided as follows:—

I. (a) To determine to what extent the programme of engineering education serves *collegiate* type of training employing science and technology as its principal media; and to what extent it provides a *professional* type of training comparable with that in medicine.

(b) To indicate how engineering curricula may be coordinated more effectively with the needs of industry and the requirements of engineering practice.

It is the desire to determine how adjustment between the need for specific training on the one hand and for broad training on the other may be effected so as to provide to a reasonable degree for the immediate demands upon graduates in their earlier positions, and at the same time to provide the foundation for advancement to broader duties in the industrial and professional world and in public life.

(c) To determine whether or not it may be desirable and practicable to vary the extent of training in engineering to accord with:

(1) the capacities of students, and

(2) the requirements and opportunities of industry.

(d) To determine what responsibilities the colleges should assume for the further training of graduates.

To ascertain the needs of graduates for more extended training and to determine how the responsibility for such training may best be shared by the colleges and the industries.

II. (a) To formulate criteria for selection of the content of the scientific, technological, economic and cultural subjects of instruction, and for the proportioning of these major divisions of curricula.

(b) To promote more effective articulation of instruction in the various subjects which make up an engineering curriculum.

There is much evidence of the need for more effective co-operation in teaching groups of closely related subjects, such as mathematics, physics and mechanics, and the necessity for more direct and valid articulation of instruction in mathematics, economics and the physical sciences with that in technological subjects.

(c) To indicate means of more valid correlation of instruction in engineering with the technical and economic problems of engineering practice and to indicate how such problems may be used as means of teaching fundamental principles inductively.

(d) To ascertain directions which may be taken to improve methods of teaching in engineering colleges and to encourage study and experimentation in those directions.

III. (a) To determine what steps may be taken to insure the entrance of properly qualified students.

To consider how the entrance requirements of engineering colleges and the programme of secondary schools may be mutually adjusted; to consider what selective processes of a non-scholastic type may be used as a valid supplement to a scholastic requirement for admission; and to consider what information concerning an engineering career should be provided and what guidance given, both before and after admission, in the choice of educational programmes.

(b) To determine what measures may be taken to deal more effectively with the problem of eliminations.

To learn at what periods and for what reasons students are eliminated or withdrawn from college; to ascertain the fundamental causes of failures; and to determine how cases of impending failure may best be dealt with.

(c) To ascertain the methods which may best be used by the colleges to facilitate the obtaining of suitable employment by their graduates and to promote their further development.

To canvass the economic demand for engineering graduates through the co-operation of the industries and professional organizations; to ascertain the types of positions and fields of work which graduates are required to fill; and to consider what records, supplementary to the usual scholastic record, are best designed to facilitate the employment of graduates.

(d) To indicate how methods of recruiting and developing engineering teaching staffs may be improved.

To learn from what sources teachers of junior and senior rank are being drawn or may be drawn; to learn what methods are being used to develop younger teachers and how such methods may be made more effective; to determine how adequate contacts of teachers with industry and practice may be afforded; and to examine into the mutual responsibilities of the colleges, the industries and the profession for the development and maintenance of teaching staffs of high order.

IV. (a) To indicate the extent to which further development of group action by engineering colleges is desirable, and to point out how such action may be effected.

(b) To determine how the engineering colleges and the professional organizations of engineers may effect a closer association for the mutual benefit of engineering education and the profession of engineering.

V. (a) To compare the positions occupied by the engineering colleges in the educational systems of Europe and America.

(b) To compare the educational practices of the several groups of institutions relative to admission standards, teaching and examination methods, curricula, the development and status of teachers and the like.

(c) To compare the relations of the several groups of institutions to the industrial life, the governmental and public services, and the professional organizations of engineers of their respective countries.

Under the various headings outlined above, the investigation is being carried out along the following lines or successive steps:—

1. Collection of facts and data.
2. Analysis and classification of facts.
3. Interpretation of the evidence.
4. Experimentation where desirable.
5. Summaries and reports.

It is expected that there will be periods of study and discussion by faculty committees and in faculty meetings, from which conclusions should be reached and plans for action formulated. As the plans are put into effect, their results should be observed. It is not the aim to bring the project to a definite stage of conclusion, but rather to prepare the way for a continuing process of educational enquiry and adjustment, and to develop within the Society's organization the means of making the co-operation of the colleges in this process effective. Wm. E. Wickenden is Director of the Investigation.

I have extracted somewhat at length from the statement of objectives and outline of procedure of the committee because it furnishes a fairly complete idea of the problems which confront engineering educators and also because the committee has already collected such a large amount of data that we may with profit proceed to analyze and interpret it.

In any attempt to compare Canadian and American universities with those in Europe, we must bear in mind the vast distances which affect every western problem. Students entering our universities are drawn from geographical areas having median lines averaging between one and two hundred miles from the university. In Europe the institutions are closer together, and each great university has in time built up its reputation around a particular type of training or scientific research or culture. On this continent there has been a tendency to endeavour to found universities which would embody all these features within the boundaries of a single institution, this attempt being imitated by each new university in turn. The effort to bring to each locality as many advantages as possible, in spite of isolating distances, contributed to this attitude of imitation until prescribed curricula are so similar in general that our scholastic accountants, the registrars, the czars who sit in final judgment upon all phases of collegiate proficiency, have the effrontery to propose a complete standardization of courses. One can hardly conceive of a more deadly foe to educational progress.

It has been stated quite freely in university circles that the type of students attracted to engineering would be found on the average of lower intellectual standing and intelligence than the average student in the faculty of arts. This remained a mere matter of opinion until the rather general use of intelligence tests brought out the fact that not merely the engineering student but also the practising engineer was rated higher than any other group by these tests. Excuses have been made that the tests were more suited to the engineering type of mind; but it must be remembered that it was the educational psychologists, and not the engineers, who evolved them.

This statement that the engineering student is at least on a par with students in more liberal courses takes on still further significance when it is considered side by side with the fact that over 95 per cent of engineering students are native-born, with 74 per cent native-born parents and over 60 per cent native-born grandparents. I am using the term native-born to apply jointly to the United States and Canada. Ninety-one per cent of the grandparents were either native-born or came from the northwestern part of Europe. This appears to show good stock.

A study of the high school records of about 4,000 students disclosed the fact that 18 per cent were honour students, 42.6 per cent were classed in the upper third of their group, 36.8 per cent were in the middle third, while only 2.6 per cent came from the lowest third. Over two-thirds of these students did well in chemistry, physics, mathematics and other science, while less than ten per cent were poor in history and English, and about twenty per cent were poor in modern languages. Place these facts alongside of the fact that not one-third of the students entering engineering courses manage to graduate without losing one or more years, and barely forty per cent graduate at all, and you have another of the problems facing engineering educators. It might be urged that engineering courses are too severe; but no one has ever complained that engineering graduates are too well prepared, or that they are more than equal in their training to the engineering graduates of European colleges. In fact, it is stated that the Europeans are superiors, but this is once more a matter of opinion only, and the records of engineers on both continents do not appear to indicate a serious discrepancy in the ability of western men.

But if the engineering schools are drawing from the cream of high school graduates, why is it that a careful analysis of the causes of scholastic failure among students in engineering indicates that practically seventy per cent fail through poor preparation, lack of ability and lack of interest; while only 1.8 per cent fail through the much-berated over-participation in undergraduate activities? This raises the question of accredited high schools, entrance examinations, intelligence tests and other methods of determining the fitness of applicants for entrance to engineering schools. It seems unfair that 60 per cent of those who chose engineering as their life work should be turned back into the community with failure stamped across their collegiate records, while another 10 per cent graduate with minimum requirements.

An analysis of the motives leading to the choice of engineering courses indicates that only 28.6 per cent felt a definite appeal in engineering. Only 13.6 per cent made the choice on the basis of advice. It appears that well over one-half of the students have little or no conception of the field of engineering, though a majority make this most vital decision before reaching the last year of high school. One may be pardoned for wondering whether instruction in science and mathematics, in which these students were proficient, is really basic in preparing a man to become an engineer.

The average high school student is active and is interested in doing things. Indifferent though he may be in the class room, he will show plenty of interest and will work long hours in fields where there are rewards which appear to him to be worth while. At this age he seems to be just as interested in life and in himself as a living being as he was interested in learning things when as a little child he first trudged to school and was squelched by a flood of numbers and names and rules. Why is it that the child of six is such a bundle of questions and interests in everything that it is almost impossible to supply him adequately with answers and activities, yet a few years of our school system leave him apathetic and indifferent to instruction? Why is it that twelve years of instruction in mathematics still leave the average student uncertain in addition, multiplication, subtraction and division? The entire school system is in effect a preparation for entrance to colleges or universities, yet a group drawn from what are admittedly the best students is only 30 per cent efficient in passing the requirements of an engineering course.

One need not be timid in suggesting that changes are needed somewhere. Educators who are familiar with freshmen students point out that their mental grasp is practically limited to passages in the text books they study, and that they are utterly unable to read books and grasp them as a whole. Instructors in engineering find a similar difficulty regarding their training in sciences and mathematics. The student is simply stuffed with undigested, unrelated ideas and information. Is this not the necessary outcome of a system of teaching which in defiance of every rule of nature proceeds from the unrelated and abstract to the related and concrete?

It is well known that nearly any child in good health, if deprived of ordinary schooling until ten or twelve years of age, will in about two years equal in scholastic ability children of the same age who have been constantly in school. Why, in the face of all that a child of twelve should know and has never heard of, should he be forced to spend six years obtaining what he can obtain easily in two? In spite of the fact that there are still psychologists who maintain that training in one field does not carry over into other fields of knowledge, one is forced to admit that Asiatics whose scholastic preparation can hardly be said to parallel ours, are able to compete favourably with our own students in our universities and learn our language into the bargain. It would seem that the qualities which make for scholastic success exist in spite of, rather than because of, the preparation the student receives.

In those years when the child's body is growing; when the emotional and social nature is unfolding; when it is thirsty for information; can easily learn languages and yet despises grammar; when it has not yet begun to reason about things, but accepts them at their face value; why should it not be engaged in studying nature and the habits of living things, including human beings? Every educationalist admits that it is necessary to have a background of experience before it is possible to draw abstract principles from that experience; yet most of them reverse the process when they begin to teach and give the abstractions before they lay the basis in experience.

We talk glibly about providing the fundamentals of a branch of knowledge, but how many have stopped to consider whether or not the fundamental is necessarily the foundation? These two terms are used as if they were synonymous, and they are not synonymous at all. The fundamental idea of a tree is not the root. The fundamental idea of a building is not the foundation; but in each case the fundamental idea does determine the superstructure. If your fundamental idea of a building is limited to warehouses and elevators, you will hardly be able to design a modern hotel, yet the foundation and the structural materials might be the same in each instance. It is doubtless true that mathematics and the sciences are the fundamental bases of all engineering, but the foundation for engineering activity lies in an appreciation of the purposes and needs of the human race, not in the pursuit of abstract knowledge.

Where in all the years of pre-collegiate instruction has there been opportunity to bring the student into an appreciation of nature and of human beings? If it were not for the games that school children are granted as a concession to health, the ordinary curricula would leave them almost totally ignorant of their own natures and the world in which they are expected to be good citizens.

Of course, you will point to the courses in civics or history or geography, and say that here the student is taught about the life and places of abode of his fellowmen, but all that he obtains is superficial and lifeless when compared with what he might learn of the life and habits of men and animals by actual observation and even participation.

All children should know the basic principles which underlie successful gardening, but what course in botany ever supplies this knowledge? Everyone should be trained in the care of his body, but what course in biology ever prevented anyone from becoming a dyspeptic through ignorance of the laws of diet? Good citizens should know the laws of self-control, and the cause and cure of selfish, brutal quarrelling, but what course in history ever stopped a fight or prevented a theft? The training which they receive in mathematics and science only too often merely increases the skill with which they rob and betray their fellows.

All this may seem to be wandering from the subject which we are supposed to be discussing, but when we consider that the student in high school probably chooses his career in the field of engineering because that seems to offer the most intimate contact with his desire to fill a useful place in the world, and thereby merit the rewards offered to useful citizens, is it any wonder that he shrinks from a mere continuance of the apparently useless instruction he has been enduring, and turns to engineering as an opportune substitute? Thousands of students make engineering their choice as a profession or a vocation, not because of knowledge of the field, but because they feel that they may find in it a dignified and profitable outlet for the intelligence and strength they possess. They turn to it as an unvoiced protest against the abstract and narrow so-called liberal training they have received.

Having spent some time tearing the ordinary school curricula to pieces, we may now ask ourselves the question whether or not engineering curricula are similarly guilty.

Engineering curricula seem to be a compromise between academic abstractions and pure science on the one hand, and utilitarian applications on the other. In the early history of engineering instruction, the teachers of applied science were recruited almost entirely from the ranks of the pure scientists, and practically all text books were written by these recruits or by men who remained in the realm of pure science.

Engineering curricula took the form of a simple extension of the field of pure science to such applications as could be conveniently dealt with in the classroom or college laboratory. Contact with the outer world of engineering practice and with the difficulties which engineers met from day to day soon began to colour the methods of instruction and the content of courses by injecting the pragmatic influence of engineering practice; but the old fallacy remained. The instructors were thoroughly familiar with the fundamentals of science, and to them it was unbelievable that any progress in knowledge could be made before these fundamentals were established in the mind of the student, therefore all the mathematics, all the physics, and all the chemistry must be taught to the student before he be contaminated with the crude and vulgar applications which arise in engineering. As more and more it became necessary to draw upon the rank and file of engineers to satisfy the demand for engineering instructors, engineering instruction took on a more and more practical turn. Laboratory methods, instead of being merely demonstrations of previously expressed and intricate theory, became the means of training the student in engineering practice, and of research leading to improvement and discovery. The effort in regard to the student changed from merely acquainting him with that portion of science which it was expected might prove useful in his career as an engineer to an effort to train him before leaving college in the active, though elementary, practice of engineering. This inevitably opened the flood gates of engineering practice, and the courses of study became swollen with the details of engineering methods. A cry was raised for more time in the engineering laboratories and necessarily something had to be sacrificed.

Courses in languages, history, logic and economics were crowded out in order that the young engineer might be sufficiently trained in things as he would find them when he left college. It was plain that the engineer could not get along without a good grounding in mathematics and science, so anything that appeared as non-essential had to give way.

For a brief time, this modification of the course of study appeared to be satisfactory. Engineering instruction was becoming practical, and therefore it was thought to be better. Young engineering graduates were not so likely to be sent on foolish errands when they tackled their first jobs. The older men will all remember the days when the collegiate greenhorn was likely to be sent after left-handed monkey wrenches, sacks of ready-made hub holes, or sets of cast iron standard contours. But in thus extending his efforts to make the graduate engineer familiar with the details of engineering practice in his particular line, the engineering educator had created a Frankenstein which soon threatened to destroy him.

Engineering practice is constantly changing and the field of engineering is ever enlarging and its details multiply incessantly; until now the teacher of engineering has been obliged to call a halt. It is frankly impossible to do more than skim over the field which opens before the engineer in every branch, and our men are in danger of leaving college with a limited training in methods and without that essential basic training in fundamentals which alone can ensure their continued growth as engineers.

One answer to the problem has been suggested in the lengthening of the course to include five or even six years; but unless there goes with this a drastic change of purpose, it will be merely a postponement of real solution. Perhaps some light may enter our deliberations if we try to rise above the attitude of the passing generation in its slavish worship of the subject matter and the content of courses, and view the question from the standpoint of the student. Too little consideration has been given to him in the past. He has been treated simply as average raw material which must be in some manner forced through the educational mill in order that a standard product may be placed upon the market of the world's activities.

But the employers who had previously ridiculed the impractical theoretician are now complaining about the unimaginative automaton who is unable to rise to positions which make extreme demands upon men's higher creative faculties. Whereas he used to complain about the waste time spent in getting the young engineer fitted into the industrial machine, the employer now complains that the engineering graduate does not show sufficient likelihood of every occupying the driver's seat.

I have sufficient faith in the average young man to believe that he is just as well endowed with all the necessary faculties today as he ever was, and, if the product of our educational system is not what it should be, it is the system that is wrong. It may be a new idea to consider the student as the only true unit and end of education, but it is none the less a necessary one if we are to approach a solution of educational problems in general.

One of the reasons why the eleven or twelve years of preparation which a student receives before entering college do not prepare, is due to the fact that much of that time is spent in destroying his natural ability, nullifying his initiative and vigorously preventing him from thinking about anything except in unrelated fragments. More appreciation of the student's place in the educational scheme and less worship of subject matter would serve to remove this shameless outrage against all that is worth while in human destiny.

If the ordinary student can reach the high school entrance stage in two years (and there is ample evidence to show that this amount of time is sufficient), six of the previous years have been mostly wasted because this is practically all that has been accomplished.

Suppose that the child's interests had been extended instead of curtailed; that he had been given an opportunity to deal with the practical, understandable side of the world as it faces him on all sides; that the unfoldment of high ideals had been stimulated, not by precept but by exemplification in his daily relationship with his fellows in games, contests and in the active search for knowledge of the natural world; that instead of being classified and pigeonholed according to his deficiencies, he had been given freedom to unfold his abilities. Might he not come to the high school with his thirst for knowledge unquenched and still acute, and be ready for the more precise knowledge of science and the abstract mathematics and grammar because these subjects enable him to more thoroughly understand what he already partially knows? The foundation for an education does not lie in the abstract principles which learned men in all centuries have drawn from the fields of human experience, but in a realization of each man's relationship to his environment, his fellow-man and the universe.

To some who pride themselves on a coldly intellectual attitude towards these problems, this may sound like sentimentality, but the most damnable factor in human civilization to-day is the scientist who perjures himself and his calling by devising means of increasing human misery, torture and destruction. Too great a divorcement of science from the broader phases of human affairs leads to an apathy toward human suffering.

Unless man solves the problem of his relationship to his fellow-man in a manner naturally beneficial, civilization will once more destroy itself. In a similar manner, if we are to prevent our educational system from crashing through sheer top-heaviness, educational methods and the content of the curricula must not be divorced from an active interest in the growth and unfoldment of the inner powers and purposes of the student.

Many efforts are now being made to balance more carefully the instruction in engineering colleges. It has been recognized that it is unfair to ask a student to specialize too soon, so attempts have been made to make the first and sometimes the second years of applied science uniform for all branches of engineering.

It has also been evident that two years of abstract science give the student little or no intimation concerning the nature of the engineering course he expects to enter, and he often becomes aware of a mistaken choice only long after it seems too late to change that choice. Orientation courses and engineering problem courses have been introduced in many schools, partly to provide an opportunity for the student to choose his engineering branch more intelligently, and partly to correlate the instruction in mathematics, physics and engineering. Instead of waiting until the student is through a subject before giving him a necessity for its application, the student is plunged into the solution of engineering problems contemporaneously with the instruction in mathematics and science in order that he may feel the need of these branches of knowledge while he is taking them. Incidentally he may discover either a real aptitude, or a dislike, for engineering, and thereby hasten the time when he enters a more attractive field of action.

Another phase of these problem courses is definite training in the application of scientific methods to the solution of problems, as well as training in the mere mechanics of intelligible and accurate computations. In accordance with this effort to make engineering courses more effective in the training of young engineers, an engineering problem course has been established at the University of British Columbia. The students in the first year of applied science are engaged for two two-hour periods per week in the solution of engineering problems drawn from the fields of physics and mathematics, and special emphasis is laid upon individual work which must be brought up to a definite standard of excellence before it is acceptable.

In spite of initial resistance from the students who have not previously been required to tackle a problem before it has been fully explained, there is soon developed a splendid reaction to the situation, in which the best students actually resent an offer of assistance, and, at the other end of the scale of performance, the load imposed by the necessity for unaided effort brings to the mediocre or lazy student an early realization of his deficiencies. If he has grit, he really begins to work; if not, he is likely to drop out and take some more congenial course. In the second year of applied science at the University of British Columbia, this course is being continued as one three-hour period per week. The aims are the same, but much greater emphasis will be placed upon the use of higher mathematics. It is not expected that courses of this type will solve all our difficulties; but the experience of the past ten years indicates conclusively that this sort of instruction improves the work done by the students in the later years at college, and many students have testified that the training has played an important part in fitting them for their engineering activities.

Recognizing that the effort to satisfy the demands made by the employers of young graduates had led to the introduction of too great a preponderance of instruction in current engineering practice, to the exclusion of broader training, educators have been endeavouring recently to eliminate training which may be secured much more quickly and efficiently outside of college, and to introduce more courses in economics, business administration and law, as well as cultural subjects only remotely associated with engineering.

Naturally, this awakens much unthinking criticism. We often find the outside man who complains that the engineering course is too narrow, unfitting a man to play a major part in community affairs, objecting to the introduction of subjects which have a purely cultural significance. This contradictory attitude arises from the old fallacy of worshipping subject matter, instead of making the goal of educational effort the unfoldment of a thinking man within the student.

No course can give a man all the essentials of success, but any course has some effect upon his character, and may either stimulate or stultify faculties which he already possesses. Therefore an effort is being made to reach a reasonable balance between the three most important factors ruling the plan of education for an engineer; first, a foundation adequate to support the structure of life to be erected thereon; second, a superstructure of fundamental laws and basic facts essential to the chosen branch of engineering, and, third, sufficient technical training to make the structure livable.

The foundation can be laid and gradually perfected throughout the entire period of educational supervision, and must provide sufficient appreciation of the factors which determine the main currents of human affairs to enable the student to cope with the problems arising in his dealings with his fellows, be they his equals, his inferiors or his superiors. The ideals which alone make knowledge in this field safe and worth while should be stimulated by the teaching and exemplified in the environment of the child before he enters the high school; but at no time should they be allowed to sink so far into the background that he becomes unconscious of their presence. Such a foundation must open the mind of the student to a general recognition of the principal channels of civilization's activities, or else it will fall short of its goal.

In mathematics and the sciences lie those fundamental laws and principles without the application of which engineering works are impossible. The student must be made sufficiently conversant with those dealing with the branch of engineering he has chosen that he may rely upon them in the face of new difficulties, rather than upon memories of similar situations presented to him in his various text books. Without such knowledge and self-reliance, he will never leave the beaten paths of established practice and mediocre achievement. Training in mathematics and science may begin in the high school, but it must never be separated from wholesome applications and must continue throughout the entire period of university studies.

Specialized technical training in the elementary groundwork of engineering practice introduces the student to the more common activities in his chosen field and enables him to hold his own more comfortably during the period in which he is gaining experience and establishing a reputation. This valuable phase of his education must not be ignored, but it must not be allowed to grow into an effort to make the student proficient in the standard practice of all the various by-paths of his profession. Such effort belongs to the subsequent career of the individual, and can be made much more effective outside the college walls.

Although it is fairly easy to define an objective, it is not quite so easy to agree upon it, and it is hard indeed to agree upon the methods by which it is to be attained. Nevertheless, the widely-spread effort to define and solve engineering educational problems must bear some good fruit. Leading educators and leading engineers are lending their time and their training to the project, and are bringing together data from all angles. We may well hope that many splendid ideas will be brought forward and that vital suggestions will appear for the benefit of those who are constantly seeking to improve engineering education.

One phase of the investigation involves a comparison between European universities and those on this continent. It discloses an important difference. In Europe the great centres of research are in the universities, and it is to them that the industries look for new discoveries and progress; but in this country the major industries conduct their own researches, and equip themselves with vast laboratories for their own private gain. Here the keenest scientific minds are often drawn from the universities into the industries; but in Europe the very best talent which the industries produce is encouraged to enter the research laboratories of the universities.

This essential difference is further intensified by the fact that our western professional schools are actively and often fully engaged in giving undergraduate instruction to that great mass of students who are unfit for professional careers and should be receiving technical vocational training instead. These students graduate from high schools and continue their academic training for several years in higher institutions without any real desire to carry their studies beyond a glorified high school stage, and even if finally granted an engineering degree serve only to fill the ranks of routine employees. European universities make no attempt to teach this class of students, and direct them to intermediate schools specially designed to give technical and vocational training.

The foundational training for entrance to such schools should be similar to that outlined above as essential for professional careers; but the emphasis on the sciences and mathematics need not be so pronounced, and the training in the less technical branches of engineering practice should be carried far enough to provide a really efficient introduction to the more general and routine phases of engineering work.

Intermediate technical schools of this nature play practically no part in our educational system. The junior college is not a substitute; consequently the universities are carrying a heavy burden of extra high school instruction, with the inevitable result that the average teacher of engineering is reduced to the level of routine teaching, with little opportunity for advancing either his own or the world's store of knowledge. Not that teaching, as such, suffers by comparison with research; but no teacher can long remain a vital stimulus to his students if he has no time to extend his field of knowledge and engage in the invigorating search for new facts and laws.

An analysis of the teaching load in our universities shows that it is uniformly distributed among professors, instructors and assistants, both as to time and college years of students taught. Roughly speaking, the average requirement amounts to between forty-five and fifty-five hours of collegiate work per week throughout the teaching session. This varies somewhat with the faculty concerned and with the amount of committee and conference work assigned to the instructor. Comparisons are often misleading; but perhaps the fact that the average salary of teachers of engineering is only slightly over one-half that of practising engineers who graduated in the same years may throw some light on the fact that educational vocations are more often directed to remunerative ends than to the advancement of engineering knowledge.

A survey of the achievements of engineers encourages us to seek means of giving engineering students the very best preparation conceivable. Analysis of the collegiate records of successful engineers shows conclusively that they come as a body from the upper sections of their classes, and the odds are overwhelmingly in favour of the student with a high scholastic record. Our engineering graduates continue in engineering or closely allied work in very satisfying percentages, showing no more likelihood of changing than do individuals in any other walk of life, and, in spite of current opinion to the contrary, engineers are taking their share of the important tasks. Statistics show that over a long period of years engineering graduates are two-thirds of them occupying executive, administrative or directive positions.

Were it not for the fact that engineers and engineering educators take their work seriously, we might view the past with complacency and let the future take care of itself; but such is not the engineering temperament. It must improve that which it is doing, and we cannot be content while the possibility of progress stands knocking at the gates of our educational institutions.

Aeronautical Research

The remarkable developments in aeronautics which have taken place during the last few years are strikingly illustrated by the work of the Aeronautical Research Committee in Great Britain, as shown by its reports.

The investigations of this committee, which works in close touch with the Society of British Aircraft Constructors, are carried out at the universities, at the National Physical Laboratory and at the Royal Aircraft Establishment, Farnborough, and are financed by the Air Ministry and the Department of Scientific and Industrial Research.

Among the problems recently dealt with may be mentioned: the stability and control of aeroplanes in stalled flight and at low speeds; the causes of various accidents arising from spins and dangerous vibrations of aeroplane wings; the investigation of novel wing sections; the theory of air-screws; the behaviour of seaplane floats at high speeds; the corrosion and durability of metal aeroplanes; the development of a satisfactory method for mooring airships to masts; detonation in high-compression internal combustion engines; the elasticity and fatigue of metals used in air-craft construction, and the development of new light alloys.

Very great interest has been aroused in two entirely new types of air-craft, namely, the "autogyro," a machine in which the ascending force is provided not by wings as in the normal design but by means of a large wind-mill rotating about a nearly vertical axis, and the Hill tailless light aeroplane, the performance of which is not inferior to that of the normal design of aeroplanes, while there are several inherent advantages in the tailless type.

The results achieved by the work of the Committee are paralleled by those of the American Advisory Committee for Aeronautics, and bear eloquent testimony to the great technical advance which results from a thoroughly organized programme of research, placed in the hands of properly trained engineers and investigators and provided with adequate financial backing.

Nominations for Officers' Ballot

Regulations

Not later than the seventh day of November, the secretary shall mail to each corporate member of *The Institute* the officers' ballot, as prepared by the nominating committee and the council.

Additional nominations for the officers' ballot signed by ten or more corporate members and accompanied by written acceptances of those nominated, if received by the secretary on or before the first day of December, shall be accepted by the council and shall be placed on the ballot. The words "Special Nomination" shall be printed conspicuously near such names, and the names of the members making such nominations shall be printed on some part of the ballot.

Notices shall be deemed to have been mailed to members as presented by the By-laws if such notices are printed in *The Journal* of *The Institute* and mailed by the dates prescribed in the By-laws.

Officers' Ballot

The following is a list of the nominees submitted by the Nominating Committee, and approved by Council at the meeting held on September thirtieth, nineteen twenty-six:—

PRESIDENT: A. R. Decary, M.E.I.C., Quebec.

VICE-PRESIDENTS: Zone a*—S. G. Porter, M.E.I.C., Calgary; Patrick Philip, M.E.I.C., Victoria; H. S. Carpenter, M.E.I.C., Regina; Wm. Smaill, M.E.I.C., Vancouver.

Zone c*—J. H. Hunter, M.E.I.C., Montreal; O. O. Lefebvre, M.E.I.C., Montreal.

COUNCILLORS: *Victoria Branch:* J. N. Anderson, A.M.E.I.C., Victoria; F. G. Aldous, A.M.E.I.C., Victoria.

Vancouver Branch: E. A. Cleveland, M.E.I.C., Vancouver; W. G. Swan, M.E.I.C., Vancouver.

Calgary Branch: A. L. Ford, M.E.I.C., Calgary; C. C. Richards, M.E.I.C., Calgary.

Edmonton Branch: R. W. Boyle, M.E.I.C., Edmonton; A. G. Stewart, A.M.E.I.C., Edmonton.

Lethbridge Branch: P. M. Sauder, M.E.I.C., Lethbridge; John Dow, M.E.I.C., Lethbridge.

Saskatchewan Branch: H. R. MacKenzie, A.M.E.I.C., Regina; P. C. Perry, A.M.E.I.C., Regina.

Winnipeg Branch: †† A. G. McGillivray, A.M.E.I.C., Winnipeg; H. A. Bowman, A.M.E.I.C., Winnipeg.

(*Continued on next page*)

Lakehead Branch: J. Antonisen, M.E.I.C., Port Arthur; M. W. Jennings, A.M.E.I.C., Buffalo, N.Y.

Sault Ste. Marie Branch: C. H. E. Rounthwaite, A.M.E.I.C., Sault Ste. Marie; Carl Stenbol, M.E.I.C., Sault Ste. Marie.

Border Cities Branch: J. Clark Keith, A.M.E.I.C., Windsor; J. J. Newman, M.E.I.C., Windsor.

Niagara Peninsula Branch: B. Atkinson, M.E.I.C., St. Catharines; E. P. Johnson, A.M.E.I.C., Welland.

London Branch: W. C. Miller, A.M.E.I.C., St. Thomas; E. V. Buchanan, M.E.I.C., London.

Hamilton Branch: W. F. McLaren, M.E.I.C., Hamilton; H. B. Stuart, A.M.E.I.C., Hamilton.

Toronto Branch: ‡ T. R. Loudon, M.E.I.C., Toronto; N. D. Wilson, M.E.I.C., Toronto.

Kingston Branch: L. F. Goodwin, M.E.I.C., Kingston; L. F. Grant, A.M.E.I.C., Kingston.

Peterborough Branch: R. L. Dobbin, M.E.I.C., Peterborough; A. H. Munro, A.M.E.I.C., Peterborough.

Ottawa Branch: †† A. F. MacCallum, M.E.I.C., Ottawa; J. D. Craig, M.E.I.C., Ottawa.

Montreal Branch: † C. J. Desbaillets, M.E.I.C., Montreal; W. C. Adams, M.E.I.C., Montreal; P. L. Pratley, M.E.I.C., Montreal; F. A. Combe, M.E.I.C., Montreal.

Quebec Branch: A. B. Normandin, A.M.E.I.C., Quebec; Alex. Lariviere, A.M.E.I.C., Quebec.

Saguenay Branch: G. F. Layne, A.M.E.I.C., Riverbend; Hew G. Cochrane, A.M.E.I.C., St. Joseph d'Alma.

Moncton Branch: J. D. McBeath, M.E.I.C., Moncton; H. W. McKiel, M.E.I.C., Sackville.

St. John Branch: W. R. Pearce, M.E.I.C., St. John; Geoffrey Stead, M.E.I.C., St. John.

Cape Breton Branch: S. C. Mifflen, A.M.E.I.C., Sydney; W. C. Risley, M.E.I.C., Sydney.

Halifax Branch: K. L. Dawson, A.M.E.I.C., Halifax; G. S. Stairs, A.M.E.I.C., Windsor.

*(One Vice-President to be elected for two years.)
†(Two Councillors to be elected for three years each.)
‡(One Councillor to be elected for three years.)
††(One Councillor to be elected for two years.)

Annual Meeting—Tentative Programme

Brief announcements regarding the forthcoming Annual General and General Professional Meeting of The Institute have appeared in the Journal during the past few months. The Executive Committee of the Quebec Branch has now announced the tentative programme of the sessions to be held in Quebec City, and from the outline given this meeting promises to be one of great interest to engineers throughout Canada. The sessions in Quebec will occupy three days, and it will be noticed that a well-balanced programme of technical sessions, visits to points of interest and general entertainment has been provided.

The programme, including the business session in Montreal, is given below:—

Annual General Meeting in Montreal

(To be convened at Headquarters, 176 Mansfield Street, on Thursday, January 28th, 1927.)

Appointment of Scrutineers.
Appointment of Auditors.
Motion to adjourn to Quebec City, to reconvene at the Chateau Frontenac on Tuesday, February 15th, 1927.

Annual General and General Professional Meeting in Quebec

TUESDAY, FEBRUARY 15TH, 1927.

9.00 a.m.	Registration.
10.00 a.m.	Reception and discussion of reports from Council, Committees and Branches. Scrutineers' report and election of officers. Retiring President's address. Induction of new President.
1.00 p.m.	Lunch—complimentary to visitors. Welcome to members by Chairman of the Quebec Branch, who will preside. Brief address by the Mayor of Quebec and the Hon. A. Galipeault, Minister of Public Works of the Province of Quebec.
3.00 p.m.	Continuation of Annual General Meeting. Unfinished and new business.
9.00 p.m.	Ball at Chateau Frontenac. Admission by ticket.

WEDNESDAY, FEBRUARY 16TH, 1927.

10.00 a.m.	First technical session. Forest Conservation and Operation.
2.00 p.m.	Visit to Quebec Bridge, or St. Malo Shops.
7.30 p.m.	Annual dinner of Institute. Admission by ticket. President in the Chair.

THURSDAY, FEBRUARY 17TH, 1927.

10.00 a.m.	Second technical session. Papers on Power developments.
2.00 p.m.	Third technical session. Papers on Mining Activities. Discussion of papers previously presented.
5.00- 7.00 p.m.	Reception at the Lieutenant-Governor's residence, Spencer Wood.
8.30 p.m.	Smoker or special entertainment. Admission by ticket.

Education and the Engineer

Questions and problems connected with the training of young engineers have recently received much attention, particularly during the years since the War, and many of them still clamour for solution.

Why do so many young men choose the engineering courses at our universities; why do so few of them complete their courses successfully; should such courses be for the many or for the few; are our engineering schools giving the best possible training; what should be the relation between the university work and training in field or workshop; how can the young graduate be aided in obtaining employment which will continue and round out his college training? These are only a few of the lines of enquiry which suggest themselves when the subject is approached. The importance of an investigation of these and other points is obvious; the future of the profession depends upon the proper utilization of the information obtained.

The subject has been brought up repeatedly in the proceedings of our various branches, its discussion occupied a great part of the time at the Annual General Professional Meeting of The Institute in 1925, and many contributions concerning it will be found in the columns of the Journal.

A noteworthy effort to clarify the situation is being made by the Society for the Promotion of Engineering Education, an organization which has for some years been collecting data and information in the United States and Canada, some of the results being now available for analysis and consideration.

The preliminary report, contained in that Society's Journal for September 1926, gives a general view of the present situation as revealed by the Society's enquiry, and is well worthy of study, and the Society's reports have formed the basis for a thoughtful and stimulating paper recently presented before the Vancouver Branch of the Engineering Institute by Professor W. E. Duckering, and printed in the present issue of the Journal.

Such a paper might well be the subject of discussion at the meetings of more than one of our branches, for it presents constructive rather than destructive criticism, and marks the lines along which the work of reform might with advantage be directed. The facts accumulated by the enquiry do not appear to indicate the necessity for any revolutionary changes, but do undoubtedly point out the desirability of the readjustment of many of our ideas regarding the training of the young engineer.

Since the development of systematic engineering education began in the Eighties, great changes have taken place in the conditions governing engineering activities. The sphere of the consulting engineer is apparently becoming more limited, opportunities on the technical staffs of great industrial companies are more numerous and attractive, the services of members of the profession have become more largely administrative, and the importance to the engineer of the art of organizing and controlling men has become more marked.

The greater complexity of the technical knowledge in his own branch which an engineer should now possess, and the greater degree of specialization now required, makes it increasingly difficult for a man to be expert in his own realm and at the same time well informed in many others.

The work of bodies like the Engineering Institute of Canada in disseminating professional knowledge among their members does much to assist in this regard. The publications of the various engineering societies afford an opportunity to every member to continue his general engineering education and to maintain a proper interest in the achievements taking place in lines of work with which he is not specially associated. It will indeed be regrettable if the investigation and research now directed to the education of the engineer fails to give rise to definite constructive steps towards improvement in our present methods and system.

Meeting of Council

Meeting of October 15th, 1926

A meeting of Council was held at eight p.m. on Friday, October 15th, President Geo. A. Walkem, M.E.I.C., in the chair, and five members of Council being present.

The report of the Finance Committee, with the financial statement to September 30th, was approved, and a number of requests for further extension of credit to various members were considered. Two requests for reinstatement were considered and approved.

In accordance with the By-laws, Council examined and approved the report of the Nominating Committee now published in the Journal.

In response to suggestions received from members, Council considered the desirability of drawing the attention of the Dominion Government to the resolution passed by Council in June 1924 regarding the Hudson's Bay Railway, in which Council suggested that the completion of this railway and its attendant works should not be carried out until the proposed railway has been thoroughly investigated from the engineering, economic and national viewpoints. The secretary was directed to forward a copy of this resolution to all members of the present Federal Government.

Consideration was given to the question of the employment of other than Canadian engineers by the Federal Government, and the secretary was directed to address a letter to the government suggesting that, in future, important public works should be designed as well as executed by Canadian engineers.

The committee which is considering the advisability of making changes in the present method of expending the funds available for prizes for Students and others reported progress, the chairman stating that the opinions of the various branch executive committees with regard to this matter were being awaited.

The secretary reported that, largely as a result of the removal of names for non-payment of fees, a reduction in the total membership of The Institute had taken place, this being particularly marked in the case of the Student class, and he was directed to communicate with the various branch executives, pointing out the importance of enrolling suitable members in this class.

Dean H. M. MacKay, M.E.I.C., and A. G. Tapley, A.M.E.I.C., were requested to attend the meeting of the Canadian Board of Trade at St. John, N.B., as the representatives of The Institute.

A progress report was received from the Papers Committee, the chairman announcing that arrangements have been made, in several cases, for an interchange of speakers and papers between various branches. This was noted with appreciation.

The death of A. A. Dion, M.E.I.C., who was for five years a member of Council, was noted with great regret, and the secretary was directed to write to Mr. Dion's family expressing Council's condolence with them in their bereavement.

The list of officers for the Lakehead Branch for the year 1926-27 was noted and approved.

The following elections and transfers were effected:—

Elections

Members	4
Associate Members	5
Juniors	2
Students	2

Transfers

Associate Member to Member	3
Junior to Associate Member	2
Student to Associate Member	3
Student to Junior	8

Eighteen applications for admission and transfer were scrutinized and classified for the ballot returnable November 16th, 1926.

Six special cases were considered in connection with applications for admission.

The Council rose at eleven thirty-five p.m.

OBITUARIES

Alfred Adolphe Dion, M.E.I.C.

Members of the Engineering Institute have learned with deep regret of the death of Alfred Adolphe Dion, M.E.I.C., which occurred at his home in Ottawa, Ont., on October 8th, 1926. His death followed a serious operation which he underwent about two weeks prior, and for days he lingered at death's door, and after signs of slight improvement in his condition he suffered a relapse which proved fatal.

The late Mr. Dion had been a Member of The Institute since 1901 and had taken a great interest in its affairs, particularly in the days of the Canadian Society of Civil Engineers, during which time he was a member of Council of the years 1907, 1908, 1915, 1916 and 1917. As one of Canada's most prominent electrical engineers, Mr. Dion was recognized as an authority on electricity and electrical developments, and in Ottawa was widely-known through his activities in civic circles and through his connection with educational boards and societies.

ALFRED ADOLPHE DION, M.E.I.C.

Born in the city of Quebec on June 14th, 1858, the late Mr. Dion, when only sixteen years of age, became a telegraph operator with the Dominion Telegraph Company. From 1882-89 he was with the Canada Atlantic Railway and Cape Breton Railway on construction and operation. The following three years he was electrician with the Intercolonial Railway, and in 1891 he became superintendent and engineer of the Chaudiere Electric Light and Power Company, at Ottawa, five years later being appointed general superintendent and chief engineer of the Ottawa Electric Company. In 1912 he was appointed superintendent of the Ottawa Gas Company, still retaining his position with the Ottawa Electric Company, and in 1921 he was general manager and engineer for both companies when they were placed under one control and ownership. In 1917 he was appointed a director of the Ottawa Light, Heat and Power Company. In 1918 he was elected president of the Moose Jaw Electric Street Railway, which position, together with his connections in Ottawa, he held until the time of his death.

The late Mr. Dion was president of the Canadian Electrical Association in 1899 and in 1902, and again in 1911. He was elected Member of the American Institute of Electrical Engineers in 1893 and Fellow in 1912. He was also a member of the Institute of Electrical Engineers (Great Britain), a past-president of the Canada Gas Association and served on the council of the Ottawa Board of Trade.

Despite his busy life, Mr. Dion managed to contribute numerous articles and technical papers to various scientific journals in this country and elsewhere, and was regarded as an authority on all matters pertaining to his profession.

Practically every phase of the life of the Capital was represented at the funeral, the largest seen in Ottawa in recent years. The cortege included in its ranks members of the federal and provincial parliament, the mayor and controllers of Ottawa, members of the city council, representatives of the Board of Trade, the Engineering Institute of Canada, and numerous other societies and clubs.

Members of the Engineering Institute were present in large numbers to pay their last respects to a highly-respected fellow-member. The parent body was represented by Col. W. P. Anderson, M.E.I.C., and the Ottawa Branch by Chairman J. D. Craig, M.E.I.C., and the Secretary, F. C. C. Lynch, A.M.E.I.C.

Lt.-Col. Bryce Johnston Saunders, M.E.I.C.

On Monday, October 11th, 1926, there passed away one of The Institute's distinguished members and one of Edmonton's best known and popular citizens in the person of Lt.-Col. Bryce Johnston Saunders, M.E.I.C., at his residence in Edmonton, Alta. Although the late Colonel Saunders had been in ill health for some time, his sudden death came as a shock.

He was a former commissioner of the city of Edmonton and was at one time candidate for the office of mayor, and was at all times interested in affairs of the city. He was prominent in military service, being one of the four officers chosen by the Canadian Government to represent Canada at King Edward's funeral in 1908. At the time of his death he was president of the Alberta Land Surveyors' Association.

Colonel Saunders was born at Lyndhurst, Ont., on October 17th, 1860, and received his early education in the public schools of Brockville and Athens, graduating from the high school at Athens in 1877. He entered the School of Practical Science, Toronto, in 1881, but transferred to McGill University the following year, graduating in 1896 with the degree of B.A.Sc. in civil engineering. It was during the years 1882-83 that Colonel Saunders first located temporarily at Edmonton, at which time he was engaged in Dominion land surveys. In 1884 he became Dominion Land Surveyor and in 1889 Ontario Land Surveyor.

He carried on a general practice in Brockville, Ont., from 1888 to 1897, while from 1893 to 1897 he was city engineer, and was county engineer for Leeds and Granville during part of that period. During this period he designed many bridges and supervised the construction of extensive drainage works in eastern Ontario. In 1897 he was Ontario commissioner in laying out the Ontario-Manitoba boundary.

During the years 1898-99 and 1900 he was engaged on Dominion land surveys in Alberta, and in August, 1900, went to Regina as assistant chief engineer and surveyor of irrigation. In 1902 he was appointed chief engineer on this work and also deputy minister, chief engineer and surveyor of public works for the North-West Territories.

In 1904 he resumed private practice at Edmonton. He carried on his practice until 1914, when he was appointed commissioner of public works in that city. He went overseas with the first contingent of the Canadian Expeditionary Force, and on returning home in 1919 resumed private practice.

Colonel Saunders had a long and interesting military career. He was a drummer boy in 1870 in a small unit of scouts at Brockville during the Fenian Raid. In 1885 he was with the D.L.S. Intelligence Corps during the time of the North-West Rebellion, and was present at Batoche. He volunteered for service in South Africa in 1900, and in 1906 joined "A" Squadron, Canadian Mounted Rifles, at Edmonton.

He made an immediate response when the World War broke out in 1914, joining up in August. He left Valcartier in September of the same year with the First Canadian Contingent, serving in England, France and on the high seas until the conclusion of hostilities, returning to Canada in January 1919. He was mentioned in despatches and raised to the rank of lieutenant-colonel.

Colonel Saunders joined the Engineering Institute of Canada as Associate Member on April 9th, 1890, and was transferred to Member on March 16th, 1899. He was also until recently a member of the Association of Professional Engineers of Alberta.

Thomas Shanks, B.A., B.A.Sc.

Thomas Shanks, B.A., B.A.Sc., former assistant director-general of surveys, Department of Interior, at Ottawa, and one of the most prominent members of the Masonic Order in eastern Ontario, died suddenly from heart disease on the morning of October 13th, 1926. He was 57 years old and unmarried.

News of Mr. Shanks' passing came as a great blow to a host of friends, as he appeared to be in good health at a late hour on the previous evening, when he gave an address describing his recent trip around the world.

A man of lovable character, Mr. Shanks enjoyed the esteem of the entire community for his sterling worth and fine citizenship. He was born at Moose Creek, Stormont County, Ontario, on April 23, 1869, and was educated in schools of that district, the Ottawa Collegiate Institute and the Normal School.

Ready for university at 16 years of age, Mr. Shanks could not enter college owing to his youth, so he taught school for several years. He then enrolled at the University of Toronto in the School of Practical Science, where he graduated in 1900 with the degree of B.A.Sc. He also graduated with the degree of Bachelor of Arts. In 1902 he was commissioned as a Dominion Land Surveyor.

Entering the Federal Civil Service at Ottawa in 1900, as a member of the staff of the Topographical Survey, Mr. Shanks' talents were quickly appreciated. In 1911 he was appointed chief draughtsman and in 1914 was made assistant surveyor-general. On October 1st, 1923, he was promoted to the position of assistant director-general of surveys, from which he was superannuated on November 1st, 1924, owing to ill-health.

Since his retirement, Mr. Shanks had spent much of his time in travel, first to the Mediterranean, and but recently he had returned from an eight-months' trip around the world.

Mr. Shanks was equally prominent in club life. He was a charter member of the Rivermead Golf Club and the Laurentian Club, and he was also a Rotarian. He joined the Engineering Institute of Canada in 1922, being elected

THOMAS SHANKS, B.A., B.A.Sc.

Member on May 22nd of that year, but subsequent to his retirement from active work he resigned from The Institute on November 17th, 1925.

The very high regard in which Mr. Shanks was held was given tangible expression when citizens representative of every phase of the life of the Capital were present at his funeral to pay their last tribute of respect.

PERSONALS

H. K. Wyman, A.M.E.I.C., of the Shawinigan Engineering Company, has been transferred by the company from St. Narcisse, Champlain County, Que., to St. Alban, Portneuf County, Que.

Arnold V. Armstrong, S.E.I.C., is at present located in Toronto, Ont., with the English Electric Company of Canada, Limited. Mr. Armstrong received his degree of B.Sc. from McGill University in 1923.

A. d'Orsonnens, A.M.E.I.C., of the Topographical Surveys Branch of the Federal Government, has been transferred to the Natural Resources Intelligence Service, Department of the Interior, Ottawa.

Prof. L. M. Arkley, M.E.I.C., head of the Department of Mechanical Engineering of Queen's University, has been appointed a member of a committee of the National Research Council of Canada, on the Insulation and Heating of Buildings.

John R. Kaye, S.E.I.C., who graduated from McGill University in 1924, is at present with the Venezuela Power Company, Limited, at Maracaibo. Mr. Kaye is a native of Halifax, N.S., and graduated from Dalhousie University, subsequently completing his engineering studies at McGill.

C. R. Bown, Jr.E.I.C., who has been with Messrs. Stone and Webster, Inc., at Beaumont, Texas, has been transferred to Paulsboro, N.J., and is resident engineer for the company on the remodelling of the boiler house of the Vacuum Oil Company. Mr. Bown is a graduate of McGill University of the year 1923.

K. M. Kent, S.E.I.C., of Montreal, is now residing in London, England, where he is manager for the Armstrong Cork and Insulation Company, Limited, and his present address is Sardinia House, Kingsway, London, W.C.2. Mr. Kent graduated from McGill University with the degree of B.Sc. in 1924.

T. W. W. Parker, A.M.E.I.C., until recently with Messrs. Monsarrat and Pratley, consulting engineers, Montreal, is now with the Anticosti Corporation, in Montreal. Mr. Parker was for a time assistant in the office of A. D. Swan, M.E.I.C., in Montreal, and was subsequently in the resident engineer's office of the new harbour works at Vancouver, B.C.

President Geo. A. Walkem, M.L.A., M.E.I.C., has just returned from a visit to a number of The Institute branches, and while in Eastern Canada took the opportunity to attend the McGill Reunion in Montreal. Major Walkem was the representative of The Institute at the recent annual meeting of the American Society of Civil Engineers at Philadelphia, Pa.

Brig.-Gen. C. J. Armstrong, C.B., C.M.G., M.E.I.C., for the past seven years Officer Commanding Military District No. 4 at Montreal, has left to take command of Military District No. 1 at London, Ont. General Armstrong joined The Institute as Student in 1894, and was transferred to Associate Member in 1902 and to Member in 1912. He is at present chairman of the Honour Roll and War Trophies Committee of The Institute.

Brig.-Gen. T. L. Tremblay, C.M.G., D.S.O., M.E.I.C., was re-elected vice-president of the American Association of Port Authorities at the recent annual convention at Norfolk, Va. General Tremblay is a native of Quebec, having been born at Chicoutimi in 1886. He is a graduate of the Royal Military College of Canada of the year 1907, and at the present time occupies the position of commissioner and chief engineer of the port of Quebec.

Chas. Ed. Potter, Jr., Jr.E.I.C., has severed his connection with the Wayagamack Pulp and Paper Company, and is now located in Toronto with the Toronto Transportation Commission. Mr. Potter graduated from the University of Toronto with the degree of B.A.Sc. in 1925, subsequently being employed with the Geodetic Survey of Canada, and early in 1926 accepted the position of transitman with the Wayagamack Pulp and Paper Company, at Three Rivers, Que.

Charles E. Marlatt, Jr.E.I.C., is with the Consolidated Mining, Smelting and Power Company, in the engineering office at Trail, B.C. Mr. Marlatt graduated from Queen's University in 1923 with the degree of B.Sc., and immediately following graduation was topographer with the Department of Highways with the British Columbia government. Subsequently, in March 1924, he joined the engineering staff of the West Kootenay Light and Power Company as instrumentman in connection with the construction of the company's new hydro-electric plant.

R. H. Farnsworth, Jr.E.I.C., has been appointed to the engineering staff of Price Brothers and Company, Limited, and is located at the company's head office in Quebec city. Mr. Farnsworth has until recently been with the Newfoundland Power and Paper Company, Limited, Corner Brook, Nfld. He is a graduate of Queen's University of the year 1916, and at the end of the War took post-graduate work at London University. On returning to Canada, he was appointed to the engineering staff of the Brompton Pulp and Paper Company, at East Angus, Que., and subsequently was engaged on design in connection with the work at the St. Lawrence Paper Mills, Three Rivers, Que.

Roy A. Crysler, A.M.E.I.C., of Toronto, has resigned from his position with the Rust Engineering Company, of Pittsburgh, Pa., and is now with Messrs. H. K. Ferguson Company, of Cleveland, Ohio. Mr. Crysler graduated from the University of Toronto in 1920, and, following graduation, was assistant engineer with the Ontario Provincial Board of Health for a few months, later joining the staff of the Hydro-Electric Power Commission of Ontario, at Niagara Falls, Ont. During the past six years, Mr. Crysler has been engaged mainly on reinforced concrete work, particularly in design. He was concrete engineer with the architect's department, city of Toronto, for nearly four years, and was later with Messrs. Chapman and Oxley, of Toronto, Ont.

C. H. Donnelly, A.M.E.I.C., has since May of this year been on the staff of the United States Light and Heat Corporation, at Niagara Falls, N.Y., with which firm he was appointed assistant maintenance engineer at that date. Mr. Donnelly has for the past six years been with the construction department of the Hydro-Electric Power Commission of Ontario as assistant to the superintendent at the Queenston power house. He is an honour graduate of Queen's University, from which he received the degree of B.A. in 1914 and B.Sc. in 1919. His first engineering work was with the Donnelly Salvage and Wrecking Company, Kingston, where he was employed during the summer months of his university course. He served overseas with the Canadian Field Artillery from 1915 until the end of the War. After receiving his degree in science, he was engaged with a firm of engineers and architects in Toronto on the design of reinforced concrete building, and later with the Trussed Concrete Steel Company on similar work.

T. C. MacNabb, A.M.E.I.C., Receives Appointment

T. C. MacNabb, A.M.E.I.C., who since 1917 has been superintendent for the Canadian Pacific Railway Company at Revelstoke, B.C., has been appointed engineer of construction of the company's western lines with office at Winnipeg, Man.

Mr. MacNabb is a graduate of the University of Manitoba, from which he received his degree of Bachelor of Arts with honours in 1902. Immediately following graduation, he joined the staff of the Canadian Pacific Railway Company, and has been engaged on various works with that company throughout Canada ever since. His first work was with the construction department, and in succession he occupied various positions, commencing as chainman and rodman in 1902, being promoted to topographer in 1903, and later draughtsman in the field office at Winnipeg, in the following year instrumentman and in 1905 resident engineer. In this latter capacity his work took him to Saskatoon, Lethbridge and Battle River. In 1908 he became assistant engineer on construction, the following year division engineer on maintenance and in 1916 assistant engineer for Saskatchewan and in the following year superintendent at Revelstoke.

T. C. MacNABB, A.M.E.I.C.

Mr. MacNabb is also a member of the American Railway Engineering Society and the American Association of Railway Superintendents.

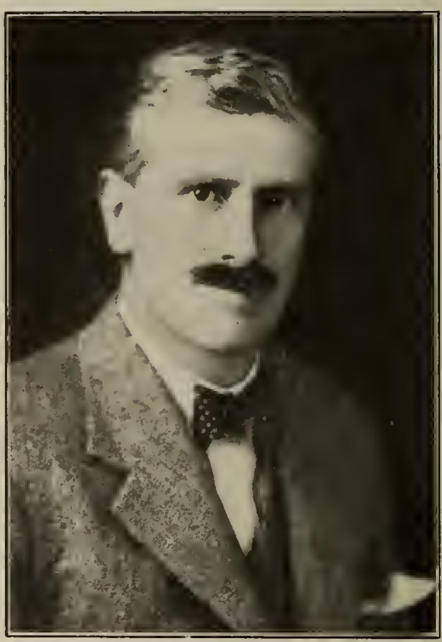
H. M. Goodman, A.M.E.I.C., Enters Legal Profession

H. M. Goodman, A.M.E.I.C., formerly of Goodman and Goodman, accountants and bankruptcy trustees, Toronto, Ont., has entered partnership with Alderman Nathan Phillips, and will in future practice law in Toronto under the firm name of Nathan Phillips and Goodman. Mr. Goodman is a graduate of the University of Toronto, where he received his degree of B.A.Sc., in 1913. During his course he was engaged in hydrographic, general survey and construction work in connection with irrigation in Saskatchewan. During the first eighteen months following graduation he was engaged on various works where he secured experience in steel bridge and building construction, after which for four years he was with the engineering department of the city of Montreal on the outside construction staff engaged in construction of sewers, waterworks, pavements, bridges, etc. He later joined his brother under the firm name of Goodman and Goodman, engineers and accountants, and was in charge of the branch office in Toronto from 1921 until he recently formed partnership with Alderman Phillips. His recent work entailed the close study of accountancy and required him to specialize in bankruptcy work, and as a result he was led to take up the study of law, which he completed last spring, and was finally called to the Ontario Bar on September 16th last.

L. F. Merrylees, A.M.E.I.C., Chief Engineer, Anticosti Corporation

L. F. Merrylees, A.M.E.I.C., has been appointed chief engineer of the Anticosti Corporation to deal with the development of harbours and railways on Anticosti Island, and the entire problem of transportation and shipping.

Mr. Merrylees was born and educated in Scotland. He was articled to James Barron, M.INST.C.E., consulting engineer in Aberdeen, Scotland, and after the term of his pupilage acted as assistant engineer on a number of harbour construction schemes around the north of Scotland and the east coast of England and Ireland.



L. F. MERRYLEES, A.M.E.I.C.

On coming to this continent in 1909, Mr. Merrylees was successively employed on municipal and survey work with Mason L. Brown and Company, of Detroit, Michigan; the Canadian Pacific Railway Company on maintenance-of-way; the Canadian Northern Railway Company on construction; and on the Quebec Bridge under the Board of Engineers. He left for overseas on the outbreak of war, in August 1914, and served with the Royal Engineers in the 26th (Field) Company, 1st Division, and later with the 212th and 222nd (Field) Companies of the 33rd Division.

After his return in 1919, Mr. Merrylees was engaged in various works in Ontario and Quebec and as inspecting engineer on the valuation of the Grand Trunk Railway, and went to Vancouver in 1921 to act as construction engineer for the Northern Construction Company and J. W. Stewart, on the Ballantyne pier, and later on the No. 2 elevator.

Mr. Merrylees has been in private practice in Vancouver since 1924, and has been identified with a variety of work in the province, and leaves it only to take charge of a very large undertaking which will occupy him fully for a number of years.

On the occasion of the departure of Mr. and Mrs. Merrylees from Vancouver, they were met by a number of engineers, and a bouquet of flowers was presented to Mrs. Merrylees, with the following letter of appreciation to Mr. Merrylees:—

"The Executive of the Vancouver Branch of the Engineering Institute of Canada, together with the Council of the Association of Professional Engineers of the Province of British Columbia, in wishing you farewell with all good wishes, take this opportunity of expressing their appreciation for the services you have rendered them in the past few years by your activity in branch affairs, and by the activity you have shown in the Engineering Bureau of the Board of Trade, and both Bodies wish you all success and good fortune for the future."

EMPLOYMENT BUREAU

Situation Wanted

Civil Engineer

B.Sc., member Corporation of Professional Engineers of Quebec, age 40, in excellent health, speaking both languages, with 12 years of experience on hydro-electric construction, municipal and industrial work, desires connection with engineering or contracting firm where quick, accurate and efficient work is desired. At present employed but available on few weeks' notice. Personal interview sought. Address replies to Box 216-W, Engineering Journal.

Situations Vacant

Mechanical Engineer

Graduate mechanical engineer for large paper specialty mill to take charge of maintenance under engineering department. Must be well experienced to supervise shop and repair department, do incidental machine design and keep records of maintenance and interruptions. Broad experience and executive ability. Give full particulars in first letter. Address replies to Box 158-V, Engineering Journal.

Mechanical Draughtsman

Graduate mechanical draughtsman with practical paper mill experience wanted for general work. Address replies to Box 159-V, Engineering Journal.

Mapping the Area Adjoining Red Lake in Ontario

The federal authorities have been engaged upon a mapping programme covering the region in the vicinity of Red lake, and in accordance with this programme a provisional map of the Red lake district itself was issued to meet the urgent need for the presentation of authentic topographic information, and the subsequent publication of map sheets lying on all sides of the Red lake region was provided for. Two of these projected sheets were issued during the past few weeks, namely, the Lac Seul sheet and the Pointe du Bois sheet, lying respectively to the southeast and the southwest of Red lake, and north from the main line of the Canadian National railways. The mapping programme has been carried on by the Topographical Survey, Department of the Interior, in co-operation with the Surveys Branch of the Department of Lands and Forests, Ontario, and the Royal Canadian Air Force.

A third sheet is now ready for issue to the public. This is known as the Carroll lake sheet and comprises an area lying northwest of and adjoining Red lake, included within latitudes 51° and 52° and longitudes 94° and 96°.

These sheets are published on the scale of four miles to the inch. They are issued in folder form for convenience in carrying in the pocket or in plain form, unfolded.

ELECTIONS AND TRANSFERS

At the meeting of Council held on October 15th, 1926, the following elections and transfers were effected:—

Members

KING, Harry Molyneux, operating supt., Ontario Power Plant, H.E.P.C., Niagara Falls, Ont.

LAVOIE, Alphonse Joseph, President Lavoie Automotive Devices Ltd., Montreal, Que.

NORRIS, Richard Norman Bond, managing director, Harland Engrg. Co. of Canada Ltd., Montreal, Que.

SCHREIBER, John W., M.E., (Univ. of Pittsburgh) asst. to ch. engr., Aluminum Co. of America, Pittsburgh, Pa.

Associate Members

BARBER, Herbert Campbell, B.A.Sc., (Univ. of Toronto), mgr. of Ontario district, Standard Underground Cable Co., Toronto, Ont.

BRUCE, William Joseph, C.E., (Univ. of Toronto), engr. i/c surveys for Foundation Co. of Canada Ltd., Maniwaki, Que.

COATES, James Percy, locating and res. engr., Dept. of Public Works, B.C., Nelson, B.C.

FRASER, Archibald Norman, B.Sc., (McGill Univ.), senior radio elect'l engr., Radiotelegraph Branch of Naval Service, Ottawa, Ont.

STARLEY, Bernard, asst. engr. Nigerian Eastern Ry. Construction survey, Kakuri, N.P., Nigeria, West Africa.

Juniors

BAILLIE, Edward Leonard, B.Sc., (N. S. Tech. Coll.), asst. engr. on highway constrn. with N. S. Highway Board, Stellarton, N.S.

FISHER, Frederick Sorley, B.Sc., (Univ. of Alta.), equipment engrg., Northern Electric Co., Montreal, Que.

Transferred from class of Associate Member to that of Member

BOWNESS, Ernest William, B.Sc., (McGill Univ.), consulting engr. in Edmonton, Alta.

DEVEY, John Hardy, designer, Chesapeake & Ohio Ry. Co., steel and concrete structures, Richmond, Va.

SMYTHIES, Reginald Eric, vice-pres. and ch. engr., Lincoln Electric Co. of Can. Ltd., Toronto, Ont.

Transferred from class of Junior to that of Associate Member

ADAM, Joseph A., Public Works Department, Montreal, Que.

GLOVER, Thomas Stanley, B.A.Sc. (Univ. of Toronto), asst. engr., Public Works Dept., Nigeria.

Transferred from class of Student to that of Associate Member

COLES, Eric Morrell, B.A.Sc., (Univ. of B. C.), instructor of elect'l engrg., Univ. of B. C., Vancouver, B.C.

GALBRAITH, Reginald Arthur Harvey, B.A.Sc., M.A., (Univ. of Toronto), officer i/c R.C.C.S. radio station, Fort Simpson, N.W.T.

POLLOCK, Frank Jones, B.A.Sc., (Univ. of Toronto), transmission tower dept., Can. Bridge Co., Walkerville, Ont.

Transferred from class of Student to that of Junior

COLLYER, Ernest, B.Sc., (Queen's Univ.), erecting engr., Can. Gen. Electric Co., Toronto, Ont.

COSSITT, Lawrence Sulis, B.Sc., (McGill Univ.), dftsman in estimating dept., Robert Mitchell Co., Montreal, Que.

DESBARATS, George Henry, B.Sc., (McGill Univ.), journeyman electrician, with Can. Comstock Co., Ottawa, Ont.

FARRAR, Norman, B.Sc., (McGill Univ.), instrman., Riordon Pulp Corp. Ltd., Montreal, Que.

FARRELL, Alfred James, B.Sc., (McGill Univ.), installation of rubber flooring for Can. Cons. Rubber Co., Montreal, Que.

GRAY-DONALD, Erceldonne, B.Sc., (McGill Univ.), apprenticeship course with Shawinigan Water & Power Co., Montreal, Que.

RICHARDSON, Roderick McDougald, B.A., (Dalhousie Univ.), foreman, cable mtce. in constrn. dept. Bell Telephone Co., Montreal, Que.

STAIRS, Henry Gerald, rodman, Town Dept., Temiskaming, Que.

Power Developments on the Gatineau River

On October 16th, 1926, through the courtesy of the International Paper Company, members of the Ottawa Branch of the Institute, together with a large number of engineers from other points in eastern Canada, were afforded an opportunity of visiting the power developments on the Gatineau river as the guests of the Fraser Brace Engineering Company, and as these developments are rapidly nearing completion it will be of interest to record here a few details of this extensive undertaking, the present work being the first part of what ultimately will be the complete power development of the Gatineau river.

The work naturally divides itself into two distinct parts, (1), the regulation of the Gatineau river and, (2), the development of power.

Regulation of the River

Under the present natural conditions, the flow of the river varies from 2,500 c.f.s. to about 75,000 c.f.s. and regulating works are being constructed in order that the flow may be more uniformly distributed throughout the year.

This will be accomplished by damming the river about 35 miles above Maniwaki, below the outlet of lake Baskatoug, and creating a new lake that will include lake Baskatong. This lake will have a capacity substantially exceeding 80,000,000,000 cubic feet, and is expected to increase the minimum flow of the river from 2,500 c.f.s. to from 8,000 to 10,000 c.f.s.

Power Development

Two plants are now in construction, one at Chelsea falls and the other at Farmers Rapids, while a third at Paugan chutes will probably be undertaken in the near future.

Chelsea Falls Hydro-Electric Development

The dam and power house which are now being constructed at Chelsea falls will create a lake of considerable size, extending some twelve miles above the development. This has necessitated the relocation of some seven miles of railway track and also the diversion of the Gatineau highway.

The Chelsea falls plant is about nine miles north of Ottawa, and on the completion of the work, the effective head created at this point will be 95 feet. The main dam at this site will be approximately 100 feet in height while the height of the power house will be 160 feet.

The initial installation will consist of three 34,000-h.p. vertical Francis type turbines which are being built by the Dominion Engineering Works, Montreal. Provision is made for a fourth unit of the same capacity. The effective head will be 95 feet, the minimum being 88 and the maximum 100 feet.

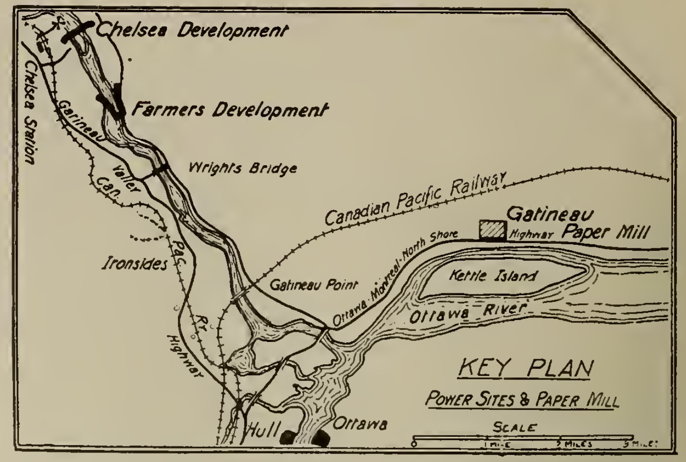


Figure No. 2.—Key Plan—Power Sites and Paper Mill.

The speed of the turbines will be 100 r.p.m., at full load and normal head, and Woodward type governors will be provided.

The generators will consist of two 34,000-kv.a., 60-cycle, 6,600-volt, 3-phase, and one 32,000-kv.a. 25-cycle, 6,600-volt,3-phase.

The transformers will be six 11,000-kv.a., 60-cycle, 6,600/110,000-volt, single-phase and three 11,000-kv.a. 25-cycle, 6,600/110,000-volt, single-phase.

There will also be eight 110,000-volt oil circuit breakers. This electrical equipment is all being manufactured and supplied by the Canadian Westinghouse Company.

A 110,000-volt outdoor switching station will be located near the power house on the west bank of the river, comprising oil circuit breakers for two 60-cycle and one 25-cycle feeder line.

A steel tower transmission line is under construction between Chelsea and the company's new paper mill, comprising two 3-phase circuits of 605,000 C.M. steel core aluminum cable for transmitting 60-cycle power at 110,000 volts to the company's mill. A second steel tower transmission line for 25-cycle power is to be constructed in the near future.

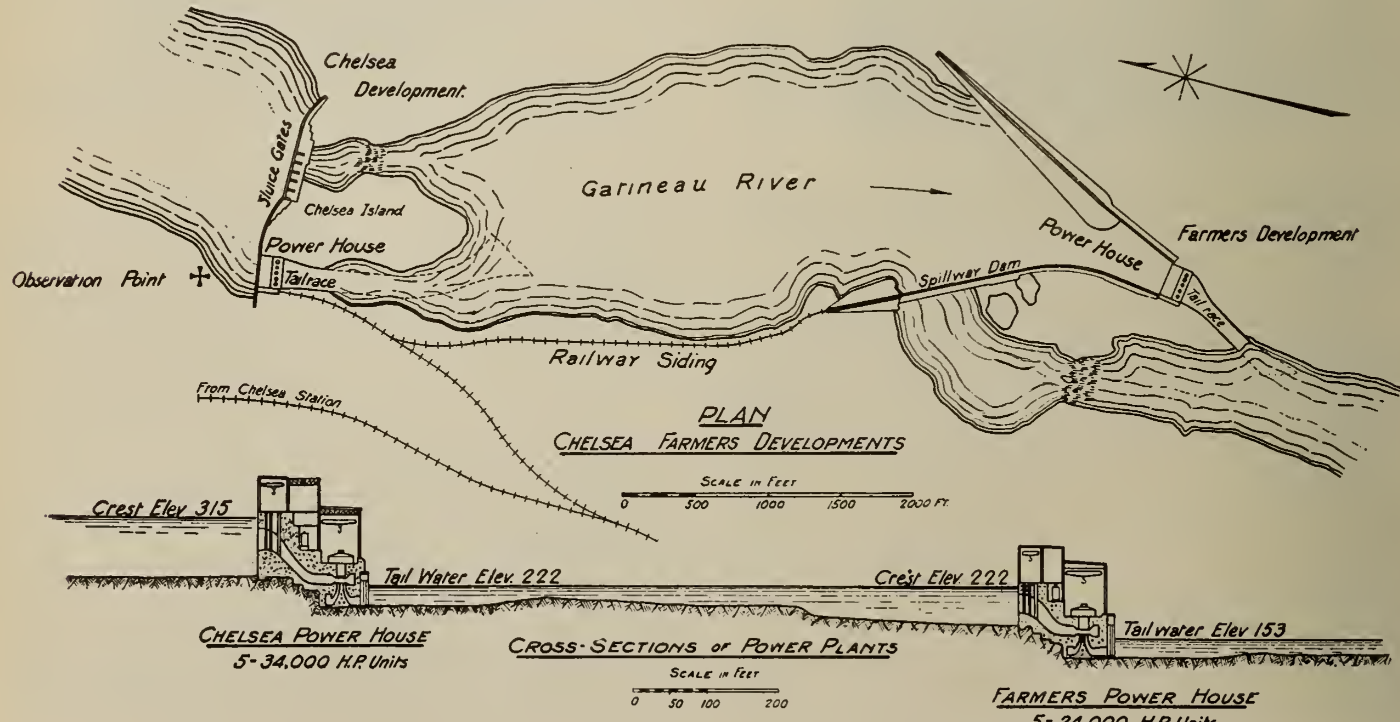

Figure No. 1.—Gatineau River Hydro-electric Developments.

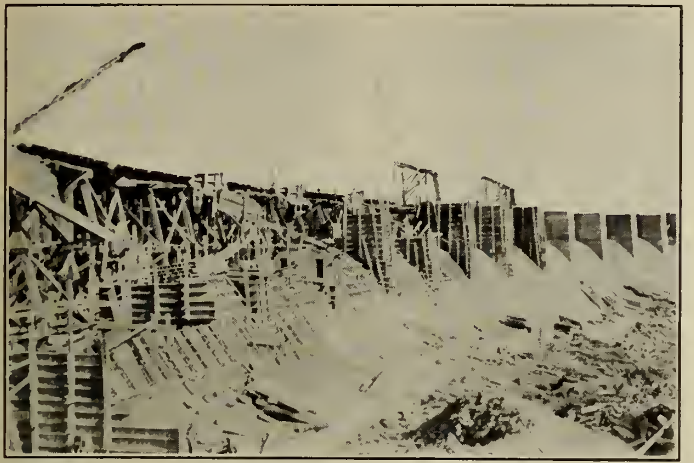

Figure No. 3.—Farmers Rapids—Downstream Side of Dam.

Farmers Rapids Hydro-Electric Developments

This development is located five and a half miles from the city of Ottawa, where an effective head of 65 feet will be created, the minimum head being 55 feet and the maximum 72 feet.

The ultimate development at this site will be 120,000 h.p., and the initial installation will be 72,000 h.p., with three 24,000 h.p. vertical runner Francis type turbines, manufactured by the Dominion Engineering Works. The speed will be 90 r.p.m., at full load and normal head. The wheels will be equipped with Woodward type governors.

The electrical equipment is being supplied by the Canadian General Electric Company, and will consist of two 25,000-kv.a., 60-cycle, 6,600-volt, 3-phase generators, one 22,500-kv.a., 25-cycle, 6,600-volt, 3-phase generator, six 8,333-kv.a., 60-cycle, 6,600/110,000 single-phase transformers, and three 7,500-kv.a., 25-cycle, 6,600/110,000 single-phase transformers. There will also be eight 110,000-volt oil circuit breakers supplied by the Canadian Westinghouse Company.

A 110,000-volt outdoor switching station comprising two 60-cycle and one 25-cycle feeder at 110,000 volts and one 60-cycle feeder at 11,000 volts will be located on the east bank of the river, outside the station, while connections will be made for the 110,000-volt switching station to the 60- and 25-cycle lines running from Chelsea to the new mill.

The dam at this point will have a total length of 4,600 feet.

The work on the Chelsea developments was commenced in November, 1925, and that on the Farmers Rapids plant at the end of January, 1926.

Gatineau Paper Mill

This mill is being constructed at a point known as West Templeton, a few miles below the city of Ottawa on the Ottawa river. It is designed for an initial installation of four paper machines with provisions for enlargement at a later date.

These machines are designed each to produce a sheet of paper 256 inches wide at the rate of more than 1,000 feet per minute. The total capacity of the four machines should exceed 500 tons per day.

Figure No. 4.—Gatineau Mill—View from Water Tower.

The mill will include slasher and barker plant, ground wood mill, sulphite mill, newsprint and wrapper machines, and all accessories necessary to turn the logs as they come down from the river into completed newsprint.

The buildings now under construction will cover more than 10 acres, and they require 200,000 cubic yards of excavation, 65,000 cubic yards of concrete, 8,000 tons of structural steel and six million bricks.

The storage reservoir work is being carried on by the company in conjunction with the Quebec Streams Commission, of which O. O. Lefebvre, M.E.I.C., is chief engineer; the dams are being constructed by The Foundation Company; the power plants at Chelsea and Farmers Rapids are being designed by the Fraser Brace Engineering Company Limited, associated with the Shawinigan Engineering Company, and the works are being constructed by the Fraser Brace Engineering Company Limited. The paper mill has been designed by the company's own staff. The entire work is being carried on by the Canadian International Paper Company and the Gatineau Power Company, of which A. R. Graustein is president, General J. B. White, vice-president; A. H. White, M.E.I.C., chief engineer; A. I. Cunningham, resident engineer. G. Gordon Gale, M.E.I.C., is general manager of the Gatineau Power Company.

ANNOUNCEMENT OF MEETINGS

Information may be secured from the secretaries of the various Branches, whose addresses will be found under "Officers of Branches" on page 452 of the Journal.

MONTREAL BRANCH

Secretary-Treasurer, C. K. McLeod, A.M.E.I.C.

Nov. 4th: Address on "The American Railway Engineering Association and Its Work," by J. E. Armstrong, Esq., M.E.I.C.

Nov. 11th: Student Papers.

Nov. 18th: Address on "Vacuum Process for Drying Paper," by Mr. Ogden Minton.

Nov. 25th: Address on "Hydro-Electric Development of Bryson," by H. E. Pawson, Esq., M.E.I.C.

Dec. 2nd: Address on "Railway Supplies," by L. C. Thompson, Esq.

VANCOUVER BRANCH

Secretary-Treasurer, E. A. Wheatley, A.M.E.I.C.

Nov. 3rd: Address on "The Influence of the Medical Profession on the Education of a Medical Student," by Dr. H. W. Hill, M.B., M.D., D.P.H., L.M.C.C., Director, Vancouver General Hospital Laboratories.

Nov. 10th: Address on "The Geology of Britannia Mines," by S. J. Schofield, M.A., B.SC., PH.D., F.G.S.A., F.R.S.C.

Nov. 17th: Open date.

Nov. 24th: Address on "Reproducing Engineering Drawings," by H. B. Muckleston, Esq., M.E.I.C.

Dec. 1st: Open date.

ABSTRACT OF PAPER

Diesel Engines

Professor E. A. Allcut, M.E.I.C., Associate Professor of Mechanical Engineering, University of Toronto, Toronto, Ont.

Niagara Peninsula Branch, September 25th, 1926

One of the most remarkable developments of the twentieth century has been the rapid rise of the Diesel engine to its present status in the engineering world. Dr. Rudolf Diesel took out his patents in 1892, and therefore this type of prime mover is only thirty-four years old. Originally it was an attempt to realize in practice the potential economy of the Carnot cycle, and the fuel first used was pulverized coal, but on account of troubles due to ash in the cylinder and other practical disadvantages, oil was substituted for this at an early stage and is the fuel now used.

The ordinary constant volume cycle gives its best efficiency when the compression ratio is high, and the constant pressure cycle used in the Diesel engine follows the same general rule. For this reason a high compression pressure is used, and as this also involves a high compression temperature, the oil is ignited automatically as it is injected into the cylinder at or near the end of the compression stroke. This high compression ratio makes it possible to obtain much higher efficiencies and lower fuel consumptions than can be obtained with the constant volume cycle. In the constant pressure cycle, however, the ratio of expansion is less than the ratio of compression and therefore, the greater the amount of fuel put into the cylinder, the lower will be the expansion ratio and the less the possible efficiency.

Cut off	Maximum temp. in cycle	Possible efficiency
1/22 of stroke	1641° F.	59.3 per cent
1/11 "	2342° F.	56.7 per cent
1/6 "	3743° F.	51.7 per cent

Thus, if no fuel were injected, the maximum efficiency could be obtained, but no power would be developed, and therefore in practice it is necessary to arrive at some compromise between power and economy. All kinds of liquid fuels, such as crude oils, shale oils and coal tars may be used, but thick oils must be heated to about 100° F. so that they will flow readily through the pipes and valves.

If the engine operates on a cut-off of 10 per cent at 200 r.p.m., the firing period occupies 1/30 second, and some engines, (e.g. the "Maybach"), run at 1,300 r.p.m. With so short a period available for injection and combustion, it is evident that the best possible combustion conditions must prevail in the cylinder, and this involves the following essentials, some of which are mutually exclusive:—

(1) *Atomization.*—The fuel must be split up into small fragments to enable the globules of oil to burn completely and quickly without "cracking." The experiments of Dr. Kuehn in Germany give average diameters of 0.0028-inch at 640 lbs. per sq. in. injection pressure to 0.0071-inch at 71 lbs. per sq. in. The pressure of injection, therefore, must be high.

(2) *Penetration.*—Small particles have little momentum and, therefore, will not penetrate sufficiently far into the very dense air contained in the compression space to give good combustion.

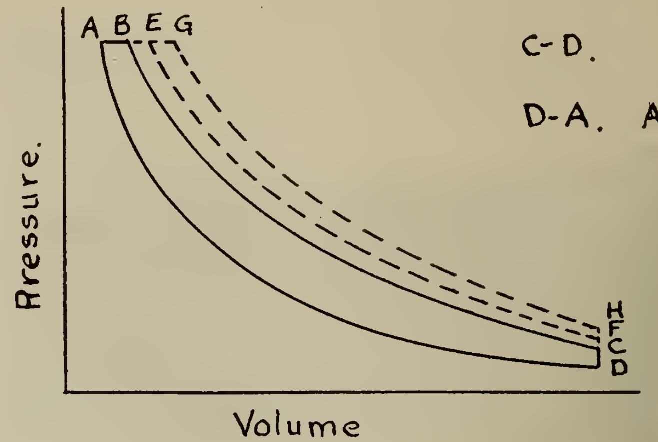
(3) *Shape of Combustion Chamber.*—This should have the smallest ratio of surface to volume, so that the cooling losses may be minimized. The ideal form is spherical, but this is not always easy to obtain.

(4) *Turbulence.*—The air and fuel should be moving as rapidly as possible to give the maximum opportunity for air and fuel particles to meet in a short time. This may be produced by:

- (*a*) A plunger on the end of the piston.
- (*b*) A projection on the piston head to direct the air flow.
- (*c*) Tangential fuel sprays which give a rotary motion to the air.

The small quantity of oil injected per stroke demands a rapid and accurate method of measurement. This quantity may be varied by:—

- (*a*) Variable stroke to the fuel pump.
- (*b*) Governor control for the suction valve of the fuel pump.



Diesel or Constant Pressure Cycle.

A-B Fuel burning at constant pressure.
B-C Adiabatic expansion of products of combustion.
C-D Rejection of heat at constant volume.
D-A Adiabatic compression.

Dotted lines E-F and G-H show effect of increasing the quantity of fuel injected. More work is done but more heat is rejected.

- (*c*) A valve to interrupt the delivery of oil from the fuel pump to the cylinder for a definite period.*

Methods of Injecting Fuel Into Cylinder

There are three principal methods used for injecting the fuel into the cylinder:—

(1) *Air Injection.*—This was the first method used and is still widely employed. As the compression pressure is about 450 lbs. per sq. in. the air pressure for injecting the fuel must be about 800 lbs. per sq. in. for low speeds and 1,000 to 1,200 lbs. for high speeds. The quantity of air used is about 6 per cent of the air in the cylinder, and its expansive action gives good atomization and turbulence. The adiabatic expansion of the air entering the cylinder, however, lowers the temperature about 100° F., and this makes firing difficult at light loads. As the temperature must be at least 700° F. for self-ignition, a higher compression pressure than would otherwise be necessary, must be used. Also the cost and complication of a three or four stage air compressor must be incurred, and the power absorbed by it reduces the mechanical efficiency of the engine.

(2) *Mechanical or Solid Injection.*—In this case a pump is used, giving a fuel pressure of about 9,000 lbs. per sq. in. In this case earlier injection of fuel is necessary, and a rise of pressure averaging about 100 lbs. per sq. in. takes place at the end of the compression stroke, but as a lower compression pressure is used, (about 300 lbs. per sq. in.), the maximum cylinder pressure is not greater than in the case of air injection. The mean effective pressure is about 25 per cent less, but on account of the greater simplicity of operation this method is superseding air injection in many of the modern engines.

(3) *Partial combustion* of the oil (as in the "Hvid" system) to inject the remainder of the fuel.

As in other internal combustion engines, the Diesel engines are divisible into four and two-stroke types. The latter gives about 70 per cent more work for the same cylinder dimensions and has a much simpler cylinder head, but the heat flow is greater and the efficiency rather less. The cylinder head of the four-stroke engine is very complicated, and unless very carefully designed and constructed, heavy casting stresses are liable to be set up. It is also difficult to cool on account of the large number of valves which have to be accommodated. It would appear that the two-stroke engine is more likely to be adopted in future for large powers.

Scavenging, or the removal of exhaust products, is produced by rotary blowers delivering air at about 5 lbs. per sq. in., and this, combined with supercharging, makes it possible to produce about 40 per cent more power per cylinder.

These and other refinements have contributed to the develop-

*This is a recent development described by Chorlton ("The High Efficiency Oil Engine") Proc. Inst. Mech. Eng., March, 1926.

ment of the engine for large powers, particularly in marine work, so that most of the new tonnage under construction is being equipped with internal combustion engines. A notable example is the "Asturias" which completed her maiden voyage a few months ago. This is a passenger liner of 22,500 tons displacement, and has two engines of 10,000 h.p. each. A large German engine produced during the war had an overload capacity of 3,200 h.p. per cylinder and an oil consumption of 0.44 lbs. per b.h.p. hour. The adoption of this type of engine for passenger marine work is the best proof of its reliability and freedom from breakdowns.†

With its perfection and adoption for large powers and its low fuel consumption, the Diesel engine promises to play an important part in power production, particularly in view of the fact that our fuel supplies are not inexhaustible, and that fuel economy will therefore become increasingly important in the future. Also, as the Diesel engine rejects its heat at a high temperature, the attainment of further economies by utilizing the exhaust and waste heat is very probable.

†At this point the author gave a description of several of the latest types of engine, including the Cammell-Laird-Fullagar opposed piston, Beardmore director valve and MacLagan sliding cylinder.

BOOK REVIEWS

Elementary Steam Engineering

E. V. Lallier, D. Van Nostrand Company, New York, 1926, 2nd ed. Cloth, 5¼ x 7¾ in., 288 pp., diagrs., $2.50.

This is the second and revised edition of a work first published in 1913 and written by E. V. Lallier, instructor in engineering, Hebrew Technical Institute, New York, and a professional engineer. The book is said to have been written to help both the theoretical man lacking practical experience, and the practical man lacking technical training, and it makes use of only the most simple formulas, and even these are not numerous.

Looking over the chapter headings one finds Heat, Formation of Steam, Fuel, Boilers, Boiler Calculations, etc., Engines with their Gears and Governors, Engine Calculations, etc., Pipes and Fittings, Auxiliary Apparatus, Packing and Lubrication, and finally Internal Combustion Engines—the latter scarcely coming under the category laid out in the title of the work.

In order to give an idea of the method of treatment adopted throughout, one of the chapters is selected at random, namely, that headed "Reciprocating Engines", which is covered by fifteen pages and nine illustrations. Starting with a description of the Corliss engine, the action of the cut-off gear and dash pot are explained, this being followed by a three-page description of the Unaflow Engine, which is all too brief. Four pages illustrate and describe the two types of compound engines, and the chapter closes with two pages on condensers. A list of fourteen questions is also given.

It will be seen that the treatment is extremely brief and elementary and the illustrations are very largely diagrammatic, instead of being taken from practice. The cuts are not particularly well made, but the book has a place in some schools and amongst men who wish information on steam engines in a very simple form. There are 116 figures.

R. W. Angus, M.E.I.C.

An Elementary Treatise on Statically Indeterminate Stresses

John Ira Parcel and George Alfred Maney. John Wiley & Sons, Inc., New York; Cloth, 6 x 9 in.; 368 pp.; Illus., $5.00.

Professors Parcel and Maney have done a conspicuous service to those who have to teach the analysis of statically indeterminate structures and to those who have to work up the subject by themselves, in their preparation of this volume. Few writers on this admittedly difficult subject have succeeded in approaching the clearness of presentation that characterizes the work under review. Undoubtedly, long experience in teaching and the knowledge of the particular points of difficulty encountered by students has enabled the authors to do their work exceedingly well. An incidental feature contributing interest to this reputedly dry subject, is the frequency of historical references and examples.

The volume opens with an effective exposition of the nature of statical indetermination and of the principle of consistent distortions. Chapters I to III, comprising more than one-third of the book, are given over to a presentation of the theory of elastic deflections and to a broad statement of the general problem of indeterminate stresses. It is not a one-idea presentation that is followed. While the general basic method for the treatment of deflections adopted by the authors is the method of work, it is recognized that this is not generally the shortest or most direct method for dealing with special problems, but that as a broad fundamental method for use in developing a comprehensive general theory, its advantages are conspicuous. Consequently, the authors have found it desirable to deal with the subject of deflections, not only with the Maxwell-Mohr method and that of Castigliano, but also by the special methods of moment areas, elastic weights and Williot diagrams.

Continuous beams and girders receive a somewhat brief but effective treatment in Chapter IV, and application of the theory discussed is made to a swing bridge. Special consideration is given to the subject of rigid frames, now rapidly growing in importance, Chapter V being devoted entirely to this subject. The slope-deflection method is considered by the authors as by far the most effective analytical instrument in the investigation of these problems and the method is used almost exclusively in this chapter. The elastic arch, both of the two-hinged and the hingeless variety, is discussed in Chapter VI. While the treatment is comparatively brief, it is nevertheless clear and effective. Secondary stresses form the subject of Chapter VII. Brevity and clearness here again go hand in hand.

Chapter VIII contains a general discussion of statically indeterminate construction, a historical review, and a bibliography. The authors here assemble for the reader a series of opinions of authorities as to the merits of statically indeterminate construction as compared with the statically determinate variety. The extraordinary divergence of opinion amongst authorities of equal standing is one of the most striking facts in structural engineering at the present time. The authors accept the notable conclusions of F. H. Cilley that there is no intrinsic economic advantage in statically indeterminate construction, but nevertheless hold that there are many cases where such construction can be profitably employed. They might have added the illuminating generalization stated recently by A. G. Hayden and Henry Babcock that where the deflection under the loading is less in the indeterminate structure than in the determinate one, the former will be more economical of material than the latter. This frequently occurs.

Careful perusal of the book shows that it is by no means so formidable as the reader might at first fear. It is after all not any advanced work with the difficulties that commonly accompany such, but is really an elementary treatise on the subject. As such, it is a particularly good one and one that should receive the hearty approval of both instructors and learners in this field.

C. R. Young, M.E.I.C.

Mathematical and Physical Papers

B. O. Peirce, Harvard University Press, Cambridge, Mass., 1926. Cloth, 6½ x 9½ in., 444 pp., illus., $5.00.

On looking over this series of papers by Professor B. O. Peirce, one cannot help being struck by the remarkable way in which the writer has brought to bear the skill of the accomplished mathematician, the wide knowledge of the physicist, and the practical outlook of the engineer.

The subject matter might be divided as follows:—

(a) Papers of a mathematical character dealing mainly with questions in potential theory;

(b) Papers bearing on the characteristics and design of instruments used in electrical and magnetic measurement;

(c) Papers dealing with practical questions of magnetic testing.

The two latter classes will appeal more particularly to readers of this Journal. The group of papers dealing with instruments includes the treatment of a number of questions of importance in accurate electrical measurements, such as the temperature coefficient and ageing of galvanometer magnets, the determination of the proper damping factor to be applied to ballistic galvanometer readings, and the theory and design of ballistic galvanometers of very long period, which are essential whenever the electrical impulse to be measured is not instantaneous. Among the papers on magnetic testing there are a number of studies of the magnetic properties of finely divided cores, on the building up of the current in electromagnet windings, as well as on the testing of various types of magnetic material ranging from pure Norway iron to hardened tool steels. Anyone interested in accurate testing and design will certainly find this volume a very useful work of reference.

Etienne T. Bieler.

Wasserkraft—Jahrbuch, 1925-1926

Richard Pflaum, Munich, 1926, Cloth, 6 x 9¼ in., 386 pp. Illus. and tables

The new edition of this annual maintains the standard set by the first issue, and while dealing more particularly with hydraulic engineering practice in Europe, contains papers which will be found of interest.

For example, an article on "Beauty in Engineering Works" gives an idea of the importance attached to appearance in European engineering practice, and its illustrations show the characteristic and usually pleasing effect that has been secured in the buildings and dams of many German and Scandinavian hydro-electric installations.

Among other contents may be mentioned useful data on the present status of water power development in various countries; articles on electro-metallurgical work, including the aluminum industry; on water measurement, surge problems, installations using runners of the Kaplan type, with some results obtained; and studies of the effect of draft tubes on efficiency.

Diesel Engines, Marine, Locomotive and Stationary

D. L. Jones. N. W. Henley Publishing Co., New York, 1926. Cloth, 6 x 9½ in., 565 pp., illus., $5.00.

This book is written on one of the most interesting developments going on at the present time in the power field, i.e., the application of the Diesel engine to transportation. The high thermal efficiency of the Diesel engine has been recognized for years, but like all new machines it required some time to develop it to the degree of reliability which is essential in a prime mover.

The author devotes the first chapter to a very elementary discussion of thermodynamics and in the second chapter describes the elementary principles of operation of the two- and four-stroke cycle engines. In chapter three the efficiencies of different types of gas engine and steam plants are compared. The next five chapters are used in describing details of construction of the engine and accessories, such as spray valves, fuel pumps, governors, fuel systems, valve gears, starting and reversing gears and lubrication. These things are discussed in a thoroughly practical way and the cuts used are excellent. In the next chapter is given a very complete description of the Diesel-electric drive for ships, together with some data on operating costs. A short chapter on the properties of lubricating and fuel oils follows, and then a chapter is devoted to marine rules for vessels propelled by Diesel oil engines.

The application of the Diesel engine to railroad service is described and an interesting comparison of the cost of operation of a Diesel electric and a steam locomotive given.

The book does not go far into the theoretical design of the Diesel engine, but will prove especially valuable to any one in charge of the operation of this type of prime mover.

This volume contains 565 pages, with many excellent illustrations and is published by the Norman W. Henley Publishing Company, New York City.

L. M. Arkley, M.E.I.C.

Canadian Engineering Standards Association

Reports of Recent Meetings and Conferences

Machine Screw Threads

Under the auspices of the Canadian Engineering Standards Association, a conference on Machine Screw Threads was held in Toronto on September 8th.

After considerable discussion it was felt that the situation with regard to machine screw threads in Canada could be greatly improved, especially in the reduction in the number of varieties of threads, and it was further felt that the carrying on of a campaign of education among customers would tend to gradually reduce variety in orders received. A small panel of the committee was formed to go further into the problem and prepare tentative data sheets to be used in the drafting offices of the various concerns interested, and on which would be shown the standard screw threads which would be stocked, all other threads being classed as special and their use gradually discouraged. Information from various company representatives will be collected and used in the preparation of these data sheets. The consensus of opinion was that the Canadian market could be met with a two-thread series, using a close fit tolerance, and it is hoped to prepare tentative data sheets on these lines.

Sheet Metal Gauges

The association have organized a committee in the sheet metal trade to discuss the question of simplifying sheet metal gauges. This committee had its first conference in Toronto on September 10th.

The discussion at this conference revealed the fact that the situation with regard to sheet metal gauges is very confused in Canada at the present time, owing to the fact that British and United States gauges are both used, also that appraisals for customs are made on Imperial Standard gauge, which differs from Birmingham gauge and also from United States gauge. There seemed to be no doubt but that it was in the interests of Canadian firms generally to conform to the United States gauge, this fact having been recognized by certain British manufacturers, who now make shipments of material rolled to United States gauge. A panel of the committee was appointed to go further into this question, and it is hoped before long to make practical suggestions for the simplification of the situation. The general feeling at the meeting was that an investigation into the situation was desirable and that considerable improvement could be effected.

Standardization of Power and Distribution Transformers

The Committee on Power Transformers held its third meeting at the headquarters of the Engineering Institute of Canada in Montreal on September 24th.

This committee was organized by the Canadian Engineering Standards Association to consider the drafting of standard specifications for single-phase and three-phase power transformers along similar lines to the specification for single-phase distribution transformers, issued by the Association in December, 1920. The committee was instructed at the same time to consider any suggested revisions to this latter specification. At the meeting in Montreal, reports covering a tentative specification for power transformers, from Mr. A. B. Cooper of the Ferranti Meter and Transformer Company, were received. Discussion at the meeting centred on the suggested revisions to the specification for distribution transformers, and a new draft was approved. The specification as issued had effected considerable improvement in the transformer situation, but experience in its use had suggested some revisions. When these revisions have been approved by the Association, it is proposed to issue a new edition of the specification, and it is believed that this revised edition will appeal particularly to consumers.

Revisions to Bridge Specifications

On September 22nd a meeting of the Joint Committees on Steel Railway Bridges and Steel Highway Bridges was held at the headquarters of the Engineering Institute of Canada in Montreal.

Consideration was given to revisions of specifications as issued by the Association in 1922. The chief items under discussion were the proposal to add a specification covering the use of silicon steel and drafting of new paint specifications. It was decided to abandon the specifications now used for the use of nickel steel and substitute therefor a specification for silicon steel. The question of a new paint specification was also considered and it was decided to work in co-operation with the Canadian Paint, Oil and Varnish Association. To that end it is proposed to organize a panel on paint, the membership to include representatives from the Canadian Engineering Standards Association and the Canadian Paint, Oil and Varnish Association, with the idea of endeavouring to formulate a specification which will meet with the approval of the manufacturers as well as the users.

The question of increasing the allowable unit stresses was considered and an increase from 16,000 to 18,000 pounds per square inch was suggested for the highway bridge specification. It was felt, however, that further study should be made before recommending any increase in the allowable unit stresses for railway bridges. A panel of the committee was appointed to look into this.

It was also decided that plates should be ordered by thickness only and not by thickness or weight, as stated in the specification now in use.

Another panel of the committee was appointed to gather together up to date information on live loads for highway bridges, with the object of making revisions in the load schedules now specified.

It is planned to issue a new edition of both the Railway Bridge and Highway Bridge Specifications, in which all these revisions will be incorporated.

BRANCH NEWS

Lethbridge Branch

N. H. Bradley, A.M.E.I.C., Secretary-Treasurer.

About thirty-five years ago a sixteen-year-old boy rode into southern Alberta on a load of baled hay. Alternately he had walked or ridden all the way from the state of Montana. It was a cold journey, snow was on the ground and many nights were spent on the prairie.

Ahead of him was the promise of his first job in his chosen profession. He was to be rear-chainman on a narrow-gauge line, the Turkey Trail as it was known then, under construction between Lethbridge and Medicine Hat. It is not related just what salary he received. The job was the big thing, and the boy thought so much of the opportunity that he was willing to walk 150 miles to get it.

The job was finished. The road was through. Years went by and the old Turkey Trail was forgotten. The little coal mining town of Coalbanks grew into the splendid city of Lethbridge. The old trail from Montana that had crossed a prairie strewn with buffalo skulls was now traversed with steel rails. Bumping hay wagons and bull teams were replaced by powerful locomotives. The rear-chainers who had wrought these changes were forgotten.

The sixteen-year-old boy went on to other fields. He saw opportunity in the wide reaches of the Pacific ocean. He discovered a faith in Canada's newest seaport. He went to Vancouver when it was young, grew up with it and developed a large machinery and towage industry. He took an active part in public affairs, sat in the council of his home town; was honoured with a seat in the legislature of his province; served as a soldier when Canada called to her men.

Thirty-five years—and then this rear-chainman of the yesterdays came back to southern Alberta. Came back this time as *Head* "Chainman." Members of his profession gathered to do him honour. Engineers young and old were grouped around the tables.

"Gentlemen," the Chairman said, "it is my privilege to introduce to you Major George A. Walkem, M.L.A., M.E.I.C., President of the Engineering Institute of Canada."

The Lethbridge Branch delighted in doing honour to Major Walkem when he passed through on his way to Philadelphia. His visit was rather unexpected. We had little advance notice, but nevertheless forty sat down to the dinner in his honour on Saturday night, September 25th.

The Major has been with us before. On the last occasion he came with our Charter. In the light of what we have since learned of his earlier connection with Lethbridge, it was peculiarly appropriate that it should have been from his hands that Lethbridge was officially enrolled in the brotherhood of the Institute.

We promise to the Major that if he will visit us again we will put on a real celebration.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

The first meeting of this season was celebrated on Saturday, September 25th, in a somewhat moist manner. In provinces other than Ontario there might be two meanings to that statement, but in this case the moisture was caused solely by water.

The itinerary included visits to the new filtration plants of both St. Catharines and Welland. The steady downpour of rain was incidental and due, it is understood, to a slight underestimation of their powers by the executive.

Unfortunately, the St. Catharines station is on a by-way and the road became impassable. Chairman Alex. Milne, A.M.E.I.C., who is also manager of the Water Commission, sent one of the Commission's cars over the trail in the morning and the driver reported an average speed of one m.p.h. It was a good car, too, when it started. That trip was cancelled. The main highway, however, was in fair condition, so the party met at the Welland pumping station about 4.30 p.m.

The new wing was the centre of interest. It contains the sand filtration beds, alum run and precipitation tanks, as well as the most modern recording gauges and operating controls.

After listening to expressions of approval for some time, Mr. Milne glanced out to make sure that it was still raining and then remarked that he was sorry we couldn't have seen his plant.

Of some interest also were the two old-fashioned turbine driven, horizontal, triplex pumps, very few of which are in operation on this continent. The superintendent, a most practical man, is enthusiastic about them. "You don't have to touch them at all," he says, "just let them run."

It was unfortunate that Willis Chipman, M.E.I.C., the designer, could not have been present to explain his handiwork, particularly as there seems to have been some delicate problems in the foundation work, but in his absence Mr. Milne did the honours.

The dinner was excellent. Afterwards Messrs. Sam Lambert and F. W. Barley essayed a piano duet and then Professor E. A. Allcut, M.E.I.C., of Toronto, gave a most agreeable dissertation on the merits of the Diesel engine—even that, it appears, is water cooled.

In moving the vote of thanks, E. G. Cameron, A.M.E.I.C., and E. P. Johnson, A.M.E.I.C., expressed the feeling of the meeting by saying that an abstruse and technical subject had been handled in such a clear manner that even the casual engineers were able to grasp the details.

Visit of London Branch

Members of the London Branch motored to and through the Niagara Peninsula on Saturday, October 2nd. The trip was arranged by W. P. Near, M.E.I.C., who, before going to London, was city engineer of St. Catharines.

As the primary object was to see something of the Welland ship canal while in process of construction, the party proceeded to lock No. 1 and Port Weller harbour at the lake Ontario end and from there drove along the canal to the large double flight locks at the escarpment.

In common with most other engineers and laymen who have visited this district, they expressed their surprise at the magnitude of the work. "One hundred and thirty feet straight drop from the top of this lock to the bottom of the lock below? Why! That's incredible. How many cubic yards of concrete are there in the whole works? I would certainly like to get a contract for something like this." "Yes," his friend queried, "and have to put up about a million dollars security for a bond?" Finis.

After dinner that evening A. W. L. Butler, A.M.E.I.C., of the ship canal staff, gave a short talk on various features of the canal illustrated by lantern slides, after which the party drove to Niagara Falls to witness the illumination.

The following day was taken up with that section on the lake Erie level between the escarpment at Thorold and Port Colborne, and also in visiting the St. Catharines water filtration plant at DeCew Falls.

E. G. Cameron, A.M.E.I.C., assistant chief engineer of the Welland ship canal, and several of the staff accompanied the party and were sorely pressed at times to give accurate answers to the many questions that were asked.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Visit to Gatineau Power Developments

The two great power development projects of the Canadian International Paper Company of Canada, known as the Gatineau Power Company, at Chelsea and Farmers Rapids, are rapidly nearing completion.

Members of the Ottawa Branch of the Institute, numbering nearly 350, with ladies and prominent engineers from all parts of eastern Canada, who, through the courtesy of the International Paper Company, were the guests of the Fraser Brace Engineering Company at the Chelsea plant on Saturday afternoon, October 16th, were frankly astonished at the progress which has been made in such short time.

The first sod was turned in November last year, and yet the visitors, who were afforded every possible facility for viewing the huge development work, saw the power houses nearing completion, while the dams in each case are across the river and only await the filling-in process prior to the fitting of the sluice gates.

The visitors, headed by J. D. Craig, M.E.I.C., chairman of the Ottawa Branch, assembled at Parliament Hill at 12:45 noon and thence motored to the Chelsea plant of the International Paper Company.

Met at the plant by Major J. H. Brace, M.E.I.C., G. Gordon Gale, M.E.I.C., general manager of the Gatineau Power Company, A. H. White, M.E.I.C., chief engineer of the International Paper Company, and a host of other officials of the International and Fraser Brace companies, the visitors were ushered into the big dining room of the company, where the inner man was amply refreshed by a meal which was as excellent in quality as it was surprising.

Following luncheon Mr. Craig, who was in the chair, in a few well chosen words expressed, on behalf of the visitors, their appreciation of the privilege accorded them in the visit to the plant, and the fine hospitality of their hosts. Mr. Craig struck a responsive chord among his hearers when he urged that the developments of the International Paper Company should be looked upon as a local rather than an outside enterprise. "I feel we are quite right in taking this attitude," said Mr. Craig, "in view of the fact that an Ottawa engineer, a past-chairman of our branch, is the general manager of the Gatineau Power Company. I am sure that there are few in Ottawa who realize the magnitude and importance of these developments in their application to the future of the Capital of Canada and the Dominion as a whole."

Chief engineer A. H. White, M.E.I.C., of the International Paper Company, then delivered an interesting address in which he outlined the development, paid a tribute to Major J. A. Brace for his genius in construction and engineering, and said the company was to be congratulated in the choice of Mr. Gale as the general manager.

Major Brace, called upon to speak, belittled his own accomplishment, furnished some figures with regard to specifications for the two big plants, outlined the proposed trip, and paid a tribute to the genius and good engineering sense of Chief Engineer White, which, he stated, he had never seen equalled. Major Brace informed the visitors that the first of the five power units to be installed at the Chelsea plant will be in operation by January first next year, while the wheels of the Farmers Rapids plant will likely begin to revolve early in March. He submitted figures showing what construction materials has gone into the two plants since they were started a year ago and up until October first, 1926: At the Chelsea plant 110,730 cu. yds. of concrete, 3,260,000 lbs. reinforcing steel, 1,810,000 lbs. structural steel have been placed, and 136,050 cu. yds. of rock and 63,350 cu. yds. of earth excavated; at Farmers Rapids, 107,804 cu. yds. concrete poured, 2,320,000 lbs. reinforcing steel and 112,030 cu. yds. rock and 73,900 cu. yds. earth.

Leaving the luncheon room the guests were taken by Major Brace and a number of his officers, including Superintendent Morris, on a sightseeing trip.

Work has already been started and is well under way at the Paugan Falls project of the International Paper Company in Low township, where five hundred men have built permanent camps and are at work. The primary power to be produced at this plant will be 200,000 h.p. All three plants will be inter-connected.

Those who had been on the trip to the plants in May last with the Technical Electric Association were very much surprised at the great progress which has been accomplished during the past six months, and expert opinion was that the completion of two plants of such magnitude in little over a year is an engineering and construction feat worthy of note.

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

Visit to Sewage Disposal Plant

The first meeting of the season took the form of a visit to Peterborough's new disposal plant on September 22nd, 1926, the occasion of its formal opening by Mayor W. T. Holloway. This was arranged through the courtesy of R. H. Parsons, M.E.I.C., city engineer, who has been responsible for the design of this plant, which is of the activated sludge type. The equipment is of course electrically operated, the blowers, pumps, etc., being driven by induction motors.

Following the visit the party gathered at the cottage of one of the members on the Otonabee river and indulged in "hot dogs," "golden bantam" and coffee, around a bonfire.

Peterborough's Sewage Disposal Plant

The system adopted for the disposal of the sewage is that known as activated sludge. This consists essentially of a prolonged aeration and agitation of the sewage followed by a settling of the solids. The design provides for return of the effluent to the Otonabee river and the disposal of the sludge by lagooning.

The whole plant is designed to dispose of a maximum of 6,000,000 Imperial gallons of sewage per day with a maximum hourly flow of one-eighteenth of the above. The average flow at the present time is about 3,500,000 Imperial gallons per day.

Under this system the sewage will be conveyed from the chamber at the foot of Park street through two eighteen-inch cast iron pipes under the Otonabee river to the pumping sump at the sewage disposal site.

From the sump, sewage is raised by means of pumps and conveyed to aerating tanks. The electric control will be so arranged that as the flow of sewage increases and the sewage level in the sump rises, the pumps will be automatically put into operation, and as the sewage level falls they will be cut out.

The aerating tanks are divided into two independent units with two independent sludge re-aerating tanks between them. The capacity of the aerating tanks is 119,000 cubic feet. This is based on a two-hour detention of the maximum flow plus an allowance for sludge returned. The two sludge re-aerating tanks located between the sewage aerating tanks are entirely independent of each other and each has a capacity of 8,200 cubic feet.

There are two settling tanks with a combined capacity of 113,000 cubic feet. This allows a settling period of about two hours during the time of maximum flow. These settling tanks are equipped with sludge concentrating devices which consist essentially of revolving arms equipped with vanes moving in a circular direction close to the bottom of the tank. The vanes are set at such an angle that the sludge is slowly pushed down into the sump at the centre of the tank. From this sump the sludge is either returned to the aeration tanks or drawn off to the lagoons.

There are about 560 square feet of air diffusing plates in each aerating tank and about 112 square feet in each sludge re-aerating tank. These plates are set in containers and piping is so arranged that the plates can be taken out in short sections even when the tanks are in operation. The ratio of plate area to the total surface area in the sewage aeration tanks is approximately 1 to 10 and in the sludge re-aerating tanks about 1 to 7.5. Air is supplied to the under side of the plates under a pressure of about ten pounds through a system of wrought-iron pipe.

The compressed air is supplied by three blowers each direct connected to a slow-speed motor. The total capacity of the three blowers is 5,400 cubic feet of free air per minute or 7,776,000 cubic feet per day against a pressure of ten pounds per square inch. This is at the rate of about 1.3 cubic feet per gallon when all three compressors are working. With the capacity of the tanks as designed, one of the compressors acts as a stand-by.

Sludge for the sludge re-aerating tanks is raised from the bottom of the settling tanks by air lift pumps. The excess sludge is drawn off into lagoons for final disposal until such time as a more efficient method is discovered.

The pump house is a brick structure and houses the pumps and motors for raising the sewage to the tanks and also the compressors and motors for supplying air under pressure to the aerating tanks.

Regular Meeting, October 14, 1926

With recollections of the fine address given by Wing Commander E. W. Stedman, M.E.I.C., last year, members were not slow to respond to the invitation to another paper on the work of the Royal Air Force. In introducing the speaker, Flight Lieutenant T. A. Lawrence, the chairman, B. L. Barns, A.M.E.I.C., referred to the splendidly illustrated article by another officer of the Royal Canadian Air Force in the current National Geographic Magazine. Lieutenant Lawrence gave a most interesting talk, describing in a clear and concise way the formation of the Force, the work carried out at the various stations and the value of this work to the country.

The speaker referred to the fact that it was twenty-three years ago that the Wright brothers flew the first aeroplane, and since then aeronautics have passed through a period of very rapid progress. From 1903 to 1908 things went along slowly, but from 1908 to 1914 a quickening in the pace of air flying was seen and by 1914 there was already under way an attempt to fly the Atlantic, but, with the war, civil aviation came to an end, for up to that time it had been more of a sporting venture. By 1919 it was beginning to take the form of a commercial enterprise.

Since then aviation has had a hard struggle, for the promoters forgot to take into account that the people had to be educated to commercial aviation and that it was a very expensive means of travelling. So they had to find other ways of employing the air force and in Canada a way soon presented itself in the form of patrolling the forests and making photographic surveys.

The speaker then described the Air Force and its various departments. Today there are stations at Vancouver, High River, Winnipeg, Halifax, Ottawa and Camp Borden. The first station after the war was Camp Borden and the equipment used had been left by the American force which had been patrolling the eastern coast in war days at Halifax. There was no intention of having the force a military one at that time, but in 1922 the Government put the force under the Minister of National Defence and all stations commenced to operate on a military basis, which has proved a great help. All the air craft now used have been built to Canadian designs. All aviators have a certificate and the air craft have to be examined once a year.

Lieutenant Lawrence then showed, by a fine series of slides, the work the force does and the different air stations. Many of these had been taken in the air and were very interesting.

It was explained by the speaker that in the cruising of the woodlands, forestry officers have been able to estimate the number of feet of lumber just as exactly as they could by cruising the wood lot on foot, doing in two hours work which would take three weeks on the ground.

The Halifax station was left after the war by the Americans and the chief duty of this station is to take aerial photographs. Roberval station, in the lake St. John district, was one of the first forest patrol stations, but to-day it is being run by the Quebec Government. Ottawa is the head operating station and has four machines for photographic work and one for the use of the department. At present these machines are doing a great deal of work in the Rouyn district. It is at this station that all new experiments are tried out.

Winnipeg is the largest Canadian station and has five sub-stations. The chief duty is forest patrol. Forest fires are discovered by small machines with one passenger and these report the fire by wireless to the station and here a larger machine starts out equipped with a pump and 1,000 feet of hose. Of the 200 fires which have been discovered this year in the district surrounding these stations, all have been successfully suppressed. They also do much photographic work at these stations for the department in Ottawa.

At the High River station in Alberta there is the most difficult and dangerous flying, and each machine in this station is equipped with a parachute. This station patrols the valleys and the forests of that country.

The Vancouver station is for sea flight training, fishery patrols and for acting as escorts to the ships coming in from the Orient so as to prevent the throwing over of opium and other narcotics to smaller boats as the ship nears land. In the Province of Ontario the Department of Forests has its own machines for patrolling and fire fighting.

Visit of the President, October 16, 1926

The branch was honoured by a visit from the president of the Institute, Major Geo. A. Walkem, M.L.A., M.E.I.C., on Saturday, October 16th. In the afternoon he inspected the plants of the Canadian General Electric Company and Wm. Hamilton Limited, and in the evening was entertained at an informal dinner at the Empress Hotel, about 35 members being present.

A most cordial welcome to the city was tendered him by Mayor W. T. Holloway, E. A. Peck, M.P., and B. L. Barns, A.M.E.I.C., branch chairman.

Major Walkem gave a most interesting address, dealing with his recent trip to eastern Canada. The rapid development of the Saguenay district came in for special mention, in particular the great plant of the Aluminum Company of Canada, at the new city of Arvida. He will have visited all the branches, except three, and took his hearers across Canada mentioning the characteristics and activities of each branch in turn.

A number of those present were from British Columbia and by special request Major Walkem described the natural resources and outstanding engineering developments of that province. He also spoke on the subject of student prizes, a proposal being under consideration at the present time for an increase in the number and value of these prizes.

At the conclusion a hearty vote of thanks, tendered Major Walkem by A. L. Killaly, M.E.I.C., was enthusiastically approved by those present.

Victoria Branch

E. G. Marriott, A.M.E.I.C., Secretary-Treasurer.

Visit to Cable Ship "Restorer"

On September 18th the Victoria Branch members were able to enjoy an unusually interesting visit, on the invitation of Captain Livingston, to the Commercial Pacific Cable Company's ship "Restorer."

Some fifty members and friends, including a good number of ladies and young people, gathered at the Ogden Point docks and at 3 p.m. were welcomed by the Captain aboard ship. Splitting up into several parties, one led by the Captain, the others by officers of the ship, a tour of inspection was made of the main deck.

The "Restorer," constructed at Newcastle-on-the-Tyne in 1903, is a vessel of 3,180 gross tons, with a length of 377 feet over all, beam 44 feet and draught 21 feet.

Samples of the grapnels that were used in getting hold of the cable in order to raise it for repairs had been laid out on deck and were of interesting variety, four-pronged, chain-link, umbrella automatic, etc., according to the type of floor, rock, coral or sand, on which the cable lay. The locating of the cable itself in the waters of an ocean such as the Pacific is a matter of considerable trouble, and is solved not only by the application of scientific means as to the exact position of the ship by latitude and longitude, but by that happy intuition that some men have in every line of endeavour, and that Captain Livingston is reported to possess in the matter of locating cables.

The location of the break in the cable having been found as closely as possible by use of a Wheatstone bridge or a Kelvin galvonometer, the "Restorer" proceeds to the spot indicated and prepares for work.

The deck of the ship is carried a considerable distance ahead of the bow, and looked at from the side appears somewhat like a crane. At the forward end are three sheaves, over the centre one of which is run the rope to which the grappling iron is attached. The depth, which is known at every point along the whole course of the cable, is first checked by a sounding line, and the ship then steams at right angles to the line of cable, a close watch being kept on the dynamometer, which indicates the pull on the rope. Should the prongs catch in rock the pull would greatly increase, and experience soon teaches when it is the cable that is hooked.

At a depth of a mile or so and, incidentally, Captain Livingston mentioned having assisted in repairing a break that occurred at a depth of 3,032 fathoms, or 18,192 feet, the small percentage of give in a cable precludes it being raised to the surface, and it is necessary to cut it, bringing the ends to the surface in turn. For this a patent grapnel is used that, after hooking the cable, twists it into a position to be tightly gripped. As the progress of the ship increases the pull, a bolt with a weakened section breaks, releasing a pair of jaws that shear the cable, and the end tightly held is drawn to the surface. The knives are so arranged on the jaws that the cable is automatically cut on whichever side of the grip is desired. Both ends having been secured and buoyed, the distance to the break is tested and calculated by the electrical department, a new length of cable is spliced in and the cable relowered.

The ship contains four cable tanks, and inspection of one of these showed a considerable mileage of cable lying in some seventeen feet of water, which is changed every week in order that storage conditions may approximate to final working conditions, the cable lasting must longer when kept from exposure to the air.

The drums and machinery by which the cable is fed, either in or out of the ship, were fully explained, and the job of walking round and round the 33-foot diameter tanks to guide the incoming cable in ever-increasing or diminishing circles was recommended as a unique form of exercise.

To the uninitiated the engine-room, with its height and depth and narrow open-barred gangways and ladders, seemed a great maze of pipes, rods and engines. The twin screws are driven by 4,500 I.H.P. engines, steam being raised by oil-fired boilers, the oil being heated to 200° Fahr. before being fed to the furnaces.

The stern of the vessel is constructed for the laying of cable; drums, dynamometers, and roller guides being duplicated on each side of the deck to carry the cable from the tanks. Among many other interesting things was a row of various devices used in sounding, by which samples of the bottom formation could be obtained. Captain Livingston explained the necessity for running a survey line, and obtaining a profile of the bottom, and some knowledge of its formation before a cable was laid, in order to avoid deep holes, sharp ridges, or precipices of a thousand feet or more, giving as an example the way the cable was brought round the north end of the Island of Guam to a point on the western shore to avoid an area to the east known as the Nero Depth, that is some 5,269 fathoms, or 31,614 feet deep.

The officers' quarters occasioned much interest, also the large batch of bread fresh from the oven; while the ladies and, it is believed, a good many of the men, too, can testify to the excellent pastry, cake and tea that were provided for their refreshment.

It was with a good deal of regret to many that the time came to leave, for there was so much of interest, one bit of knowledge gained creating a thirst for more; and it was with the hearty endorsement of all who shared in the visit that the branch chairman, J. H. Anderson, A.M.E.I.C., expressed the thanks of the members to Captain Livingston and his officers for making such an interesting visit possible.

It was noted with pleasure that some of the less frequently seen members of the Branch were in evidence.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

A regular meeting was held on September 24th, 1926, in the Y.W.C.A. rooms following a dinner.

Vice-Chairman G. H. Kohl, A.M.E.I.C., called the meeting to order and the general business was first dealt with. A letter was read from President Walkem saying that he would be unable to visit the branch this fall. The members all expressed their regret at this as they had looked forward with pleasure to having him with us again.

The following were appointed members of the Nominating Committee: F. Smallwood, M.E.I.C.; R. A. Campbell, A.M.E.I.C.; H. A. Morey, A.M.E.I.C.

As this was the first meeting after the summer months, C. Stenbol, M.E.I.C., chairman of the Papers Committee, was unable to get a speaker, but he promised a real live one for next meeting. A general discussion of engineering, fishing, and other problems was carried on by the members.

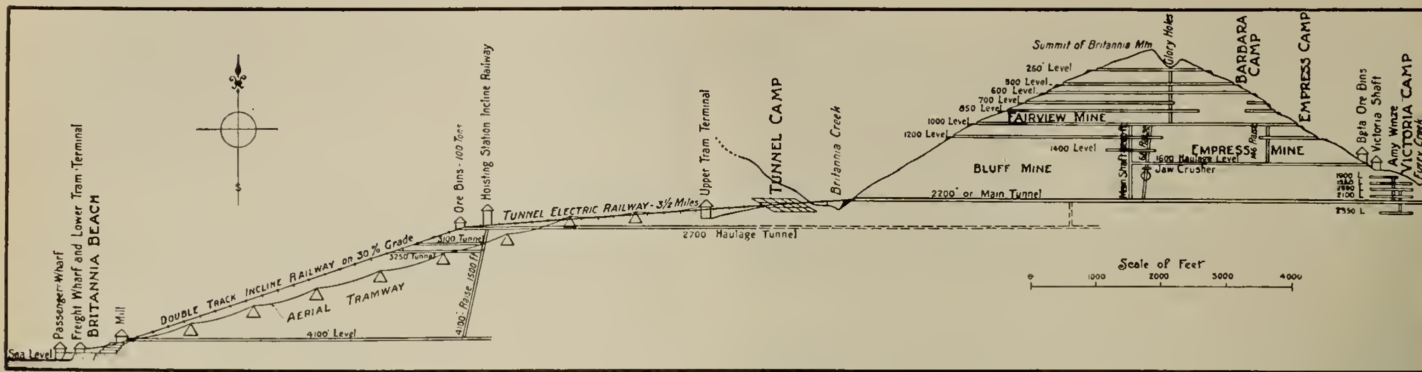


Figure No. 1.—Section of Britannia Mine.

Vancouver Branch

E. A. Wheatley, A.M.E.I.C., Secretary-Treasurer.

Inspection of Britannia Mine

A party of ninety engineers, being members of the Vancouver Branch of the Institute, together with some members of the Vancouver section of the American Institute of Electrical Engineers, and some members of the Association of Professional Engineers, made a trip of inspection to the Howe Sound Mining Corporation at Britannia Beach, B.C.

The day was glorious and the party embarked on the new steamer "Lady Cynthia" of the Union Steamship Company at 9 o'clock and proceeded up the coast to Howe Sound. They were met at the mine by Mr. C. P. Browning, E.M., (Columbia).

The party then divided, some seventy members going by electric railway to the Upper or Mine camp, where Mr. J. I. Moore, Jr., superintendent of the mines, took charge of the party and acted as their host. Mr. Browning took charge of the lower party of some twenty.

Flow sheets of the concentrator and a sectional drawing of the mine were handed to all the party, and in each case a short explanation was given.

A luncheon was then held which was provided by the company. As usual, the table groaned under the good cheer provided.

The thanks of the concentrator party was voiced by H. B. Muckleston, M.E.I.C., and was replied to by Mr. C. P. Browning.

The mine camp party had as their speaker the chairman of the branch, W. H. Powell, M.E.I.C. Mr. Powell conveyed the thanks of the Institute, and his remarks were replied to by Mr. J. I. Moore, Jr.

The mine and the concentrator were then closely examined, the party breaking into smaller numbers with a technical guide provided in each case. The concentrator party were fortunate in having the advice of Mr. O. Wiser, the consulting metallurgist of the company. Some of the difficulties which the company have met and have overcome were explained by Mr. Wiser and his technical assistants.

The party re-embarked at 4:30 o'clock, after which refreshments and a concert party under the masterly direction of A. E. Foreman, M.E.I.C., with Mr. H. L. Lloyd at the piano, enlivened the return to town.

A vote of thanks was passed to the executive of the branch for a most enjoyable and successful day.

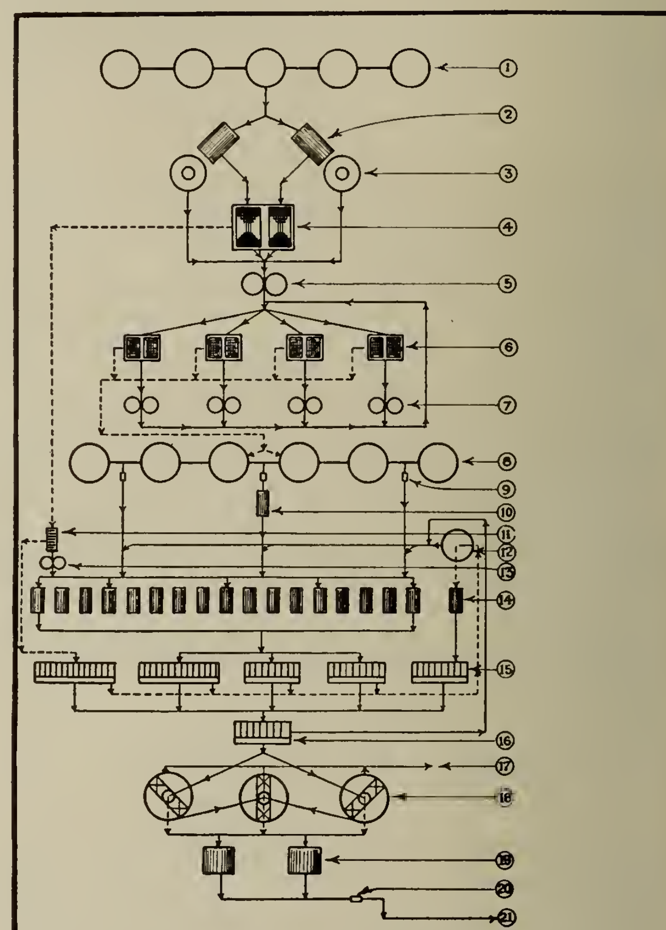

Figure No. 2.—Flow Sheet No. 3 Britannia Mill.

1—Five 500-ton Coarse Ore Bins.
2—Two sets of 7' Grizzly Bars.
3—Two 7½ K-Gyratory Crushers.
4—Four Washing Screens.
5—One set 72" x 20" Traylor Rolls.

11—One 7' x 10' Drag Classifier.
12—One 20' Dorr Thickener.
13—One set 42" x 16" Rolls.
14—Eighteen 7' x 10' Traylor Mills, each with 3' x 20' Simplex Dorr Classifier in Closed Circuit.
15—Three 14 and two 21-Cell M.S. Roughers.
16—One 14-Cell M.S. Cleaner.
17—Overflow to Waste.
18—Three 44' x 14' Dorr Thickeners.
19—Two 6-Leaf American Filters.
20—Concentrates Weightometers.
21—Concentrates to Storage.

Preliminary Notice

of Applications for Admission and for Transfer

October 19th, 1926.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in November, 1926.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BUSS—PAUL E., of Thorold, Ont., Born at Three Rivers, Mich., Aug. 31st, 1891; Educ., chem. and mech. engrg., Univ of Michigan, 1916 (3 yrs.); 1917, constrn. engr., Provincial Paper Mill, Port Arthur; 1918-19, 33rd Engrs. FOR TRANSFER FROM ASSOCIATE MEMBER TO MEMBER

PETERS—HUGH, of Esquimalt, B.C., Born at Victoria, B.C., Aug. 21, 1890; Educ., graduated R.M.C., 1910; 1910, topographer, C.N.R. surveys, Vanc. Island; 1911, asst. engr. marine dept., Victoria; 1912, asst. to supt., Pacific Coast Constrn. Co., Victoria; 1913-15, asst. to dist. engr., Dom. Public Works; 1915-19, War service with Pioneers and Railway Troops; 1919-21, jr. engr., Dom. Public Works, Victoria; 1921-26, asst. engr. with same department.

References: A. E. Hodgins, J. P. Forde, A. F. Mitchell, F. C. Green, E. E. Brydone-Jack, K. M. Cameron, F. H. Peters, G. B. Mitchell.

WOLFF—A. OSCAR, of Brownville, Jct., Me., Born at Copenhagen, Denmark, May 14th, 1889; Educ., private tuition, I.C.S. grad. in civil engrg.; 1908-12, transitman on general rly. mtce. and constrn. with C.P.R.; 1913-15, i/c field work, etc., Windsor St. yard improvements, asst. engr.; 1916 to date, resident and division engr.

References: J. M. R. Fairbairn, J. W. Orrock, A. C. Mackenzie, J. E. Armstrong, C. C. Kirby.

FOR TRANSFER FROM JUNIOR TO A HIGHER GRADE

CUNNINGHAM—ADAM, of Riverbend, Que., Born at Edinburgh, Scotland, Aug. 23rd, 1897; Educ., B.Sc., Univ. of Edinburgh, 1923; 1913, for 5 yrs. apptce. with West End Engine Works Co., Edinburgh; 2 yrs. 8 mos. in Imperial Army in Palestine and Egypt in technical unit; mech. staff sergt. i/c of sect. of base heavy repair dept., Alexandria; 1923-24, Mactaggart Scott & Co., Scotland, on design of hydraulic gear, cranes, etc., for the British Admiralty; 1924 to present time, with Price Bros. & Co. Ltd., in record dept. Kenogami paper mills for 8 mos., since then asst. to mech. supt. at Riverbend paper mill, supervision of steam plant, repair shops and general mtce. work, design and erection of paper mill equipment.

References: A. A. MacDiarmid, W. G. Mitchell, G. E. Lamothe, C. N. Shanly, G. F. Layne.

FOR TRANSFER FROM STUDENT TO A HIGHER GRADE

ELLEGETT—HENRY VICTOR, of Toronto, Ont., Born at London, England, Dec. 8th, 1898; Educ., concrete engrg. I.C.S.; 1923, tracer, jr. dftsman., Dom. Bridge Co., Winnipeg; 1924, asst. dftsman special boiler work, Dom. Engrg. Co., Winnipeg; 1925, supervisor reinforcing steel, Son Valley Sewage disposal plant, H. A. Wickett Co.; at present, tech. supervisor of reinforcing steel for Goldie Constrn. Co., Danforth Park sewage disposal plant.

References: E. C. Goldie, R. O. Wynne-Roberts, L. W. Wynne-Roberts, L. F. Grant, F. P. Fleet.

GREENWOOD—WILLIAM, of New Liskeard, Ont., Born at Toronto, Ont., Mch. 2nd, 1898; Educ., B.Sc., Queen's Univ., 1922; 1920 (summer), rodman and instman., Geol. Survey of Canada; 1921 (summer), topographer for Ont. Dept. of Mines; 1922 (summer), asst. geologist, Ont. Dept. of Mines; Nov. and Dec. 1922, instman. for Ont. Dept. of Highways, as asst. engr. on highway constrn; 1923-25, i/c field party on survey work in Peru, S.A., doing precise triangulation, boundary surveys, railroad location, etc.; 1926, i/c surveys for Int. Petroleum Co. in Peru, S.A., this inc'd. supervision of two to three field parties.

References: A. A. Paoli, W. F. Noonan, C. B. Bate, H. C. Cochrane, L. Malcolm.

GRENZEBACH—SYLVESTER LESLIE, of Toronto, Ont., Born at Tavistock, Ont., Nov. 26th, 1892; Educ., B.A.Sc., Univ. of Toronto, 1924; 1914-17, running threshing outfit with gas engine expert work as side line; 1923, 4 mos. and 1924, 6 mos., power station constrn. work; Dec. 1924 to present, load supervising engr., Toronto Hydro-Electric System, supervision of all switching operations on the Toronto Hydro system.

References: R. W. Angus, C. R. Loudon, J. R. Cockburn, C. R. Young, C. H. Mitchell.

MACNAUGHTON—MORAY FRASER, of Westmount, Que., Born at Westmount, Apl. 8th, 1899; Educ., B.Sc., McGill Univ., 1922; M.S., Univ. of Mich., 1924; 1915-1916, testing of materials and general laboratory work, Milton Hersey Co.; 1917-19, overseas with R.C.H.A. brigade signals; 1920 and 1922 (summers), inspector, paving dept., Milton Hersey Co.; 1923-24 (winter), Roy D. Chapin fellow in highway engrg., Univ. of Mich.; 1923-24 (summers), ch. inspector, paving dept., Milton Hersey Co.; 1925 to date, employed by Milton Hersey as ch. inspector on constrn. of sub-structure Mtl. South Shore Bridge.

References: C. A. Mullen, E. A. Forward, P. L. Pratley, A. C. Tagge, C. N. Monsarrat.

SPRIGGS—WILLIAM, of Montreal, Que., Born at Birmingham, England, Mch. 25th, 1898; Educ., B.Sc., McGill Univ., 1923; 1918-19, aeroplane pilot; 1921 (summer), Geological Survey; 1922 (summer), constrn. work; 1923-24, grad. students' course at Westinghouse E. & Mfg. Co., Pittsburgh; 1924 to March 1926, metering engr. in the supply engrg. dept. of Westinghouse Electric & Mfg. Co., Pittsburgh, responsible for experimental development design and application of the equipment of the impulse type of meter, spent considerable time supt'g. installation; at present, working on relay protection with Shawinigan Engineering Co.

Foundations in the Winnipeg District

An Outline of Conditions, a Description of Experience of Various Works and a Comparison of Types of Foundations and Cost

A. W. Fosness, A.M.E.I.C.
Designing Engineer, Carter-Halls Aldinger Company, Winnipeg, Man.

Paper read before the Winnipeg Branch of The Engineering Institute of Canada, October 7th, 1926

The entire Winnipeg district is underlaid with limestone bed rock. The highest elevation we have encountered in caisson work in the city was at the site of the Hudson's Bay Company's new store and was 51½ feet from prairie grade. The lowest was the Manitoba Cold Storage building and was 73 feet from grade. Test holes in various parts of the city have shown bed rock as low as 100 feet from grade, but these are not in the central part of the city and the test hole may have struck a pocket or seam in the rock. A good average for the central district is 60 feet from grade.

The level of the rock over any particular building area seldom varies more than a few inches except for spots where glacial action has ripped out blocks of various sizes or where strains in the rock bed caused by ordinary earth crust movements have shattered the rock with vertical fissures running in very irregular lines; these fissures being filled with the shattered rock. In many cases the broken rock has only been moved a fraction of an inch from its old location, especially in the lower part of the fissure, while in the upper part naturally a considerable portion has been removed by glacial action. Until the caissons for the Hudson's Bay Company's store were put in, the writer was of the opinion that glacial action was the cause of most of the pockets found in the bed rock, but, although we were fortunate enough to find good bed rock at a high level on this job, we ran across more trouble with rock pockets than on any work we have had in the city.

These were certainly fissures in the rock and not glacial rips. One crevice ran across the south-west corner of the building, and although several caissons were just on the bed rock at the edge of the crack only one hit directly on it. The other fissure on the north-east corner of the building ran directly under six caissons, although it was not more than twelve feet wide at the top. These crevices were filled with sharp-edged shattered limestone except for the top few feet, and this broken rock certainly had never been glaciated. Along with the shattered rock was a filling of fine white sand with some white clay in it, and just above the solid rock at the bottom of the fissure there were very often pockets of fine jet black clay; these materials being entirely different from the hardpan material above and must have been deposited before or during the early part of the glacial period.

The caissons along these fissures were sunk 80 to 95 feet below grade, and in no case were we at the bottom of the fissure, but were able to get good bearing either on one wall of the fissure or by bridging across at the bottom of the caisson where the fissure was very narrow. The bed rock got very hard as we got below water level, in fact at 95 feet we were scarcely able to drill it with a large size jackhammer running at high pressure.

Just above the good bed rock is a thin strata of a pink coloured rock commonly called " shale," but which is really decomposed limestone. This is about 18 inches thick as a rule and must be cleaned off to get a good bearing for the caisson. Above this is a glacial deposit which is called " hardpan " locally. This, of course, varies greatly in thickness on account of its character and is composed of boulders of granite and limestone in a mixture of sand, glacial clay and ground up limestone dust, making a mixture practically as impervious as the clay above. In Winnipeg, this hardpan layer averages about 5 to 10 feet thick, although when we were excavating for the School for the Deaf we struck boulders in hardpan at one corner of the building 12 feet below grade. Sometimes this hardpan is underlaid by a small layer of sand and gravel and in some cases is replaced by large glacial moraines, as at Birds Hill.

Above the hardpan is a thin layer of soft white clay of a somewhat different character than the blue clay above and containing considerable water. Above this, to the surface of the ground, is clay deposited in the bottom of old lake Agassiz. The top few feet of this clay is surface soil and yellow clay running gradually into brown clay, and as a rule at a depth of from 8 to 13½ feet is a sharply-defined band of yellow clay about six inches thick. The lowest level at which the writer has seen this layer, except along the rivers, is at the Daniel McIntyre school, where it was 13½ feet below grade. It may be lower further west in the city, but we have not any data for that district. Nine feet is about the standard depth through the business part of the city. This band of yellow clay runs over the entire Winnipeg district except in places along the rivers where the soil has been washed out to a lower level and silt deposited. This streak of yellow clay has been the curse of many of the old foundations in this district.

From this point down to the white clay above the hardpan is a fairly firm clay locally called blue clay. This blue clay, although it contains a fairly high percentage of moisture, is practically impervious to the passage of water through it. This bed of blue clay is usually about 40 feet thick.

In some parts of the city this blue clay is streaked with brown clay for a considerable depth, which of course somewhat reduces the bearing value of the soil. On the St. Boniface side of the river the percentage of brown clay in the blue clay gets considerably larger, so that conditions for floating foundations are considerably worse than in the central part of Winnipeg.

The best clay in Winnipeg, fortunately, is in the central business section, say roughly from Eaton's to the McArthur building. At the Hudson's Bay building site considerable brown clay was mixed with the blue to a depth of 25 feet in some places. A similar condition existed at the Public Press building, and the writer understands from Mr. Russell the same condition was noted at the Y.M.C.A. building. Along the river, where considerable cut and fill has been caused by the water, soil conditions are often very different. Not only does silt replace the top soil, but for some reason or other the blue clay is replaced by brown and yellow clay in some cases to a depth of as much as 35 feet from grade. This condition exists sometimes for at least a block back from the river. Since this yellow clay absorbs a great amount of water with a corresponding change in volume and firmness, and apparently permits water movements through it to a much greater extent than the blue clay, it makes a very bad foundation condition.

Allowable Bearing on Soil Foundations

The general opinion as to the allowable bearing on soil foundations has changed considerably within recent years. When heavy buildings first were put up in the city 3 tons per square foot on blue clay was considered permissible for warehouses and 2½ tons for office buildings, and they were not always careful to see that the footings were on blue clay. As settlement troubles developed with the old buildings, the allowable bearing values were decreased until in the new building code we are endeavouring to bring out the following bearing capacities are permitted for various soils. The higher value allowed is for warehouses, manufacturing buildings, etc., and the lower value for office buildings, apartments, etc.:—

Firm blue clay with no underlaying strata of yellow clay	2 tons	and	1½	ton per square foot
Mixed clay—moderately dry...	1 ton	"	¾	" " " "
Soft yellow clay and silt......	½ "	"	⅜	" " " "

The reason for the lower allowance for office buildings, etc., is that settlement in this type of a building makes so much more trouble with the interior finish and plumbing. In all cases we are endeavouring to keep the live load to a reasonable value and are in addition allowing a cumulative live load reduction that should give a design load at the foundation very close to the actual load. Foundation sizes are then to be based on the combined dead and live load, with no adjustment for the relative percentage of dead and live loads on the different footings. In modern fireproof construction the dead load is so large that this adjustment does not amount to much in any case. We have been fairly conservative in unit stress allowances in columns, and this seems to be a far more logical way to design a building frame than to call for a larger floor load than will ever be required, and then allow high stresses in the columns the way some ordinances do at the present time.

Of course the ordinance will not prohibit an owner from having his floors designed for heavy loads throughout the entire building to permit of his changing departments, or moving heavy concentrated loads, and taking a larger percentage reduction as long as he keeps within the ordinance's minimum requirements. For instance, consider a 6-storey mail order warehouse. The architect may plan with the owner that the heavy hardware and groceries will go on the basement, first and second floors, crockery on the third floor, and so on up to furniture on the sixth floor. He designs the lower floors for 300 pounds and the upper floors from 200 to 100 pounds. The first thing a new manager will do when he takes over the plant will be to change the grocery department to the sixth floor and the furniture to the second floor. This causes trouble with over-loading of the top floor. If all the floors were designed for 300 pounds, and a large cumulative live load reduction taken on the columns, the owner would have a very flexible building with no larger columns. The building department would then only need to see that there were not too many floors placarded for the heavy loads at the same time. The same method would apply to buildings with concentrated loads, such as printing buildings.

The allowance for wooden piles in the new code is a maximum of 20 tons per pile and for concrete caissons 30 tons per square foot or 417 pounds per square inch at the base of the caisson if on rock. If the caisson is stopped on hardpan it must be belled to twice its diameter, which gives an allowable value of 7½ tons per square foot on the hardpan. For both piles and caisson foundations an additional 25 per cent reduction in the live load is to be permitted in order to encourage owners to use either of these types in preference to a floating foundation.

Floating Foundations

There are two types of floating foundations. One where each column has its own independent footing and the other with a complete mattress over the whole building area. The mattress foundation has the advantage of taking up the whole available area for bearing, and not permitting heaving of the basement paving between footings, but it has one bad disadvantage for building construction.

If the building is on soft soil the ground under the matt begins to squeeze out under load. Since the matt covers the whole building, the material can only squeeze outside. As a result, the centre of the building settles only a little, while the walls of the building settle considerably. This happened on a building we built on a matt foundation in the Winnipeg district some time ago; within a short time after the building was erected, there was a variation in level of 1½ inch between the floor at the walls and at the interior of the building. With separate footings the settlement would have been more and the basement paving would have heaved, but the floors above would have been level. Extending the matt beyond the basement walls as far as is structurally possible would have helped this condition, but would not have remedied it entirely. The ideal use for a matt foundation is under a set of concrete grain tanks, where settlement must be uniform over the entire area on account of the monolithic construction of the reinforced concrete tank walls.

Another type of footing, consisting of a combination mattress and short pile footing, has been used only once, as far as the writer knows, in the city, and that is on the Watkins Medical building. The total load on the matt under this building is about 1½ tons per square foot. The soil in that part of Winnipeg has a poor bearing value. However, the distance to rock for a pile foundation was excessive, and instead of endeavouring to put in a pile foundation to rock, 30-foot piles were driven about 2½-foot centres both ways over the whole area. This not only compressed the soil and increased its bearing value at the top, but also through the friction on the piles transferred some of the load to the clay at lower levels, and although the piles drove quite easily the combined matt and pile foundation has given excellent satisfaction and there has been practically no settlement in the building although it is very heavily loaded.

There are no very great difficulties to be overcome in connection with putting in clay foundations in Winnipeg, except the trouble with shoring the banks and trenches. When blue clay is fairly dry, as in the winter or during a dry spell in the summer, it stands up well with quite a steep bank, but when the frost is coming out in the spring or during wet weather an unshored bank needs to have a slope of at least one horizontal to one and one-half vertical to stand any length of time, and a 45° slope is desirable, if possible. Where vertical banks are necessary and shoring must be used, the most important thing is to keep the *toe* of the bank well braced, since this is where the slide invariably starts. The shores should have a firm base to strut against. This is easy in the winter because the frozen ground in the bottom of the general excavation gives an excellent bearing, and in summer work, if possible, the interior footings should be poured first to give support to the struts before the bank is cut down and shored. Putting the base of the shoring timbers against a short timber in the mud is not very satisfactory because the least movement allows the bank to break and the pressure is then very greatly increased. In fact, after a bank breaks, shoring against ordinary mud sills simply will not hold except on low banks. The main things to keep in mind are: keep the main struts against the toe of the bank, have a rigid bearing for the thrust of the struts, and keep them wedged tight so that the bank will not break.

In cases where the excavation goes to the street or pro-

Figure No. 1.—Taking out General Excavation and Sinking Caissons on Hudson's Bay Building, Winnipeg, Man.

The light coloured material at the mouth of some of the shafts is hardpan and soft limestone rock. The thin yellow clay streak at 8 feet 6 inches from grade, which causes trouble with many of the shallow floating foundations in the city, can be seen on the farthest bank just under the gravel-heating grid of the winter concreting plant.

perty line the safest way is to take out the general excavation, leaving a generous slope back from the property line. The exterior walls can then be trenched and braced, using the interior berm of unexcavated material to brace against. The walls can then be formed, poured, and backfilled on the outside, and the ground floor framing can be used as a brace before removing the berm of unexcavated material in the basement, or timber struts can be used to the interior footings from the inside face of the completed wall.

In spite of all this good advice, we nearly lost the south bank of the Hudson's Bay job. A sub-basement that goes down 45 feet below grade runs along this entire end of the building. Our plan was to excavate the general basement, which is 19 feet deep, and slope it out 18 feet beyond the south building line. Then we took out 10 feet of the sub-basement with a steam shovel. This was done to permit the forming of the basement floor above the sub-basement which is used to strut the top of the sub-basement walls. Then the caissons along the sub-basement walls were sunk and poured to the bottom of the sub-basement, following which the trenching for the sub-basement wall was started. This trench was 8 feet wide and lagged with 3-inch vertical lagging on both sides as we went down and with 8- by 12-inch whalers about 3-foot centres on both sides, with 8- by 8-inch struts about 5-foot centres along the whalers, all of these struts being jacked into place with trench jacks. We had just finished the trenching and were ready to pour the footing when the entire south bank broke at a line about 40 feet away from the building. The bottom of our trench was in the white clay just above the hardpan, and apparently the slide started at this line, squeezing our trench over several inches at the bottom. It then held at this point and the maximum pressure seemed to keep coming at higher levels every day; the top of the bank meanwhile moving a fraction of an inch every day. We could see how the pressure zone kept raising by the way the strut timbers crushed into the whalers. The maximum pressure at the base must have been one ton per square foot. Finally the top of the trench began to move north, and we then put in heavy timbers against the bank, which had a frozen crust about 4 feet thick, just above the trench and braced against the frozen crust of ground in the sub-basement. These were jacked into place with 45-ton jacks, and at last the bank was stopped. We then started transferring struts in the bottom of the trench and pouring the wall and caissons in 3-foot lifts, which was not very easy to do.

With caissons, the only great difficulty comes after going through the hardpan. If the hardpan is directly on the bed rock, water will not interfere with the work. The clay and hardpan make such an excellent seal that a pump is practically never necessary, no matter to what height the water rises in an adjacent bad hole. The method used in Winnipeg to put in caissons, or piers in open shafts or wells as they should be called, is to dig a circular hole 4 feet deep, lag this with 2-inch vertical staves, then put in two split steel rings and wedge them tight. Then another 4-foot hole is dug in the open and the process repeated, the excavated material being taken up with a tripod winch and bucket. Sometimes the lagging is only 3 feet or 2 feet at a lift if the pressure is bad. After the hardpan is reached lagging is usually dispensed with. There are frequently large boulders in the hardpan, which are often larger than the caisson shaft and have to be broken up by drilling and plugging.

If there is a layer of gravel just above the rock you do not get any indication of it, as a rule, until you break through the last of the hardpan, when the water rushes in sometimes at the rate of a foot a minute, or more. This is what happened with most of the caissons we put in at the Manitoba Cold Storage building, at the St. Norbert bridge and at the Canada Cement plant. At St. Norbert the water rose over the top of the shaft and ran down into the river several feet below. So far, the holes of this type that we have encountered have had a comparatively shallow layer of gravel, so that pumps could control the water as fast as it came in. Sometimes two large pulsometers have been required per hole, and in one case the only way we could control the water was by lowering a large vertical drive centrifugal pump into the hole and driving it with a 60-h.p. engine at grade. This condition is the exception inside the city.

The only other trouble to be encountered is fissures in the rock. If these fissures have broken rock and clay for a filling you are fortunate, because this can be dug out and lagged the same as the clay, except that it is much slower. Then you also have the pumping to contend with. Your worst trouble is with the white sand in a wet caisson. This sand is firm and easy to dig and lag when dry, but is as bad as quicksand when wet. It flows into your pump sump in spite of anything you can do, and this causes the walls behind your lagging to disappear and forms cavities above where you are working, with the danger that these will fill in with a rush, break the lagging, and fill in the caisson below, with the loss of the lives of the diggers. It is nearly always impossible to drive lagging ahead of you in these holes on account of the broken rock.

Of the first three bad caissons to be started on the Hudson's Bay job all three were on the same fissure, all in broken rock and sand. In one of them, however, the rock was packed almost solid while in the other two there was more sand than rock. The first to be attempted was one of the sand holes, and in endeavouring to pump this caisson we formed the famous cave under Portage avenue, which was nothing but an opening about 4 feet high and about 8 feet wide, and maybe 20 feet long, caused by leaching the sand out of the bottom of the trench and causing the broken rock to slide down and leave the hardpan cap. This cavity, by the way, was filled with concrete when the caisson was finally poured. When we found that several of these holes were on the same fissure we abandoned the bad ones and sunk the one that was in the closely-packed rock and could be easily lagged, to a depth of nearly 95 feet, at which point the fissure was very narrow and good bearing could be obtained on both sides. We then left this caisson open as a pump shaft and the sand dried out in the other holes which were at a higher level, and these were then sunk in the dry without any trouble and concreted. The deep caisson was then allowed to fill with water and was poured by means of a tremmi, the only one on the job not poured in the dry. On one other caisson at the opposite end of the building we finally gave up our attempt to find bottom and put down a trench across the crevice and bridged it with a heavy reinforced concrete girder.

Relative Cost of Various Foundations

As to the relative cost of various types of foundations. It seems that there is an idea in the mind of most owners and architects that a caisson foundation is rather an expensive luxury. On account of the desirability of a rigid foundation wherever it is economically feasible, the following comparisons are given:—

In the first place, the cost of a floating foundation increases rapidly as the column load increases. The reason for this is that as the load increases not only is the area of the footing increased but the depth increases also in order to provide for shearing stresses and the reinforcing increases rapidly to take care of the bending moment. For example, a 1½-ton independent footing, to take care of a column load of 750,000 pounds, costs about $400 including excavation, while a 1½-ton footing to take care of a column load of 1,500,000 pounds costs about $1,050.

On the other hand, the cost of a caisson foundation increases at a slower rate than the load. The reason for this is that shear and bending moment do not enter into the design but merely cross-section, since it is nothing but a centrally loaded pier. A larger hole is easier for the men to work in than a small one, and the unit rate per cubic yard for excavation is therefore less, also the cost of lagging and rings only increases at the same rate as the diameter, or as the square root of the ratio of increase of the load. As an example, with a ten-foot basement and 55 feet from grade to rock a caisson to carry a column load of 1,500,000 pounds would be 6 feet in diameter and cost $1,000, while a caisson to carry half that load, or 750,000 pounds, would be 4 feet 3 inches in diameter and cost $650. These are average costs and are based on conditions in the central business district of the city, and would cover caissons anywhere from the line of the Parliament Buildings and Hudson's Bay building to Main street, at least, and probably much further west. We are assuming nine out of ten caissons to hit rock at the regular level without trouble and the tenth to cost at least double on account of striking a pocket or crevice and thus running into greater depth of very bad digging and lagging, with the added cost of pumping and additional concrete.

No building in this central district has had a higher percentage of bad caissons than that assumed above, although naturally it is somewhat of a gamble as to what you will strike on any particular site. A test hole or two on any site would help clear up some of the uncertainty. As mentioned previously, if gravel or sand is encountered above the rock pumping becomes a large part of the cost, and the cost of caissons in such a location is often double or more the cost where the caisson can be put down dry. Another point that helps the comparative cost of caissons is a deep basement or high rock level either of which shortens the caisson but does not affect a floating footing. From the above prices it will be seen that for loads of 1,500,000 pounds per column a 1½-ton floating foundation costs as much as a caisson foundation in this central district, and a 750,000-pound caisson only costs $250 more than a 1½-ton floating foundation. This load of 750,000 pounds is about what you would get with a 10- to 12-storey office building with 16- to 20-foot panels, or a 6-storey warehouse. For an office building of this height costing $1,000,000 the

Figure No. 2.—Forming for Basement Floor over Sub-basement on Hudson's Bay Building, Winnipeg, Man.

The trench, which started to fill in from the sliding of the bank, is along the left side of the picture along the line of the caisson lagging. The bank broke on a line that ran through the centre of the shack at the extreme left. At the time this picture was taken the movement of the bank had been stopped.

extra cost of the foundations would be under $10,000, or less than 1 per cent of the total building cost, and the owner will save several per cent by using caissons due to the trouble settlement in an office building causes with the finish in the building, and the mechanical trades. Also, there is the uncertainty of how much settlement future water conditions in the soil or excavation near the site will cause and the worry incidental thereto.

The only drawback to a caisson foundation for low buildings is that a 4-foot diameter caisson is about as small as can be economically put down. If made any smaller the difficulty of working in the small space takes as much extra money as you save in the lessened qualities of excavation and concrete. A caisson this size will carry 700,000 pounds and cost about $600. This means that while the cost of a floating foundation decreases rapidly for loads under this amount the cost of caissons remains a constant, and for a 7- or 8-storey office building the cost of a caisson foundation would be double that of a 1½-ton floating foundation, or $600 against $300 per column. If the building is quite low a one-ton foundation on blue clay makes a fairly good substitute for caissons since the settlement at this load is very small.

Any conditions that cause heavy column loads, such as heavy live and dead loads, big panels, a large number of storeys or deep basements and high rock levels, are in favour of the use of caissons.

The most remarkable case we have ever had as regards cost is the Hudson's Bay job. The building is designed for a future height of ten storeys; the panels are very large, 24 by 28 feet; the live and dead loads are about 250 pounds per square foot, and the basement column load on a typical interior column is 1,500,000 pounds requiring a 6-foot diameter caisson, the heaviest being 2,500,000 pounds. The basement is 19 feet deep and bed rock only 51½ feet from grade, making a 32½-foot shaft for the caissons. These caissons averaged in cost less than $750 each complete, or $1.00 per ton. This meant a saving of $60,000 on the entire job over the cost of a 1½-ton floating foundation, or a saving of $10,000 over the cost of a 2-ton floating foundation. It certainly is an unusual thing to have a caisson foundation costing less than a two-ton floating foundation. As the loads increase to 2,000,000 pounds or more, nothing can touch the cost of caissons.

Caissons to hardpan only are not to be recommended except under exceptional circumstances. Where the hardpan is only 5 feet thick it is just about as cheap to go through it to bed rock, and certainly a lot more satisfactory since you are then on a bearing that water conditions above the rock will not interfere with in the future. However, if the hardpan should be 15 feet thick, or more, it would greatly shorten the shaft to stop on hardpan and thus save a considerable part of the cost. Another condition where caissons to hardpan only would save a great deal of expense is where the hardpan is underlaid with water bearing gravel. Here the saving would be very great. In both these cases drill holes should be put down in each caisson to be sure that solid bed rock exists under the hardpan and gravel, and that there is not a fissure or pocket of soft materials directly under. Also, if gravel underlays the hardpan it should be definitely determined that the gravel does not contain much fine sand that would be liable to flow or squeeze out. If the hardpan cap is quite thick a small fissure in the rock could be bridged over without much danger. However, caissons to rock are to be preferred wherever possible.

Pile Foundations

The next preference to a caisson foundation is a pile foundation. The length of piles required for most parts of the city to drive to refusal from about a 10-foot basement is 35 to 55 feet, except for certain districts along the river where longer piles are required. These piles drive to refusal in the hardpan and boulders, seldom going to bed rock. The new ordinance is allowing 20 tons per pile for wooden piles driven to refusal, and assuming an average of 45-foot piles these will cost about $20.00 each driven, or $1.00 per ton. To this must be added the cost of the footing cap, and assuming a spacing of 2 feet 6 inches each way for the piles this cap will cost about half the cost of a 1½-ton floating foundation for the same load. Again, taking the example of a 750,000-pound load, a complete pile and cap foundation will cost about $600, or very nearly the same as a caisson foundation for the same load. The advantage of pile foundations over caissons in the matter of cost shows up for the smaller loads, since the number of piles and the cost can be varied to agree with the load, while, as mentioned before, a caisson cannot be reduced in cost below the 700,000-pound size. A pile footing and cap for a 250,000-pound load will cost complete about $200; a floating foundation for the same load at 1½ tons $75, at one ton $115, and a caisson foundation $600. Another place where a pile foundation has a great advantage is along the rivers or wherever water conditions would interfere with the building of caissons. In these locations the pile foundation would cost less than the caissons for even heavy loads.

Approximate relative cost of various types of footings for varying loads in the central business district of Winnipeg:—

Types of Foundations—Loads	250,000 pounds	500,000 pounds	750,000 pounds	1,500,000 pounds	2,250,000 pounds
Caisson	$600	$600	$650	$1,000	$1,300
Wood piles and cap	200	375	600	1,300	2,200
2-ton footing	55	150	275	785	1,450
1½-ton footing	75	210	400	1,050	.....
1-ton footing	115	315	600	.....	.....

Note: Caissons running into water trouble may easily cost double the amount given above.

Where a mattress foundation without piles is used it will cost about the same as an independent floating foundation to cover three-quarters of the area. In other words, a mattress foundation at 1½ tons costs about the same as a series of 2-ton independent footings.

Concrete piles vary in relative cost the same as wood piles, but are relatively somewhat more expensive here and are therefore not often used.

All the above prices are based on foundations for new buildings. On account of the large number of caissons that have been used for underpinning in this city, a large part of the unit prices that have been obtained are too high for new work.

Causes of Foundation Settlement

The causes of settlement of foundations are numerous. In the first place, a caisson foundation to rock or hardpan, or a pile foundation driven to refusal, if properly designed and built, should give a practically rigid foundation. The only thing that can affect a caisson is alkali, and the only trouble that can occur with a pile foundation is from dry rot.

As regards alkali, there have been few cases of this action on building foundations that have come to my attention. A footing poured in place in the clay is very effectively sealed against seepage of ground water, and without movement of ground water carrying alkali leached out of the soil this chemical action on the cement cannot take place. Small pockets of alkali in the clay that are in contact with the concrete will sometimes cause local action, but this is not dangerous. The writer has seen the footings uncovered at different times of many Winnipeg buildings, and the only cases of alkali trouble were where drains had broken near a footing or around the outside walls where they were not waterproofed and the weeping drains did not properly take the surface water away.

The only really bad case was on a building where the downspouts from the roof were connected to the weepers, and the outlet from the weepers was two feet above their level around the building. As a result, the basement was flooded after every rain and was pumped out sometimes. This went on for fifteen years and gave a wonderful chance for the alkali in the soil to leach out and get at the concrete along the outside ledge of the wall footings. As a result, alkali action penetrated from one to six inches. This was a most unusual case, however, and with proper methods of handling the rain water and weepers, this would never have happened. Walls of buildings adjacent to this one, which had no weepers and had clay backfill, were not affected in any way. Caissons that do not run into water troubles are the same in respect to alkali action as footings in the clay, and where water troubles are encountered the best protection against alkali is to use a very rich concrete, (say a 1:1:2), in the lower part of the caisson up to a point that seals off the water entirely.

As to dry rot in pile caps, this is very likely to happen unless care is taken to keep the cut-off level in moist ground, (not necessarily below water), and sealed from the air. Trouble from this source rarely happens where there is a concrete cap poured over the top of the piles, and the concrete capping is poured against the clay on all sides, and the cut-off is in blue clay. The blue clay retains moisture so well that, if air is kept away from it, rotting of the piles is almost impossible.

Nearly every case of trouble with pile foundations that the writer has seen has been where there was a wooden basement floor with no concrete paving and very shallow caps on the piles. This allowed the air to be in contact with the soil and dry it out to a depth below the cut-off, and the piles naturally started to decay.

Drying out of the soil on account of ovens, boilers, etc., also has caused trouble with two cases of pile foundations in the city. When we were remodelling the old Clarendon Hotel building, the footings, consisting of heavy spruce or pine plank, were found to be in perfect condition and were used to support the present building. They were about 12 feet from grade in moist blue clay. Since this is one of the oldest buildings on Portage avenue, it is as good an example as can be found.

Foundations on Clay

Foundations on clay all settle, since it is the nature of clay to flow under pressure. Where this type of foundation is used the footings should be so designed as to make the settlement as uniform as possible, and of an amount in keeping with the character of the building.

The amount of settlement of a properly designed footing in blue clay is hard to compute exactly. If the soil is not in very bad water conditions blue clay will harden under pressure and the settlement will continue at a much reduced rate. When the Paris building was being built it was necessary to underpin the wall of the Avenue Block adjacent, which had a bearing of about three tons per square foot. This footing was in blue clay, and the clay below the footing was so hard that picks had to be used to break it up. On the other hand, the yellow clay above the blue clay does not show this property of hardening under pressure, probably because of the greater permeability of the material. Cases have occurred in Winnipeg of buildings built on this yellow clay that have stood fairly well for a number of years and then started to collapse. When this occurs the yellow clay is always found to be wet and very soft.

The best record the writer has of amount of settlement under heavy load is in connection with a set of grain tanks we built in the city a few years ago. The basement connection between this set of tanks and the old tanks had a flush ceiling joint. The tanks were loaded to capacity immediately after completion and the total pressure on the floating mattress foundation was 3¼ tons per square foot. Under this load the tanks settled 2 inches while being loaded, and the total settlement at the end of two years was 4 inches. The soil at this location is quite badly saturated, which somewhat increases the amount of settlement. The total additional settlement in the next ten or fifteen years will probably be about 2 inches, making a total of 6 inches.

The only office building of which the writer has any records as to settlement is the Paris building. The footings on this building are in good blue clay and designed for two tons per square foot dead and live load. When the first five storeys were erected the settlement was very small, since the total dead and live load was under one ton per square foot. When the upper six storeys were added the building settled ¾ inch the first year, ⅛ inch the second year and slight settlement has occurred each year since; the total settlement now being about 1½ inch. The settlement at the present time is very small.

In spite of this 1½-inch settlement, no noticeable cracking has occurred in the partitions throughout the building due to the careful proportioning of the footings. Far more trouble can be caused by unequal settlement than by a comparatively large uniform settlement. Taking the Paris building again as an example, some of the column loads in this building are not much over half of other columns. If the footing required for the heaviest column had been used throughout the building as a typical footing, the settlement would have varied from ¾ to 1½ inch in many cases at adjoining panels, with a consequent shattering of every partition in the building. If it were proper to do so, the writer could name dozens of buildings in the city where this very thing has been done with consequent trouble afterwards; in fact, it is by far the most common source of trouble. As mentioned before, the new building code is being prepared with an idea of eliminating this trouble as far as possible, but the only safe rule is to proportion every footing according to the load, no matter how unimportant it may seem. The following are some of the more common mistakes of this character:—

(*a*) Making all the column footings the same size in a building which has different-sized panels.

(*b*) Making the corner column footings in a skeleton building the same size as the other wall column footings when the load is usually considerably lighter. This causes the corners of the building to stand up more rigidly than the balance and diagonal shear cracks occur in the end walls or spandrils. There are two good examples of this in the city.

(*c*) Designing, say, an apartment house wall footing for a three-storey load and containing this same width under a one-storey section along a light court. The one-storey part stands up more rigidly and the arch action in the brick wall causes the building to *break its back*. This is a common trouble with apartments, churches and wall-bearing buildings of all kinds.

(*d*) Having interior basement brick partition walls, such as coal bin walls, rigidly built into the outside walls. As a rule, these inside wall footings are kept in a drier condition than the outside footings or are not loaded as heavily, and as a result stand up comparatively rigid while the outside walls settle. This causes the inside wall to act as a lever and pushes the outside wall out at the top causing the wall to tip and the joists to pull out. This is a common cause of trouble in many houses of the larger type and apartments, and you often see repairs attempted by tie rods, etc., when all that is needed is to disconnect the inside partition wall and footing from the outside wall.

(*e*) Permitting surface water to get at the wall footings and cause them to settle while the interior footings are dry. This is particularly noticeable in footings in brown and yellow clay, such as many apartment blocks have.

Foundations in the soft brown and yellow clays overlaying the blue clay should be discouraged except for very light loads. In the early days of heavy building in this city this was not realized as fully as it is now, with the result that many of these fairly heavy buildings were built on this yellow clay and have given trouble ever since. The yellow clay is very soft when wet, and since it absorbs water easily it simply squeezes out under load and apparently does not harden under pressure unless kept dry. Many of the apartment buildings being erected in the city at the present time have their footings in this yellow and brown clay. After they are up for a few years nearly all of them need underpinning when at a comparatively small additional cost they could get a good foundation in the first place.

Water conditions make a considerable difference in the amount of settlement of a footing. Even the blue clay in its plastic form contains a high percentage of moisture. Since it is so nearly impervious it absorbs water slowly, but if the surface water level is kept above the footing level for a long period an increase in settlement will be noticed over normal conditions. Artificial drying out of the clay will also cause settlement, since the volume of the clay shrinks greatly as the water is removed and the footing is thus let down. The writer has seen four very good examples of this in the city, two under bake ovens, one under a boiler installation and one under a gas retort. The best example was under the old Spiers-Parnell ovens. We removed these when building the new addition. The ovens were two storeys high and started with fire pots on the basement floor. The soil under them was dried to a powder for from 4 to 6 feet, and not only the ovens had settled but the whole building in the vicinity of the ovens.

Foundations at Different Levels

Having the foundations of a building at different levels is another source of trouble. The footings at the higher level slip and squeeze down to the lower level if at all possible, and the soil at the higher level dries out due to the drainage of the low part, all of which causes the higher footings to settle more than those at the lower level. Where a difference in level cannot be avoided, the levels should be stepped back as gradually as possible.

Frost

Frost is another common trouble maker. As the clay under a footing freezes it naturally expands, and if the load is not too heavy on the footing the wall or column is raised accordingly, the amount of heaving depending on the amount of moisture in the soil and the depth to which the frost extends. Sometimes, if the load on the footing is very heavy, a different action occurs. In one of the cold storage warehouses in the city the owners decided to make one of the basement rooms a freezing storage room. It was kept at below freezing temperatures for several years with no sign of heaving. It was finally decided to change this room back to a warm storage, and a few months later the columns in this room settled two inches, cracking the reinforced concrete girders framing into these columns at all floors. What happened was that, the load on the columns being very heavy, when the frost penetrated to the soil under the footings the clay squeezed sideways into the unfrozen area around this room and when the ground thawed out the footings settled. In all cases of heaving from frost and subsequent settlement from thawing, the amount of settlement depends on the load per square foot on the footing. In the case of light loads, such as house foundations, etc., the footings sometimes settle back very little, while in the case of heavily-loaded footings the settlement is often more than the heaving.

Another peculiar case of frost action was in connection with a set of grain tanks in the city. This battery of tanks was 40 feet wide by 100 feet long, and the long axis was east and west. The tanks rested on a mattress footing with 3¼ tons per square foot bearing. The basement was unheated, with the result that the ground was frozen several feet under the mattress. In the spring the sun shining on the south side of the tanks melted the bank along the south side and permitted ground water to get at the footings along this side long before the north side thawed out; in fact, the frost was scarcely out of the north bank before cold weather set in. As a result, the clay along the south, softened by the sun and the surface water, permitted the soil below the mattress to squeeze out along this side very much more than at the north, with the result that in fifteen years the tanks leaned to the south 26½ inches. Most of this occurred during the first two years, the blue clay becoming packed hard enough by that time to retard this action greatly.

Foundations Along River Banks

The last foundation difficulty is in connection with the river banks. A whole paper could be given on this alone. Settlement of buildings along the river is caused mainly by two things,—both of which are related to the change in river levels. In the first place, when the locks are closed in the spring the river is kept to an artificial level considerably above normal summer level. The water soaks back into the banks, especially where the yellow and brown clay goes to low levels, as it does in some places along the river, and since this yellow clay will absorb a large amount of water and will permit water to be absorbed through it quite rapidly, this action sometimes goes back quite a distance from the river's edge. This soaking of the clay seems to somewhat increase its volume because in the fall when the locks are opened and the water level drops the water is drained out of the soil, and many houses all over the city along the rivers immediately show settlement. This is distinct from the sliding of the banks.

One very fine house in North Winnipeg, several hundred feet back from the river, has this happen every year, and, as previously mentioned, we tested the soil below this house and found brown clay for 34 feet, and then a bright yellow streak one foot thick and then very wet blue clay. This was not river silt but regular Winnipeg clay.

The breaking of the banks and sliding is the cause of trouble with many houses and apartments very close to the bank. The reason is very similar to the former case. The high summer water level soaks up the clay in the bank and at the same time by its hydrostatic head tends to keep the bank in balance. When the water is let out in the fall this back pressure of the river on the bank is suddenly removed while the soil in the lower stratas of the bank is thoroughly "lubricated," and, since the banks are always in a rather delicate state of balance, the bank breaks and slides down until the stresses are again in balance.

A walk along the Assiniboine river banks in the fall after the locks are opened will show this very conclusively. The most unfortunate cases are where the break in the bank happens to come through a building. Permanent repairs in a case like this are nearly hopeless, because the bank may slide along the same plane again and take any underpinning with it.

If building must be done near a river, the following precautions should be taken:—

> Trying to keep the bank from slipping by the use of piles along the water's edge is of no permanent value unless the piles are driven through a fairly thick strata of very firm material, or unless the top of the piles are anchored far back into the bank to rows of anchor piles and deadmen. Even with this anchorage of the top, the toe of the piles must be in firm material. Along the Assiniboine river, in most cases, the water's edge is practically at hardpan and boulders, so that only very short piles can be driven, and in many cases there is little or no firm material for an anchorage.
>
> Another way of taking care of the slip of the bank in a location where rock level is not too far from water level is to put in a reinforced concrete retaining wall near the water's edge, keyed and anchored into the rock. This would need to extend only a few feet above water level, but it would positively keep the bank from starting to slide. The only trouble is the expense. Along the banks of the Assiniboine this would cost at least $50 per foot.
>
> No increase in load should be put on the bank. A light building with a basement will not increase the load on the bank if the excavated material is taken away. Excavated material should never be graded along the bank, since this is just inviting trouble. If grading must be done, take it off the bank instead of putting it on.
>
> Heavy buildings should be on piles or caissons, thus carrying the load to the hardpan and rock below direct. Also, the mattress or foundation capping these piles or caissons should be well tied together.

Conclusion

In conclusion, when designing foundations in the Winnipeg district, and where the size and value of the building will permit, use a rigid foundation of caissons or piles,—caissons probably are to be preferred where conditions are favourable. If a floating foundation must be used, keep the bearing on the low side if settlement will cause trouble; keep the size of footings proportioned to the loads; keep them on as near the same level as possible; and use good concrete.

Power Distribution Problems of the Toronto Transportation Commission

Some Features of Operation and Maintenance Affecting the Electrical Department

J. F. Neild, Electrical Engineer,
Toronto Transportation Commission, Toronto, Ont.

Paper read before the Toronto Branch of The Engineering Institute of Canada, November 11th, 1926

The Toronto Transportation Commission is in the business of selling transportation, and each employee must have as his objective safe, rapid, efficient and economical service.

The service must be safe because our modern ideas demand it. It must be rapid because our modern conditions require it. It must be efficient because our modern commercial system compels it. It must be economical because it is a peoples' project, and, as their servants, the Commission must give them full value for their money.

Source of Power

The Commission purchases its power from the Toronto Hydro-Electric System, who in turn receive it from the Hydro-Electric Power Commission of Ontario. This power reaches Toronto over two different rights-of-way, and is received at four terminal stations, as shown in figure No. 1. The lines are in phase, but not necessarily always in synchronism. As each line may be fed from a different source of power at Niagara Falls, the inter-connection of the substations to feeders running from the various terminals gives the Toronto Transportation Commission a ready alternative source of power if either fails. Direct current power is distributed to the trolley from eleven substations; four of these having a capacity of 16,000 kilowatts in rotary converters are the property of the Toronto Transportation Commission; the remaining seven having a capacity of 16,000 kilowatts in rotary converters are the property of the Toronto Hydro-Electric System, who sell the converted power at the bus bar.

Special Operating and Maintenance Facilities

In the equipping of the Toronto Transportation Commission's substations, the original work, as carried out by the old Toronto Railway Company, has made possible the quick transfer of operators from one substation to another by having a standard arrangement so that in each substation all pieces of apparatus are placed in the same relative positions and carry the same numbering. This is a very great advantage; also, the furnishing of all the substations with identical equipment enables the maintenance to be kept up with a minimum of spare parts.

In order to get machines back into service in the least time possible when repairs are required, several interesting tools have been developed. One is a device for changing field coils without disturbing any portion of the machine. This device consists of a band with clamps attached, a plate and a suspending arm. The band is fastened around the field coil, the clamps holding the pole piece in place, the plate is drilled so the band can be bolted to it. No matter what angle the field may be at, the suspending arm attached to the plate will be vertical. The pole piece bolts are taken out, the whole section, weighing some 300 pounds, is swung out, lowered down, slipped out of the band, the new one slipped in, raised up in the crane, and, since the angle is kept by the plate fastening the new field, it can be swung into position and bolted in, the whole process taking some 30 minutes, as compared to 3 to 4 hours without this device.

Another interesting tool is a machine for slotting commutator sections. This tool is erected on the shaft with the armature in place in the machine. Two guides rest on the commutator while a slide bar passes across the face of it, a motor driving a shaft with three milling saws on it are pushed across, riding on the slide bar, thus milling the mica out of three slots at once. As there are 864 slots on each commutator, you can readily appreciate the saving in time over the one-saw slotters.

These devices and others have greatly reduced the out-of-service time of our rotaries and increased their utilization time.

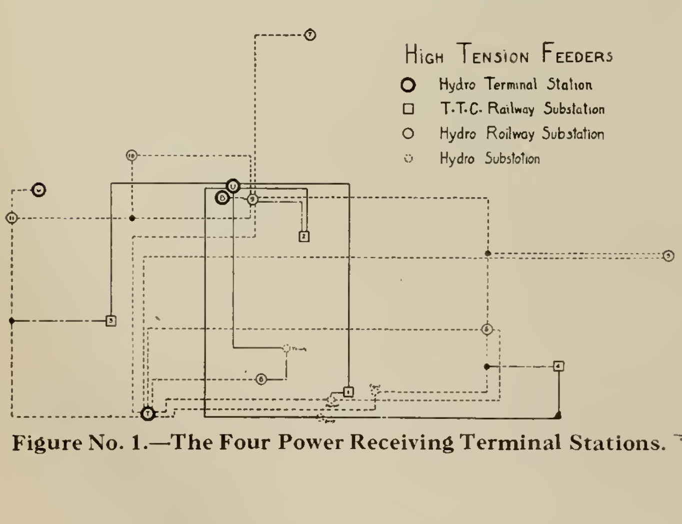

Figure No. 1.—The Four Power Receiving Terminal Stations.

Trolley Wire Sections and Feeder Arrangements

The trolley wire is divided into 119 sections, each section being fed by its own feeder. These sections are so divided that there will be a maximum load of about 1,500 amperes on each, thus giving a controllable load on each feeder panel which has its own control switch, ammeter and circuit-breaker. This division of sections also enables trouble, such as fires, falling wires, etc., to be isolated and made dead with the least traffic disturbances. The splitting-up of the system also enables the operators to build up their load very easily and safely after a total interruption.

Good judgment can be shown in the way the sections are laid out, having in mind the possibility of giving a service during a partial interruption or power shortage by having strategic intersections on tie feeders or on substations feeding downtown areas. In this way, if there is power downtown the cars can be run out for some distance and there will be turn-back points which will be alive.

It will be seen from the layout of the direct current feeders for Harrison Substation area, as shown in figure No. 2, that the outlying sections are all tie feeders. In this way, if any power is available, the downtown substation can be cut in and as good a service as possible operated out to turning-back points on the tie feeders, power can then be taken off the tie feeders at the dead substation end and fed out again on feeders which feed adjacent sections to the ties, and a skeleton service given to farther out points. These tie feeders have pilot lights on each end so that the operators can tell when other substations are alive.

All feeders are numbered. The numbering of the simple feeders shows the source of power; for instance, feeder 312 is number 12 feeder fed from number 3 substation. The numbers on the tie feeders are compound, and show which substations are tied; for instance, 116-616-316 indicates that substations 1, 6 and 3 are tied on number 16 feeder.

The negative feeder system, as shown in figure No. 3, is somewhat different, and serves a different purpose, as the whole of the negative network is tied together solidly. If there were only one large feeder run out from the negative bus there would be a very large concentration of current in the track return at this point, so feeders are fanned out so as to collect the current at different points, thus preventing excess flow of current in any track. At times it may be necessary to introduce resistances in the shorter feeders to force the current to take some other provided path home.

The point where the real trouble of the operating engineer begins is now reached. Figure No. 4 shows the 24-hour loads on the various substations, and the following considerations should be kept in mind:—

The Hydro-Electric Power Commission of Ontario has set a rate for the Toronto Hydro-Electric System to charge the Toronto Transportation Commission of $15 per horse power year for each highest monthly 10-minute peak demand

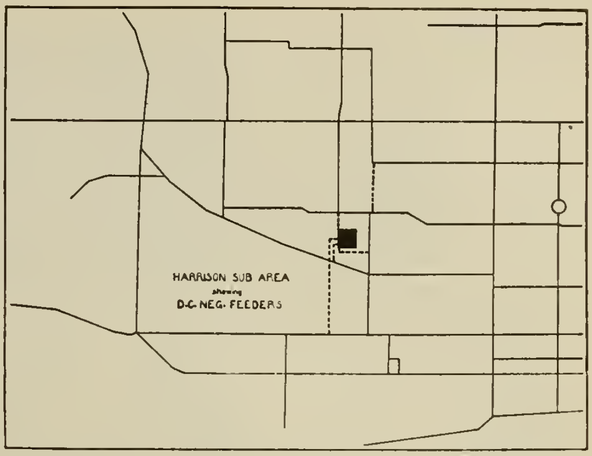

Figure No. 2.—Layout of Direct Current Feeders for Harrison Station.

metered at each Toronto Hydro-Electric substation, plus 0.9 cent per kilowatt hour consumption. This means that the loads on Duncan, Junction, High Level and Danforth substations are each separate individual sources of billing. These substations, of course, are owned and operated by the Toronto Hydro-Electric System. For Front street, Yonge, Harrison and Russell substations, which are owned and operated by the Toronto Transportation Commission, the rate set for the Toronto Hydro-Electric System to charge is $24 per horse power year for the highest 20-minute coincident peak each month.

The job before the electrical department of the Toronto Transportation Commission is to supply power to run the street cars at the lowest possible cost per mile, and, in trying to do this, some extraordinary conditions are encountered.

Referring now to figure No. 4, showing the character-

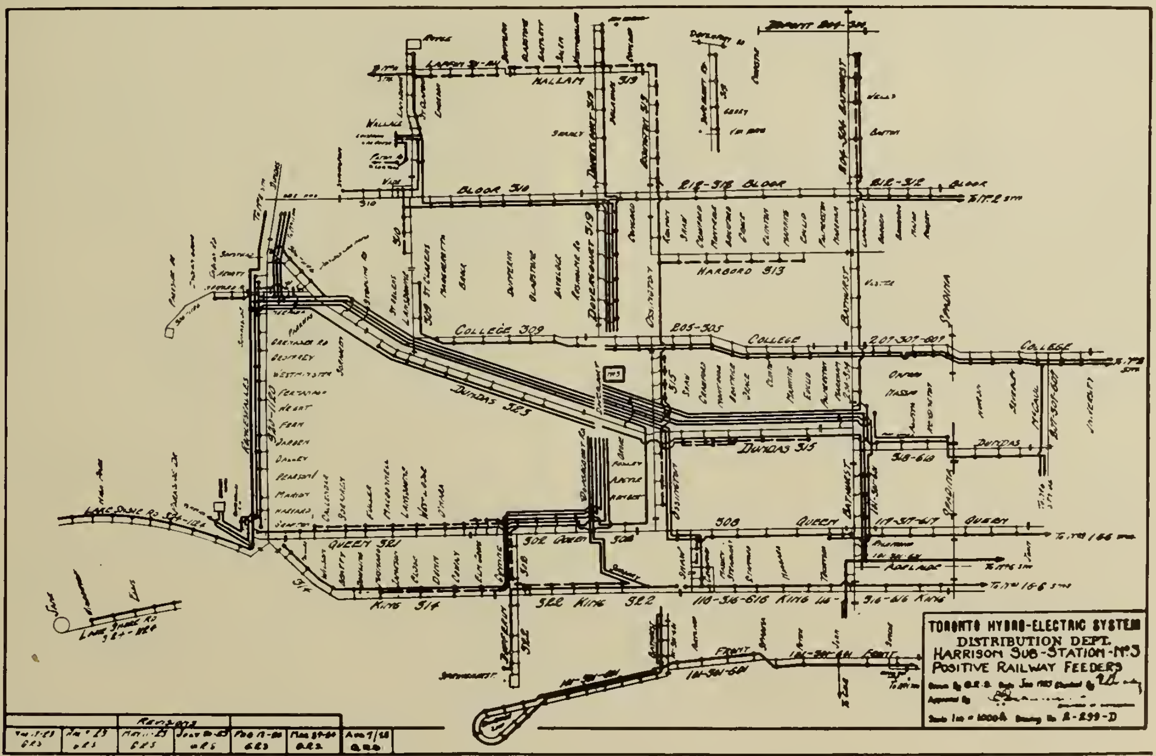

Figure No. 3.—Negative Feeder System, Harrison Station.

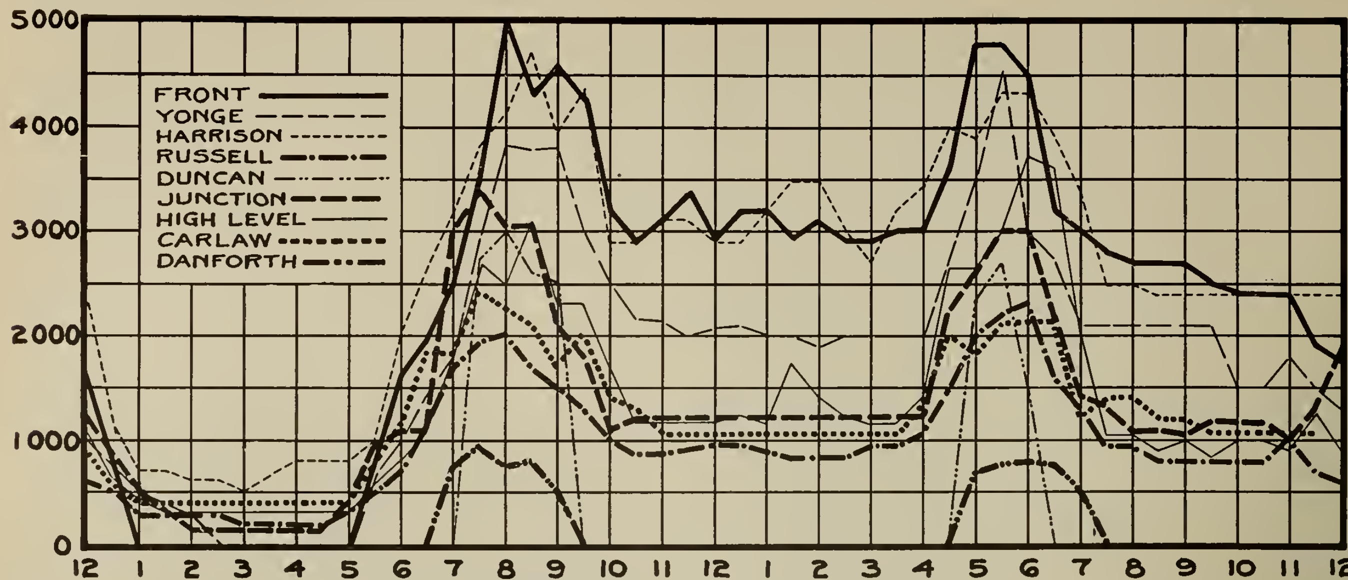

Figure No. 4.—Characteristic Loads for the Various Substations.

istic loads for the various substations, the prevailing low night valley will be noted, and in some instances the mid-day valley, but in practically every case we have sharp rising and falling peaks. You will also note there is very little time lag between the peaks.

Picture a long straight car route running across town, such as the Bloor route, passing through the areas of various substations. Suppose there is a traffic jam at the time of peak load caused by a fire in the west end. What happens? The peak goes up on Junction; the jam travels across town, then the peak goes up on Carlaw and on Danforth, and if it just so happens that it is passing through the centre of the city about 5.20 p.m. to 5.30 p.m., up goes the coincident peak on the centre group. Thus, while perfectly innocent in the matter, it is quite possible for the Toronto Transportation Commission to have to pay four times for one traffic jam, and the electrical department has to account for the increased cost of power.

It also sometimes happens, in the case of the coincident peak on the centre group of substations, that some peculiar traffic condition will advance or retard an individual peak by ten or fifteen minutes, thus eliminating the diversity between the various sections, and up goes the coincident peak. At $2 per horse power per month, plus additional charges, you can see that a changing condition can easily shoot up the bill by $1,000 to $1,500 for the month. The writer has known such a condition to mean over $4,000 in a month.

Certain other causes of an increase in load are shown on the curves of figure No. 5, which are the average of some five years' observation, and generally hold good for any property operating cars of approximately 26 tons.

The increase in load due to the greater traffic density, i.e., number of passengers per car mile, is simply a matter of having to move a heavier mass. An increase in schedule speed may also have a tendency to increase the peak unless the motormen are trained to coast their cars where possible. In both these points, it is practically a question of mass times velocity.

In the matter of the increase in power due to the lower average monthly temperature, there are several factors; one of the principal ones appears to be an increase in the friction at the gauge line, due to frozen particles causing a grinding action. This seems to be proven by what is noticed on a very dry day in summer when a sudden shower comes down, washing the rail, and a drop in load of sometimes as high as 15 per cent has been noticed.

In these days of heavy automobile traffic, the number of stops per mile has a very important bearing on the increased peaks that are carried, as every time a motorman has to stop and start his car there is a direct effect on the power demand, and, if he is not stopping for revenue passengers, there is a direct loss. It does not require any great imagination to see how the loads have been creeping up from the above-named causes.

It is in such cases that our tie feeders prove their value, as, by means of a variation on bus voltage, such conditions can be balanced in some measure.

Let us now consider this question from an entirely dif-

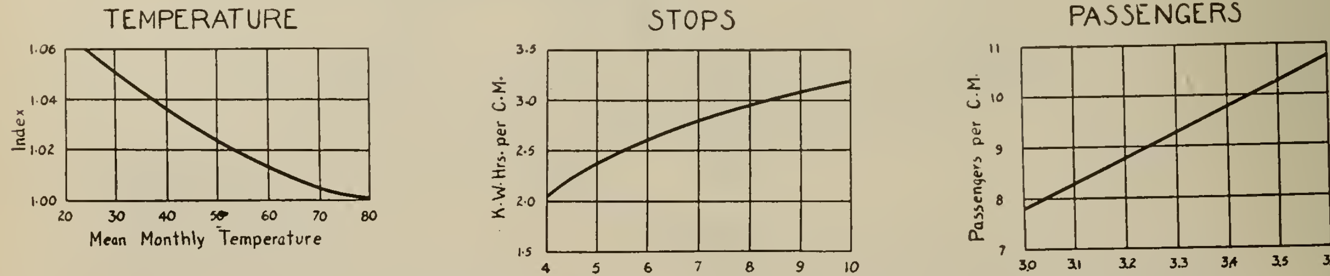

Figure No. 5.—Curves Showing Causes of Increase in Load.

ferent angle. Look at the characteristic totalized system load curve shown in figure No. 6, made up of the various substation loads as shown in figure No. 4. This represents the 24-hour day's work the plant has done. Note the long low valley at night, from the downward slide after 5.30 p.m., which falls sharply to 7.30 p.m., then more slowly until the theatre load is taken home at 11.00 p.m. After midnight the slump is rapid again until 1.00 a.m., then a sweeping dip, which rises to 5 a.m., and so on the whole story of the city's activities are clearly shown. Very pretty, indeed, but let us do some philosophising. Wellington, in his book "The Economic Theory of Railway Location," says this:—"It would be well if engineering were less generally thought of, or even defined, as the art of constructing. In a certain important sense it is the art of not constructing, or, to define it rudely but not inaptly, it is the art of doing that well with one dollar which any bungler can do with two after a fashion."

This definition of engineering is peculiarly applicable to power plant engineering for an electric railway system, where conditions are such that it is very easy for a man to sell himself the idea that he should carry an ample margin of capacity when a cold-blooded analysis of facts will cast doubt on the necessity or advisability of this. The tendency is to think too much in terms of peak loads, looking to installing such additional capacity of machines as to secure oneself against the day of the storm peak. This would be fine if we did not have such pessimistic people as comptrollers, who, immediately you purchase a piece of apparatus or install a new substation, take all the joy out of life by telling you that in twenty years it will all be junk and only fit for the scrap pile, and that you must proceed forthwith to pay so much per annum for the rest of its natural life for amortization, depreciation, etc.

The whole square of the utilization chart (figure No. 7)

Figure No. 6.—Characteristic Totalized System Load Curve.

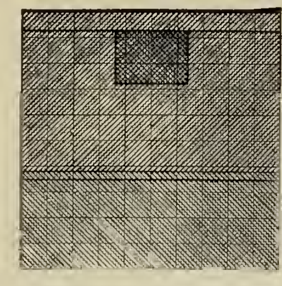

Figure No. 7.—Utilization Chart Showing Total Capital Charges on Plant for one Week-Day.

represents the total capital charges on the plant for one week-day. The block below the lines marked "base schedule demand" represents the utilization of plant actually used to operate your cars if there were no peak loads; over and above this there has to be some margin, so, based on experience, the writer has allowed up to the line marked "base schedule capacity." When you superimpose peaks, you must raise the ante up to your peak load demand, then on top of that put your peak load capacity margin, and, having done this, gaze on the little cross-hatched square in the centre, for that is all the use you get of your plant over your "base capacity." We purchase machines with a 150-per cent two-hour rating; why not take advantage of the excellence of the manufacturers' production, particularly when you have paid for it?

The more the utilization of plant on a street railway property is studied, the more is it apparent that Wellington expressed sound engineering philosophy for the street railway man to ponder over.

Trolley Wire

Let us now turn away with a sigh of relief from the very necessary self-suppression dictated by sheer economic necessity to a field where the same economic necessity compels the fullest factor of safety, the trolley wire. No one factor can cause a more widespread disturbance to traffic than a broken trolley wire, unless it be a power interruption, and these two brothers in iniquity are often closely associated.

The trolley wire used in Toronto is of round section, .365 inches in diameter, and is of two classes. One class is hard-drawn copper having a tensile strength of some 55,000 pounds per square inch, the other is an alloyed wire having a tensile strength of 70,000 pounds per square inch.

The city is divided into five sections for inspection purposes, with a foreman in charge who is responsible for the inspection and alignment of the wires and for making all the necessary repairs on the 40 odd miles in his district. The inspections are carried out systematically, and a progress report sent to the general manager each week. We find this regular re-alignment of the wire one of the greatest factors in saving wear, as it takes but very little off centre to cause a wire and the ears to wear very rapidly.

A daily report is sent in by each foreman, listing any renewals made; these are entered up in a record book, so that any cases of frogs, crossovers or curve wires which are having to be renewed too frequently stand out. The locations are then specially gone over to find out the reason for the excessive wear at that particular point. In this way, we have a continuous check on the whole of the overhead system.

At the present time, trolley wire is being renewed on a 7.5 per cent annual replacement. In order to eliminate any trouble due to excessive frost strains, we renew the worn

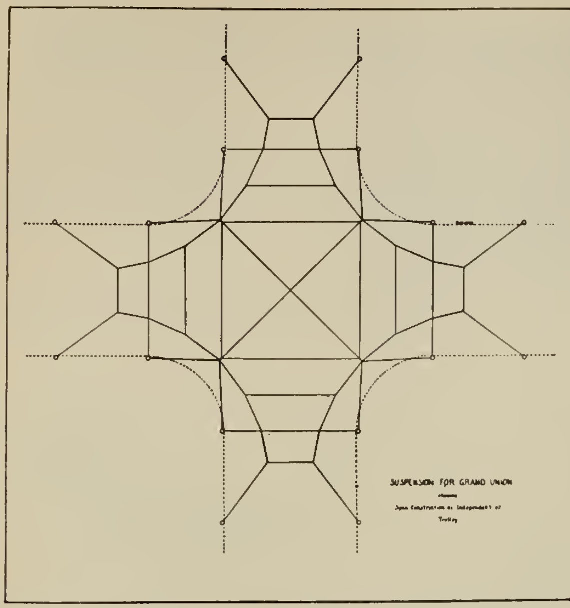

Figure No. 8.—Suspension for Grand Union showing Span Construction as Independent of Trolley.

wire during the winter time, taking care to leave the reels outside long enough to reach maximum contraction before stringing. We then pull the wire up as tightly as possible, leaving the sag in summer to take care of itself. The temperature in Toronto ranges from a probable 25 degrees below zero to a probable 100 degrees above zero.

Speaking of trolley wires, an interesting controversy is now going on between the trolley wire users and some of the United States manufacturers over the relative value of a " twist test " in trolley wire specifications. The trolley wire users claim to have found out by experience that a wire with a high twist test will wear longer than a wire with a low twist test, while the manufacturer contends that the twist test cannot altogether be controlled, and that as a general proposition it has no bearing on the wearing qualities of the wire.

The twist test is made by clamping a ten-inch piece of wire and twisting it not faster than 10 turns per minute. The American Electric Railway Engineering Association claims that a .365 hard-drawn trolley wire should stand 20 twists, while the American Society for Testing Materials will not concede more than 10 twists. For the present, the American Electric Railway Engineering Association are accepting the 10-twist test for the sake of a uniform specification, but a series of very elaborate tests are under way under actual service conditions in some of the large cities of the United States to determine this very interesting point. My experience in Toronto leads me to the opinion that the wear will vary almost directly with the number of twists the wire will stand, if the wire is otherwise apparently the same.

Intersection Suspension

After years of experimenting and experience in various methods of intersection suspension, we determined that the curve formation should be independent of the trolley wire itself, so that if a trolley wire should break there would be no sag in the structure to obstruct traffic.

The suspension is erected first, and, as will be seen from figure No. 8, the network of spans is self-contained. It is strong and easily erected, as it is based on straight lines; further, when the curve offset line is located it is not lost, as the backbone construction holds the pullovers in place, allowing a curve wire to be renewed without losing the alignment.

Along with this, we erect a device for permanently keeping the frog locations. This device is a clamp which is suspended on a cross-span and holds the trolley tangent wire and curve wire in place. The frog pan is then placed up against the clamp and fastened to the wire by the frog approaches. This device permits changing a frog pan in less than two minutes, which is a very valuable consideration. After the suspension is erected the tangent trolley wires are run into place, and the bridle wires pulled up, then the curves are put in.

This standard type of construction is adapted for the other intersections with lesser number of curves. Of course, it must be understood also that there are times when poles cannot be erected within a few feet of the desired locations, in which case the construction is varied to suit.

Overhead Emergency Calls

On any overhead system, the number of emergency calls per month for overhead troubles, compared to previous months, may be taken as a very fair indication of the condition of the system. Every emergency call is a potential source of traffic delay, and there are enough of such delays due to foreign causes without any internal department contributing to worries of the traffic men, consequently any reduction in the number of emergency calls must result in an improvement in the maintenance of the traffic schedule.

The effect of the system of inspection and the following-up of the records have had the result shown in figure No. 9. The rise in maintenance cost up to 1923 was caused by the increasing heavy maintenance which occurred on the lines purchased from the Toronto Railway Company. These lines could possibly have been rehabilitated as a capital charge, but the advisability of this was open to question, so the work was done on maintenance, and consequently we are now reaping the benefit in a falling average monthly cost. The 1926 cost will no doubt fall in about the same proportion as 1925.

By analyzing the number of emergency calls per year with reference to the hours of call over a period of years, some very interesting comparisons are obtained. Such an analysis is shown in figure No. 10. The great number of calls between 8 a.m. and 10 a.m. in 1923 were principally

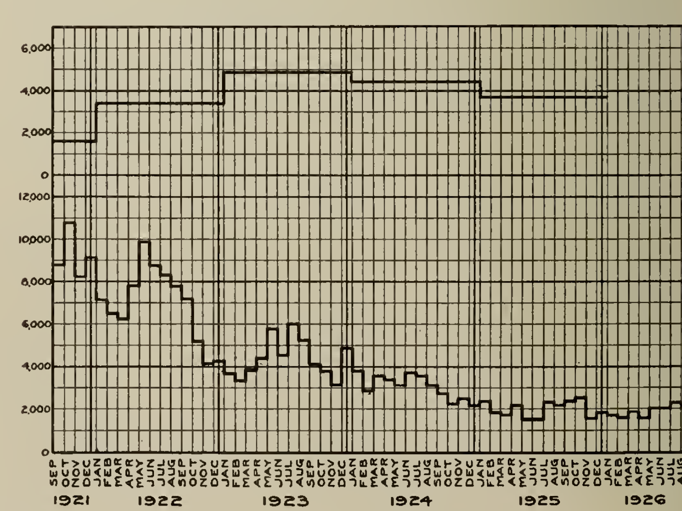

Figure No. 9.—Chart showing Average Monthly Cost per Year of Trolley Maintenance and Emergency Calls.

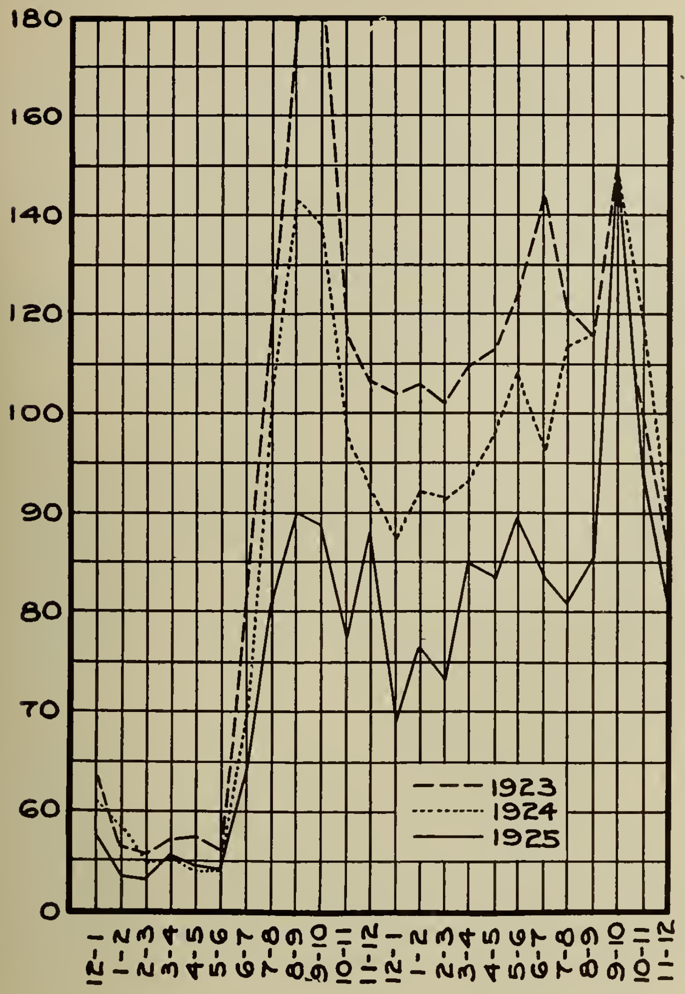

Figure No. 10.—Analysis of Number of Emergency Calls per Year.

due to broken spans and generally distorted intersections, due to high night car speeds, together with the fact that the morning inspectors were usually occupied with getting the cars out for the morning peak and had no time to report troubles until later. A determined attack was made upon the weak spots which caused these reports, with the result that by 1925 they were all well in hand. A peculiar fact appears to be that we cannot reduce the number of calls between 9 p.m. and 10 p.m., which have practically remained constant for the three years. This is partially explained by the fact that many of them are lights which are reported out, and are probably delayed until a slack time of the evening before reporting.

As an example of what constant attention to small things will do, we may take the matter of following-up broken trolley wires to determine the cause and to eliminate it. The fractured ends of all broken trolley wires must be sent to the head office, accompanied by a form giving details of the location, etc., of the break. If the circumstances do not appear to give the reason for the broken wire, an enlarged photograph of 20 times the diameter is made and studied. Such a photograph may show, for instance, the effect of a slight burn on top of the wire, setting up crystallization which finally caused a break. Many cases of crystallization may be traced to hard spots in the suspension, due to tight spans, or again it may be due to the shape of the trolley ear causing the wheel to pound the wire. This usually causes a wire to break about one to two inches in from the outer ends of the ear.

Electric Switches

Another interesting feature of the electrical department's work is the installation and maintenance of electric switches; a cut of a simplified circuit of which is shown in figure No. 11. The principle of operation is that the current limited by the resistance coil passes through the series, and operates the point for the straight, as soon as the trolley wheel bridges over from " B " to " C." If the motorman wishes to set the point for the curve, he puts his controller on the second or third notch and draws enough current to raise the plunger in the " circuit changer coil " from the straight track contact to the curve contact, with the result that the current flows through the other magnet in the track box and throws the point for the curve.

As the pull in the track box is a matter of some 400 pounds, some trouble has been experienced with the breaking of the connecting rod between the plunger and the point. This has been partially solved by the introduction of a damping spring. Investigations are still in progress, and we are looking to obtain a probable complete elimination of this trouble. We find the electric switch, when carefully maintained, a very efficient piece of apparatus, as our last twelve months' experience has shown approximately 81,500 operations for every trouble call. The actual economic value of the electric switch is very high with one-man-car operation, but they must be maintained, as one failure with a one-man-car operator during a peak load rush will probably cost more than a month's maintenance.

In 1885, what is claimed to be the first under-running trolley cars in the world was operated regularly between Strachan avenue and the Exhibition grounds, and after the passing of forty odd years, since that time, we are still searching after the factors which enter into the life of the trolley wire, and so it is in other phases of our work. To-day is witnessing one of those periods in the evolution of things where progress seems to leap ahead and development is very rapid. Traffic congestion such as was never known before is with us. Competition is keen, and all transportation systems are being tried in the economic balance, but the writer has no hesitation in saying that, with sound management and sane engineering, the trolley car will hold its own in the mass transportation field for many years to come.

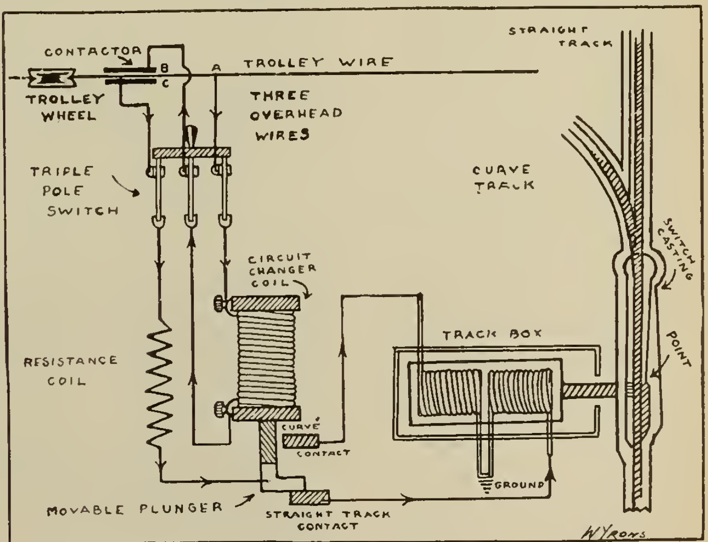

Figure No. 11.—Simplified Circuit of an Electric Switch.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME IX DECEMBER 1926 No. 12

The Work of the Committee on Biographies

In view of the desirability of preserving some record, however brief, of the life and work of prominent Canadian Engineers, who are no longer with us, Council appointed the Committee on Biographies in 1922, under the Chairmanship of Professor P. Gillespie. As a result of that Committee's work, a number of sketches have been prepared which, for the first time, make such biographies available to members of the Engineering Institute of Canada.

They are prepared in each case by members having knowledge of the people of whom they write, and, as might be expected, vary greatly in length and method of treatment. Most of them, however, will be found to throw an interesting side light on the many difficulties encountered in carrying out engineering work in the old days.

It is intended to publish these papers from time to time in the columns of the Journal, and in the present issue will be found the first of the series, the life of Mr. Walter Shanly.

Meeting of Council

Meeting of November 16th, 1926

A meeting of Council was held at eight p.m. on Tuesday, November the 16th, 1926, Councillor J. H. Hunter in the Chair and four other members of Council being present.

The report of the Finance Committee with the financial statement to October 31st was approved, and a number of cases involving special consideration were dealt with.

The Secretary reported that in accordance with the directions of Council at the October meeting, the following letters had been forwarded to the Prime Minister and members of the Cabinet:—

October 22nd, 1926.

The Right Honourable W. L. Mackenzie King, C.M.G.,
Parliament Buildings,
Ottawa, Ont.

Sir:—

The Council of the Engineering Institute of Canada, as a result of suggestions received from a number of members of the Institute, has had under consideration statements which have recently appeared to the effect that the completion of the Hudson's Bay Railway, with harbour and other constructional works connected with it, is to be proceeded with at no distant date by the Dominion Government.

I have been directed to transmit to you, and to the members of the Cabinet, a copy of the resolution passed by my Council in June, 1924, and forwarded at that time to the Dominion Government, which reads as follows:

> "Resolved, that the Council of The Engineering Institute of Canada place itself on record in affirming that the proposed Hudson's Bay Railway be thoroughly investigated from the engineering, eonomic and national viewpoints, before any decision is made to construct, complete or operate the said railway."

It is believed that the above resolution embodies the considered opinion of the Engineering Profession in Canada.

In bringing the matter again to your notice, my Council is influenced by the fact that a number of important portfolios in the Dominion Government are now held by ministers who were not in office in 1924, and it is hoped that your new Government will accord favourable consideration to the suggestion now put forward.

I have the honour to be, Sir,
Your obedient servant,
R. J. DURLEY, Secretary.

October 23rd, 1926.

The Right Honourable W. L. Mackenzie King, C.M.G.,
Parliament Buildings,
Ottawa, Ont.

Sir:—

The attention of the Council of The Engineering Institute of Canada has been drawn from time to time to cases in which the design of important engineering works in Canada has been entrusted to engineers other than Canadians, and at the last Council meeting I was directed to bring this matter to your notice, and to say that in the case of public works in which the Dominion Government is interested, my Council would respectfully suggest that these be designed as well as executed by Canadian engineers.

It is felt that the necessity for the employment of foreign engineers in such cases no longer exists, since Canadians who have been responsible for the design and construction of important works in all principal branches of engineering are available for consultation and employment.

I have the honour to be, Sir,
Your obedient servant,
R. J. DURLEY, Secretary.

It was stated that these letters had been duly acknowledged, and in several cases Ministers had been good enough to express appreciation of the communications.

The views of all members of Council having been ascertained by correspondence with reference to the suggested removal of the age limit of thirty-three years for the class of Junior, it was reported that a considerable majority expressed the opinion that no change should be made in the present By-law, while a number of suggestions were made, including one that the By-law should be amended so as to empower Council to waive the limit in special cases. After discussion it was thought advisable to take no action in this matter at the present time.

The Secretary having reported that difficulty and delay had been experienced in completing the organization of the St. Maurice Valley Branch, Council approved the suggestion that a meeting of the members of this Branch should be called at an early date for the purpose of discussing the situation.

A report was submitted from Mr. A. G. Tapley and Dean H. M. MacKay, who attended the Annual Meeting of the Canadian Board of Trade at St. John, N.B., as representatives of The Engineering Institute of Canada. The Secretary was directed to draw the attention of the Executive Committees of the various branches of The Institute to the desirability of co-operation with local Boards of Trade in regard to matters involving engineering or technical considerations.

The design and inscription for the proposed tablet to be erected on the Fraser Canyon Highway by The Engineering Institute of Canada and the Association of Professional Engineers of British Columbia was submitted and approved; the inscription reading as follows:—"In commemoration of the engineering achievement of the two companies of Her Majesty's Royal Engineers who, in 1868, were responsible for the construction of the Cariboo Road. This tablet is erected by The Engineering Institute of Canada and the Association of Professional Engineers of British Columbia."

Action was taken in the cases of a number of Students from whom no communications have been received and who are over-age for the Student grade. Their names were removed from the membership list.

The following elections and transfers were effected:—

Elections	
Associate Members	1
Juniors	1
Affiliates	3
Students	23
Transfers	
Associate Member to Member	4
Student to Associate Member	2
Student to Junior	7

Fourteen applications for admission and transfer were scrutinized and classified for the ballot returnable December 14th, 1926.

Six special cases were considered in connection with applications for admission.

The Council rose at eleven-fifteen p.m.

Canadian War Memorials

In all periods of history, the natural impulse to commemorate warlike achievements and to honour those who sacrificed their lives in action has led to the erection of War or Battle Memorials. Some of these fitly enshrine the names of men from a particular locality or society, as in the case of The Institute's war memorial. Others are of larger outlook, national in their scope, like the series of Canadian war memorials now under construction in France and Belgium. These are not only landmarks, but records in enduring stone of the prowess of Canadian troops on important battlefields.

It seems fitting, on the eighth anniversary of Armistice Day, to give to the members of The Institute some account of what has been accomplished by the Canadian Battlefields' Memorial Commission to mark the scenes of the heroic encounters of 1915-1918. The scheme which the Commission is carrying out provides for a few important monuments rather than a number of minor ones, aims at the avoidance of triviality in design, and recalls the most striking episodes in which Canadians were engaged during the four years' conflict in the three-hundred-mile zone of desolation.

Saint Julien Memorial.

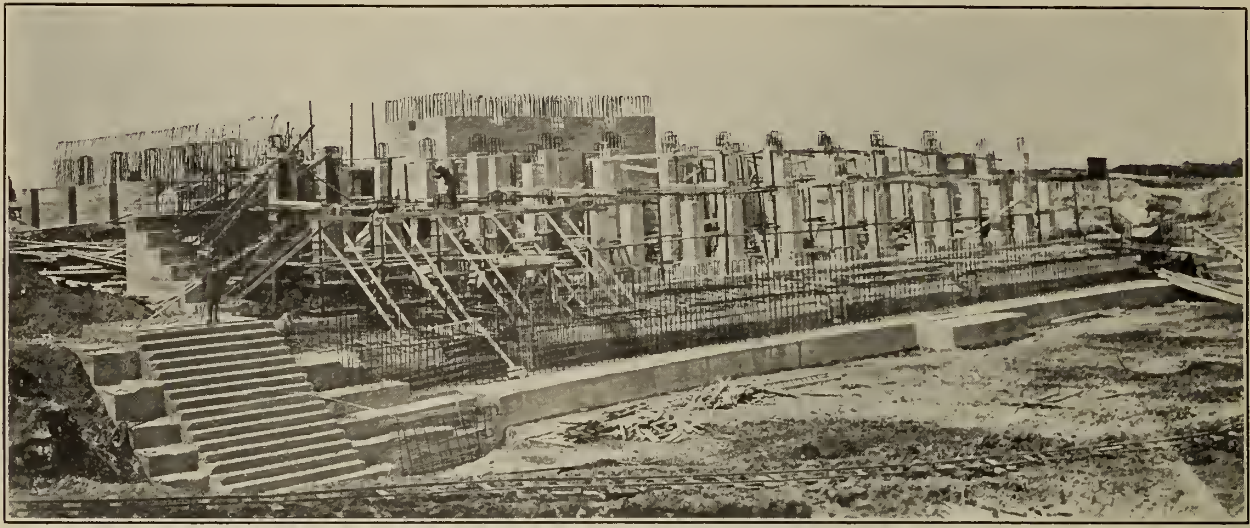
The general question of Allied War Memorials was first considered by a Battle Exploits Memorials Commission formed in February 1919, on which one of our own members, Brigadier-General H. T. Hughes, C.M.G., D.S.O., was appointed the Canadian representative. General Hughes subsequently proceeded to France and Belgium to secure eight sites which had previously been recommended at a meeting of senior Canadian officers. The necessary funds were appropriated by Parliament, and on September 2nd, 1920, the Canadian Battlefields Memorial Commission was appointed, by Order-in-Council, for the purpose of organizing and carrying out the work. This Commission has the following membership:—

- Major-General the Hon. S. C. Mewburn, C.M.G., K.C., M.P.;
- The Hon. Rodolphe Lemieux, K.C., M.P., (now chairman);
- Lt.-General Sir R. E. W. Turner, V.C., K.C.B.;
- Lt.-Colonel R. W. Leonard;
- The Hon. J. G. Turriff.

Colonel H. C. Osborne, C.M.G., is the Honorary Secretary; Professor P. E. Nobbs, R.C.A., is the Architectural Adviser, and Brigadier-General H. T. Hughes, A.M.E.I.C., who has been connected with the movement from its very inception, is the Chief Engineer of the organization in France, which comprises Lieut.-Col.-Ross, D.S.O., in charge of Landscape work, and Captain Simpson as Assistant Engineer.

The sites selected and the events commemorated are as follows:—

1. Saint Nazaire, land-

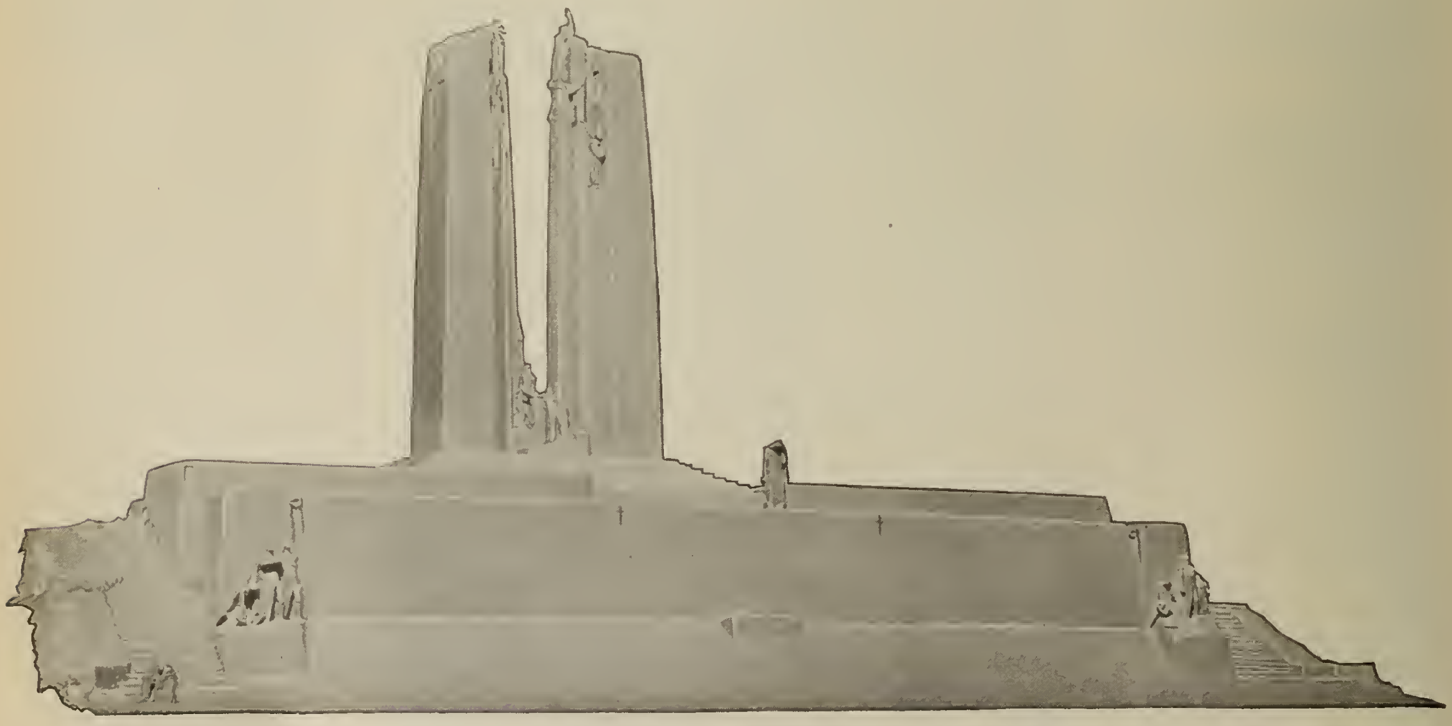


Sub-structure for Vimy Memorial.

ing of the First Canadian Division, February 12th, 1915.
2. Saint Julien, action of April 22nd-24th, 1915, when the Canadians on the British left withstood the first German gas attacks.
3. Hill 62—Battle of Mount Sorrel; Battle of Sanctuary Wood; April-August 1916.
4. Courcelette—Battles of the Somme, September-November 1916.
5. Vimy Ridge—April-May 1917.
6. Passchendaele—October-November 1917.
7. Le Quesnel—Eight-mile advance of the Canadian Corps. August 8th, 1918.
8. Dury—Battle of Arras, August 1918—breaking of the Queant-Drocourt switch of the Hindenburg line.
9. Bourlon Wood—forcing of the Canal du Nord, September 1918.
10. Mons—entry into this city of Canadian Troops on the last day of the War.

The memorial at St. Nazaire takes the form of a bronze tablet, designed by General Hughes, placed in the Town Hall, and bearing the following inscription:—

"Ici, le 12 fevrier, 1915, debarquèrent dix-huit mille soldats Canadiens, avant-garde d'une armée de trois cent trente-huit mille hommes; cette armée com-



Model of Vimy Memorial.

battit les Allemands pendant quatre ans; livra vingt-six batailles, et avec les Alliés victorieux marcha sur le Rhin."

"Here landed the First Canadian Division, eighteen thousand strong, on the 12th February, 1915. Three hundred and twenty thousand followed; throughout four years the Canadians fought the Germans; after engaging in twenty-six battles they marched in victory to the Rhine."

The inscription on the Mons tablet is as follows:—

"Mons was recaptured by the Canadian Corps on 11th November 1918; after fifty months of German occupation, freedom was restored to the city: Here was fired the last shot of the Great War."

The sites for the memorials at St. Julien, Sanctuary Wood and Passchendaele were given by the Belgian Government. The Bourlon Wood site was given by Comte de Francqueville, and later the Vimy site, two hundred and fifty acres in extent, was presented by the French Government. The three remaining sites were purchased.

Immediately after its formation, the Canadian Battlefields Memorials Commission organized a competition for designs, to be judged by three architectural assessors, from Canada, France and England respectively, and the successful designs were finally chosen from those submitted by over 160 competitors. The principal award was made in favour of Mr. W. S. Allward, R.C.A., of Toronto, whose design was recommended for erection at Vimy Ridge, while that of Mr. F. C. Clemesha, of Regina, was adopted for the Saint Julien site. There is considerable similarity of spirit and feeling between these two designs. They are, in fact, of the same school of thought, and have a distinctive character of their own; something romantic, imaginative, and unconventional.

The Vimy monument, when completed, will commemorate not only the taking of the Ridge and other engagements generally described as the Battle of Arras, but also the whole achievement of the Canadian troops in France during the Great War. It is situated on Hill 145—the King's Observation Post. From this point an extensive view is had over a wide valley towards Lens, Mericourt and, in the far distance, Douai.

In looking at a work of art, the observer often supplies his own symbolism. Mr. Allward's idea at the time his design was accepted is contained in the following paragraph:—

> At the base of the strong impregnable walls of defence are the Defenders, one group showing the breaking of the sword, the other the Sympathy of the Canadians for the Helpless. Above these are the mouths of guns covered with olive and laurels. On the wall stands an heroic figure of Canada brooding over the graves of her valiant dead; below is suggested a grave with a helmet, laurels, etc. Behind her stand two pylons symbolizing the two forces—Canadian and French—while between, at the base of these, is the Spirit of Sacrifice, who, giving all, throws the torch to his comrade. Looking up they see the figures of Peace, Justice, Truth and Knowledge, etc., for which they fought, chanting the hymn of Peace. Around these figures are the shields of Britain, Canada and France. On the outside of the pylons is the Cross.

In the case of the Saint Julien Memorial, which was unveiled by the Duke of Connaught on July 8th, 1923, the head and shoulders of a Canadian soldier surmount a great grey column. The hands are folded on a reversed rifle; the figure watches over those who sleep beneath. There is great power in this impressive monument.

BRIG.-GEN. H. T. HUGHES, C.M.G., D.S.O.

For the six sites other than Vimy and Saint Julien, one design has been used, a simple fifteen-ton block of Canadian granite from Stanstead being placed in the centre of the plot. The general scheme for these memorials shows a flight of terraced steps leading up to a stone platform in a small park with shrubs and flowers. At the present time, all the sites are complete, the sub-structure for the Vimy monument has been finished, the Saint Julien monument has been completed and dedicated, and the grading and landscape work on all the sites has been carried out.

The memorial parks and monuments in France and Belgium will be visited annually by an increasing number of pilgrims from this side of the Atlantic. No one who saw the war zone, even a year or two after the Armistice, can fail to recognize the magnitude of the task, and the difficulties which confronted the Commission, or to appreciate the imagination involved in the shaping of these parks from the torn and devastated fields.

Remember—

The FORTY-FIRST ANNUAL GENERAL *and* GENERAL PROFESSIONAL MEETING

Will be held at QUEBEC CITY

TUESDAY, WEDNESDAY *and* THURSDAY, FEBRUARY 15TH, 16TH *and* 17TH, 1927

Walter Shanly — A Biography

By M. J. Butler, M.E.I.C., and *J. S. Dennis, M.E.I.C.*

Walter Shanly was born at the Abbey, Stradbally, Queens County, Ireland, on the 11th of October 1817. He was the fifth son of the late James Shanly, Esq., a member of the Irish Bar, of the Abbey, Queens County, and Normans Grove, County Meath, Ireland, who came to Canada and settled at Thorndale, Middlesex County, Ontario, in the year 1836.

Walter Shanly was given his early education by private tuition. While living at Thorndale with his father, he was fortunate in becoming acquainted with the late Hamilton H. Killaly, who owned property in the neighbourhood. Shortly afterward Mr. Killaly was appointed to the position of Commissioner of Public Works for the recently united provinces of Upper and Lower Canada, and through him Mr. Shanly obtained an appointment in the Department. In the fall of 1840 he came to Montreal and was put in charge of the construction of a section of the turnpike roads on the island of Montreal. Subsequently, he was employed on the St. Ours lock on the Richelieu River canal and for a short time on the Cornwall canal, under the late Samuel Keefer. He was later transferred to the Beauharnois canal as resident engineer, where he remained until the completion of the work. From there he was moved to the Welland canal, where he held the position of assistant engineer and afterwards of chief engineer.

WALTER SHANLY

The railway era was just opening up about 1850, and Mr. Shanly felt that it was important to learn the work. He resigned from his position on the Welland canal and secured an appointment as resident engineer on the Ogdensburg and Lake Champlain Railway, (then known as the Northern New York Railway), and had charge of the work from Ogdensburg to Malone. On the completion of the railway, he returned to Canada and took charge, as chief engineer, of the Bytown and Prescott Railway, (now the Prescott branch of the Canadian Pacific Railway). On its completion, he removed to Toronto and was appointed chief engineer of the Toronto and Guelph Railway, which was soon merged into the Grand Trunk Railway, and, so known, was built under his supervision from Toronto to Sarnia. On the completion of this work, and the opening of the line from Sarnia to Montreal, he was appointed chief engineer and manager of the company. It may be said that Mr. Shanly was one of the moving spirits in the organization of the Grand Trunk Railway and of the building of the Victoria bridge across the St. Lawrence river at Montreal. He acted as general manager of the Grand Trunk Railway of Canada from 1858 to 1862.

In 1857, Mr. Shanly, at the request of the government, made an exploration of and reported upon the Georgian Bay canal, via the Ottawa and French rivers, a project that has been more or less in the public mind from that day to this. He ever afterwards took a great deal of interest in the scheme, was a firm believer in it and felt that a day would arrive when it would be an accomplished fact. In 1868, Mr. Shanly, having reached his fifty-first year, ripe in experience as an engineer on canal work, railway work and in management of the greatest railway then in Canada, and having had, as a Member of Parliament, another kind of training, decided, in partnership with his brother, the late Frank Shanly of Toronto, to enter the contracting field. At that date, and for some considerable time previously, there was under construction the largest and most difficult work on this continent. This was the Hoosac tunnel, a short history of which will, it is hoped, be found of interest, and with the successful completion of which the names of Walter and Frank Shanly are associated.

The building of a tunnel through Hoosac mountain, in the north-westerly corner or Massachusetts, was first suggested for canal purposes before the days of railroads.

In 1825, the state of Massachusetts appointed a board of commissioners to consider the practicability of building a canal from Boston to the Hudson river, its western terminus to be at the point where the then Great Erie canal, —the pride of the time,—emptied its waters into the river.

The commissioners recommended a route for the canal by way of the Deerfield and Hoosac rivers, piercing Hoosac mountain by a tunnel. Just as the commissioners' report began to be discussed, however, railroads began to be heard of, public attention was focused on rail transportation, and the labour and arguments of the canal commission were soon forgotten. The first railroad across Massachusetts through to the Hudson river was that now known as the Boston and Albany, which is leased to the New York Central, running from Boston, by way of Worcester, Springfield and Pittsfield, to Albany. A little later an east and west railroad across Massachusetts was begun following substantially the line of the proposed canal from Boston to the Hudson river.

Only six years after the Boston and Albany Railroad was completed, the farmers of Massachusetts began to denounce that road as a "grinding monopoly," and they sought the construction of another road through to the Hudson river.

Accordingly, the Troy and Greenfield Railroad was incorporated May 10th, 1848. To it was granted the right to build a railroad from near Greenfield, in the Connecticut valley, to the state line at Williamstown, there to connect with the railroad which would be built from Troy to that point. This project contemplated a tunnel through the Hoosac mountain, although the tunnel was not specifically mentioned in the charter.

The history of the Hoosac tunnel from the incorporation of the Troy and Greenfield Railroad in 1848 to July 1861 is that of a private enterprise backed by state aid. The location of the railway was not decided upon until 1850, and in the two years following the granting of the road's charter the enthusiasm of the people of the state for this new road as a competitor to the Boston and Albany

Railroad seems to have died out, and subscriptions to the capital stock of the Troy and Greenfield were very few.

The railway company met with great difficulty in securing funds. The first contract in 1855 was awarded to E. W. Sewell and Company, of Philadelphia, for the sum of $3,500,000, which sum was intended to cover the cost of building the tunnel through the Hoosac mountain, but was to build the entire road from Greenfield to the state line at Williamstown, a distance of approximately 45 miles. Some work was done under this contract, but a shortage of funds soon tied up the work. A second contract with the Sewell Company was made in January 1856, contingent upon the company securing additional funds to the extent of $100,000 by May 15th, 1856. This undertaking failed, and the Sewell contract was annulled.

The management of the railway, however, did not give up the contest. Shortly afterward the firm of Herman Haupt and Company, in July 1856, undertook for the sum of $3,800,000 to build the railway and the tunnel. Very little cash was provided, barely 10 per cent, the balance being in bonds of the state and in railroad securities. The firm actually started the construction of a small single-track tunnel at both the westerly and easterly sides of the mountain in 1856. Various difficulties arose, chiefly of finance, and the work dragged along slowly. In 1858 the old contract with Herman Haupt and Company was cancelled and a new one made, increasing the price for the road and tunnel to $4,000,000. Of this amount, $2,000,000 in state bonds were to be used exclusively for tunnelling. By August 1858, the Haupt concern had constructed 788 feet of tunnel at the easterly end and 240 feet at the westerly end. This, however, was a small bore, only large enough for a single track. Up to this time, all work had been done by hand drilling. A rock-cutting machine was then tried, but it proved to be a complete failure.

In 1859, the railroad again appeared before the legislature for a modification of the loan act of 1853, which was granted in a complicated act which made easy the terms of payment of the state's contribution and stipulated that the tunnel should be 14 feet wide and 18 feet high. Construction advanced very slowly, and in July 1861, the contractor having failed to do the prescribed amount of work on the tunnel, the state refused to make payments and the Troy and Greenfield Railroad gave up the project altogether.

From 1862 to 1868 the Hoosac tunnel project was carried on under state management, the work being done directly by a state commission.

In January 1863, the state commission on the tunnel, appointed under the Act of 1862, made a report to the legislature in which it recommended the building of a larger tunnel, 22 feet wide at grade line, 24 feet wide at its widest point and 21 feet in height, with a circular roof. The commission estimated the total cost at $5,179,330 and the time necessary for completion at 7½ years, provided the central shaft be constructed down from the top of the mountain, such that work could proceed simultaneously on four headings. The commission was unanimously of the opinion that the state should carry out the work alone.

When the state commission entered upon its work in 1863, it was found not only that little had been accomplished but that what had been done had been done wrong to a great extent. For example, the west shaft, which had pierced the mountain only a little way, was found to be 10 feet out of proper alignment. Work was begun by the state commission in December 1863 by the sinking of the central shaft, which it was hoped would be completed in time to be of much use in expediting the work of the tunnel as well as affording sufficient ventilation. Up to this time, all the actual work had been accomplished by hand power. The much-vaunted "boring machines" which were to run straight through the mountain had left their unpleasant memories behind them.

It was at this time, however, that the use of compressed air as a motive power was suggested. After much discussion, it was decided to dam the Deerfield river at a point about three-quarters of a mile from the eastern portal and to bring the water thence to the tunnel, the water power to be utilized in making compressed air. It was some time before this water power scheme was carried out. It was completed in 1866, and in June of that year rock drills operated by compressed air were first put to use in the easterly shaft of the tunnel. This marks the beginning of the use of the rock drill in tunnelling operations.

In this same year also, nitro-glycerine was first put to use in the westerly shaft. For the two succeeding years work on the tunnel appears to have been carried on under the state commission's direction, either by direct labour or by separate small contracts. In 1868, the legislature passed an act ending the work of tunnel construction by state commission and authorizing the making of a single contract to complete the entire tunnel, provided it could be done in 7 years at an expenditure of not more than $5,000,000. Of this sum, $250,000 was to be set aside for the payment of certain outstanding liabilities. Under the act, the contractor was to furnish satisfactory guarantees and at least $1,000,000 was to be held from the contract price until the enterprise was completed. The tunnel was to be built of sufficient size for two tracks, and one track was to be laid under the contract. When the bids were received by the Governor and Council in 1868 for the completion of the tunnel, it was found that twelve bids had been submitted, ranging in amount from $4,027,780 to $5,378,534.

Messrs. Walter and Francis Shanly, of Canada, made a bid at $4,623,069. Although this was next to the highest bid of those which came under consideration, the legislature had not required that the contract should be given to the lowest bidder, and in consideration of the deposit of public securities to the amount of $5,000,000 as a satisfactory guarantee, as well as in view of the long experience and excellent reputation of the firm, Governor Bullock gave the contract to the Messrs. Shanly, after long consultation with the Council. The contract was signed December 19th, 1868, and it provided that the tunnel should be completed March 1st, 1874. The work was carried on with the greatest possible energy and skill and to the satisfaction of all concerned.

The depth of the central shaft is 1,040 feet; the length from the shaft to the east portal is 12,837 feet, the length from the shaft to the western portal is 12,194 feet, making a total length of tunnel of 25,031 feet.

Mr. Shanly thereafter carried on a general practice as consulting engineer, and had for his clients both federal and provincial governments, the Grand Trunk Railway of Canada, the Canada Atlantic Railway and various other large corporations. His services were frequently sought as an arbitrator in disputes between companies, the government and contractors, and such was his reputation for honesty, ability and justice that his awards were seldom disputed by either party.

Mr. Shanly sat in the old Parliament of Canada from 1863 to the Union in 1867, and was the contemporary, colleague and friend of Sir John A. Macdonald, Sir George Cartier, Sir Alexander Galt and the Hon. T. D'Arcy McGee, and of the many other brilliant statesmen of the period.

When Confederation was accomplished, he sat in the House of Commons of Canada during the whole of the First Parliament of Canada, and subsequently during the greater portion of the Fifth and during the whole of the Sixth Parliament. A Conservative from conviction, he gave an unyielding support to Sir John A. Macdonald, both before and after the Union.

Mr. Shanly was a delegate to the Detroit Trade Convention, 1864, along with the late Hon. Joseph Howe, John Young and other representative men from the British Province. He was for some years president of the Mechanics' Bank. Mr. Shanly retired from public life at the General Election of 1891, and he died at Montreal on December 17th, 1899, and was buried at London, Ont.

OBITUARIES

John Rigney Barlow, M.E.I.C.

Sincere regret is expressed at the death of John Rigney Barlow, M.E.I.C., one of The Institute's oldest members, which occurred at his home in Montreal on October 29th, 1926.

The late Mr. Barlow had for many years been connected with the affairs of the city of Montreal in the capacity of city surveyor, which position he held until he retired in 1918. He was born at Stornoway, Isle of Lewis, Scotland, on July 29th, 1850, and came to Canada in 1855 with his father, who was for many years connected with the Geological Survey of Canada and was at one time with the Royal Engineers.

JOHN RIGNEY BARLOW, M.E.I.C.

Mr. Barlow received his education in this country and carried on his professional studies under his father. In 1872 he entered the Federal Government service on the staff of the Geological Survey of Canada, remaining on this work until 1875. He then spent one year on railway work in the United States, and upon his return to Canada joined the staff of the city of Montreal. He was for a short time chief assistant to Mr. J. A. W. Beaudry, on the construction of the St. Henry waterworks. In 1892 he received his appointment as deputy city surveyor, and in 1900 became city surveyor, retiring from active service eighteen years later.

The late Mr. Barlow joined The Institute in the days of the Canadian Society of Civil Engineers as Member on February 3rd, 1887, prior to its incorporation.

James Ewing, M.E.I.C.

James Ewing, M.E.I.C., president of the Town Planning Institute of Canada and senior member of the firm of Ewing and Tremblay, engineers, Montreal, died at his residence in Montreal on November 5th, 1926.

In the death of Mr. Ewing, the Town Planning movement in Canada has lost one of its strongest exponents.

JAMES EWING, M.E.I.C.

For some years past, Mr. Ewing had devoted his time and energy to the preparation of advocacy of a comprehensive plan for the development of the city and district of Montreal. Due to his splendid persistency by pen and voice, this movement has in recent months become a most active issue.

The late Mr. Ewing was born at Ardrossan, Scotland, on December 9th, 1859. He was educated at Greenock Academy and Greenock School of Science, passing the government examinations in various technical subjects. In July 1875 he became a pupil, and afterwards assistant, to Mr. James Wilson, superintendent of Greenock Waterworks, and was engaged on the construction of numerous waterworks and sewage disposal systems until October 1883. He came to Canada in December of that year, and his first position in this country was in the office of the harbour engineers in Montreal. In March 1884 he joined the engineering staff of the Canadian Pacific Railway Company. It was in the office of the chief engineer his services with this company were extended over a period of about twenty-nine years, during which time he occupied various positions, finally being appointed chief draughtsman in the construction department. Subsequently, he established the engineering firm of Ewing, Lovelace and Tremblay, which later become Ewing and Tremblay.

Mr. Ewing joined the Engineering Institute of Canada, then the Canadian Society of Civil Engineers, as Associate Member on November 11th, 1892 and was elected Member on October 24th, 1907.

PERSONALS

J. L. Bieler, S.E.I.C., is at present located in London, England, on the engineering staff of the Industrial Combustions Engineers, 31 Wybert street, London, N.W. 1.

Ralph C. Silver, S.E.I.C., Danville, Que., has been awarded the Jenkins Bros., Limited, scholarship for students entering the fourth year on engineering at McGill University.

Professor R. W. Angus, M.E.I.C., of the University of Toronto, has been elected secretary of the Toronto branch of the American Society of Mechanical Engineers.

T. L. Crossley, A.M.E.I.C., has been appointed special lecturer on pulp and paper in the department of chemical engineering at the University of Toronto.

Charles R. Stein, CAPTAIN R.C.E., A.M.E.I.C., who was for some time district engineer of Military District No. 10, Winnipeg, Man., is at present at the Royal Military Academy, Woolwich, S.E. 18.

F. L. Grindley, S.E.I.C., who graduated from the University of Alberta in 1926, is at present located at Arvida, Que., where he has received an appointment on the staff of the Aluminum Company of Canada, Limited.

W. R. Wonham, Jr.E.I.C., has resigned from the staff of the Montreal Tramways Company and has accepted a position with the Power Engineering Company in Montreal. Mr. Wonham graduated in electrical engineering from McGill University in 1922.

F. W. Townsend, A.M.E.I.C., who for the past six years has been located in Peru as chief engineer for the International Petroleum Company, Limited, has been transferred to Dartmouth, N.S., where he is chief engineer of the refinery of the Imperial Oil Limited.

Edward M. Velasco, S.E.I.C., who graduated from McGill University with the degree of B.Sc. in 1925, is with Messrs. Fraser, Brace Limited, and is located at Santiago, Antioquia, Colombia, S.A. Mr. Velasco was formerly with the woods department of the Wayagamack Pulp and Paper Company, Limited.

A. M. Toye, Jr.E.I.C., is with the John V. Gray Construction Company of Toronto, and is at present located in London, Ont., on the construction of a new hotel in that city. Mr. Toye is a graduate of the University of Toronto of the year 1925. He was until recently with Messrs. Chapman and Oxley, architects of Toronto, on the design of reinforced concrete work.

J. S. G. Shotwell, Jr.E.I.C., has been appointed to the staff of Price Brothers and Company, Limited, at their Riverbend mill, Riverbend, Que. Mr. Shotwell graduated from McGill University with the degree of B.Sc. in 1925, and has until recently been with the Forest Products Laboratories at Montreal. During the past year he was engaged on research work for the preparation of the thesis for which he was recently granted his degree of M.Sc. at McGill University.

F. T. Kaelin, M.E.I.C., chief engineer of the Shawinigan Water and Power Company, Montreal, who has been away for the past year, on account of his health, has returned, and it is gratifying to his many friends to learn that his health has been greatly improved. During his absence, Mr. Kaelin spent most of the time in his native land, Switzerland, and while there he represented the Canadian National Committee at the World Power Conference Meeting at Basle, Switzerland. Mr. Kaelin is a graduate of the Federal Technical University of Zurich, Switzerland. He joined the staff of the Shawinigan Water and Power Company in 1902, becoming assistant chief engineer in 1909 and chief engineer in 1919.

R. G. Johnstone, Jr.E.I.C., has joined the staff of the Harland Engineering Company of Canada, and is at present located at the plant of the Brompton Pulp and Paper Company, Bromptonville, Que., where he is engaged on the erection of a new paper machine for this mill. Mr. Johnstone was previously with the electrical department of the Newfoundland Power and Paper Company, Limited, Corner Brook, where he had charge of the electrical equipment for the new plant then under construction. He is a graduate of Nova Scotia Technical College, where he received his degree of B.Sc. in electrical engineering in 1924.

Louis Beaudry, A.M.E.I.C., secretary-treasurer of the Quebec Branch of The Institute, has joined Messrs. Wm. I. Bishop, Limited, on the construction of the Anglo-Canadian Pulp Company's mill at Limoilou, Que. Mr. Beaudry graduated from Ecole Polytechnique in 1921, at which time he received the degree of B.A.Sc. in civil engineering. During the summers of his college course he was engaged with the Department of Roads, Province of Quebec, with the exception of the last summer, when he was engaged with the engineering department of the city of Outremont. Following graduation he entered the construction field under the firm of Trepanier and Beaudry. In February 1923 he entered the Provincial Civil Service in the Department of Public Works of Quebec and was engaged on location, surveys, designing, estimating and inspecting of bridges.

M. A. Pooler, M.E.I.C., vice-president and general manager of the New Brunswick Power Company, Saint John, N.B., has been appointed general manager of the Tucson Gas, Electric Light and Power Company and the Tucson Rapid Transit Company, Tucson, Arizona. Mr. Pooler is a graduate of the Case School of Applied Science, where he received the degree of B.S. in 1904, and also of Perdue University, where he received his degree of E.E. in 1905. He was at one time superintendent of the New Castle Electric Company, New Castle, Pa., and later general manager of the Potomac Public Service Company, Hagerstown, Md. At the meeting of the directors of the New Brunswick Power Company on the occasion of Mr. Pooler's departure from Saint John, he was presented with a wrist watch on behalf of the board of directors.

Aerial Mapping in 1926

Aerial photography as an aid in economic mapping has steadily gone ahead in Canada since its inception five years ago. During the 1926 field season, operations extended into various parts of the Dominion, the major portion, however, being over lands where the need for maps was urgently felt in connection with the opening up of newly-discovered and newly-uncovered resources. Over such lands the lack of maps showing topographic features in an adequate manner was felt to be a severe handicap to development.

Thus, some of the most extensive operations included the new Rouyn mining district in the province of Quebec, and adjacent territory; a region in northwestern Ontario lying in general to the east of that covered by the 1925 season and extending from the Red lake area into the Woman lake and lake Nipigon districts, and an extensive territory in the vicinity of The Pas and Norway House in Manitoba. In the case of the new Rouyn mining district, the ground control was provided by the Geological Survey of Canada, and the survey section of the Quebec government.

In addition to this there were many smaller photographic operations, all with the ultimate object of providing data of value in the development of the natural resources of the country.

The value of the photographs taken is not alone confined to their actual use in mapping. Apart from this entirely they provide a most complete record of the features of the country, a record that may be called upon at any time when questions of any kind arise wherein the topography with its surface characteristics has a bearing. This is particularly true when used for geological, forestry, water power, road location, or other purposes.

The work of aerial mapping by the Dominion is carried on by the Topographical Survey, Department of the Interior, in co-operation with the Royal Canadian Air Force. The Topographical Survey has been made the central mapping organization for aerial photography of the Dominion Government service, and in their office, also, are carefully indexed and filed all photographs taken, thus providing for their use at any time in the future.

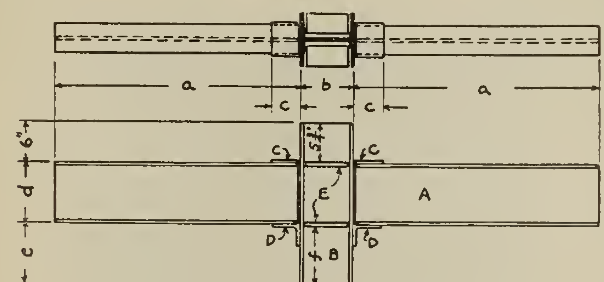
TESTS OF ARC WELDED STRUCTURAL STEEL

A. M. Candy, Welding Engineer,

and

G. D. Fish, Consulting Structural Steel Engineer,
Westinghouse Electric and Manufacturing Company

The series of test specimens which are described and discussed in this article were all welded with the various members located in the same position and manner as would be required if they were actually a part of a building structure. As a result, all of the welds made were executed from the same directions and were located in the same position as will be found in actual practice. For example, to weld the web of a beam to a column required welding along a vertical direction. To weld the under side of the top flange and the bottom face of the bottom flange of an I-beam to a column required the operator to execute overhead welds. For such operations as welding seat angles to columns and welding wed plates to the web and inside faces of the flanges of columns, the column sections were turned so as to permit the operator to make practically all such welds in the downward position due to the fact that in actual fabricating work these welds would be executed in the shop where it would be not only permissible but advisable to turn the material in such positions as to make the welding most easily executed by the operator, and thereby obtain welds which would be thoroughly dependable. All joints made with a single bead of metal were executed so as to make the bead of metal approximately 5/16-inch in thickness at the centre of the bead, and to extend out from the corner of the members so joined, a distance of approximately 5/16-inch.



Tests No. 1, 2, 3, 4, 5.

All specimens were loaded by means of rocker blocks 5 inches wide, 8 inches long, 10 inches high, finished on two faces to a radius of approximately 2 feet. Plates 1½ inches thick, 5 inches wide by 8 inches long were placed between the rocker blocks and the specimen so as to distribute the load through the rocker block over an area 5 inches wide across the specimen. Cantilever specimens, of course, were loaded at a point approximately 3 inches from the end, whereas simple beam specimens were supported by means of the rocker blocks on various spans, as indicated by the sketches, the load being applied at the centre of the specimen through a similar block 5 inches wide by 1½ inches thick.

The amount of weld metal used to make the various joints is unquestionably in excess of that actually required to produce joints of 100 per cent strength, but this was intentionally incorporated in the design of the test specimens so as to prove beyond the shadow of a doubt that structural members can be joined by arc welding, making joints which will not fail even up to rupturing loads on the members so joined.

In carrying out further tests in the future, determinations will be made as to the minimum amount of weld metal which can be used for such joints and still retain the requisite strength at the joints.

By perusal of the data which are given in this article it is manifest that the tests fully demonstrate the following facts:—

(*1*) That welded joints can be constructed in such manner as to develop fully the ultimate strength of the structural members connected.

(*2*) That beams and girders can be connected to columns so as to produce absolute fixation.

(*3*) That lines of beams or girders can be connected so as to provide complete continuity across the supports, whether the supports be girders or columns.

(*4*) That a steel I-beam of given section and length will sustain a far greater load if fixed at its ends by a suitably designed welded joint than if supported by standard rivetted connections consisting of top and bottom angles. A 9-inch standard I-beam framed between rigid upright columns 8 feet apart by means of specially designed welded connections sustained a load 25 per cent greater than a beam of the same size and length framed between columns by means of rivetted top and bottom angles of ½ inch thickness.

(*5*) That a plate girder assembled by welding and consisting of nothing but sheared plates, has a far greater bending strength than a rivetted plate-and-angle girder of the same weight, due to the better distribution of the steel in the cross-section. A 15-inch plate girder assembled by welding and simply supported on a 14-foot span developed more than 50 per cent greater strength than a rivetted plate-and-angle girder of the same depth and the same weight.

(*6*) A double angle tension member such as is used in trusses was connected at the ends by welding, and when tested to tension failure broke through the angles at a load 30 per cent greater than the load at which a hanger consisting of the same size angles with rivetted end connections failed.

The prevailing impression among the witnesses was that these tests demonstrated the superiority of welded connections to rivetted connections in every case where direct comparisons were made, and brought out two general facts:

(*1*) That complete continuity of lines of beams can be obtained in welded construction, whereas it is well known that this cannot be done in rivetted construction.

(*2*) That in a welded building it will be possible to make every joint develop full strength of the main members, whereas in a rivetted building many joints are weaker than the members due to the weakening effects of the rivet holes and the weakness of steel angles which have to be used for transmitting tension between two members at right angles to each other.

It was proved that a welded plate girder was 50 per cent stronger than the rivetted girder of relative depth, length and weight.

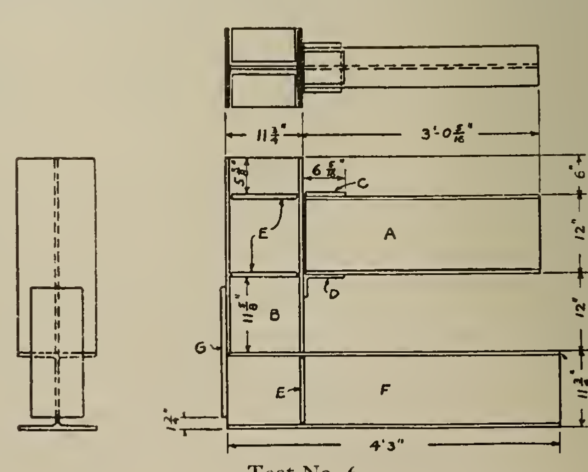
An Olsen testing machine, capable of applying 400,000 pounds, was used.

The tests proved the entire practicability of welding without any misgivings as to safety.

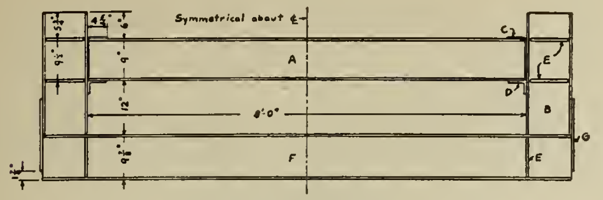
The joints that were demonstrated here are being used in the five-storey steel building 70 by 220 feet, and 80 feet high, now being fabricated and erected for the Sharon Works of the Westinghouse Electric and Manufacturing Company. The typical beam and girder connections are fully continuous connections thereby permitting large percentage of saving in the weight of the beams and girders to carry a given load. The same type of connection which develops continuity also effectively stiffens the building against wind. The equivalent cannot be obtained by any known rivetted joint.

Test No. 1

In test No. 1 a double cantilever specimen was used, comprising cantilever I-beams *A* weighing 21 8/10 pounds to the foot, 3 feet long, secured to the column *B* which is an 8-inch H-section weighing 32 pounds to the foot, 2 feet long. Seat angles *D* com-



Test No. 6.



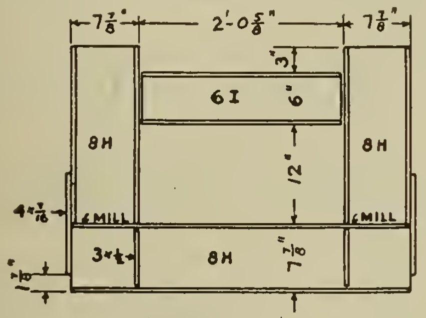
Tests Nos. 7, 8, 9.

prising 4 by 3 by ⅜-inch angles, 5 inches long, were welded to the column faces on which the beams *A* were landed, after which the entire end of the beams *A* were welded to the column faces. The edges of the bottom flanges of beams *A* were also welded to the seat angles *D*. After completing the weld between the top flanges of beams *A* to the column, plates *C*, 4 by 7/16 by 5 inches long were placed in position and welded to the column face. Due to the fact that plates *C* were wider than the top flanges of beams *A* it was necessary to make overhead welds along the edges of the top flanges to the under surfaces of plates *C*.

The web plates *E* are 3 by ⅝ by 6⅝ inches long, four of which were used; two on each side of the column as indicated. These web plates were cut so as to provide approximately 3/16 inch gap between their ends and the inside faces of the column flanges. These plates were securely welded at their ends to the inside faces of the column flanges and were located directly in line with the top and bottom flanges of beams *A*.

This test demonstrated several facts:—

First. That properly designed joints between beams and columns can be executed by arc welding so that the resulting joint is a great deal stronger than the members so joined. Such a joint is not only stronger but much more rigid than any similar joint



Test No. 10.

could be made by riveting practice, due principally to the use of web plates *E* which give the identical effect of the beams *A* being continuous through the column.

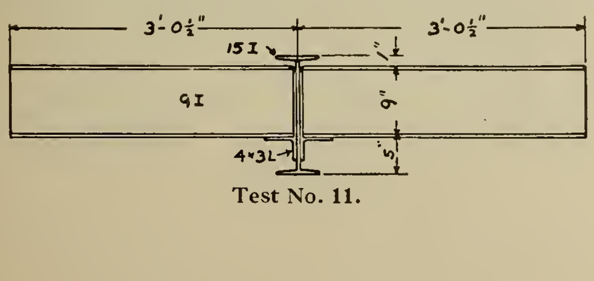
The total weight of the complete specimen was 224 pounds; 6 pounds of welding wire was required and the time to make the specimen was 4 hours. The span for loading this specimen was 6 feet 2¾ inches. The yield point of this specimen was 50,000 pounds and the ultimate load was 75,100 pounds. Failure was by web crippling of beams, and the ultimate bending moment at column face was 125,000 inch-pounds.

Test No. 2

The specimen in test No. 2 was similar to that in No. 1, the difference being that the beams *A* are 9-inch Bethlehem I-section, weighing 20½ pounds to the foot; plates *C* are 4 by ½ by 4½ inches; seat angles *D* are 6½ inches long. In this case the welding procedure was exactly the same as described for No. 1 with the single exception that the plates *C* being narrower than the top flanges of beams *A* it was possible to weld downward when securing the edges of plates *C* to the top face of the flanges of beams A.

This specimen demonstrated the same facts as pointed out for the first specimen.

The complete weight of this specimen was 214 pounds 8 ounces. The amount of welding wire used was 5 pounds 12 ounces



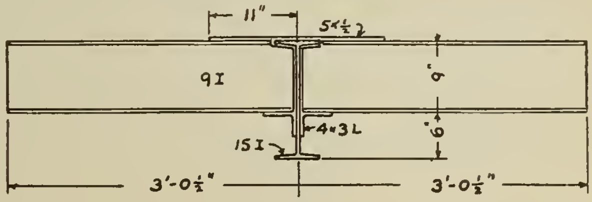
Test No. 11.

and the total time required to weld the specimen 2 hours 35 minutes. The span for loading this specimen was 6 feet 2½ inches. The yield point of this specimen was 57,000 pounds and the ultimate load was 70,000 pounds. Failure was by web crippling of beams, and the ultimate bending moment at column face 116,500 inch-pounds.

Test No. 3.

This test was very similar to the preceding specimen, the difference being that seat angles *D* and plates *C* were omitted; the beams *A* were welded directly to the column faces entirely around their ends without any means provided for landing or any reinforcement provided other than the weld metal itself.

This specimen weighs 198 pounds 8 ounces. The amount of welding wire used was 4 pounds 9 ounces, and the total welding time was 2 hours 20 minutes. The span for the loading on this specimen was 6 feet 1¾ inch. The yield point for this specimen was 50,000 pounds



Test No. 12.

and the ultimate load was 60,000 pounds. Failure was by web crippling of beams, and the ultimate bending moment at face of column 99,000 inch-pounds.

These loads are lower than the loads obtained on specimen Nos. 1 and 2 which is attributed to the fact that the omission of landing brackets *D* and the reinforcing plates *C* reduces the stiffening produced in the flanges of the beams *A*, which is obtained where these parts were used in specimen 1 and 2.

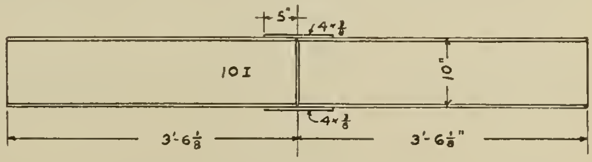
Test No. 4

This specimen is to be directly compared with specimen No. 2, the only and vital point of difference being that web plates *E* were omitted. The test on this specimen demonstrated very clearly the greatly increased strength and rigidity of specimen No. 2 which employed the use of the web plates *E*.

The total weight of this specimen is 199 pounds, there being 3 pounds 8 ounces of welding wire used. The time required for welding was 2 hours 15 minutes. The span for loading this specimen was 6 feet 2½ inches. The yield point for this specimen was 28,000 pounds, and the ultimate load was 50,000 pounds, which is to be compared with the yield point of 57,000 pounds and ultimate load of 70,000 pounds for test No. 2. Failure took place by buckling of web of column between beams in specimen No. 4. Ultimate bending moment at face of column 83,000 inch-pounds.

Test No. 5

Test No. 5 is also a double cantilever specimen made up of the following members: Two beams *A* comprising 8-inch H-beams

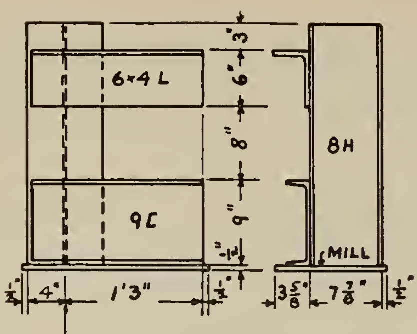


Test No. 13.

weighing 32.6 pounds to the foot, 4 feet long; one column *B* comprising a 10-inch H-section weighing 49½ pounds to the foot, 2 feet long; two plates *C* 7 by ½ by 7 inches and two seat angles *D* comprising 6 by 3½ by 7/16-inch angles, 9 inches long; four web plates *E* 4 by ¾ by 8¼ inches long. This specimen is to be compared directly with specimen Nos. 1 and 2. It demonstrates the same features as shown by them.

This specimen has a total weight of 442 pounds, there being 7 pounds 9 ounces of welding wire required to completely weld the specimen. The total welding time was 5 hours 5 minutes. The yield point of the specimen was 50,000 pounds, and the ultimate load 79,900 pounds. The span for loading this specimen was 8 feet 4 1/16 inches, and the bending moment at face of column 180,000 inch-pounds.

The ultimate failure for this specimen took place by rupture through the web and upper part of weld of one of the beams *A*. Upon investigating and removing the beam entirely from the column



Test No. 14.

we found that the overhead welds on the under side of the top flange of the beam were very poorly executed and furthermore that the main weld between the top flange of the beam *A* and the column and also between the plate *C* and the column was only fused 30 to 40 per cent of the total area. It is interesting to note that even under these conditions of poor welding the specimen carried load to the point of severe deformation of the beams and rupture of the beam web, which was far beyond that which could have been carried by any rivetted joint.

Test No. 6

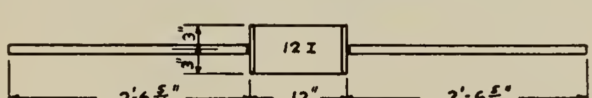
Specimen No. 6 is a single cantilever specimen comprising a 12-inch Bethlehem I-beam *A* weighing 28½ pounds to the foot, 3 feet long; one 12-inch., H-column *B* weighing 65½ pounds to the foot, 2 feet 6 inches long; a base member *F* comprising a 12-inch H-section weighing 65½ pounds to the foot, 4 feet 3 inches long; one seat angle *D* 6 by 3½ by 7/16 inch angles, 7½ inches long; one reinforcing plate *C* 5 by ⅝ by 6 inches long; 6 web plates *E* 5 by ¾ by 10 inches long; one reinforcing plate *G* 8 by ¾ by 20 inches long.

This specimen completed weighs 649 pounds, there being required a total of 12 pounds of welding wire. The time required was 6 hours 40 minutes to execute the welding. The span from centre of load to face of column was 2 feet 9 11/16 inches. The yield point was 35,000 pounds and the ultimate load 59,200 pounds. Ultimate bending moment at face of column 200,000 inch-pounds.

This specimen failed by web crippling of the cantilever beam *A*, there being no indication of any distress in any of the welded joints. Incidentally, considerable deformation was produced in the web of the base *F* to the left of the reinforcing plates *E* located in this base, in line with the right hand flange of column *B*.

Test No. 7

No. 7 is a typical example of a beam of reasonable length compared to the depth when secured to the faces of two rigid columns. The beam *A* is a 9-inch I-beam, weighing 21.8 pounds to the foot,



Test No. 16.

7 feet 11⅝ inches long. The columns *B* are 10-inch H-sections, weighing 49½ pounds to the foot, 2 feet 3 inches long. The base *F* is the same section as the column *B* but is 9 feet 7¾ inches long. The web plates *E* are 4 by ⅝ by 8¼ inches long. The seat angles *D* are 4 by 3 by ⅜-inch angles, 5 inches long. The re-enforcing plates *C* are 4 by 7/16 by 5 inches long.

The total weight of this specimen was 976 pounds 8 ounces. The total weight of welding wire used was 16 pounds 3 ounces, and the time required 12 hours 45 minutes. The span for loading this specimen was 7 feet 11⅝ inches. The yield point of this specimen was 50,000 pounds, and the ultimate load 73,500 pounds. Failure by web crippling and flange buckling of beam.

The sum of positive and negative bending moments was 1,760,000 inch-pounds. As the welds showed no distress and as the columns did not perceptibly deflect, the negative moment at either end must have been nearly as great as the positive moment at mid-span. For purposes of comparison with tests 8 and 9; assume this test a case of perfect fixed ends, positive and negative moments being each 880,000 inch-pounds. This corresponds to maximum fibre stress of 46,500 pounds per square inch.

Test No. 8

Specimen No. 8 is very similar to No. 7, the only difference being the omission of the landing angles *D* and the reinforcing plates *C*.

The total weight of this specimen is 967 pounds, the weight of welding wire required being 15 pounds. The total time to weld the specimen is 9 hours. The span for loading this specimen was 8 feet 3/16 inches. The yield point of the specimen being 50,000 pounds and the ultimate load 67,200 pounds. Failure by web crippling and flange buckling of beam.

It was interesting to note that the ultimate load on this specimen is appreciably less than that on specimen No. 7 which again demonstrates the additional restraint imposed on the beam where seat angles *D* and reinforcing plates *C* are provided.

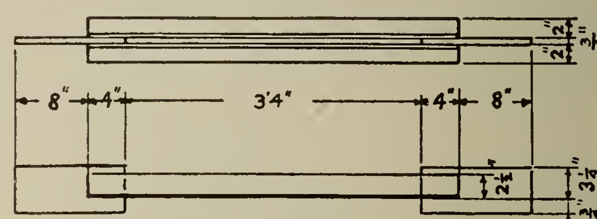
Sum of positive and negative bending moments was 1,618,000 inch-pounds. Assuming same ultimate positive bending moment as in test No. 7, the negative moment at column face would be 738,000 inch-pounds, indicating 84 per cent fixation.

Test No. 9

This specimen is made up so as to be directly comparable with specimen 7 and 8, the difference being that the beam *A* is secured to the column *B* by means of exceptionally rigid rivetted joints, using ½-inch top and bottom angles and a total of twenty ¾-inch diameter rivets in 13/16 diameter holes.

The span for loading this specimen was 8 feet 3/16 inches. The yield point for this specimen was 42,000 pounds and the ultimate load 58,700 pounds. Failure by web crippling and flange buckling and bending of connection angles.

It was interesting to observe in comparing these three specimens that specimen No. 7 making use of the seat angles and reinforcing plates shows 25 per cent greater ultimate strength than



Test No. 17.

specimen No. 9. Also, that specimen No. 8 in which only the beam ends are welded to the column without the landing brackets and the reinforcing plates shows 14 per cent greater ultimate strength than rivetted specimen No. 9.

Sum of positive and negative bending moments was 1,410,000 inch-pounds. Assuming same ultimate positive bending moment as in test no. 7, negative moment would be 530,000 inch-pounds, indicating 60 per cent fixation. Such a degree of fixation could not have been obtained with an ordinary type angle 5/16 inch or ⅜ inch thick.

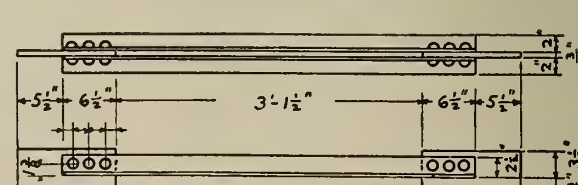
Test No. 10

This is to demonstrate principally a beam subject to shear load. This specimen comprises a 6-inch I-beam weighing 12½ pounds to the foot, 2 feet long secured between two 8-inch H-columns weighing 32 pounds to the foot, 1 foot 9 inches long each and one base member comprising a similar 8-inch H-section 3 feet 4⅜ inches long, using four web plates 3 by ½ by 6⅝ inches, located in the base member in line with the inside flanges of the columns. Also two stiffening plates 4 by 7/16 by 12 inches long each located as illustrated.

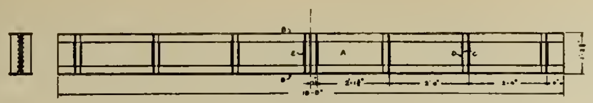
This specimen completed weighs 266 pounds, there being required 7 pounds 2 ounces welding wire. The total time for making the weld was 3 hours 40 minutes. The span for the load was 2 feet ⅜ inch. The yield point of this specimen being 50,000 pounds and the ultimate load 83,000 pounds. The load was applied at the centre of the specimen on a block 5 inches wide located on the top flange of the I-beam. Failure in this case took place by web crippling of the I-beam.

Test No. 11

This specimen is to illustrate two cantilever I-beams secured to the web of a larger I-beam representing a main girder of a



Test No. 18.



Test No. 19.

structure. The 9-inch I-beams weighing 21 8/10 pounds to the foot are 3 feet long. The 15-inch I-section weighs 42 9/10 pounds per foot and is one foot long. The two seat angles are each 4 by 3 by ⅜-inch angles, 5 inches long.

Owing to the very cramped and inaccessible space between the top face of the 9-inch I-beam flanges under the upper flange of the 15-inch I-section, it was next to impossible for an operator to make a good weld at this point where the tension stresses are concentrated. Therefore to assist in welding, wedge blocks were inserted so as to permit the operator to build up arc deposited metal over the end and edges of these wedge blocks thereby producing a tie between the flanges of the 15-inch I-section and the flanges of the 9-inch cantilever I-beams. This specimen complete weighs 187 pounds, there being required 4 pounds 2 ounces of welding wire and the total welding time required 2 hours 10 minutes.

The span for loading this specimen was 5 feet 7⅝ inches. The yield point of this specimen was 55,000 pounds and the ultimate load 64,000 pounds.

Test No. 12

Specimen No. 12 is similar to specimen No. 11 with the exception that the 9-inch I-beams are coped so as to throw the top face of the top flange in a plane with the top face of the top flange of the 15-inch I-beam. A reinforcing plate, 5 by ½ by 22 inches long, is provided across the specimen as illustrated. This reinforcing plate was wider than the flanges of the 9-inch I-beams which necessitated welding overhead in order to tie the edges of the top flanges to the under surface of the reinforcing plate. This design should be revised so as to make the reinforcing plate narrower than the I-beam flanges thereby providing for welding in the downward position.

The total weight of this specimen was 194 pounds, the welding wire required was 3 pounds 12 ounces and the total welding time 2 hours 15 minutes. The span for loading was 5 feet 4 15/16 inches. The yield point of this specimen was 65,000 pounds and the ultimate load 94,000 lbs. The ultimate failure taking place by progressive tearing of the overhead welded joint between the reinforcing plate and the top flange of one of the 9-inch I-beams. This specimen shows a very material increase in strength over that of specimen No. 11, namely, approximately 48 per cent.

Test No. 13

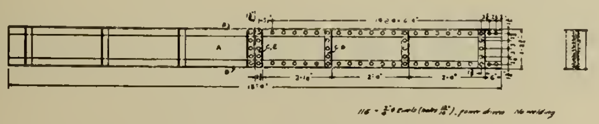
Specimen No. 13 represents a test of two spliced 10-inch Bethlehem I-beams, each weighing 23.5 pounds to the foot, 3 feet long, welded together at their abutting ends and reinforced by top and bottom cover plates, each of which is narrower than the flange of the beam so as to permit downward welding along the edge of the cover plate to the outer faces of the beam flanges. This particular specimen was considered a shop fabricating job, and therefore the beam was turned over so as to make all welding in the downward direction, whereas all of the preceding specimens were welded in the position shown to exactly duplicate regular building construction work.

Failure took place in this specimen by web crippling of the two joined 10-inch I-beams. The elastic limit of the specimen was approximately 65,000 pounds, and the ultimate load was 72,900 pounds. The loading span was 6 feet 6 1/16 inches, the load being concentrated at the centre on a loading block 5 inches wide. This gives a maximum bending moment of approximately 118,000 foot-pounds, and represents a fibre stress of approximately 58,200 pounds per square inch in the beams at the ultimate load.

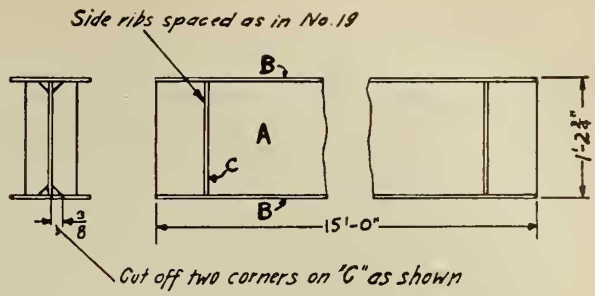
The weight of this specimen complete is 180 pounds 9 ounces, it being required to use one pound and 11 ounces of welding wire and the total actual welding time of 1 one and 15 minutes.

Test No. 14

This specimen is to represent a small bracket secured to a column, the bracket comprising a 6 by 4 by ½-inch angle, 1 foot 6½ inches long, welded across the end and the top and bottom



Test No. 20.



Test No. 21.

edges. The 8-inch H-column weighs 32 pounds to the foot and is 2 feet 2 inches high. Failure took place in this specimen by buckling of the column flange edge, midway between the bracket and the lower supporting channel welded to the column and to the base. The web of the column was also distorted at the same time. The yield point for this specimen was 25,000 pounds, and the ultimate load was 34,600 pounds. The span from the centre of the applied load to the edge of the column was 7½ inches. The maximum bending moment therefore is 21,700 foot-pounds, and the maximum fibre stress in the angle is 59,500 pounds per square inch.

The weight of this specimen is 148 pounds 8 ounces, and the amount of welding wire required is 3 pounds 3 ounces, and the total welding time is 1 hour 25 minutes.

Test No. 16

This specimen comprises a pair of 15/16-inch diameter hot rolled steel rods welded to the two faces of the 12-inch I-beam weighing 31.8 pounds to the foot, 6 inches long. It is to represent the construction where similar rods are to be attached to the bottom faces of the I-beams and girders for hangers to support balconies and mezzanines. Each rod was welded to the under face of the I-beam in an overhead position to exactly duplicate field construction work. The specimen failed by breaking the rod approximately 12 inches from one face of the I-beam section. The yield point was 23,200 pounds, and the ultimate load 35,000 pounds. The amount of welding wire required to weld both rods to the I-beam is 8 ounces, and the total welding time 45 minutes.

Test No. 17

This specimen comprises two 2½ by 2 by 3/16-inch angles 4 feet long, welded to two plates 5 by ¾ by 12 inches long, the 2½-inch leg of each angle being welded to the plates across the ends of the angle and along the heel and toe of the leg of the angle in contact with the plate. The specimen is for a tension test, the yield point being at 70,000 pounds, and the ultimate load being 94,000 pounds, the maximum elongation being 3 inches in the 40-inch length between shank plates. Failure took place by progressive failure through the 2½-inch legs of the angles, carrying on out through the 2-inch leg.

The complete specimen weighed 48 pounds 7 ounces, the amount of welding required was 8 ounces, and the actual welding time 20 minutes. All of the welding in this specimen was done in the downward direction, which shows the difference between overhead welding and downward welding by comparing with the amount of metal used and welding time for specimen No. 16. In the case of these two specimens, the amount of welding wire used was exactly the same and yet the welding time was 20 minutes in the case of No. 17 against 45 minutes in the case of No. 16. Mean tensile stress, ultimate, 58,000 pounds per square inch.

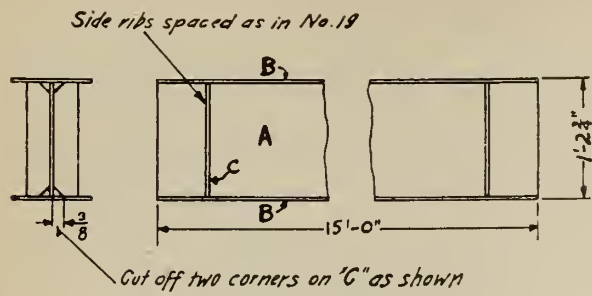
Test No. 18

This specimen is similar to specimen No. 17, the difference being that the angles were rivetted to the shank plates with ⅝-inch diameter rivets power driven in 11/16-inch diameter holes.

The elastic limit of this specimen was 60,000 pounds and the ultimate was 72,000 pounds, and the elongation was only 1.12 inch, failure taking place through the first rivet hole. The stress strain diagram curves of these two specimens make a very interesting comparison. Ultimate mean tensile stress on gross section 44,500 pounds per square inch; on net section 53,000 pounds per square inch.

Test No. 19

This specimen comprises a 15-foot by 14¾-inch deep girder employing one web plate, *A*, 14 by 5/16 inches by 15 feet long, four flange angles, *B*, 4 by 3 by 5/16-inch and 15 feet long; sixteen web stiffener angles 3 by 2 by ¼ inch and 13¾ inches long; twelve filler plates 2½ by 5/16 by 8⅝ inches long, and two filler plates 5 by 5/16



Test No. 21-A.

by 8⅝ inches long. The parts of this girder were assembled by welding. The top flange angles were welded to the web plate by intermittent welds 1 inch long on 3-inch centres along the toe of both the top angles. The backs of the angles were welded together and to the edge of the flange plate intermittently using 2-inch long welds on 3-inch centres. At each end the angles were welded solid to the web plate at both the heel and toe for a distance of 3 inches. The bottom flange angles were welded to the web plate solid for a distance of 6 inches at each end of the toe, the remainder of the weld along the toe of the angle being 2 inches on 5-inch centres. The heels of these angles were welded solid and also to the edge of the web plate for a distance of 6 inches. The remaining portion of this same joint was intermittently welded 2 inches on 5-inch centres. The filler plates were welded to the web plate by means of 2-inch long welds at the neutral axis and ½-inch welds at the ends of the filler plates along the web plate. The stiffener angles were completely welded around the entire periphery making contact with the flange angles, and also 2-inch welds at the heel and toe of these angles exactly in line with the 2-inch welds made at the edge of the filler plates to the web plate. The completed specimen weighed 785 pounds. The amount of welding wire required to complete the specimen was 27 pounds 8 ounces. The total time to complete the specimen was 14 hours and 10 minutes. The specimen was tested by centre loading on a block 5 inches wide, the span being 14 feet. The specimen failed by crippling of the top flange of the girder, the elastic limit being reached at 65,000 pounds, the ultimate load being 77,200 pounds, and the maximum bending moment being 270,000 foot-pounds. This gives a maximum fibre stress of 53,800 pounds per square inch based on the section modulus of 60.2.

Test No. 20

Specimen No. 20 is a 15-foot girder 14 15/16 inches deep, made up of duplicate parts used for specimen No. 19, except that all parts are rivetted together using ¾-inch diameter rivets power-driven in 13/16-inch diameter holes. The completed weight of this specimen was 798 pounds. This specimen was tested by centre loading on a block 5 inches wide, the span being 14 feet and ⅛ inch. Failure took place by buckling of the top flange, the yield point being 55,000 pounds, and the ultimate load being 68,900 pounds. A duplicate girder was also tested, the span being 14 feet 3/16 inch. The elastic limit was reached at 60,000 pounds, the ultimate load being 74,000 pounds, the depth of this girder being 14 15/16 inches. Maximum fibre stress, ultimate, for first specimen, 47,400; for second specimen, 51,000; section modulus for both specimens 61.1.

By comparing these figures with those for specimen No. 19 it is interesting to observe that although all parts joined were exactly the same, the welded specimen had a higher yield point than either of the rivetted specimens, and also an ultimate load carrying capacity appreciably above that of the rivetted specimens. Allowance should also be made for the fact that the depth of the welded specimen, namely No. 19, was less than either of the specimens No. 20, causing 1½ per cent less section modulus.

Test No. 21

Specimen No. 21 is a specimen designed strictly to take all advantage of the possibilities of joining structural steel members by the use of arc welding. In this respect it is entirely different from No. 19, which is simply a rivetted design welded.

The specimen comprises a web plate, *A*, 14 by 5/16-inch, and 15 feet long; two flange plates, *B*, 10 by ⅜ inch and 15 feet long; and sixteen web stiffener plates 3 by ¼ by 12 inches and 1¾ inch long. The top flange was welded to the web plate continuously along each side of the web plate. The bottom flange was welded to the web plate solid for a distance of 6 inches from each end and then intermittent welds 2 inches long on 4-inch centres the rest of the distance on each side of the web plate. The web stiffeners were welded solid to the flanges around the entire periphery at each end of each web stiffener. Each web stiffener was also welded 2 inches on each side at the neutral axis and at intermediate points 1 inch long at each side of each stiffener halfway between each stiffener and the flanges of the girder. This specimen was tested by centre loading on a block 5 inches wide, the span being 14 feet. Failure took place by buckling of the top flange. The elastic limit of the specimen was 65,000 pounds, and the ultimate load 78,000 pounds. This specimen had a total finished weight of 656 pounds, which is very materially less than that of the rivetted girder, namely approximately 18 per cent, and approximately 16½ per cent less than the weight of the rivetted design welded, namely specimen No. 19. A total of 30 pounds 2 ounces of welding wire was required, and the total welding time was 12 hours and 33 minutes. This shows the advantage of designing structures for welding, by placing the metal in the locations where the greatest strength can be developed with the amount of material used. It also demonstrates the fact that the parts to be joined need not be lapped as is required where rivets are to be used for securing the members. Maximum fibre stress 52,700 pounds per square inch section modulus 62.2.

Test No. 21-A

Specimen No. 21-A is similar to No. 21, except that the web stiffening plates are 4½ by ¼ by 12 inches, and 2 inches long, there being a total of twenty used and a top reinforcing plate 9 by 5/16 inch and 6 feet long was welded to the top flange. This plate was welded solid across each end and solid along each edge from the centre of the girder to a point 1 foot 2 inches from the centre of the girder. The remaining length of the edge of the plate was welded intermittently 2-inch welds on 4-inch centres. This girder had a completed weight of 795 pounds, and required 30 pounds 12 ounces of welding wire to complete the welding work. The total welding time was 16 hours and 50 minutes. This specimen failed ultimately by buckling of the top flange, the top cover plate blistering away from the flange at the centre where it was tied into the web plate. This blistering was approximately ½ inch in depth and did not result in the cracking of any of the welds. The elastic limit of this specimen was reached at 60,000 pounds and the ultimate load was 110,350 pounds. A very interesting feature developed in connection with this test, namely when the ultimate load was removed from the girder it sprung upward a distance of ¾ inch before coming to rest. Some very interesting comparisons can be made between this girder and the two preceding girders 19 and 20, which will show the very decided increase in strength which can be obtained by properly designing to take advantage of the possibilities of arc welded construction. The maximum bending moment in the case of this specimen is approximately 386,000 foot-pounds. The maximum fibre stress in tension would appear to be 69,300 pounds per square inch, based on a section modulus of 66.8; but the buckling of the top flange before ultimate load was reached would naturally lower the neutral axis below the calculated position, so that the figure given above for maximum tensile stress is undoubtedly much too high. At the elastic limit, the figure for tensile stress is 37,700 pounds per square inch.

Members of Institute doing Valuable Work in Forest Protection

That many members of the Engineering Institute are engaged in forest protection work and form part of an intensive organization which by efficient performance has been able to keep losses both of timber and valuable young growth at a surprisingly low figure during the past season, in spite of bad conditions, is the message brought back by D. Roy Cameron, M.E.I.C., associate director of the federal forest service, who made an extended trip through western Canada on general inspection work.

He found the forest fire season in Alberta and British Columbia was perhaps the most serious yet encountered in the history of forest fire protection, while suppression costs were high and the results achieved were strikingly good as indicated. Only those who have worked on the fire lines can realize the strain, both physical and mental, under which the personnel directing fire fighting operations on a large scale, labour, during a prolonged period of high fire hazard.

In the railway belt of British Columbia, which was the region hardest hit, the excellent system of fire detection by means of permanently occupied intervisible lookout stations equipped with telephones and special fire finders functioned perfectly. The elapsed time between start of fire and arrival of suppression forces was cut to the minimum, and no fire burned undiscovered for any appreciable period of time.

A feature of the fire season in the interior of British Columbia, particularly, was the occurrence of a series of heavy, dry electrical storms followed by high temperature and strong winds. An unusually high percentage of serious fires started by lightning resulted and enormously increased the difficulties of suppression.

ELECTIONS AND TRANSFERS

At the meeting of Council held on November 16th, 1926, the following elections and transfers were effected:—

Associate Member

NIKLASSON, Gunnar, Chem. Engr., (Chalmers Tech. Inst.), mill supt. Western Quebec Paper Mills, St. Andrews East, Que.

Junior

CULLWICK, Ernest Geoffrey, B.A. (Cambridge, Eng.), mech. dept. Can. Gen. Electric Co., Limited, Peterborough, Ont.

Affiliates

NELSON, Maxwell Stewart, B.Sc. (McGill Univ.), asst. mgr. and sec. treas., A. Faustin Ltd., Montreal, Que.

PARMELEE, Edward Henry, Eastern dist. mgr. Ferranti Meter and Trans. Mfg. Co., Montreal, Que.

QUIGLEY, Harry Stephen, contractor of aerial services, Montreal, Que.

Transferred from class of Associate Member to that of Member

DeCARTERET, Samuel Laurence, Ph.B. (Yale Univ.), Hammermill Paper Co., Quebec, Que.

MACNABB, Thomas Creighton, B.A. (Univ. of Man.), engr. of constrn. Western lines, C.P.R., Winnipeg, Man.

RIPLEY, Wilfred Jamieson, B.Sc. (McGill Univ.), designer and squad boss engrg. dept. and acting ch. dftsman, Dom. Coal Co., Sydney, N.S.

WILSON, Robert Starr Leigh, B.Sc. (McGill Univ.), prof. of civil and municipal engrg. Univ. of Alta., Edmonton, Alta.

Transferred from class of Student to that of Associate Member

PARKER, Walter J., B.A.Sc., (Univ. of Toronto), res. engr., Dept. of Northern Devel. Prov. of Ont., Preston, Ont.

VAUGHAN, Harold Wilfred, B.Sc. (McGill Univ.), asst. supt. light dept., City Hall, Montreal, Que.

Transferred from class of Student to that of Junior

BURCHILL, George Herbert, B.Sc. (N.S. Tech. Coll.), asst. engr., alternating current engrg., dept. Can. Gen. Elect. Co., Peterborough, Ont.

COULTER, Stanley L., B.A.Sc. (Univ. of Toronto), asst. to elect'l. engr., Aluminum Co. of Am., Massena, N.Y.

DYER, Joseph Wilson, B.A.Sc. (Univ. of Toronto), asst. to supervisor of bldgs. and vehicles, Bell Telephone Co., Toronto, Ont.

HAYES, St. Clair Joseph, B.S. (N.S. Tech. Coll.), B.A. (St. Mary's Coll.), D.C. Engrg., dept. Can. Gen. Elect. Co., Peterborough, Ont.

JENKINS, Thos. Harding, B.A.Sc. (Univ. of Toronto), structural dftsman, Can. Bridge Co., Walkerville, Ont.

JOHNSTON, Oswald Daniel, B.A.Sc. (Univ. of Toronto), asst. to gen'l mgr., D. M. Fraser, Ltd., Toronto, Ont.

SILLS, Herbert Ryerson, B.Sc. (Queen's Univ.), asst. engr. A. C. generator and synchronous motor engrg. dept. Can. Gen'l Elect. Co., Peterborough, Ont.

EMPLOYMENT BUREAU

Situation Wanted

CIVIL ENGINEER

Civil engineer, university graduate, age 26, three and one half years' experience in municipal engineering including the construction of concrete pavements, sanitary sewers, water supply systems, etc. Some business experience. At present employed. Address replies to Box 217-W, Engineering Journal.

Members' Exchange

For sale one Dumpy Level, three-screw, inverting, with special light tripod, Abney hand lever and clinometer. Apply Box No. 13-E, Engineering Journal.

ABSTRACT OF PAPER

Pigments

M. Doyle, Works Superintendent, British America Paint Corporation

Victoria Branch, October 6th, 1926

Beginning with the pigments, Mr. Doyle stated that white lead is the greatest standby of the paint trade, on account of its anti-corrosive and great covering qualities. Under present practice it is mostly made by pouring molten pig lead into water, when it is broken up into flakes; these are collected into a large holder, containing several tons, perhaps, and are then sprinkled with acetic acid, forming acetate of lead, which is a clear solution. Carbonic acid gas is passed through this liquid, the result being the formation of a fine white powder known as white lead. It is then washed free from acid, dried, and ground in oil.

The disadvantage of white lead is that it is an oxidizing agent, and gradually *burns*, as it were, the oil. The oil is the life of the paint, and consequently after a time the oil disappears and the white lead remains merely as a powder which can be easily rubbed off. Another disadvantage is that it can be attacked by sulphuretted hydrogen gas, given off perhaps from decomposing matter, and lead sulphide formed, the paint becoming grey.

Zinc oxide, a largely used white pigment, is formed by the burning of zinc ore. The fumes are carried through long tubes, and deposit on them a white dust; the finer in grain the further from the point of combustion. This is zinc oxide. Zinc oxide paint is largely used for interior painting, and on marine work and for boilers. In distinction from white lead, which dusts off when lifeless, zinc oxide comes off in flakes.

Lithopone, composed of zinc sulphide, and barium sulphate, finds a place among the white pigments, for interior flat wall paints, etc. Coming to black and coloured pigments, Mr. Doyle pointed out that those in the mineral class, such as oxide of iron and ochre, are lasting in colour, while the chemical colours, such as greens and chromes, are not so permanent.

OILS

Various oils are used, the chief being, of course, linseed oil, obtained by the crushing and treatment of flax seed. Whereas the Baltic linseed oil was for a long time considered the best, he believed that it has been superseded by the Canadian; climatic conditions under which the flax is grown in Canada having much to do with this. Linseed oil is the life of paint and varnish, it does not dry by evaporation, but by oxidization; in fact, it gains about ten per cent in weight in drying.

Wood oil, from China, obtained from a nut of that country, is found useful in the manufacture of waterproof varnishes, having decided advantage over linseed oil in this respect. Fish oil, which is now being manufactured in the fish reducing plants on the west coast of Vancouver Island, is looked upon by many as only an adulterant; as a matter of fact, it is far too expensive for such a use, even if such were sought. Its particular value is in cases where ordinary drying conditions are not encountered, such as baking enamel, and japan, where heat is used. Similarly in places where there was large variation in temperature and consequent contraction and expansion, such as smoke-stacks, a percentage of fish oil gave additional elasticity. Mineral oils should have no place in paint, as they have no drying action or wearing qualities.

VOLATILES

Turpentine is the volatile utilized in paint, this is practically all obtained from the Long Leaf Georgia pine; the sap heated in stills, gave off the turps, leaving behind rosin. The use of turps is merely to provide a mechanical means of spreading the paint; in a short time the turps evaporate, and in itself it has no action on the paint. It provided a volatile agent that takes long enough to evaporate to enable the paint to be properly spread. While a small amount of benzine might be used in some cases without much disadvantage, it is not advisable.

VARNISHES

Varnishes are a combination of gum, oil and turpentine, in which the gum provides the gloss, the oil the elasticity and the turps the mechanical means of spreading the others. There are some forty or fifty varieties of gum, the best being the Kauri gum from New Zealand. The reason for the large number of varnishes is the large variation of uses to which varnishes are put. For instance, a piano is not expected to stand the same exposure as a motor car. The difference between an inside and an outside varnish is largely in the percentage of oil; a rubbing varnish must contain much less oil.

For floor varnishes, China wood oil is largely used, as it dries much harder. Shellac varnish is made of shellac gum, a gum formed by an insect in India, dissolved in alcohol; it is not soluble in oil, and is turned white by contact with water.

General

Mr. Doyle claimed that reinforcing steel, either in the way of structural shapes or bars, should be painted before being encased in concrete; that if corrosion sets in beforehand the expansion of the oxide of iron formed has been known in cases to be sufficient to crack the concrete. A further advantage of the painting of the reinforcement is claimed to be the insulation from electrical currents, thus preventing electrolysis.

Though not connected with actual engineering work, the development of nitro-cellulose lacquers was mentioned by Mr. Doyle, who explained that, originally used for the treatment of aeroplane wings, a commercial market had been sought for them. Owing to the extremely volatile character of the solvent, such as amyl acetate, they had to be applied by spraying, and that while such lacquers are now produced for brushing on, they are rather in the experimental stage, there not having been enough time to prove their lasting qualities. The advantage of these lacquers is that a motor car, for instance, can be given several coats in a day compared to the length of time required to dry each coat otherwise.

Coming to the application of paint to wood, it was pointed out that new wood would absorb about 30 per cent of the oil in the paint, so that for the first or priming coat, about 25 per cent more oil should be used; for the second coat, less oil and some turps, in order to flatten down the surface, and for the third coat a larger percentage of oil, to give a durable finish. On iron or steel, however, there is no absorption, and therefore less oil is needed; the first coat should be of red lead, which is non-corrosive, and the hardest drying pigment known. For further coats, graphite paint is best, as it has no action on the oil.

He pointed out that they had been experimenting with various coloured paints in regard to the heat reflection for tanks, and found that the temperature with black paint rose to as much as 30° to 40° above that with a white paint, and that was the reason that oil tanks, for instance, should always be painted a light colour.

Mr. Doyle also dealt briefly with marine paints and other points of interest.

ANNOUNCEMENT OF MEETINGS

Information may be secured from the secretaries of the various Branches, whose addresses will be found under "Officers of Branches" on page 494 of the Journal.

MONTREAL BRANCH

Secretary-Treasurer, C. K. McLeod, A.M.E.I.C.

Dec. 9th: Symposium of Municipal Papers, by G. R. MacLeod, M.E.I.C., and P. E. Jarman, M.E.I.C.
Dec. 11th: Annual Meeting.

VANCOUVER BRANCH

Secretary-Treasurer, E. A. Wheatley, A.M.E.I.C.

Dec. 15th: Annual Meeting.
Jan. 5th: Address on "Engineering Education—The Development of an Engineer's Education," by E. E. Brydone-Jack, M.E.I.C.
Jan. 12th: Address on "The Mines of the Province," by J. D. Galloway, Esq.
Jan. 19th: Address on "Oscillographs," by Dr. H. Vickers.
Jan. 26th: Address on "Mountain Roads," by W. G. Swan, M.E.I.C.

OTTAWA BRANCH

Secretary-Treasurer, F. C. C. Lynch, A.M.E.I.C.

Dec. 9th: Address on "Thermit," by Prof. H. T. Barnes, M.E.I.C.
Dec. 16th: Luncheon.
Jan. 13th: Luncheon.
Jan. 13th: Annual Meeting.
Jan. 20th: Annual Ball.

The Coventry Company, Reg'd., have removed their Toronto Branch Office to the Otis-Fensom Building, at 170 Bay Street, where larger and more commodious quarters are provided. The telephone number, Elgin 4795, remains the same.

B. J. Coghlin Co., Limited, announce the enlargement of their plant in Montreal. The addition to their manufacturing plant, which will provide for double their present capacity, will be ready early in the new year.

BOOK REVIEWS

Elements of Heat-Power Engineering

Barnard, Ellenwood and Hirschfeld. Part I. John Wiley & Sons, Inc., New York, 1926. Cloth, 6 by 9½ in., 493 pp., diagrs. $4.50.

The new edition of the well-known text by Hirschfeld and Barnard is substantially a new book. The subject matter has been entirely re-written and expanded to two volumes, of which the first relates primarily to thermodynamics and the elementary principles of prime movers.

A brief summary will indicate the scope of Part 1.: Energy and its transformation, availability, reversibility, entropy; properties and thermodynamic processes of gases and vapors; compressed air; gas cycles; mechanical features, operation, power and performance of internal combustion engines; simple vapor cycles; reheating, regenerating and binary vapor cycles; steam engines and turbines. Numerous diagrams are employed and these are uniformly well executed and form a valuable feature.

The treatment is logical and sound and reflects the mature experience and broad viewpoint of the authors. In the opinion of the reviewer the book should take its place as a standard text-book and work of reference, useful alike to the student and practising engineer.

A. R. Roberts, A.M.E.I.C.

Metal-Plate Work

C. T. Millis, E. and F. N. Spon, London, 1926. Cloth, 5 x 7 in., 503 pp., diagrs. 7/6.

In this volume the geometrical constructions required in the laying-off of sheet-metal work are described and illustrated. They are arranged in the form of exercises carefully graded from the simplest to the most complex and include patterns for articles of equal and unequal taper and for miscellaneous articles such as elbows, mouldings, etc.

The ready solution of difficult problems in setting out patterns will be appreciated by all sheet-metal workers.

A. R. Roberts, A.M.E.I.C.

Coal and Ash Handling Plant

John D. Troup, Editor, 'Engineering and Boiler House Review,' Chapman & Hall, Limited, London. First Edition, 1926, 5¼" x 8½", 146 pages. 13/6.

A comprehensive review and general description of the different equipment used for handling coal, ashes and refuse in boiler plants. The book deals particularly with English practice and some of the apparatus, such as the coal car tipplers described, are of course not applicable to service on the American Continent.

A large number of excellent photographic illustrations are included and the subject is dealt with in a very interesting manner. The scope is indicated by the chapter headings:—

Handling Coal on Delivery
Automatic Coal Weighing
Coal Storage
Coal Conveyors
Ash Handling Plant
Aerial Ropeway Conveyors
Flue Dust Removal Plant
Recovering Unburnt Fuel.

Particular reference may be made to the chapter on Recovering Unburnt Fuel, the possibilities of which are dealt with.

F. A. Combe, M.E.I.C.

Draft and Capacity of Chimneys

J. G. Mingle, C.E., D. Van Nostrand Company, New York, 1925. First Edition, 5¼" x 7¾", 340 pages. $3.50.

The subject matter of this book was published serially in the technical periodical, "Combustion," during 1924 and 1925. The stated aim of the author has been to review the data available regarding the proportioning of chimneys for power plants and to deal with the matter more fully than has been done heretofore in view of the importance of proper design, especially in connection with large, modern steam stations.

The recognized chimney formulæ are given and developed in an elementary, theoretical manner with curves and tables to illustrate the effect of the different factors which enter into such calculations.

The subject is treated very fully, and the book may be of interest to those who wish to analyze any particular case or to become familiar with the general principles. At the same time, there are so many conditions which have to be assumed, and so many variables which affect the draft and capacity of chimneys under 'natural draft,' in addition to the importance of providing for change in fuel or method of burning, or for possible increased output from the boilers, that, in determining the most suitable diameter and height, one must allow a considerable 'factor of safety' or allowance over the sizes theoretically arrived at. Usually also, the question of cost is one which must be taken into consideration.

As a matter of fact, modern large boiler plants almost invariably include some heat recovery apparatus, such as economizers or air preheaters which necessitate the use of induced draft fans, which may be arranged to discharge through short stacks or into chimneys of sufficient height only to carry the gases above the point of nuisance. In such cases, an entirely different problem is presented, the fan then being designed to take care of the draft requirements, while the chimney is not working under natural gravity laws.

F. A. Combe, M.E.I.C.

Corrosion, Causes and Prevention, an Engineering Problem

Frank N. Speller. McGraw-Hill Book Co., New York, 1926. Cloth, 6 x 9½ in., 588 pp., illus., diags., $6.00.

To quote from the preface "the aim has been to combine in this volume a useful reference book for those who are interested in the many phases of this problem and a handbook for the engineer and architect who may desire only a practical knowledge of the developments in prevention of corrosion. The subject matter has been written with particular reference to the ferrous metals."

The book is divided into two parts. Part I—General Principles; Part II—Preventive Measures. The first part includes a chapter on the theories of corrosion in which the author justly and strongly favours the electrochemical theory. This chapter may be a little difficult for the engineer, although the subject is well presented.

The second part, Preventive Measures, should appeal strongly to anyone with a practical interest in corrosion. It includes among others, chapters on the Prevention of Corrosion in the atmosphere, under water, in the steam plant, and underground.

The book is well written, up to date and subject matter admirably presented. Many references are given for those requiring further information. There is a good index.

Any engineer with a corrosion problem to solve will find this book almost indispensable.

F. M. G. Johnson.

BRANCH NEWS

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

Unfortunately, the opening meeting of the lecture season had to be postponed owing to the illness of the speaker, Mr. James W. Davidson, F.R.G.S., who was to have given a talk on "The Head Hunters of Formosa." This postponed meeting is now arranged for December 6th.

Some Problems of Water Power Development

On November 1st the first meeting of the season took place with J. H. Ross, A.M.E.I.C., in the chair. The secretary read the minutes and the report of the activities of the Branch since the annual meeting in the spring. F. J. Robertson, A.M.E.I.C., general superintendent of the Calgary Power Company, the speaker of the evening, gave a most interesting address on "Some Problems of Water Power Development and Operation." One pleasing feature was the manner in which the speaker explained in sequence the progressive steps of water power control and development.

He commenced by explaining the necessity of a careful survey of the conditions in connection with probable power markets; the nature of the expected power load; and fluctuations in load from season to season; continuing, he referred to the preliminary investigation necessary in the selection of a suitable site for a storage dam, together with alternative sites; the final selection of the most promising site, and the choice of the type of dam. He then referred to the investigation of probable cost of transmission lines, and whether one or more line would be necessary, and in the case of towns being supplied he advocated a minimum of two lines. In connection with the design of the power plant, he explained in detail the necessary investigation to determine the available head and the importance of long-time records of run-off on which to base the estimate of available water supply. He went on to state that the average minimum flow over low water periods should be averaged over a number of years. The question of possible storage reservoirs and pondage were also dealt with, and in referring particularly to the dam site investigations, he said that drill holes should be put down and cores carefully examined to determine whether any rock fissures or faults exist.

Referring to the construction of earth dams, he explained the necessity for a masonry spillway to take care of flood conditions, and also touched on such details as provision, ice and driftwood; design of flashboards; use of syphons; and the design of pipe lines, flumes, or headrace channels. A detailed explanation of the use of surge tanks was given, followed by a discussion of various types of hydraulic turbines and water wheels and the various electrical equipment of the plant. In connection with the electrical installation, the speaker explained the wonderful advances that had been made in recent years with the aid of relays to operate switches, pointing out that a modern plant can be practically automatic in operation.

In conclusion, Mr. Robertson related some of his experiences during his recent visit to San Salvador, Central America, in the interests of the Montreal Engineering Company. He gave an interesting résumé of conditions in that country, referring particularly to the ambitious road-making policy. He mentioned the golden opportunity that exists for Canadian manufacturers and financiers to create beneficial trade relationship. The impression gained throughout the address was that Mr. Robertson knew his subject from A to Z, and his audience listened to an address that was well worth while from every point of view.

A vote of thanks was very suitably phrased by A. G. Graves, Commissioner of Calgary, and seconded by A. L. Ford, M.E.I.C. Chairman J. H. Ross also voiced the thanks of those present in suitable terms.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

The opening meeting of the season was held on October 26th in the Y.M.C.A. banquet hall, and was marked by one of the most enthusiastic and largely attended gatherings since the formation of the branch. Following the supper the chairman, A. S. Gunn, A.M.E.I.C., introduced the speaker of the evening, K. L. Dawson, A.M.E.I.C., superintendent of the gas plant of the Nova Scotia Tramways and Power Company, Halifax, N.S., who gave a highly instructive address on "Coal and Other Fuels Derived Therefrom."

COAL AND OTHER FUELS DERIVED THEREFROM

Coal, declared Mr. Dawson, is, and for many years to come will continue to be, our principal source of fuel supply. Wood as a fuel is no longer used. Our oil reserves are being depleted with alarming rapidity. Even water power has its limitations. It is said that if manufacturing conditions in Ontario were normal, steam generating plants would have to be erected, or else the use of hydro would have to be curtailed.

The burning of bituminous coal is unfortunately accompanied by the smoke nuisance, due to failure to ignite the volatile gases which are given off. In the case of household use, this cannot be avoided. In the large centres, where bituminous coal is used, it is estimated that the annual additional cost of laundrying clothes is twenty dollars per person. Cities that can obtain coke and gas, (the two clean and smokeless fuels obtained from soft coal), are indeed lucky. It is interesting to note that the use of gas, in Halifax, has doubled within the past fifteen years, and that the Tramways Company has not the slightest difficulty in disposing of its coke.

The speaker described the manufacture of gas and coke, and illustrated the process by means of a miniature gas plant. This process consists in separating the coal into its two main constituents, gas and coke. The burning of these two constituents, as fuel, separately, is much more economical than burning them together in the original state as coal, for the reason that no fuel is wasted in smoke.

Mr. Dawson was not very optimistic as to the erection of coking plants in Montreal and other large cities unless a market could be found for the gas that is produced when coke is manufactured.

Another by-product of coke and gas manufacture may be mentioned, viz., tar, from which many useful substances are derived. Chief among these are oils used in driving gas and oil engines, ammonia, aniline dyes, and last but not least, the humble moth ball.

At the close of the address a vote of thanks was tendered Mr. Dawson by the chairman.

During the evening enjoyable vocal selections were rendered by Mr. Geo. C. Davidson, and clarinet solos by Dr. Fred E. Burden.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, Jr.E.I.C., Branch News Editor.

The first meeting of the Hamilton Branch, for the season 1926-1927, was held on October 20th, 1926, in the Hamilton Chamber of Commerce Rooms, with an attendance of 24.

The following officers were elected for the ensuing season:—

Chairman	L. W. Gill, M.E.I.C.
Vice-Chairman	W. L. McFaul, M.E.I.C.
Secretary-Treasurer	W. F. McLaren, M.E.I.C.
Branch News Editor	J. R. Dunbar, JR.E.I.C.
Executive	H. A. Lumsden, M.E.I.C.
	G. R. Marston, A.M.E.I.C.
	F. P. Adams, A.M.E.I.C.
	A. H. Munson, A.M.E.I.C.
Members Emeriti	C. J. Nicholson, A.M.E.I.C.
	H. B. Stuart, A.M.E.I.C.

After routine business was transacted, J. J. MacKay, M.E.I.C., gave a very interesting talk on proposals for a scenic development of Hamilton and its surroundings, including harbour plans. Following this W. L. McFaul, M.E.I.C., presented a plan and explained the details of the proposed $567,000 extension of the Hamilton water works. He dealt also with the necessity for a considerable extension of the sewage system. Both talks were not only interesting but very instructive.

EXECUTIVE COMMITTEE MEETING, NOVEMBER 9TH, 1926

A meeting of the Executive Committee of the Hamilton Branch was held on November 9th, 1926, in the office of the chairman, L. W. Gill, M.E.I.C., in the Hamilton Technical Institute.

Besides the chairman, W. F. McLaren, M.E.I.C., secretary-treasurer, and four other members of the executive were present.

The following committees were appointed:—

Papers	H. A. Lumsden, M.E.I.C. (*Chairman*)
	E. H. Darling, M.E.I.C.
	J. A. McFarlane, M.E.I.C.
	H. S. Philips, M.E.I.C.
	F. P. Adams, A.M.E.I.C.
	D. W. Callander, Branch Affiliate.
Membership	H. B. Stuart, A.M.E.I.C. (*Chairman*)
	F. H. Midgly, A.M.E.I.C.
	H. G. Bertram, M.E.I.C.
	J. J. MacKay, M.E.I.C.
Entertainment	Arthur Munson, A.M.E.I.C. (*Chairman*)
	W. D. Black, A.M.E.I.C.
	A. R. Hannaford, A.M.E.I.C.
	A. M. Jackson, A.M.E.I.C.
	R. J. Clench, S.E.I.C.
	O. W. Titus, A.M.E.I.C.
Publicity	J. R. Dunbar, JR.E.I.C., (*Chairman*)
	F. I. Ker, A.M.E.I.C.
	E. M. Coles, A.M.E.I.C.

In each case the committee has power to add to its numbers and the chairman is to report to the executive for his committee.

Several excellent suggestions for papers were handed to the chairman of the Papers Committee. These included papers of all branches of engineering which are of interest to members of the Hamilton Branch.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
H. W. B. Swabey, M.E.I.C., Branch News Editor.

The fall programme of meetings was opened on Thursday, October 7th, when a paper was read by H. R. Wake, A.M.E.I.C., on the Arvida Townsite. Mr. Wake is the town manager in charge of this new town in the Lake St. John district, which is being developed in connection with the large works of the Aluminum Company of Canada, at present under construction. The townsite is planned for an ultimate population of thirty to forty thousand.

The description given in this paper illustrates how rapidly a modern townsite can be developed with up-to-date machinery, under proper engineering management and supervision.

ENGINEERING FEATURES IN BREAKING THE ALLEGHENY ICE GORGE

On October 14th an interesting description was given by Dr. H. T. Barnes, M.E.I.C., of the breaking up of the ice gorge in the Allegheny valley last spring. This great feat was carried out under the supervision of Dr. Barnes by the use of Thermit.

In the discussion on Dr. Barnes' paper, Dr. R. A. Ross, M.E.I.C., took part, and referred to the work accomplished by Dr. Barnes in the Allegheny valley as an outstanding performance by "an Eskimo from Canada in enlightened America."

Major Geo. A. Walkem, M.E.I.C., the president of the Institute, was present at this meeting, and was given a cordial welcome by the branch. Previous to Dr. Barnes' lecture, he gave a short address describing his recent tour across the Dominion, during which he visited most of the branches of the Institute.

A vote of thanks to the speaker of the evening was proposed by Major Walkem.

The hall was crowded for this meeting, which was under the chairmanship of C. J. Desbaillets, M.E.I.C.

MANUFACTURE OF CARBIDE

The branch was fortunate in having a most interesting lecture on this subject by R. A. Wetherspoon of the Canadian Carbide Company, on October 21st. A history of the industry was given, with a description of the most recent developments in electric furnaces for the manufacture of calcium carbide, illustrated by plans and sketches. Dr. A. Stansfield, M.E.I.C., was chairman at this meeting.

SPECIAL GENERAL MEETING

On October 28th, before the regular meeting, a special general meeting was held, with C. J. Desbaillets, M.E.I.C., in the chair, at which three members were appointed to the Nominating Committee for the nomination to the Executive Committee for 1927.

BEARING METAL BRONZES

After the special general meeting on October 28th, Mr. H. J. Roast, of the Society of Chemical Industry, read a paper on the subject of Bearing Metal Bronzes. This paper was under the joint authorship of Mr. Roast and F. Newell, M.E.I.C., chief mechanical engineer of the Dominion Bridge Company. The paper embodies the results of a great deal of research work by the authors, on bronzes for bearing purposes.

Eleven typical bronzes were discussed and illustrated by lantern slides taken from photo-micrographs of specimens under discussion, showing the structure of the metal before and after heat-treatment. Several microscopes were set up on a table in order to give those present the opportunity of examining the original specimens of bronze described in the paper.

Copies of a data-chart were distributed, giving particulars of the chemical and physical properties of the bronzes under discussion.

The American Railway Engineering Association and its Work

At a meeting on November 4th, under the chairmanship of D. Hillman, M.E.I.C., J. G. Armstrong, M.E.I.C., assistant engineer of the Canadian Pacific Railway, read a paper describing the work and giving a history of the A.R.E.A. from its inception in 1899. The author explained the workings and value of the association now recognized by all railways throughout the world. He described the wide range covered by the information given in the association's Manual, covering specifications for track material, to those for the grading of a railway; economics of the location of a railway to the economics of railway operation.

In 1900 the association had a membership of 280, which has risen to 2,300 at its 27th annual convention in the present year. The author described how the work of the association is carried on by twenty-three standing committees divided into sub-committees, handling special assignments.

During the discussion Mr. Gardener, assistant engineer of the Montreal Tramways, gave some information in regard to the operations of the American Electric Railway Engineering Association, which carries out very similar functions to the A.R.E.A. in connection with electric railways.

R. V. Look, AFFILIATE E.I.C., president of the Canada Creosoting Company, and O. C. Steinmayer, M.E.I.C., superintendent of treating for that company, were amongst those who took part in the discussion.

Manufacture of Kraft Pulp

A very creditable paper was read on November 11th by J. B. Phillips, fourth-year chemical engineering student of McGill University, on the manufacture of pulp for paper, with special reference to the kraft process.

The speaker gave a description of the process of manufacture of kraft pulp, dealing particularly with the sulphate method of cooking the wood. He mentioned that the word *kraft* is Swedish for *strong*, and that paper made by this process is brown in colour, as in the case of most wrapping papers. Fibre boards are also made from kraft pulp.

Mr. Phillips referred to the manufacture of paper from a variety of plants, such as flax, indian corn, pineapple leaves, straw, etc.

The paper was of a highly technical nature, involving a great deal of study and investigation into the methods of pulp-making.

Professor Goodwin of Queen's University, and E. P. Cameron, A.M.E.I.C., of the Forest Products Laboratory, were amongst those who took part in the discussion. H. L. Johnston, Jr. E.I.C., was chairman.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

Engineering in Peru

In accordance with a policy suggested by Chairman Alex. Milne, A.M.E.I.C., whereby branch members are to present a series of papers on technical or semi-technical subjects, J. C. Street, M.E.I.C., of Welland, described an engineering jaunt to the interior of Peru for the Foundation Company of New York. A number of lantern slides were shown giving a good idea of the nature of the country, types of inhabitants, buildings and works of engineering interest.

Mr. Street reached the Port of Callao in June, 1920, via the Panama canal, and was almost immediately taken to police headquarters. (He explained that this was merely to have his papers examined and a photograph taken at the expense of the State.) However, upon his liberation, he departed hurriedly in an easterly direction for less civilized portions of the country.

The work upon which he was at first engaged was the Yanamayo hydro-electric project on the Oyon river, remarkable on account of the proposed head under which the power was to be developed. Twenty-five thousand horse-power were to be developed under a head of 1,200 feet, utilizing 245 c.f.s. of water and requiring a storage of 22,000 acre-feet.

This work was all at high altitudes, 13,000 to 16,000 feet above sea level, and breathing for the normal person was somewhat difficult. Doctors accompanied the trains which ran into the interior and attended to the many passengers who were overcome with mountain sickness. Some of these passengers were unable to stand the strain and had to be taken off the trains and returned to Lima.

The natives, although short of stature, have a tremendous chest and lung development and experienced little difficulty in breathing the rarefied air.

There is little or no rainfall in the coastal region of Peru visited by Mr. Street. Lima is practically without vegetation other than that grown by means of irrigations, and the uplands, or pampas, are little better, although grass grows and is excellent for sheep raising.

One of the main difficulties was the question of supplies. Most of these had to be packed in from the nearest railway station on the backs of small burros and the natives were not particularly honest. Kodak films appeared to be a great temptation and, whether by design or accident, very few reached the party.

Then before the preliminary surveys were fully complete the Yanamayo project was abandoned. Due to new mineral discoveries in another part of the world altogether, and to improved metallurgical treatments of vanadium ores it became commercially impracticable.

Mr. Street returned to Lima. This time he was unmolested and allowed to work in peace for the better part of a year on paving and street improvement contracts which the Foundation Company had secured. Lima is a wonderful city and the smells, fleas, open sewer troughs or gutters, etc., are fast becoming a thing of the past. It is noted for its old adobe buildings and churches; some of the latter dating back from two to four hundred years; together with their carved woodwork and interior decoration, existing in an almost perfect state of preservation, due to the dry state of the atmosphere.

The adobe construction, local mud, water-tamped into oblong forms about 10 by 20 by 24 inches, is still used extensively although a few concrete buildings are apparent. Adobe is a good non-conductor of heat and will last indefinitely under the local conditions.

Peruvian civil engineers are few in number and some are not very conversant with concrete design. One building foundation that Mr. Street noticed had a surplus of reinforcing steel embedded in the concrete,—1¼ inch round bars at about 12-inch centres both vertically and horizontally, but this steel had been placed in the compression side of the walls and consequently when the backfill was made the structure collapsed.

The supply of drinking water for the city of Lima is, and always has been a problem. The Rimac river rises in the foot hills of the Andes and is quite intermittent in flow. Combined with the fact that it also furnishes irrigation for some of the intervening country, by the time it reaches Lima the supply is not very satisfactory.

Attempts were made to cut parallel side ditches and tunnels with the idea that the water would filter through a glacial strata of lime cemented gravel and boulders, but this strata quickly clogged up with sediment and the flow gradually diminished. Now a new filtration plant is in process of construction and will undoubtedly do away with the epidemics of typhoid which were of such frequent occurrence.

This lecture was given on October 20th, 1926, at St. Catharines, after a dinner meeting at the Welland Inn, and following Mr. Street's remarks S. R. Frost, A.M.E.I.C., proposed a vote of thanks and this was heartily endorsed by the meeting.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

There was a large attendance of the Ottawa Branch members at the first luncheon of the season, held in the Chateau Laurier on October 28th, when N. F. Parkinson, A.M.E.I.C., Deputy Minister of the Department of Soldiers' Civil Re-establishment, spoke on the subject of "Duralumin," with particular reference to the use of this metal by the Canadian Government in the manufacture of "all metal" artificial limbs.

Duralumin

If any members of the Institute entertained a thought that engineering skill did not enter largely into the manufacture of artificial limbs, such idea was rapidly dispelled as the speaker traced the research work on materials and the experiments which finally led to the fashioning of the present all-metal limbs which not only have brought comfort and happiness to hundreds of the unfortunate amputation cases resulting from the war, but have been an important factor in their complete re-establishment.

In speaking of the properties of duralumin as utilized in the construction of artificial limbs, Mr. Parkinson stated that it combined lightness, high tensile strength, high elastic limit and high resistance to shock. He outlined the features of the design of the all-metal limbs, comparing their practical utility and long life with wooden limbs, demonstrating the various points with samples which were passed among the members for inspection. The members marvelled at their lightness, less than half the weight of wood in some models; at the excellent design of the joints which permitted almost natural articulation, and at the care which was bestowed in modelling each limb to take care of the peculiarities of each individual case with a precision which could not be accomplished with wood. Duralumin could be readily beaten out to any desired shape. The speaker also dwelt at some length on the tests which had determined the exact proportions of aluminum and steel to give the alloy best suited to resist corrosion, and to have the requisite strength and malleability, resulting in the production of a highly polished and durable article which would provide a maximum of comfort and freedom from the inconvenience formerly necessary when the old wooden limbs had to be replaced, due to wearing out.

Mr. Parkinson disclosed the fact that the total number of amputation cases resulting from war service was 3,175, and remarked that the metal artificial limbs were being manufactured in Canada by ex-soldiers at the department's limb factory in Toronto. He paid high tribute to the sympathetic understanding of Hon. Dr. Beland, who, as former Minister, had greatly assisted the work of developing proper appliances.

J. D. Craig, M.E.I.C., chairman of the Ottawa Branch, presided, and at the conclusion of Mr. Parkinson's address conveyed the thanks of the Branch for his interesting talk on the use of duralumin in a highly important and humanitarian work.

Patents

On November 18th an Ottawa Branch member was the speaker at the luncheon held in the Chateau Laurier. Alex. E. MacRae, A.M.E.I.C., spoke on a subject of great interest to engineers—"Patents."

A patent grants a limited monopoly, Mr. MacRae said. In the reign of King James I. a statute was passed substantially prohibiting monopolies, which had been so prevalent at the time, but making an exception, which proved of incalculable importance, in granting a limited monopoly to " the true and first inventor " of " any manner of new manufacture within this realm."

The principle of patent law is to stimulate invention and encourage development of new industries. The American patent system has been held to be the greatest factor in the industrial development of the nation. Without patent protection progress in industry would be greatly retarded, for the industrialist could not afford to spend time and money in the development of a new enterprise or installation of new methods, knowing that his neighbour or competitor could immediately utilize his experience without restriction. Patents are thus essential to industrial development and are perhaps the most constructive force in our economic life. In the present day large industrial corporations maintain their own corps of inventors and their inventions are promptly patented.

To be patentable in Canada, Mr. MacRae said, a thing must be new the world over, and useful, and the result of invention. The requirement of utility usually needs little consideration as most, if not all, real inventions are useful to some degree. Applications for patent for perpetual motion machines, however, which are not altogether uncommon, usually fall before this requirement in the hands of the patent examiner. A theory or mere scientific principle is not patentable, but the process or means for applying the theory or principle to practical use is patentable. Many engineers, as well as lawyers and others, showed a lack of understanding in drawing up patent applications. Instead of details, what was required was a broad statement which would limit the use of the principle patented in its application in the arts and industries.

The speaker dwelt at some length on the provision embodied in the 1923 Patent Act relating to inventions made by persons in the public service. He maintained that the right of a public servant to patent his invention made in the course of his investigation or research resulted in great benefit to the public, as well as to the individual. The Commissioner of Patents has rights to grant license to use such invention on terms fixed by him, determining the amount payable to the government and to the inventor, but in no case shall the latter receive less than half of what would have been his had he not been a public servant. If the privilege of patenting the improvements in processes or machines developed in government research was not exercised there was great danger that patents covering the same would issue to outsiders, perhaps even citizens of foreign countries, and that Canadians would be called on to pay prohibitive prices to utilize the fruits of work carried on with public money.

A. F. Macallum, M.E.I.C., past chairman of the Ottawa Branch, presided in the absence of J. D. Craig, M.E.I.C., through indisposition, and conveyed the thanks of the meeting for an able address on a subject of great interest to engineers.

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

At the regular meeting of the Branch on October 28th, 1926, the speaker was Mr. W. Flavelle, of Lindsay, Ontario, whose subject was " The Life of Sir Wm. Van Horne and the Construction of the Canadian Pacific Railway." This was an historical and descriptive address of great interest, commencing with the original necessity for a transcontinental railway after Confederation, and dealing particularly with the tremendous difficulties in finance and engineering which had to be overcome.

The necessity for such a line of communication was emphasized when in 1870 the young Dominion found itself with the task of crushing the Riel rebellion, and the fact that it took 95 days to transport troops from Toronto to Winnipeg.

The incorporation of British Columbia into the Canadian Confederation in 1871 was on the express stipulation that the Dominion within two years would begin, and within ten years complete, a railway linking the new province with eastern Canada.

Reference was made throughout the address to the many illustrious engineers, financiers and politicians who took part in the work, —Sir John A. Macdonald, Sanford Fleming, George Stephens, R. B. Angus, Sir Charles Tupper, Sir Wm. Van Horne,—to mention only a few.

Of all these, the speaker singled out Sir Wm. Van Horne, the first general manager and president of the C. P. R., for the highest of praise and admiration for his great mental and physical power. When he was selected as general manager it was said of him that " He will take all the authority he gets, and more, so advise how much you want him to have."

Van Horne arrived in Winnipeg on December 31st, 1881, when the temperature was 40° below zero, and began his work in temporary quarters. His welcome had some of the chilliness of the Manitoba frost, but he was not the man to be deterred by this, and it was not long before he had won the admiration and co-operation of his fellow workers.

His proposition to build 500 miles of track in the season of 1882 was held to be ridiculous, but during that year 620 miles of line were located, 508 built, 807 miles of telegraph line, 30 station houses, and some score of other buildings erected.

Later on came the difficult Rocky Mountain section, and the north shore of lake Superior. As these engineering difficulties were overcome, the financial ones increased, and there were many critical stages for the company when only the strength and faith of such men as Van Horne pulled them through.

On November 7th, 1886, track layers met at a spot in Eagle Pass in the Selkirks, and here in the presence of Van Horne and many others of the company's officers and engineers, the last spike was driven, so linking Montreal with the Pacific, and adding a great imperial highway to the advantage and glory of the Empire.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

Coal and Other Fuels Derived From It

The members of the Saint John Branch, were addressed on October 27th, 1926, by K. L. Dawson, A.M.E.I.C., of Halifax, N.S., speaking on " Coal and Other Fuels Derived from It." An interesting feature of Mr. Dawson's talk was the demonstration with laboratory apparatus of the manufacture of coke and gas. Several samples of coal were experimented with and the advantages in coking properties obtaining in some fuels over others shown by actual demonstration.

Touching on the smoke nuisance in cities the speaker declared much of it, in addition to showing a waste of fuel owing to poor combustion conditions, was also unnecessary. Statistics were quoted from London and Glasgow showing the deposits of carbonaceous materials from smoke were heaviest in the residential and office-building sections of the cities, rather than the popularly-accepted belief that factory districts are the worst sections. The speaker explained that by the fact that more attention is paid to proper firing and burning of fuel in the factory where the enormous waste is realized. It is largely from the many small fires in private houses and business blocks that the smoke screen seen over any city originates.

The monetary loss from unnecessary smoke is realized when the cost of extra laundry work, paint to renovate smoked walls and woodwork, and for cleaning materials, is taken account of, without considering the matter of health. Most of the stoves and furnaces waste 60 to 70 per cent of the fuel; the average steam plant from 35 to 40 per cent, while the best steam plants waste about 20 per cent.

The waste in burning raw coal was plainly shown, and the advantage of coke explained with the possible recovery of so many valuable by-products. In making coke there is also obtained gas for domestic use and for further re-heating the coke, for domestic fuel and metallurgical purposes, tar, also valuable liquids, benzol, tuluol, creosote, carbolic acid, etc., which are necessary in dye and explosion industries and so important in pharmaceutical and photographic trades. Coal made into gas and coke is changed into products worth three times as much as in their raw state and in Canada provides work annually for 4,000 men receiving $6,000,000 annually in salaries, and represents an investment in plant of at least $50,000,000.

An interesting feature of the meeting was the discussion on this subject. Almost every one present wanted to relate his experiences in using some particular fuel in stove or furnace and tell how much it cost him, and then to ask what the matter was. Every one was interested in a matter affecting the pocket-book and asked Mr. Dawson many questions which he ably answered.

Geoffrey Stead, M.E.I.C., moved a vote of thanks, seconded by J. D. Garey, A.M.E.I.C., and this was tendered to Mr. Dawson by A. R. Crookshank, M.E.I.C., who acted as chairman of the meeting.

Survey of Civic Administration

The City of Saint John has contracted with the Citizens Research Institute of Canada under Dr. H. L. Brittain to make an examination of form of government, assessment, taxation, departmental organization, engineering services, and accounting systems at present in vogue. Assisting Dr. Brittain in this work will be an engineer, lawyer and accountant. William Storrie, M.E.I.C., of Gore, Nasmith and Storrie, consulting engineers, Toronto, is engaged on this work. The Mayor and Commissioners form of government is at present in operation in Saint John.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

The October meeting of the Saskatchewan Branch was held at the C. P. R. banquet hall, Moose Jaw, on October 20th, 1926. A large number of the Regina members took advantage of the pleasant evening and the good roads and motored to Moose Jaw, where they were joined by members from Moose Jaw. Guests included Mr. S. P. Grosch of Regina, newly appointed chairman of the local government board of the province, and Mr. Fraser Stewart, city solicitor of the city of Regina. John G. Hall, A.M.E.I.C., representative of the Combustion Engineering Corporation, was also present and conveyed greetings from the Winnipeg Branch of the Institute.

A special committee composed of members from Moose Jaw had charge of the arrangements. The meeting opened with a sumptuous banquet, followed by the toast to The King. Mr. Jack Brooksbank and Mr. "Dutch" Macpherson delighted the audience with suitable songs.

Past-Chairman G. D. Mackie, M.E.I.C., and J. R. C. Macredie, M.E.I.C., both of the city of Moose Jaw, were presented with past-chairmen's badges, consisting of gold membership pins. R. N. Blackburn, M.E.I.C., also a past-chairman, spoke of the service which each of these members had rendered to the branch, in making the presentation. Mr. Mackie replied in a humorous vein and thanked the branch for the recognition thus taken of his service as chairman. While the past few years had been none too rosy for the engineers in this province, he prophesied a brighter outlook for the future. Engineers, he stated, should aim to assist in the development of agriculture, our dominating industry. Mr. Macredie suitably expressed his thanks to the Branch for the honour conferred upon him and stated that the year he had spent as chairman of the branch had been a most enjoyable one.

Sewer and Water Conditions in Saskatchewan

R. H. Murray, A.M.E.I.C., sanitary engineer for the province of Saskatchewan, read a paper on "Present Sewer and Water Conditions in Saskatchewan," in which he outlined briefly the work of the department with which he is connected. He spoke of the extension and development of sewer and water services in urban centres in the province and the costs of installations to date. He referred to recent changes in the Public Health Act empowering municipalities to enforce householders whose property is served by sewer and water mains to connect their houses thereto, and the action of the city of Saskatoon in enforcing the act in this connection.

The cities of Saskatoon and Prince Albert have no sewage disposal works and the sewage is discharged into the South Saskatchewan and the North Saskatchewan rivers respectively. Owing to the fact that there are no urban centres within the zone where the polluted river water reaches there has as yet been no urgent demand for the construction of these works, but it is anticipated that these will be required in the near future. The only new sewage disposal plants constructed in the province since the war are those at Gravelbourg and Shaunavon and the plant at Melfort, which has been entirely remodelled.

At Shaunavon and Melfort the activated sludge system of sewage disposal has been installed, and although these plants have been operating only a comparatively short time they are both giving very satisfactory effluents. Shaunavon enjoys the distinction of being the only municipality in the province which has a sewerage and sewage disposal system and yet has no watermains in the town. The explanation is that practically every householder has his own private well and there is no demand for water to be laid down for domestic purposes.

The discussion on Mr. Murray's paper was led by J. W. D. Farrell, superintendent of waterworks for the city of Regina, who quoted figures showing the number of services per mile of watermains in Saskatchewan cities as compared with cities in the United States. Regina has an average of 91, Saskatoon 70, Moose Jaw 76 and Prince Albert 36 services per mile, while the average in the American cities is about 100 per mile. Amongst the towns, Biggar has 88, Indian Head 60, Melfort 26, Melville 26, Swift Current 41, Weyburn 41 and Yorkton 63. In the three larger cities of the province the population per connected service is from 6 to 8. In the smaller towns the per capita consumption of water is from 8 to 11 gallons, and in the larger cities and towns as follows:—Moose Jaw 43, Prince Albert 87, Regina 68, Saskatoon 60, Swift Current 125, Estevan 173. In Regina the number of installed services in use compared with the total installed services increased from 59 per cent in 1919 to 70 per cent in 1926. In 1919 there were in Regina 69 services per mile of watermains and in 1926, 96 services per mile.

Mr. Mackie also discussed Mr. Murray's paper. He referred to the fact that the cities in Alberta use on an average 100 gallons per capita as against an average of 36 gallons per head in the cities in Saskatchewan, the larger amount used in the Alberta cities being no doubt due to the larger number of rivers as sources of water supply in that province. He stated that the cities in Saskatchewan must obtain their water supply from visible sources or they will not grow in population.

The Growth of Industrial Power in Saskatchewan

J. D. Peters, A.M.E.I.C., electrical superintendent of the city of Moose Jaw, gave an address on "The Growth of Industrial Power in Saskatchewan." He compared the increased consumption of electricity in five of the larger centres of the province, viz:—Regina, Saskatoon, Moose Jaw, Prince Albert and Weyburn, over the period 1915 to 1925. The total consumption of what might be termed industrial power in these five centres has increased in that period from 12,676,347 k.w. hrs. to 27,650,600 k.w. hrs., or an increase of 118 per cent. Including other cities and towns and private plants in the province using electrical energy for industrial purposes Mr. Peters computes the total consumption for this purpose in 1915 as 15,846,347 k.w. hrs., and in 1925 as 34,550,600 k.w. hrs., or an increase of 112 per cent. Assuming the annual load factor at 50 per cent of maximum load, the power required to serve the above load would be 4,820 h.p. in 1915, and 10,507 h.p. in 1925. Saskatchewan being an agricultural province the electrical energy used for industrial purposes is comparatively small, but the increase of over 100 per cent in a ten-year period leads one to believe that a much greater increase may be expected in the future. The total electrical output for the five centres above referred to for all purposes was 24,208,410 k.w. hrs. in 1915, and 56,495,446 k.w. hrs. in 1925, or an increase of 133.3 per cent. Taking the annual load factor at 40 per cent of maximum load, the power required to serve fully the five centres under discussion was 9,200 h.p. in 1915 and 21,500 h.p. in 1925. The development has been more along the lines of cooking and lighting rather than purely industrial lines. Considerable power, however, is used in lumber mills, brick plants, coal mines, etc. In fifteen years the power consumed in the Estevan mining field has increased about 2,000 per cent.

E. W. Bull, superintendent of the city of Regina power plant, led the discussion on Mr. Peters' paper. He exhibited a chart showing the increase in electrical energy distributed from the city of Regina power house over a number of years. He stated that the large increase in the number of electric ranges in Regina had been responsible for a large portion of the increase, and this increased demand will shortly require a new system of distribution to take care of the load.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

A regular meeting was held at 8:00 p.m., October 29th, in the Y.W.C.A. rooms. C. H. Speer, M.E.I.C., chairman, called the meeting to order and disposed of the regular business.

Storm Swept Florida

An article was read by Mr. Speer from B. E. Barnhill, M.E.I.C., who is on construction work with Foley Brothers, Inc., in Florida. The article was entitled "Storm Swept Florida," and gave a most vivid description of the recent flood that swept from Jupiter inlet on the north to Key Largo on the south, a distance of 120 miles, and thence in a north westerly direction through the state and on into Alabama.

Wind velocities were estimated to have reached as high as 135 miles per hour thus exerting approximately 90 pounds per square foot pressure. This wind was accompanied by a downpour of rain estimated at four and one-half inches in two hours.

DIVERSION OF LAKE MICHIGAN WATER AT CHICAGO

Mr. Speer then called upon R. S. McCormick, M.E.I.C., general superintendent and chief engineer of the Algoma Central and Hudson Bay Railway Company of this city, who gave a most interesting paper on "The Diversion of Lake Michigan Water at Chicago." Mr. McCormick outlined extensively the historical and geographical aspect of the situation, clearly showing why the scheme of the Chicago drainage canal was initiated about forty years ago. He went through the early stages, through all the legal controversies and finished up by showing the extent to which this project has been developed and the possible results if allowed to be continued.

The members and visitors, including Mayor Irwin, entered actively into the discussion that followed. A hearty vote of thanks and appreciation was tendered to Mr. McCormick by J. W. LeB Ross, M.E.I.C., and Mayor Irwin, for his instructive address on a subject in which all residents of this district have such a deep interest.

The local paper, The Sault Daily Star, published Mr. McCormick's address verbatim, as they considered that the people of Algoma should get the facts that were so clearly outlined in this address.

Toronto Branch

J. W. Falkner, A.M.E.I.C., Secretary-Treasurer.

THE FUNCTIONING OF THE RIGHT-OF-WAY DEPARTMENT OF THE TORONTO TRANSPORTATION COMMISSION

The Toronto Branch held their first regular meeting of the season on October 28th, 1926, when the first of a series of three illustrated papers dealing with the Toronto Transportation Commission was given by H. W. Tate, A.M.E.I.C., engineer-of-way on the functioning of the rightof-way department of the Toronto Transportation Commission.

After briefly touching on the general history of the Commission, and giving a few figures comparing mileage of system when Commission took over the street railway with the mileage today, and the area of city served then with that served now, the average fare of 6.15 cents was then discussed, showing that out of this average fare 0.422 cents was spent on maintaining track work, overhead and structures.

The way department therefore had only a proportion of this 0.422 cents per passenger to carry out its work, and the object of this address was to show how this money was disbursed.

The general organization of the department by sections was taken up, first head office, then the roadmaster's, followed by the paving, the concreting and excavating, and the material yard sections.

The work of each section was taken up in detail, showing in the first place how the expenditures of the department were controlled by an annual budget, which budget before it could be put into effect had to be approved by the management.

The system of accounting was described, and the application of work orders and job orders for isolating various expenditures.

Coming to the roadmaster's section, which also includes the track equipment and bonding section, the division of the city system into four assistant roadmaster districts was taken next, and the daily duties of this important section throughout the twelve months of the year were outlined.

The work of the other sections was also described in detail, and finally the routine necessary before and during a construction job was carefully gone over.

A number of lantern slides were used, showing the organization of the Commission, and that of the way department, and also illustrating the various stages in construction work and the equipment used.

Slides of Rosedale loops and North Yonge street were shown to bring before the audience the improvements to a property or a district brought about by the construction of a loop or tracks.

There was a large attendance and those present showed their appreciation by the discussion at the close of the address.

POWER DISTRIBUTION PROBLEMS, TORONTO TRANSPORTATION COMMISSION

The second paper of the series was given on November 11th, 1926, when Mr. J. F. Neild gave an instructive and well illustrated paper on Power Distribution Problems of the Toronto Transportation Commission. Mr. Neild's paper appears in this issue of the Journal.

It was a pleasure to have General Secretary R. J. Durley, M.E.I.C., present with us at this meeting, and to have a few remarks from him regarding Institute affairs.

Vancouver Branch

E. A. Wheatley, A.M.E.I.C., Secretary-Treasurer.

During the month of October, four meetings of the branch were held. These included an address on Engineering Education by Professor W. E. Duckering, A.B., B.S., C.E., of the University of British Columbia. This meeting was well attended and proved of the very greatest interest. The discussion that followed the Professor's address showed the great thought which engineers at the moment are giving to this subject. Those leading the discussion were:—J. Porter, The Chairman W. H. Powell, M.E.I.C., and H. B. Muckleston, M.E.I.C.

The second meeting took the form of an address by Professor J. M. Turnbull, B.A.SC., Head of the Department of Mining Engineering of the University of British Columbia, who addressed the members on the subject of "Changing Aspects of Mining." This address was the first of a series of addresses by well-known mining engineers, and proved of great interest to the audience, which consisted, not only of mining engineers, but of engineers of all branches of the profession.

The third meeting held on October 20th in the nature of a discussion on the Professional Engineer Movement. The view was expressed by members present that this practice might well be repeated. It showed the very close connection between the Engineering Institute and the Professional Engineers' Association, and afforded an opportunity to those few members of the Institute who are not yet members of the Professional Engineers' Association, to understand and to learn how the absence from the rank of registered professional engineers injures the profession. The meeting was addressed by Frank Sawford and J. Muirhead, M.E.I.C., members of the council of the Association of Professional Engineers.

The final meeting of the month was addressed by Dr. H. W. Hill, M.B., M.D., D.P.H., L.M.C.C., in charge of the Pathological Laboratories of the General Hospital, Vancouver, B.C. Dr. Hill has been an authority for many years on the education of the medical student and was thus well qualified not only by his position, but by his delightful manner of public speaking, to address the members on such a subject. The engineers present remarked with interest that many points of control of the medical student's education by the medical profession, or by the members of the medical profession, was absent in the case of the engineering profession. Advanced copies of the Doctor's address were supplied to Prof. W. E. Duckering, H. B. Muckleston, M.E.I.C., and Mr. J. Porter, which resulted in a very keen and enjoyable discussion.

The Nominating Committee, consisting of J. Muirhead, M.E.I.C., W. O. Marble, M.E.I.C., and T. A. McElhanney, A.M.E.I.C., drew up the election ballot for the year. The committee recommended that written or printed by-laws be drawn up in order that future nominating committees be provided with a written guide.

During the month, the Vancouver Branch came very closely into touch with the Professional Engineers' Club, and with the Engineering Bureau of the Board of Trade of the City of Vancouver.

A number of very interesting addresses and discussions were held in connection with the Engineering Bureau of the Board of Trade, and representations were made to the Council of the Board of Trade, recommending that Canadian consulting engineers be employed before further steps were taken towards any decision to build the First Lions' bridge. This resolution was accepted by the council of the Board of Trade, and forwarded to the four municipalities concerned, and to the Minister of Public Works, Ottawa. The discussion is still continuing.

The Professional Engineers' Club enjoyed two splendid addresses by J. W. Allen on the subject of "The Amalgamation of Greater Vancouver" and an outstanding address given by J. W. de B. Farris on "The Canadian Constitution."

Victoria Branch

E. G. Marriott, A.M.E.I.C., Secretary-Treasurer.

On October 6th, Mr. M. Doyle, works superintendent of the British America Paint Company, of Victoria, addressed members of the Victoria Branch and members of the Professional Association of British Columbia on the subject of "Paints."

Mr. Doyle stated that in preparing to speak on this topic he had considered what would be of most use to the engineer, and had decided to leave out at this time description of the actual methods of manufacture, so as to deal rather with the materials used in the various classes of paint, and in mentioning at times the disadvantages of certain materials, he did not wish to be taken as condemning them, but only as emphasizing the conditions under which they gave the best service. An abstract of Mr. Doyle's paper appears on another page in this issue.

Mr. Doyle was subjected for the next quarter of an hour to a steady stream of questions, covering such things as Japan driers, enamels, flat finish paints, the use of boiled linseed oil, the painting of reinforcement, etc.

In conclusion Mr. Doyle stated that the company had a well-fitted laboratory, and a good library, and would be glad to be of assistance to engineers in any of their paint problems.

A hearty vote of thanks for such a clear description of many of the materials entering into paints, and their advantages and disadvantages, was offered Mr. Doyle by the branch chairman, J. N. Anderson, A.M.E.I.C., and unanimously endorsed by those present.

LUNCHEON TO HIS HONOUR LIEUT.-GOVERNOR R. R. BRUCE

On Tuesday, October 19th, a joint luncheon of the Victoria Branch and of local members of the Association of Professional Engineers of British Columbia was held, the guest being His Honour R. R. Bruce, Lieut.-Governor of the Province.

His Honour was introduced to the gathering by the branch chairman, J. N. Anderson, A.M.E.I.C., who pointed out that the engineers had been among the first, if not the first, to invite the Lieut.-Governor to address them, but owing to the numerous calls on his time, and the number of engineers who were away during the summer, it had not been possible to meet him before; however, it was with great pleasure that they now welcomed him.

Received with loud applause, and offering his congratulations to his fellow-engineers, His Honour expressed his great pleasure at meeting so large a gathering.

Referring to his early days with the C. P. R. as cheery days, though the work was rough and salaries modest, he remarked what a marvellous career the profession had had in Canada, and as one looked at the thousands of miles of railway, the large hydro-electric developments, the wonderful roads of the Dominion, and the rapid growth in mining development, one could not but be proud to belong to the engineering profession.

It was curious, he said, that engineers occupied so few public positions, or seats in the legislatures; it was noticeable that other professions were much more largely represented, and engineers should take steps to remedy this.

When he attended Glasgow University, it was the only university in Scotland granting a B.Sc. degree in engineering, but now a new generation of engineers has arisen who have received a thorough technical training in some university, almost a necessity for advancement at the present time.

The advantages of a technical training had been evident in very many ways, of which perhaps an outstanding local example was the development of methods of separation of metals at Trail, which had won world-wide reputation.

It had been suggested that there were too many engineers, but the resources of Canada were so vast that there was much room yet. In the province of British Columbia, mining, hydro-electric, and pulp and paper development were in their infancy, while in the commercial and industrial engineering fields such progress was made from day to day that opportunities were many for the young engineer. To be successful demands from them courage and persistence, and in concluding he would wish every one success, at the same time repeating his suggestion that engineers should take a more prominent part in public affairs.

P. Philip, M.E.I.C., Deputy Minister of Public Works, expressed the thanks of the membership for the encouraging and optimistic outlook for engineers that had been given them, and also for the exceptional pleasure it had given them to listen to His Honour as being Lieut.-Governor of the Province and also an engineer.

A wire was received from Major Geo. Walkem, M.E.I.C., president of the Institute, expressing his regrets at being unable to be present, also a letter from the registrar of the Association of Professional Engineers of British Columbia, asking Mr. Philip, in the unavoidable absence of the president and vice-president, to represent the council of the Association at the luncheon and to convey the respects of the council to His Honour.

Winnipeg Branch

James Quail, A.M.E.I.C., Secretary-Treasurer.

A regular meeting of the Winnipeg Branch was held on the evening of Thursday, October 7th. In addition to sending the announcements of the meeting to the members of the Institute, the secretary had been instructed to send them to the members of the Manitoba Association of Architects and to the Building Owners' Association of Winnipeg. The attendance was gratifyingly large.

Preceding the address of the speaker of the evening, reports and special business were considered. Some of the items under those heads are of general interest. They all indicate the activity of Winnipeg Branch.

The chairman, Prof. N. M. Hall, M.E.I.C., reported for the Executive Committee the visit to Winnipeg during the summer of the general secretary of the Institute, R. J. Durley, M.E.I.C. He drew the attention of the meeting to the coast to coast scope of the Institute and to the increasingly intimate part it was taking, through its branches, in the life of the communities in which the branches are located. The periodical visits of the general secretary tended toward the co-ordination of the activities of the branches.

J. G. Hall, A.M.E.I.C., reported the meeting that was held at Estevan, Sask., in July, when the Saskatchewan and the Winnipeg branches of the Institute met in convention with the Canadian Institute of Mining and Metallurgy and the Saskatchewan Branch of the American Institute of Electrical Engineers. He gave details of the papers presented and of the trips taken as part of the programme of the convention.

The convention held at Duluth, Minn., in August, was reported by C. H. Attwood, A.M.E.I.C., C. A. Clendening, A.M.E.I.C., R. W. Moffatt, A.M.E.I.C., D. L. McLean, A.M.E.I.C. This convention was held by the Minnesota Federation of Architectural and Engineering Societies, in conjunction with the Architectural and Engineering Fraternity of Manitoba. It will be remembered that Winnipeg was the meeting place of a similar convention in 1925, and noted that a convention has been arranged for Minneapolis and St. Paul in 1927.

Mr. Attwood, who had been chairman of the Arrangements Committee, from Winnipeg, told of how the interest of the Winnipeg engineers had been crystallized to produce a delegation to Duluth of some forty of the engineers and their wives. He told of the "wonderfully good time" the hosts in the United States city had provided for the visitors. He contrasted the wide newspaper and journalistic publicity given in the Duluth papers and the United States technical press with the small space devoted in Canadian publications last year. He quoted from newspaper editorials and displayed front page group photographs of interest.

Among the "papers" presented at the convention was one by N. M. Hall, M.E.I.C., chairman of Winnipeg Branch, in description of the Organization of the Engineering Fraternity in Canada.

Mr. Clendening, following Mr. Attwood, described with interesting detail the visits of parties of the convention to the various workings of the Iron Range in the vicinity of Duluth. Of interest is the production of ore,—from Eveleth 80,000,000 tons; from Virginia 70,000,000 tons; from Chisholm 60,000,000 tons; from Hibbing 225,000,000 tons. Substantial reserves of ore still exist at the centres mentioned.

Mr. Moffatt reported the visit to the Minnesota Steel Company works, and Mr. McLean reported the "Good Roads" activities in Minnesota and compared them with those of Manitoba.

FOUNDATIONS AND FOUNDATION PROBLEMS

A. W. Fosness, A.M.E.I.C., was introduced by the chairman as the speaker of the evening; his subject being Foundations and Foundation Problems. In his introduction, the chairman mentioned the fact of the speaker's broad experience in the design and construction of foundations.

Mr. Fosness addressed the meeting under four main heads,—(1) Types of Problem; (2) Types of Foundation; (3) Relative Costs of Foundations; (4) Settlement and Causes of Settlement. The various phases of foundation problems were treated both broadly and in detail, illustrated from the speaker's experience.

The paper is given in full elsewhere in this issue.

Among those taking part in the discussion were Messrs. W. G. Chace, M.E.I.C., J. N. Finlayson, M.E.I.C., C. T. Barnes, A.M.E.I.C., T. Kipp, Jr., M.E.I.C., H. W. McLeod, A.M.E.I.C., Mr. Chisholm, J. W. Porter, M.E.I.C., and D. A. Ross, M.E.I.C., closed the discussion and moved the vote of thanks.

Plan Now —

To attend the

ANNUAL MEETING

in QUEBEC CITY

FEBRUARY 15TH *to* 17TH, 1927

FULL DETAILS WILL APPEAR IN THE JANUARY ISSUE OF THE JOURNAL

Preliminary Notice

of Applications for Admission and for Transfer

October 19th, 1926.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in November, 1926.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BACKTEAROW—EVAN, of Toronto, Ont., Born at Eisk, Russia, May 5th, 1896; Educ., B.E., Prague Univ., 1925; 5 mos. inspector tunnels for ry. City of Mijava, Slovakia; at present with P. Lyall & Sons Constrn. Co. Ltd. on concrete constrn. Union Station, Toronto.

References: C. H. Mitchell, J. R. W. Ambrose, J. A. Knight, E. M. Proctor, J. H. Barber.

BRIDGLAND—MORRISON PARSONS, of Calgary, Alta., Born at Fairbank, Ont., Dec. 20th, 1878; Educ., B.A., Univ. of Toronto, 1901; 1905, obtained D.L.S. commission; 1902-09, asst. to A. O. Wheeler, Dept. of Int., engaged on topographical surveys in Rocky and Selkirk Mts. and examination of land in the ry. belt of B.C.; 1910-12 and 14, i/c triangulation survey of ry. belt of B.C.; 1913-25, i/c phototopographical surveys; 1925, topographical surveys, Calgary; at present, i/c Calgary office, Topographical Survey of Canada.

FOR TRANSFER FROM CLASS OF ASSOCIATE MEMBER TO MEMBER

FOSNESS—ARTHUR WILLIAMS, of Winnipeg, Man., Born at Winnetago, Minn., Nov. 19th, 1890; Educ., E.M., Univ. of Minn., June 1911; 1911-13, dftsman, designer, estimator for C. A. P. Turner Co., mainly reinforced concrete design work; 1913-19, i/c of Can. branches for C. A. P. Turner Co. doing all design on their Can. work independent of the American office; 1920 to date, chief engr. for Carter-Halls-Aldinger Co. of Winnipeg, doing all reinforced concrete design, also constrn. plant design and layout, estimating, etc.

References: J. G. Sullivan, T. Kipp, H. B. Henderson, D. A. Ross, J. Woodman, J. Quail.

McNAUGHTON—ANDREW GEORGE LATTA, of Ottawa, Ont., Born at Moosomin, Sask., Feb. 25th, 1887; Educ., B.Sc. 1910, M.Sc. 1912, McGill Univ.; 1910-14, staff dept. of elect'l engrg., McGill Univ.; 1914, engrg. practice, Montreal, carried numerous investigations on subjects connected with elect'l engrg., member Can. Gov't. Committee on St. Lawrence Waterways; 1921 to date, Deputy Chief of the General Staff, Canada.

References: E. G. Burr, D. W. McLachlan, A. M. Harraway, J. L. Rannie, C. H. Mitchell, O. S. Finnie.

PRATT—FOREST MILLEN, of Ottawa, Ont., Born at Ottawa, Mch. 21st, 1891; Educ., B.A.Sc., Univ. of Toronto, 19'2; 1912-13, res. engr. on constrn. of ground wood mill and power plant for E. B. Eddy Co. Ltd., Hull; 1914-15, res. engr. on design and carrying out of alterations, etc., to machinery and bldgs. with same Co.; 19 6-19, overseas with 7th Field Co. Can. Engrs. as captain; 1920 to present, with E. B. Eddy Co. as, 1920-24, constrn. engr. i/c design and constrn. of alterations and additions to machinery and bldgs., 1925 to date, ch. engr. i/c plant improvements and mtce.

References: C. S. L. Hertzberg, T. R. Loudon, A. R. Harkness, G. G. Gale. J. B. McRae.

WEST—FRANK LESLIE, of Sackville, N.B., Born at Cole's Island, N.B., May 24th, 1891; Educ., B.Sc. McGill Univ. 1916, B.A. 1912, M.A. 1914, Mt. Allison Univ.; Sept. to Jan. 1914, rodman, James Bay & Eastern Ry.; C.N.R. System; May to Oct. 1916, asst. to A. V. Anrep on investigation and mapping of peat bogs near Farnham, Que.; Oct. 1916 to Dec. 1917, testing engr., Imperial Munitions Bd. in plants in and about Montreal; 1918-19, lieut. Can. Engrs. C.E.F.; 1919-20, instrumentman, C.N.R. Mtl. Div.; June to Sept. 1920, transitman, C.N.R. survey of Halifax and Southwestern branch; 1920 to date, professor of engrg., Mt. Allison Univ., Sackville, N.B.

References: H. W. McKiel, F. R. Faulkner, W. P. Copp, C. S. G. Rogers, A. S. Gunn.

YUILL—ALEXANDER CLAUDE ROY, of Vancouver, B.C., Born at White Lake, Ont., May 25th, 1880; Educ., private tuition and self-study; 1899-1900, power house operator, Valleyfield Elect. Co. and Mtl. Cotton Co.; 1900-08, constrn. work, C. G. E. Co. and Mtl. L. H. & P. Co.; 1908-15, consulting and contracting engr. under name of Mather Yuill & Co. Ltd., Vancouver; 1915-19, consulting engr.; 1919-22, designed and supervised constrn. of dams, hydro-electric plant and irrigation systems, and reports on various hydro-electric developments and irrigation systems; 1922-23, preliminary plans and report on Wigwam Pulp & Paper Co. paper mill, Elko, B.C.; 1924, design and supervision of installation of hydro power development for Gilley Bros. Ltd., Pitt River, B.C., investigation and report Cowichan River and Oil Engine development for City of Duncan, B.C.; 1925, investigation and report on Cheakamus River, B.C., and City of Prince Rupert hydro power systems, design and supervision of elect'l services for Univ. of B.C. buildings; 1926, extension to City of Merritt steam plant and water works, incldg. reinforced concrete reservoir, layout hydro-electric power house for Engr. Gold Mines Ltd.

FOR TRANSFER FROM CLASS OF JUNIOR TO A HIGHER GRADE

BOWMAN—NELSON, of Baden, Ont., Born at Washington, Ont., Dec. 29th, 1894; Educ., B.A.Sc., Univ. of Toronto, 1921; 1918-19 and 1920 (summer), dftsman for Can. Aeroplanes, Toronto, Dominion Tire Co., Kitchener, and Ames-Holden Tire Co.; 1920 to date, ch. engr., Dom. Linseed Oil Co. at Baden, Ont., and Montreal i/c design and erection of grain elevators and warehouses, development of mfg. processes of special character, and sole charge of equipment of all new bldgs.

References: C. R. Young, P. Gillespie, C. K. MacLeod, H. Holgate, S. G. Talman, W. I. Bishop.

ELMSLIE—GORDON ALEXANDER, of Sarnia, Ont., Born at Boston, Mass., Feb. 21st, 1897; Educ., private tuition in engrg. Military Academy, Oxford and Denham, England, Alexander Hamilton business course; 1912-13, jr. dftsman and estimating, Dom. Bridge Co.; 1913-15, dftsman and template maker, St. Lawrence Bridge Co. Ltd.; 1916-17, war service in France; July to Dec. 1917, Military Academy, Oxford and Denham; Jan. to Sept. 1918, flight commander, R.F.C.; 1918-19, Captain on staff of the R.F.C.; 1919-22, plant engrg. with Dom. Bridge Co. and Dom. Engrg. Works Ltd.; 1922-23, i/c dept. for H. & R. contracts, Dom. Bridge Co.; 1923-25, asst. ch. inspector for same Co.; 1925 to present time, sales engr. for Sarnia Bridge Co. Ltd.

References: C. J. Madgett, A. Jackson, A. Peden, LeR. Wilson, D. C. Tennant.

ROOT—STEPHEN EASTMAN, of Beaupre, Que., Born at Rochester, N.H., on Jan. 3rd, 1898; Educ., 3 yrs. at McGill Univ., Faculty of Applied Sci., one year Mass. Inst. of Technology; May to Sept. 1922, rodman and inspector for St. Lawrence Paper Mills Ltd., 1922-23, field engr. for St. Lawrence Paper Mills i/c layout; April to Dec. 1923, asst. supt. of constrn. for Donnacona Paper Co.; 1924-25, cnstrn. supt. and res. engr. for Can. Explosives Ltd.; Mch. to Oct. 1925, asst. to ch. engr., St. Lawrence Paper Mills Ltd., Oct. 1925 to Mch. 1926, with Int. Paper Co. i/c of layout of Gatineau millsite, and on ry. location at Chelsea; Mch. to Aug. 1926, res. engr. for W. I. Bishop Ltd. on Belgo-Can. Paper Co.'s mill at Shawinigan; at present, with same Co. at Beaupre on Ste. Anne Power Co. work.

FOR TRANSFER FROM CLASS OF STUDENT TO A HIGHER GRADE

CALDWELL—CHARLES EDWARD, of Rochester, N.Y., Born at New Harbour, Nfld., Feb. 8th, 1896; Educ., B.Sc., McGill Univ., 1923; 1914-19, overseas with Royal Nfld. Regiment, sergeant; 1920 (summer), air compressor attendant, Can. Vickers, Ltd.; 1921 (summer), coal mining, Dom. Coal Co.; 1922 (summer), asst. foreman, scaffolding gang, Thos. Starret Co., Mt. Royal Hotel, Mtl.; 1923 to date, with Taylor Instrument Companies, Rochester, N.Y., as, 1923-24, machine shop inspector, machine shop comprises automatic and hand-screw machines, turret lathes, milling and drilling machines and punch presses; 1925 to present, time study engr. installing the Bedaux system in machine shop.

References: J. B. Porter, E. Brown, C. M. McKergow, A. J. Kelly, H. M. MacKay.

FENWICK—JAMES REID, of Montreal, Que., Born at Toronto, Mar. 4th, 1897; Educ., B.Sc., Univ. of Toronto, 1922; 1916-18, wireless operator i/c ship station for Marconi Co. of Canada; 1920 (summer), surveying for Hydro-Electric Comm'n. at Chippawa; 1922-23, responsible operating charge of broadcasting station for Northern Electric Co.; 1923 to date, responsible charge of design work on radio receiving equipment for Northern Electric Co.

References: W. C. Adams, H. J. Vennes, N. E. D. Sheppard, W. B. Cartmel, W. S. Vipond.

HULBURD—WILLIAM CHAUNCEY, of Montreal, Que., Born at Cowansville, Que., Aug. 23rd, 1896; Educ., B.Sc., McGill Univ., 1922; 1915 (summer), Q. S. Comm. on survey party in Lake St. John district; May to Sept. 19-6, inspn. at Can. Ingersoll Rand Co.; 1916-17, manufacture of munitions at plant of Mtl. Tramways Co.; 1923-24, asst. ch. dftsman for Harland Engineer Co.; 1924 to date, mech. engr and ch. dftsman for same Co.

References: C. M. McKergow, R. N. Norris, C. U. Vessot, A. Roberts, G. Wallace.

LANGSTROTH—CECIL CRAVEN, of Hampton, N.B., Born at Hampton, N.B., May 2nd, 1896; Educ., B.Sc., McGill Univ., 1921; 1919 (summer), in machine shop N.S. Tramways Co., Halifax; 1920 (summer), asst. bridge inspector with Grand Trunk Administration Bd.; 1921-22, inspector of sprinkler risks with Can. Bd. of Fire Underwriters; 1923-24, asst. engr. under Mr. E. G. Cameron on installation of boilers, turbines and auxiliaries at power house of St. John Drydock and Shipbuilding Co.; 1924 to date, asst. engr. on plant operation and mtce. at Atlantic Sugar Refinery, St. John, N.B.

References: E. G. Cameron, C. M. McKergow, W. R. Pearce, F. W. Taylor-Bailey, F. P. Vaughan.

VALLIERES—IRENEE A., of Montreal, Que., Born at Montreal, Apr. 10th, 1884; Educ., B.Sc., Ecole Polytechnique, 1907; 1907-09, asst. engr. with Water Works Dept., City of Mtl.; 19.0, i/c laying of steel pipes in St. Lawrence River for intake of Montreal aqueduct; 1910-13, on first enlargement of canal, Mtl. aqueduct; 1913-17, on second enlargement of canal, Mtl. aqueduct, i/c estimate, also design of plain and reinforced concrete retaining walls, culverts, bridges, etc., on constrn. of La Salle bridge and Church st. bridge; 1918, preparation of tech. data, plans, profiles, diagrams, etc., re arbitration Cook. Constrn. Co. vs. City of Mtl. and Sullivan vs. the City; 1919, with R. S. and W. S. Lea, studies, designs and estimates in connection with report on Montreal aqueduct; 1920, with Mtl. Water Board, engr. i/c expropriation for aqueduct blvds.; 1921-26, private business; at present, asst. engr. grade 1 with tech. service, City of Mtl.

Engineering Index

This Index is prepared by the American Society of Mechanical Engineers.

In this department will be published from month to month the titles of current engineering papers with the authors and source and a brief extract of the more important. It is designed to give the members of The Institute a survey of all important articles relating to every branch of engineering profession.

PHOTOSTATIC PRINTS

Photostatic copies of the articles listed in this section, or others on engineering subjects, may be obtained from the Engineering Societies Library.

Price of each print (up to 11 by 14 in. size) 25 cents, plus postage. Where possible, two pages, up to 7 by 9 in. size, will be photographed on one print. Larger magazines require a print per page. Bills will be mailed with the prints.

The Library is also prepared to translate articles, to compile lists of references on engineering subjects and render assistance in similar ways. Charges are made, sufficient to cover the cost of this work. Correspondence is invited. Information concerning the charge for any specific service will be given those interested. In asking for information please be definite, so that the investigator may understand clearly what is desired.

The Engineering Societies Library is under the management of the United Engineering Society, which administers it as a public reference library of engineering. It is maintained jointly by the American Society of Civil Engineers; the American Institute of Mining and Metallurgical Engineers; the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. It contains 150,000 volumes on engineering and allied subjects, and receives currently most of the important periodicals in its field.

Orders and correspondence should be addressed to

Harrison W. Craver, Director,
Engineering Societies Library,
29 West Thirty-ninth Street. New York, N.Y.

A

AIR PUMPS

Ejector. The Ejector Air Pump, D. G. McNair. Power Engr., vol. 20, no. 235, Oct. 1925, pp. 367-370, 3 figs. Practical considerations on installation and efficient operation of steam-jet ejector air pumps.

AIRPLANE ENGINES

Development. Some Aspects of Aircraft-Engine Development, G. J. Mead. Soc. Automotive Engrs.—Jl., vol. 17, no. 5, Nov. 1925, pp. 496-507, 19 figs. Discusses requirements and limiting factors of dependability, size, speeds, and power-plant weight and cost; relation of thrust to weight of power plant; various engines in vogue are classified into groups according to their horsepower; advantages of air-cooled and handicaps of water cooled engines.

AIRPLANE PROPELLERS

Airflow Around. The Airflow Round a Body as Affecting Airscrew Performance C. N. H. Lock, H. Bateman and H. C. H. Townend. Aeronautical Research Committee (Lond.), Reports and Memoranda, No. 956, Jan. 1925, 22 pp., 13 figs. on supp. plates. Experiments determined variation of thrust with radius by measurements of total head on three airscrews with one body, and actual velocity and direction of air-stream round one airscrew and front of one body by experiments with a yawmeter; results are presented in form of streamlines and of curves of axial component velocity. Airfoil element theory suggested which would apply to an airscrew working in front of a tractor body, involves a single empirical curve representing effect of body on axial inflow at each radius; same curve is assumed to apply to screws of any design or diameter relative to that body.

AIRPLANES

Aileron Tests. Full Scale Tests of Different Ailerons on Bristol Fighter Aeroplane, H. M. Garner and E. T. Jones. Aeronautical Research Committee (Lond.), Reports and Memoranda, No. 966, Jan. 1925, 7 pp., 10 figs. on supp. plates. Three different types of ailerons, standard F. 2B, Handley Page balanced and Bristol "Frise" were fitted in turn to a Bristol Fighter airplane; for each type flights were made with and without loads on wing tips; airplane was flown straight with no bank, engine being switched off, and measurements were made of aileron angle, rudder angle, and lateral force on control column, from which calculations were made of rolling moment, yawing moment, and hinge moment coefficients for three types of ailerons. Effect on hinge moment coefficient caused by setting ailerons up or down also discussed.

Inspection. Some Aspects of Airplane Inspection, J. J. Feeley. Soc. Automotive Engrs.—Jl., vol. 17, no. 5, Nov. 1925, pp. 441-447, 9 figs. Following description of airplane structure, author discusses structural requirements and outlines main features of properly co-ordination engineering and manufacturing activities; states that no inspection is worth name or money spent on it that does not include constructive work and knowledge at all times that intentions of designers are being carried out so that safety of craft is assured; outline of inspection procedures.

Lateral Controls. Full Scale Tests of a New Slot-and-Aileron Lateral Control, H. L. Stevens. Aeronautical Research Committee (Lond.), Reports and Memoranda, No. 968, Mar. 1925, 3 pp., 4 figs. on supp. plate. Describes a modified form of lateral control for airplanes, designed to reduce danger of an accidental stall; discusses desirable characteristics of such a control; extracts from reports of model tests on this form of control showing that it should possess such features; summarizes flying experience obtained on an Avro, 504K airplane fitted with this control.

Pitching and Yawing Moments. Pitching and Yawing Moments With Sideslip on a Model Aeroplane With Zero Stagger, F. B. Bradfield. Aeronautical Research Committee (Lond.), Reports and Memoranda, No. 965, Jan. 1925, 14 pp., 15 figs. on supp. plates. Describes tests made on a model of an airplane with zero stagger, fairly small gap-chord ratio, and a round section fuselage, and wind channel tests of pitching and yawing moments with sideslip made with a view to finding any reasons why it should be difficult to bring an airplane of this type out of a spin.

Wind-Tunnel Tests. Wind Tunnel Tests of Fuselages and Windshields, E. P. Warner. Nat. Advisory Committee of Aeronautics—Tech. Notes, no. 226, Sept. 1925, 6 pp., 4 figs. on supp. plates. Results of tests made in 1918 in old 4-ft. wind tunnel at Mass. Inst. of Technology, for purpose of securing data on effect of windshield form on total resistance of fuselage of good streamline shape.

Wings. Determination and Classification of the Aerodynamic Properties of Wing Sections, M. M. Munk. Nat. Advisory Committee for Aeronautics—Tech. Notes, no. 227, Sept. 1925, 22 pp. Remarks on possible improvement of experimental determination of aerodynamic properties of wing sections; shows how errors of observation can subsequently be partially eliminated, and how computation of maxima or minima of aerodynamic characteristics can be much improved.

Preliminary Wing Model Tests in the Variable Density Wind Tunnel of the National Advisory Committee for Aeronautics, M. M. Munk. Nat. Advisory Committee for Aeronautics—Report, no. 217, 1925, 15 pp., 23 figs. Results of series of tests with 3-wing models, made to obtain general information on air forces on wing sections at high Reynolds Number and in particular to make sure that Reynolds Number is really important factor.

Wing Spar Stress Charts and Wing Truss Proportions, E. P. Warner. Nat. Advisory Committee for Aeronautics—Report, no. 214, 1925, 18 pp., 24 figs. In order to simplify calculation of beams continuous over three supports, series of charts have been calculated giving bending moments at all critical points and reactions at all supports for such members; using these charts as basis, calculations of equivalent bending moments, representing total stresses acting in two bay-wing trusses of proportions varying over wide range, have been determined, both with and without allowance for column effect.

AIRSHIPS

Commercial Value. The Airship and Its Place in Commerce, H. H. Blee. Mech. Eng., vol. 47, no. 11a, Mid-November, 1925, pp. 961-972, 19 figs. General survey of development of airship and discussion of its commercial possibilities: author predicts that within a few years this type of airship, especially when using helium as lifting medium, will be classed as safe, reliable, time-saving, comfortable craft, admirably adapted to carrying heavy loads of passengers, mail and express on profitable commercial service over long non-stop flights.

ALIGNMENT CHARTS

Construction and Use. Graphical Methods of Calculation, H. L. Seward. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 1019-1033, 38 figs. Construction of Cartesian diagrams and alignment charts for use in rapid determination of values of unknown quantities in mathematical expressions.

ALLOY STEELS

Special-Purpose. Steels for Special Purposes. Metal Industry (Lond.), vol. 27, no. 17, Oct. 23, 1925, pp. 391-392. Gives examples of steels made for special purposes, such as for drawing and extrusion dies, stamping and press tools, drawing mandrils, etc.

ALLOYS

Aluminum. *See Aluminum Alloys.*

Brass. *See Brass.*

Inner Structure. The Inner Structure of Alloys, W. Rosenhain. Roy. Soc. Arts—Jl., vol. 73, nos. 3803, 3804 and 3805, Oct. 9, 16 and 23, 1925, pp. 1000-1021, 1022-1037 and 1039-1052, 31 figs. Oct. 9: Discussion of atomic structure of alloys. Oct. 16: Deals with question of interaction of different kinds of atoms when they are brought together in single crystal. Oct. 23 Considers question of conduction of electricity through metals.

Tests. Comparative Slow Bend and Impact Notched Bar Tests on Some Metals, S. N. Petrenko. U. S. Bur. Standards, Technologic Papers, No. 289, June 27, 1925, pp. 315-346, 25 figs. partly on supp. plates. Describes parallel impact and slow-bend tests made by Bur. of Standards on some materials, mostly non-ferrous alloys, to determine whether a slow-bend test may be used as a substitute for an impact test or as a valuable addition to it, and to determine also its practicability; results obtained; interpretation of a slow-bend diagram. Bibliography.

ALUMINUM ALLOYS

Aging of. The Effect of Artificial Ageing upon Age-Hardened Aluminum Alloys, K. L. Meissner. Metal Industry (Lond.), vol. 27, no. 15, Oct. 9, 1925, pp. 333-338, 10 figs. Author replies to criticisms advanced by Dr. Marie Gayler in same journal, July 10, 1925, of certain statements, in his article under above head in this Journal, June 26, 1925. He does not dispute small aging at room temperatures of aluminum copper alloys, but such aging is of negligible practical mportance; disagreement as to what is understood by age-hardening; fundamental differences in aging temperatures; Gayler's researches under different conditions; author points out that Gayler's results are inconsistent proof of age-hardening influence of $MgZn_2$.

Castings, Improving Aluminium Alloy Castings. Machy. (Lond.), vol. 27, no. 679, Oct. 1, 1925, p. 7. Review of report published by Engineering Co-ordinating Research Board, describing experiments, by S. L. Archbutt, with object of improving soundness and mechanical properties of aluminum-alloy castings.

Castings, Permanent-Mold. Permanent Mold Aluminum Castings and Their Field of Usefulness, J. B. Chaffe, Jr. Am. Foundrymen's Assn.—advance paper, no. 478, for mtg. Oct. 5-9, 1925, 15 pp., 8 figs. Greatest difficulty encountered is that caused by crystallization shrinkage which is shrinkage in volume on freezing, and amounts to from 7 to 5 per cent of volume of molten metal; to get solid casting this shrinkage must be fed with hot metal and molds are therefore designed so that there is progressive freezing from points furthest from gates to metal in gates and sprues; venting of mold and thermal expansion must also be considered; compares sand-casting with permanent-mold method; many points of former are not applicable to latter; shows important differences between pressure die castings and permanent-mold castings. See also Am. Mach., vol. 63, no. 19, Nov. 5, 1925, pp. 743-744.

Castings, X-Ray Examination. X-Ray Examination of Aluminum-Alloy Castings for Internal Defects, Rob. J. Anderson. Am. Foundrymen's Assn.—advance paper, no. 459, for mtg. Oct. 5-9, 1925, 19 pp., 15 figs. Discusses application of X-ray examination and presents results of experimental work; advantages are stated to be: (1) inspection may be made without cutting or otherwise damaging parts; (2) dangerous flaws can be detected before parts are put in service; (3) flaws which might be uncovered in machining can be located before expensive machine work is done; (4) correlation of nature, amount, and distribution of internal defects in castings may be made with method of gating or some other factor, thus permitting use of smaller sections and lower factor of safety with simultaneous decrease in cost; apparatus and equipment for radiography and method of making exposures.

AMMONIA COMPRESSORS

CYLINDER LUBRICATION. Lubrication of Ammonia Compressor Cylinders, R. J. Nadherny. Power Plant Eng., vol. 29, no. 18, Sept. 15, 1925, pp. 964-965, 3 figs. Discussion of lubricants and lubricating methods used on modern types of open and closed ammonia compressors.

AUTOMOBILE FUELS

DEVELOPMENTS AND RESEARCH. Motor Fuels, J. S. S. Brame. Roy. Soc. Arts.—Jl., vol. 73, nos. 3797, 3798 and 3799, Aug. 28, Sept. 4 and 11, 1925, pp. 920-929, 930-940 and 942-954, 4 figs. Considers ways in which greatly increased demands for motor fuel have been met hitherto, and prospects of meeting still greater demands of near future by alternative or supplementary fuels; knowledge of relative merits of different components of various types of fuels, which can be applied to their improvement and production of blends which impart best characters to mixtures; light shed upon question of more efficient utilization of automobile fuels. Three Howard lectures.

AUTOMOBILES

CHARCOAL GAS PRODUCERS FOR. The Malbay Charcoal-Gas-Engine Plant with Producer (Neue Entwicklungswege beim Sauggasgenerator). Wirtschaftsmotor vol. 7, no. 7, July 25, 1925, pp. 8-9, 2 figs. About 50 per cent thermal efficiency is calculated for this plant developed by French firm, R. Malbay; to attain which use is made of heat of producer gases themselves and heat of exhaust; hot gases are guided around retorts and preheat charcoal that is contained therein; exhaust gas is carried into producer itself.

HEADLIGHTING. Motor-Vehicle Headlighting. U. S. Bur. Standards, Circular No 276, Aug. 5, 1925, 28 pp., 20 figs., partly on supp. plate. Requirements for good road lighting are discussed and construction and operation of present-day types of electric head lamps explained; latest specifications for gas head lamps as approved by Soc. Automotive Engrs. are given; gas head lamps are used on trucks; methods used at Bur. of Standards for making laboratory tests on electric headlighting devices briefly described; state laws and regulations are discussed and suggested paragraphs for a state law presented. Appendix containing specifications under which tests for approval of types of devices by state officials are made. Bibliography.

SHIMMYING. Prevention of Shimmy by Hydraulic Steering-Control, J. W. White. Soc. Automotive Engrs.—Jl., vol. 17, no. 5, Nov. 1925; pp. 490-493, 7 figs. Experiments with hydraulic steering control with object of preventing or reducing shimmying and tramping were made by author, who asserts that elimination of backlash by doing away with mechanical joints and by holding front wheels as rigid as rear wheels has been amply proved by results to be long step in right direction; front and rear end differences that cause shimmying; how hydraulic steering is accomplished; main cylinder and master pump.

TRANSMISSION NOMENCLATURE. Parts Nomenclature for Three-Speed Transmission. Am. Mach., vol. 63, no. 18, Oct. 29, 1925, p. 687, 1 fig. Standardized terms suggested by committee of Am. Gear Mfrs.' Assn.

AVIATION

HIGH SPEEDS. The Attainment of High Speeds. Aviation, vol. 19, no. 18, Nov. 2, 1925, p. 633. Discusses engineering achievements which render high speeds a possibility.

RADIO SIGNAL. Air Mail Radio Signal Developed. Aviation, vol. 19, no. 20, Nov. 16, 1925, pp. 720-721. Invisible beacon, which guides pilots by day, night or in thick fog successfully tested by Air Mail Service.

RELIABILITY IN TRANSPORTATION. Reliability As a Factor in Air-Transportation Efficiency, J. P. Van Zandt. Soc. Automotive Engrs.—Jl., vol. 17, no. 5, Nov. 1925, pp. 433-436, 6 figs. On-time records of passenger trains compared with Air-Mail Service; how prevailing winds affect regularity; planes are said to be more reliable than trains.

B

BEARINGS

SLEEVE. Results Obtained Through the Use of an Improved Type of Sleeve Bearing, J. S. Murray. Indus. Engr., vol. 83, no. 10, Oct. 1925, pp. 473-475, 5 figs. Details of operating conditions that were encountered before and after making several installations in a large steel plant.

BOILER FEEDWATER

PURIFICATION. Boiler-Feedwater Purification, A. S. Behrman. Mech. Eng., vol. 47, no. 11, Nov. 1925, pp. 909-910. Inquiry into present status of art, and into fundamental considerations responsible therefor. (Abridged.)

BOILER FURNACES

AIR PREHEATERS. Air Preheaters in the Power Plant. Power Plant Eng., vol. 29, no. 18, Sept. 15, 1925, pp. 940-943, 6 figs. Description of types in general use and summary of results which may be expected from their use.

BOILER AND CHAIN-GRATE OPERATION. Practical Points on Boiler and Chain Grate Operation, J. T. Ruddick. Elec. Times, vol. 68, no. 1773, Oct. 8, 1925, pp. 400-401. Air and its calorific values; simple formula for flue-gas losses; effect of arch design on combustion rate, trouble with brickwork and bad furnace-wall design; highest CO_2 not necessarily best operating point; cases of growth of cast-iron links; etc.

HEAT LOSSES FROM WALLS. Heat Losses from Boiler Furnace Walls, L. B. McMillan. Power Plant Eng., vol. 29, no. 18, Sept. 15, 1925, pp. 944-946, 4 figs. Radiation and convection losses determined by air velocity as well as temperature difference

PULVERIZED FUEL. Boiler Furnace Design for Pulverized Fuel, J. G. Coutant. Combustion, vol. 13, no. 5, Nov. 1925, pp. 278-279, 4 figs. Changes in boiler-furnace design to meet conditions imposed by use of pulverized fuel, with particular reference to Ashley Street Station of Union Elec. Light & Power Co.

Radiant Heat Absorption in Pulverized Coal Furnaces, W. Lulofs. Elec. Times, vol. 68, no. 1773, Oct. 8, 1925, pp. 397-398, 1 fig. Author's views on theory developed by E. G. Ritchie, in Elec. Times of Aug. 27, as to effect of waterscreen and water-cooled sidewalls on radiant heat absorption in pulverized-fuel furnaces, in which he concluded by indicating that there was still ample efficiency to be won if boiler heat-absorbing surface were so disposed as completely to surround combustion chamber. Claims that theory is bound to lead to wrong results.

BOILERS

EDGE MOOR SINGLE-PASS. A New Boiler Design. Combustion, vol. 13, no. 5 Nov. 1925, pp. 284-285, 1 fig. Discussion of new Single Pass Boiler developed by Edge Moor Iron Co.

HIGH-PRESSURE. The Atmos High-Pressure Boiler. Engineering, vol. 120, no. 3122, Oct. 30, 1925, pp. 538-540, 10 figs. Principal feature of design is that steam is generated in rapidly revolving tubes, which are so arranged that they may expand freely without setting up internal stresses.

BRAKES

OPERATION AND MAINTENANCE. Loss, Damage and Discomfort Due to Improper Handling of Locomotive and Air Brakes. Ry. & Locomotive Eng., vol. 38, no. 10, Oct. 1925, pp. 284-287, 4 figs. Points out that best way to reduce damage to equipment and lading is for engineer to set brakes while slack is stretched, then gradually close throttle until train comes to rest with no steam in cylinders; fundamental enemies of modern air brake are uneven piston travel and leaks. Report presented to Travelling Engrs.' Assn.

BRASS

HIGH-STRENGTH. High Strength Brasses, M. Thibaud. Metal Industry (Lond.), vol. 27, no. 19, Nov. 6, 1925, pp. 434-435, 1 fig. General notes on composition and resulting strengths of high-strength brasses, as well as on methods of mixing, melting, casting, etc., on which special emphasis is laid. Abridged translation of paper presented before Franco-Belgian Foundry Congress.

NICKEL. Special Nickel Brasses, O. Smalley. Am. Inst. Min. & Met. Engrs.—Trans., no. 1508-E, Oct. 1925, 35 pp., 12 figs. Physical tests on nickel brass, tin brass, iron brass, nickel-aluminum brasses, iron-aluminum brass, nickel-iron-aluminum brasses and nickel-aluminum-tin brass, as cast or forged; impurities; problems of manufacture, crucible melting, electric furnace, casting, etc.

BRICK

PAVING. Progress Report on Research of Paving Brick from Iowa Shales, D. A. Moulton. Am. Ceramic Soc.—Jl., vol. 8, no. 11, Nov. 1925, pp. 694-701, 3 figs. Test on full-size pavers made from 11 shales showed that 5 would make excellent paving material and others had possibilities of making block that would give service; various processes were tried as soft-mud, roller expression machine, dry-press, and new belt machine, also additions of magnesium and colloidal materials; gives results.

BRIDGES

EAST YORK-LEASIDE, CANADA. Proposed East York-Leaside Bridge, F. Barber. Can. Engr., vol. 49, no. 16, Oct. 20, 1925, pp. 473-476, 3 figs. Discussion of its economic effect on city of Toronto; would form vital link in new North-east highway entrance project. Address delivered before Toronto Bldg. Owners and Mgrs. Assn.

BRIDGES, CONCRETE

CONTINUOUS-GIRDER. Continuous-Girder Bridges of Concrete, J. F. Seiler. Eng. News-Rec., vol. 95, no. 18, Oct. 29, 1925, pp. 722-725, 12 figs. Increasing use of type; graphical analysis by simple method adapted to variable moment of inertia; adjustment of supports and span length of 3-span girder.

THROUGH-ARCH. Concrete Arch Bridge of Unusual Form and Details, W. H. Rabe. Eng. News-Rec., vol. 95, no. 19, Nov. 5, 1925, pp. 750-751, 3 figs. Through-arch crossing being built at Piqua over Miami River; reinforced-concrete hangers have hinge joints.

BRIDGES, LIFT

BASCULE. Double-Leaf Bascule Bridge Over Canal at Seattle. Eng. News-Rec., vol. 95, no. 21, Nov. 19, 1925, pp. 826-829, 5 figs. New form of trunnion support; bridge designed for 12-year-old foundations; anchored against sliding; novel center lock.

BRIDGES, STEEL

WEIGHTS. Steel Bridge Weights, W. H. Thorpe. Engineering, vol. 120, no. 3122, Oct. 30, 1925, pp. 534-538, 11 figs. partly on supp. plate. Attempt is made to furnish, by use of diagrams based upon actual cases, means of determining probable steel weights in bridges of various types, down to, but not including, bearings, by reference to live load carried by bridge.

BRIQUETTING

SAWDUST AND WOOD SHAVINGS. The Briquetting of Sawdust and Wood Shavings, J. Petipas. Engineer, vol. 140, no. 3645, Nov. 6, 1925, pp. 483-484. Account of investigations and discoveries made in connection with agglomeration or briquetting of sawdust and wood shavings. Translated abstract of paper presented to Société des Ingénieurs Civils de France.

BUILDINGS

COLLAPSE. Concrete Hotel Building Collapses After Cold Weather. Eng. News-Rec., vol. 95, no. 20, Nov. 12, 1925, pp. 800-801, 2 figs. 12 bays of 4-story structure fall when forms are stripped; tarpaulins and salamanders absent.

BUSBARS

SPECIFICATIONS. British Standard Specification for Bus-Bars and Connections Constructed of Bare Copper or Aluminium. Brit. Eng. Standards Assn., no. 159, Mar. 1925, 7 pp. Specification covering quality of metal, manufacture, temperature rise and current density, joints and connections, and recommended sizes of flat and round bars. Appendix giving International standards of resistance for copper.

C

CAMS

RADIAL OR ROTARY-ENGINE. Radial and Rotary Engine Cams, P. Cormack. Automobile Engr., vol. 15, no. 207, Oct. 1925, p. 322, 2 figs. In notes referring to multilobe cam disk of radial or rotary engine, principle of operation is dealt with in manner which brings to light new possible cam arrangements of interest to designer.

CANADIAN GAS WORKS. Coke Ovens in a Canadian Gas Works, J. Stephenson. Gas Age-Rec., vol. 56, no. 16, Oct. 17, 1925, pp. 563-566 and 574, 6 figs. Notes on practices at plant of Hamilton By-Products Coke Ovens, Ltd., Ontario; coke oven plant flexibility. See also, Gas Wld., vol. 83, no. 2150, Oct. 3, 1925, pp. 12-15.

CANALS

SHIP, SEA WATER FLOWING INTO. The Control of Sea Water Flowing into the Lake Washington Ship Canal, E. Victor Smith and Thos. G. Thompson. Indus. & Eng. Chem., vol. 17, no. 10, Oct. 1925, pp. 1084-1087, 4 figs. Results of investigations by authors of invasion of sea water into Lake Union; lock control of sea water; methods of sampling and analysis; salinity variation in locks; flow of sea water into canal and lakes; conclusions.

CARBURETORS

CALIBRATING JETS. Method of Calibrating Carbureter Jets Standardized in England. Automotive Industries, vol. 53, no. 20, Nov. 12, 1925, pp. 820-822, 4 figs. Engineering Standards Assn.'s plan provides for use of master jets at National Laboratory, and reference jets for regular work, latter calibrated from master jets with benzol.

CARGO HANDLING

SLIPWAY FOR. Ships Unloaded by Barges Operating on Slipway Structure. Eng. News-Rec., vol. 95, no. 18, Oct. 29, 1925, pp. 707-708, 1 fig. Method used where construction of piers is impracticable because of distance of deep water from shore; describes structure erected on west coast of Guatemala.

CAST IRON

Graphitization. One of the Causes of Variations in Rates of Graphitization of White Cast Iron, A. Hayes and H. E. Flanders. Am. Foundrymen's Assn. —advance paper, no. 481, for mtg. Oct. 5-9, 1925, pp. 2-5, 4 figs.; also (abstract) in Foundry Trade Jl., vol. 32, no. 478, Oct. 15, 1925, p. 329, 4 figs. Study made as part of program for purpose of making feasible commercial use of greatly shortened annealing cycle; use of greatly reduced annealing period necessitates rather precise knowledge of factors that cause variations in rates of graphitizations of white cast irons of normal chemical composition; authors conclude that sulphur has great influence on rates of graphitization of white cast irons and difference in this case can be completely corrected by addition of small amount of manganese.

The Catalysis of the Graphitization of White Cast Iron by the Use of Carbon Monoxide Carbon Dioxide Mixtures When Applied Under Pressure, A. Hayes and G. C. Scott. Am. Foundrymen's Assn.—advance paper, no. 480, for Mtg. Oct. 5-9, 1925, 21 pp., 12 figs. Conclusions reached from results of investigation are: (1) at temperature of 920 deg. cent. CO-CO_2 mixtures increase their rate of absorption of free iron carbide nearly 100 per cent; (2) during cooling at rates varying from 3½ deg. cent. per hr. to 400 deg. per hr. it inhibits almost completely graphitization in critical range; (3) action of gas mixture offers very convenient method of obtaining pearlitic matrix in present graphitization of white cast iron.

Gray, Effect of Heat Treatment. The Effect of Heat Treatment on the Properties and Microstructures of Gray Cast Iron and Semi-Steel, O. W. Potter. Am. Foundrymen's Assn.—advance paper, no. 462, for mtg. Oct. 5-9, 1925, 50 pp., 22 figs. Series of investigations dealing with effects on 10 different heat treatments, details of which are included; it is concluded that proper heat treatment can greatly improve general properties of gray cast iron and semi-steel; one important result is uniform hardness and elimination of massive cementite under annealing; to properly heat treat, correct critical temperature must be located and obtained in heat treatment; properties of gray cast iron and semi-steel can be greatly varied by heat treatment.

Nickel and Nickel Chromium in. Nickel and Nickel-Chromium in Cast Iron, T. H. Wickenden and J. S. Vanick. Am. Foundrymen's Assn.—advance paper, no. 486, for mtg. Oct. 5-9, 1925, 60 pp., 13 figs. Discusses results of investigation of effects on properties of gray iron of nickel and nickel-chromium additions, and commercial applications of nickel and nickel-chromium cast iron; tests were made also on cast iron of high alloy content—up to 30 per cent nickel.

Oxygen Content. The Oxygen Content of Coke and Charcoal Cast Irons, J. R. Eckman, L. Jordan and W. E. Jominy. Am. Foundrymen's Assn.—advance paper, no. 479, for mtg. Oct. 5-9, 1925, 12 pp., 1 fig. General tendency of charcoal cast iron to exhibit greater strength and contain finer and more nodular form of graphitic carbon than coke cast iron of similar composition, melted and cast under identical conditions, has been attributed to higher oxygen in stronger irons; careful analyses of 12 charcoal and 8 coke irons failed to show that stronger irons contained more oxygen than weaker irons; values for oxygen in both stronger and weaker cast irons were very much lower than general range of values reported by Oberhoffer and Johnson; vacuum fusion method of analysis is more accurate than methods employed in previous investigations.

Perlit Process. A Description of the Perlit Process, H. J. Young. Foundry Trade Jl., vol. 32, no. 477, Oct. 8, 1925, pp. 294-295. Describes new method of production of gray iron castings under new conditions; process, in author's opinion, represents first distinct and definite advance in ordinary iron-foundry practice. See also (discussion) in no. 478, Oct. 15, 1925, pp. 331-332.

Phosphorus, Effect of. The Influence of Phosphorus on the Total Carbon Content of Cast Iron, J. T. MacKensie. Am. Foundrymen's Assn.—advance paper, no. 493, for mtg. Oct. 5-9, 1925, 24 pp., 8 figs. Investigation undertaken to see how small an increment of phosphorus would really affect total carbon enough to count in ordinary foundry processes, and how much would net effect be on fluidity and life of molten iron, and on strength, deflection and impact resistance of test bars.

Synthetic. Synthetic Cast Iron and Its Possibilities for the Seattle District, G. S. Schaller. Am. Foundrymen's Assn.—advance paper, no. 484, for mtg. Oct. 5-9, 1925, 28 pp. Discusses factors entering into production of synthetic cast iron and pig, and shows possibilities of this process as applied to Seattle district, from which application can be made to other districts; historical review of development of process and discussion of types of furnaces erected and causes for development; present problems and materials used in process; application to Seattle district, taking up factors of material, supplies, labour, costs and markets.

CASTINGS

Hydraulic Cleaning. Cleaning Castings Hydraulically Proves Economical, E. C. Barringer. Iron Trade Rev., vol. 77, no. 21, Nov. 19, 1925, pp. 1267-1269 and 1318. Compared with old hand method, cleaning of castings by hydraulic pressure at Allis-Chalmers Mfg. Co., Milwaukee, is matter of minutes to hours; castings up to largest size of turbines, motors and heavy machinery of every sort, are swung by travelling crane into concrete chamber and deposited on turntable. See also article by R. A. Fiske, in Iron Age, vol. 116, no. 21, Nov. 19, 1925, pp. 1383-1385, 5 figs.

CEMENT, PORTLAND

Manufacture. Producing High Grade Portland Cement From Unusual Raw Materials, E. D. Roberts. Pit & Quarry, vol. 11, no. 3, Nov. 1, 1925, pp. 49-58, 12 figs. Describes operations of Pacific Portland Cement Co., especially Redwood City (California) plant.

CENTRAL STATIONS

Lighting Service Department. A Lighting Service Department, D. J. Finn. Elec. World, vol. 86, no. 19, Nov. 7, 1925, pp. 943-945. What it is and what it can accomplish for central station; how it can increase revenue and improve public relations; suggested organization for utilities.

Maintenance and Changes. Keeping a Modern Station Up to Date, Jas. F. Brown. Elec. World, vol. 86, no. 17, Oct. 24, 1925, pp. 839-842, 3 figs. How, in period of five years, changes were made in Tulsa generating station from time to time to meet changing operating conditions and keep it up to desired standard of reliability of service, economy of operation and simplicity.

Prime Movers for, Design of. Tendencies in the Present Design of Prime Movers for Central Stations, A. M. Greene, Jr. Engrs. & Eng., vol. 42, no. 9, Sept. 1925, pp. 246-249. Discusses early accomplishments, influence of travelling cranes, low-temperature exhaust, influence of steam turbine, bucket conveyor, mercury turbine, and regenerative cycles.

CHEMICAL PLANTS

Layout and Design. Layout and Design of Chemical Plants on a Philosophical Basis, C. Field. Chem. & Met. Eng., vol. 32, no. 16, Oct. 1925, pp. 794-799, 15 figs. Notes on method of developing plants in rational manner which results in nearest possible approach to ideal.

COAL

Sulphur Compounds in. The Powell and Parr Method for the Determination of Sulphur Compounds in Coal, T. G. Woolhouse. Fuel, vol. 4, no. 10, Oct. 1925, pp. 454-456. Results of investigations show that dilute nitric acid employed appears to be complete solvent for iron compounds found in coal samples used, since residues after nitric acid extraction did not contain iron; method is fairly accurate, but it seems desirable always to estimate iron values together with sulphur values, so that some idea of probable error involved can be arrived at.

COAL BREAKERS

Synchronous-Motor-Driven. Synchronous Motors with Magnetic Clutches Are Successfully Applied to Breaker Machinery, E. J. Gealy. Coal Age, vol. 28, no. 15, Oct. 8, 1925, pp. 488-490, 4 figs. Describes installation of breaker with synchronous motors by Geo. F. Lee Coal Co., near Avondale, Pa.; motors start heavy loads without shock or strain; power factor is improved and peak demands reduced so that penalty charges on bill are avoided.

COAL HANDLING

Power Plants. Coal and Ash Handling Plant at East Greenwich Power Station, G. F. Zimmer. Indus. Mgt. (Lond.), vol. 17, nos. 9 and 10, Sept. and Oct. 1925, pp. 431-433 and 467-470, 6 figs. Two hundred tons of coal are hourly converted at this power plant, situated on south bank of Thames river, into power which gives life to tramway system of London County Council; how necessary coal is unloaded from river craft, and brought to boilers and reserve stocks of power house; describes conveying installation.

High Speed Coal Towers at Brooklyn Edison Company's Hudson Avenue Station. Indus. Mgt. (Lond.), vol. 12, no. 10, Oct. 1925, pp. 470-473, 4 figs. Description of coal handling plant having capacity of 500 tons per hour.

COAL MINES

Blasting. Air-Cushioned Blasting. Colliery Eng., vol. 2, no. 19, Sept. 1925, p. 397. Refers to alleged merits of various special ways and means of arranging explosive and tamping in shot holes; from experience available air cushioning seems to be most rational and promising method to employ, but there is clearly room for further investigation of tamping methods in general.

Reconditioning. Reconditioning Cuts Valier Mine Costs, F. H. Kneeland. Coal Age, vol. 28, no. 19, Nov. 5, 1925, pp. 623-627, 9 figs. Labour and power saved and safety increased by program of changes that already has made total reductions estimated at 20 cents a ton.

COAL MINING

Blasting. Method of Increasing Lump-Coal Production, With Especial Reference to Southern Illinois, J. E. Tiffany and J. J. McKitterick. U. S. Bur. Mines, Reports of Investigations, Serial No. 2697, Aug. 1925, 7 pp., 7 figs. Results of study of blasting methods conducted through an arrangement made by Supt. of Central District Experiment Station of Bur. Mines with a coal company operating mines in Southern Illinois, in one of their mines, by authors.

Scraper Loaders. Scraper Loaders Cut Cost in Two Hazard Mines, A. Brosky. Coal Age, vol. 28, no. 18, Oct. 29, 1925, pp. 589-593, 10 figs. Two mining companies in southeastern Kentucky are proving that in thin beds of clean coal, scraper loader fitted to system of rather long faces produces considerably larger output per man-shift than is obtained by hand loading in conventional system.

COMPRESSED AIR

Cooling and Drying. Cooling and Drying Compressed Air, J. B. Leonard. Ry. Mech. Engr., vol. 99, no. 11, Nov. 1925, pp. 721-722, 1 fig. Describes installation, at one of car shops of Mich. Cent., Detroit, Mich., of system for cooling and drying compressed air.

CONDENSERS, STEAM

Tube Failures. Causes of Condenser Tube Failures. Power Plant Eng., vol. 29, no. 22, Nov. 15, 1925, pp. 1143-1144, 3 figs. Mechanical and chemical actions, latter due in part to crystal arrangement of metals employed, may cause tube to fail.

COILS

Magnetic Blowout. Action of Relays and Starting Boxes, Chas. G. Green. Power Plant Eng., vol. 29, no. 22, Nov. 15, 1925, pp. 1147-1149, 4 figs. Principle of magnetic blowout and use of protective equipment are explained.

Concrete. Method of Casting and Setting Concrete Posts. Eng. & Contracting (Gen. Contracting), vol. 64, no. 4, Oct. 21, 1925, pp. 896-899, 1 fig. How a contractor handled a 23.3-mile fencing job for Board of Water Supply of New York City.

CONCRETE

Deterioration. The Deterioration of Concrete in Sea and Alkali Water, O. L. Grover. Concrete, vol. 27, no. 4, Oct. 1925, pp. 17-18, 2 figs. Notes on the subject, with list of requirements for concrete in order to compare favourably in durability with other materials.

Deterioration in Alkali Soils. Concrete Deterioration in Alkali Soils, C. J. Mackenzie. Eng. Jl., vol. 8, no. 11, Nov. 1925, pp. 462-464. Review of first chemical paper published by Dr. Thorvaldson and assistants, in connection with investigation initiated by Eng. Inst. Committee into disintegration of concrete by alkali waters.

Disintegration. The Fundamental Cause of the Disintegration of Concrete, A. H. White. Mun. & Cty. Eng., vol. 69, no. 1, July 1925, pp. 27-33, 2 figs. Discusses permanence and hardening of portland cement, expansion of cement in water, contraction of cement products in air, alternate expansion and contraction of cement structures with change in moisture, secondary causes of destruction of concrete, conditions for usefulness and long life of concrete, and factors affecting strength. Paper read at Highway Engineering conference.

Laitance in. Cause and Remedy for Laitance in Concrete, R. M. Miller. Eng. & Contracting (Gen. Contracting), vol. 64, no. 4, Oct. 21, 1925, pp. 887-892, 2 figs. Practical suggestions based on experiences on railway construction job. Paper presented at Am. Concrete Inst. convention.

Water-Cement Ratio. Furnishing Concrete by a Strength Specification. Eng. News-Rec., vol. 95, no. 17, Oct. 22, 1925, pp. 674-677, 3 figs. Practical application of water-cement ratio theory with aid of new scale-weighing device which fixes that ratio for each batch. Contains following articles: Water-Cement Theory as a Fact in Field Control of Concrete, J. G. Ahlers; Scale-Weighing Device Applies Water-Cement Ratio Theory, describing regulator devised by Ahlers.

CONCRETE CONSTRUCTION

Sliding Forms. A Manual for Building and Operating Sliding Forms, R. F. Egelhoff. Eng. News-Rec., vol. 95, no. 20, Nov. 12, 1925, pp. 786-792, 14 figs. Fabrication, placing, filling, jacking, swelling, leveling; bending and placing steel; crew organization; plant, aggregates, and mix; practice in structures with columns and floors.

CONCRETE MIXERS

Central Plants. Central Mixing Plants for the Manufacture of Pre-mixed Concrete, W. E. Hart. Contractors' & Engrs.' Monthly, vol. 11, no. 4, Oct. 1925, pp. 51-54, 2 figs. Advantages and disadvantages of central plant; established plants; location of plant. Published by permission of Am. Concrete Inst. from its Proceedings, vol. 21, 1925.

Standardization. Benefits of Mixer Standardization, P. A. Koehring. Contract Rec., vol. 39, no. 41, Oct. 14, 1925, pp. 1002-1004. Economic waste involved in an unnecessary variety of types and sizes; what happens when manufacturers disregard standards determined upon.

CONDENSERS, ELECTRIC

Rotary Variable. "The Straight-Line Frequency" Variable Condenser, H. C. Forbes. Inst. Radio Engrs.—Proc., vol. 13, no. 4, Aug. 1925, pp. 507-508. Equation for shape of rotary plates in rotary variable condenser is developed so that frequency—angular setting characteristic is a straight line; equation for capacity of this condenser at any angular setting is also given.

CONDUITS

Penstock Breaks. Further Data on Mocassin Creek Penstock Breaks. Eng. News-Rec., vol. 95, no. 17, Oct. 22, 1925, pp. 666-667, 3 figs. Defective welds give way when operator's mistake in opening hydraulic valve causes severe water hammer.

CONVERTERS

ROTARY. On the Synchronization of Rotary Converters, Y. Takahashi. Inst. Elec. Engrs. Japan—Jl., no. 445, Aug. 1925, pp. 639-650, 24 figs. Discusses the various methods of correcting polarity, and instant of polarity reversals; explains switching in phenomena of converters after synchronism; concludes with best condition of switching in on high tension side taps of transformer, and makes remarks on polarity reversal, and operation of automatic synchronizing by polarized relay. (In Japanese, with English abstract.)

COOLING TOWERS

OPERATION. The Theory of Cooling-Tower Operation, D. K. Dean. Power, vol. 62, no. 20, Nov. 17, 1925, pp. 754-757, 6 figs. Presents relationships of various factors governing such operation.

COPPER

SAMPLING AND ASSAYING. Commercial Practice in Sampling and Assaying Copper, A. M. Smoot. Eng. & Min. Jl.—Press, vol. 120, no. 16, Oct. 17, 1925, pp. 605-611. How established customs in industry enter into transactions between producer, smelter, and refiner; weighing of ores, mattes, and bullion; metal sampling; gathering drillings; drying blister; settlement assays; etc.

CORES

CORE OILS. The Qualities of Commercial Core Oils, H. L. Campbell. Am. Foundrymen's Assn.—advance paper, no. 467, for mtg. Oct. 5-9, 1925, 12 pp., 5 figs. Study of properties of 23 commercial core oils; chemical and physical properties of core oils were obtained as well as physical properties of cores made with oils, in order to note any relationship in these characteristics; properties determined were specific gravity, refractive index, iodine number, and unsaponifiable matter; summary of conclusions reached.

COST ACCOUNTING

INVENTORY CONTROL. The Control of Inventory Through the Scientific Determination of Lot Sizes, H. S. Owen. Indus. Mgmt. (N.Y.), vol. 70, no. 5, Nov. 1925, pp. 289-295. Building charts for order-quantity determination.

PRICE CONTROL AND. Cost Accounting and Price Control, D. L. Moran. Indus. Mgmt. (Lond.), vol. 17, no. 19, Sept. 1925, pp. 445-447. Discusses selling policy, uniform methods of costing, method of stabilization, issue of stocking orders, etc. Paper read before Fourth Annual Costing Conference held in London.

CRANES

FOUNDRY. Dust-Proof Foundry Cranes. Foundry Trade Jl., vol. 32, no. 479, Oct. 22, 1925, pp. 347-349, 6 figs. Describes overhead electric travellin gcrane introduced by S. H. Heywood & Co., Reddish, specially designed for use in foundries and other places where dust and dirt are inevitable, with object of reducing to minimum breakdowns and stoppages associated with unprotected open-type overhead travellers used under such conditions.

Transport in Foundries. Foundry Trade Jl., vol. 32, no. 481, Nov. 5, 1925, pp. 385-386, 3 figs. Characteristics of type of crane introduced by Wellman Smith Owen Eng. Corp., London, which has been standardized by this firm; it is electric overhead travelling type designed primarily to meet requirements of iron and steel foundries.

CUPOLAS

FLAMES. Cupola Flames. Metal Industry (Lond.), vol. 27, no. 16, Oct. 16, 1925, pp. 367-368. Describes what appearance of flames above charge and in stack above charging door indicate; continuous flaming above charge; probable defects it indicates; color of flame in stack.

MELTING RATE AND TUYERE RATIOS. Cupola Melting Rate as Affected by Tuyere Ratios, J. Grennan. Am. Foundrymen's Assn.—advance paper, no. 477, for mtg. Oct. 5-9, 1925, 7 pp., 1 fig. Series of experimental heats were run to determine whether any differences could be noticed in cupola melting when tuyere area ratios were changed; observations were taken of air pressures in wind belt and cupola, together with temperature of iron at spout as determined by optical pyrometer; author concludes that there is nothing vital in size of tuyeres and that small tuyeres do not have marked influence on melting.

THERMAL CONTROL. The Regulation of Cupolas from Heat-Economical Standpoint (Die wärmewirtschaftliche Einstellung des Kuppelofens), E. Piwowarsky and F. Meyer. Stahl u. Eisen, vol. 45, no. 26, June 25, 1925, pp. 1017-1022, 7 figs. Description of cupola installation and experimental equipment charging; values obtained and experimental results.

CUTTING METALS

RESEARCH IN. Research in Metal Cutting, O. W. Boston. Am. Mach., vol. 63, no. 21, Nov. 19, 1925, pp. 805-806, 4 figs. Discovery of fundamental facts is aim rather than investigation dealing only with practical results.

CYLINDERS

HOLLOW, COLD WORKING. Effect of Cold Working on the Strength of Hollow Cylinders, F. C. Langenberg. Am. Soc. Steel Treating—Trans., vol. 8, no. 4, Oct. 1925, pp. 447-471 and (discussion) 471-473, 16 figs. Describes process of manufacture in which physical properties of large-size simple hollow cylinders may be greatly increased over usual properties obtained; discusses principles involved in computation of strength of gun tubes and jackets; apparatus employed in manufacture of gun tubes by cold-working progress; effect of annealing operations on elastic strength of cold-worked simple and compound cylinders, after different amounts of cold working had been applied.

D

DAMS

CONSTRUCTION. Wanaque Dam Construction. Pub. Wks., vol. 56, no. 10, Oct. 1925, pp. 349-352, 7 figs. Most extensive use of belt conveyors ever made for a construction project, about 13,000 ft. being used for transporting sand, gravel, cement, concrete and embankment materials; steel conveyor trestle built into concrete core wall.

HYDRAULIC REGULATING GATES. Hydraulic Regulating Gates, F. Newell. Eng. Jl., vol. 8, no. 11, Nov. 1925, pp. 439-450 and (discussion) 450-451, 18 figs. Field engineering and erection problems in connection with various types of hydraulic regulating gates.

MULTIPLE-ARCH. Large Multiple-Arch Dam Being Built in Italy, J. B. Lippincott. Eng. News-Rec., vol. 95, no. 18, Oct. 29, 1925, pp. 710-711, 4 figs. Tidone dam for irrigation and power 170 ft. high; cement plant with vertical kilns built especially for concrete.

STORAGE. Storage Dams at Lake Kenogami, Que., A. F. Dyer. Can. Engr., vol. 49, no. 17, Oct. 27, 1925, pp. 489-494, 8 figs. Construction of dams for Quebec Streams Commission for increasing water storage for industries in that district; main dams across Chicoutimi river at Portage des Roches and Pibrac; six other dams built.

DIESEL ENGINES

CENTRIFUGAL COMPRESSORS FOR. Centrifugal Compressors for Diesel Engines, S. A. Moss. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 1075-1084, 12 figs. Installations of centrifugal compressors for scavenging and supercharging; centrifugal compressors for Diesel Engines; advantages of centrifugal compressors for 2-cycle scavenging; supercharging experiments; theory of supercharging Diesel engine; exhaust-gas turbine for scavenging and supercharging.

EFFICIENCY. The Diesel Engine and Its Overall Economy, C. B. Jahnke. New England Water Wks. Assn.—Jl., vol. 39, no. 2, June 1925, pp. 105-134, 16 figs. Discusses oil situation of United States; status of Diesel and steam-engine efficiency; estimated total cost of steam, motor, and oil-engine-driven plants; actual oil-engine-plant operating costs.

FORGE PLANTS. Diesel Engine Experience in a Modern Forge Plant, J. P. Harbeson, Jr. New England Water Wks. Assn.—Jl., vol. 39, no. 2, June 1925, pp. 138-140. Cities facts and figures that have occurred and are occurring in operation of two Diesel engine generator sets under author's supervision at Camden Forge Co., Camden, N. J., together with reasons for adopting this source of power, troubles encountered and how overcome, and results obtained.

DOCKS

EQUIPMENT. Modern Dock Equipment, H. J. Deane. Inst. Transport — Jl., vol. 6, no. 9, July 1925, pp. 503-514 and (discussion 515-522. Notes on hydraulic and electric capstans; hydraulic power pumps and impounding pumps; vehicular and freight elevators; heavy lift cranes; floating derricks and cranes; quay cranes; tractors; portable piling and stacking machines; warehouse gantry cranes; timber discharging; grain handling; discharging ore and coal; coal bunkering; etc.

E

EDUCATION, ENGINEERING

DANZIG. The Technical High School at Danzig (Die Technische Hochschule zu Danzig), Roessler. Elektrotechnische Zeit., vol. 46, no. 41, Sept. 3, 1925, pp. 1332-1337, 5 figs. Details of building and equipment, especially of electrotechnical and machinery laboratories, heating power plant in course of construction, welfare arrangements for students.

EJECTORS

PNEUMATIC. Pneumatic Ejectors, E. Johnstone-Taylor. Mech. Wld., vol. 78, no. 2020, Sept. 18, 1925, pp. 224-226, 6 figs. Description of pneumatic ejector as a means of raising liquids; is entirely automatic, and pumping medium is compressed air; working of ejectors; self-contained sets; ejectors in tandem; automatic engine equipment.

ELASTICITY

MODULUS AND LIMIT OF. Elastic Limit and Modulus of Elasticity (Limite d'élasticité et module d'élasticité), L. Guillet. Bul. Technique du Bureau Veritas. Vol. 7, no. 9, Sept. 1925, pp. 175-178, 2 figs. Reviews nature and methods of determination of elastic coefficients in general, and examines variations of elastic limit of various alloys; shows that this limit is always maximum for eutectoid alloy; discusses possible researches which may lead to improved elastic limits and moduli; more is to be expected from quarternary and ternary alloys than from binary.

ELECTRIC CURRENTS

SHORT-CIRCUITS. Short-Circuit Calculating Table, S. Murray Jones. Elec. World, vol. 86, no. 17, Oct. 24, 1925, pp. 847-850, 6 figs. New and interesting features incorporated in board built by Alabama Power Co.; arrangement of apparatus and details of use.

ELECTRIC DISTRIBUTION SYSTEMS

INCREASED VOLTAGES. Increased Voltages for General Supply of Light and Power, J. E. King. Elec. World, vol. 86, no. 20, Nov. 14, 1925, pp. 997-1000, 2 figs. Past practice hampered by shortsightedness as to load growth; advantages of 4600-volt service; example of its successful adoption on Connecticut Light & Power system.

ELECTRIC FURNACES

HIGH-FREQUENCY INDUCTION. High-Frequency Induction Furnace, D. F. Campbell. Iron & Steel Inst.—advance paper, no. 3, for mtg. Sept. 1925, 7 pp., 2 figs. Advantages of high-frequency furnaces for research work are very great, owing to speed with which small heats can be made, either in vacuo or in air.

IRON-MELTING. The Electric Melting of Cast Iron, Geo. E. Lamb. Am. Foundrymen's Assn.—advance paper, no. 464, for mtg. Oct. 5-9, 1925, 16 pp. Discusses use of electric furnace in melting cast iron in localities where cost of suitable materials for cupolas for melting are such that electric furnace can compete disregarding entirely quality of iron produced by electric melting process; describes melting equipment of plant with which author is associated in Pacific northwest; operation of furnace; type of lining used was acid type consisting of silica brick walls and roof and cotton made of silica sand with binder rammed in place; troubles encountered in melting alternate heats of iron and steel; practices tried in endeavor to keep down carbon in steel heats following those of iron; tabular data.

MELTING, REFRACTORY PROBLEM. Some Refractory Problems in the Non-Ferrous Electric Furnace Casting Shop, G. F. Hughes. Am. Foundrymen's Assn.—advance paper, no. 469, for mtg. Oct. 5-9, 1925, 15 pp., 6 figs. Discusses refractory problem when using induction and rocking-arc electric melting furnaces to melt yellow brass, copper-tin alloys and that which has been done and remains to be done to bring induction furnace into field where its use may be universal in non-ferrous melting; discusses lining construction of induction furnace together with method of operation to secure best results; careful preheating of newly lined furnace is one of most important factors; consideration of refractory cements.

RESISTANCE. An Electric Resistance Furnace for Laboratory Roasting, A. T. Fry. Chem. Eng. and Min. Rev., vol. 17, no. 204, Sept. 5, 1925, pp. 479-481, 1 fig. Describes electric resistance furnace installed by E. R. Crutcher in research laboratory of Mt. Lyll M. and R. Co., Ltd., under direction of R. Sticht.

TYPES AND APPLICATIONS. Electric Heat as Used in Modern Industry, C. L. Wilson. Indus. Mgmt. (N. Y.), vol. 70, no. 5, Nov. 1925, pp. 277-282, 7 figs. Requirements for various heat-treating industrial processes; analysis of different kinds of electric furnaces and their capabilities.

ELECTRIC METERS

THREE-PHASE POWER, FOR. The Metering of Three-Phase Power, G. D. Malcolm. Elec. Rev., vol. 97, no. 2501, Oct. 30, 1925, pp. 689-690, 1 fig. Effect of abnormal conditions on single-phase and polyphase meters.

ELECTRIC MOTORS, A. C.

CIRCULATING PUMPS, FOR. Synchronous Motors for Dual-Driven Circulating Pumps, J. W. Anderson. Elec. World, vol. 86, no. 19, Nov. 7, 1925, pp. 954-955, 3 figs. Describes installation of power-factor synchronous motors on pumps at Delaware station of Phila. Elec. Co.

INDUCTION. The Reversed-Rotation Short-Circuit Temperature-Rise of Induction Motors, J. H. R. Nixon. Instn. Elec. Engrs.—Jl., vol. 63, no. 346, Oct. 1925, pp. 1012-1017, 3 figs. Analyzes method of testing induction motors for temperature rise, used mainly when means of loading are not available; it is shown that results of such tests are of greatest value when studied in conjunction with certain design features of machines, and simple expressions are developed which enable test measurements of heating to be converted to probable value of full-load temperature rise.

ELECTRIC POWER

HIGH-TENSION, MEASUREMENT OF. Errors in High-Tension Power Measurement When Instrument Transformers are Employed, E. Lienbard. Brown Boveri Rev., vol. 12, no. 8, Aug. 1925, pp. 168-173, 8 figs. Phase errors of current and potential transformers; errors in single and three-phase measurements due to "angle or error" of current and potential transformers; numerical examples.

ELECTRIC SWITCHES

RECHARGEABLE FUSE. Preliminary Tests on New Rechargeable Fuse Switch. Elec. World, vol. 86, no. 20, Nov. 14, 1924, p. 1004, 1 fig. Results of 16 consecutive short-circuit tests conducted by C. F. Harding, on combined rechargeable fuse and disconnecting switch made by Roy. Elec. Mfg. Co.

ELECTRIC TRANSMISSION LINES

CALCULATING DEVICE FOR. The Instant Heavisidion—A Kinematic Computing Device for Long Transmission Lines, V. Karapetoff. Gen. Elec. Rev., vol. 28, no. 11, Nov. 1925, pp. 746-751, 4 figs. Describes modification of author's original device, which is not so universal in its adjustments, but much easier to build, and requiring no previous practice to operate; its theory and practical use.

CIRCLE DIAGRAM FOR. Circle Diagram for Long Lines, P. H. Thomas. Elec. World, vol. 86, no. 18, Oct. 31, 1925, pp. 899-902, 7 figs. Working formulas and graphical solutions developed for calculating power factor or out-of-phase component of receiving and sending ends of long transmission lines.

EARTH POTENTIALS OF A. C. The Regulation of the Earth Potentials of Alternating-Current Systems, T. R. Warren. Instn. Elec. Engrs.—Jl., vol. 63, no. 346, Oct. 1925, pp. 1018-1022, 3 figs. Determination of change in value of earth potential of any part of a.c. system, when that part is earthed through impedance of known value; discussion of Petersen-coil method of earthing, special reference being made to transient-current phenomena; dangers attending use of coil are explained; this method of earthing would be expected to fulfill same duties on any type of a.c. system, irrespective of form of its voltage diagram.

ELECTROPLATING

CHROMIUM, PLATING OF STEEL. Chromium Plating is Brought Down to Commercial Basis, A. H. Packer. Automotive Industries, vol. 53, no. 20, Nov. 12, 1925, pp. 831-832. Process is worked out by Vacuum Can. Co. whereby surface coating one-fourteen-thousandth of inch thick is applied to ferrous metal parts to increase resistance to heat, wear and corrosion.

ELECTRIC WELDING

BUTT-WELDING MULTI-THROW CRANKS. Butt-welding Multi-throw Cranks, A. M. Lount. Machy. (N. Y.), vol. 32, no. 3, Nov. 1925, pp. 222-223, 5 figs. Cutting off stock, bending and forging sections; turning pins and cutting off sections; welding sections together; turning ends and line bearings.

ELECTRIC WELDING, ARC

A. C. WELDING REGULATION. Arc Welding, O. Thanning. Brown Boveri Rev., vol. 12, no. 9, Sept. 1925, pp. 186-190, 6 figs. Discusses the various systems of regulation employed for arc welding by direct current, which are: generator voltage constant, regulation by series rheostat; generator voltage variable, series resistance fixed; generator characteristics sharply falling, no series resistance.

TANK CONSTRUCTION. Automatic Arc Welding in Tank Construction, W. L. Warner. Am. Mach., vol. 63, nos. 17 and 18, Oct. 22 and 29, 1925, pp. 643-645 and 689-692, 6 figs. Oct. 22: Development of arc welding to replace riveting; welding methods for tanks; design of tanks to be welded; strength formulas. Oct. 29: Automatic hand welding; tests on hand and automatically welded tanks; safety factor; specifications for design.

ELECTRIC WELDING, RESISTANCE

TESTS. Mechanical and Metallographic Test of Electric Resistance Welding (Mechanische und metallographische Prüfung von elektrischen Widerstandschweissungen), E. Bock. Maschinenbau, vol. 4, no. 20, Oct. 1, 1925, pp. 989-993, 32 figs. on supp. plates. Discusses structure of material; compares micrographs of weld joints and transition zones for butt and fusion welding; gives hardness tests of welds and adjacent points.

EMPLOYMENT MANAGEMENT

PERSONNEL FORMS. An Analysis of Personnel Forms, D. R. Craig. Indus. Mgmt. (N. Y.), vol. 70, no. 2, Aug. 1920, pp. 122-124, 6 figs. Keeping red tape at minimum by studying current practice in personnel work; service records; how these forms can be used.

ENGINEERING

MEASUREMENT OF WORK. Measurement of Engineering Work, T. G. Price. Elec. Light & Power, vol. 3, no. 10, Oct. 1925, pp. 15-17 and 84, 11 figs. Describes system for measurement of effort expended and amount of engineering work accomplished, devised and placed in operation in Distribution Engineering Division of Commonwealth of Edison Co. of Chicago, purpose of which is to provide engineer of distribution, heads of various subdivisions under his jurisdiction, and interested executives of company with information as to volume of work, effort, cost, etc.

EXPLOSIVES

STANDARDIZATION. Standardization of Explosives, R. N. Van Winkle. Pit & Quarry, vol. 11, no. 3, Nov. 1, 1925, pp. 59-61. Article in which author introduces new viewpoint.

F

FACTORIES

LOCATION. Taking Advantage of "Complementary" Plants, J. A. Piquet. Indus. Mgmt. (N. Y.), vol. 70, no. 5, Nov. 1925, pp. 313-316. Discusses question of location near other plants whose needs or products fit in at one or other end of plant in question; points out that this is often matter, not of relocating, but of attracting such plants to locate in vicinity.

FATIGUE

INDUSTRIAL. Carbon Dioxide as an Index of Fatigue, W. N. Polakov. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 1043-1046, 3 figs. Suggests simple and practical procedure for reducing (if not eliminating) ill effects of fatigue through joint study of work and workman; apparently immediate and reliable indications offered by measurement of CO_2 content in exhalations of workman will enable management to organize work so that organism of workman will produce maximum result with minimum exertion.

FIRECLAYS

PROPERTIES. The Chemical and Physical Properties of Fire Clays from Various Producing Districts, M. C. Booze. Am. Ceramic Soc.—Jl., vol. 8, no. 10, Oct. 1925, pp. 655-665, 29 figs. Chemical analyses, fusion points and firing characteristics of number of flint and plastic clays from various districts, together with short discussion of results and use which can be made of them.

FITS

DESIRABILITY DIAGRAMS. Measuring Systems and Tolerance Limits, P. J. Darlington. Mech. Eng., vol. 47, no. 11, Nov. 1925, pp. 903-905, 4 figs. Fit-desirability diagrams and what they show about systems of measuring.

LIMIT SYSTEM. A System of Limits for Different Kinds of Fits, C. D. Albert. Mech. Eng., vol. 47, no. 11, Nov. 1925, pp. 901-903. Hole vs. shaft as basis of fit system; best method of expressing tolerances; Newall and A. E. S. C. systems; standard method needed to express tolerances.

FLOTATION

P. S. N. PROCESS. The P. S. N. Flotation Process, R. D. Nevett. Chem. Eng. & Min. Rev., vol. 17, no. 202, July 5, 1925, pp. 392-394. Patented by Palmer, Seale and Nevett; process depends solely on use of elemental sulphur which may be added to pulp in form of a powder, or it may be dissolved in any suitable solvent and added to pulp as a solution; application of process to dump material plant.

SULPHIDIZING OXIDIZED ORES. Barium Polysulphide in Sulphidizing Oxidized Ores for Flotation, E. S. Leaver and H. M. Lawrence. U. S. Bur. Mines, Reports of Investigations, Serial No. 2698, Aug. 1925, 4 pp. Results of comparative investigation of sulphides and polysulphides of alkaline and alkaline-earth metals; it is thought that barium polysulphide may prove to be a more satisfactory sulphidizing reagent than others now in use under conditions that favor cheaper barium reagent; for investigation two fairly typical oxidized ores of copper and lead were selected; results obtained by J. B. Lain on sample of ore from Chino Copper Co. included.

FLOW METERS

APPLICATION. Practical Application of Steam Flow Meters. Steam Power, Vol. 4, July and Aug. 1925, pp. 6, 8 and 10; and 6 and 10, 8 figs. Describes practical application in power plant.

FORGINGS

BRASS BARS AND SECTIONS. British Standard Specification for Brass Bars and Sections Suitable for Forgings and Drop Forgings. Brit. Eng. Standards Assn., no. 218, June 1925, 8 pp., 7 figs. Specification covering quality of material, methods of manufacture, freedom from defects, provision of test pieces, mechanical tests, re-tests, inspection, and testing facilities. Appendix giving forms of British standard tensile test pieces.

RING, MANUFACTURE OF LARGE. A Method of Manufacturing Large Ring Forgings, W. L. Blankenship. Am. Soc. Steel Treating—Trans., vol. 8, no. 4, Oct. 1925, pp. 74-483, 10 figs. Presents unique method for production of large ring forgings when using forging press or steam hammer having insufficient space between supporting columns to accommodate forging; describes method employed in production of 8-in., 56-caliber training circle forging starting with split I-bar; method of bending, opening and finish; method of heat treating finished forging.

FOUNDATIONS

CONCRETE PIT FOR ROCK CRUSHER. Concrete Pit Structure Subjected to Diverse Stresses, A. E. Wynn. Eng. News-Rec., vol. 95, no. 19, Nov. 5, 1925, pp. 762-763, 2 figs. Provides watertight foundation and inclosure for rock crusher; copper construction joints; winter construction.

FOUNDRIES

HEAVY CASTINGS. Handling Heavy Castings. Foundry, vol. 53, no. 20, Oct. 15, 1925, pp. 814-817, 6 figs. Describes foundry of Dominion Eng. Works, Montreal, Can., engaged in manufacture of paper-making, hydraulic and hydro-electric machinery and general heavy foundry and machine-work business; mold-drying equipment; coke-fired ovens; charging platform.

MANAGEMENT. Foundry Progress: Past, Present and Future, J. D. Towne. Am. Foundrymen's Assn.—advance paper, no. 473, for mtg. Oct. 5-9, 1925, 13 pp. Early historical developments of ferrous-casting industry; discusses reasons why industries' management has not, as whole, developed as has that of certain other industries; states that average foundry manager misunderstands meaning and extent of modern methods of management; author believes that planning and manufacturing are two headings under which most progress is being made; gives detailed results obtained by analytical study of cleaning-room operations of steel foundry.

FRICTION

CAUSE OF. The Prime Cause of Friction, E. W. Davis. Mech. Eng., vol. 47, no. 11, Nov. 1925, p. 906. Cohesion, under certain conditions, friction; friction wear merely minute and continued breakage.

FUELS

CHEMISTRY. Progress in Chemistry and Use of Fuels (Fortschritte auf dem Gebiete der Brennstoffchemie und Brennstoffverwertung), W. Zisch. Brennstoff- u. Wärmewirtschaft, vol. 17, no. 15, Aug. (1st no.), 1925, pp. 293-298. Reviews recent work done in field of solid, liquid and gaseous fuels.

SELECTION OF. Factors Affecting the Selection of Fuel. Forging—Stamping—Heat Treating, vol. 11, no. 10, Oct. 1925, pp. 366-370, 3 figs. Ultimate choice should be based on cost per unit of goods manufactured, and various secondary advantages of convenience and cleanliness.

[*See also Oil Fuel; Pulverized Coal.*]

FURNACES, INDUSTRIAL

EFFICIENCY. Industrial-Furnace Efficiency, V. J. Azbe. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 1061-1064. Heat losses encountered in industrial-furnace operation; dilution of products of combustion; application of waste-heat boilers to industrial furnaces; incomplete combustion; furnace design.

G

GAS

HEATING VALUE OF. Relation Between Heating Value of Gas and Its Usefulness to the consumer, A Critical Review of the Published Data, E. R. Weaver. U. S. Bur. Standards, Technologic Paper No. 290, July 21, 1925, pp. 347-463, 51 figs. Character of available data; direct observations upon use of gas; discussion of direct evidence regarding usefulness of various qualities of gas; data regarding quantity of gas used by customers and its relation to usefulness of gas; discussion of changes in volume of gas used before and after a change of heating value.

GAS TURBINES

HOLZWARTH. The Holzwarth Gas and Oil Turbine. Mar. Eng., vol. 30, no. 10, Oct. 1925, pp. 570-574, 7 figs. Is of constant-volume combustion or intermittent explosion type in which a slightly pre-compared mixture of gas or oil and air is burned at constant volume in a number of explosion chambers, gases being allowed to expand in turbine nozzles only after complete combustion has occurred in chambers; developments in Germany show commercial possibilities; tests being made on 5000-kw. turbine.

GEAR CUTTERS

DISK, INSPECTION OF. Recommended Practice for the Inspection of Disk Gear Cutters. Am. Mach., vol. 63, no. 19, Nov. 5, 1925, p. 737. Report made by Inspection Committee of Am. Gear Mfrs.' Assn. and adopted as recommended practice.

GEAR CUTTING

SYKES GENERATOR. Sykes Herringbone Gear Generator. Iron Age, vol. 116, no. 18, Oct. 29, 1925, pp. 1189-1191 and 1225, 5 figs. Machines now being placed on market; method of cutting continuous gears, and operation of equipment.

Generating Herringbone Gears, W. E. Sykes. Machy, (N. Y.), vol. 32, no. 3, Nov. 1925, pp. 233-236, 6 figs. Sykes process of cutting double helical gears of continuous-face type, and important features of generators used.

GEARS

EFFICIENCY AND DURABILITY TESTS. Recent Tests on the Efficiency and Durability of Gearing, C. W. Ham. Machy. (N. Y.), vol. 32, no. 3, Nov. 1925, p. 197. Results of tests carried out by author and J. W. Huckert, using testing machine designed and built by W. Lewis; summary of conclusions in regard to durability. (Abstract.) Paper read before Am. Gear Mfrs.' Assn.

INTERNAL. A New Development in Internal Gearing—Comment, A. Fisher. Machy. (Lond.), vol. 27, no. 683, Oct. 29, 1925, pp. 147-149, 5 figs. Analyzes tooth action of new gearing, described in previous issue of same journal, and compares it more closely with tooth action of ordinary involute gearing than is done in original article, so as to arrive at clearer view of relative value of two systems; author concludes that new development in internal gears is theoretically and fundamentally incorrect, and odontoidal tooth contact is non-existent.

STANDARDIZATION. Standardization by Gear Manufacturers. Machy. (N. Y.), vol. 32, no. 3, Nov. 1925, pp. 194-197, 3 figs. Review of papers and reports presented before Am. Gear Mfrs.' Assn.

TOOTH LOADS. Gear Tooth Loads, E. Buckingham. Am. Mach., vol. 63, no. 20, Nov. 12, 1925, pp. 783-785, 5 figs. Elementary treatment of various factors that enter into gear-tooth loads, such as torque, horsepower, pitch-line velocity.

GIRDER, DEFLECTION OF. The Deflection of and the Unit Influence Lines of Deflection for Girders Beams, H. W. Coultas. Concrete & Construcional Eng., vol. 20s, no. 9 and 10, Sept. and Oct. 1925, pp. 491-496 and 565-570, 9 figs. Deflections of continuous beams carrying single unit load in only one bay; unit influence lines of deflection as unit load passes over span.

GRAPHITE

ONTARIO, CANADA. Graphite-Called Plumbago and Black Lead, R. C. Rowe. Power House, vol. 18, no. 17, Sept. 5, 1925, pp. 21-26, 10 figs. Describes deposits in Renfrew county, Ontario, and various methods of reclaiming graphite.

GRINDING

CENTERLESS. Centerless Grinding. Mech. Eng., vol. 47, no. 11, Nov. 1925, pp. 943-946, 7 figs. "Through feed" and "in feed" methods of centerless grinding; increased production of pistons and piston pins obtained by use of centerless grinder; new theory on relation between control wheel, cutting wheel and work. Discussion of paper by W. J. Peets, published in Sept. issue of Journal.

GRINDING WHEELS

FAILURE. Some Causes of Wheel Failures, O. J. Lof. Abrasive Industry, vol. 6, no. 9, Sept. 1925, pp. 279-281. Explains causes of wheel accidents; a thorough investigation of each failure should be made as soon as possible.

GUNITE

CLINGING STRENGTH, REASON FOR. Does Scour Explain Why Gunite Clings Tight to Rock, J. D. Paton. Coal Age, vol. 28, no. 15, Oct. 8, 1925, p. 490. Theory advanced is that blast removes oxidized surface and enables cementing material to react with raw rock face.

GYPSUM

MANUFACTURE. A New and Efficient Gypsum Plant, E. D. Roberts. Pit & Quarry, vol. 11, no. 3, Nov. 1, 1925, pp. 63-70, 8 figs. Describes new plant and equipment of Standard Gypsum Co., at Long Beach, California.

H

HARDNESS

TESTING. Hardness Testing of Hardened Steels (Die Härteprüfung von gehärteten Stählen), R. Mailänder, Stahl u. Eisen, vol. 45, no. 43, Oct. 22, 1925, pp. 1769-1773, 5 figs. Influence of hardness of balls employed in test; tests with diamond balls and cold-hardened steel balls; limits for accurate measurements; Meyer's law for hardened steels.

HEAT

RESISTANCES. Heat Resistances (Die Wärmewiderstände), Wierz. Gesundheits-Ingenieur, vol. 48, no. 37, Sept. 12, 1925, pp. 457-460, 12 figs. Develops calculation of heat resistance in sense of electric resistance, temperature drop, etc., and its application to heat transmission in simple and compound walls, heat delivery of radiators in hot-water and in steam heating, heat transmission in heating boilers, etc.

HEAT TRANSMISSION

HEAT EXCHANGERS. Heat Exchangers (Die Einführung eines Formwertes bei Wärmetauschern), H. Preussler. Stahl u. Eisen, vol. 45, no. 41, Oct. 8, 1925, pp. 1705-1709. Relation of heat-carrier volume to construction design; calculation of design coefficient; load coefficient; feature of heat carrier; importance of heat-absorption and heat-emission capacity; heat accumulators and air heaters.

HEATING

BUILDINGS. Heating Buildings of Large Areas and High Roofs, W. W. Gaylord. Heat & Vent. Mag., vol. 22, no. 10, Oct. 1925, pp. 66-68, 1 fig. Discussion with comparative installation and operating costs, using direct radiation in one case and unit heaters in other.

HEAT REQUIREMENTS, DETERMINATION OF. Heat Requirements of Intermittently-Heated Buildings, W. Sommer. Heat & Vent. Mag., vol. 22, no. 10, Oct. 1925, pp. 72-75, 7 figs. New graphic method of computation, for walls of any construction and for all outside and inside temperatures.

HEATING, HOUSE

GAS AND OIL COMBINATION, USE OF. House-Heating by Combining the Use of Gas and Oil, H. O. Loebell. Heat & Vent. Mag., vol. 22, no. 9, Sept. 1925, pp. 84-86, 1 fig. Characteristics which a desirable fuel for house heating should have; production of oil and its uses; gas best fuel, limited by price; characteristic house-heating load problem; application of degree-day; effect on gas load-factor of duplexing oil and gas fuel.

HEATING, STEAM

CENTRAL. Central Steam-Heating in Winnipeg, J. W. Sanger. Can. Inst. Min. & Metallurgy—Bul., no. 161, Sept. 1925, pp. 874-889, 1 fig. Central steam heating system inaugurated in Winnipeg, October 1924; events which led up to proposal of central steam heating; notes on conditions favoring central heating in Winnipeg, preliminary estimates, location of steam plant, pipe estimates, conduits, pipe insulation, etc.; description of steam plant, with cost data, and losses.

HIGHWAYS

SEAWALL FOR RETAINING. Seawall Retains Picturesque California Highway, H. D. Miller. Eng. News-Rec., vol. 95, no. 18, Oct. 29, 1925, pp. 720-721, 4 figs. Structure 20 ft. high and 1¼ mi. long, built along Rincon Cliffs; will retain sand fill upon which highway will be built.

SNOW-DRIFT CONTROL. Snow Drift Prevention and Control on Highways, V. R. Burton. Eng. News-Rec., vol. 95, no. 19, Nov. 5, 1925, pp. 752-754, 6 figs. Based on state-wide snowfall survey; prevention and control of drifts advocated as best and most economical way of keeping roads clear.

HOUSES

CONCRETE, CORK-LINED. Cork Lined Concrete Houses, H. Whipple. Concrete, vol. 27, no. 5, Nov. 1925, pp. 15-20, 14 figs. How Parmeter-Curns organization is erecting concrete dwellings for Detroit market, using cork for a lining, at a cost that is quite low, competing with frame.

HYDRAULIC TURBINES

INSPECTION. Compressed Air Used for Hydraulic-Turbine Inspection, C. R. Reid. Power, vol. 62, no. 19, Nov. 10, 1925, pp. 716-717, 1 fig. In La Gabelle power house of St. Maurice Power Co., Shawinigan Falls, Quebec, compressed air is used to lower tailwater in wheel chamber of 33,000-hp. turbines when inspections are to be made.

ISLE MALIGNE PLANT, QUEBEC. Erection of Turbines at Isle Maligne, C. M. Scudder. Can. Engr., vol. 49, no. 15, Oct. 13, 1925, pp. 449-452, 7 figs. Description of procedure followed in installation of twelve 45,000 hp. hydraulic turbines at Grande discharge for Duke-Price Power Co., Ltd.; fast time made under severe climatic conditions.

HYDRO-ELECTRIC DEVELOPMENTS

BONNINGTON FALLS, B. C. Power Plant at Lower Bonnington Falls. Contract Rec., vol. 39, no. 41, Oct. 14, 1925, pp. 992-994, 9 figs. Particulars of hydro-electric development recently completed by West Kootenay Power & Light Co., comprising three 20,000 hp. units; replaces an old 4000-hp. low-head plant.

ISLAND PORTAGE, CANADA. Hydro-Electric Development at Island Portage. Can. Engr., vol. 49, no. 14, Oct. 6, 1925, pp. 429-431, 7 figs. General description of project on Abitibi River which will supply power to Hollinger Consolidated Gold Mines, Ltd., at Timmins, Ont.; two 12,000-hp. vertical turbines direct-connected to 12,000-kva. generators.

NIAGARA FALLS PROBLEMS. Some Problems at Niagara Falls. Can. Engr., vol. 49, no. 18, Nov. 3, 1925, pp. 520-521, 1 fig. Horseshoe Falls receding in center; submerged dams would evenly distribute flow over crest and release more water for power purposes; proposal to take water from whirlpool rapids for power development.

NOVA SCOTIA. Capital Costs of Sheet Harbor System, H. S. Johnston. Can. Engr., vol. 49, no. 18, Nov. 3, 1925, pp. 509-511, 4 figs. Further notes covering hydro-electric power developments of Nova Scotia Power Commission at Malay Falls and Ruth Falls; actual costs of both development and transmission line between Sheet Harbor and Pictou.

ST. LAWRENCE RIVER. Hydro Report on St. Lawrence River. Can. Engr., vol. 49, no. 12, Sept. 22, 1925, pp. 339-340. Abstract from statement and report by Hydro-Electric Power Commission of Ontario submitted to International Joint Commission together with supplementary information; report refers to three proposed schemes for power development.

SWITZERLAND. Hydro-Electric Progress in Switzerland. Elec. Rev., vol. 97, no. 2498, Oct. 9, 1925, pp. 581-582, 5 figs. Some details of Amsteg (Uri) power station; barrage is located at Pfaffensprung, and impounds 200,000 cu. meters of water at an available head of 270 m.; turbines are of Pelton type, coupled direct to Oerlikon alternators, designed to work with water under a head of 902 ft. and a delivery of 1045 gal. per sec., running speed being 333½ r.p.m.

HYDRO-ELECTRIC PLANTS

DIX RIVER, KENTUCKY. Dix River Hydro-Electric Development, F. A. Dale. Elec. World, vol. 86, no. 19, Nov. 7, 1925, pp. 939-942, 7 figs. Existence of superpower system makes possible practically 100 per cent utilization of stream flow; plant designed for variation of head from 165 ft. to 235 ft.

GREAT FALLS, TENNESSEE. Great Falls Plant Provides Peak Load Capacity, L. R. Lee. Power Plant Eng., vol. 29, no. 22, Nov. 15, 1925, pp. 1150-1151, 3 figs. Hydro plant of 30,000-kva. capacity is designed to tie in with steam plants; dam provides storage for dry periods.

ISLE MALIGNE, CANADA. Saguenay River Furnishes 540,000 Hp. Power Plant Eng., vol. 29, no. 18, Sept. 15, 1925, pp. 966-968, 8 figs. Isle Maligne hydro-electric plant near Lake St. John, containing twelve 45,000-hp. units, to be completed beginning of 1926; construction work electrical equipment.

OPERATION. Operating Practice in Hydro-Electric Plants, C. B. Hawley. Engrs. & Eng., vol. 42, no. 9, Sept. 1925, pp. 235-245, 4 figs. Discussion of some of the more important considerations governing selection and operation of hydro-electric machinery and accessory equipment; subject is treated from point of view of designing and operating engineers whose province is to select and assemble standard and special equipment available from manufacturer.

SEMI-AUTOMATIC OPERATION. Semi-Automatic Operation for Small Hydro Plants, C. W. Geiger. Power Plant Eng., vol. 29, no. 21, Nov. 1, 1925, pp. 1106-1107, 5 figs. Installation of automatic equipment to convert manually operated plants into semi-automatic plants proves successful.

I

IMPACT TESTING

NOTCHED-BAR TESTS. The Effect of Temperature on the Behaviour of Iron and Steel in the Notched-Bar Impact Test, R. H. Greaves and J. A. Jones. Iron & Steel Inst.—advance paper, no. 9, for mtg. Sept. 1925, 40 pp., 27 figs. Results of study carried out by authors to determine influence of changes of atmospheric temperature on test, to investigate embrittling action of cold, and elucidate, if possible, features of blue brittleness of iron and steel, and temper brittleness of alloy steels. Bibliography. See also Engineering, vol. 120, no. 3121, Oct. 23, 1925, pp. 524-527, 23 figs.

SLOW-BEND vs. Comparative Slow Bend and Impact Notched Bar Tests on Some Metals, S. N. Petrenko. Am. Soc. Steel Treating—Trans., vol. 8, no. 5, Nov. 1925, pp. 519-564, 26 figs. Results of tests to determine whether slow bend test may be used as substitute for, or as useful addition to, impact test; they were made in Izod pendulum-type impact machine 120 foot-pounds capacity and Humfrey slow-bend machine of 100 foot-pounds capacity, on cantilever beam-type specimens, having 10-by-10-mm. sections; slow-bend test gave values lower than impact for non-ferrous materials and higher than impact for steels; slow-bend is less convenient than impact test for ordinary routine practice. Bibliography.

INDUSTRIAL MANAGEMENT

PLANNING DEPARTMENT. A Planning Department—for What? Automotive Industries, vol. 53, no. 18, Oct. 29, 1925, pp. 734-736. If only for production, without taking into equal account such important factors as market conditions and sales possibilities, its value is apt to be small; sales and production must be planned together.

SALES ORGANIZATION. Liquid Carbonic Sales Organization, W. J. Graham. Mgmt. & Admin., vol. 10, no. 5, Nov. 1925, pp. 255-258. Organization of sales department of Liquid Carbonic Co.; territorial organization; general sales manager; assistant sales manager; special sales executives; branch manager; sales research and planning; classes of customers, orders, and terms; sales information manual; sales conventions; contests among salesmen and branches.

SIMPLIFICATION. Are There Any Real Obstacles to Simplification, R. M. Hudson. Factory, vol. 35, no. 4, Oct. 1925, pp. 537-538, 586, 588 and 590. These obstacles are discussed under heads of antipathy to government, fear of government regulation or control, fear of prosecution, lack of co-operative spirit.

INDUSTRIAL PLANTS

DESIGN. Influence of Plant Design on Plant Efficiency, H. T. Moore. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 1059-1060. Economical selection of industrial site; basic data which determine plant design; site limitations which affect plant layout; design of plant.

ELECTRIC-POWER COSTS. Electrical Power Costs, D. Ross-Ross. Mgmt. & Admin., vol. 10, no. 5, Nov. 1925, pp. 285-286, 4 figs. Analysis of how to avoid maximum demand charges.

INDUSTRIAL RELATIONS

FOREMAN'S HELP IN IMPROVING. Winning the Foreman's Help, H. Diemer. Am. Mach., vol. 63, no. 20, Nov. 12, 1925, pp. 775-777. Existing attitudes toward industrial relations and personnel policies; winning foreman's help in promoting satisfactory relations; things foreman can do.

INTERNAL-COMBUSTION ENGINES

MICHELL CRANKLESS. The Michell Crankless Engine. Automobile Engr., vol. 15, no. 207, Oct. 1925, pp. 316-320, 13 figs. New form of high-speed multi-cylinder engine which, by radical novelty of its construction, evades several of most serious difficulties confronting designers of conventional type of engine; new design is in perfect dynamic balance.

See also Airplane Engines; Automobile Engines; Diesel Engines; Gas Engines; Oil Engines.

IRON

Desulphurization of. Desulphurization of Ferrous Metals, Geo. A. Drysdale. Am. Foundrymen's Assn.—advance paper, no. 463, for mtg. Oct. 5-9, 1925, 10 pp. Author states that in dealing with ferrous metals, good deal of trouble encountered is caused by action of sulphur and oxides when metal is poured into mold and while it is setting; action of sulphur on cast iron is very detrimental, causing excessive shrinkage, hardness, porosity, and blowholes; effect of using sodium compound as desulphurizer and purifier, in melting of high-sulphur iron, produces softer iron and eliminates hard spots, excessive shrinkage, porosity and sulphur scab; resulting castings tend to give higher physical properties and lower Brinell hardness; use of sodium compound as flux; results of experiments.

Magnetic Permeability. Checking the Magnetic Permeability of Iron, P. B. Findley. Scientific Am., vol. 133, no. 4, Oct. 1925, p. 233, 3 figs. Notes on a new method for quick testing of cores and wire for radio and other apparatus.

IRON AND STEEL

Electrolytic Corrosion. The Electrolytic Corrosion of Ferrous Metals, W. M. Thornton and J. A. Harle. Faraday Soc.—Trans., vol. 21, part 1, no. 61, Aug. 1925, pp. 23-32 and (discussion) 32-35, 4 figs. From experimental results, conclusion is reached that not only have pure metals definite rates of corrosion according to Faraday's law of electrolysis, but that every ferrous alloy examined has specific rate of electrolytic corrosion by which it can be identified with certainty.

Hardness. The Influence of Strain and of Heat on the Hardness of Iron and Steel, A. Saveur and D. C. Lee. Iron & Steel Inst.—advance paper, no. 18, for mtg. Sept. 1925, 7 pp., 4 figs. Experiments show that on heating normalized iron and steel above atmospheric temperature their strength and hardness are at first slightly decreased, this being followed by increase which reaches its maximum in blue-heat range of temperature; straining normalized iron or steel above their elastic limit increases both strength and hardness; hardness resulting from cold deformation at room temperature is increased further by heating metal above atmospheric temperature.

IRON CASTINGS

Design. Metallurgical Points on Casting Design, F. C. Edwards. Metal Industry (Lond.), vol. 27, no. 16, Oct. 16, 1925, pp. 365-367, 6 figs. Influence of size of section on strength of cast iron; thickness of section and size of graphite; differential shrinkage; points out typical case in historic example of failure of hydraulic cylinder during building of Menai bridge; shrinkage more important than crystal structure at sharp corners; reinforcing cast-iron section.

L

LIGHTING

Street. Electric Street Lighting in Rural Areas, E. C. Lennox. Gas Jl., vol. 172, no. 3256, Oct. 7, 1925, pp. 38-40, 2 figs. Discusses electric lamp, switching, fittings, underground cables. Abstracts from paper before Instn. Pub. Lighting Engrs.

LIQUIDS

Characteristic Curves of Jets. The Characteristics Curves of Liquid Jets, E. Tyler and E. G. Richardson. Physical Soc. Lond.—Proc., vol. 37, part 5, Aug. 15, 1925, pp. 297-311, 10 figs. Continuing work of S. W. J. Smith and H. Moss upon relation between length of capillary jet and its velocity of efflux from cylindrical orifice, further examination has been made of causes to which main features of curves obtained by these authors are due; results indicate that, while surface tension is of prime importance in first parts of these curves, viscosity is dominating factor in second.

Viscosity at Boiling Point. On the Viscosities of Liquids at Their Boiling Points, D. B. Macleod. Faraday Soc.—Trans., vol. 21, part 1, no. 61, Aug. 1925, pp. 160-167. Concludes that boiling points are unsatisfactory temperatures at which to compare viscosities of liquids; by correcting boiling points to condition of equal free space, viscosities of liquids become proportional to their molecular weights in liquid state.

LOCOMOTIVES

Coaling Plants. Locomotive Coaling Plant: Latest German Practice, H. Koblenz. Indus. Mgmt. (Lond.), vol. 12, no. 10, Oct. 1925, pp. 474-476 and 486, 12 figs. Chief requirements that a locomotive coaling plant should fulfill; describes development of German system.

Diesel-Engined. The Baden Diesel Locomotive (Die "Baden"-Motor-Lokomotive). Motorwagen, vol. 28, no. 22, Aug. 10, 1925, pp. 480-481, 4 figs. Locomotive contain hydraulic transmission in successful commercial service; transmissions consist of vane pump and vane engine; speed is changed by connection in a varying number of compartments in pump.

Feedwater Treatment. Treated Water Increases Locomotive Efficiency, R. C. Bardwell. Ry. Rev., vol. 77, no. 18, Oct. 31, 1925, pp. 669-671. Notes on scale pitting, and foaming; boiler compounds, soda-ash treatment, zeolite, lime-soda plant, and continuous plants; savings effected by treatment. Paper presented at Am. Ry. Bridge & Bldg. Assn.

Stokers for. *See Stokers, Locomotive.*

Testing Plant. The Locomotive Testing Plant and Its Influence on Steam-Locomotive Design, L. H. Fry. Mech. Eng., vol. 47, no. 11, Nov. 1925, pp. 881-886, 7 figs. Brief history of locomotive testing plants and their contributions to development of locomotive; work done by Altoona testing plant; contracts of size and economy of locomotives made 20 years ago and at present time. (Abridged.) See also Ry. Age, vol. 79, no. 17, Oct. 24, 1925, pp. 752-755, 3 figs.

LOGGING

Machinery for. Logging Machinery Used on the Pacific Coast, Wm. C. Shaw. Mech. Eng., vol. 47, no. 11, Nov. 1925, pp. 913-914, 1 fig. Notes on steam engines, frames, gears and drums, boilers and Diesel engines.

LUBRICANTS

Grease. Lubricating Grease, G. B. Vroom. Am. Soc. Naval Engrs.—Jl., vol. 37, no. 3, Aug 1925, pp. 551-559, 4 figs. Discusses consistency, flow point, characteristics of contained oil, and freedom from impurities and fillers; determination, by experimental laboratory data, of behavior of greases made up to conform to known operating conditions, in respect to bearing temperature and pressure, and temperatures of cups, both gravity and continuous feed types; answers to objection that placing grease on a scientific footing would result in an increase of costs.

LUBRICATING OILS

Density at Low Temperatures. Density of a Lubricating Oil at Temperatures from -40° to +20° C., H. K. Griffin. Indus. & Eng. Chem., vol. 17, no. 11, Nov. 1925, pp. 1157-1158, 2 figs. Properties of oil; filling pycnometer; experimental procedure.

Filter for Recovery of. The Steam-Line Oil Filter. Petroleum Times, vol. 14, no. 351, Sept. 26, 1925, pp. 535-536, 2 figs. Describes invention by H. S. Hele-Shaw for recovery of used lubricating oils.

LUBRICATION

Problems. Lubricants and Lubricating, Jas. Duguid. Mech. Eng., vol. 47, no. 11, Nov. 1925, pp. 887-894. Supply of lubricating oils; theory of lubrication; cylinder oils; lubrication of cylindrical bearings; bearing loads and temperatures; application of lubricants to bearings; power losses; packing waste; reclamation of used packing and oil; cost of lubrication. (Abridged.)

M

MACHINE DESIGN

Analysis of Problems. The Question of Mark in Machine Design, F. E. Cardullo. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 1009-1011, 3 figs. Difficulties encountered in analysis of design problems that call for exercise of judgment; loose thinking and its probable effects on engineering design; false impressions current with regard to design of machine foundations, bearings, open-side machine frames, etc.

MACHINE-TOOL INDUSTRY

Future of. Future of the Machine Tool Industry, O. B. Iles. Mech. Eng., vol. 47, no. 11, Nov. 1925, pp. 894-896. Forecast covering next 15 or 20 years, dealing with design, construction, and business phases, and based on opinions held by leaders in industry.

MACHINE TOOLS

Arrangement for Processing Parts. Machine-Tool Arrangement for Processing Parts, H. H. Edge. Am. Mach., vol. 63, no. 20, Nov. 12, 1925, pp. 759-761, 10 figs. Successful operating plan that provides for dividing parts to be machined into two classes, round work and flat work.

MATHEMATICS

Dimensional Notation. Dimensional System of Notation, V. Petrovsky. Gen. Elec. Rev., vol. 28, no. 11, Nov. 1925, pp. 757-761. Presents modification of older attempts at dimensional notation.

MALLEABLE IRON

Annealing. A Consideration of the Annealing Operation in the Malleable Foundry, C. J. McNamara and C. H. Lorig. Am. Foundrymen's Assn.—advance paper, no. 466, for mtg. Oct. 5-9, 1925, 11 pp., 14 figs. Results of data secured by experiments which were carried out with object of obtaining knowledge of rate at which iron graphitizes; continued slow cooling below critical point is said to be of little purpose in producing good malleable iron; specimens quenched in water from temperature just below critical range were as ductile as those which were allowed to cool in furnace; excessive oxidation of annealing pots is one real disadvantage resulting from opening annealing oven at too high a temperature.

Rapid Annealing. The Effects of Some Modifications of a Rapid Annealing Method on the Physical Properties of Malleable Iron, A. Hayes, E. L. Henderson and G. R. Bessmer. Am. Foundrymen's Assn.—advance paper, no. 481, Oct. 5-9, 1925, pp. 6-11, 9 figs. Preliminary report of careful study being made of influences of modification of various rapid methods of annealing upon physical properties of product: results of author's investigations lead to conclusion that any annealing method which produces small grain structure and well rounded carbon spots, and which results in complete graphitization, will duplicate physical properties of malleable iron produced by present commercial methods; such properties can be duplicated in annealing periods of 40 hours or less.

MANGANESE STEEL

Heat Treatment, Effect on. Certain Unsolved Problems Relating to Manganese Steel, Rob. Hadfield. Chem. & Industry, vol. 44, no. 43, Oct. 23, 1925, pp. 1042-1044, 4 figs. Effect of heat treatment on hardness and magnetic character; photomicrographic examination.

MATERIALS HANDLING

Problems. Materials-Handling Problems and Their Solution, F. D. Campbell. Mech. Eng., vol. 47, no. 11a, Mid-November, 1925, pp. 973-978, 9 figs. Deals with problems of movement of products in industrial plants, whether goods are being received or are going through various processes of operation, distribution, assembly, collection, packing, storage and shipment, and application of mechanical means to effect such movement.

Transferring, Without. Handling Without Transferring, M. W. Potts. Indus. Mgmt. (N. Y.), vol. 70, no. 5, Nov. 1925, pp. 296-300, 10 figs. Systems which do away with unnecessary rehandling.

MEASUREMENTS

Bibliography. Literature on Measuring. Eng. Progress, vol. 6, no. 9, Sept. 1925, pp. 307-308. Bibliography of general articles; length and capacity measuring; time measurement; pressures, velocities, etc.; mechanical properties and composition of bodies; heat measurements; electric and magnetic measurements; optical and acoustic measurements.

Precision. Precision Measurements, G. Berndt. Eng. Progress, vol. 6, no. 9, Sept. 1925, pp. 289-291, 4 figs. Their significance and utility in engineering; examples taken from machine construction and instrument making, illustrating great savings achieved by applying precision measuring. (Abstract.) Lecture presented before Cologne Mtg. on Measuring Instruments.

MEASURING INSTRUMENTS

Optical. Optics as Applied to Measuring. O. Eppenstein. Eng. Progress, vol. 6, no. 9, Sept. 1925, pp. 293-301, 23 figs. Applications in construction of apparatus and machines; notes on magnifying glass; optical dividing head; measuring microscope; projecting apparatus; thread-measuring comparator; micrometer; optimeter; measuring machine; measuring by light interference.

MECHANISMS

Geneva-Stop Analysis. Graphical Analysis of the Geneva Stop, C. M. Conradson. Machy. (N. Y.), vol. 32, no. 3, Nov. 1925, pp. 212-214, 9 figs. Analysis presented with view to making study of this mechanism easier; it is shown that pair of imaginary arms connected by imaginary link van be substituted for Geneva stop mechanism and be kinematically identical with it.

METALS

Fatigue Tests. High-Frequency Fatigue Tests. Metallurgist (Supp. to Engineer, vol. 140, no. 3644), Oct. 30, 1925, pp. 145-146. Review of account by C. F. Jenkin, of Oxford, of series of tests at very high speeds; he has succeeded in reaching 2000 alternations per second in oscillatory bending test.

X-Ray Examination. New X-Ray Studies of the Ultimate Structures of Commercial Metals, Geo. L. Clark, E. W. Brugmann, and S. D. Heath. Indus. & Eng. Chem., vol. 17, no. 11, Nov. 1925, pp. 1142-1146, 17 figs. Presents monochromatic pinhole method as most fruitful for utilizing X-rays in practical identification of working and heat-treating processes in metals; reproduces representative X-ray photographic diagrams for metals with different properties, to show great possibilities of obtaining purely scientific information, of fundamentally relating physical properties with ultimate structures, and of controlling and perfecting manufacturing technique by this method.

MINERAL DEPOSITS

Canada. The Mineral Resources of Northern Ontario, W. A. Parks. Roy. Soc. Arts—Jl., vol. 73, no. 3796, Aug. 21, 1925, pp. 898-915 and (discussion) 915-917. Outline of general geology of Canadian Shield, drawing attention to certain superficial conditions that seriously affect discovery and winning of ores; review of silver, nickel, gold, iron, copper, cobalt and other metals, with short reference to non-metals and general conditions.

MOLDING MACHINES

Electric. The Electric Molder, A. Jensen, Jr. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 984-986, 4 figs. Analysis of its power requirements and production possibilities in woodworking, and comparison with belt-driven molder.

MOTOR TRUCKS

DENNIS. A 30-cwt. Dennis. Motor Transport (Lond.), vol. 41, no. 1077, Oct. 19, 1925, pp. 481-483, 9 figs. Low first cost, simplicity in design and ease of upkeep characterize entirely new chassis; four-cylinder engine with 18-21 hp. R.A.C. rating.

TRANSMISSION CASE, MACHINING. Machining the Transmission Case of the Mack Truck and Bus, F. W. Curtis. Am. Mach., vol. 63, nos. 19 and 20, Nov. 5 and 12, 1925, pp. 729-733 and 765-768, 26 figs. Nov. 5: Inspection of rough castings; limits of accuracy required; variety of milling operations; boring of shaft holes in one setting; unusual types of trunnion jigs. Nov. 12: Method of driving studs; forming selector-shaft holes; rigid inspection methods employed; machining operations for top cover.

N

NICKEL PLATING

ADHESION TO BASE METAL. Adhesion of Deposited Nickel to the Base Metal, E. A. Ollard. Faraday Soc.—Trans., vol. 21, part 1, no. 61, Aug. 1925, pp. 81-87 and (discussion) 87-90, 6 figs. Investigation undertaken with intention of studying factors governing adhesion of deposits, and of obtaining definite test of true adhesion; experiments were made with nickel on steel shafts; it is shown that considerable adhesion is attained when nickel is deposited on mild steel under correct conditions.

NON-FERROUS METALS

ENDURANCE PROPERTIES. Endurance Properties of Non-ferrous Metals, D. J. McAdam, Jr. Am. Inst. Min. & Met. Engrs.—Trans., no. 1506-E., Oct. 1925, 22 pp., 14 figs. Typical stress-cycle graphs for non-ferrous metals as obtained at Naval Engineering Experiment Station, University of Illinois, and McCook Field; form of stress-cycle graph; possible reasons for abnormal graphs for some non-ferrous metal obtained at University of Illinois and at McCook Field. Bibliography.

MELTING, ATOMIZED-COAL SYSTEM OF. Atomized Coal System of Non-Ferrous Melting, R. Black and C. L. Shafer. Am. Foundrymen's Assn.—advance paper, no. 472, for mtg. Oct. 5-9, 1925, 7 pp. Atomized coal system is name applied to use of specially prepared bituminous coal for melting non-ferrous metal which, so far has been applied only to crucible melting; describes preparation of coal, and method and equipment used in burning; it is stated that theory of burning as worked out for pulverized coal does not hold good for atomized coal as related to requirements of combustion; for atomized coal, air supply and combustion space in experimental work has been steadily diminished; costs of atomizing coal and of melting with it are given.

TEMPERATURE DETERMINATION. The Temperature Determination of Non-Ferrous Alloys, R. L. Binney. Am. Foundrymen's Assn.—advance paper, no. 470, for mtg. Oct. 5-9, 1925, 11 pp. Discusses points brought out in author's study of temperature control; types of devices investigated were optical, radiation, base-metal pyrometers, temperature cones, potentiometer vs. high- and low-resistance meters and combinations of these methods.

O

OIL ENGINES

CYLINDER WEAR DUE TO DIRTY FUEL. How Dirty Fuel May Damage Oil-Engine Cylinders, A. B. Newell. Power, vol. 62, no. 17, Oct. 27, 1925, pp. 644-645, Points out that engines burning dirty fuel always show abnormal cylinder wear, thus wear ultimately is traceable to foreign substances; absence of abnormal wear at lower end of cylinder indicates that abrasive in fuel is not directly causing trouble; better lubrication needed.

OIL FUEL

BURNERS. Some Hints on Installing and Operating Domestic Oil Burners, C. H. Chalmers. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 31, no. 10, Oct. 1925, pp. 471-475, 1 fig. Notes on oil storage, and sub-basement tank; U. S. Government recommendations on boiler and furnace design for oil burners.

The Filam Oil Burner. Petroleum Times, vol. 14, no. 347, Aug. 29, 1925, pp. 365-366, 2 figs. Simplified oil-firing device in which complete atomization of fuel at low velocity has been perfected in such manner that there is correct combustion, resulting in flame of high temperature, short length and soft diffusion.

OIL WELLS

DRILLING. Drilling Screen Holes in Oil-Well Casing, C. S. Ashley. Machy. (N.Y.), vol. 32, no. 3, Nov. 1925, p. 190, 2 figs. Describes method adopted in oil wells in Southern California of drilling screen pipe or casing from inside; equipment used consists of 2 multiple-spindle drilling machines.

ORE DRESSING

CRUSHING PLANTS. A Model Crushing Plant at Douglas, Arizona, G. J. Young. Eng. & Min. Jl.—Press, vol. 120, no. 17, Oct. 24, 1925, pp. 653-657, 11 figs. Describes crushing plant of Calumet & Arizona Min. Co. at its smelter at Douglas, Ariz, designed to receive run-of-mine ore and to crush to ½-in. size for reverberatory smelting; provision is made for mechanical sampling; individual drives liberally used; remarkably little dust when running.

CRUSHING PRACTICE. Crushing Practice at Ajo, D. Cole. Min. & Metallurgy, vol. 6, no. 226, Oct. 1925, pp. 524-526, 2 figs. Describes crushing plant of New Cornelia Copper Co. constructed to serve its new flotation concentrator; flow scheme and machinery which were finally adopted; unique method separating finished portion from center of stream issuing from rolls, results in rod-mill feed that is not at all definitely sized but which, when roll shells are in good condition, contains much smaller percentage of oversize than would be imagined.

OXY-ACETYLENE WELDING

PIPE LINES. Welding City Pipe Lines, E. E. Lungren. Gas Industry (Mfrd. Gas Edition), vol. 25, no. 8, Aug. 1925, pp. 285-290, 5 figs. Discusses use of oxy-acetylene welding in city lines service. Welding pipe joints ends gas leak troubles; preventing breaks from contraction stresses; comparative installation costs; uses of blowpipe in gas industry.

P

PAINTS

TESTING. Testing Paint by the Removed Film Method. Ry. Mech. Engr., vol. 99, no. 11, Nov. 1925, pp. 693-697, 4 figs. Presence of inferior bases and reducing oils can be easily determined; tests of new stock prevent waste. Abstracts of paper by W. O. Quest, and committee report before Am. Ry. Assn.

PAPER MANUFACTURE

PULP MANUFACTURE. Pulp Making in British Columbia, Geo. M. Taylor. Can. Machy., vol. 34, no. 13, Sept. 24, 1925, pp. 13-14, 4 figs. Outlines methods in manufacture of pulp and describes outstanding mills in British Columbia.

WOOD PULPING. Soluble Sulphites and Their Bisulphites In the Pulping of Wood, J. D. Rue. Paper Trade Jl., vol. 81, no. 16, Oct. 15, 1925, pp. 54-56. Review of literature.

PAPER MILLS. A Proposal for Reducing the Contamination of Streams by Strawboard Mills, D. Rue and F. G. Rawling. Paper Trade Jl., vol. 81, no. 15, Oct. 8, 1925, pp. 48-49. Discusses difficulties of disposing of waste from lime process, and new process which it is believed will obviate many of the difficulties; cost of new process. Paper to be presented at Technical Assn. Pulp & Paper Industry convention, Oct. 14-15, 1925.

PAVEMENTS

ASPHALT RESURFACING. Salvaging Old Streets by Asphalt Resurfacing and Oiling. Eng. News-Rec., vol. 95, no. 19, Nov. 5, 1925, pp. 758-761. Abstracts of papers presented to Asphalt Assn., giving details of methods and costs of resurfacing streets with asphalt, as follows: Resurfacing of Paved Streets at Columbus, Ohio. R. H. Simpson: Double-Seal Method of Resurfacing Macadam at Rockford, Ill. B. C. Harvey; Resurfacing Gravel at Grand Rapids, Mich., C. A. Paige; Methods and Cost of Oiling Macadam, Rockford, Ill., C. B. Harvey; Reconditioning Macadam for Resurfacing, Springfield, Mass. W. H. Woodward; Cost of Oiling Gravel Roads in Cuddo Parish, Louisiana, J. T. Bullen; Surface Treating Gravel Streets, Springfield, Mass., W. H. Woodward.

PLANERS

GEAR. 14-inch Spiral Bevel Gear Planer. Machy. (Lond.), vol. 27, no. 684, Nov. 5, 1925, pp. 171-173, 5 figs. New machine by Alfred Herbert, Coventry, suitable for cutting all standard tooth pitches up to and including 5-diametrical, or equivalent, in circular or module pitch, and is notable for simplicity and convenience with which it can be set and operated.

VARIABLE-VOLTAGE REVERSING DRIVE. Variable-voltage Reversing Planer Drive, A. L. Harvey. Machy. (N. Y.), vol. 32, no. 3, Nov. 1925, pp. 215-216, 1 fig. Enumerates advantages of variable-voltage equipment; describes Westinghouse planer equipment, which consists of reversing planer motor, motor-generator set, panel for field-reversing contactors, field rheostats to obtain proper speed on cutting and return strokes, etc.; comparison of constant-voltage and variable-voltage drives.

POLES, CONCRETE

CENTRIFUGAL METHOD, BY. Hollow concrete Poles by the Centrifugal Method. Concrete, vol. 27, no. 4, Oct. 1925, pp. 40-41, 1 fig. Hennebique patents; uses for concrete poles; centrifugal process; mixing concrete.

POWER FACTOR

NOMOGRAM FOR CALCULATION. Determination of the Reactive Kv-a. and the Capacity Necessary to Improve Power-factor, J. Hak. Gen. Elec. Rev., vol. 28, no. 11, Nov. 1925, pp. 798-799, 2 figs. Describes nomogram which offers labor-saving tool with which many engineering calculations may be shortened and tedious work of repeated slide-rule calculations avoided. Translated from Revue Générale de l'Electricité.

POWER TRANSMISSION

LINESHAFT ERECTION. Practical Pointers on the Groundwork Necessary Before Erecting a Lineshaft, G. Trimm. Indus. Engr., vol. 83, no. 11, Nov. 1925, pp. 519-523 and 554, 8 figs. Points out methods of rigidly supporting lineshafts so that they will maintain proper alignment in various types of buildings.

PULVERIZED COAL

COMBUSTION. Chemistry of Combustion of Pulverized Coal, S. C. Martin. Power Plant Eng., vol. 29, no. 21, Nov. 1, 1925, pp. 1091-1092, 2 figs. High velocity of both air and fuel necessary in removing inert gaseous envelope surrounding particles of fuel.

PULVERIZERS. The Development of a Unit Pulverizer, R. S. Riley. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 1047-1052, 10 figs. Describes machine for preparing coal to be burned in powdered form and of its development; results of tests to determine its reliability, ability to pulverize wet coal, power consumption, durability, fineness of grinding, etc.

MALLEABLE FURNACES. Malleable Furnace Fired With Pulverized Coal, W. Hathaway. Foundry, vol. 53, no. 20, Oct. 15, 1925, pp. 824-828 and 832, 5 figs. Economy in operation secured through replacement of hand-fired method with new system.

PUMPING STATIONS

DIESEL ENGINES IN. Diesel Engine Experience in a Pumping Plant, L. C. L. Smith. New England Water Wks. Assn.—Jl., vol. 39, no. 2, June 1925, pp. 135-137. Describes large economy and satisfactory service on ten months initial run at Huntington, Long Island.

HYDROPNEUMATIC. Some Novel Hydro-Pneumatic Pumping Plants. Engineer, vol. 140, no. 3642, Oct. 16, 1925, pp. 413-414, 6 figs. Describes various developments arising from water-lifting device called hydrautomat, which is self-acting device for using energy of low heads of running water to raise liquids to high levels through agency of compressed air.

PUMPS

CIRCULATING, MOTOR-DRIVEN. Control for Dual-Driven Circulating Pumps, J. W. Anderson. Elec. World, vol. 86, no. 20, Nov. 14, 1925, pp. 1006-1007, 1 fig. Philadelphia Electric Co. uses synchronous motors in its Delaware station for circulating pumps; describes detailed control system.

PUMPS, CENTRIFUGAL

STARTING WITHOUT PRIMING. Starting Centrifugal Pumps Without Priming, C. H. S. Tupholme. Power Plant Eng., vol. 29, no. 18, Sept. 15, 1925, pp. 946-947, 2 figs. Device, installed at one of big London plants, consists of closed steel plate cylinder located on suction line of pump and somewhat higher level; inlet to device is at top and outlet to pump immediately beneath, conical pipe being fixed between the two; describes action of device.

R

RADIOTELEGRAPHY

FREQUENCY MEASUREMENT. The Measurement of Frequency and Allied Quantities in Wireless Telegraphy, K. E. Edgeworth and G. W. N. Cobbold. Instn. Elec. Engrs.—Jl., vol. 63, no. 345, Sept. 1925, pp. 919-920 and (discussion) 920-922. Authors suggest description of frequencies in terms of "pitch", a term which is defined as relationship of particular frequency to some standard frequency; proposed standard is frequency of 1 cycle per sec., and relationship suggested is such that pitch is logarithm of ratio between there frequencies; possible advantages of use of pitch.

SHORT-WAVE TRANSMITTERS AND RECEIVERS. Recent Commercial Development in Short Wave Transmitters and Receivers, S. E. Anderson, L. M. Clement and G. C. De Coutouly. Inst. Radio Engrs.—Proc., vol. 13, no. 4, Aug. 1925, pp. 413-436, 13 figs. Describes transmitter and receiver recently developed for use of U. S. Coast Guard, for operation on wave lengths between 100 and 200 m.; summary of various circuit considerations; actual transmitter finally developed and its operating characteristics; various problems to be met in design of radio receiver of this character; frequency characteristics of receiver as developed and method of determining them.

RADIOTELEPHONY

AMPLIFIERS. Selective Amplifiers, P. K. Turner. Experimental Wireless, vol. 2, no. 25, Oct. 1925, pp. 801-809, 11 figs. A short review of question of correct selectivity, with simple graphs and charts for design purposes.

History and Future. History and Future of Radio, S. M. Kintner. Iron & Steel Engr., vol. 2, no. 10, Oct. 1925, pp. 418-424. Notes on radiotelephony; continuous waves; heterodyne; world's war radio uses; entrance of large electrical companies into radio; perfection of trans-oceanic service; carrier-current developments; radio broadcasting; short waves; future of radio.

RAILWAY ELECTRIFICATION

Great Northern, Washington. Great Northern Electrification, E. Marsball. Ry. Age, vol. 79, no. 20, Nov. 14, 1925, pp. 899-901, 3 figs. Motor-generator locomotives will be used on 24-mi. heavy-grade section including Cascade tunnel.

RAILWAY MANAGEMENT

Materials Inspection. The Inspection of Railway Materials. Ry. Engr., vol. 46, no. 549, Oct. 1925, p. 353. Writer urges need for improving inspection arrangements in order to secure more effective supervision and economy in time.

RAILWAY MOTOR CARS

Gasoline-Electric. Double End Controlled Brill Gas-Electric Car. Ry. Age, vol. 79, no. 17, Oct. 24, 1925, pp. 757-758, 5 figs. Driven by Brill-Westinghouse 250-hp. gas engine; flexible control incorporated in one throttle.

Oil-Electric. New C. N. R. Oil-Electric Passenger Cars. Can. Engr., vol. 49, no. 19, Nov. 10, 1925, pp. 529-533, 5 figs. Canadian Nat. Rys. introduce two new types of self-propelled car for passenger service; power plant in both cases consists of Diesel engine direct connected to d.c. generators; standard railway-type motors mounted on trucks.

RAILWAY OPERATION

Stopping and Starting Trains, Cost of. Estimated Cost of Stopping and Starting Trains, O. O. Carr. Ry. & Locomotive Eng., vol. 38, no. 10, Oct. 1925, pp. 291-292. Results of series of tests and checks made with dynamomenter car in connection with other tests being made at time.

Train Control. Reading Three-Speed Control. A. H. Yocum. Ry. Signaling, vol. 18, no. 11, Nov. 1925, pp. 409-412, 7 figs. Continuous system installed on high-speed dense traffic line of double track Camden, N. J., to Atlantic City.

RAILWAY SHOPS

Locomotive. Some Impressions of Burnham Locomotive Sbop. Ry. Mech. Engr., vol. 99, no. 11, Nov. 1925, pp. 713-718, 11 figs. Improved morale evident at new Denver & Rio Grande Western sbop; effective routing and material-delivery systems; time-saving shop devices.

RAILWAY SIGNALING

Automatic Block. I. C. C. Signal Statistics. Ry. Signaling, vol. 18, no. 11, Nov. 1925, pp. 429-433, 3 figs. Review of block-signals statistics issued by Bur. of Safety of Interstate Commerce Commission from information furnished by railroads; automatic block mileage increased 2302 miles in 1924.

Colored-Light Signals. Light Signals Replacing Semaphores. Ry. Signaling, vol. 18, no. 11, Nov. 1925, pp. 413-415, 12 figs. New York Central makes this change between Buffalo, N. Y., and Cleveland, O.

Economic Operation. The Economic Aspect of Signalling, A. E. Tattersall. Ry. Gaz., vol. 43, no. 16, Oct. 16, 1925, pp. 454-456, 4 figs. How signaling may be arranged to reduce operating expenses; track circuiting and power signaling; triangular junctions.

RAILWAY TIES

Composite Cross. A New Substitute Tie. Ry. Eng. & Maintenance, vol. 21, no. 11, Nov. 1925, pp. 438-440, 1 fig. Composite cross tie, consisting of two pieces of 100-lb. scrap rail enclosing core of concrete; tested by Terminal Railroad Assn of St. Louis.

Concrete. Experiments witb Concrete Ties. Eng. News-Rec., vol. 95, no. 18, Oct. 29, 1925, pp. 708-709 2 figs. Satisfactory experience with trial lot of 22 reinforced-concrete ties laid in 1916 at Eagle Pass, Tex., has led Southern Pac. Ry. to make 100 ties of same type, to be placed in heavy-traffic main-line service.

RAILWAY TRACK

Grade Crossings. Highway Crossing Protection, A. H. Rudd. Ry. Signaling, vol. 18, no. 11, Nov. 1925, pp. 417-420. Advantages of center of road location for signal; disadvantages of center mounting; advantages and disadvantages of roadside location; summary of points to be considered; uniformity of indication and signals needed; study of results of crossing accidents. (Abstract.) Committee report before Am. Ry. Assn.

REFRACTORIES

Gray-Iron Foundry. Refractory Requirements in the Gray Iron Foundry, R. Moldenke. Am. Ceramic Soc.—Jl., vol. 8, no. 11, Nov. 1925, pp. 712-719. Calls attention to lack of information on foundry refractories on part of both foundrymen and makers of refractory materials; enumerates application of tbcse materials in foundry practice, and details requirements sufficiently to enable manufacturer to select proper grades of brick and clay for cupola and air-furnace operation, as well as for lining up of ladles.

Thermal Efficiency. The Relation of Structure and Composition to Thermal Efficiency of Refractories When Used in Regenerators, S. M. Phelps. Am. Ceramic Soc.—Jl., vol. 8, no. 10, Oct. 1925, pp. 648-654, 5 figs. Study shows relative rates of heat transmission in typical clay, silica, diaspore, fused alumina and silicon carbide refractories, when used as checker brick; it is shown tbat by lowering porosity of checker brick increase in efficiency is obtained by virtue of its greater heat capacity, which is function of weight and specific beat of material.

REFUSE DISPOSAL

Incinerator Practice. Basic Principles in Refuse Incinerator Practice. Mun. & Cty. Eng., vol. 69, no. 4, Oct. 1925, pp. 221-224. Outlines principles of design, construction and operation of municipal refuse incinerators. Text of progress report of Committee of Am. Pub. Health Assn.

REGULATORS

Induction. The Use of Induction Regulators in Feeder Circuits, L. H. A. Carr. Instn. Elec. Engrs.—Jl., vol. 63, no. 345, Sept. 1925, pp. 864-873 and (discussion) 874-876, 18 figs. Uses and possibilities of induction regulators as applied to feeder and interconnector circuits; describes three types of induction regulators, together with their characteristics, namely, single polyphase, double polyphase, and single-phase regulators; application to various types of circuit; effect of regulator impedance; operation, construction and control of induction regulators.

Mercury-Controlled Pressure. Pressure Regulators at the Inland Steel Co., C. J. Smitb. Iron & Steel Engr., vol. 2, no. 10, Oct. 1925, pp. 424-426, 5 figs. Describes mercury-controlled pump governor eliminating all counterweights, springs, stuffing boxes, etc., and their resulting friction, used with thin rubber diaphragm which has equal water pressure on both sides; same principle has been developed to bandle regulation problems of various kinds; patented under name of Mercon regulators.

RESERVOIRS

Color of Water. Color and Other Phenomena of Water From an Unstripped Reservoir in New England, C. M. Saville. New England Water Wks. Assn.—Jl., vol. 39, no. 2, June 1925, pp. 145-163 and (discussion) 163-170, 11 figs. Facts regarding conditions in Nepaug and other reservoirs of Hartford (Conn.) water supply system.

Covered. 8-Million Gallon Covered Service Reservoir at Bushey Heath. Engineer, vol. 140, no. 3644, Oct. 30, 1925, pp. 456-457, 5 figs. partly on p. 464. Describes reservoir being constructed by Colne Valley Water Co.; it is rectangular in plan and being built partly in excavation and partly above ground level, walls being of mass concrete; roof, which is composed of concrete arches, is supported on brick piers.

ROAD CONSTRUCTION

Types. Modern Road Construction, W. Bell. Surveyor & Mun. & Cty. Engr., vol. 68, no. 1760, Oct. 9, 1925, pp. 295-299. Author's opinions and experience with the various methods of road construction at present in vogue, including macadam, bituminous, wood block, sett paving; footways. Paper read before Instn. Mun. & Cty. Engrs.

ROADS

Amiesite. Laying Amiesite Pavements, Longueuil, H. Bertrand. Can. Engr., vol. 49, no. 1, Sept. 15, 1925, pp. 217-218, 4 figs. Amiesite laid at Longueuil when Quebec, Montreal & Soutb. Ry. relaid tracks through city; as a result this material was laid on all streets having concrete foundations; method employed in laying amiesite.

Creosoted-Block. Maintenance of Creosoted Block Pavements, A. D. Carpenter. Eng. & Contracting (Roads & Streets), vol. 64, no. 4, Oct. 7, 1925, pp. 782-784. Methods and costs of treatment. Paper read before Minn. Engrs. & Surveyors' Soc.

Drainage. The Surface and Subsoil Water Drainage of Roads, A. H. Richards. Surveyor & Mun. & Cty. Engr., vol. 68, no. 1759, Oct. 2, 1925, pp. 283-285, 1 fig. Design of a surface and subsoil water drainage systems.

Maintenance. Highway Maintenance in Manitoba, A. McGillivray. Contract Rec., vol. 39, no. 39, Sept. 30, 1925, pp. 959-961 and 947. Highway system of this province consists almost entirely of gravel and earth roads; organization for keeping them in shape and methods employed. See also Can. Engrs., vol. 49, no. 15, Oct. 13, 1925, pp. 461-464.

Quebec, Canada. Good Roads in the Province of Quebec, J. L. Boulanger, Can. Engr., vol. 49, no. 11, Sept. 15, 1925, pp. 305-308, 5 figs. Remarkable development of good roads movement in Quebec; provence has 31,000 mi. of roads of which 6600 have been permanently improved; about 300 mi. of main roads built in 1925; traffic supervision and regulation. See also Contract Rec., vol. 39, no. 37, Sept. 15, 1925, pp. 894-897, 10 figs.

Subgrades. The Present Status of Subgrade Studies, A. C. Rose. Pub. Roads, vol. 6, no. 7, Sept. 1925, pp. 137-162, 11 figs. Review of progress of subgrade research and results of highway research in all its phases. Bibliography.

ROADS, ASPHALT

Life of. What is the Life of Aspbaltic Pavements? R. H. Simpson. Contract Rec., vol. 39, no. 41, Oct. 14, 1925, pp. 995-998, 2 figs. Cost of repairs averaged on a square yard per year basis; how maintenance expense varies from year to year; 30 to 35 years service is a reasonable expectation. See also Can. Engr. Vol. 49, no. 13, Sept. 1925, p. 368.

ROADS, BITUMINOUS

Design. Bituminous Pavements for Heavy Traffic, P. Hubbard. Can. Engr., vol. 49, no. 1, Sept. 15, 1925, pp. 313-315. Trend in design of bituminous wearing courses and pavement structures. Paper read at convention of Assn. Highway Officials of N. Atlantic States.

ROADS, CONCRETE

Comparison of Sections. A Comparison of Typical Concrete Road Sections, H. B. Breed. Am. City, vol. 33, no. 4, Oct. 1925, pp. 414-418, 1 fig. Discusses subsoil conditions; comparison of the different types of design in use among the various states.

Hexagonal Slab Design. The Hexagonal Slab Design of Concrete Pavement. L. A. Perry. Am. Soc. Civ. Engrs.—Proc., vol. 51, no. 9, Nov. 1925, pp. 1793-1808, 11 figs. Records results of experiments conducted by writer to learn what relation shape of pavement slab has on its strength; witb record of these experiments, study of moments, as developed in various shaped slabs, is reported; also discusses current practice in light of information gained from these studies; pavements of correct slab shape, as determined from these studies, are illustrated and described.

ROADS, GRAVEL

Dust Elimination. Dust Elimination on Gravel Roads, B. C. Tiney. Contract Rec., vol. 39, no. 39, Sept. 30, 1925, pp. 955-957. Discusses two distinct lines of treatment, viz., use of dust palliatives and application of bituminous surfacings; manner of using materials and cost of treatments. See, also Can. Engr.; Vol. 49, no. 13, Sept. 29, 1925, pp. 359-363, 2 figs.

ROADS, MACADAM

Bituminous. Design of Bituminous Macadam Pavements, J. S. Crandell. Can. Engr., vol. 49, no. 16, Oct. 20, 1925, pp. 477-479. Developments in design and maintenance; construction of foundation and wearing course; application of surface treatments.

Machine Maintenance of. Machine Maintenance of Macadam, Monroe County, Mich. Eng. News-Rec., vol. 95, no. 17, Oct. 22, 1925, pp. 681-682, 4 figs. Manpower reduced by dust blower, mechanical chip distributor, tar sprinkler and locomotive crane.

S

SAND, MOLDING

Core Sands. Methods of Testing Core Sand Mixtures, J. F. Harper and W. J. Stevenson. Am. Foundrymen's Assn.—advance paper, no. 496, for mtg. Oct. 5-9, 1925, 12 pp. 2 figs. It would appear that green or unbaked strength of core sands should be determined by means of Doty cohesiveness test and baked strength by means of transverse test as outlined; transverse test has proved excellent method of comparison and it lends itself to easy operation without large number of testing variables.

Mixtures, Control Tests of. Control Tests of Steel Molding and Core Sand Mixtures. Research group News, vol. 2, no. 3, Oct. 1925, pp. 4-7, 3 figs. Review of activities of Joint Committee on Molding Sand Research, undertaken by Am. Foundrymen's Assn. in co-operation with other organizations; describes routine methods which have been very beneficial in maintaining uniformity in molding and coresand mixtures.

Treating and Handling. A Method of Treating and Handling of Molding Sand, M. Sklovsky. Am. Foundrymen's Assn.—advance paper, no. 482, for mtg. Oct. 5-9, 1925, 12 pp., 8 figs. Describes method and special apparatus in handling molding sand in continuous-operation unit; molding sand is not hand shoveled at any stage of production operation; special revolving shelved apparatus is used to cool, aerate and cut sand so that sand passes through complete cycle every 30 minutes; number of field molds at any time is less than 5 per cent of total daily production; this rapid cycle permits use of very few flasks and facilitates quick change over jobs. See (abstract) in Foundry, vol. 53, no. 21, Nov. 1, 1925, pp. 882-885, 8 figs.

SEMI-STEEL

Mixing. Semi-Steel, J. H. List. Foundry Trade Jl., vol. 32, no. 479, Oct. 22, 1925, p. 343. Describes method of mixing with which author has had several years of experience.

SEWAGE DISPOSAL

Activated Sludge Process. A British View of the Activated Sludge Process, F. W. Harris. Mun. and Cty. Eng., vol. 69, no. 4, Oct. 1925, pp. 198-201. Discusses tanks and their equipment, mechanical and aeration problems, the three systems of activated sludge process, etc. Paper read before Royal Sanitary Assn. Scotland.

Chlorine in. Chlorine in Sewage and Waste Disposal, J. C. Baker. Indus. and Eng. Chem., vol. 17, no. 10, Oct. 1925, pp. 1059-1060, 1 fig. History of sewage chlorination; methods and applications; theory of action of chlorine.

Sludge Disposal. Utilization of Sewage Sludge Report to Two Societies. Eng. News-Rec., vol. 95, no. 21, Nov. 19, 1925, pp. 836-837. Progress in several cities and sewerage districts; special outlets for sale of sludge; present research. Identical report of Committee on Sewage Sludge to Sanitary Section, Am. Puc. Health Assn. and to Am. Soc. Mun. Improvements.

Treatment Works. The Sewage Treatment Works of Syracuse, N. Y., Am. City, vol. 33, nos. 4 and 5, Oct. and Nov. 1925, pp. 356-359 and 501-502, 12 figs. System involves large intercepting sewer, plain sedimentation, dilution, and sludge sterilization.

Works. New Sewage Purification Works for Epsom. Surveyor and Mun. and Cty Engr., vol. 68, no. 1761, Oct. 16, 1925, pp. 315-317, 2 figs. Describes new disposal works which has recently been completed for purification of sewage from large mental hospitals in Epsom district, England, by "Simplex" surface aeration process; operation.

SEWAGE TREATMENT

Purification. Methods of Sewage Purification, F. W. Harris. Surveyor and Mun. and Cty. Engr., vol. 68, no. 1755, Sept. 4, 1925, pp. 197-198. Discusses activated sludge or bio-aeration process. Paper read before Roy. Sanitary Assn. Scotland.

SEWERS

Intercepting. Intercepting Sewers and Disposal Plant at Laramis, Wyoming, F. M. Veatch. Eng. News-Rec., vol. 95, no. 20, Nov. 12, 1925, pp. 794-795, 2 figs. Details of investigation, disposal plant and sludge bed.

Pipe, Laying of Vitrified-Clay. How to Lay Vitrified Clay Sewer Pipe. Contract Rec., vol. 39, no. 40, Oct. 7, 1925, pp. 974-975. Practice recommended by Clay Products Assn.; specifications cover excavation, bracing and shoring, foundations, pipe laying, joints and backfilling.

SHEET METAL

Drawability of Sheets and Strips. Drawability of Sheets and Strips, H. S. Marsh and R. S. Cochran. Iron Age, vol. 116, no. 19, Nov. 5, 1925, pp. 1251-1252, 1 fig. Marco system of measuring; simplified method of expressing Erichsen and similar results.

SHEET-METAL WORKING

Hot Stampings. Hot Stampings and Their Production, G. F. Keyes. Soc. Automotive Engrs.—Jl., vol. 17, no. 5, Nov. 1925, pp. 452-454, 5 figs. Dies are cast from models; make "pick-ups" for "break-downs"; quality results from long experience.

SLIDE RULES

Making of Special. The Making of Special Slide Rules, G. W. Greenwood. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 1002-1006, 14 figs. Details of steps to be taken in constructing arithmetical and logarithmic scales, and of their use in construction of slide rules; description of slide rules for solution of various formulas.

SNOW REMOVAL

Streets. Snow Removal from City Streets, L. W. Russel. Am. City, vol. 33, nos. 4 and 5, Oct. and Nov. 1925, pp. 389-392 and 503-506, 4 figs. Anticipation of storms is a great aid in determining nature, severity, and probable time of their arrival; attack should be planned in advance; in Worcester, Mass., storms should be divided into 8 divisions as follows: heavy rain-storms, slush-storms, slippery streets and walks, light snow, heavy snow, blizzards with very heavy snow, heavy ice storms, and unexpected emergencies.

SPRINGS

Electric Measuring Instruments. Springs for Electrical Measuring Instruments, B. W. St. Clair. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 1057-1058, 4 figs. Brief statement of general spring problem in so far as it relates to electrical instruments.

Helical. Manufacture of Commercial Steel Helical Springs, F. H. Brown. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 1053-1055, 2 figs. Present status of art of manufacturing small- and medium-diameter springs; trade requirements; methods of manufacture; materials and their selection.

STEAM

High-Pressure. Electrotechnics and High-Pressure Steam (Elektrotechnik und Hochdruckdampf), Löffler. Elektrotechnik u. Maschinenbau, vol. 43, no. 28, Sept. 20, 1925, pp. 738-744, 4 figs. Discusses production of high-pressure steam, safety of high-pressure vessels, application in electric power plants, bleeding steam for feedwater preheating, pulverized coal firing, etc.; concludes that with high-pressure steam operation greater efficiency can be obtained than with any other method of energy production.

Growth of Steam Pressure and Economies, W. R. Herod. Power Plant Eng., vol. 29. no. 22, Nov. 15, 1925, pp. 1137-1138, 2 figs. Recital of events that have reduced steam consumption from 150,000 to 11,000 B.t.u. per kw-hr. generated.

Natural, from Geyser. Electric Generators Driven by Geyser Power, J. Hammond. Assn. Chinese & Am. Engrs.—Jl., vol. 6, no. 7, July 1925, pp. 73-75. Two wells were drilled in Sonoma County, California; at depth of 203 ft. unharnessing constant flow of live, superheated steam; electrical possibilities were tried out by connecting 35-kw. General Electric turbine-generator to original tap; nearby hotel, cottages, etc., were electrically illuminated from this source.

Pressure Regulation. Pressure Regulation in Process-Heating Installations (La distribution de la vapeur à pression constante). Génie Civil, vol. 87, no. 13, Sept. 26, 1925, pp. 271-273, 7 figs. Live steam has often to be used to supplement steam exhausted or extracted from prime movers, and there are frequently considerable variations in pressure owing to independent fluctuations in demand for power and process steam; as result of such variations in pressure, valves in heating mains are commonly opened too widely; consumption of steam is therefore excessive, and materials may be damaged by overheating; best results are obtained by operating heating mains at constant pressure, and by not subordinating running of prime movers to steam demand of heating apparatus; describes use of Ruths steam accumulator, controlled by Arca pressure regulator.

STEAM ENGINES

Foundations. Fractures in Horizontal Engine Beds, E. Ingham. Power, vol. 62, no. 18, Nov. 3, 1925, pp. 688-689, 2 figs. Principal causes are unsatisfactory design, faulty casting, and yielding of foundations, each of which is discussed.

STEAM METERS

Siemens & Halske. Steam Meters. Power Engr., vol. 20, no. 235, Oct. 1925, pp. 386-388, 7 figs. Utility of these instruments is displayed by means of several examples, after which principles and construction of Siemens & Halske design are described.

STEAM POWER PLANTS

Cost Analysis. Cost Analysis Indicates Way to Economy. Power Plant Eng., vol. 29, no. 18, Sept. 15, 1925, pp. 947-950, 5 figs. Careful analysis of power costs in Cincinnati office building shows advisability of retaining their private plant.

Economical Operation. Results of an Engineering Study of Paper Coating Factory's Power Plant, J. G. Berger. Power, vol. 62, no. 20, Nov. 17, 1925, pp. 752-753, 2 figs. Outline of method followed in study of power problems of factory; engines were over loaded to point of poor economy; purchased current was recommended for auxiliary power, which plan reduced cost of power.

Fuel Waste. An Amazing Example of Fuel Waste, F. C. DeWeese. Power Plant Eng., vol. 29, no. 22, Nov. 15, 1925, pp. 1152-1154, 2 figs. Investigation of conditions in individual power plant reveals loss of $17,000 per year.

Industrial. The Supply of Industrial Power, Wm. H. Larkin, Jr. Mech. Eng., vol. 47, no. 11a, Mid-November 1925, pp. 993-1001, 7 figs. To assist in determining efficiency of plant operation, tables of actual operating data and costs from industrial power plants scattered about country are shown, including plants which use purchased electric power; paragraphs are included on economy of operation which indicate desirability of power-plant supervision from manager's office—need of instruments so that what is taking place can be known; necessity and value of feedwater treatment; importance of accuracy in making up power costs; advisability of coal and fuel testing; outlines methods by which quality and relative cost of supply of industrial power may be estimated.

Small. Justifiable Small Power Plants, A. B. Mallison. Instn. Elec. Engrs.—Jl., vol. 63, no. 345, Sept. 1925, pp. 896-901 and (discussion) 901-915. Discusses power plants, water, wind, by-product to process steam, from process refuse, household and town refuse; comments on small self-contained power plant relative to superpower station and its network; examples of capital and operating costs of typical installations in various industries.

STEAM TURBINES

Back-Pressure. Steam-Consumption Tests on a Back-Pressure Turbine Built by Brown, Boveri & Co., Ltd., Baden, Switzerland, A. Stodola. Mech. Eng., vol. 47, no. 11, Nov. 1925, pp. 915-916, 1 fig. Results of tests on 1000-kw. back-pressure turbine fitted with single-row impulse wheel and 28 reaction stages mounted on a drum. Translated from Zeit. des Vereines deutscher Ingenieure, vol. 69, no. 37, Sept. 12, 1925.

Brown-Boveri. The New Brown Boveri Turbines for Large Outputs, W. G. Noack. Brown Boveri Review, vol. 12, no. 10, Oct. 1925, pp. 199-202, 4 figs. Describes new type of turbine for large outputs which is a reaction turbine constructed in three cylinders for normal heat drops; only first and second stages work on impulse principle but with a certain amount of reaction.

Efficiency. Steam Measurements of a BBC Maximum Efficiency Turbine (Dampfmessungen an einer BBC-Grenzleistungsturbine), Ad. Meyer. Elektrotechnik u. Maschinenbau, vol. 43, no. 40, Oct. 4, 1925, pp. 800-805, 9 figs. Details of verification test for determining thermodynamic efficiency at various loads of Kopenhagen turbine, carried out by Prof. Dresden of Delft, showing an efficiency of 80.3-83 per cent at full load, 78.9 per cent at 70 per cent load, and 81.6 per cent at 30 per cent excess load, considered as very good for a turbine of simple design.

STEEL

Aeronautics, Use in. Steels Used in Aero Work, W. H. Hatfield. Roy. Aeronautical Soc.—Jl., vol. 29, no. 178, Oct. 1925, pp. 469-511 and (discussion) 511-534, 30 figs. Deals with use of steel in aeronautics; discusses use of high-class material; scientific methods in works practice; duties of various parts; factors of strength; mechanical tests; thermal phenomena of steels; typical steels; forging and drop stamping; normalizing and annealing; hardening and tempering; machining properties; case-hardening; specifications.

Alloy. *See Alloy Steels.*

Defective. Defective Material and Processes, H. Brearley. Forging—Stamping—Heat Treating, vol. 11, no. 10, Oct. 1925, pp. 375-378, 6 figs. Commends use of simple means of investigation for defects such as pickling, etching and sulphur printing.

Definition. Definition of "Steel" and "Cast Iron," K. Honda. Iron and Coal Trades Rev., vol. 111, no. 3003, Sept. 18, 1925, p. 450, 2 figs. Discusses different definitions.

Iron and. *See Iron and Steel.*

Manganese. *See Manganese Steel.*

Rolled, Defects in. Developments in Drop Forging Production. Forging—Stamping—Heat Treating, vol. 11, no. 10, Oct. 1925, pp. 353-354. Brief review of most prevalent defects in rolled steel found by regular bar inspection; accurate checks possible on forging qualities of steel.

STEEL CASTINGS

Manufacture for Navy Use. Making Miscellaneous Steel Castings for Navy Use, D. F. Ducey. Am. Foundrymen's Assn.—advance paper, no. 475, for mtg. Oct. 5-9, 1925, 13 pp. 4 figs. Methods used in managing steel foundry supplying repair castings for U. S. Navy; describes equipment of foundry; discusses special green sand facing together with use of special fillets; describes system of planning and routing and forms used. See (abstract) in Foundry Trade Jl., vol. 32, no. 478, Oct. 15, 1925, p. 330, 1 fig.

Samples, Preparation for Chemical Analysis. Preparation of Samples from Steel Castings for Chemical Analysis. Research Group News, vol. 2, no. 3, Oct. 1925, pp. 7-8. Enumerates cause from which incorrect determinations may result; emphasizes importance of precautions such as are outlined.

STEEL, HEAT TREATMENT OF

Alloy Steel. Steel Treating and Its Value to the Steel Engineer, R. F. Crump. Iron and Steel Engr., vol. 2, no. 10, Oct. 1925, pp. 409-416, 5 figs. Development of machinery parts; methods and materials in use to give more effective results in wearing problems encountered; nature and physical properties of Stroh steel, its advantages and use in steel-plant wearing problems; definite application of special alloy to steel industry, with comparative costs and wearing life.

Electric Annealing. Electric Annealing of Steel, H. Fulwider. Iron and Steel of Can., vol. 8, no. 10, Oct. 1925, pp. 208-209. Advantages of electric heat; aging iron castings; annealing silicon sheet steel. (Abstract.) Report included in power committee report of Nat. Elec. Light Assn.

Fundamental Purposes and Effects. Heat Treatment and Metallography of Steel, H. C. Knerr. Forging—Stamping—Heat Treating, vol. 11, no. 10, Oct. 1925, pp. 361-365, 11 figs. Practical course in elements of physical metallurgy. Heat treatment: fundamental purposes and effects; annealing.

Principles of. Facts and Principles Concerning Steel and Heat Treatment, H. B. Knowlton. Am. Soc. Steel Treating—Trans., vol. 8, no. 4, Oct. 1925, pp. 484-506, 7 figs. Objectives of annealing and lonealing; relieving strains; softening; refining grain and toughening; purchase of annealed steel; annealing process; heating for annealing; soaking at annealing temperature; cooling; effect of heat treatment on free cementite; normalizing; spheroidizing; lonealing.

Quenching. Initial Temperature and Mass Effects in Quenching, H. J. French and O. Z. Klopach. U. S. Bur. Standards, Technologic Papers, no. 295, Aug. 25, pp. 590-618, 11 figs. Results of quenching experiments with high-carbon steels in which speed of cooling was determined at center of spheres, rounds, and plates of various dimensions quenched from various temperatures into different coolants, such as water, 5 per cent NaOH, oils, and air; cooling velocity at 720 deg. cent. is taken as best measure of hardening produced, and relations are developed between this and size and shape of steel quenched.

STEEL MANUFACTURE

Basic Process. The Production of Different Kinds of Steel in Basic Steel Works (Die Herstellung verschiedener Stahlsorten im Thomaswerk), E. Faust. Stahl u. Eisen, vol. 45, nos. 41 and 42, Oct. 8 and 15, 1925, pp. 1701-1704 and 1739-1742 and (discussion) 1742-1743. Characteristics of suitable pig-iron compositions for blasting of weldable steel, rail and hard steel, as well as different kinds of wire steel; comparison of methods employed by different works for production of these steels.

Converter Process. Carbon Steel and Carhon Vanadium Steel by the Converter Process, S. R. Robinson. Am. Foundrymen's Assn.—advance paper, no. 474, for mtg. Oct. 5-9, 1925, 8 pp. Practice is that of plant making castings, entering into such product as locomotive cranes, which plant is using converter method of producing steel; gives physical specification for "as cast" unannealed steel, then discusses melting and refining equipment used; refining processes are detailed; heat treatments for regular carhon steel and for cast tooth gears for extra heavy duty; carhon-vanadium steel practice; use of special skim gates for steel castings is said to have eliminated much trouhle due to dirty castings.

STOKERS

Developments. Stokers and Furnaces. Combustion, vol. 13, no. 5, Nov. 1925, pp. 280-284 and 290, 4 figs. Discussion of air heaters, water-cooling furnace walls, furnace repairs, foreign practice, etc., together with statements hy memher companies. From 1925 Report of prime Movers Committee of Nat. Elec. Light Assn.

STREAM POLLUTION

Investigations and Problems. Stream Pollution—A Symposium. Am. Soc. Civ. Engrs.—Proc., vol. 51, no. 9, Nov. 1925. Contains following contributions: Review of the Work of the United States Public Health Service in Investigations of Stream Pollution, W. H. Frost, pp. 1810-1818, including hibliography; Rate of Deoxygenation of Polluted Water, E. J. Thériault, pp. 1819-1828, 3 figs.; Rate of Atmospheric Reaeration of Sewage Polluted streams, H. J. W. Stokim, pp. 1829-1842, 10 figs.; Quantitative Studies of Bacterial Pollution and Natural Purification in the

STREETS

Widening and Resurfacing. Pavements Salvaged by Widening and Resurfacing. Eng. News-Rec., vol. 95, no. 21, Nov. 19, 1925, pp. 838-840, 4 figs. Rough and narrow Chicago streets being converted into adequate traffic ways serviceable for another decade by asphalt topping and expansion sideways.

STRUCTURAL STEEL

Commercial and Technical Problems. Larger Markets and Better Methods for Structural Steel. Eng. News-Rec., vol. 95, no. 21, Nov. 19, 1925, pp. 844-845. Fabricators at meeting of Am. Inst. Steel Constr. take up commercial and technical prohlems; fireproofing, earthquakes, welded joints and rivet heating, are discussed.

SURVEYING

Stereoscopic Photography. The Predhumeau Stereotopometer. Engineering, vol. 12, no. 3122, Oct. 30, 1925, pp. 531-533, 8 figs. Special system of surveying hy stereoscopic photography developed hy M. J. Predhumeau of France; main novelty of methods lies in instrument used for measuring or mapping "virtual model" provided by stereoscopic photographs; describes also instrument for taking photographs.

SWITCHGEAR

Design. Some Considerations on Modern Switchgear, E. Brian. Brown, Boveri Rev., vol. 12, no. 10, Oct. 1925, pp. 209-213, 4 figs. Influence on switchgear design of experience gained in operating power stations in parallel.

T

TELEPHONY

Testing Methods. Telephone Testing Methods, P. K. Higgins. Telephone Engr., vol. 29, no. 10, Oct. 1925, pp. 33-37 and 48, 20 figs. Description of various instruments employed and methods of using them; importance of insulation tests; locating alternating current crosses; determining and testing assorted troubles.

TEXTILE MACHINERY

Wool-Spinning. Wool-Spinning Machinery at the British Empire Exhibition. Engineering, vol. 120, no. 3122, Oct. 30, 1925, pp. 558-559, 5 figs. Details of exhibits at Australian pavilion; includes collection of working machinery which shows whole process which wool goes through after it has been washed and dried up to its delivery in hanks or "heads" of yarn in hundles ready for wrapping and distribution.

TRAFFIC

Control. Some Unconsidered Factors in the Control of Street Traffic, A. G. Dalzell. Contract Rec., vol. 39, no. 38, Sept. 23, 1925, pp. 922-925, 8 figs. Consideration not usually given to effect of curb obstructions in slowing up traffic; there must he fewer inducements for traffic to stop if congestion is to be prevented.

Synchronized Traffic Control is Costly to Street Railway, L. D. Bale. Aera, vol. 14, no. 2, Sept. 1925, pp. 163-169, 5 figs. Cleveland has synchronized traffic control system in operation in part of its downtown district, and it is proposed that system be extended to certain parallel streets; Cleveland Ry. finds by investigation that while such regulation of vehicular traffic speeds movements of autos and prohably makes for safety of pedestrians, it slows schedules of cars, increases amount of power consumed and creates new problems costly to solve.

TRANSFORMERS

Magnetizing-Current Wave Forms. Polyphase Transformer Magnetizing-Current Wave Forms, P. Kemp. and H. P. Young. Instn. Elec. Engrs.—Jl., vol. 63, no. 345, Sept. 1925, pp. 877-895, 25 figs. Deals with analyses of magnetizing currents taken by groups of transformers connected in various manners for operating on polyphase (and particularly on 3-phase) systems; discusses properties of star, delta, tee- and vee-connected windings, particularly with reference to harmonics, oscillographic confirmation being given where possihle. Bibliography.

Testing. Testing Westinghouse Transformers. C. H. Champlain. Mgmt. and Admin., vol. 10, no. 5, Nov. 1925, pp. 265-266, 4 figs. Equipment and methods used at new Sharon plant.

TRANSPORTATION

Munich Show, Germany. German Transportation Exposition at Munich, 1925 (Deutsche Verkehrs-Ausstellung München 1925), D. Przygode. Elektrotechnische Zeit., vol. 46, nos. 38 and 40, Sept. 17 and Oct. 1, 1925, pp. 1431-1436 and 1504-1508, 16 figs. Details of design and construction of electric, Diesel-electric, and storage-battery locomotives; trucks; electric communication, telegraph and telephone; instruments; generators; etc.

Railplane System. The "Railplane" System of Transport. Ry. Gaz., vol. 43, no. 13, Sept. 25, 1925, pp. 381-382, 4 figs. Aerial cars, driven by screws, suspended from overhead guide-rail structures carried over existing railways or roads; system devised by Geo. Bennie, of Bute, N. B.

Railway and Highway, Co-ordination of. The Co-ordination of Rail and Road Transport, D. R. Lamb. Inst. Transport—Jl., vol. 6, no. 9, July 1925, pp. 468-478 and (discussion) 478-491. Author endeavors to set forth present position in connection with commercial road transport, in so far as it affects railways, road haulers and traders; to indicate lines of possible development and to suggest methods of co-ordination calculated to prove of mutual advantage to road transport and railway industries.

TUBES

Flexible. Production and Use of Thin-walled Flexible Metal Tubes (Entstehung, Herstellung und Verwendung dünnwändiger defernder Metallrohre), H. Sandvoss. Gesundheits-Ingenieur, vol. 48, no. 36, Sept. 5, 1925, pp. 445-450, 38 figs. Discusses production of tubes of 0.2 mm, wall thickness from red brass seamless tubes, and their application in construction of thermostats for various uses; water temperature control apparatus, steam pressure redness, draft regulators for hot-water heating boilers and low-pressure steam hoilers, distance thermostats, etc.

Steel, Seamless. Making Seamless Steel Tuhes by Improved Processes, E. F. Ross. Iron Trade Rev., vol. 77, no. 18, Oct. 29, 1925, pp. 1079-1083 and 1091, 9 figs. Most recent development is perfection of new process which features use of square hillets; Wellman-Peters process has been known in Germany for over 2 years hut most recent and modern installation is at steel works of Howell & Co., Sheffield, Eng.; also known as push-hench process.

Steel, Welding. Welding Steel Tuhing and Sheet with Chromium-Molybdenum Welding Wire, F. T. Sisco and H. W. Boulton. Am. Soc. Steel Treating—Trans., vol. 8, no. 5, Nov. 1925, pp. 589-619 and (discussion) 619-620 and 665-668, 26 figs. In welding chromium-molybdenum steel seamless tubing and chromium-vanadium steel sheet, chromium-molyhdenum welding wire produces weld which has more desirable and uniform structure than low-carhon welding wire; in welding chromium-molyhdenum steel tubing to plain carbon steel tuhing chromium-molybdenum steel welding wire is not greatly superior and may even be inferior to low-carbon welding wire.

TUNNELING

Windsor-Detroit. Tunnels Planned from Windsor to Detroit, Contract Rec., vol. 39, no. 43, Oct. 28, 1925, pp. 1034-1039, 8 figs. Details regarding construction of a system of electric railway and automohile tunnels under Detroit River between Detroit, Mich., and Windsor, Ont., excellent terminal arrangements.

V

VENTILATION

Nature of. What is Ventilation? P. West. Am. Soc. Heat and Vent. Engrs.—Jl., vol. 31, no. 10, Oct. 1925, pp. 477-485. Definition of ventilation; necessity of ventilation; kind of ventilation to use; advantages of ventilation; cost of ventilating equipment and of its operation; kind of ventilating apparatus to use; design and operation of ventilating apparatus.

VIBRATION

Effect on Metals. Vibration. Metallurgist (Supp. to Engineer, vol. 140, no. 3644), Oct. 30, 1925, p. 145. Results of fatigue tests carried out hy C. F. Jenkin, of Oxford; it seems that, provided amplitude of vihrations is kept well below normal fatigue range, no injury to material need be feared as result of more rapidity of oscillations.

Recorder. An Instrument for Recording Vibrations, L. H. Young. Mech. Eng., vol. 47, no. 11, Nov. 1925, pp. 907-908, 6 figs. Portahle instrument for measuring and recording amplitude and frequency of vibrations encountered in buildings, bridges, and small earth tremors, developed in Laboratory of Indus. Physcis at Mass. Inst. of Technology.

W

WAGES

Group-Bonus Plan. Wage Incentives—The Group-Bonus Plan, B. R. Mayne. Am. Foundrymen's Assn.—advance paper, no. 483, for mtg. Oct. 5-9 1925, 11 pp., 1 fig. Describes method of setting bonuses for various groups as follows: core-room labor; core delivery and assembly; pouring iron; shifting weights and molds; operating bull ladles; night work; melting; hard iron smelting; sorting and grinding; annealing; and foreman bonuses; time study is used in determining rates.

Incentives. Payment and Incentive in Industry, C. Haslett. Indus. Mgmt. (Lond.), vol. 12, no. 10, Oct. 1925, pp. 479-481. Discusses payment in relation to output, pricing committees, piecework price lists or "parish paters," labor costs, railway work-shops, payment by premium bonus, calculating premium, overcoming fluctuations, and "Pluck" system.

WATER PIPES

Iron Bacteria and Incrustation. Iron Bacteria and Water-Pipe. Surveyor and Mun. and Cty. Engr., vol. 68, no. 1757, Sept. 18, 1925, pp. 241-242. Notes on investigation into its causes.

WATER POWER

Comparison with Steam Power. Water Power and Steam Power (Vattenkraft och Angkraft), S. Velander. Teknisk Tidskrift (Elektroteknik), vol. 55, no. 9, Sept. 5, 1925, pp. 145-152, 4 figs. Contribution to subject of economical comparisons between water and steam power; author maintains that accepted standards of comparison between two possihilities of future development in Sweden to not place some of important features of water-power development in their proper light; conclusions indicate that future development in Sweden should be centered on water power, and that steam-power generation should be used only in cases where waste material from sawmills and similar fuels are availahle.

WATER PURIFICATION

Bacteriological Examination. Bacteriological Examination of Water, C. T. Butterfield. Can. Engr., vol. 49, no. 17, Oct. 27, 1925, pp. 500-501. Detailed description of methods which constitute good practice for water purification plant lahoratories. Paper read at Third Annual Ohio Conference on Water Purification.

WATER SUPPLY

Hetch Hetchy Project, California. Present Status of Hetch Hetchy Water Supply and Power Project, N. A. Eckert. Mun. and City, Eng., vol. 69, no. 4, Oct. 1925, pp. 213-218. Notes on Lake Eleanor dam, O'Shaughnessy dam, watershed, early intake diversion dam, aqueduct tunnel, Priest dam and reservoir, Moccasin power tunnel, surge chamber penstocks, power house huilding, water wheels and generators, transformers, transmission line, power contract and Bay Crossing division.

Intakes. Construction of Intake at Goderich, Ont., E. H. Darling. Can. Engr., vol. 49, no. 16, Oct. 20, 1925, pp. 469-471, 5 figs. Low water necessitated laying of new intake into Lake Huron to increase water supply; new intake is 24-in. diameter, 2482 ft. long, and is made up of both cast iron and steel pipe.

WATER TREATMENT

Sedimentation. The Value of Sedimentation in the Treatment of Turhid River Water, W. Kiersted. Am. City, vol. 33, no. 5, Nov. 1925, pp. 469-473. Discusses history of sedimentation, observed action of settling basins, forces influencing sedimentation, conditions influencing sedimentation, conditions affecting structural economy, principles of flow, method of operating settling basin, inlet and outlet arrangements, layout of sedimentation basin. From paper read before Texas Section of Southwest Water Wks. Assn.

WELDING

Definitions and Symbols. Definitions and Designations in Welding Technics und Bezeichnungen auf dem Gehiete der Schweisstechnik), G. Hilpert. Maschinenbau, vol. 4, no. 20, Oct. 1, 1925, pp. 999-1001, 3 figs. Details of definitions and symbols proposed hy German Committee on Welding to designate the various kinds of welding and symbols for seams resulting.

Electric. *See Electric Welding; Electric Welding, Arc; Electric Welding-Resistance.*

Oxyacetylene. *See Oxyacetylene Welding.*

Engineering Index

This Index is prepared by the American Society of Mechanical Engineers.

In this department will be published from month to month the titles of current engineering papers with the authors and source and a brief extract of the more important. It is designed to give the members of The Institute a survey of all important articles relating to every branch of engineering profession.

PHOTOSTATIC PRINTS

Photostatic copies of the articles listed in this section, or others on engineering subjects, may be obtained from the Engineering Societies Library.

Price of each print (up to 11 by 14 in. size) 25 cents, plus postage. Where possible, two pages, up to 7 by 9 in. size, will be photographed on one print. Larger magazines require a print per page. Bills will be mailed with the prints.

The Library is also prepared to translate articles, to compile lists of references on engineering subjects and render assistance in similar ways. Charges are made, sufficient to cover the cost of this work. Correspondence is invited. Information concerning the charge for any specific service will be given those interested. In asking for information please be definite, so that the investigator may understand clearly what is desired.

The Engineering Societies Library is under the management of the United Engineering Society, which administers it as a public reference library of engineering. It is maintained jointly by the American Society of Civil Engineers; the American Institute of Mining and Metallurgical Engineers; the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. It contains 150,000 volumes on engineering and allied subjects, and receives currently most of the important periodicals in its field.

Orders and correspondence should be addressed to

Harrison W. Craver, Director,
Engineering Societies Library,

29 West Thirty-ninth Street. New York, N.Y.

A

AIR COMPRESSORS

Centrifugal, Testing. The Heat Balance Method of Testing Centrifugal Compressors, M. G. Robinson. Am. Soc. Mech. Engrs.—advance paper for mtg. Nov. 30-Dec. 4, 1925, 23 pp., 11 figs. Describes method which is simple and direct, in which principle is used that balance exists between mechanical energy supplied by rotation of shaft and heat-energy increase in air which is being compressed, heat-energy increase in cooling water used, and heat lost from casing, bearings, and packings; with proper testing apparatus and due precautions this heat energy may be accurately measured and hence power input established; very satisfactory results have been obtained by application of method.

Electrically-driven. A New Type of Electrically-driven Air Compressor. Commonwealth Engr., vol. 13, no. 1, Aug. 1, 1925, pp. 17-18. Particulars of N-SE electrically-driven compressors manufactured by Consolidated Pneumatic Tool Co., Fraserburgh, Scotland, made in capacities from 107 to 1196 c. ft. of free air per minute piston displacement, which in horsepower rating is from 20 to 100; suitable for all classes of work where air pressure does not exceed 125 lb. per sq. in.

AIR PUMPS

Steam-Jet. New Developments in High Vacuum Apparatus, G. L. Lothny. Soc. Nav. Architects & Mar. Engrs.—advance paper, no. 1, for mtg. Nov. 12-13, 1925, 7 pp., 13 figs. on 11 supp. plates; also (abstract) in Mar. Eng. & Shipg. Age, vol. 30, no. 12, Dec. 1925, pp. 717-718, 3 figs. and (discussion) pp. 689-690. Records most important developments in design and performance of steam air ejectors made during last 6 years.

AIRPLANE ENGINES

Design. Designing Engines Into Airplanes, J. G. Vincent. Aviation, vol. 19, no. 22, Nov. 30, 1925, pp. 776-778, 3 figs. Air and water-cooled engines; types of water-cooled engines; geared or direct drive; advantages of geared drive; engines for pursuit types.

Splines and Serrations. Splines and Serrations, H. T. Wright. Machy. (Lond.), vol. 27, no. 687, Nov. 26, 1925, pp. 259-262, 13 figs. Principles underlying design of splined connections and serrated shafts, with special reference to aircraft work.

AIRPLANES

Aerodynamic Characteristics. Aerodynamic Characteristics of Aircraft with Reference to Their Use, M. Panetti. Nat. Advisory Committee for Aeronautics—Tech. Memorandums, no. 339, Nov. 1925, 12 pp. Definition of characteristics of airplanes, gradually becoming more precise, minutely describes and almost identifies type, by imposing choice of ever more perfect shape for satisfying requirement; necessity of positive knowledge of properties of wing profiles and of aerodynamic characteristics of wings and stabilizing planes, is pointed out. Translated from L'Ala d'Italia, Apr. 1925.

All-Metal. Advantages of the All-Metal Airplane, W. B. Stout. Automotive Mfr., vol. 67, no. 7, Oct. 1925, pp. 8-10 and 26. A consideration of airplane transport from a purely commercial viewpoint, and type of "ship" which has resulted; constructional details.

Statics. Stage of Development and Problems in Modern Airplane Statics (Entwicklungsstand und Probleme der modernen Flugzeugstatik), K. Rühl. Bauingenieur, vol. 6, no. 25, Sept. 25, 1925, pp. 58-75, 6 figs. Discusses importance of statics and gives numerical examples; examines static structure of airplane; discusses principal post-war tendencies, influence of airplane statics on general building statics.

Wings. A Method for the Direct Determination of Wing-Section Drag, A. Betz. Nat. Advisory Committee for Aeronautics—Tech. Memorandums, no. 337, Nov. 1925, 8 pp., 3 figs. on supp. plate. Explains theoretical principles on which method developed by Ackeret for calculating wing-section drag directly from energy loss of air is based. Translated from Zeit. für Flugtechnik u. Motorluftschiffahrt.

AIRSHIPS

Large. Some Matters Relating to Large Airships, G. Fulton. Soc. Nav. Architects & Mar. Engrs.—advance paper, no. 12, for mtg. Nov. 13-14, 1925, 14 pp., 12 figs. on 11 supp. plates; also (abstract) in Mar. Eng. & Shipg. Age, vol. 30, no. 12, Dec. 1925, pp. 702-703. Author thinks there is no room for doubt as to ultimate future of airship as means for bridging long over-water distances, and one thing stands out clearly—use and handling of large airships is intimately bound up with marine knowledge. Includes appendix, giving comparatively characteristics of Shenandoah and Los Angeles.

ALLOY STEELS

Electric. Electric Alloy Steel, F. E. Clark. Am. Iron & Steel Inst.—advance paper, for mtg. Oct. 23, 1925, 10 pp. Basic electric process; acid process; general considerations.

See also Silicon Steel; Tool Steel; Vanadium Steel.

ALLOYS

Aluminum. *See Aluminum Alloys.*

Brass. *See Brass.*

ALUMINUM ALLOYS

Duralumin. *See Duralumin.*

Influence of Various Metals on. On the Influence of Various Metals in Small Quantities On the Nature of Aluminium Alloys, T. Harada. College of Eng.—Memoirs, Kyoto Imper. Univ., vol. 3, no. 9, June 1925, pp. 231-265, 86 figs. on supp. plates. Particulars of research whose aim was based on study of influence of various metals in small quantities upon physical, chemical, and mechanical properties and structure of aluminum, and to obtain some new alloys with improved properties applicable to present-day aluminum industry.

AMMONIA COMPRESSORS

Lubrication. Notes on the Lubrication of Ammonia Compressors, C. H. S. Tupholme. World Power, vol. 4, no. 23, Nov. 1925, pp. 272-273. Quality of oil is essential property influencing amount of feed necessary for maintenance of proper lubrication and piston seal, and oil of poor quality will do neither; other objectionable results from use of unsuitable oils.

Sleeve-Valve. New Sleeve Valve Compressors at Barking. Cold Storage, vol. 28, no. 311, Oct. 15, 1925, pp. 414-417, 8 figs. Results achieved at ice making, cold-storage, and ice-cream plant of East London Cold Storage and Ice Co., Ltd., at Barking, where two three-cylinder high-speed compressors of sleeve-valve type have been running almost continuously day and night since April.

AMMONIA CONDENSERS

Care and Operation. Operation and Care of Ammonia Condensers, H. R. Halterman. Universal Engr., vol. 42, no. 5, Nov. 1925, pp. 24-26. Condensers classified; care and operation; condenser water supply; cooling ponds; cooling towers. Papers read before N.A.P.R.E.

APPRENTICES, TRAINING OF

Self-Supporting System. A Self-supporting Apprenticeship System. Machy. (N. Y.), vol. 32, no. 4, Dec. 1925, pp. 326-328, 4 figs. Features of apprenticeship system conducted by Marion Steam Shovel Co., Marion, O.

ARCHES

Pressure Pipe-Line. Pressure Pipe-Line Arch over the Durance. Engineering, vol. 120, no. 3123, Nov. 6, 1925, pp. 506-507, 11 figs. partly on supp. plates. Describes conduit in the Hautes Alpes, France, which has interior diam. of 2.688 m. (8 ft. 9¾ in.) and span of 68 m. (223 ft.); it is entirely self-supporting.

AUTOMOBILE ENGINES

Carburetors. *See Carburetors.*

Developments. Recent Tendencies in the Field of Automobile Engines (Nutida sträbanden på automobilmotoromradet), E. Hubendick. Teknisk Tidskrift, vol. 55, nos. 38 and 42, Sept. 19 and Oct. 17, 1925, pp. 113-122 and 130-137, 50 figs. Discusses constructive improvements, behavior at maximum compression, size and form of combustion chamber, reduction of piston weight, light metal and cast-iron pistons, fuel consumption, Daimler-Mercedes engine, etc.

Six-Cylindered. Six-Cylinder Commercial-Vehicle Engine. Engineering, vol. 120, no. 3128, Dec. 11, 1925, pp. 738-739 and 742, 4 figs. Details of 6-cylinder engine with side-by-side valves, designated by makers, W. H. Dorman & Co., as 6-J.U. model.

Spark Plugs. *See Spark Plugs.*

AUTOMOBILES

Headlights. Improved Automobile Headlighting, A. W. Devine. Illuminating Eng. Soc.—Trans., vol. 20, no. 9, Nov. 1925, pp. 937-956, 2 figs. Gives short history of development of automobile headlamps and of efforts by state authorities to handle problem of headlighting; outline of problem given and solution offered which is based on improvement in headlamp construction and more stringent specifications for laboratory test; principles upon which approval of electric headlamps by state authorities is based; etc.

Improving Motor Vehicle Headlighting Under the American Standard System, R. N. Falge. Illuminating Eng. Soc.—Trans., vol. 20, no. 9, Nov. 1925, pp. 957-969 and (discussion) 969-980, 10 figs. partly on supp. plates. Outlines development of motor-vehicle headlighting practice and factors that at present make night-driving conditions unsatisfactory; takes up especially limitations of fixed beam system and great advantage to be gained with depressible beams; explains in detail new two-filament lamp for depressible-beam lighting and optical principles involved in its most effective application in equipments.

Transmissions. Arrangement of Mechanical and Hydraulic Power Transmission Between Engine and Driving Axle in Motor Vehicles (Anordningar för mekanisk och hydraulisk kraftöverföring mellan motor och drivaxlar å motorfordon), E. Nothin. Teknisk Tidskrift, vol. 55, no. 38, Sept. 19, 1925, pp. 122-128 (Mekanik), 12 figs. Discusses A.E.G., Delavauds, and Constantinesco mechanical types, Föttinger, Lenz, Williams-Janney hydraulic types, their design, construction and operation.

B

BEARINGS

Oil Film in, Study of. Charts for Studying the Oil Film in Bearings, Geo. B. Karelitz. Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 30-Dec. 4, 1925, 22 pp., 14 figs. It has been shown several times that hydrodynamical theory of lubrication satisfactorily explains mechanism of lubrication; charts presented give designer or investigator means of determining with sufficient accuracy shape and pressures in oil film for bearings under different conditions.

BEARINGS, BALL

Lubrication. The Lubrication of Ball and Roller Bearings. Commonwealth Engr., vol. 12, no. 12, July 1, 1925, pp. 443-447, 6 figs. Aim of ball and roller bearings is to replace sliding friction by rolling friction, but they must be well lubricated, otherwise they deteriorate rapidly; aim of lubricant is to provide a fluid film between balls and cages, to preserve polished film on surfaces of balls, and to seal bearings against ingress of dust, moisture or corrosive influences where housings are not capable of so doing; points are dealt with.

BELTING

Leather. Applications of Leather Belting, R. F. Jones. Textile Wld., vol. 67, nos. 14 and 19, Oct. 3 and Nov. 9, 1925, pp. 85, 87, and 89; and 77 and 79, 12 figs. Summary of research work by Leather Belting Exchange Foundation, covering pulley diameter, pulley ratio, center distance between pulleys, effect of high belt speeds, gravity idler, and new rating curves and tables for leather belting.

Determining the Quality of Leather Belting, L. W. Arny. Paper Mill, vol. 49, no. 44, Oct. 31, 1925, pp. 6, 16, and 46, 5 figs. Discusses methods of determining quality and requirements of a good belt.

Tension Ratio and Transmission Power. The Tension Ratio and Transmissive Power of Belts, C. A. Norman. Mech. Eng., vol. 47, no. 12, Nov. 1925, pp. 1111-1113, 5 figs. Investigation of increase of transmissive power with slip was conducted on apparatus patterned after that of Friedrich at Ohio State Univ. on rubber, leather, and fabric belts; results of investigation are given in form of curves, and conclusions drawn from tests are noted.

BLAST FURNACES

Tapping. Tapping the Furnace in Safety, E. B. Speer. Blast Furnace & Steel Plant, vol. 13, no. 12, Dec. 1925, pp. 478-481, 6 figs. Increasing size and capacity of blast furnaces demands replacement of old-fashioned hand methods by modern mechanical equipment.

BLASTING

Explosives, Use of. Blasting and the Use of Explosives, F. F. McLaughlin. Eng. & Contracting (General Contracting), vol. 64, no. 6, Nov. 18, 1925, pp. 1107-1111. Describes accident prevention measures in quarrying. Paper presented at convention of Nat. Safety Council.

BOILER FEEDWATER

Treatment. Zeolite Method, C. W. Sturdevant. Pac. Ry. Club—Jl., vol. 9, no. 5, Aug. 1925, pp. 28-30 and (discussion) 30-39. Advantages of base-exchange softening process, and experiences with zeolite plant in boiler plant of general shops of Southern Pac. Co. in Los Angeles.

BOILER FURNACES

Pulsations, Influence on Combustion. Influence of Pulsations on Combustion, J. Deschamps. Fuels & Furnaces, vol. 3, no. 9, Sept. 1925, pp. 957-958. Transverse movements of air in gas-producer fuel bed created by air pulsations improve operation. Translated from Revue Universelle des Mines.

Radiation in. Radiation in Boiler Furnaces, B. N. Broido. Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 30-Dec. 4, 1925, 27 pp., 9 figs. Analysis of fundamentals of radiation and of effect of water-cooled walls on gas temperatures in furnaces; standard curve is drawn which enables designer to determine with sufficient accuracy what part of total heat generated in furnace at different ratings is absorbed by water-cooled walls; this curve can also be used to find heat transmission by radiation per sq. ft. of heating surface for any given conditions of furnace; based on number of installations with water-cooled walls, most advantageous arrangement of such surface for given conditions is suggested; effect of radiation from gases on heat transmission and influence of radiation upon measurement of gas temperatures.

BOILER PLANTS

Instruments. The Fallacy of "Dead Reckoning" in Power Plant Operation, F. Juraschek. Indus. Mgmt. (N. Y.), vol. 70, no. 6, Dec. 1925, pp. 362-366, 6 figs. How even smallest plant can cut its power costs; as instance of what indicating and recording instruments mean to power plant, author cites case of Connecticut manufacturer operating three boilers with total rated capacity of 485 b.hp. and annual coal consumption of 2,500 tons; simple corrections in firing methods and damper control resulted in fuel saving of $1,540. per year —almost 3 times cost of instruments and changes.

BOILERS

Efficiency. What Is Boiler Efficiency? M. A. Rooney. Am. Soc. Heat & Vent. Engrs.—Jl., vol. 31, no. 8, Aug. 1925, pp. 419-422, 3 figs. Makes calculation, in connection with design of boilers for maximum economy; gives curves.

Evaporation Tests. Results of Evaporation Test On a Water Tube Boiler, F. H. Bivens. Gas Age-Rec., vol. 56, no. 19, Nov. 7, 1925, p. 667. Results of an evaporation test made on a water-tube boiler equipped with underfeed stokers; maximum rating obtained was 254 per cent.

Flue Handling. How Two Men Handle 1000 Flues a Week. F. C. Hudson. Am. Mach., vol. 63, no. 25, Dec. 17, 1925, pp. 955-957, 7 figs. Apparatus and methods that enable Grand Trunk shop at Battle Creek to handle boiler and superheater flues at very low cost.

Locomotive. *See Locomotive Boilers.*

Rating. Rating Heating Boilers for Hot Blast Service, Chas. L. Hubbard. Domestic Eng. (Chicago), vol. 113, no. 5, Oct. 31, 1925, pp. 20-21 and 45, 4 figs. Methods employed in obtaining usual catalog ratings; in general, these are based on the pound of low pressure steam (about 5-lb. gage) generated per hour, without driving or priming, when using coal having an average calorific value of 13,000 B.t.u. per lb. Considers boiler capacity.

See also Steam Generators.

BRAKES

Foundation. Foundation Brake and Leverage, M. C. Meehan. Car Foremen's Assn. of Chicago—Official Proc., vol. 20, no. 1, Oct. 1925, pp. 32, 35-36, and 39-42, 8 figs. Compilation of data on abuse of foundation brake and consequent destruction of wheels by sliding and means and ways of reducing this waste.

BRASS

Nickel-Manganese. Nickel-Manganese Brasses, Metal Industry (Lond.), vol. 27, no. 20, Nov. 13, 1925, p. 456. Composition recommended; varying equivalent copper-zinc content; mixing, melting, and casting. Abridged translation of paper presented before Franco-Belgian Foundry Congress. See also Foundry Trade Jl., vol. 32, no. 484, Nov. 26, 1925, p. 447.

Flux, Use of. Profitable Use of Flux, R. Micks. Can. Foundryman, vol. 16, no. 11, Nov. 1925, pp. 20-21, 1 fig. Points out that there are still many brass founders who fail to see advantage of using good flux when melting their metal; boron sux-oxide is acknowledged to be best flux for copper, while yellow prussiate of potassium has also given good results; chloride of zinc most popular flux for aluminum; fluorspar as flux for nickel.

BRIDGES, CONCRETE

Highway. Reinforced Concrete Bridges, W. N. Twelvetrees. Roads & Road Constr., vol. 3, no. 35, Nov. 2, 1925, pp. 329-311, 7 figs. Discusses applicability of reinforced concrete as material for building of new bridges, and reconstruction, strengthening and widening of existing bridges.

BRIDGES, HIGHWAY

Strengthening. The Strengthening of Bridges, C. G. Mitchell and C. S. Crettoe. Engineering, vol. 120, no. 3127, Dec. 4, 1925, pp. 721-723, 22 figs. Types of bridges; and methods of strengthening them. Paper read before Pub. Works, Roads & Transports Congress.

BRIDGES, RAILWAY

Strengthening by Electric Welding. Strengthening Railway Bridge by Electric Welding, W. D. Chapman. Commonwealth, vol. 13, no. 1, Aug. 1925, pp. 21-22, 2 figs. Particulars of strengthening of bridge over Murray river at Echuca for heavier locomotives, in connection with construction of Moama to Balranald railway; work is being carried out by Quasi-Arc system of welding.

BUILDING CONSTRUCTION

Lakeolith Method. Lakeolith—Houses Built in Sections by New Methods, H. E. Smith. Cement, Mill & Quarry, vol. 27, no. 10, Nov. 20, 1925, pp. 50, 52, 54, 56 and 58, 10 figs. Particulars of a new method of constructing houses and other buildings by means of concrete units; lakeolith is a new product suitable for all kinds of building construction from a bungalow or garage or even to largest skyscraper; it is constructed with sealed hollow walls, floors and roofs and in that respect resembles a vacuum bottle, thus providing thorough insulation from heat and cold.

C

CABLES, ELECTRIC

High-Tension. Analysis of High-Tension Cables, K. Konstantinowsky. Elec. World, vol. 86, no. 22, Nov. 28, 1925, pp. 1102-1104, 8 figs. Study of dielectric field of cables; Höchstädter design details; experimental work carried on; discussion on dielectrics.

Joints. Investigation of High-Tension Cable Joints, E. W. Davis and C. J. Crowdes. Am. Inst. Elec. Engrs.—Jl., vol. 44, no. 12, Dec. 1925, pp. 1354. Essential properties of good joint are simplicity of design, high dielectric strength, low dielectric loss; data from experimental tests carried out on 7 different types. Abstract of paper, complete copy of which is available in pamphlet form only. See also (discussion), pp. 1342-1347.

CABLEWAYS

Mine. Ropeways of Compania Espanola de Minas del Rif. Iron & Coal Trades Rev., vol. 91, no. 3009, Oct. 30, 1925, pp. 684-686, 7 figs. Properties of this company, consisting of large and rich ore deposits, are situated about 15 miles from port of Melilla on north coast of Morocco, and to bring ore down to port a railway was constructed up to a point about 1½ miles from mines; transport over intervening distance between rail-head and mines is accomplished by aerial ropeways, which have a heavy hourly capacity. Description of installation; operating costs.

CAR DUMPERS

Loading Coal into Ships. Pennsylvania R. R. Car-Dumper for Loading Coal into Ships. Eng. News-Rec., vol. 95, no. 23, Dec. 3, 1925, p. 907, 1 fig. Cradle operated by d.c. engines instead of by gearing; large sheaves for operating cables.

Sand. Quantity production of Automatic Unloader Cars for Transporting Sand (Reihenanfertigung von Selbstentladewagen für Sandtransport), Werner. Werkstattstechnik, vol. 19, no. 18, Sept. 15, 1925, pp. 656-660, 9 figs. Details of design and construction of cars having a capacity of 60 tons and weighing 16 tons, which for unloading are run onto a side rail, the deviation from the vertical resulting in unloading by tipping.

CARBURETORS

Characteristics. Commercial Carburetor Characteristics, C. S. Kegerreis, O. Chenoweth and M. J. Zucrow. Purdue Univ., Eng. Expert. Sta., Bul. No. 21, Aug. 1925, 115 pp., 84 figs. Details and results of investigation carried to determine by actual test how nearly available commercial carburetors meet service demands.

CARS, PASSENGER

Steel. All-Steel Cars of the New South Wales Railways. Commonwealth Engr., vol. 12, no. 12, July 1, 1925, pp. 440-442, 3 figs. Leading dimensions are generally similar to those of large E.B.B.-type cars on North Shore and Bankstown lines, but arrangement of doorways, interior partitions, and seating accommodation is slightly different; particulars of car.

Main Line Metal Cars for First and Second Class (Voiture métallique mixte de 1re et 2e classes pour grandes lignes étudiée par l'office central d'études de matériel de chemins de fer), J. Vallancien. Revue Générale des Chemins de Fer, vol. 44, no. 4, Oct. 1925, pp. 263-284, 12 figs. Design and construction of new corridor cars by Central Office for Railway Material Research in France for use on new electrified main and suburban lines; length 20 m., 58 seats; Vickers lighting system, Westinghouse brakes; resistance tests.

CASE-HARDENING

Gears. Case-Hardened Gears for Street Cars and Electric Locomotives (Gehärtete Zahnräder für Strassenbahnen und elektrische Lokomotiven), Gräfer. Verkehrstechnik, vol. 42, no. 40, Oct. 1925, pp. 792-793, 7 figs. Discusses basic conditions for faultless working of gears; describes new process of case-hardening by Krupp, in which a hardening powder giving off carbon is placed in a layer 3-4 cm. thick around tool to be hardened which is inserted in a box, heated to 850 deg. and subsequently tempered in oil or water.

Process. Case-Hardening (Die Einsatzhärtung), P. Schweibguth. Werkstattstechnik, vol. 19, no. 18, Sept. 15, 1925, pp. 653-656, 8 figs. Discusses treatment of gun-tool and machine parts such as spring bolts, piston pins, etc., with very hard contact surfaces and soft heads; case-hardening process, hardening powders; annealing depth of penetration, etc.

CAST IRON

Alloy Additions, Effect of. Structure Change with Alloy Additions in Ladle. Foundry, vol. 53, no. 22, Nov. 15, 1925, pp. 927-928, 4 figs. Results of series of experiments carried out at Driver-Harris Co's foundry at Harrison, N.J., to determine if addition of material conferred any real benefit on cast iron and to devise method by which addition might be made with minimum amount of trouble and in such manner that amount of each element added might be controlled accurately.

Aluminum, Influence of. The Influence of Aluminium on Cast Iron, A. B. Everest. Brit. Cast Iron Research Assn.—Bul., no. 10, Oct. 1925, pp. 4-6. Review of investigations and bibliography.

Brinell Hardness and Tensile Strength. Brinell Hardness and Tensile Strength of Cast Iron. Brit. Cast Iron Research Assn.—Bul., no. 10, Oct. 1925, pp. 6-9. It is shown that no concordant results are obtained by plotting either actual tensile or actual compression against actual Brinell values; it can be said that as thickness of finger increases, hardness decreases and tensile and compression decrease, but there is no definite relationship connecting the two; formulas proposed by Portevin and Schuz for cast iron give calculated tensile values from Brinell figure 1.5 to 3 times as great as actual tensile value, so that they do not appear to be of any service whatever.

Gray, Mechanical Tests. Correlating Gray Iron Tests, J. W. Bolton. Foundry, vol. 53, nos. 22 and 23, Nov. 15 and Dec. 1, 1925, pp. 912-915 and 958-961, 18 figs. Outline of more commonly used tests for gray irons; consideration of more common mechanical tests, related engineering properties and correlation of these tests to observations of structure of gray iron. Author points out that while four major components, pearlite, ferrite, graphite and steadite, may be approximated closely from analysis, still sizes and distribution of grain structures are determined best microscopically. Annual exchange paper prepared under auspices of Am. Foundrymen's Assn. for presentation before Belgian and French foundrymen's associations.

Research. Practical Points from Recent Researches in Cast Iron, B. Rogers. Foundry Trade Jl., vol. 32, no. 483, Nov. 19, 1925, pp. 427-429. Deals principally with those writers who have themselves experimented upon practical lines; factors influencing total carbon; casting temperature. Recommends list of papers as being capable of giving sound information upon study.

Thyssen-Emmel Process. Low Carburized Cast Iron Produced in Cupolas, K. Emmel. Am. Metal Market—Monthly Rev. Section, vol. 32, no. 222, Nov. 17, 1925, pp. 3-5, 8 figs. Describes Thyssen-Emmel process; problem has been solved of producing with ordinary cupola a cast iron of total carbon content guaranteed below 3 per cent; nature of process concerns measures in cupola working which revolutionize former conceptions and practice. Translated from Stahl u. Eisen.

CEMENT, PORTLAND

Retarders for. Retarders for Portland Cement, E. E. Berger. Pitt & Quarry, vol. 11, nos. 3 and 4, Nov. 1 and 15, 1925, pp. 81-88, and 55-64, 12 figs. Nov. 1: Discusses form or mixture of forms best adapted for retarder. Nov. 15: effect of different retarders on consistency and plasticity of clinker.

CENTRAL STATIONS

Colfax, Pittsburgh, Pa. Recent Developments at Colfax Station. Duquesne Light Co., Chas. W. E. Clarke. Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 30-Dec. 4, 1925, 21 pp., 13 figs. Test results of 3-A element of station which showed net heat rates of 12,750 B.t.u. per kw-hr. at 30,333 kw., 13,021 B.t.u. per kw-hr. at 22,400 kw., and 14,200 B.t.u. per kw-hr. at 15,050 kw.; brief history of physical plant involved in original station and in unit extensions Nos. 1, 2 and 3, with data on boiler and turbine outages and condenser cleaning; total cost of station haa been to date $115,80 per kw. for 190,000 kw. of installed capacity.

Hell Gate, New York City. An American Super-Power Station—The Hell Gate Station at New York, J. B. N. Kershaw. World Power, vol. 4, no. 23, Nov. 1925, pp. 245-249, 5 figs. Details of layout and equipment; operating data.

Hydro-electric vs. Steam. Will Hydro Finally Displace Steam Power? L. M. Arkley. Power House, vol. 18, no. 20, Oct. 20, 1925, p. 91. It is demonstrated that hydro-electric power plants will never replace all steam-driven plants, but that there will be a judicious combination of both, in interests of efficiency and economy.

Private Plant, vs. Central-Station Service Most Economical, H. C. Thuerk. Elec. World, vol. 86, no. 22, Nov. 28, 1925, pp. 1112-1114, 3 figs. How careful analysis of hot water required for process work and study of costs with isolated plant showed marked saving by purchasing power.

Steam. Steam Station Design and Equipment, C. F. Hirshfeld. Elec. Light & Power, vol. 3, nos. 11 and 12, Nov. and Dec. 1925, pp. 27-28, 84, 86, 88, 90 and 92; and 25-26, 82 and 84, 6 figs. An analysis of past, present and future trend.

CITY PLANNING

Iowa. City-Planning Procedure for Iowa Municipalities, R. S. Wallis. Ia. State College of Agriculture & Mechanic Arts—Official Pub., vol. 24, no. 7, June 24, 1925, Bul. 74, 19 pp.

COAL

Carbonization. Low Temperature Carbonization in Revolving Retorts, A. Thau. Blast Furnace & Steel Plant, vol. 13, no. 11, Nov. 1925, pp. 434-441, 8 figs. Deals with one of three designs of revolving retorts which have been developed in Germany and with which writer was particularly acquainted as superintendent; retort is constructed by Fellner & Ziegler at Frankfurt, and is being operated at blast-furnace works at Gelsenkirchen, Westphalia.

Low Temperature Carbonization as a Commercial Process, Wm. H. Blauvelt. Chem. & Met. Eng., vol. 32, no. 18, Dec. 1925, pp. 925-927. Discusses probable market for smokeless fuel, high-heat value gas and tar oils produced.

Conversion by Hydrogenation. Conversion of Coal into Oil by Hydrogenation, J. K. Graham. Iron & Coal Trades Rev., vol. 91, no. 3008, Oct. 23, 1925, pp. 635-637. Historical data; Mining Research Laboratory experiments; action of steam on coal. Abstract of paper read before North Staffordshire Inst. Min. Engrs., Oct. 19, 1925. Also in Colliery Guardian, vol. 130, no. 3382, Oct. 23, 1925, pp. 973-975.

COAL HANDLING

Power Plants. Where Gravity Helps the Power Bill, M. W. Potts. Indus. Mgmt. (N. Y.), vol. 70, no. 6, Dec. 1925, pp. 351-354, 6 figs. Handling coal and ashes at Hammermill paper plant at Erie, Pa.

COAL MINES

Electrical Coal Strip Pit. First All-Electric Coal Strip Mine Is Saving Northern Pacific $700,000 a Year, H. E. Stevens. Coal Age, vol. 28, no. 20, Nov. 12, 1925, pp. 660-663, 4 figs. First completely electrified coal strip pit in country at Colstrip, Mont.

Water Problems. Colliery Water Problems, W. H. Bellin. Colliery Eng., vol. 2, no. 21, Nov. 1925, pp. 487-488, 2 figs. Discussion on considerations governing inrushes of water from disused workings.

COAL STORAGE

Sulphur Oxidation as Factor. The Oxidation of Sulphur as a Factor in Coal Storage, S. W. Parr and E. R. Hilgard. Fuel, vol. 4, no. 11, Nov. 1925, pp. 492-493, 2 figs. Points out that sulphur may be initial source of heat after all, and that judgment should be suspended in matter until further evidence is in hand.

COAL WASHING

Flotation. Sand Flotation Process Engers Bituminous Field, A. F. Brosky. Coal Age, vol. 28, no. 23, Dec. 3, 1925, pp. 769-773, 8 figs. Cleaning method well known in anthracite is now used in central plant serving 3 broad-top mines; cuts ash content to uniform percentage.

COMPRESSED AIR

Aircraft Manufacture. Some Typical Uses of Compressed Air in the Manufacture of Aircraft, P. G. Johnson. Compressed Air Mag., vol. 30, no. 11, Nov. 1925, pp. 1429-1432, 13 figs. Mentions some of most striking applications that have proved of especial value to single concern, the Boeing Airplane Co., Seattle, Wash.

CONCRETE

Diatomaceous-Earth Admixture. Concrete Improved by the Use of Diatomaceous Earth, C. N. Conner. Eng. News-Rec., vol. 95, no. 25, Dec. 17, 1925, pp. 995-996, 1 fig. Tests by North Carolina Highway Dept. show strength and workability increased with included celite.

CONCRETE CONSTRUCTION

Defects. Defects in Concrete, H. C. Badder. Roads & Road Construction, vol. 3, no. 34, Oct. 1, 1925, pp. 296-297. Discusses laitance, crazing, and efflorescence; waterproofing.

Precast Unit for Railway Structures. Precast Concrete Units for Railway Structures, T. H. Strate. Eng. News-Rec., vol. 95, no. 25, Dec. 15, 1925, pp. 990-990. Varied uses and sizes; bridge decks; building blocks and structural parts; piles, poles and track signs. (Abstract.) Report presented before Am. Ry. Bridge & Bldg. Assn.

CONCRETE CONSTRUCTION, REINFORCED

Rapid-Hardening Cement Concretes. Reinforced Concrete Design With Rapid Hardening Cement Concretes, G. D. Balsille. Commonwealth Engr., vol. 12, no. 12, July 1, 1925, pp. 439-440. Author has found that introduction of rapid-hardening cements makes most of the design tables dealing with Portland cement obsolete as regards new material; he has therefore revised his tables and presents them herewith in a tentative form.

CONCRETING

Winter. Rigid Control of Winter Concreting, J. R. Macauley and H. L. Mahaffy. Contract Rec., vol. 39, no. 47, Nov. 25, 1925, pp. 1125-1128. Modern methods of placing concrete during cold weather; wherein salamanders are defective; outline of specification which should be insisted upon.

CONDENSERS, STEAM

Locomotive. The Locomotive Condenser. Ry. Engr., vol. 46, no. 551, Dec. 1925, p. 433, 1 fig. Survey of various types and their characteristics.

Surface. Efficient Marine Steam-Plant Operation. Mar. Engr. & Motorship Bldr., vol. 48, no. 578, Nov. 1925, pp. 413-415. Practical problems affecting working of surface condensers.

CONVEYORS

Pneumatic. Pneumatic Conveying Plants of Large and Small Capacity (Pneumatic Förderanlagen für grosse und kleine Leistungen), O. Kleier. Fördertechnik u. Frachtverkehr, vol. 18, no. 18, Sept. 20, 1925, pp. 288-289, 5 figs. Design and operation of Luther plant for unloading grain from ships; capacity up to 300 tons per hour; small-grain coal from railway cars, etc.

Types. Modern Conveying in Factory Operation (Neuzeitliche Förderungen in Fabrikbetrieben), O. Hochstetter. Fördertechnik u. Frachtverkehr, vol. 18, no. 16, Aug. 18, 1925, pp. 241-246, 32 figs. Discusses types of chains for conveying and driving, continuous and intermittent; belt conveyors, rocking conveyors and elevators, bucket chains, band conveyors, roller conveyors, coal-handling plants, etc.

COUPLINGS

Shaft, Flexible. Flexible Shaft Coupling. Textile Wld., vol. 68, no. 18, Oct. 31, 1925, p. 53, 2 figs. Describes new type of shaft coupling placed on market by Farrel Foundry & Machine Co., Buffalo, N. Y., called "Sykes universal shaft coupling"; differs from other flexible couplings in that it is really a universal joint and is therefore capable of not only taking care of small errors in alignment but of successfully connecting shafts which are grossly misaligned, its limit of angularity is stated to be 5 deg.

CRANES

Overhead. Traction and Adhesion in the Design of Overhead Cranes. Mech. World, vol. 78, no. 2026, Oct. 30, 1925, pp. 343-345, 4 figs. Deals with question of design of electric travelling cranes from point of view of obtaining satisfactory travel motions.

Steam Titan. 50-Ton Steam Titan Crane. Engineer, vol. 140, no. 3647, Nov. 20, 1925, p. 561, 2 figs. partly on p. 552. Built by Stobert & Pitt, Bath, Eng., for Union of South Africa; it consists of upper structure of double cantilever type which revolves by means of live ring of steel rollers upon truck, which forms full portal for passage of traffic and block trucks.

CRUSHING

Surface Measurement of Particles. Surface Measurement on Finely Ground Particles and Its Relationship to the Crushing Laws, J. Gross, S. R. Zimmerly and S. J. Swainson. Univ. of Utah, (Research Investigation)—Bul., no. 16, Aug. 1925, pp. 57-76. Investigation to devise method whereby actual surface of finely ground and irregularly shapel particles can be measured; this method, when developed, is to be used in fundamental study of energy consumed in crushing.

CUPOLAS

Mechanical Charging. Charges Cupolas Mechanically, Wm. G. Hammerstrom. Foundry, vol. 53, no. 22, Nov. 15, 1925, pp. 908-911, 8 figs. Electric charging device with one operator replaces crew of 8 men on charging platform at Radford, Va., works of Lynchburg Foundry Co., Lynchburg, Va.

CURING

Semi-Arid Climate, in. Curing Concrete in a Semi-Arid Climate. Contract Rec., vol. 39, no. 47, Nov. 25, 1925, p. 1130. Conclusions drawn from an investigation conducted under auspices of Structural Materials Research Laboratory.

CYLINDERS

Aircraft Engines. The Design of Air-Cooled Cylinders, C. F. Taylor. Aviation, vol. 18, nos. 23 and 24, June 8 and 15, 1925, pp. 634-636 and 664-667, 4 figs. Sets forth ideas based largely on results of experiments made by Engineering Division, Air Service, and corroborated in laboratories of Wright Aeronautical Corp.

Lapping. Commercial Cylindrical Lapping, C. T. Appleton. Mech. Eng., vol. 47, no. 12, Dec. 1925, pp. 1106-1110, 6 figs. Cylindrical lapping machine and its operation; production of piston pins; tolerances; conservative rate of commercial lapping; work holders; truing lapping wheels; lapping experiments and conclusions drawn therefrom. Discussion of paper by P. M. Mueller, published in Sept. 1925 issue of Journal.

D

DAMS

Test, Experiments on Large. Experiments on a Large Test Dam. Eng. Jl., vol. 8, no. 12, Dec. 1925, pp. 493-495, 3 figs. Tentative outline for experiments on test dam in California by Committee of Engineering Foundation.

DIESEL ENGINES

FUEL FOR. Diesel Engine and Its Fuel, L. Wolff. Pac. Mar. Rev., vol. 22, no. 12, Dec. 1925, pp. 558-560, 2 figs. Review of developments in design of Diesel engines; advantages of Diesel operation; question of suitable and adequate fuel supply.

LUBRICATION. Lubrication of the Diesel, P. Aikens. Power House, vol. 18, no. 20, Oct. 20, 1925, pp. 95-96. Minimizes repairs; oil of correct body; lubrication requirements of air-compressor cylinders; oxidation; lubrication bearings; treatment of oil; contaminated oil; reliability with economy.

MANUFACTURE. Building Diesel Engines for the Panama Canal, F. W. Curtis. Am. Mach., vol. 63, no. 25, Dec. 17, 1925, pp. 959-962, 8 figs. Specifications of units; assembling bedplates; planing cylinders; turning pistons; machining cylinder heads. Built by Nordberg Mfg. Co., Milwaukee, Wis.

TORSIONAL VIBRATION. Torsional Vibration in the Diesel Engine, F. M. Lewis. Soc. Nav. Architects & Mar. Engrs.—advance paper, no. 9, for mtg. Nov. 12-13, 1925, 32 pp., 19 supp. plates. Review of more fundamental aspects; calculation of natural frequencies of vibration; vibration in multi-cylinder engine; types of installation and their vibration characteristics; elimination of vibration; speed regulation—action of flywheel. Bibliography.

WORTHINGTON. The Double-Acting, Two-Cycle Oil-Engine, O. E. Jorgensen. Soc. Nav. Architects & Mar. Engrs.—advance paper, no. 14, for mtg. Nov. 13-14, 1925, 9 pp., 15 figs. on 14 supp. plates. Describes new Worthington engine and compares its method of operation with single-acting engines and double-acting 4-cycle type; comparison is made of weights, power output and heat transfer of different types and of their relative costs; describes features peculiar to Worthington engine; experiments to determine rate of heat transfer in cylinder walls and variations of pressure in piston-rod stuffing boxes. See also discussion in Mar. Eng. & Shipg. Age, vol. 30, no. 12, Dec. 1925, pp. 704-705.

DIRECTION FINDING

EQUIPMENT. The Direction-Finding Equipment at Niton and Cullercoats, J. H. Reyner. Instn. Elec. Engrs.—Jl., vol. 63, no. 347, Nov. 1925, pp. 1138-1140, 3 figs. These stations are first to be equipped for regular direction-finding service; apparatus, which is of Bellini-Tosi pattern, is described and methods employed in taking a bearing discussed; influence of neighboring bodies on error curve is investigated; satisfactory installation of apparatus is followed by calibration in co-operation with ship.

DRYDOCKS

ESQUIMALT, B. C. The New Esquimalt Drydock, J. P. Forde. Eng. Jl., vol. 8, no. 12, Dec. 1925, pp. 477-482, 5 figs. General details of construction and equipment of new drydock in British Columbia; choice of site and its characteristics; general dimensions and comparison with other docks; construction details; tunnel for compressed air, water and power mains; lighting equipment; sanitary provisions; mechanical equipment; electric power supply and capstans; caissons for closing dock; landing and fitting-out wharf.

DRILLING MACHINES

ROTATING TABLES ON MULTIPLE. Using Rotating Tables on Multiple Drills, W. F. Sandmann. Machy. (N. Y.), vol. 32, no. 4, Dec. 1925, pp. 310-312, 6 figs. Combined drilling and tapping machines; combined drilling and reaming operations; set-up for drilling closely spaced holes; fixed type of bushing plate.

DURALUMIN

DETERIORATION, IN "SHENANDOAH". Deterioration of Duralumin in the "Shenandoah". Eng. News-Rec., vol. 95, no. 25, Dec. 17, 1925, pp. 1000-1001. Results of Bur. of Standard tests brought out before court; intercrystalline corrosions widespread.

TREATMENT. The Duralumin Problem (Das Duraluminproblem), W. Fraenkel. Zeit. für angewandte Chemie, vol. 38, no. 33, Aug. 13, 1925, pp. 696-699, 1 fig. Discusses scientific problem of improving aluminum alloys by heat treating, hardening, tempering, etc.; increase of tensile strength, mixed crystal formation, electric conductivity, etc.

E

EDUCATION, ENGINEERING

COLLEGES, OPPORTUNITY FOR SERVICE. The Engineering College—Its Opportunity for Service, A. A. Potter. Jl. Eng. Education, vol. 16, no. 1, Sept. 1925, pp. 4-24. Points out that industry and engineering colleges are interdependent; outstanding characteristics of engineering colleges; technique of engineering education; concentric methods of engineering education; instruction along functional lines: commercial training; character building and development of personality; guiding students to discover their aptitudes; cultural training; research as aid to engineering education.

GERMAN ASSOCIATION FOR TECHNICAL INSTRUCTION. Technical Works Instruction in Germany. Engineering, vol. 120, no. 3128, Dec. 11, 1925, p. 752. Organization and aims of the DATSCH (Deutsche Ausschuss für Technisches Schulwesen), which has become central office for intermediate technical instruction, training of apprentices and employees, coming from ordinary or trade schools and intending to proceed in due time to technical high schools.

GRADUATES AND TEACHING PERSONNEL. Engineering Graduates and Engineering Teaching Personnel. Mech Eng., vol. 47, no. 12, Dec. 1925, pp. 1181-1197, 4 figs. Reports of committees of Soc. for Promotion of Eng. Education as follows: Report of Committee on Engineering Students and Graduates, June 1, 1925; Preliminary Report of Committee on Teaching Personnel.

RESEARCH AND. The Relation between Engineering Education and Research, R. W. Sorensen. Am. Inst. Elec. Engrs.—Jl., vol. 44, no. 12, Dec. 1925, pp. 1288-1290. With particular reference to California Inst. of Technology plan.

STUDENTS AND GRADUATES. Society for the Promotion of Engineering Education, Report of Committee on Engineering Students and Graduates. Jl. Eng. Education, vol. 16, no. 1, Sept. 1925, pp. 75-84, 3 figs. Results of study based upon returns covering approximately 4000 individual students attending 32 institutions; secondary school preparation; educational guidance of entering students; conclusions.

ELECTRIC COMMUNICATION

ADVANCES. Recent Advances in the Communication Art. Am. Inst. Elec. Engrs.—Jl., vol. 44, no. 12, Dec. 1925, pp. 1302-1308, 3 figs. Summary of advances which have been made of come into prominence during past year in telegraphy, telephone signaling, machine switching, telephone distributing frame wire, telephone transmission, radio and radio broadcasting, inductive relations of power and communication circuits, communication in railway operation, electric transmission of pictures. Report of Committee on Communication.

ELECTRIC CONDUCTORS

MAGNETIC-FLUX ENERGY. Magnetic Flux Energy, C. Hering. Franklin Inst.—Jl., vol. 200, no. 6, Dec. 1925, pp. 747-756. Author shows that in calculating stored energy in magnetic flux more care should have been taken not to add together again, as by integration, energies whose components had already been added. Supplement to author's paper, published in Feb. 1925 issue of same journal, giving results of investigation of properties of single, straight conductor, far removed from all others.

ELECTRIC DRIVE

SECTIONAL. The Evolution of the Sectional Drive, H. W. Rogers. Paper Trade Jl., vol. 81, no. 18, Oct. 29, 1925, pp. 99-102, 5 figs. Discusses horsepower per ton daily, influence of drive on product, exacting requirements, two types of drives and difference between the types, stages of development, etc.

ELECTRIC FURNACES

CONVERSION FROM OIL-FIRED FURNACE. Converting an Oil-Fired Furnace to Electric Heating, W. J. Walsh. Elec. World, vol. 86, no. 22, Nov. 28, 1925, pp. 1110-1111, 2 figs. Describes reconstruction of oil-fired unit consisting of 3 heating chambers; Leeds & Northrup 2-point special gun furnace control was adopted; check-up of cost of both types of operation.

ELECTRIC FUSES

DESIGN AND BEHAVIOR, FACTORS AFFECTING. Fuses and Fusible Cut-Outs, P. G. Ashley. Instn. Elec. Engrs.—Jl., vol. 63, no. 347, Nov. 1925, pp. 1133-1137. Reviews history of development of fusible cut-outs, and discusses in turn the various factors affecting design and behavior of wire and plate fuses in air; considers main features of fuse wires in oil, and also how their design and behavior compare with those of fuses in air; describes various types of enclosed and semi-enclosed cut-outs, as well as oil-immersed switch fuses; theoretical aspect of mechanism of fusing; present position as to standardization.

ELECTRIC GENERATORS, A.C.

LARGE 3-PHASE. Europe's Largest Three-Phase Generator. Elec. World, vol. 86, no. 23, Dec. 5, 1925, p. 1150. New generator built by Siemens-Schuckert Works for one of large Rhenish-Westphalian generating stations in Germany, is coupled to steam turbine of 80,000 hp., operating at 1,000 r.p.m., electrical output being 60,000 kw., 3-phase, at 7,000 volts; it is composed of 26 rotor disks mounted on continuous shaft, 1.1 m. in maximum diam. and 8.7 m. in total length.

ELECTRIC LOCOMOTIVES

DIESEL-ELECTRIC. Comparative Tests with Diesel and Steam Locomotives. Eng. Progress, vol. 6, no. 10, Oct. 1925, pp. 319-320, 7 figs. Results of comparative tests conducted in November 1925, on Russian test bed at Maschinenfabrik Esslingen with first 1-E-1 Diesel-electric locomotive of Russian Government Rys. and one of 700 Russian E-coupled freight engines built in Germany; results showed savings of fuel with Diesel locomotive.

OIL-ELECTRIC. Oil-Electric Switching Locomotive of 100 Tons Weight Developed for Long Island Railroad. Ry. & Locomotive Eng., vol. 38, no. 11, Nov. 1925, pp. 328-329, 2 figs. 100-ton locomotive will have 2 oil-engine-driven generator sets to furnish power to 4 direct-current, geared traction motors; engines, manufactured by Ingersoll-Rand Co., are 6-cylinder, vertical units of 4-cycle type, with piston of 10-in. diam. and 12 in. stroke.

ELECTRIC METERS

RECORDING DATA. Methods that Expedite Meter Work, K. H. Bausman. Elec. World, vol. 86, no. 22, Nov. 28, 1925, pp. 1093-1096, 10 figs. System used by Dayton Power & Light Co. to maintain information that is essential to convenient operation without involving unnecessary records.

ELECTRIC MOTORS

BALL-BEARING. Ball-bearing Electric Motors, T. C. Delaval-Crow. Machy. (N. Y.), vol. 32, no. 4, Dec. 1925, pp. 265-269, 9 figs. Advantages of ball bearings for motors and methods of mounting and lubricating.

LUBRICATION. Electric Motors and Their Lubrication. Lubrication, vol. 2, no. 10, Oct. 1925, pp. 109-120, 21 figs. Notes on function and construction of electric motor; discusses lubricating systems, including ring oilers, ball and roller bearings, wick lubrication, waste packed and wool yarn systems of lubrication, electric railway motors, flushing and cleaning of bearings.

OUTPUT TEMPERATURE RISES. The Output of Totally-Enclosed Electric Motors for Specified Temperature Rises, F. Murgatroyd. Engineering, vol. 120, no. 3123, Nov. 6, 1925, p. 563, 1 fig. Gives curve showing maximum output of machine plotted against time; methods of measuring temperatures; heating curves.

ELECTRIC MOTORS, A.C.

CASCADE INDUCTION. The Two-Speed Cascade Induction Motor, A. H. M. Arnold. Instn. Elec. Engrs. — Jl., vol. 63, no. 347, Nov. 1925, pp. 1115-1122, 15 figs. Considers general conditions of operation of two motors in direct and differential cascade, with special reference to possibility of set running at speed near synchronous speed of primary machine, while still connected in cascades; describes Hunt's cascade motor.

SQUIRREL-CAGE. High-Torque High-Efficiency Squirrel-Cage Motor. Mech. World, vol. 78, no. 2025, Oct. 23, 1925, pp. 319-320, 6 figs. High-starting-torque induction motor, introduced by Metropolitan-Vickers Elec. Co., Manchester, Eng., known as C. K. B. motor.

ELECTRIC RAILWAYS

CAR DESIGN. Report of Committee on Unification of Car Design. Elec. Traction, vol. 21, no. 10, Oct. 1925, pp. 535-536. Report to Am. Elec. Ry. Assn.

CHICAGO, NORTH SHORE & MILWAUKEE R. R. North Shore Speeds Service. Elec. Traction, vol. 21, no. 11, Nov. 1925, pp. 582-586, 6 figs. 36 mi. of new double-track being constructed by Chicago, North Shore and Milwaukee R. R. through Skokie Valley as cut-off for high-speed service.

EQUIPMENT. Report of the Committee on Equipment. Elec. Traction, vol. 21, no. 10, Oct. 1925, pp. 536-542. Recommendations for bearing clearance; axle bearings; babbitting bearings; tinning alloy; tinning bronze shells that are to be babbitted; anchor holes in iron shells; heating mandrels and shells for babbitting; methods of car painting; motor-coach design problems; devices for trolley contact; helical and spur gearing; gearing noises and methods of reducing them; sources of track noise and suggested remedies; wheels, trucks, brakes, gearing, motors, body, etc. Bibliography. Report to Am. Elec. Ry. Assn.

REPLACEMENT OF OBSOLETE EQUIPMENT. Replacement of Obsolete Equipment Demands Serious Attention. Elec. Ry. Jl., vol., 66. no. 20, Nov. 14, 1925, pp. 853-854, 2 figs. Analysis of condition of present electric railway rolling stock shows minimum of 25,000 obsolete cars in service; new physical equipment is important from standpoint of merchandising railway transportation.

ELECTRIC TRANSMISSION LINES

CALCULATION. Three-phase Transmission Lines, G. Ashworth. Elec. Rev., vol. 97, no. 2503, Nov. 13, 1925, pp. 767-770, 2 figs. Rapid preliminary electrical calculations with aid of charts.

FAULT LOCATION. Locating Circuit Faults, S. Aronoff. Elec. World, vol. 86, no. 21, Nov. 21, 1925, pp. 1041-1045, 16 figs. Inherent errors of generally used methods and relative merits; other methods which have better characteristics for this class of work and are inherently capable of better and desired accuracy.

WASHINGTON. The Long Span Across the Narrows at Tacoma, J. V. Gongwer and A. F. Darland. Am. Inst. Elec. Engrs. Jl., vol. 44, no. 12, Dec. 1925, pp. 1296-1302, and (discussion) p. 1351, 11 figs. Double transmission lines being built by City of Tacoma, Wash., as part of its new Cushman Power Development, reaches 44 mi. from North Fork of Skokomish River across Narrows to Tacoma; notes on choice of conductor; circuit arrangement; general structural design; economical considerations affecting sag and tower heights; cables and fittings; insulator assemblies; towers and tower footings, anchorages and sheaves; construction and erection; cost of development.

ELECTRIC WELDING, ARC

COSTS. Arc Welding Costs, K. R. Hare, Am. Welding Soc.—Jl., vol. 4, no. 9, Sept. 1925, pp. 17-19, 1 fig. Presents table showing pounds of metal deposited per hour with different heat values and different sizes of electrodes, from which it is apparent that there is distinct advantage along lines of increased production in using larger sizes of electrodes wherever possible.

MANUFACTURING PROCESS. Arc Welding as a Manufacturing Process, H. M. Hobard and W. Spraragen. Am Welding Soc.—Jl., vol. 4, no. 10, Oct. 1925, pp. 71-103, 15 figs. Deals with fundamental considerations, such as design, material, welding rods, jigs and fixtures, inspection, testing, cost data, speed of arc welding, etc., examples of arc-welding applications; use of arc welding in Westinghouse Elec. & Mfg. Co's works.

WELDABILITY OF FERROUS METALS. Metallic Arc Weldability of Ferrous Metals, C. J. Holslag. Am. Welding Soc.—Jl., vol. 4, no. 10, Oct. 1925, pp. 37-43. Discusses weldability of various alloy steels, cast iron, malleable iron, and cast steel.

ELECTRIC WELDING, RESISTANCE

NON-FERROUS METALS. Welding of Non-Ferrous and Special Metals by the Resistance Welding Process, H. A. Woofter. Am. Welding Soc.—Jl., vol. 4, no. 9, Sept. 1925, pp. 46-49. Notes on welding of aluminum brass, copper, duralumin, monel metal and special metals.

SPOT AND SEAM. Prescot Spot and Seam-Welding Machines. Engineering, vol. 120, no. 3127, Dec. 4, 1925, pp. 724-726, 9 figs. Salient features of two types of machines, made by Brit. Insulated & Helsby Cables, Ltd., Prescot, Lancashire, Eng.

ELECTRICITY SUPPLY

ECONOMICS AND INDUSTRIAL. Economics and Industrial Electrification, A. Tustin. Instn. Elec. Engrs.—Jl., vol. 63, no. 347, Nov. 1925, pp. 1141-1146. Attempts to define exactly what aim should be in policy of power supply; discusses degree of dependence of British foreign trade upon cheap power, and implications of ordinary methods of comparing economy of various schemes; suggests lines of investigation by which best policy may be selected, and discusses methods of charging for power.

ELECTRONS

MOTION IN GASES. Motion of Electrons in Gases, J. S. Townsend. Franklin Inst. Jl., vol. 200, no. 5, Nov. 1925, pp. 563-590, 10 figs. Most direct method of investigating motion of electrons through gas is to determine experimentally velocity of agitation and velocity in direction of electric force; from results of these experiments effect of collision with molecule on motion of electron may be estimated by methods similar to those used in kinetic theory of gases.

ELEVATORS

FAULT LOCATION. Locating Faults in Electric Elevatrrs—Direct-Current Controllers, Chas. A. Armstrong. Power, vol. 62, nos. 18, 20 and 25, Nov. 3, 17 and 22, 1925, pp. 674-677, 4 figs.; 760-763, 6 figs.; and 969-972, 13 figs. Nov. 3: Faults that may cause main fuses to blow and make potential switch fail to function properly. Nov. 17: Faults in controllers of mechanically controlled elevators that may cause motor to start or fail to come up to speed if it does start. Dec. 22: Faults in full-magnet-type controllers.

ENAMELLING

PISTOL SPRAY FOR. The Aerograph Pistol Spray. Engineering, vol. 120, no. 3123, Nov. 6, 1925, pp. 590-591, 1 fig. Describes latest design of pistol spray introduced by Aerograph Co., London; it is known as G. P. model and is particularly suitable for cellulose enamels, but may also be used for general purposes with ordinary paints and varnishes.

EQUIPMENT MANUFACTURE. Engineering Planning for Manufacture, G. A. Pennock. Bell System Technical Jl., vol. 4, no. 4, Oct. 1925, pp. 542-560, 6 figs. Discusses complete analysis, from a manufacturing point of view, to which every item of telephone apparatus is submitted at Hawthorne Plant of West. Elec. Co.; these works employing, at present, about 25,000, produce over 110,000 different kinds of parts which enter into some 13,000 separate forms of apparatus; advantages of careful engineering analysis of each new job coming to factory, as well as those which have been in connection; the various steps which are worked out in connection with each analysis.

ESCALATORS

ITALY. Escalators for the Urban Section in Naples of the Rome-Naples Express (Scale mobili per il tratto urbano in Napoli della drettissima Roma-Napoli), E. D'Andrea. Rivista Tecnica delle Ferrovie Italiane, vol. 28, no. 4, Oct. 15, 1925, pp. 129-137, 9 figs., partly on supp. plates. Details of design and construction of escalator plants at Montesaeto and Cavour subway stations, mechanical and electric equipment, power consumption, etc.

EVAPORATORS

POWER-HOUSE. Power-house Evaporators, D. McHutchison. Mech. World, vol. 78, no. 2028, Nov. 13, 1925, pp. 382-383, 2 figs. Discusses design, developments and types.

F

FACTORIES

BUILDINGS. The Modern Manufacturing Plant, Mgmt. & Admin., vol. 10, no. 6, Dec. 1925, pp. 339-342, 3 figs. E. R. Squibb & Sons complete first unit of thoroughly planned new building program at Brooklyn plant.

PLANNING. Some Problems in Works Planning, A Whitehead. Mech. World, vol. 78, nos. 2028 and 2029, Nov. 13 and 20, 1925, pp. 387-388 and 406-407, 4 figs. Consideration of such problems as labor supply, space for extension, form of building, arrangement of machines, lighting and heating.

FANS

PROBLEMS. Fan Problems, H. Briggs. Colliery Eng., vol. 2, nos. 15, 16, 17, 18, May, June, July, and Aug., 1925, pp. 197-199, 245-248, 292-294 and 367-369, 13 figs. May: Notes on efficiency and cost of power; need for effective criticism; causes of exaggerated efficiencies; inaccuracies in measurement of volume; plea for manometrical efficiency; what happens when fan speed is varied. June: Characteristic curves; natural ventilation; mine characteristics and natural ventilation; measuring resistance of fan. July: Flow of air in converging and expanding channels; purpose of evasee, its shape and efficiency. Aug.: Power available for conversion by evasee; venturi blowers and velocity indicators.

FILTERS

DESIGN. Some Features of Filter Design. J. W. Armstrong. New England Water Wks. Assn.—Jl., vol. 39, no. 3, Sept. 1925, pp. 254-266 and (discussion) 266-271, 1 fig. Notes on water, watershed, mixing basins, coagulating basins, pipe galleries, concrete, economy in construction, principles of design, potentiometer for recording hydrogenion concentration of water, filter bottoms, filter sand, wash water, chemical feed devices, turbidimeter for reading low turbidities, sign glass for determining clarity of filter effluent.

FILTRATION PLANTS

MONTREAL, CANADA. The Filtration Works of the City of Montreal, F. E. Field. New England Water Wks. Assn.—Jl., vol. 39, No. 3, Sept. 1925, pp. 213-224. General description of municipal filtration works of city of Montreal, Quebec, Can., prior to Sept. 12, 1925.

FLOW OF AIR

ROTATING CYLINDER, AROUND. Flow of Air Around a Rotating Cylinder. E. N. Fales. Air Service Information Circular, vol. 6, no. 510, June 1, 1925, 4 pp., 6 fig. Test made as simple means of demonstrating change of air flow about cylinder when latter is rotating.

TRANSMISSION OF WAVES THROUGH PIPES. On the Transmission of Air-Waves through Pipes, L. F. G. Simmons and F. C. Johansen. Lond., Edinburgh & Dublin Philosophical Mag. & Jl. Sci. vol. 50, no. 297, Sept. 1925, pp. 553-570, 8 figs. Results of experiments, conducted at Nat. Physical Laboratory on transmission of waves through rubber pipes, which deal with propagation of single wave resulting from sudden application of known pressure, at one end of pipe, and with waves generated by simple harmonic variation of pressure of displacement, applied at one end; results pertaining to closed pipes indicate relationship existing between pressures at any instant at two ends, and extent to which these are affected by size and length of pipe, and by type of gage used; measurements of displacement made at end of open pipes may be compared with calculations based on theory given by Rayleigh.

FLUE-GAS ANALYSIS

CO_2 AND CO RECORDERS. Developments in Flue-Gas Analysis. Power Engr. vol. 20. no. 236. Nov. 1925, pp. 430-432, 9 figs. Descriptions of Cambridge combined CO_2 and Co. instruments.

FLYWHEELS

INTERNAL-COMBUSTION ENGINES. Flywheels for Otto Cycle Horizontal Internal-Combustion Engines. Power Engr., vol. 20, no. 236, Nov. 1925, pp. 413-416, 9 figs. Presents reasonable basis for computation of weight of flywheels necessary for multi-cylinder engines.

FORGE SHOPS

ECONOMIES IN. Effecting Economics in a Forge Plant. Jos. Haas. Forging—Stamping—Heat Treating, vol. 11, no. 11, Nov. 1925, pp. 397-398. Cites several examples to show how production costs can be reduced; experienced foremen should be placed in charge of all departments.

FORGING

COLD HEADING. Cold Heading. Macky (Lond.) vol. 27, pp. 683, 684, 685 and 686, Oct. 24, Nov. 5, 12 and 19, 1925, pp. 126-134, 161-168, 193-196 and 225-226, 33 figs. Recent developments in cold-heading machines and cold-headed products; manufacturing practice in production of cold-headed parts.

The Physical Aspect of Cold Heading and Cold Heading Material. C. E. Hill, Macky (Lond.), vol. 27, No. 687, Nov. 26, 1925, pp. 265-269, 14 figs. Chemical analysis of material for cold heading; heat treatment, during manufacture; cold work during heading process; tests applicable to material.

FOUNDATIONS

UNDERPINNING. Inclined-Pile Underpinning for Special Condition. Eng. News. Rec., vol. 96, no. 23, Dec. 3, 1925, p. 916, 1 fig. Method devised to avoid disturbing mat foundation of 18-story building resting on wet fine sand and clay.

FOUNDRIES

CRUCIBLE COST REDUCTION. How to Cut Crucible Costs. Metal Iudustry (N.Y.) vol. 23, no. 11, Nov. 1925, pp. 448-450. Notes on unpacking, storage, storage oven, dampness, preheating, annealing, furnace tending, fuels, pouring, tongs and shanks; crucibles for various conditions and mixtures. Abstract from pamphlets published by Plumbago Crucible Assn.

FUELS

OIL. *See Oil Fuel.*

FURNACES, HEAT-TREATING

RECUPERATIVE. Recuperation in Carbonizing Steel, P. W. Hey, Forging—Stamping—Heat Treating, vol. 11, no. 11, Nov. 1925, pp. 403-404, 1 fig. Describes gas-fired carbonizing furnace which constitutes part of equipment in heat-treating department of Buda Co. of Harvey, Ill.; recuperators in each stack comprises 8 sections arranged in 2 tiers; results of tests made to ascertain results obtained with recuperators.

G

GAS PRODUCERS

OPERATION. Operation of Gas Producers, F. S. Bloom. Fuels & Furnaces, vol. 3, no. 11, Nov. 1925, pp. 1227-1229, 2 figs. Factors determining capacity of gas producer and quality of gas produced.

TIN-PLATE PLANT. Producer Gas Used in Tin House. Iron Trade Rev., vol. 77, no. 25, Dec. 17, pp. 1535-1537, 4 figs. Plant for gasifying and claening 3000 lb. of bituminous coal an hour is installed by tin-plate producer in Pittsburgh district; tar is extracted from raw gas and utilized beneath boilers. See also description by R. A. Fiske, in Iron Age, vol. 116, no. 25, Dec. 17, 1925, pp. 1665-1668, 6 figs.

GEAR CUTTING

MACHINES, SPECIAL USES FOR. Special Work on Gear-cutting Machines. Machy. (N. Y.), vol. 32, no. 4, Dec. 1925, pp. 289-292, 11 figs. Use of gear-cutting machines for drilling and milling, and application of gear generators for special operations.

SYKES GENERATOR. The Sykes Herringbone Gear Generator. Blast Furnace & Steel Plant, vol. 13, nos. 11 and 12, Nov. and Dec. 1925, pp. 456-458 and 497-498, 8 figs. Most interesting features connected with Sykes machines is method of cutting herringbone and double helical teeth, having right and left hand portions of teeth joined at centre of face without any clearance whatever for cutting tools; operations in production of Sykes double helical continuous tooth gears.

GEARS

HOUSINGS, MACHINING. Machining the Bevel-Gear Housing of the Mack Truck and Bus, F. W. Curtis. Am. Mach., vol. 63, nos. 22 and 23, Nov. 26 and Dec. 3, 1925, pp. 841-844 and 883-886, 20 figs. Methods adopted by Int. Motor Co. in its New Brunswick, N. J., plant for manufacturing of its bevel-gear housing; large trunnion drill jig; method of driving studs; inspecting work in group form; variety of gages used.

NORMAL PITCH. Normal Pitch—the Index of Gear Performance, G. M. Eaton. Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 30-Dec. 4, 1925, 27 pp., 20 figs. Brings out certain departures from previously accepted practice which are useful in manufacture of heavy involute gearing, as they aese performance during breaking-in stage of operation; shows that material improvement in performance may be secured by adopting proper relation between normal pitches of driving and driven gears, measured at point of tooth engagement; outlines development of normal-pitch indicators.

SPUR, SPEED REDUCERS. Data for Selection of Spur Gear Speed Reducers, F. A. Emmons. Belting, vol. 27, no. 4, Oct. 1925, pp. 40, 42, and 44, 5 figs. Importance of carefully calculating actual torques on driven unit, as a basis of determining horsepower required to move load.

TEETH, WEAR EXPERIMENTS. Some Comparative Wear Experiments on Cast-Iron Gear Teeth, G. H. Marx, L. E. Cutter, and B. M. Green. Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 30-Dec. 4, 1925, 37 pp., 22 figs. Results of experiments made in laboratories of Stanford Univ.; deductions indicated by tests are as follows: standard-depth 20-deg. involute tooth form appears to be better one to resist wear than standard-depth 14½-deg. involute form; stub-tooth, 20-deg. involute tooth form appears to be better than standard-depth 14½-deg. involute form; standard-depth 20-deg. involute tooth form appears to be better than stub-tooth 20-deg. involute form; etc.

VARYING-CENTER-DISTANCE. Varying-Center-Distance Gears, H. Walker. Am. Mach., vol. 63, no. 22, Nov. 26, 1925, pp. 853-856, 6 figs. Calculations for design of varying-center-distance gears; methods for avoiding undercutting; tooth-thickness and pressure-angle formulae.

GRAIN HANDLING

FLOATING PNEUMATIC PLANTS. Floating Pneumatic Grain Handling Plant at Cardiff. Indus. Mgmt. (Lond.), vol. 12, no. 11, Nov. 1925, pp. 507-511, 5 figs. Describes plant which has been installed at port of Cardiff, Wales; advantages are speedy, convenient, and dustless operation; capacity 120 tons per hour.

H

HEAT TRANSMISSION

CONVECTION. Film Effect and Influence of Wall Vibration on Heat Transmission by Convection (Etude sur l'effect de film et l'influence des vibrations des parois sur la transmission de la chaleur par convection), Ch. Roszak and M. Vernon. Société des Ingénieurs Civils de France—Mémoires et Compte Rendu des Travaux, vol. 78, nos. 7-8, July-Aug. 1925, pp. 584-618. Discusses mechanics of process of convection, including simultaneous mechanical flow and heat flow, film phenomenon, interior and exterior circulation, role of film; effect of wall vibration; experimental study of this effect on heat transmission between two fluids which it separates; concludes that wall vibration favors ebullition and vapor-bubble formation, accelerates turbulent flow and heat transmission at low flow, expecially in gaseous media, etc.

HEATING AND VENTILATION

SUPERPOWER PLANT. Heating and Ventilating a Superpower Plant, S. Sayward. Domestic Eng. (Chicago), vol. 113, no. 6, Nov. 7, 1925, pp. 22 and 24, 6 figs. Problems in connection with heating and ventilating of Weymouth power station of Edison Elec. Illuminating Co. of Boston, a steam station of most modern design.

HEATING, ELECTRIC

APPLIANCE FOR INDUSTRIAL USE. Types of Electric Heating Appliances for Industrial Use, Rob. M. Keeney. Chem. & Met. Eng., vol. 32, no. 17, Nov. 1925, pp. 855-859, 7 figs. Discusses various designs of heaters and their application, with some remarks on heating control and purchase of equipment.

HIGH-TENSION. Maximum Prices for Electric Heat (Höchstpreise für Elektrowärme), Windel. Elektrotechnische Zeit., vol. 46, nos. 46 and 47, Nov. 12 and 19, 1925, pp. 1721-1725 and 1771-1775, 2 figs. Develops formulae and gives examples of cost of high-tension current compared with gas, coal, and wood, and gives complete table of calculations for various uses of heat; explanation of table concludes that high-tension heating is quite capable of meeting competition.

INDUSTRIAL. General Application Data on Industrial Electric Heating. Nat. Elec. Light Assn., Serial Report of Power Committee, Nos. 25-54, Aug. 1925, 4 pp. Points out some of the steps in development of industrial electric heating, reasons for this work and what general plan of future development appears to be, dealing with resistance -type heating medium almost entirely.

HEATING, GAS

COSTS. Method of Comparing Cost of Central Heating by Anthracite and by Gas (Méthode de comparaison des prix de revient au chauffage central à l'anthracite et au gaze) G. Richard. Journal des Usines à Gaz. vol. 49, no. 20, Oct. 20, 1925, pp. 307-313, 7 figs. Discusses advantages of gas; develops alignment charts for graphic calculation of cost from price of fuel and its calorific value, efficiency of boilers, etc., time of operation and wages and depreciation of plant, showing superiority of gas, expecially in mild weather.

HOISTS

ELECTRIC LOCOMOTIVE. Portable Electric Locomotive Hoists. Engineering, vol. 120, no. 3124, Nov. 13, 1925, pp. 602-603, 27 figs. partly on p. 610. Details of type of power hoist made by Ransomes & Rapier, London.

HOUSES

CONCRETE-UNIT, EARTHQUAKE-RESISTANT. Earthquake-Resistant Concrete Unit Building. Concrete Products, vol. 29, no. 5, Nov. 1925, pp. 55-59, 15 figs. Describes a type of concrete unit construction which is earthquake-resistant, because of unit strength of product, extreme strength of joints in walls, method of reinforcing and lightness of structure, which has been classed by experts as being resistant to earthquakes up to ninth magnitude.

HYDRAULIC PRESSES

CONTROL VALVES FOR. Control Valves for Hydraulic Presses. Machy. (Lond.), vol. 27, no. 687, Nov. 26, 1925, pp. 273-275, 8 figs. Notes on control valves of screw-down type for operating presses from pump or accumulator.

HYRDAULIC TURBINES

DEVELOPMENTS. Progress in Design of Hydraulic Turbines Since the War (Progresos en la construccion de turbinas hidraulicas desde la guerra mundial), J. M. Voith. Energia Electrica, vol. 27, nos. 12, 13, 14, 15, 16, 17, 18, 19, and 20, June 25, July 10, 25, Aug. 10, 25, Sept. 10, 25, Oct. 10 and 25, 1925, pp. 157-162, 179-183, 192-195, 206-209, 225-228, 244-245, 258-259, 273-275, and 290-292, 44 figs. Details of turbine installations for small and medium heads built by Voith of Heidenheim; Francis turbines with vertical axis; lubrication; Kaplan turbines with vertical axis at Siebenbrunn central station; Kaplan turbines at Auerhammer central station; Amlezten Heller central station with somewhat larger head using high-speed Francis turbines coupled direct to generator; Francis turbines with horizontal axis; power plants of Froendenberg and Raanaasfoss; power plant at Mauer; Hirten Holzfeld central; Kaplan propeller turbines.

GOVERNORS. Hydraulic Turbine Governing—General Principles; S. L. Kerr. Power, vol. 62, no. 25, Dec. 22, 1925, pp. 976-979, 6 figs. Ourlines characteristics that good governor must possess, how these are incorporated in governor, and shows what takes place in various parts of hydraulic system when full load or half load is taken off the unit.

HIGH-SPEED. High-Speed Capacity and Efficiency of Modern High-Speed Turbines Schnelläugigkeit und Wirkungsgrade moderner Schnelläuferturbinen), W. Zuppinger. Schweiz, Elektrotechnischer Verein—Bul., vol. 16, no. 8, Aug. 1925, pp. 445-450, 7 figs. Discusses high-speed capacity of Francis Kaplan and other turbines, showing that, with regard to quantity of water, propeller turbines have a much lower efficiency, choke of favorable high-speed types; proposes new type of two-wheel turbine giving 85 per cent, 80 per cent, 70 per cent efficiency at full, half and quarter load.

IMPULSE. Hydraulic Impulse Turbines (Turbinas hydraulicas de Impulsão), Greenwood. Revista Brasileira de Engenharia, vol. 10, no. 4, Oct. 1925, pp. 117-131, 17 figs. Discusses developments in turbine design generally and that of impulse turbines in particular; speed regulation; vertical and horizontal arrangements, with examples.

KAPLAN. Kaplan Turbines or Propeller Turbines? (Kaplanturbin eller propellerturbin?), E. Englesson. Teknisk Tidskrift, vol. 55, no. 33, Aug. 15, 1925, pp. 67-111 (Mekanik), 23 figs. Discusses efficiency, performance and field of application of both turbines; details of tests carried out, water losses of propeller, Kaplan and Francis turbines; performances with various heads of water, safety in operation, etc.

Present state of Kaplan Turbines and Propeller Turbines (Der heutige Stand der Kaplanturbine und Propellerturbine). C. Reindl. Elektrotechnische Zeit., vol. 46, no. 42, Oct. 15, 1925, pp. 1581-1584, 9 figs. Compares efficiency and design of Kaplan propeller and Francis turbines; details of Kaplan-turbine installation at Siebenbrunn, Ulm, etc.; vertical and horizontal types; propeller turbines of Kachlet plant, etc., showing superiority of Kaplan type.

PELTON WHEELS. Design of Pelton Wheel by Means of Specific Speed, K. Minamioji and Y. Yokoyama. Soc. Mech. Engrs.—Jl., Tokyo, Japan, vol. 28, no. 100, Aug. 1925, pp. 471-488, 11 figs. Some practical notes on design of Pelton wheel by means of specific speed, ns expressing wheel ratio, number of buckets and ridge inclination as functions of ns and therefrom drawing standard jet diagram to determine chief dimensions of wheel. (In Japanese, with English abstract.)

TURGO. A New Design of Water Wheel. Elec. Rev., vol. 97, no. 2504, Nov. 20, 1925, p. 832, 4 figs. New jet arrangement for medium-capacity impulse wheel, designed by G. Gilkes & Co., and known as Turgo.

HYDRAULICS

DEVELOPMENT OF SCIENCE OF. The Development of the Science of Hydraulics, E. P. Hamilton. Boston Soc. Civil Engrs.—Jl., vol. 12, no. 8, Oct. 1925, pp. 344-354, 4 figs. Résumé of early investigations; hydraulic measuring devices; modern developments of the science.

HYDRO-CARBONS

INORGANIC ORIGIN. On the Inorganic Origin of the Hydro-Carbons, J. W. Young. Can. Inst. Min. & Metallurgy — Bul., no. 162, Oct. 1925, pp. 952-956. Author believes undue stress has been laid on conception of organic origin of hydrocarbon compounds, and not sufficient thought given to alternative hypothesis, that of their magmatic derivation; he presents notes under headings of gas, petroleum, coal, carbon, and diamond, which may help to elucidate his point of view.

HYDRO-ELECTRIC DEVELOPMENTS

CALIFORNIA. Klamath River Plant Completed by the California Oregon Power Company. Jl. Electricity, vol. 55, no. 10, Nov. 15, 1925, pp. 364-371, 7 figs. Copco No. 2 hydraulic plant is 30,000-kva. development, and has largest wood-pipe line in the country; details of dam, intake structure, tunnels, wood-stave pipe, surge chamber, penstocks, power house, generating equipment and electric arrangements.

CANADA. Some Economic Aspects of Hydro-electric Development in Canada. Contract Rec., vol. 39, no. 46, Nov. 18, 1925, pp. 1108-1110. Discussion answering questions: Has Canada unlimited water power? How soon will she require all of it? Would it be good business to allow export? Could exported power be recovered?

GOLD AND SILVER MINES, ONTARIO. Hydro-Electric Development for Gold and Silver Mines in Northern Ontario, A. R. Webster. Ont. Dept. Mines, vol. 33, part 7, 1925, pp. 99-119, 20 figs. Power development of Northern Ontario Light & Power Co.; Northern Canada Power Co.; Great Northern Power Co.; Gowganda and South Bay companies; Canadian Associated Goldfields.

NEW BRUNSWICK, CANADA. Generating Power in New Brunswick, S. R. Weston. Power House, vol. 18, no. 20, Oct. 20, 1925, pp. 70-73, 4 figs. Details of New Brunswick Elec. Power Commission's project at Grand Falls; few power developments offer an equal opportunity to industry, in so far as supply is concerned.

NORTHERN ONTARIO, CANADA. Power Development in Northern Ontario, A. R. Webster. Power House, vol. 18, no. 20, Oct. 20, 1925, pp. 73-75, 1 fig. Particulars of hydro-electric development in mining districts of northern Ontario which, with substantial increases in production looming, is of unsual interest.

NOVA SCOTIA. Generating Power in Nova Scotia in 1925, H. A. Hatfield. Power House, vol. 18, no. 20, Oct. 20, 1925, pp. 76-77, 2 figs. Despite coal miners' strike in Nova Scotia in first half of 1925, interesting work was done at several power plants in province, and developments in hydro-electric field were quite extensive.

SAGUENAY RIVER, CANADA. Saguenay River Developments from the Standpoint of Power, Pulp and Paper Electro-metallurgy, L. E. Westman. Can. Chem. & Met., vol. 245-250, 6 figs. Review of what has been done and outline of what is in promise, from industrial standpoint.

HYDRO-ELECTRIC PLANTS

BONNINGTON FALLS, CANADA. Power Plant at Lower Bonnington Falls. Elec. News, vol. 33, no. 21, Nov. 1, 1925, pp. 37-39, 9 figs. First unit of ultimate group of three, each 20,000 hp., has been placed in operation.

BRITISH COLUMBIA. Some Further Interesting Views of Stave Lake Power Plant. Elec. News, vol. 33, no. 22, Nov. 15, 1925, pp. 35-37, 7 figs. Shows phases of development work of Brit. Columbia Elec. Ry. Co.

Some Further Interesting Views of Stave Lake Power Plant. Contract Rec., vol. 39, no. 46, Nov. 18, 1925, pp. 1096-1098, 7 figs. Stave Lake total capacity now 87,500 hp.; Brit. Columbia Elec. Ry. Co. total for all plants 212,200 hp.

Stave Falls Power Development, W. G. Murrin. Power House, vol. 18, no. 20, Oct. 20, 1925, pp. 80-82 3 figs. Plant has capacity of 87,500 hp.; Stave Lake has a storage capacity of 471,000 acre feet, and plant has an annual capacity of 250,000,000 kw. hr.

ICE MANUFACTURE

ENGINE-ROOM COSTS. Engine Room Costs in Ice Making, J. H. Howell. Power House, vol. 18, no. 21, Nov. 5, 1925, pp. 20-21, 2 figs. Necessity of having accurate information on engine-room costs, in ice-making and cold-storage plants, is daily becoming more apparent; calculations on a theoretical basis being useless to operating engineer. Abstract of paper read before Pacific Coast Cold Storage Warehousemen's Assn.

INDUSTRIAL MANAGEMENT

FLOW-OF-WORK REGULATION. Effecting Economies by Regulating Work Flow, A. Whitehead. Indus. Mgmt. (Lond.), vol. 12, nos. 3 and 9, Mar. and Sept. 1925, pp. 191-192 and 441-442, 1 fig. Factors which influence economy; how economies have been effected by eliminating losses arising from a poor or irregular flow of work.

PRODUCTION CHECKING. A Policy That Catches Errors Before Production Begins, B. J. Dowd. Am. Mach., vol. 63, no. 25, Dec. 17, 1925, pp. 975-976, 3 figs. Checking, re-checking, and checking again as practised in typewriting plant has made tool and product losses occasioned by mistakes practically negligible.

PRODUCTION CONTROL. Production Control in the Newsprint Industry, Geo. D. Bearce. Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 30-Dec. 4, 1925, 18 pp., 10 figs. Outlines manufacturing processes and production methods of majority of mills in North America making "standard" newsprint paper; describes general production controls used in groundwood, sulphite and paper departments; manufacturers have adopted standard methods of calculating 3 "operating reports" and 4 "conversion cost reports" covering important operations in pulp and paper departments; former are described in detail and illustrated by forms.

SALES PROGRAM. How We Inject the Operating Point into the Sales Program, A. M. Williamson. Factory, vol. 35, no. 6, Dec. 1925, p. 899. By system in plant, in which author is superintendent, sales department is able to forecast with surprising accuracy demand for product several months in advance. (Abstract.) Paper before Production Executives Division, Am. Mgmt. Assn.

SUCCESSFUL. Successful Industrial Management, J. S. Gray. Machy. (N. Y.), vol. 32, no. 4, Dec. 1925, pp. 303-304. Lack of information as cause of much dissatisfaction; foreman's place in organization; encouraging loyalty and co-operation; all-important matter of wages; rules and regulations around factory; avoiding cost of labour turnover; importance of understudies; need of accurate records.

INSULATING MATERIALS, ELECTRIC

DIELECTRIC ABSORPTION. Dielectric Absorption in Fibrous Insulating Materials, R. E. Marbury and E. R. Le Ghait. Elec. Jl., vol. 22, no. 11, Nov. 1925, pp. 526-534, 15 figs. Describes device developed for studying absorption and discusses results obtained; device, known as dielectric lag meter, makes possible a measure of absorption where transient takes place very quickly.

INSULATING MATERIALS, HEAT

TESTING. Guaranties for Heat Insulation Material and Their Verification (Wärmeschutztechnische Garantien und ihre Nachprüfung), J. S. Camerer. Zeit. für die gesamte Kälte-Industrie, vol. 32, no. 11, Nov. 9, 1925, pp. 157-164, 9 figs. Discusses development of technical guaranties and examines methods of testing for acceptance generally used, showing that temperature drop in a hot or cold transmission line and so-called coefficient of heat saved are entirely unsuitable as criteria of quality and efficiency of material supplied; gives practical examples.

INTERNAL-COMBUSTION ENGINES

ROMEISER. The Romeiser Two-Stroke Reaction Motor and Compressor (Der Romeiser Zweitakt-Reaktionsmotor mit Kompressor), Wirtschafts-Motor, vol. 7, no. 6, June 1925, pp. 1-7, 9 figs. Details of ballistic principle and design of engine with pistons, combustion in cylinder taking place purely adiabatically, all water or air cooling being dispensed with, energy hitherto taken up by cooling water being also converted into mechanical work; fuel consumption reduced to 50 per cent.

SWEDISH. Swedish Internal-Combustion Engines (Schwedische Verbrennungskraftmaschinen), E. Hubendick. Zeit. des Vereines deutscher Ingenieure, vol. 69, no. 45, Nov. 7, 1925, pp. 1403-1408, 22 figs. Description of engines now employed in Sweden; data on dimensions, working performance and characteristics in ourboard, carburetor, hot-bulb, ignition-chamber, and Diesel engines.

See also Airplane Engines; Automatic Engines; Diesel Engines; Oil Engines.

IRON CASTINGS

CLEANING. Reducing the Cost of Cleaning Ferrous Castings, J. H. Hopp. Am. Metal Market—Monthly Rev. Section, vol. 32, no. 222, Nov. 17, 1925, pp. 14-15. Facing and molding sand character; fins; effects of gates and risers; composition of cores; cleaning-department factors; mills; sand blasting vs. milling; determining cleaning method; estimating costs, grinding; rubber bonded grinding wheels. Paper presented on behalf of Chicago Foundrymen's Club.

IRON, PIG

MERCHANT, FUTURE OF. The Future of Merchant Pig Iron, C. E. Wright. Iron Age, vol. 116, no. 25, Dec. 17, 1925, pp. 1657-1659, 3 figs. Points out that high freight rates, large imports of foreign iron and economic changes have put many furnaces on inactive list; by-product coke ovens considered as possible remedy.

IRRIGATION

CO-ORDINATION OF POWER AND. Co-Ordination of Irrigation and Power, Wm. Kelly. Am. Soc. Civ. Engrs.—Proc., vol. 51, no. 10, Dec. 1925, pp. 1946-1984, 16 figs. General presentation of factors entering into problem, illustrating difficulties, and pointing out certain solutions by describing special cases that have come before Federal Power Commission.

L

LABOUR

DAY LABOUR IN PUBLIC CONSTRUCTION. Day Labour in Public Construction, J. H. Ellison. Pub. Wks., vol. 56, no. 11, Nov. 1925, pp. 407-410. Arguments against practice from point of view of contractor, presented by an officer of Associated General Contractors of America; government should not compete with private business; day labour more expensive to taxpayers than contract work; declaration of Hennepin County Taxpayers' Assn. Paper read before Am. Soc. for Mun. Improvements.

LATHES

SINGLE-SPINDLE. Single-Spindle Automatic. Machy. (Lond.), vol. 27, no. 687, Nov. 26, 1925, p. 278, 2 figs. Machine made by firm of Boehringer, Goeppingen, Germany, has single pulley drive and self-selecting speeds.

LIGHTING

FACTORIES. Ways of Obtaining the Best Lighting, A. G. Anderson. Mgmt. & Admin., vol. 10, no. 6, Dec. 1925, pp. 345-348, 5 figs. How to plan factory illumination and upkeep of equipment.

LIQUID AIR

PLANT CALCULATION. Calculation of Air Liquefaction Plants on the Basis of New Measurements of the Thomson-Joule Effect (Ueber die Berechnung von Luftverflüssigungsanlagen auf Grund neuer Messungen des Thomson-Joule-Effektes), H. Hausen. Zeit. für die desamte Kälte-Industrie, vol. 32, nos. 7 and 8, July and Aug. 1925, pp. 93-98 and 114-122, 16 figs. Calculation of diagrams of state for up to 200 atmos. and —175 deg. cent. on known thermodynamic relations; calculation of liquefaction plants from diagrams of state liquefaction by Linde process; liquefaction by Claude and Heylandt processes; comparison of the three processes.

LIQUIDS

VISCOSITY UNDER PRESSURE. The Viscosity of Liquids under Pressure, P. W. Bridgman. Nat. Acad. Sciences—Proc., vol. 11, no. 10, Oct. 1925, pp. 603-606. Method developed by which relative viscosity of liquids may be determined over wide range of pressures at various temperatures.

LOCOMOTIVE BOILERS

LAYING OUT OF. Laying Out Locomotive Boilers, W. E. Joynes. Boiler Maker, vol. 24, nos. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12, Jan., Feb., Mar., Apr., May, June, Aug., Sept., Oct., Nov., and Dec. 1925, pp. 1-5, 40-44, 72-75, 99-102, and 108, 129-134, 166-168, and 170, 235-238, 261-267, 292-296, 324-326, and 350-351, 49 figs. Jan.: Longitudinal seams; firebox design; plates; development of one-piece crown and side sheets. Feb.: Development of backhead and roof sheet of boiler. Mar.: Method of finding outline of one-piece crown and side sheet. Apr.: Spacing of rivets; outline of one-piece roof and side sheet; locating radial stays and staybolts on roof sheet. May: Practical suggestions to follow in boiler development; triangulation development of one-piece crown and side sheets and three-piece roof and sides. June: Combustion-chamber development; radial stays and staybolts; roof-sheet development. Aug.: Flanged-sheet development; backhead and firebox back sheet; tapering flange radius. Sept.: Firebox tube, inside throat, outside throat and front tube-sheet plate developments. Oct.: Finding developed size of plain ring course, laying out dome course. Nov.: Smokebox-shell development, laying out fire-holes; method of locating flexible staybolts. Dec.: Tapering backhead and firebox back-sheet flange radii; arch tubes.

LOCOMOTIVES

COALING PLANTS. Coal and Sand Facilities Embody Novel Features. Ry. Age, vol. 79, no. 22, Nov. 28, 1925, pp. 982-983, 5 figs. Santa Fe is now using new stations of unique design at Argentine, Kan., and Shopton, Ia.

ELECTRIC. *See Electric Locomotives.*

LEHIGH-VALLEY-RAILROAD, DEVELOPMENT OF. The Motive Power of the Lehigh Valley Railroad, P. T. Warner. Baldwin Locomotives, vol. 4, no. 2, Oct. 1925, pp. 14-36, 59 figs. Development from 1896 to present time; weights and dimensions of locomotives now in service, as given in paper, conform to official records of Railroad Co.

LIMA 2-8-4. The 2-8-4 Lima Locomotive. Cent. Ry. Club of Buffalo, N.Y.—Official Proc., vol. 33, no. 4, Sept. 1925, pp. 1867-1878 and (discussion) 1879-1880, 11 figs. Practical tests prove it has 30 per cent increased operating capacity; features of construction; improved design of cylinders and high steam pressure giving great horsepower output backed up with boiler producing greater energy.

MECHANICAL FEATURES. Ideas and Suggestions for Future Locomotive Development, Wm. A. Newman. Boiler Maker, vol. 24, no. 12, Dec. 1925, pp. 337-341, 3 figs. General outline of mechanical features of proposed steam locomotive with special reference to boiler details.

STEAM-TURBINE. Steam Turbine Locomotives, C. S. Darling. Ry. Engr., vol. 46, no. 551, Dec. 1925, pp. 435-439, 1 fig. Consideration of problems involved in design of efficient steam-turbine locomotive.

WHISTLES. A Study of Locomotive Whistles, A. L. Foley. Ry. Age, vol. 79, no. 23, Dec. 5, 1925, pp. 1043-1047, 7 figs. Points out that more effective warnings can be obtained when whistle is located in front of stack.

LUBRICATING OILS

RESEARCHES. Laboratory Researches on Mineral and Lubricating Oils (Le ricerche di Laboratorio sugli olii minerali e di lubrificazione), C. A. Bertella. Ingegneria, vol. 3, no. 12, Dec. 1, 1924, and vol. 4, no. 8, Aug. 1925, pp. 408-415 and 283-291, 40 figs. Discusses tests as to acidity, viscosity, and other physical properties, calorimetry, temperature of combustion, flash-point, chemical properties; behavior of oil in contact with metal; lubricating power of oil, etc.

LUBRICATION

JOURNAL. A Graphical Study of Journal Lubrication (Part III), H. A. S. Howarth. Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 30-Dec. 4, 1925, 23 pp., 48 figs. Continuation of investigation reported to Society under same title in 1923 and 1924; friction curves are presented for central and offset bearings whose curvature radius exceeds that of journal; characteristics of fitted partial bearings are then studied, including their carrying capacities and friction.

M

MACHINE TOOLS

PUNCHING-SLOTTING MACHINES. The "Butler" Puncher Slotter. British Machine Too Eng., vol. 3, no. 34, July-Aug. 1925, pp. 290-292, 3 figs. Heavy costs of forging or stamping many large pieces used in locomotive and car building and in fact in almost every branch of engineering trade, may be now enormously reduced by use of Puncher Slotting Machines; puncher slotters will remove steel of good quality at rate of 4-5 lb. per min.; suitable for all kinds of slotting and shaping work within their capacity, and by reason of their extreme rigidity, work produced is of exceptional finish and accuracy.

RAILWAY SHOPS. Some New Machine Tools at North Road Works, Darlington, London & North Eastern Railway. Ry. Engr., vol. 46, nos. 550 and 551, Nov. and Dec. 1925, pp. 392-398 and 425-430, 20 figs. Deals with developments at Company's locomotive works at Darlington; describes vertical drilling and boring machine, slot drilling machine, machine for manufacture of staybolts, etc.

MAGNETIC FIELD

AIR-GAP. The Air-Gap Magnetic Field in Non-Salient Pole Machinery, B. Hague. World Power, vol. 4, no. 23, Nov. 1925, pp. 264-271, 10 figs. Theory of field due to currents in uniform air gap with plane iron boundaries; magnetic field due to linear currents.

MALLEABLE CASTINGS

BLACK-HEART PROCESS. Malleable Iron Castings, R. Micks. Can. Foundryman, vol. 16, no. 11, Nov. 1925, pp. 11-13. Points out that of the two processes of manufacturing malleable iron castings, black heart, or American process, produces better malleable iron in shorter time and with less expense.

MASONRY

CALCULATION. Calculation of Solid Masonry (Calculo de massicos de alvenaria), O. Nunes. Revista Brasileira de Engenharia, vol. 10, no. 3, Sept. 1925, pp. 77-81, 6 figs. Develops a simple formula for determining dimensions of base of trapezoidal masonry, conveniently applicable to other profiles; calculation of joints, etc., and examples.

MATERIALS HANDLING

ACCIDENT PREVENTION. Safety in Materials Handling, D. S. Beyer. Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 30-Dec. 4, 1925, 30 pp., 15 figs.; also (abstract) in Am. Mach., vol. 63, no. 23, Dec. 3, 1925, pp. 890-891. After demonstrating seriousness of materials-handling accident hazard, author computes yearly economics loss to be $250,000,000; analyses such accident hazards in general broad classifications and points out few methods of prevention; calls attention to necessity for including in construction drawings and specifications means for prevention of such accidents.

HIDDEN COSTS. The Hidden Costs in Handling Bulk Materials. Factory, vol. 35, no. 6, Dec. 1925, pp. 896-899, 966, 968. and 970, 972, 974, 976 and 978, 6 figs. Contains following contributions: Handling Coal and Ashes Is a Simple Matter Now, C. H. Kirkpatrick; Conveyors Pave the Way to Lower Handling Costs, E. T. Cristiani; A Monorail Conveyor Cut Our Handling Costs 29%, H. H. MaComber; $7,805.47 Saved Annually by Improved Handling Methods, F. A. Ory.

MEASURING INSTRUMENTS

HIGH SPEED BY SOUND VIBRATION. Measuring High Speed by Sound Vibration, C. R. Alden. Machy. (N. Y.), vol. 32, no. 4, Dec. 1925, pp. 286-288, 3 figs. Device invented by author is arranged so that pitch of sound emitted by high-speed spindle is compared with sound or note emitted by speed-measuring device; latter is so calibrated that it indicates directly revolutions per minute corresponding to given note in musical scale, which, in turn, is equivalent to certain of vibrations per second.

STRESS RECORDERS. Fereday-Palmer Stress Recorder, F. Johnstone Taylor. Can. Engr., vol. 49, no. 20, Nov. 17, 1925, pp. 557-558, 2 figs. Notes on an instrument designed for measuring stresses on bridges; employes a beam of light.

METALS

CORROSION. Wear and Corrosion in Metal Work (L'usure et la corrosion dans les ouvrages métalliques), J. Jacquart. Annales des Ponts et Chaussées, vol. 95, no. 4, July-Aug. 1925, pp. 5-66, 13 figs. Theory of corrosion, sublimation and dissolution of metal; chemical action, precipitation of ions, galvanic action, electrolytic action, theory of stray currents; wear of ferrous metals, oxidation and rust formation, errosion; non-ferrous metals, protection of metals, coatings, etc.

FATIGUE OF. High-Frequency Fatigue Tests, C. F. Jenkin. Roy. Soc.—Proc., vol. 109, no. A749, Sept. 1, 1925, pp. 119-143, 8 figs. Experiments on high-frequency fatigue in copper, Armco iron, and mild steel carried out in Engineering Laboratory, Oxford, for Fatigue Panel of Aeronautical Research Committee; results show that mechanism of fatigue requires time.

MILLING CUTTERS

SIZES OF STANDARD. Sizes of Standard Milling Cutters (Simplified Practice). Am. Mach., vol. 63, no. 23, Dec. 3, 1925, p. 907. Reference book sheet.

STANDARDIZATION. Standardizing Milling Cutters, T. R. Jones. Am. Mach., vol. 63, no. 23, Dec. 3, 1925, p. 916, 1 fig. Revised design of shell-end mills; suggests that still further simplification of end mills can be had by adopting uniform design.

MILLING MACHINES

DIVIDING HEADS. Dividing Head Designed for Heavy Work, O. S. Marshall. Machy. (N. Y.), vol. 32, no. 4, Dec. 1925, pp. 305-306, 3 figs. New type of dividing head designed to cover wider range of precision indexing and to handle heavier work than ordinary type.

MINERALS

HARDNESS, QUANTITATIVE STANDARDS FOR. Quantitative Standards for Hardness of the Ore Minerals, S. B. Talmage. Economic Geology, vol. 20, no. 6, Sept.-Oct. 1925, pp. 531-553, 4 figs. Variation in results obtained by different workers, of tests on minerals adopted as standard for Mohs scale; instruments for quantitative measurements; new scale of hardness; quantitative data; etc.

MINES

ONTARIO. The Creighton Mine, W. E. Bawden. Can. Inst. Min. & Metallurgy—Bul., no. 163, Nov. 1925, pp. 1054-1068, 10 figs. Mine is situated 12 mi. west of Sudbury, Ont., on Algoma Eastern railway, and is owned and operated by Int. Nickel Co.; ore is smelted at Copper Cliff, and matte is refined at Port Colborne, Ont., on Lake Erie; mining methods; pillar development and recovery; chute drawing and tramming; elimination of sub-levels.

MINING INDUSTRY

MANITOBA. Recent Mining Developments in the Central Manitoba Mining District, H. A. Wentworth. Can. Inst. Min. & Metallurgy—Bul., no. 162, Oct. 1925, pp. 941-951, 3 figs. District embraces two known mineralized belts: gold area in north, a zone 8 or 10 mi. wide and about 40 mi. long; and Bird River copper and copper-nickel deposits.

MOULD

CONCRETE-UNIT, FIRE TESTS OF. Building Inspector Conducts Fire Test on Concrete Unit House, L. F. Morgan. Concrete Products, vol. 29, no. 5, Nov. 1925, pp. 41-45, 5 figs. Particulars of fire test made on concrete units as result of inquiries on part of members of Connecticut Valley Concrete Products Assn. as to what way they collectively could at one time get their products before eyes of public, architects, builders, engineers and prospective home builders; building was erected, filled up with combustible material, fire set to it and then hose turned on it; results obtained.

MOULDING METHODS

CAST-IRON PISTONS. Pistons for Internal Combustion Engines, A. J. Richman and J. L. Francis. Metal Industry (Lond.), vol. 27, nos. 17, 19, and 21, Oct. 23, Nov. 6 and 20, 1925, pp. 389-390, 437-438 and 489-491, 16 figs. Authors describes what they have found to be best moulding and metallurgical practice in production of cast-iron pistons of various types; moulding and allied processes for pistons of small gasoline and paraffin engines are first considered; followed by discussion of larger-type pistons and also chief metallurgical problems involved.

DRY-SAND. Dry-Sand Moulding, C. H. Brown. Foundry Trade Jl., vol. 32, no. 482, Nov. 12, 1925, pp. 415-416 (including discussion). Milling of sand; ramming a dry-sand mould; venting; effects of bat gating; loam cores.

MOULDS

PERMANENT. Production of Castings in Permanent Moulds. Brit. Cast Iron Research Assn.—Bul., no. 10, Oct. 1925, pp. 9-10. Bibliography covering more important papers and patent specifications since 1911 dealing with production of castings in permanent moulds.

MOTOR BUSES

DEVELOPMENT. Motor Bus Developments. Motor Transport (Lond.), vol. 41, no. 1081, Nov. 16, 1925, pp. 665-666. A survey of conditions responsible for production of present-day light, high-speed public service vehicles. Résumé of paper read by L. G. Wyndham Shire at C.M.U.A. Road Traffic Conference, Nov. 5, 1925.

ENGINES. The Prospects of the Six-cylinder Engine, E. Reeve. Motor Transport (Lond.), vol. 41, no. 1083, Nov. 30, 1925, pp. 711-713, 7 figs. Advantages of 6-cylinders for commercial vehicles, particularly for passenger carrying.

N

NICKEL STEEL

IMPACT VALUES. Impact Values of a Nickel Steel, F. T. Sisco. Iron Age, vol. 116, no. 23, Dec. 3, 1925, pp. 1513-1514, 2 figs. Effect of quenching and drawing temperatures on Izod results. Published by permission of Chief of Air Service, U. S. War Dept.

MACHINERY. Nickel Steels in Machinery, J. W. Urquhart. Mech. World, vol. 78, no. 2028, Nov. 13, 1925, pp. 383-384. Machining qualities of nickel steel; case-carburizing qualities; primal cause of nickel-steel strength; finer "grain" in nickel steels; outstanding advantage; simplified heat treatment.

O

OIL

ENGINEERING DEVELOPMENTS. Progress in Petroleum Engineering. Mech. Eng., vol. 47, no. 12, Dec. 1925, pp. 1126-1132. Report contributed by Petroleum Division of Am. Soc. Mech. Engrs. Need for co-operative research; trends in production of petroleum; leading problems of storage; transportation; marine transportation; refining and manufacturing; materials of construction; lubricating oils; physical properties of petroleum and its products; testing of petroleum products; research work in progress; economics; opportunities for engineers in petroleum industry. Bibliography.

OIL ENGINES

INDUSTRIAL PLANTS. Some Uses for Oil Engines. Power, vol. 62, no. 22, Dec. 1, 1925, pp. 840-841, 5 figs. Suitability of oil engines for oil plants needing process hot water; comparative operating expenses and first cost of Diesels and steam engines.

PLENTY-STILL. The Plenty-Still Oil Engine. Mar. Eng. & Motorship Bldr., vol. 48, no. 578, Nov. 1925, p. 397, 1 fig. Preliminary particulars of latest adaptation of Still principle in engine undergoing tests at Newbury; single-cylinder heavy-oil engine intended to be applied to trawlers.

OIL FUEL

CENTRIFUGES FOR PURIFYING. Centrifuges for Diesel Fuel (Zur Reinigung der schweren Brennöle durch Zentrifugen), H. Wittmaack. Wirtschaftsmotor, vol. 7, no. 8, Aug. 1925, pp. 11-13. It has been found that Diesel fuel oils of 24 to 36 deg. B. gravity can be used without disadvantage in Diesel engine after ordinary filtration; impurities can be centrifuged out especially if fuel oil is heated; centrifuges involving gas-proof containers have been developed and heavier fuels should be treated in these.

ECONOMICAL APPLICATION. Research in Liquid Fuel Economy, M. Sklovsky. Am. Iron & Steel Inst.—advance paper, for mtg. Oct. 23, 1925, 19 pp., 11 figs.; also (abstract) in Fuels & Furnaces, vol. 3, no. 11, Nov. 1925, pp. 1247-1252, 4 figs. Discussion is limited to application of liquid fuel to metallurgical operations in industrial production furnaces; points out that three distinct directions of effort may be applied for obtaining better fuel economy: (1) by proper combustion efforts; (2) by better furnace adaptation and construction; (3) by better attention to furnace.

OIL SHALES

TESTING. The Development of a Standard Canadian Laboratory Distillation Method for Examination of Oil Shale, R. E. Gilmore and A. A. Swinnerton. Can. Chem. & Metallurgy, vol. 9, nos. 10 and 11, Oct. and Nov. 1925, pp. 215-217 and 235-239, 2 figs. Reviews comparative results of distilling a standard oil shale by different methods, and discusses factors to be considered in selection of a simple and reliable laboratory, which authors hope may be adopted as a Canadian standard laboratory distillation method. Paper read at Dominion Convention of Chemists, Guelph, Ont., June 4, 1925.

OIL TANKS

STEEL, STANDARDIZATION. Report of Special Committee on Standardization of Steel Storage and Production Tanks as Applied to the Production of Oil. Am. Petroleum Inst.—Bul., vol. 6, no. 51, Sept. 4, 1925, pp. 101-104. Recommendations from manufacturers of small bolted and riveted tanks; recommendations for storage tanks of capacity of 30,000 bbl. or greater; recommendations for field tanks.

OIL WELLS

PUMPING EQUIPMENT. Special Committee on Standardization of Pumping Equipment and Engines as Applied to the Production of Oil—Report of Status of Work. Am. Petroleum Inst.—Bul., vol. 6, no. 51, Sept. 4, 1925, pp. 92-98. Digest of discussion on tubing; letter of transmittal on tubing recommendations sent to Pipe Manufacturers' Subcommittee; etc.

VERTICALITY, CHECKING OF. Method of Checking Verticality of Wells, V. Svimonoff. Petroleum Wld., vol. 22, no. 300, Sept. 1925, pp. 382-383, 3 figs. Recent research disclose that in case of even shallow wells vertical direction of a well is purely a product of imagination and that hole of a well follows every conceivable form of deviation from vertical; deep drilling; start is important; disadvantages of crooked wells.

OSCILLOGRAPHS

CATHODE-RAY. The Use of the Cathode-Ray Tube as a Wattmeter and Phase-Difference Measurer for High-Frequency Electric Currents, J. A. Fleming. Instn. Elec. Engrs.—Jl., vol. 63, no. 347, Nov. 1925, pp. 1045-1046, 1 fig. Account of manner in which cathode-ray tube can be employed to measure high-frequency power, that is, as wattmeter, by delineation and measurement of ellipse formed on phosphorescent screen by cathode-ray spot, which is oscillated in two directions at right angles by current and voltage of circuit under test.

ELECTROMECHANICAL SYSTEMS, FOR SOLVING. Oscillographic Solution of Electromechanical Systems, C. A. Nickle. Am. Inst. Elec. Engrs.—Jl., vol. 44, no. 12, Dec. 1925, pp. 1277-1288, 16 figs. Simple and practical method has been developed for investigating certain important classes of dynamic systems, as represented by power system comprising synchronous or induction generating units, with prime movers, connected through transmission lines to receiving apparatus of same character; behavior of individual units can also be investigated; describes method and its application to few of possible cases; method is to have "equivalent electrical circuit" solve problem, and oscillograph plot solution. See also (discussion) pp. 1341-1342.

OXY-ACETYLENE CUTTING

METALS. Advancement in the Gas Cutting of Metals, A. S. Kinsey. Am. Welding Soc.—Jl., vol. 4, no. 9, Sept. 1925, pp. 20-22. Tests show that there is saving of from 10 to 20 per cent in oxygen consumption, and equivalent saving in time when purity of oxygen is increased from 99 to 99.5 per cent.

STEEL FOUNDRY. Steel Industry Uses Acetylene Gas to Advantage. Iron Trade Rev., vol. 77, no. 22, Nov. 26, 1925, pp. 1345-1346. Review of paper read before Int. Acetylene Assn., by R. W. Thomas, on influence of oxy-acetylene cutting on steel-foundry practice.

OXY-ACETYLENE WELDING

BRONZE WELDING OF LOCOMOTIVE CYLINDERS. Bronze Welding of Locomotive Cylinders. Acetylene Jl., vol. 27, no. 4, Oct. 1925, pp. 174-176, 7 figs. Describes operation in welding broken parts of locomotive after collision; advantages of bronze welding over welding with cast iron or steel rods.

P

PATTERNS

ALUMINUM-PAINTED. Protecting Patterns with Paints. J. D. Edwards and R. I. Wray. Iron Age. vol. 116, no. 24, Dec. 10, 1925, p. 1568. Advantages of aluminum paint recently developed by Aluminum Co. of Am.; various mixtures compared; savings claimed by their use; appreciable advantages in ease, with which patterns may be withdrawn from mold.

PILES

CONCRETE. Determining Factors in Selection of Piling for Waterfront Structures, G. F. Nicholson. World Ports, vol. 13, no. 11, Sept. 1925, pp. 34-46 and (discussion) 46-47, 5 figs. General causes of failure of concrete in sea water; outline of methods used in conducting piling tests, Los Angeles harbour; etc.
Concrete Jacketed Piles, F. G. White. World Ports, vol. 13, no. 11 Sept. 1925, pp. 89-98 and (discussion) 98-102, Discusses the various types of jacketed piles which have been used most extensively and presents some evidence as to relative merits of the different types.

PHOTOMETERS

UNIVERSAL PORTABLE. A New Form of Universal Portable Photometer, A. Blondel. Illuminating Engr., vol. 18, Sept. 1925, pp. 237-238, 4 figs. Particulars of new photometer based on a modification of method of Lord Rayleigh; has wide range of application, especially in connection with scientific research.

PIPE

BENDS. Notes on the Expansion of Pipe Bends, Wm. Chas. Rowe, Commonwealth Engr., vol. 12, no. 22, July 1, 1925, pp. 449-450, 4 figs. Gives results of tests of bent and straight pipes, according to Kent, no thorough attempt has been made to determine maximum amount of expansion which a U-loop or quarter bend would take up in a straight run of pipe, having both ends anchored, graphs of tests given; states that it is desirable to make bend pipes of as reasonably large radius as is practicable and not to depend upon length of straight pipe, which transfers an enormous load to flanges. Paper read before Victorian Inst. of Engrs.

PLATES

STRESSES AROUND RECTANGULAR OPENINGS. The Effect of the Radius of the Fillets on the Stresses Around Rectangular Openings in Plates, T. H. Frost, P. E. Pihi and O. D. Colvin. Soc. Nav. Architects & Mar. Engrs.—advance paper, no. 2, for. mfg. Nov. 12-13, 1925, 4 pp., 6 supp. plates. Outline of investigation, objects of which was to experimentally determine relation which exists (1) between stresses at various points on corners of square openings in flat plate and ratio of width of plate to width of opening, and (2) between stresses at these points and radius of curvature of fillet at corners. See (abstract) in Mar. Eng. & Shipp. Age, vol. 30, no. 12, Dec. 1925, pp. 690-691, 1 fig.

POLES, WOODEN

PRESERVATION. Methods of Preserving Poles and Economies of Pole Treatment, L. R. Gamble, Jl. Electricity, vol. 55, no. 9, Nov. 1, 1925, pp. 325-329, 5 figs. Describes methods and their application; economies of pole treatment. (Extracts). Paper read before Northwest Elec. Light & Power Assn.

POWER

INDUSTRIAL LOCATION, EFFECT ON. Power—and the Industrial Map. J. A. Piquet. Indus. Mgnt. (N.Y.), vol. 70, no. 6, Dec. 1925, pp. 355-361, 7 figs. How power development is changing, not only industrial location, but whole structure of industrial production.
WASTE ELIMINATION IN GENERATION AND TRANSMISSION. Spotting and Stopping the Wastes in Power Generation. Transmission and Application. Indus. Mgmt. (N.Y.) Supp. Plate, vol. 70, no. 6, Dec. 1925. Chart as noted by F. Juraschek and visualized by F. H. Peard.

POWER FACTOR

CORRECTION, COAL MINES. Good Power Factor Conditions Always Serve to Lower Capital Charges and Energy Costs, E. J. Gealy, Coal Age, vol. 28, no. 21, Dec. 10, 1925, pp. 801-806, 11 figs. Careful selection of apparatus is most necessary; corrective equipment now available permits power devices to carry larger loads and reduces bills; applications of synchronous and static condensers.

POWER TRANSMISSION

LUBRICATION IN. Reducing the Friction Tax on Power Transmission, A. F. Brewer, Indus. Mgmt. (N.Y.) vol. 70, no. 6, Dec. 1925, pp. 350-375, 11 figs. Modern lubrication and cost of power.
MECHANICAL CONTROL OF. The Control of Mechanical Power Transmission, Wm. Staniar, Indus. Mgmt. (N.Y.) vol. 70, nos, 3, 4, 5 and 6, Sept., Oct., Nov. and Dec. 1925, pp. 135-140, 7 figs.; 218-222, 5 figs.; 272-276, 4 figs.; 338-343, 9 figs. Discusses means of increasing profits through proper belting and transmission installation and control. Sept. Average methods which involve tremendous waste. Oct.: Direct influence of correct belting on profits. Nov.: Belting standardization. Dec.: Transmission applications.
ROPE DRIVE. Rope Drives. P. W. Pell. Colliery Eng. vol. 2, no. 21, Nov. 1925, pp. 519-520, 2 figs. Merits and weaknesses relative; merits of manilla and cotton; factors influencing efficiency and long life; systems compared, over-roping.

PULLEYS

BELT. Tests on Air Friction on Belt Pulleys (Versuche über die Luftreibung un Riemenscheiben. H. Cranz. Maschinenbau, vol. 4, no. 19, Sept. 17, 1925, pp. 927-931, 6 figs. Describes method followed in experiments; concludes that at usual velocities of about 25 m. per sec. losses due to air friction are exceedingly small but with further increase of velocity they increase rapidly.

PULVERIZED COAL

BOILER FIRING. Pulverized Fuel for Boilers and Furnaces, W. R. Chapman. Fuel vol. 4. nos. 8. 9, 10 and 11, Aug., Sept., Oct. and Nov. 1925, pp. 340-343, 396-400, 420-424 and 486-492. Aug.: Drying coal; pulverization; transport of powdered fuel; feeders, mixers and burners; combustion chamber. Sept.: Combustion-chamber lining; disposal of ash; suitability of fuels. Oct.: Efficiency comparison with other methods of firing. Nov.: Includes summary of principal points in these articles.
CONVEYING. Coal Dust Conveying (Kohlenstaub-förderung), Walther, Braunkohle, vol. 24, no. 20, Sept. 26, 1925, pp. 599-601. Deals with mixing dust with air or gas (1/49 to 1/25), for better conveying, and using compressed air for conveying from railway cars and bunkers.
PLANTS. Powdered Coal Installation at The Baldwin Locomotive Works, C. C. Bailey, Baldwin Locomotives, vol. 4, No. 2, Oct. 1925, pp. 37-46, 13 figs. Description of installation which comprises a main station with seven auxiliary or substations handling full requirements of 160 furnaces, 4 Babcock & Wilcox boilers of 600 hp. each, and 3 pile heating furnaces; main station; wherein is housed equipment necessary for crushing, drying, pulverizing and ejecting coal to substations, has maximum capacity of 10 tons per hour.

PUMPING STATIONS

DIESEL. Diesel Pumping Station. Portage, Wis. Power, vol. 62, no. 24, Dec. 15, 1925, pp. 924-926, 5 figs. Oil-engine plant shows estimated annual saving of $3362 over purchased electric power at prevailing rates and gasoline engine standby; when earnings have paid for plant, annual saving will exceed $7000.

PUMPS

GASOLINE. The Shell Kerbside Petrol Pump. Engineering, vol. 120, no. 3128, Dec. 11, 1925, pp. 752-754, 3 figs. Describes improved design of pump constructed to design of Shell-Mex. Ltd. in this type required quantity of fuel is delivered from actual measuring vessel, which is in full view of customer.
TROUBLES AND THEIR DETECTION. What to do when the pump Stops. Wm. S. Jones. Power, vol. 62, no. 25, Dec. 22, 1925, pp. 966-968, 3 figs. Common causes of failure of direct-acting pumps; how to put pump back into service.
TURBO, DEVELOPMENT OF. Development of the Steam Turbo-pump as a Water Works Machine (Die Entwicklung der Dampfturbopumpe als Wasserwerksmaschine), B. Rosenfeld, Gas- u. Wasserfach, vol. 68, no. 41, Oct. 10, 1925, pp. 639-644, 9 figs. Discusses its development from coaling water pump of steam turbine plants and describes the various stages of this development.

PUMPS, CENTRIFUGAL

BOILER FEED PLANT. Centrifugal Pumps as Feed Apparatus for High-Pressure Boiler Plants, G. Weyland, Eng. Progress, vol. 6, no. 11, Nov. 1925, pp. 353-354, 4 figs. Discusses use of centrifugal pumps as feed pump for high-pressure plants.
GLAND SEALS FOR. Improvement in Gland Seals for Centrifugal Pumps, J. C. Hobbs. Power, vol. 62, no. 24, Dec. 15, 1925. pp. 935-936, 3 figs. Notes on operating characteristics and proper way to seal shaft bearings from leakage.

R

RADIO COMMUNICATION

RAILWAYS. How the Railroads can use Radio, G. Y. Allen. Can. Ry. Club. Official Proc., vol. 24, No. 6, Sept. 1925, pp. 22-39 and (discussion) 39-43, 12 figs. Most obvious application of space radio communication is to supplement present wire communicating systems in case of emergencies; describes types of telegraph transmitters and receiving equipment; carrier-current communicating system.

RAILWAY CONSTRUCTION

WINTER WORK. Is Winter Work Profitable ? A. M. Bouillon. Ry. Age, vol. 79, no. 23, Dec. 5, 1925, pp. 1033-1036, 5 figs. Answer to question based on extended experience with construction at low temperatures.

RAILWAY ELECTRIFICATION

FRANCE. Main Line Railway Electrification, P. Dawson and S. Parker Smith. Engineer, vol. 140, nos. 3640 and 3643, Oct. 2 and 23, 1925, pp. 341-344 and 423-426, 11 figs. Electrification in France. Oct. 2. Historical: reasons for electrification; choice of system; Paris-Orleans railway. Oct. 9: Paris-Lyons-Mediterranean Ry.; electrification on lines in neighborhood of Nice; results of electrification.
SOUTHERN RAILWAY, ENGLAND. The World's Greatest Suburban Electrification. Ry. Engr. vol. 46, nos. 550 and 551, Nov. and Dec. 1925, pp. 383-391 and 398 and 413-424, 35 figs. Technical details of Southern Ry.'s electrified service.

RAILWAY MANAGEMENT

SIMPLIFICATION OF OPERATION. A Plan to Simplify Railroading, T. C. Powell. Ry. Rev. vol. 77, no. 21, Nov. 21, 1925, pp. 768-770. Pooling of trains, unification of terminals, extensive use of automotive facilities suggested. (Abstract). Address delivered before West. Ry. Club.

RAILWAY MOTOR CARS

DIESEL-ELECTRIC. Diesel Electric Cars, Canadian National Railway. Can. Ry. & Mar. Wld., no. 332, Oct. 1925, pp. 501-503, 5 figs. Particulars of articulated oil-electric cars, equipped with Diesel engines, and 60-ft. oil-electric cars also equipped with Diesel engines, being built at Montreal Shops of Can. Nat. Ry.
GASOLINE. Self-Propelled Cars on Steam Railways. Ca. Ry. & Mar. Wld., no. 330, Aug. 1925, p. 368, 1 fig. Describes new Brill model gasoline cars of Can. Nat. Ry.; overall length 43 ft. 5 5/16-in., length over end sills 42 ft. 7 5/16-in., width over side sills 8½ ft., extreme height 10 ft. 5 1/16-in., gasoline engine is of 4- cylinder 4-cycle type with 4¼-in. bore by 6-in. stroke with a 3-in. crankshaft carrier on 3 main bearings.

RAILWAY REPAIR SHOPS

COSTS AND OUTPUT. Shop and Output. J. W. Kennedy. Can. Ry. Club—Official Proc., vol. 24, no. 8, Nov. 1925, pp. 20-34 and (discussion) 34-41, 7 figs. Describes contract wage system employed at Can. Pac. Angus Shops, Montreal, with guaranteed hourly rate; method employed to control and record locomotive and repair costs and output.

RAILWAY SIGNALLING

APPROACH LIGHTING. Track circuits and Approach Lighting of Signals (Circuiti di binario e illuminazione d' approccio del segnali), S. Dorati. Rivista Technica delle Ferrovie Italiane, vol. 28, no. 3, Sept. 15, 1925, pp. 88-95, 13 figs. Details of system in which signals are only lighted on approach of train, either by electromechanical devices actuated by train, or by a track circuit, and its application at Sette Bagni Station, where it has been in operation since July 1924.
TRACK CIRCUITING. Direct-Current Transient Track-Circuits for Special Locations. Ry. Engr., vol. 46, no. 551, Dec. 1925, p. 431, 1 fig. Instructive particulars of experimental track circuit installed on Lond. & North Eastern Ry.

RAILWAY TRACK

WELDING. Report of Committee on Way Matters, Elec. Traction, vol. 21, no. 10, Oct. 1925, pp. 529-533, 4 figs. Standardization of frogs, tongue switches and hard center for special track work; welded rail joints; surface hardening of rails at mill and on street; "Bary" process; arc-welding processes for repairs, to rails and manganese steel; rail-joint welding; welding cupped rail end; welding manganese steel; recommendations; design of substitute ties; reduction of noise in car operation. Committee report to Am. Elec. Ry. Assn.

RAILWAYS

ECONOMICAL FORCE, AS. The Railway as an Economic Force, R. S. Binkerd. Mech. Eng., vol. 47, no. 12, Dec. 1925, pp. 1101-1102. Discusses important place of railroads in structure of modern economic society.

REDUCTION GEARS

INVOLUTE TEETH AND. Reduction Gearing and Involute Teeth, M. Delaporte. Shipbldg. & Shipg. Rec., vol. 26, no. 23, Dec. 3, 1925, pp. 594-595 and 598, 8 figs. Remarks based on earlier paper by author in which conclusions was reached that conservation in service of teeth profile demands that they should be devoid of flexibility and compressibility as far as possible. Translated from paper read before Assn. Technique Maritime & Aeronautique.

REFRIGERANTS

CRITICAL CONSTANTS. Problem of the Intermediate Fluid to Refrigerating Machines (Il problema del fluido intermediario bnelle macchine frigorifere), E. Foa. Industria, vol. 39, no. 20, Oct. 31, 1925, pp. 532-537, 3 figs. Discusses method of studying influence of choice of intermediary liquid on work and volume of liquid; application to sulphur anhydride, carbon anhydride and ammonia.

REFRIGERATING MACHINES

ABSORPTION. Absorption Refrigerator, Elec. World, vol. 86, no. 23, Dec. 5, 1925, p. 1161, 2 figs. Domestic electric refrigerator operates on continuous-absorption principle; no moving parts required; total pressure in system always same.

COMPRESSORS. High Revolution Compressors for Marine Refrigeration, E. Markham. Refrig. Eng. vol. 12, no. 4, Oct. 1925, pp. 111-116. Essentials of good refrigeration compressor; reasons for making machine vertical in preference to horizontal; reliability; efficiency, safety in operation and low initial cost; silence in operation and easy overhaul.

REFRIGERATING PLANTS

CORROSION IN. Corrosion in the Refrigerating Industry. W. G. Whitman, E. L. Chappell and J. K. Roberts. Refrig. Eng., vol. 12, no. 5, Nov. 1925, pp. 158-165, 11 figs. Survey of previous work; laboratory study of important factors, and of various methods for corrosion prevention. Condensation of report submitted to Committee on Corrosion of Am. Soc. Refrig. Engrs.

REFRIGERATION

COOLING APPARATUS. The Production of Low Temperatures, B. Von Platen and C. G. Munters. Refrig. Eng. vol. 12, no. 5, Nov. 1925, pp. 143-148, 9 figs. Describes principles for two kinds of refrigerating apparatus, one being especially suitable as to efficiency for relatively greater difference in temperature of condenser and cooler and other for relatively smaller difference. Translated from Teknish Tidskrift, Mar. 21, 1925, pp. 80-95, 11 figs.

RESERVOIRS

CONCRETE. A New Concrete Reservoir with Unusual Features. Waldo E. Smith. Fire & Water Eng., vol. 78, no. 23, Dec. 2, 1925, pp. 1233-1234, 1 fig. Reservoir is of ring-tension type; floor slab constructed monolythically with column footings; concrete poured continuously; method of construction.

RETAINING WALLS

CALCULATION. Calculation of inclined retaining walls. (Die Berechnung der Winkelstützmauern), E. Mörsch. Beton u Eisen, vol. 24, no. 20, Oct, 20, 1925, pp. 327-339, 42 figs. Results of tests carried out at institute for testing materials of Stuttgart technical highschool; treating in detail pressure conditions on inclined wall; showing that same component is reached whether starting with vertical or with inclined plane, provided angle of earth pressure and normal is properly chosen.

RETAINING WALLS

CONCRETE. River Walls of the Miami Conservancy District. Eng. & Contracting (General Contracting), vol. 64, no. 6, Nov. 18, 1925, pp. 1113-1118, 5 figs. Methods and costs of constructing gravity and semi-reinforced concrete retaining walls.

RIVERS

DEPTH AND CURVATURE OF CHANNELS. Relation of Depth to Curvature of Channels, E. C. Ripley. Am. Soc. Civ. Engrs.—Proc., vol. 51, no. 10, Dec. 1925, pp. 1907-1938, 10 figs. Results of writer's investigations into law of river hydraulics; two empiric formulae have been devised by means of which cross-profile of channel may be computed; some characteristics of law were also disclosed, which are believed to be most important discoveries in that law in more than 50 years; practical applications of these formulae are given which furnish solution to problems that heretofore have been considered not susceptible of solution.

RIVETS

HIGH TEMPERATURE, EFFECTS OF. High Temperatures Hurt Rivets. A. L. Spencer, Jr. Iron Age, vol. 116, no. 23, Dec. 3, 1925, pp. 1521-1522, 1 fig. Tests show that heating above 1950 deg. fahr. produces structure which will not withstand rapid alternate compression and tension. (Abstract). Paper read before Am. Inst. Steel Constr. See also Iron Trade Rev. vol. 77, no. 22, Nov. 26, 1925, pp. 1341-1344, 2 figs.

ROAD CONSTRUCTION

EFFICIENCY. Efficiency in Construction Operations, T. J. Wasser. Eng. & Contracting (Roads & Streets), vol. 64, no. 5, Nov. 4, 1925, pp. 1017-1021. Factors that effect efficiency of contractors organization and influence of specification interpretation on unit cost of highway construction. Paper presented at Assn. Highway Officials of North Atlantic States convention.

ROADS

EFFECT OF SIX-WHEEL TRUCKS ON. Effect of Six-Wheel Trucks on Pavements. Pub. Wks., vol. 56, no. 11, Nov. 1925, pp. 400-403, 6 figs. Tensile stress about half as great as that produced by a four-wheel truck of same gross load, practically independent of axle spacing; maximum stress occurs in bottom of slab and along edge of slab; and fiber deformation is twice as great when outer wheel is 9 in. from edge as when 21 in.

RESURFACING. Resurfacing Work Improved by Heating the Base, G. H. Lutz. Can. Engr., vol. 49, no. 20, Nov. 17, 1925, pp. 559-560, 1 fig. Not necessary to rely solely on weight of top for stability of bituminous paving surfaces; thin wearing costs can be applied to old pavements; concrete base coated and allowed to cool before applying surface.

TRAFFIC CONTROL, MECHANICAL DEVICES FOR. Traffic Control by Mechanical Devices, A. H. Blanchard, Eng. & Contracting (Roads & Streets), vol. 64, no. 5, Nov. 4, 1925, pp. 995-1000. Safety devices and regulations at railroad grade crossings for promotion of highway safety.

ROADS, ASPHALT

FOUNDATIONS. Various Foundations for Asphalt Pavements, G. C. Warren, Can. Engr., vol. 49, no. 20, Nov. 17, 1925, pp. 551-554. Black base, portland cement concrete, Macadam and other types as viewed by bituminous paving contractor; drainage, subsoil, location and other factors. Paper read at Detroit before Asphalt Paving Conference.

ROADS, CONCRETE

ASPHALTIC CONCRETE. Perth Streets Modernised with Asphaltic Concrete, R. W. Parkhurst. Commonwealth Engr., vol. 13, no. 2, Sept. 1, 1925, pp. 73-76, 3 figs. Factors influencing selection of asphalt details of construction of the different roads; comparaison of traffic records; foundations and metal available; classification of asphalt surfaces; advantages of proper asphaltic concrete; details of foundation construction; asphaltic mixture employed.

DESIGN. The Design of Cement Concrete Pavements, A. T. Goldbeck. Concrete, vol. 27, no. 4, Oct. 1925, pp. 19-21, 3 figs. Forces to be resisted by a concrete pavement.

S

SAND

FILTER. A Fineness Modulus for Filter Sands, R. G. Tyler, New England Water Wks. Assn.—Jl., vol. 39, no. 3, Sept. 1925, pp. 239-248 and (discussion) 248-253, 5 figs. Particulars of investigation undertaken to find, if possible, a more definite and a more accurate method of designing size of filter sands, since method of Hazen's at present in use seems in need of modification. References.

SAND, MOULDING

STEEL CASTINGS. Steel Moulding Sands and Their Behaviour Under High Temperature, A. L. Curtis, Iron & Steel Inst.—Carnegie Scholarship Memoirs, 1925, 89 pp., 67 figs., partly on supp. plates and folders. Deals with natural argillacerous sands, and artificial "steel facing sands" or proprietary mixtures; method adopted and apparatus used for testing steel molding sands under high temperatures; permeabilities of steel molding sands; photomicographs. See also (abstract) in Foundry Trade Jl., vol. 32, nos. 473, 475, 482, 483 and 484, Sept. 10, 24, Nov. 12 and 26, 1925, pp. 213-214, 263-269, 409-412, 423-426, and 443-447, 26 figs.

SAWS

SAFETY IN USE AND CARE. Safety in the Use and Care of Saws, S. H. Disston. Safety, vol. 4, no. 4, Sept.-Oct. 1925, pp. 101-105, 8 figs. Notes on development of saws; what manufacturer is doing to promote cause of safety with saws.

SEWAGE DISPOSAL

SEWAGE, SPRINKLER NOZZLES. Characteristics of Sewage-Sprinkler Nozzles, R. B. Wiley, F. W. F. W. Greve and M. J. Zucrow. Purdue Univ., Eng. Exper. Station, Bul. No. 20, June 1925, 57 pp. 23 figs. Notes on trickling filters; particulars and results of investigation to determine: co-efficient of discharge for each nozzle, effect of rotation of cone upon distribution of discharge, effect of a change in elevation of orifice, distribution of spray under different heads, maximum height of spray, and comparison of performance of supposedly identical nozzles.

SEWAGE TREATMENT. Sewage Treatment Plants in the United States. Pub. Wks., vol. 56, nos. 7, 8 and 9, July, Aug. and Sept. 1925, pp. 255-265, 297-306 and 345-347. July: Sewage treatment plants in several hundred cities, with details of construction and operation; percentages of residences sewered; pumping plants and amount of sewage pumped. Aug. and Sept.: Lists of plants in the several states, with information as to their type, size and other details, furnished by engineers or other officials of State Boards of Health.

TREATMENT. Normalcy in Chemical Treatment of Sewage, J. F. Jackson. Pub. Wks., vol. 56, nos. 10 and 11, Oct. and Nov. 1923, pp. 379-382 and 397-399. Tendency toward use of it as supplementary to biological processes in treatment of both sewage and sludge; no longer being installed as sole or main treatment; experiments with use of acids, saltpetre and other agents; description of experimental work at South Manchester and conclusions arrived at; necessity of co-operation in intensive study of effects of chemicals other than precipitation.

Methods Used in Sewage Purification, F. W. Harris. Can. Engr., vol. 49, no. 21, Nov. 1925, pp. 573-574. Principal features of activated sludge process; bio-aeration process; experiences at Dalmarnock and Shieldhall works. Paper read at Royal Sanitary Assn. of Scotland convention.

SEWERS

CONCRETE ARCH. Building 29-Ft. Concrete Arch Sewer at Richmond, Va. Eng. News Rec., vol. 95, no. 25, Dec. 17, 1926, pp. 996-997, 5 figs. Heavy invert for flat arch; tile liners; deep trench dug in three lifts.

SHAFTS

TORSIONAL STRESS CONCENTRATIONS. Torsion-Stress Concentrations in Shafts of Circular Cross-Section and Variable Diameter. L. S. Jacobsen. Am. Soc. Mech. Engrs.—advance paper for mfg. Nov. 30-Dec. 4, 1925, 22 pp. 13 figs. Points out electrical, experimental method for finding torsional-stress, distribution in cylindrical shafts of circular cross-section and of any axial outline method has been applied to problem considered by F. A. Willers, and paper includes series of curves that will enable designer to find; at glance, maximum torsional stress in shaft of 2 diameters for various diameter and fillet proportions.

VIBRATIONS. Torsional Vibrations in Reciprocating Shafts, G. R. Goldsbrough, Roy. Soc.—Proc., vol. 109, no. A749, Sept. 1, 1925, pp. 99-119. Analytical investigation of vibration about steady motion of elastic shaft having engine at one end and mass operating against resistance at other end; results are applicable only to relatively low-speed engines.

Vibration Phenomena of a Loaded Unbalanced Shaft while Passing Through Its Critical Speed, A. L. Kimball, Jr. and E. H. Hull. Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 3, Dec. 4, 1925, 18 pp., 13 figs. Presents in clear manner, with experimental demonstration, discussion of peculiar vibration phenomena to which unbalanced loaded shaft is subject while passing through its critical speed; basic theory is given from somewhat new viewpoint, after which experimental demonstration, which gives quantitative check on theory is described.

SILICON STEEL

PROPERTIES AND TYPES. Silicon Steel, W. E. Ruder, Am. Iron & Steel Inst.—advance paper for mtg. Oct. 23, 1925, 8 pp.; also (abstract) in Iron Age, vol. 116, no. 18, Oct. 29, 1925, pp. 1170-1171. Constitution, mechanical properties, magnetic uses, and magnetic properties; thickness of steels; effect of punching strains; mechanical condition of sheets; testing.

SLIDE RULES

A. E. G. Special Slide Rules (Sonder-Rechenschieber), F. Bahlcke, Werkstattstechnik, vol. 19, no. 20, Oct. 15, pp. 726-730, 11 fig. Details of design and application for approximate calculation of loads and velocities of belting, weight of sheet iron of a given thickness and surface, and other problems connected with machine tool work; numerical examples.

SPRINGS

CORROSION RESISTING COATING. Recent progress in Coating Steel Springs to Resist Corrosion. Jos. K. Wood. Am. Mach., vol. 63, no. 25, Dec. 17, 1925, pp. 981-984. Application of non-corrosive metallic coatings to steel spring surfaces; effect of processes on spring characteristics. Madsen process and its promise for successful solution of problem.

ELASTIC AND FATIGUE PROPERTIES. An Outline for the Application of Fatigue and Elastic Results to Metal Spring Design. T. M. Jasper, Am. Soc. Mech. Engrs. —advance paper for mtg. Nov. 30-Dec. 4, 1925, 11 pp., 9 figs. Deals particularly with steel springs used for shock-absorbing purposes and for recuperating machinery; problem of design of springs may be divided into parts; first: question of static elastic and fatigue properties of material to be used in their construction and, second, shape of springs desired, together with distribution of stresses developed in their use for given deformation; results of investigation of static properties of steel carried out. Eng. Experiment Station of Univ. of Ill.

HELICAL. Formulae for the Design of Helical Springs of Square or Rectangular Steel. C. T. Edgerton. Am. Soc. Mech. Engrs.—advance paper for mtg. Nov. 30-Dec. 4, 1925, 15 pp. Author points out lack of formulas for calculating any except springs of square-bar steel and then develops formulas for rectangular-bar steel based on work at St. Venant; for solution of these formulae he gives tabulated values for two variables which depend on ratio of bar's cross-sectional dimensions; appendix contains 4 examples in which application of formula is illustrated.

PHOSPHOR BRONZE HELICAL SPRINGS, from the Standpoint of Precision Instruments. W. G. Brombacher, Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 30-Dec. 4, 1925, 16 pp., 8 figs. Results of tests made on springs investigated at Bur. of Standards to obtain knowledge useful in design of springs for precision instruments; characteristics of spring material; method of construction of springs; apparatus in which springs were tested, and procedure followed are set forth; results relate to stiffness, maximum fiber stress, hysteresis, after-effect, drift, and buckling.

STANDARDIZATION

NATIONAL NEED FOR. Why Standardization, C. R. Skinner, Factory, vol. 35, no. 5, Nov. 1925, pp. 723-724, 748, 750 and 752. Author shows clearly need for national standards movement, amd nakes plain the difference between standardization and simplification. On p. 722 are given statements by G. Swope J. W. Lieb, L. F. Loree, G. B. Cortelyou and J. A. Farrell, on why theyb elieve in standardization.

STANDARDS

GERMAN N. D. I. REPORTS. Report of the German Industrial Standards Committee (Normenaussebuss der deutschen Industrie). Mascbinenbau, vol. 4, no. 21, Oct. 15, 1925, pp. 1063-1066, 2 figs. Proposed standards for spur and bevel gear tectb and riveted steel tubes.

Report of tbe German Industrial Standards Committee (Neue Dinormblätter), Werkstattstechnik, vol. 19, no. 18, Sept. 15, 1925, pp. 681-683, 1 fig. Details of proposed standards for threaded square units for spindles, cam wheels, and sbafts; also gages.

Report of the German Industrial Standard Committee (Neue DINormblätter), Werkstattstechnik, vol. 19, Oct. 1, 1925, pp. 715-717, 2 figs. Proposed standards for round nuts with four grooves, and round nuts witb cross holes.

Report of the German Industrial Standard Committee (Neue DINormblätter), Werkstattstechnik, vol. 19, no. 20, Oct. 15, 1925, pp. 747-749, 2 figs. Proposed standards for plates for welding of quadrilateral and trilateral profiles.

Report of the German Industrial Standards Committee (Normenausschuss der deutschen industrie). Gas- u. Wasserfach, vol. 68, no. 39, Sept. 26, 1925, pp. 615-617. Proposed standards for a nomenclature of technical gases, covering gases from liquid and solid fuels.

STEAM

HIGH-PRESSURE. The Production of High-Pressure Steam. Eng. Progress, vol. 6, no. 10, Oct. 1925, pp. 313-314, 1 fig. Higb-pressure steam plant of 100-atmos. pressure erected at Wiener Lokomotivfabrik at Vienna, Austria, according to designs of Prof. Löffler, for purpose of testing his new metbod of generating high-pressure steam for permanent service.

Tbe Value of Higher Steam Pressures in the Industrial Plant, Wm. F. Ryan. Am. Soc. Mech. Engrs.—advance paper, for mtg. Nov. 30-Dec. 4. 1925, 21 pp., 9 figs. Points out value of higher steam pressures; sbows tbat gains from high pressure are greater than in central station and except for question of suitable feedwater for high-pressure boilers, problems involved are less difficult; relative cost of power for varying initial pressures is estimated; relative efficiency of turbine and engine prime movers, and application of higher pressure to manufacturing equipment, are discussed; it is indicated that pressures up to present commercial limit, about 1200 lb. per sq. in. may be used advantageously under given conditions.

REHEATING. Steam Economy, W. D. Wylde. Indus. Mgmt. (Lond.), vol. 12, no. 11, Nov. 1925, pp. 528 and 530. Discusses steam reheating; including metbod and economy of reheating, lowering of fuel consumption, and saving of steam.

STEAM ENGINES

ISOLATED PLANTS. Tbe Steam Engine Still in Favor in the Isolated Plant. Power, vol. 62, no. 22, Dec. 1, 1925, pp. 834-835, 4 figs. Kinds of service to watch steam engine is especially adapted and factors that are reacting in its favor.

LUBRICATION OF CYLINDERS. Practical Instructions on Lubrication of Steam Engine Cylinder, P. B. Jensen. Nat. Engr., vol. 29, no. 12, Dec. 1925, pp. 595-597. Cylinder should be examined after engine stops; point of introduction of oil; amount of compounding necessary; effect of load and type of engine on lubrication; classification of steam-cylinder oils.

STEAM GENERATORS

PULVERIZED-COAL-BURNING. New Steam Generator. Iron Age, vol. 116, no. 25, Dec. 17, 1925, p. 1707. Evaporates 35 lb. of water to 1 sq. ft. of heating surface per hr.; installation in plant of Taylor Bros. in England, developed by Combustion Eng. Corp, New York.

STEAM METERS

CONSTRUCTION. Industrial Measuring of Steam (La mesure industrielle de la vapeur), J. Welter. Chaleur et Industrie, vol. 6. no. 66, Oct. 1925, pp. 451-458, 9 figs. Discusses placing of steam meters at various points of a plant, defects of steam meters generally; calculates diaphragms, orifices and other parts of steam meters, enumerates conditions that an efficient steam meter must fill.

STEAM PIPES

POWER-PLANT. Steam Piping System in Modern Power Plants, W. Tallmadge. Universal Engr., vol. 42, no. 4, Oct. 1925, pp. 22-24. Discusses strength of pipe, supports, flexibility, joints, valves, etc. Paper read before Progressive Council No. 12, Universal Craftmen's Council of Engrs.

STEAM POWER PLANTS

COMBINED HEATING AND POWER. Surplus Energy (Ueberschussenergie), F. Niethammer, Wärme, vol. 61, nos. 35 and 36, Aug. 28 and Sept. 4, 1925, pp. 446-449 and 460-463, 2 figs. Gives leading particulars concerning equipment and operating conditions in large number of installations where power and beating loads are operated conjointly; examples are cited from following industries: sugar refineries, textile works, chemical, paper and leather plants, briquette factories, and electricity works operating in conjunction with district heating schemes; reviews use of mixed-pressure turbines, steam storages, back-pressure regulators, waste-heat boilers and otber equipment; outlines difficulties in dispensing of surplus energy from and in industrial concerns.

COSTS. Cost of Energy of Power Plants With Heat Engines (Energikostnad vid kraftanläggningar med värmemotorer), M. T. Lindhagen, Teknisk Tidskrift, vol. 55, no. 31, Aug. 1, 1925, pp. 129-133 (Electroteknik), 7 figs. Discusses installation and running cost of large steam power plant, also smaller plant run with gas engines, Diesel engines, steam engines, and turbines; cost of power alone and combined with heating.

HOTELS. Economics of Heat and Power Production in Modern Hotels, E. Douglas. Nat. Engr., vol. 29, no. 12, Dec. 1925, pp. 591-594. Data on hotel power-plant service requirements and bow they can be most economically provided.

OFFICE BUILDINGS. Office-Building Plant Saves by Studying Costs; Wm. R. Goodwin. Power, vol. 62, no. 25, Dec. 22, 1925, pp. 962-966, 7 figs. As result of study motor-generator sets were installed for purchase of power in excess of tbat capable of being generated from heating steeam, in bomeoffice building of Conn. Mutual Life Insurance Co., Hartford.

RATING SYSTEM FOR SMALL. Getting Best Results from the Small Power Plant. R. S. Twogood, Indus. Mgmt. (N. Y.), vol. 70, no. 6, Dec. 1925, pp. 323-330, 5 figs. Practical rating system and how it belps efficiency.

RECORDS. An Unfailing Way to Reduce Costs of Steam, H. E. Collins, Mgmt. & Admin., vol. 10, no. 6, Dec. 1925, pp. 333-337, 2 figs. Points out tbat all factors entering into power-plant operation can be measured; instruments are available to produce records, from which accurate costs can be determined and deficiencies in operation corrected before tbey amount to serious losses.

STEAM TURBINES

BLEEDER. Bleeder Turbines for Industrial Heating (Les turbines à soutirage de vapeur pour les chauffages industriels). Génie Civil, vol. 87, no. 20, Nov. 14, 1925, pp. 413-416, 5 figs. Details of design and operation of bleeder or back-pressure turbines; power available and cost per kw-hr.; witb examples of installation.

Steam Bleeding and Turbine Performance, C. D. Zimmerman. Mech. Eng., vol. 47, no. 12, Dec. 1925, pp. 1144-1148, 20 figs. Results of tests sbowing effect of steam bleeding on total power-plant efficiency, also effect of cbanges in vacuum and superheat on turbine and condenser performance.

BUCKET VIBRATION. Tangential Vibration of Steam-Turbine Buckets, W. Campbell and W. C. Heckman. Am. Soc. Mech. Engrs—advance paper, for mtg. Nov. 30-Dec. 4, 1925, 25 pp., 15 figs. Describes how research dealt with in paper before Society in 1924 was extended to include tangential vibration; substantially same testing apparatus was used and same methods of protection adopted; in unsymmetrical reaction buckets compound vibration lying most nearly in plane of wbeel is, by definition, treated as tangential vibration; methods described suffice for protection against any combined or intermediate type.

COMBINED POWER AND HEATING PROCESSES. Higb Efficiency in the Use of Steam. Power, vol. 62, no. 22, Dec. 1, 1925, pp. 846-847, 2 figs. Discusses combined power and heating process and cites examples of practical applications tbat are earning dividends for their owners.

INTERMEDIATE SUPERHEATING. Intermediate Superheating. K. Thielsch. Elecn., vol. 95, no. 2477, Nov. 6, 1925, pp. 524-526 and 533, 6 figs. Its employment in power stations with condensing turbines; general principles; temperature and pressure limits; possible metbods. Abstract, translated from AEG. Mitteilungen.

STEEL

ALLOY. *See Alloy Steels.*

SILICON. *See Silicon Steel.*

STAINLESS. Recent Developments in Stainless Steel, D. G. Clark. Am. Iron & Steel Inst.—advance paper, for mtg. Oct. 23, 1925, 28 pp., 7 figs.; also (abstract) in Iron Age, vol. 116, no. 18, Oct. 29, 1925, pp. 1172-1173. Deals with steels wherein chromium is pre-dominant alloy; history and patents; processes; types of stainless steel; standard cutlery type; physical properties; resistance to heat; heat treatment; bard cutlery type; high-carbon, soft-steel and stainless iron types; physical properties of stainless iron for turbine blades; valve-steel and nickel types; effect of various corrosive reagents.

TOOL. *See Tool Steel.*

VANADIUM. *See Vanadium Steel.*

STEEL CASTINGS

CLEANING. Clean Steel Castings Economically, F. B. Jacobs. Foundry, vol. 53, no. 22, Nov. 15, 1925, p. 922, 1 fig. Methods employed at West Steel Castings Co., Cleveland.

HEAT TREATMENT. Heat Treatment. Data on Quality Steel Castings, A. E. White, Am. Soc. Mech. Engrs.—advance paper for mtg. Nov. 30-Dec. 4, 1925, 15 pp., 7 figs. Summarizes study wbicb has been made on beat-treatment practice for quality steel castings; gives results of laboratory tests on dendritic and dentrite-free steels after annealing, normalizing, drawing, and spheroidizing treatment; records large number of plant tests; results show tbat normalizing and drawing treatment gives superior results to those obtainable by annealing or spheroidizing.

OBSTRUCTED CONTRACTION, EFFECT OF. Effects of Obstructed Contraction on Steel Castings (Folgeerscheinungen der gehinderten Scbwindung an Stahlformgussetücken), H. Malzacher, Giesserei-Zeitung, vol. 22, no. 21, Nov. 1, 1925, pp. 653-657, 13 figs. Notes on contraction and forces resisting it; bot cracks stresses; practical examples.

STEEL, HEAT TREATMENT OF

HARDENING AND TEMPERING. Heat Treatment and Metallograpby of Steel, H. C. Kneer. Forging—Stamping—Heat Treating, vol. 11, no. 11, Nov. 1925, pp. 386-390; 11 figs. Hardening and tempering.

STEEL MANUFACTURE

OPEN-HEARTH BOILS. Differences in Open-Hearth Boils, H. D. Hibbard. Iron Age, vol. 110, nos. 23, 24 and 25, Dec. 3, 10 and 17, 1925, pp. 1511-1513, 1605-1606, and 1671-1672. Classification according to degree and violence; consideration of uses and cbaracters of 10 recognized types; causes and effects of boils. Dec. 10: Dead bath and almost dead bath; incipient, gentle and moderate boil. Dec. 17: Decarbonizing effects and Talbot reaction; effervescing steels; Martin and Siemens process.

CRUCIBLE PROCESS. Making Higb Grade Steel. J. A. Coyle. Iron Trade Rev., vol. 77, no. 24, Dec. 10, 1925, pp. 1457-1459, 2 figs. European and American adaptations of Huntsman crucible process differ; coke-hole furnace, discarded in United States, survives in England.

STOKERS

FUEL PREPARATION FOR. Fuel Preparation for Chain-Grate Stokers, F. C. Duennes. Power, vol. 62, no. 21, Nov. 24, 1925, pp. 798-799, 2 figs. Discusses two distinct operations involved in fuel preparation, namely, sizing and wetting.

SELECTION. Mechanical Stokers Offer Savings to Many Hand-Fired Plants. Power vol. 62, no. 22, Dec. 1, 1925, pp. 844-845, 5 figs. Proper selection of stoker necessary; size of plant an influencing factor.

STREET RAILWAYS

LOCOMOTIVES. Hanomag Street Railway Locomotives ((Hanomag-Strassenbabn-Lokomotiven). Hanomag Nachrichten, vol. 17, no. 142, Aug. 1925, pp. 129-130, 1 fig. Advantages of steam locomotives and their field of application; design and specifications of various types used in Holland, Germany, and Colombia, with and without housing.

METER-TESTING CAR. Preventing Power Waste, E. W. Anger. Elec. Traction, vol. 21, no. 11, Nov. 1925, pp. 577-581, 7 figs. Chicago surface lines has completely equipped meter-testing car and system of inspection.

STRUCTURAL STEEL

F-STEEL. A new German Steel (Ein neuer deutscher Stabl), Schaper, Bautechnik, vol. 3, no. 45, Oct. 16, 1925, pp. 631-632, 2 figs. Describes F-Steel, produced by Berlin A. G. Eisengiesserei und Mascbinenfabrick in a Bosshardt furnace in which iron melt is completely deoxidized, resulting in a steel greatly superior to St. 37; its C content is no greater than that of St. 37; average breaking strength: 5300 kg-cm2, limit of elongation 4670 kg-cm; elongation 27.2 per cent.

SHEAR IN COMPRESSION MEMBERS. Notes on Shear in Compression Members, R. E. Goodwin. Am. Soc. Civ. Engrs.—Proc., vol. 51, no. 10, Dec. 1925, pp. 1939-1945, 3 figs. Applies principles of mechanics to subject of shear in compression members; presents method by which given conditions can be analyzed and those which produce greatest shear can be determined, thus enabling engineer to design for most dangerous conditions that be considers it advisable to assume.

TESTING. Distribution of Elongation Over the Gauge Length of Tensile Test Bar and Some Notes on the Measurement of Ductility of Structural Steel by Tensile Breaking Test, K. Minato, Soc. Naval Architects—Jl., vol. 36, Apr. 1925, pp. 23-62, 19 figs. partly on supp. plates. Investigates distribution of elongation and reduction of sectional area over gage length of test bars, subject to tensile breaking; analyzes ultimate elongation into general uniform elongation and local extra elongation; relations between total elongation, general uniform elongation, local extra elongation, reduction of sectional area at point of rupture, and ultimate tensile strength; discusses several existing methods of measuring ductility; proposes simple, yet sound method of measuring cost probable general uniform elongation of structural steel by tensil breaking tests.—(In English).

STRUCTURES

DESIGN. Report on Effects of Tornado of March 18, 1925, West Soc. Engrs.—Proc., vol. 30, no. 9, Sept. 1923, pp. 373-396, 19 figs. Results of study on part of officers of Bridge & Structural Section of West. Soc. Engrs. who were designated a special committee to visit tornado-swept section of Southern Illinois and if possible to draw up some suggestions for better building construction; points out certain structural weaknesses that could be corrected at small cost and would add to stability and safety of buildings.

SUBSTATIONS

BROOKLYN EDISON CO. Kings Highway Substation of the Brooklyn Edison Company, C. M. Gilt, Elec. Jl., vol. 22, no. 11, Nov. 1925, pp. 521-525, 8 figs. Details of 3-phase substation built to replace old 2-phase substation; it will be fed by four 10,000-kva. transformers, connected to 3-conductor lead-covered incoming cables without any high-tension circuit breakers at substation; feeder regulators and control board; station diagram and floor plan; protection and operation.

SURVEYING

GEODETIC. The Geodetic Survey of Canada, J. L. Rannie. Eng. Jl., vol. 8, no. 12, Dec. 1925, pp. 483-487, 8 figs. Necessity for geodetic surveys and scope of this work in Canada.

STEREOPHOTOGRAMMETRIC. Stereo-Photo-Grammetric Surveying, B. J. Woodruff and D. H. Nelles. Engineer, vol. 140, nos. 3644, 3645 and 3646, Oct. 30, Nov. 6 and 13, 1925, pp. 454-455, 481-483 and 515-517, 19 figs. Describes methods employed in surveying area in vicinity of Ottawa, Can.; field operations.

T

TANKS

WATER. Standardized Elevated Steel Water Tanks, J. E. O'Leary. Am. Water Wks. Assn.—Jl., vol. 14, no. 3, Sept. 1925, pp. 190-198. Deals with size and capacity of tanks; one of the real premises on which a standardization program is justified is quality of product.

TELEPHONY

BELL SYSTEM. General Engineering Problems of the Bell System, H. P. Charlesworth. Bell System Technical Jl., vol. 4, no. 4, Oct. 1925, pp. 515-541, 18 figs. Discusses character and scope of important problems involved in caring for growth and operation of Bell system; plant extension necessary to meet service requirements and necessity of advanced planning; uses of "Commercial survey," "Fundamental Plan" and engineering cost studies are analyzed to illustrate how an engineer attacks problem of furnishing satisfactory telephone service to public; discussion of New York-Chicago toll cable and telephone problem in New York City, as illustrative of specific engineering problems.

TERMINALS, LOCOMOTIVE

DROP PITS FOR WHEEL REMOVAL. Drop Pits for Removing Wheels at Engine Terminals, J. D. Rogers. Baldwin Locomotive, vol. 4, no. 2, Oct. 1925, pp. 54-57, 8 figs. Describes drop pit for removing wheels and how they are used.

TEXTILE MILLS

WATER SUPPLY. Water Supply for Textile Mills, C. L. Hubbard. Textile Wld., vol. 68, no. 19, Nov. 7, 1925, pp. 71 and 73-74, 5 figs. General survey of methods employed to purify water for boiler feedings and process work; impureties commonly found; removal by means of filters, settling tanks, heat, lime, soda, combined lime and soda, and zeolite; boiler compounds; water softening apparatus.

THERMIT WELDING

DEVELOPMENTS. Thermit Welding Development, J. H. Deppeler, Am. Welding Soc.—Jl., vol. 4, no. 10, Oct. 1925, pp. 58-64. Description of process; developments; work which has been done in improvement of physical qualities of Thermit Steel.

THERMO-DYNAMICS

THIRD LAW. New Edition of Nernst's Monograph on Third Heat Law (Zur Neuanflage der von W. Nernst, veröffentlichten Monograpline über den 3, Wärmesatz), Schmolke. Dinglers polytechnisches Journal, vol. 340, no. 16, Aug. 1925, pp. 181-186, 2 figs. Develops scientific and mathematical bases of Nernst theorem and gives examples of its application.

TRANSFORMERS

LOADING ON TEMPERATURE BASIS. Loading Transformers on a Temperature Basis, E. G. Reed and W. A. Sumner. Elec. Jl., vol. 22, no. 11, Nov. 1925, pp. 550-553, 5 figs. For given condition of load on transformer one of main points to be considered is temperature gradient between cooling oil and hot test part of winding, as well as change in gradient as load varies; temperatures resulting from two main classes of loads need to be investigated—first a given continuous load, and second, a particular load cycle.

TAP CHANGING UNDER LOAD. Transformer Tap Changing Under Load, H. C. Albrecht. Am. Inst. Elec. Engrs.—Jl., vol. 44, no. 12, Dec. 1925, pp. 1331-1335. Attention is called to need for voltage and power-factor regulating equipment on lines used for tying together large generating stations and for interconnection of systems; discusses and compares important characteristics of three principal methods for voltage regulation on interconnecting lines, namely, synchronous condensers, tap changing under load, and induction regulators; describes three installations (2 of tap changing under load, and 1 of induction regulators) for voltage regulation and power-factor control on lines of Phila. Elec. Co.

TEMPERATURES, PREDETERMINATION OF. Predetermination of Self-Cooled Oil-Immersed Transformer. Temperature Before Conditions are Constant, W. H. Cooney. Am. Inst. Elec. Engrs.—Jl., vol. 44, no. 12, Dec. 1925, pp. 1324-1330, 10 figs. It is shown that while winding-temperature rises over room of self-cooled oil-immersed transformers follows given law only after certain time has elapsed, quite accurate results may be obtained by calculating time-temperature curves of top oil-temperature rises above room, and winding-temperature rise above top oil separately, then adding them together to get winding-temperature rise above room at any time before conditions are constant.

TREATMENT. Sewage Treatment by Septic Tanks, C. C. Halkyard. Civil Eng. Rec., vol. 2, nos. 2, 3 and 4, Aug. 15, Sept. 15 and Oct. 15, 1925, pp. 50-52, 104-106 and 118-121, 8 figs. Solution of sewage problem for small communities; science of sewage treatment is based on principle of providing suitable living conditions for certain organisms which break down sewage into more stable non-putrescible components; present status of small septic tank in Australia.

V

VANADIUM STEEL

HARDNESS. Vanadium Steels (Zur Kenntnis der Vanadinsthäle), E. Maurer. Kruppsche Monatshefte, vol. 6, Sept. 1925, pp. 165-169, 2 figs. Shows that vanadium hardenite does not exist, nor a point similer to pearlite; carbide dissolves gradually with increasing temperature like secondary cementite; on basis of mainly physical tests formula of carbide Va_4C_3.

VIBROSCOPES

HIGH-SPEED MECHANISMS, OBSERVATION OF. Observation of High-speed Mechanisms. Machy (Lond.), vol. 27, no. 687, No. 26, 1925, pp. 270-272, 3 figs. Use of apparatus that causes rapidly moving parts to appear stationary at any point in cycle of movements; arrangement of vibroscope and examples illustrating its use; determining lubrification troubles; locating cause and extent of excessive vibration.

VOLTAGE REGULATION

REGULATORS. The Extended Broad-Range Voltage Regulator, J. H. Ashbaugh. Elec. Jl., vol. 22, no. 11, Nov. 1925, pp. 559-561, 4 figs. Extended broad-range regulator functions exactly like broad-range regulator except that it operates generator field rheostat automatically, cutting it in or out as conditions warrant; thus it is possible for this regulator to control machine without any assistance on part of operator, from maximum exciter demands to minimum.

W

WAGES

ANALYSIS OF. The Meaning of Wages, L. Grier, Nature (Lond.), vol. 116, no. 2921, Oct. 24, 1925, pp. 613-617. Discusses certain aspects of wages and reviews from those aspects certain payments made to or on behalf of employees.

BARTH STANDARD SCALE. The Barth Standard Wage Scale, C. G. Barth. Mgmt. & Admin., vol. 10, no. 6, Dec. 1925, p. 357. Method is application of fundamental of Weber's law of discrimination, which declares that for sensations or responses in arithmetical relationship, corresponding stimuli form geometric series.

WALLS

SAND-LIME BRICK. Strength of Sand-Lime Brick Walls, H. L. Whittemore. Contract Rec., vol. 39, no. 46, Nov. 18, 1925, pp. 1099-1106, 7 figs. Results of compressive tests of 18 walls and 18 wallettes, built of medium grade sand-lime brick in lime, cement-lime and cement mortars.

WATER POWER

ONTARIO, CANADA. Developing Ontario's Water Power. Power House, vol. 18, no. 20, Oct. 20, 1925, pp. 89-90. With water-power resources of Ontario, including potential power of Niagara River, permitting of an installation of 9,000,000 hp. resources of province are but from 18 to 25 per cent developed.

SMALL, DEVELOPMENT BY FACTORY OWNERS. The Development of Small Water-powers by the Factory Owner. F. Johnstone Taylor. Mech. Wld., vol. 78, no. 2030, Nov. 27, 1925, p. 425. Points out that if factory is located near any appreciable volume of running water it behoves owner in his own interest to have its potential value investigated; machinery for medium and for low falls; waste water, storage, selling power.

STEAM POWER IN ITS RELATION TO. Steam-Power in Its Relation to the Development of Water-Power, R. C. Powell. Am. Inst. Elec. Engrs.—Jl., vol. 44, no. 12, Dec. 1925, pp. 1291-1295, 8 figs. Draws attention to desirability of development of water-power resources of country on comprehensive economic basis and discusses some of features of steam power in connection with economic development of water power; points out limitations of cost curves frequently used in comparing costs of water and steam power, and gives simple method whereby minimum cost of power may be found for assumed water-power development with auxiliary steam power.

WATER SUPPLY

DEVELOPMENT IN SMALL CITIES. Water Supply Development in Small Cities, C. M. Ladd. Am. Water Wks. Assn.—Jl., vol. 14, no. 4, Oct. 1925, pp. 337-342. General idea of results to be obtained in design and construction of a complete water works system, some of the things to be avoided, and done.

SMALL SERVICE PIPES. Experiences With Small Services Pipes, J. E. Gibson, Am. Water Wks. Assn.—Jl., vol. 14, no. 4, Oct. 1925, pp. 295-305, and (discussion), 305-308. A plea for better service pipes; author's efforts and experiences in eliminating mechanical difficulties with service pipes at Charleston, S. Carolina.

WATER TREATMENT

LIME-SODA PROCESS. Lime and Soda Ash Method, O. T. Rees. Pac. Ry. Club—Jl. vol. 9, no. 5, Aug. 1925, pp. 5, 7, 9, 11, 13, 15, 17 and 19. Discusses types of equipment for lime-and-soda method of treating water and systems employed by Santa Fe Railway.

STERILIZATION. Sterilization of Water by Liquid Chlorine, J. M. Mathew, Commonwealth Engr., vol. 13, no. 1, Aug. 1, 1925, pp. 31-33. Outlines experiments which are believed to represent first use of liquid chlorine for sterilization of domestic water supplies in Australia; chlorimating mechanisms; cost considerations.

WATERWAYS

LAKE MICHIGAN. The Withdrawal of Water From Lake Michigan by the Sanitary District of Chicago and the Consequent Lake Lowering Controversy, M. Knowles. Engrs. Soc. West. Pa., vol. 41, no. 6, July 1925, pp. 221-250 and (discussion) 251-258, 7 figs. Popular idea is that Chicago, by diverting a large volume of water from Lake Michigan, has lowered lake levels, with consequent damage to navigation, harbors, power, and water-supply interests in general; geological history of region; geography and recent history; early plans for a waterway from Great Lakes to Mississippi; Chicago's development; authorization of drainage canal; cause of controversy; etc.

WATER WORKS

ECONOMICS. Economics in Water-Works Engineering, R. O. Wynne-Roberts. Am. Water Wks. Assn.—Jl. vol. 14, no. 3, Sept. 1925, pp. 226-234. Discusses money value of purity hard water problem, losses due to disease; loss of head pumping station control, small water mains, and serious fire losses, municipal taxation, pumping plants, water fittings, covering water tanks.

WELDING

ELECTRIC, *See Electric Welding, Arc; Electric Welding, Resistance.*

HEAT EFFECT ON STEEL. The Effect of Heat on Steel, Especially During Fusion Welding and Cutting, S. W. Miller. Am. Welding Soc.—Jl., vol. 4, no. 9. Sept. 1925, pp. 29-45, 35 figs. It is concluded that effect of welding heat on low-carbon steel of good quality is small, but effect on high-carbon steel is great; therefore as low carbon steel should be used as possible; there is a point of maximum ductility and minimum strength at distance from weld, depending on process used, and this is point at which rupture occurs with clean steel.

OXYACETYLENE. *See Oxyacetylene Welding.*
RAILS. *See Railway Track Welding.*
THERMIT. *see Thermit Welding.*

WIRE. Welding Wire a Factor in Good Welding. C. A. McCune. Am. Welding Soc.—Jl., vol. 4 no. 10, Oct. 1925, pp. 32-36. Suggests test methods as further means of determining qualities of wire.

WOOD PRESERVATION

A. E. R. A. REPORT. Report of the Committee on Wood Preservation. Elec. Traction, vol. 21, no. 10, Oct. 1925, pp. 533-535. Specifications for open-tank treatment of wooden poles; specifications for brush treatment of wooden poles—treatment of poles in place; specifications for pressure treatment of wooden poles; methods of increasing life of timber by means other than application of preservatives. Report to Am. Elec. Ry. Assn.

WROUGHT IRON

MECHANICAL PUDDLING. The Ely Process of Mechanical Puddling, for the Production of Wrought Iron, R. H. Dechant. Am. Iron & Steel. Inst.—advance paper, for mtg., Oct. 23, 1925, 11 pp. 3 figs. Describes Ely furnace, first designed and built for purpose of busheling scrap iron mechanically; its adaptation for puddling of pig iron was started about 4 years ago and modifications, which have been promoted by experience through this period, have resulted in practical mechanical puddling machine; in author's opinion, this furnace occupies position in field of mechanical puddling of being adaptable and flexible in its application to wrought-iron works and therefore of practical and economic worth.

X

X-RAYS

RADIOLOGICAL RESEARCH. Radiological Research, V. E. Pullin, Roy. Soc. Arts—Jl., vol. 73, nos. 3800 and 3801, Sept. 18 and 25, 1925, pp. 956-970 and 974-986, 6 figs. Two Cantor lectures. Development of theory of X-Rays, and development of apparatus.

ENGINEERING INDEX—Supplementary List

A

AERONAUTICAL INSTRUMENTS

CALIBRATION. An Altitude Chamber for the Study and Calibration of Aeronautical Instruments, H. J. E. Reid and O. E. Kirchner. Nat. Advisory Committee Aeronautics—Tech. Notes, no. 229, Nov. 1925, 13 pp., 7 figs. Design and construction of altitude chamber in which pressure and temperature can be varied independently, carried out at Langley Memorial Aeronautical Laboratory, Va.; temperatures ranging from +20 deg. to —50 deg. cent. are obtained by the expansion of CO_2 from standard containers, used for calibrating research instruments under altitude conditions simulating those up to 45,000 feet.

AERONAUTICS

DEVELOPMENTS, U. S. A. Eleventh Annual Report. Nat. Advisory Com. for Aeronautics—Administrative Report, 1925, 59 pp. Organization and activities of National Advisory Committee; presents stages of aviation including aerodynamics, trend of airplane design, structural materials, airships, aeronautical research in U. S. A. and its relation to national defence, etc. See also abstract in Aviation, vol. 19, no. 25, Dec. 21, 1925, pp. 873-874.

AIR COMPRESSORS

TYPES. A New Form of Air Compressor, H. S. Hele-Shaw and T. E. Beacham. Colliery Guardian, vol. 130, no. 3385, Nov. 13, 1925, pp. 1159-1161, 13 figs. Describes Hele-Shaw Beacham compressor showing almost perfect balance at all speeds, owing to fact that reciprocity movement between cylinder and piston is really relative and not absolute, and fact that the oil which is necessarily employed for lubrication acts as packing not only for the pistons, but as a seal for central valve.

AIR CONDITIONING

HUMIDITY CHART. A New Humidity Chart, V. A. Nekrassoff. Heat. & Vent. Mag., vol. 22, no. 12, Dec. 1925, pp. 65-68, 6 figs. Effective use of the nomographic method of presentation in simplifying air-conditioning calculation.

AIRCRAFT CONSTRUCTION MATERIALS

METALS, TESTING. Testing Metals for Aircraft, N. S. Otey. Iron Age, vol. 116, nos. 25 and 26, Dec. 17 and 31, 1925, pp. 1660-1664 and 1797-1800, 21 figs. Selecting representative samples; proper design of test specimens and methods of loading them. New proposed standard specifications and methods for testing light alloys.

AIRPLANE ENGINES

FLOW THROUGH VALVE. Potential Flow in Engine Valves, B. Eck. Nat. Advisory Committee Aeronautics—Tech. Memo., no. 343, Dec. 1925, 20 pp., 25 figs. Attempts to determine by exact methods the nature of flow in valves under various restricted conditions, distinguishing two kinds of flow in simple flat-seated valves, for small valve lift and for greater valve lift.

FUELS STRAINERS, CLOGGING OF. The Clogging of Fuel Strainers, A. C. Zimmerman and E. R. Irwin. Air Service Information Circular, vol. 6, no. 542, Oct. 1, 1925, 3 pp., 4 figs. Report prepared from study of data contained in several isolated reports; concludes that clogging of fuel strainers is attributable: to accumulation of a jelly-like precipitate of hydrated aluminum oxide, caused by corrosion of aluminum parts of fuel system by water, to accumulation of a fibrous material, either asbestos or cotton fibers, on the screen, etc.

FUELS. Fuels for High-Compression Engines, S. W. Sparrow. Nat. Advisory Committee Aeronautics—Report, no. 232, Jan. 15, 1925, 20 pp., 13 figs. Report based on results of tests made by Bureau of Standards emphasizing fact that there may be a difference between fuel's ability to resist detonation and its ability to resist preignition; also discusses properties essential to a satisfactory fuel for high compression engines; certain fuels, benzol and alcohol in particular, are discussed in some detail.

RATING. The Horse Power Rating Formula for Aero Engine, O. Sugimoto. Soc. Mech. Engrs.—Jl., vol. 28, no. 101, Sept. 1925, pp. 609-615. Discusses formulas for calculating brake horsepower, assuming brake mean effective pressure as constant; i.e., expressing brake horsepower as a function of cylinder bore, piston speed, and number of cylinders; recommends three rating formulas for vertical and vee, radial and rotary engines.

TEST REGULATIONS. England Prescribes Difficult Tests for Airplane Engines. Automotive Industries, vol. 53, no. 25, Dec. 17, 1925, p. 1012. Review of revised test regulations issued by British Air Service.

AIRPLANES

AIRFOILS. An Investigation of the Air-Flow Pattern in the Wake of an Airofoil of Finite Span, A. Fage, L. F. G. Simmons. Roy. Soc. of Lond.—Philosophical Trans., vol. 225, no. A632, 1925, pp. 303-330, 13 figs. Investigation to obtain more complete picture of disturbance beyond an airfoil of infinite span and to map out changes which occur in extent and distribution of vorticity in wake as it passes downstream.

AUTOROTATION MEASUREMENT. Autorotation Measurements on a Model Aeroplane with Zero Stagger, F. B. Bradfield and L. P. Coombes. Aeronautical Research Committee—Reports and Memoranda, no. 975, April, 1925, 7 pp., 4 figs. Measurements up to 52-deg. incidence; autorotation commenced with 17 deg. and continued to beyond 52 deg., curve was then flattened off; large range and rates of autorotation seemed to depend on biplane arrangement rather than on any peculiarity of the wing section.

COMMERCIAL. The Lessons of Six Years' Experience in Air Transport, S. Brancker. Roy. Aeronautical Soc.—Jl., vol. 29, no. 179, Nov. 1925, pp. 552-585. Discusses experience with airplanes and seaplanes to evolve therefrom most important problems to be placed before scientists and designers interested in aviation, including safety, reliability, economy; aircraft specifications of the British government, etc.

STRENGTH CALCULATION. Strength Calculations on Airplanes, A. Baumann. Nat. Advisory Aeronautics—Tech. Memo., no. 341, Dec. 1925, 23 pp. Discusses allowable stresses and safety factor in airplanes, yield point of materials, value of elongation, etc.

WIND-TUNNEL TESTS. Wind Tunnel Test of Transport Study, C. E. Archer. Air Service Information Circular, vol. 6, no. 533, Sept. 1, 1925, 13 pp., 18 figs. Details of testing to determine aerodynamic characteristics of proposed transport propeller, drawing M-4012.

Wire Suspensions in Wind Tunnel Experiments, J. Kerneis. Nat. Advisory Committee Aeronautics—Tech. Memo., no. 342, Dec. 1925, 14 pp., 7 figs. Discusses substitution of wire balance for rigid supports of the models, principal advantages and drawbacks of wire balance; shows importance which errors inherent in wire suspension may assume, and under what conditions accuracy may be obtained.

WINGS. Model Tests with a Systematic Series of 27 Wing Sections at Full Reynolds Number, M. M. Munk and E. W. Miller. Nat. Advisory Committee Aeronautics—Report, no. 221, Dec. 23, 1925, 18 pp., 27 figs. Results of tests of wing sections characterized by small travel of the center of pressure, tested at 20-atmos. pressure in variable-density wind tunnel of the Natl Advisory Committee on Aeronautics, giving consistent results and showing that for stable sections a small effective camber, a small effective S-shape and thickness of 8 to 12 per cent lead to good aerodynamic properties.

ALLOY STEEL

PRODUCTION, UNITED STATES, 1925. Alloy Steels Gain Recognition, J. D. Knox. Iron Trade Rev., vol. 78, no. 1, Jan. 7, 1926, pp. 15-18, 1 fig. Production, exclusive of sheets, exceeds 1,000,000 tons annually; automotive and machine-tool industries absorb 85 per cent of national output; includes partial list of alloy-steel applications.

ALLOYS

ALUMINUM. *See Aluminum Alloys.*
BRASS. *See Brass.*
LEAD. *See Lead Alloys.*

ALUMINUM ALLOYS

PISTON CASTINGS. Aluminum Alloys for Piston Castings Must Meet Varied Requirements, R. J. Anderson. Automotive Industries, vol. 53, no. 25, Dec. 17, 1925, pp. 1030-1034, 6 figs. Points out that they must be low in cost, of ingredients easily alloyed, handle well in foundry, be easy to machine, have good mechanical and physical properties and proper microstructure.

AMMONIA COMPRESSORS

NOMOGRAPHIC CHARTS FOR. Nomographic Chart for the Refrigerating Engineer, W. H. Motz. Ice and Refrigeration, vol. 69, nos. 2, 3, 4, 5 and 6, Aug., Sept., Oct., Nov. and Dec. 1925, pp. 104-106, 160-161, 211-212, 273-274 and 381-382, 5 figs.

AMMONIA CONDENSERS

OPERATION. Operation and Care of Ammonia Condensers, H. R. Halterman. Refrigeration, vol. 37, no. 4, Oct. 1925, pp. 48-50. Discusses specification of condensers; atmosphere, double pipe, surface, and submerged, etc.; condenser water supply, cooling pumps and cooling towers; non-condensable gases.

ARCHES

SKEW. Progress Report of Skew Arch Tests, G. W. Davis. Pub. Roads, vol. 6, no. 9, Nov. 1925, pp. 185-193, 12 figs. Discusses tests made by Division of Tests, U. S. Bur. of Pub. Roads, made necessary by skew arches proposed for federal and highway system; method of tests; tests of 60, 30, 45 and 15-deg. skew arches.

ASH HANDLING

MACHINERY, OPERATION OF. Operation of Ash Handling Machinery. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 76-77, 3 figs. Discusses care of various types of equipment in use and method of testing for combustible in ash.

AUTOMOBILE ENGINES

Crankcase-Oil Dilution. Dilution Effects on Friction Coefficients and Bearing Temperatures, A. Le Roy Taylor. Soc. Automotive Engrs.—Jl., vol. 18, no. 1, Jan. 1926, pp. 41-45, 10 figs. Describes tests made to ascertain degree of crankcase-oil dilution beyond which it is unsafe to run engine bearing, and analyzes data obtained, details of apparatus used being specified; results of tests indicate that dilution of oil up to 50 per cent has no bad effect upon engine as regards increased friction and temperatures of bearings, although dilution may be injurious from other standpoints.

AUTOMOBILE FUELS

Alcohol. The Power Alcohol Problem, H. Langwell. Indus. Chemist, vol. 1, no. 1, Feb. 1925, pp. 14-16. Describes from an economical standpoint possibilities of production of power alcohol from enormous quantities of cellulosic material at our disposal, not only at home in form of waste straw and fibrous material, but also abroad in form of tropical vegetation; shows that alcohol as a fuel for internal-combustion engines is not necessarily inferior to gasoline.

Synthetic. The Production of Synthetic Liquid Fuels, A. P. Sachs Combustion, vol. 13, no. 6, Dec. 1925, pp. 358-360. Discusses absolute necessity of having gasoline or a substitute as motor fuel, storage-battery drive being limited; production of synthetic fuels by the Badische and Bergius processes.

AUTOMOBILE INDUSTRY

Bureau of Standards Research. Bureau of Standards Builds New Brake Lining Testing Machines. Automotive Industries, vol. 53, no. 25, Dec 17, 1925, pp. 1016-1018, 2 figs. Closer readings obtained with apparatus now in use; study of linings has resulted in production of higher quality; Bureau has worked out standard test for fuels; other work under way.

AVIATION

Canada. Report on Civil Aviation. Dominion of Canada, Dept. of Nat. Defence, 1924, 56 pp., 10 figs. Review of progress made in 1923, including commercial flying, Canadian air forces and operations, aircraft industry of Canada, aerial photographic mapping, etc.

Report on Civil Aviation. Dominion of Canada, Dept. of Nat. Defence, 1925, 110 pp., 33 figs. Discusses progress in aviation during 1924 in Canada and other countries; control of civil aviation, commercial flying, Canadian air-force operations, aircraft industry, etc.

Civil. Civil Aviation. Soc. Automotive Engrs.—Jl., vol. 18, no. 1, Jan. 1926, pp. 46-47. Legal status and control; Government program regarding civil and industrial uses of aircraft; public and business support; operations abroad; operations in United States.

B

BEAMS

Vibration. The Transverse Vibration of Uniform Beams, David M. Smith. Engineering, vol. 120, no. 3130, Dec. 25, 1925, pp. 808-810, 2 figs. Establishes and applies new formula which simplifies calculation of periods of vibration of multi-span beams, and also enables rational calculations to be made for case of considerable practical importance hitherto little treated, viz., that of beam held at ends in elastic fixings which imperfectly constrain its direction.

BEARINGS

Oil-Ring. Some Limitations of Oil Ring Bearings, E. G. Gilson. Am. Mach., vol. 63, no. 26, Dec. 24, 1925, pp. 1005-1007, 3 figs. Why oil-ring bearings fail at high speeds; lubricating and cooling functions of oil; how oil-ring bearings may be made successful by correct grooving.

BLAST FURNACES

Practice, 1925. Ironmakers Study Quality of Product, R. H. Sweetser. Iron Trade Rev., vol. 78, no. 1, Jan. 7, 1926, pp. 20-22, 4 figs. Blast-furnace practice in 1925; carbon in pig iron; oxidizing of pig iron; blast-furnace capacity; new stacks are shorter and broader.

BOILER FEEDWATER

Deaeration. Feed-Water Deaeration Increases Plant Economy, J. R. McDermet. Power Plant Eng., vol. 29, no. 24, Dec. 15, 1925, pp. 1268-1270, 3 figs. Deaerators are insurance against corrosion and replace other equipment.

Systems. Feed Water Systems. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 45-49, 4 figs. Methods of purification, hot and cold chemical treatment, evaporation, deaeration, recirculation and filtering; methods of heating; boiler-feeding arrangements, pumps, methods of control, economizer operation.

BOILER FIRING

Cleaning Fires. Method of Cleaning the Boiler Fires at a Pumping Station. Eng. & Boiler House Rev., vol. 39, no. 6, Dec. 1925, pp. 270 and 272, 1 fig. Particulars of principal features of station pumping capacity of which was 5,000,000 gal. per day; operating routine, with particular reference to method of cleaning fires.

Hand Firing. Hand Firing for Power Boilers. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 31-36, 12 figs. Points out that personal element is more of deciding factors in fuel saving than with power stokers.

BOILER FURNACES

Cass Type. The "Cass" Sprinkler Stoker and Self-Cleaning Furnace. Iron & Coal Trades Rev., vol. 111, no. 3014, Dec. 4, 1925, pp. 918-919, 6 figs. Design and construction of stoker and furnace introduced by Thos. Cass & Co., Bolton; furnace is arranged so that each channel bar has a slow two-and-fro motion of about 3 in. in either direction, which motion is transmitted by cams from a pair of driving shafts under front of furnace, operated through a worm wheel.

Secondary Air Supply. Modern Furnaces and Secondary Air Supply. Eng. & Boiler House Rev., vol. 39, no. 6, Dec. 1925, pp. 267-268, 1 fig. Deals with method and apparatus for securing and maintaining higher average furnace temperature; use of ventilated or perforated firebrick; furnace-arch design; use of preheated air.

Wood-Waste-Burning. Special Furnaces Required for Wood Waste. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 36-40, 5 figs. Means for handling wood waste; requirements for combustion; features of furnace and grates.

BOILER OPERATION

Fuel and Draft Control. Automatic Control of Fuel and Air to Boilers, H. M. Hammond. Power Plant Eng., vol. 29, no. 24, Dec. 15, 1925, pp. 1259-1261, 4 figs. Steam pressure shows relation of inflow and outflow of B.t.u. and controls regulate amount and proportions of fuel and air for balance.

BOILER PLANTS

Fulham Borough, Great Britain. Vickers Boilers at Fulham. Power Engr., vol. 20, no. 237, Dec. 1925, pp. 468-470, 3 figs. New generating and boiler plant recently placed in commission at Fulham Borough electricity works; boiler plant is self-contained and comprises three 40,000-lb. units, each complete with its own economizer, forced-draft fan and Prat induced-draft fan and stock.

Pulverized-Coal-Fired. Pulverized Coal to Replace Hand Firing. Power Plant Eng., vol. 29, no. 24, Dec. 15, 1925, pp. 1279-1280, 2 figs. Demand for increased economy and capacity has led Lambert Tire & Rubber Co. to build new boiler plant.

BOILERS

Design. Boilers and Boiler Auxiliaries. Power, vol. 63, no. 1, Jan. 5, 1926, pp. 4-8, 2 figs. Air preheating and water-cooled walls prominent in furnace design; improved metals give preference to high temperatures over high pressures; present limitations and status of various auxiliaries.

Feeding Equipment, Operation of. Operation of Boiler Feeding Equipment. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 52-59, 15 figs. Arrangements of piping and valves; operation of pumps; pump governors and feed-water regulators; priming and water level.

Fireless. Fireless Boiler Generates Steam at 1,500-lb. Pressure. Power, vol. 62, no. 26, Dec. 29, 1925, pp. 1007-1009, 2 figs. Evaporation produced by superheated steam blown through water in steel drum; hot gases come in contact with superheater and economizer tubes only, steam-generating drums being located outside of boiler setting; experimental plant successfully tried out in Vienna, Austria; 1000-kw. plant under construction and 18,000-kw. plant started.

Heat Balance. The Daily Heat Balance, W. H. Wood. Combustion, vol. 13, no. 6, Dec. 1925, pp. 351-354. Discusses introduction of recording steam-pressure gages, CO_2 recorders, etc.; advocated employment of a fuel and combustion supervisor for large steam plants whose duty would be to see that fuel is burned as economically as possible; chief preventable losses are: heat carried away in flue gases, carbon in ash pit, unburned combustible gases, unburned solid carbon deposited in boiler or carried out of stack.

Internal-Combustion. Another Internal Combustion Boiler. Eng. & Boiler House Rev., vol. 39, no. 5, Nov. 1925, pp. 220 and 216, 1 fig. Principles of Weir proposal, which is to burn fuel under high pressure, when products of combustion are mixed with certain proportion of water which is vaporized by heat of combustion.

Joints for Air-Leakage Prevention. Preventing Air Leakage on Cylindrical Boilers Eng. & Boiler House Rev., vol. 39, no. 5, Nov. 1925, pp. 228 and 230, 2 figs. Describes Bramwell expansion joints for keeping front and back ends of boilers air-tight.

Patents, 1925. Boiler and Auxiliary Patents of 1925, N. Frucht. Power, vol. 63, no. 1, Jan 5, 1926, pp. 26-29, 4 figs. Patent-office records reveal trend in boiler designs; new baffle arrangements; mercury-boiler developments; superheater and accumulator claims.

Scale Prevention. A New Process for Boiler Scale Prevention. Eng. & Boiler House Rev., vol. 39, no. 5, Nov. 1925, pp. 232-233, 2 figs. Describes filtrator apparatus, and principle upon which it works.

Strains in. Experiments on Strains in Boilers, C. E. Stromeyer. Engineer, vol. 140, no. 3650, Dec. 11, 1925, pp. 649-650, 6 figs. Measurements were carried out which throw light on nature and intensity of bending strains, which up to now have not been measured; results of tests on small locomotive portable boiler; donkey boiler dished crown plate; lap-joint bending; stresses near lap joints; shell-extension experiments. Memorandum of Manchester Steam Users' Assn.

Waste-Heat. Results of Questionnaire on Waste Heat Boilers, C. H. Wilcox. Gas Age-Rec., vol. 56, no. 22, Nov. 28, 1925, pp. 777-778. Details of statistics supplied by 22 different companies in answer to a question blank containing 17 questions.

Water-Level Gages A New Boiler Water Level Indicator. Eng. & Boiler House Rev., vol. 39, no. 5, Nov. 1925, p. 235, 2 figs. New design, put on market by Ferguson Superheaters, Ltd., is capable of either indicating or recording or both.

See also Steam Generators.

BORING MACHINES

Traversing Spindle. Pearn-Richards Machine with Traversing Spindle. Brit. Machine Tool Eng., vol 3, no. 36, Nov.-Dec., 1925, pp. 343-346, 4 figs. Design and operation of improved traversing spindle machine and provision of various attachments further extending varied operations that may be performed at one setting of the work.

BRAKES

Reducing Valve for Vacuum. Reducing Valve for the Vacuum Automatic Brake. Engineer, vol. 140, no. 3650, Dec 11, 1925, p. 645, 1 fig. New type of reducing valve made by Gresham & Craven, Manchester, Eng., for use with vacuum automatic brake being tested on railways in England and in India.

BRASS

High-Tensile. Notes on High Tensile Brasses, Thibaud. Foundry Trade Jl., vol. 32, no 486, Dec. 10, 1925, p. 498. Practical summary of all information already collected on subject of high tensile brasses; influence of constituents; incorporation of metal additions; melting high-tensile brass; moulding.

BRIDGES, STEEL

Demolition of Cantilever. Demolition of Niagara Falls Cantilever Bridge, H. Ibsen. Eng. News-Rec., vol. 95, no 27, Dec. 31, 1925, pp. 1058-1063, 5 figs. Expeditious fieldwork in unusual undertaking complicated by difficult location; 3-truss bridge taken down by reversal of cantilever erection method.

BRIQUETTING

Binders. Binders for Briquetting, with Special Reference to "Pulp Binders", C. J. Goodwin. South Wales Inst. of Engrs.—Proc. vol. 41, no. 5, Dec. 12, 1925, pp. 443-461. Details of experience with binders other than pitch, including starches, such as cassava or sago, sea-weed extract, mixed with pitch or bitumen, and sulphite liquor; production and cost of pulp binders.

BUILDING CONSTRUCTION

Steel. Structural Development During 1925, C. R. Young. Contract Rec., vol. 39, no. 52, Dec. 30, 1925, pp. 43-47, 4 figs. Discusses recent advance in steel frame construction, structural welding, reinforced concrete buildings, further adoptions of specifications of Am. Inst. of Steel Constr.

C

CABLES, ELECTRIC

Faults, Locating of. Locating Underground Cable Faults. Elec. World, vol. 86, no. 26, Dec. 26, 1925, pp. 1297-1300, 8 figs. Apparatus used by United Elec. Light & Power Co. traced through various stages of development; modern equipment and test methods show reliable results under all conditions.

Vibration. Overcoming Vibration in Transmission Cables, G. H. Stockbridge. Elec. World, vol. 86, no. 26, Dec. 26, 1925, pp. 1304-1305, 4 figs. Experience of Southern California Edison Co. shows necessity for damping vibration in transmission spans; special device to be installed on new line.

CABLEWAYS

Aerial Tramways. Fordson Engineers "Span" Their Difficulties, J. H. Edwards. Coal Age, vol. 28, no. 26, Dec. 24, 1925, pp. 887-888, 7 figs. Methods employed by Fordson Coal Co., at Stone, Ky., of disposing of mine refuse by aerial tram; double cable is used to support aerial hanger.

CANALS

Welland. Welland Canal Construction Progress. Can. Engr., vol. 49. no. 26, Dec. 29, 1925, pp. 667-673, 11 figs. Details of progress made in construction of Welland ship canal; locks, their location, size of gates; bridges and piers; rock drilling, breakwaters, etc.

CAST IRON

Engineering Practice and. Cast-Iron and Modern Engineering Practice, J. G. Pearce. Engineering, vol. 120, no. 3129, Dec. 18, 1925, p. 781. (Abridged.) Paper read before (Brit.) Inst. Mech. Engrs.

Graphite in. Graphite in Cast Iron. Metal Industry (Lond.), vol. 27, nos. 18 and 22, Oct. 30 and Nov. 27, 1925, pp. 411-414 and 511-513, 10 figs. Nature and influence of graphite in structure; solubility of carbon in iron and effect of other constituents; effect of mass on graphite separation and rate of cooling effects, particularly in respect to how some resulting difficulties can be overcome, as by use of low-carbon metal; photomicrographs. Nov. 27: Forging cast iron; crucible cast iron; special cases of nodular graphite.

Gray, Influence of Special Elements on. The Influence of Special Elements on Grey Cast Iron, J. W. Donaldson. Foundry Trade Jl., vol. 32, no. 489, Dec. 31, 1925, pp. 553-555 and (discussion) 555-556. Investigations of influence of manganese, chromium, nickel, tungsten, molybdenum, vanadium, copper, tin, aluminum, titanium; heat treatment of alloy cast irons; conclusions.

Growth. The Growth of Cast Iron. Metallurgist (Supp. to Engineer), Nov. 27, 1925, p. 161. Review of studies on this subject.

Research, Application of. Some Applications of Research to Modern Foundry Practice, J. E. Fletcher. Engineering, vol. 120, no. 3129, Dec. 18, 1925, pp. 781-783, 8 figs. Author seeks to illustrate in some detail a few examples of type of work and method of attack used in applying results of research to current foundry practice; skin defects, shrinkage and contraction; trend of future developments in cast iron. (Abridged.) Paper read before (Brit.) Instn. Mech. Engrs.

Silicon, Influence of. Practical Points from Published Papers, B. Rogers. Foundry Trade Jl., vol. 32, no. 489, Dec. 31, 1925, pp. 547-548. Sulphur prints; influence of silicon upon carbon in cast iron; Hamasumi's experiments on influence of silicon upon cast iron; whirling graphite; influence of silicon upon combined carbon; ratio of silicon to combined carbon; further experiments by Hamasumi.

CASTING

Centrifugal. Notes on the centrifugal Casting Process with Special Reference to the Hurst-Ball Process, J. E. Hurst. Foundry Trade Jl., vol. 32, nos. 480 and 481, Oct. 29 and Nov. 5, 1925, pp. 361-365 and 381-384, 12 figs. Oct. 29: Commercial application of centrifugal casting method; axis of rotation; method of pouring; rotating mold. Nov. 5: Life cf metal molds; typical defects; surface depressions and pinholes; inside surface defects; characteristic roughening of inside surface; chemical composition and other properties of molten metal; application and advantages of centrifugal casting process. Bibliography.

CASTINGS

Sand Blasting. Sandblasting Castings, H. Orr. Abrasive Industry, vol. 6, no. 12, Dec. 1925, pp. 367-370, 3 figs. Discusses methods of preparing surfaces and sand blasting; direct-pressure, suction, and gravity system; determination of velocity of air, abrasive materials, nozzles, etc.

CEMENT, PORTLAND

Manufacture. Calcium-Sulphate Retarders for Portland Cement. E. E. Berger, U. S. Bur. of Mines—Reports of Investigation, no. 2705, Sept. 1925, 20 pp., 9 figs. on supp. plates. Discusses reaction of Portland cement with calcium-sulphate and form or mixture of forms best adapted for retarder; determination of time of set and of tensile strength; effect of different retarders on consistency and plasticity of clinker.

CENTRAL STATIONS

Centralized Management. Record Trend to Centralized Management. Elec. World, vol. 87, no. 1, Jan. 2, 1926, pp. 24-28. Gives table of mergers of central-station systems during 1925, involving 560 companies.

Construction 1925. A Year of Intensive Construction. Elec. World, vol. 87, no. 1, Jan. 2, 1926, pp. 53-56. Statistical data on steam and hydro-electric generating plants under way in United States and Western Canada during 1925; total of 7381 mi. of high-tension transmission line erected during year.

Interconnection. Interconnection Saves South. Elec. World, vol. 87, no. 2, Jan. 9, 1926, pp. 91-94, 7 figs. Water shortage of unprecedented magnitude is met by utility executives through pooling generating resources and interconnecting their systems; details of operations future plans.

Statistics 1925. 1925 a Record Year. Elec. World, vol. 87, no. 1, Jan. 2, 1926, pp. 7-10, 3 figs. Energy generated during year totaled 59,517,000,000 kw-hr.; gross revenue is estimated at $1,470,000,000; distinct trends which were established during year.

CLAY

China. China Clay and Silica Sand in Kipling Township, Ontario, S. Hancock, Jr. Can. Min. Jl., vol. 46, nos. 51 and 52, Dec. 18 and 25, 1925, pp. 1149-1151 and 1178-1179, 4 figs. Describes properties situated in Timiskaming Mining Division; discusses discovery, exploration by bore holes, origin of deposits, uses of china clay or kaolin, comparison with Cornis china clay, market for china clay, silica sand, fireclay, timber, water power fuel; transportations, etc.

COAL

Analysis. Commercial Methods of Coal Analysis, R. P. Hudson. Modern Min., vol. 2, no. 12, Dec. 1925, pp. 382-384, 1 fig. Points out that coal cannot be properly evaluated in any way except by chemical analysis; few impurities removable; analysis alone tell how well coal is cleaned; determination of moisture ash and sulphur.

Ash. Coal Ash and Clean Coal, R. Lessing. Gas Jl., vol. 172, no 3265, Dec. 9, 1925, pp. 650-654. Chemical and physical behavior in combustion process, fusibility of coal ash, ash as inert matter, influence of ash composition and catalytic influence of mineral constituents; hydrogenation and total conversion into oils.

Carbonization. The Carbonization Plant of the Midland Coal Products, Limited. Engineering, vol. 120, no. 3129, Dec. 18, 1925, pp. 757-758, 4 figs. Review of report of test by Director of Fuel Research on carbonizing plant of Midland Coal Products, Netherfield, Nottingham; carbonizing process is effected by burning part of charge in neighborhood of tuyeres, combustion being maintained by air and steam passing through them; hot gas on its way up to off-take services to head briquettes as they find their way down the retort.

Preparation. Preparation of Commercial Coal, Thos. Fraser. Modern Min., vol. 2, no. 12, Dec. 1925, pp. 395-398. Commercial coal is defined as coal to be sold on open market as domestic, steam and general-purpose-fuel, in contra-distinction to that intended for metallurgical and other special purposes requiring special qualifications; object of preparation; sizing; method of cleaning; requisites of cleaning plant; feasibility of hand picking; washer loss or shrinkage; impurity separation and adjustment. Paper delivered before W. Va. Coal Min. Inst. See also Coal Trade Bul., vol. 54, no. 3, Jan. 2, 1926, pp. 113-116.

Pulverized. *See Pulverized Coal.*

COAL HANDLING

Equipment. Modern Coal-Handling Equipment, E. Zeuthen, Elec. World, vol. 87, no. 2, Jan. 9, 1926, pp. 87-89, 3 figs. Designed to cut labor cost for power stations and insure continuous coal supply; describes electrical equipment used in modern station.

Peck Carrier. Coal Handling with Overlapping Buckets, F. Dawson. Eng. & Boiler House Rev., vol. 39, no. 5, Nov. 1925, pp. 222-223, 2 figs. Describes principal features of Beck Carrier, adopted almost universally in United States.

COAL INDUSTRY

Nova Scotia. Marketing Nova Scotia Coals, H. A. Hatfield. Eng. Jl., vol. 9, no. 1, Jan. 1926, pp. 19-21. Suggested investigation and educational campaign to promote wider use of these fuels.

COAL MINES

Code of Standards. Union Pacific Coal Co.'s Code of Standards. Coal Age, vol. 28, nos. 26 and 27, Dec. 24 and 31, 1925, pp. 892-893 and 928-929, 17 figs. Code of standards put into effect by Union Pac. Coal Co. at its operations in Wyoming. Dec. 24: Lighting and light wires; cables and power lines; signal and phone lines; rules for wiring underground stations; hoists; switchboards. Dec. 31: Transformers and transformer values; wiring of surface buildings and tipples; overhead distributing lines; instructions to persons inspecting electrical equipment; safety standards.

Nova Scotia. No. 1-B Colliery of the Dominion Coal Company, Limited, A. L. Hay. Eng. Jl., vol. 9, no. 1, Jan. 1926, pp. 12-18, 3 figs. Describes new colliery of Dominion Coal Co. at Glace Bay, N. S., which contains features new to coal-mining practice in that province.

Permissible Equipment. Permissible Mining Equipment Approved Prior to January 1, 1925, L. C. Ilsley, U.S. Bur. of Mines, Tech. paper, no. 376, 1925, pp. 17-25. Details of permissible explosion-proof equipment approved prior to Jan. 1, 1925, including motors, electric switches, portable electric lamps, flame safety lamps; methane indicators, etc. with explanatory notes and specifications.

COAL MINING

Shot Firing. Improved Blasting Methods Increase Proportion of Lump Coal in Output, J. E. Tiffany. Coal Age, vol. 28, no. 26, Dec. 24, 1925, pp. 881-886, 16 figs. Points out that standard shooting practice should be adopted; shot-hole placement, size of cartridge, kind of stemming, all exert non-cumulative influences. (Abstract.) Paper read before West. Va. Coal Min. Inst.

COKE OVENS

By-Product. By-Product Coke-Oven Practice, R. A. Mott. Fuel, vol. 4, no. 12, Dec. 1925, pp. 528-546, 33 figs. Coke quality as related to coal used; fractures in coke; path of travel of gases in oven.

COLUMNS

Underpinning by Girders. First-Story Columns Cut Away in Building Enlargement. Eng. News-Rec., vol. 95, no. 24, Dec. 10, 1925, pp. 950-953, 5 figs. Extension of 12-story bank building required underpinning two volumns by girders at second and third floor levels.

COMBUSTION

Control. Automatic Combustion Control. Eng. & Boiler House Rev., vol. 39, no. 5, Nov. 1925, pp. 213-216, 4 figs. Describes principal features of Bailey meter control as applied to recent American superpower stations.

CONCRETE

Aggregates. Weighing vs. Measuring Aggregate for Concrete, E. E. Glass. Rock Products, vol. 28, no. 24, Nov. 28, 1925, pp. 59-61, 1 fig. Discusses advantages of weighing, and a new rule for designing concrete mixtures by weight.

Aggregate Specifications. Standardization of Specifications for Sand, Rock and Gravel, C. L. McKesson. Rock Products, vol. 28, no. 24, Nov. 28, 1925, pp. 62-63. Details of standard specifications adopted by California Highway Engineers for sand and gravel, screened sizes; demonstrates feasibility of local specification standards.

CONCRETE CONSTRUCTION, REINFORCED

Calculation. Combined Bending and Direct Force, C. E. Reynolds. Concrete & Constr. Eng., vol. 20, no. 12, Dec. 1925, pp. 673-684, 4 figs. Discusses pratical and comparatively simple method of designing and analysing reinforced-concrete members of rectangular section that are subjected to bending moments and direct thrusts or pulls.

Slabs. Tests of Hollow Tile and Concrete Slabs Reinforced in one Direction, D. E. Parsons and A. H. Stang. U.S. Bur. of Standards Technologic Papers., no. 291, Aug. 12, 1925, pp. 465-514, 19 figs. Discusses tests of beams which represented sections of typical combination hollow tile and concrete floor slabs for resisting bending and shearing stresses; concludes that for beams without topping each hollow tile and concrete rib in the combination beams is equivalent in strength to a rectangular concrete beam having a width at least equal to width of concrete rib plus $1.3 (s/w) \frac{ET}{Ec}$ where EC equals 2,000,000 lbs. /in.2, s= thickness of one vertical tide shell, inches, w= thickness of one vertical tile web, inches and Et= modulus of elasticity of the tiles, lbs. /in.2.

CONCRETING

Cold-Weather. Heating of Aggregates Necessary When Placing Concrete in Winter, A. M. Bouillon. Ry. Eng. & Maintenance, vol. 21, no. 12, Dec. 1925, pp. 485-487, 4 figs. Comparison of methods to be followed when carrying on work at extremely low temperatures.

CONDUITS

PRESSURE. The Drac-Romanche Water Power Undertaking. Engineering, vol. 140, no. 3652, Dec. 25, 1925, pp. 692-693, 7 figs. partly on p. 696. Details of pressure pipe of 6-m. internal diam. constructed in connection with power station near Grenoble in French Alps; built of reinforced concrete; construction methods.

CONNECTING RODS

MILLING. Milling Motor Lorry Connecting Rods, Machy. (Lond.), vol. 27, no. 692, Dec. 31, 1925, pp. 446-448, 6 figs. Complete tooling equipment for milling operations on connecting rods for motor trucks.

CORROSION

METALLIC. Metallic Corrosion, W. S. Patterson. Inst. Marine Engrs.—Trans. vol. 37, Nov. 1925, pp. 437-447. Discusses modern theories of mechanism of corrosion, especially electrochemical theory and its primary value in study of corrosion; type of corrosion which persists in acid and in neutral media, water-line corrosion; effect of corrosion deposits and debris.

COST ACCOUNTING

FACTORY. Business Methods, J. Craig. Can. Mfrs., vol. 45, no. 12, Dec. 1925, pp. 15-17. Cost accounting as aid to factory production and executive control.

CRANES

FLOATING. 300-Ton Floating Crane for Handling Concrete Blocks. Engineering, vol. 120, no. 3130, Dec. 25, 1925, pp. 797-798, 9 figs. partly on supp. plate. Details of 300-ton crane built by N. V. Internationale Scheepsbouw, Maatschappj de Maas, Holland, to be used for harbor work in Spain.

STANDARDIZATION. The Standardization of Crane Essentials, E. C. Fiegehen. Engineer, vol. 140, no. 3649, Dec. 4, 1925, pp. 600-602, 1 fig. Summary of chief objects which might be attained by uniformity in practice proposed, namely (1) to secure uniform basis for tendering; (2) to increase efficiency of crane inspection and testing; (3) to protect public against dangerous construction and conditions; (4) to secure undoubted economies resulting from greater uniformity in demand and manufacture; discusses technical aspects of standardization.

UNDERHUNG TRAVELLING JIB. Underhung Travelling Jib Crane. Engineer, vol. 140, no. 3650, Dec. 11, 1925, p. 648, 2 figs. One-ton, four-motor, overhead electric travelling cranes with underhung revolving jibs, constructed by Vaughan Crane Co., Manchester, Eng., for Kilindini Harbor, on Uganda Ry.

CRUSHERS

OPERATION. Notes on Grinding and Crushing Machinery, F. Lane. Ceramic Soc.,—Trans., vol. 24, part 4, 1925, pp. 310-324, 13 figs. Discusses gyratory breakers, dry grinding by edge runner mills, grinding by rolls; getting rid of reduced sizes in order to bring surfaces of material to action of the machine; arranging feed in regular and sufficient quantities to suit output of machine; limit size of largest pieces fed; limit water content of feed; and keeping discharge clear.

CUPOLAS

SUCCESSFUL PRACTICE. Successful Cupola Practice. Metal Industry (Lond.), vol. 27, no. 24, Dec. 11, 1925, pp. 561-562. In author's opinion, state of cupola practice at present time is below that which would be expected from the considerable amount that has been written on subject; he believes this is due more to impractical nature of advice than to disinterestedness of foundryman to act upon it; describes chief essentials to successful cupola practice.

TUYERES. The Tuyere Problem. Metal Industry (Lond.), vol. 27, no. 23, Dec. 4, 1925, pp. 539-540. Author consideres that there is much needless controversy about shape of tuyeres; within reasonable limits tuyere shape is relatively unimportant compared with other items in cupola practice; discusses question as to whether more than one row of tuyeres should be used, and points out that, in few cases where this might be desirable, extra rows should not be designed similarly to first.

Tuyere Arrangement. Metal Industry (Lond.), vol. 27, no. 25, Dec. 18, 1925, pp. 583-584, 1 fig. Gives experimental evidence to show that use of two rows of tuyeres can give very definite advantages over use of one row of tuyeres of same total area.

CUTTING METALS

BUTANE TORCHES. The Production of Butane and the Butane Torch. Natural Gas, vol. 6, no. 9, Sept. 1925, pp. 12, 2 figs. Production of butane and its application to cutting metals with a blow torch, especially designed to use butane.

CYLINDERS

DRAWN. The Production of Deep Drawn Cylinders, W. J. Guyer. Forging—Stamping—Heat Treating, vol. 11, no. 12, Dec. 1925, pp. 427-429, 3 figs. Discusses importance of selecting proper stock, lubrication, annealing and pickling; life and wearing properties of die steels.

D

DAMS

ARCH. Arch Dam Repaired by Fills Above and Below Structure, J. E. Field. Eng. News-Rec., vol. 95, no. 24, Dec. 10, 1925, pp. 953-954, 3 figs. Repair methods on Colorado dam designed to reduce water seepage and to relieve thrust forces on arch.

CONCRETE. Study on Reinforced Concrete Dams, E. G. Harris. Univ. of Minn. School of Mines and Metallurgy, vol. 8, no. 3, May, 1925, pp. 1-53, 16 figs. Discusses four types of dams trapezoidal gravity, arched, horizontal beam and vertical beam types; spacing of columns; expansion joints; advantages and disadvantages of each type.

DIE CASTING

PROCESS AND MACHINES. Die Casting, N. F. Budgen. Engineering, vol. 120, no. 3129, Dec. 18, 1925, pp. 777-778. Advantages of die-casting process; disadvantages of die castings; die-casting machines, their design and working; dies for die casting; metals and alloys for die castings.

DIES

STEERING-WHEEL SPIDERS. Dies for Steering-Wheel Spiders, Jas. M. Acklin. Machy (N. Y.), vol. 32, nos. 4 and 5, Dec. 1925, and Jan. 1926, pp. 283-285, 9 figs. and 388-390, 7 figs. Construction of dies used in stamping hub for spiders of automobile steering wheels.

DIESEL ENGINES

DEVELOPMENTS. Growth of the Diesel Engine Field, R. C. Paul. Power Plant Eng., vol. 29, no. 24, Dec. 15, 1925, pp. 1277-1278, 1 figs. Building units of both larger and smaller sizes has opened new fields for Diesel engines during past year.

DRILLING

ROTARY. Mechanical Safeguards in Roraty Drilling. H. C. Miller. U.S. Bur. of Mines—Tech. Paper no. 369, 1925, 39 pp., 30 figs. Discusses safety in oil fields and safeguards used on rotary draw-works, rotary table and drilling engine in oil fields of California; methods of care and safeguards used to protect life and limb; encourages installation of safeguards at drilling wells to reduce machinery hazards to a minimum.

DRILLING MACHINES

AUTOMATIC FEED. Automatic Feed on Sensitive Drilling Machines. Machy. (Lond.), vol. 27, no. 692, Dec. 31, 1925, pp. 411-445, 13 figs. Self-starting and quick-starting mechanisms.

RADIAL, TRANSMISSION AND CONTROL. Transmission and Control on Radial Drilling Machines. Machy. (Lond.), vol. 26, nos. 653, 7671 and 678, Apr. 2, Aug. 6, and Sept. 24, 1925, pp. 1-5, 580-584 and 809-813, 35 figs. Deals with methods of conveying power to spindles of radial drilling machines and arrangements for controlling positions and effecting locking.

E

ECONOMIZERS

OPERATION AND MAINTENANCE. Economizer Operation and Maintemance. Power Plant Engr., vol. 30, no., Jan. 1, 1926, pp. 62-64, 5 figs. Cleanliness of tubes and keeping of water and gas at proper temperatures are of great importance; soot removed by scraping; occasional explosions due to vapor pressure; cast-iron or steel tubes may be used.

TYPES. General Types of Fuel Economizers, W. F. Keenan, Jr. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 60-62. Higher steam pressures and temperatures have created increased demand for economizers.

EDUCATION, ENGINEERING

GRADUATES. A Study of Engineering Graduates and Former Students, Non-Graduates. Jl. Eng. Education, vol. 16, no. 4, Dec. 1925, pp. 259-268. Details of report based on questionnaire replies as to occupation and earnings of graduates and their opinion on engineering education.

TEACHING PERSONNEL. A Study of Teaching Personnel of the Colleges of Engineering. Jl. Eng. Education, vol. 16, no. 4, Dec. 1925, pp. 299-311, 2 figs. Details of report based on circular inquiry concluding that real problem is to secure right type of teachers for engineering faculties, and that this constitutes a major problem in engineering education.

EDUCATION, INDUSTRIAL

BALTIMORE PLAN. The Baltimore Plan of Industrial Education, E. B. Luce. Am. Gas Jl., vol. 123 no. 26, Nov. 28, 1925, pp. 583-584 and 598, 3 figs. Describes plan as developed and applied by Consolidated Gas, Electric Light & Power Co. of Baltimore.

ELASTICITY

MODULUS OF. Relations between Young's Modulus and Other Physical Quantities, J. P. Andrews. Lond., Edinburgh & Dublin Philosophical Mag. & Jl. of Sci. vol. 50, no. 298, Oct. 1925, pp. 665-674, 4 figs. Discusses attempts made to connect Young's modulus with other physical constants and shown that among those only that of Clemens Schaefer between temperature coefficients and melting point is borne out by experiments.

ELECTRIC DISTRIBUTION SYSTEMS

TRENDS IN DEVELOPMENT. Trends in Distribution, A. M. Kehoe. Elec. World, vol. 87, no. 1, Jan. 2, 1926, pp. 51-52, 1 fig. All systems seek to improve service reliability; increased load densities have introduced a.c. netnorks; multiple-feed systems popular; light and power supply from common mains.

ELECTRIC FURNACES

BRASS AND BRONZE. The S.B.N. Simplex Electric Furnace (Four électrique S.B.N. "Simplex"). Jl. du Four Electrique, vol. 34, no. 16, Nov. 15, 1925, pp. 219-222, 2 figs. Details of design and operation of the Nolly furnace, of special interest for brass and bronze foundries; may be worked by a.c. one, two or three phase, or even by d.c.; has two water-cooled electrodes of large cross section.

STEEL. Electric Furnace Steel, F. T. Sisco. Am. Soc. Steel Treating—Trans., vol. 8, no. 6, Dec. 1925, pp. 748-770 and (discussion) 771-781 1 fig. Basic electric process is used for manufacture of high-grade alloy and tool-steel ingots, occasionnally for castings; acid process is used principally for castings; advantages of electric process are: (1) extreme flexibility and (2) high-quality steels produced in tonnage lots; direct arc furnace with non-conducting hearth is used almost exclusively in United States; charging, melting, chemistry of oxidation, control of oxidation in melting; slagging off and carburization; deoxidation period; deoxidizing slag; deoxidation of slag and metal; desulphurization and degasification.

ELECTRIC-GENERATORS, A.C.

SELF-EXCITATION. Self-Excitation of Alternators connected to High Voltage Tranmission Lines, M. Takahashi. Electrotechnical Lab.—Researches, (Tokyo, Japan), no. 155, April, 1925, pp. 1-31, 35 figs. Discusses graphic solution of self-excitation of alternators when charging a no-load transmission line; usually explained by line-charging characteristics and saturation curve excited by armature current; proposes new exact method based on knowledge of armature leakage reactance.

ELECTRIC MOTORS

CURRENT LOCUS. General Criterion for the Circular Locus of the Current Vector in A.C. Circuits and Machinery, V. Karapetoff. Nat. Acad. Sciences,—Proc., vol. 11, no. 11, Nov., 1925, pp. 683-687, 2 figs. Deduces general equation of the circle; electromagnetic vectorial equations of stationary circuit and of revolving electrical machine at voltage E, are written, and it is shown how to eliminate one of the variables v and to reduce the resulting equation for current I to that of a circle.

ELECTRIC MOTORS, A.C.

COMPENSATED INDUCTION. Compensated Induction Motor, T. Torda. Elec. World, vol. 86, no. 24, Dec. 12, 1925, pp. 1205-1206, 4 figs. European motor uses Leblanc principle with one rotor having separate compensating winding in separate slots; design data and operating characteristics.

ELECTRIC POWER

PACIFIC NORTHWEST. Electric Power in the Northwest. Elec. World, vol. 86, no. 25, Dec. 12, 1925, pp. 1194-1199, 4 figs. Review of recent construction, with comments on future developments, interconnection, load building and market possibilities.

ELECTRIC SWITCHES

AIR-BREAK. Essential Qualities in Air-Break Switch, J. E. Reynolds. Elec. World, vol. 86, no. 24, Dec. 12, 1925, pp. 1200-1210, 1 fig. Design of switches discussed from operating standpoint, giving necessary features for successful service describes proposed quick-break air switch.

ELECTRICAL APPARATUS

DEVELOPMENTS. Developments in Electrical Apparatus, E. C. Stone. Elec. World, vol. 87, no. 1, Jan. 2, 1926, pp. 41-44, 3 figs. Outlines utility systems and their developments and surveys status of apparatus for use on three systems; indicates new developments of year.

PROGRESS, 1925. No Radical Changes in Electrical Apparatus. Power, vol. 63, no. 1, Jan. 5, 1926, pp. 24-26, 3 figs. Minor improvements, moderate increase in size of units, hydrogen as cooling medium and new types of synchronous motors mark progress during year.

ELECTRICITY SUPPLY

INDUSTRIAL LOAD, UNITED STATES. Industrial Load of the United States, R. M. Davis. Elec. World, vol. 87, no. 1, Jan. 2, 1926, pp. 44-49. Potential industrial field of central stations only 44 per cent developed; rating of generators in private plants totals 5,913,462 kva.; Mountain-Pacific states lead in degree of industrial electrification.

ELEVATORS

Machining of Units. Making Elevator Units in the Otis Plant, F. W. Curtis. Am. Mach., vol. 63, nos. 26, and 27, Dec. 24 and 31, 1925, pp. 999-1002 and 1039-1042, 19 figs. Dec. 24: Method of machining sheaves; milling magnet-frame covers; drilling and planing operations; miling and boring gear cases. Dec. 31: Type of trunnion drill jig used for various parts; procedure followed in producing laminations; details of dies used; special burring machine.

EMPLOYMENT MANAGEMENT

Absenteeism. Controlling Absenteeism in Factories, E. J. Clary. Can. Mfr., vol. 45, no. 10, Oct. 1925, pp. 18-19. Gives suggestions and remedies, to secure regular attendance of employees.

ENERGY

Forms and Classes. Energy, A. M. Boyce. Instn. Elec. Engrs.—Jl., vol. 64, no. 348, Dec. 1925, pp. 42-44. Discusses different forms of energy ,and points out that energy can be divided into two classes, viz., potential and kinetic energy.

ENGINEERS

Civilization and. The Engineer and Civilization, W. F. Durand. Mech. Eng., vol. 48, no. 1, Jan. 1926, pp. 1-5 and 66. Notes on beginnings of material civilization; arrow-head maker as prototype of industrialist and engineer; primitive utilization of mechanical laws; great antiquity of engineering profession; modern material civilization a product of the engineering guild; how engineer may best serve cause of advancing civilization; part engineering societies have played in developments signalizing last half-century; duty of engineer as regards conservation of natural resources; renewal of personnel in engineering profession through technical education; engineering method and its application to public questions.

EVAPORATION

Water. On the Influence of Thin Surface Films on the Evaporation of Water, E. K. Rideal. Jl. of Physical Chem., vol. 29, no. 12, Dec. 1925, pp. 1585-1588, 1 fig. Rates of evaporation of water and of water covered with unimolecular films of various fatty acids; the latter are found to be much slower than from a clean water surface.

EVAPORATORS

Problems in Use of. Technical Notes on Evaporators, H. Seymour. Indus. Chemist, vol. no. 5, pp. 254-258, 8 figs. Discusses problems that arise in use of evaporators.

EXPLOSIONS

Gaseous. Gaseous Explosions, Geo. G. Brown. Indus. & Eng. Chem., vol. 17, no. 12, Dec. 1925, pp. 1229-1232, 2 figs. Homogeneous and heterogeneous reactions defined and classified.

EXPLOSIVES

Detonation Gases. An Apparatus for Studying Gases of Explosives Detonated Under Confinement, J. E. Crawshaw and G. W. Jones. Eng. & Min. Jl.-Press, vol. 120, no. 25, Dec. 10, 1925, pp. 965-967, 1 fig. Describes an experimental apparatus whereby gaseous products of detonation may be obtained from explosives under confinement, and in a way approximate conditions under which explosives are used in mines. Mines investigations cover a period of 50 years.

F

FANS

Centrifugal, Motor Drives for. Motor Drives for Centrifugal Fans and Blowers, G. Fox. Power Plant Eng., vol. 30, no. 2, Jan, 15, 1926, pp. 141-144, 6 figs. Selection of motors for driving centrifugal fans requires close study of fan characteristics.

FILTRATION PLANTS

Wheeling, W. Va. The Wheeling (West Virginia) Filtration Plant and some Operating Results, J. F. Laboon. New England Water Works Assn.—Jl., vol. 39, no. 4, Dec., 1925, pp. 291-319, 12 figs. Details of new filtration plant of 20,000,000 gal. per 24 hours capable of being enlarged to 40,000,000 gal., so designed in regard to chemical equipment and mixing facilities that filtration works may serve as softening plant; details of grit chamber, mixing chamber settling basins, filters, coagulant house, results of tests and operation.

FLOW OF FLUIDS

Measurement. Measurement of the Rate of Flow of Fluids by the Rotameter, W. H. Simmons and F. C. Sutton. Indus. Chemist, vol. 1, no. 10, Nov. 1925, pp. 473-474, 3 figs. Describes flow meter known as Rotameter, which consists essentially of a vertical transparent tube with bore tapering towards lower end; some industrial processes in which Rotameters are being used.

FLUE-GAS ANALYSIS

CO Determination. Determining Carbon Monoxide in Flue Gas by Iodine Pentoxide, J. F. Anthes. Gas Age Rec., vol. 56, nos. 22 and 23, Nov. 28 and Dec. 5, 1925, pp. 769-770 and 809-810, 1 fig. Details of method and apparatus for determining carbon monoxide as followed by the laboratory of Brooklyn Union Gas Co. Determination of CO by iodine pentoxide; potassium iodide; preparation of starch solution; preparation of 0,001 N sodium thiosulphate and 0.001 N potassium dichromate.

FORGE SHOPS

Fuel Oil and Storage. Furnace Fuels and Oil Storage, C. C. Hermann. Machy. (N. Y.), vol. 32, no. 5, Jan. 1926, pp. 385-387, 3 figs. Fuel-oil system for small plant; oil-pipe intakes; oil-pressure control; atomizing system; oil-storage tanks

FORGING

Machine Dies. Pointers on Forging Machine Dies. Ry. Mech. Engr., vol. 99, no. 12, Dec. 1925, pp. 783-787, 9 figs. Die design and construction; cooperation between forge shop and tool room desirable. (Abstract.) Report of Committee presented before Am. Ry. Tool Foremen's Assn.

Machines. Universal Forging Machine. Engineering, vol. 120, no. 3129, Dec. 18, 768-769, 7 figs. Consists essentially of mechanical press with connecting rod of variable length; this combination makes it possible to forge work of any desired thickness by series of quick squeezes, effect coming between blows of hammer and prolonged pressure of press; manufactured by B. and S. Massey, Manchester, Eng.

FOUNDRIES

Methods and Equipment, 1925. Foundrymen Refine Equipment and Methods in 1925, D. M. Avey. Iron Trade Rev., vol. 78, no. 1, Jan. 7, 1926, pp. 23-24. Conditioning, handling and conservation of sand have engaged much attention; advance in permanent-mold casting practice; development of oil-cooled molding machine; lengthening life of mold; progress in die-mold or pressure-type casting machines; simplification of high-frequency induction-type electric furnaces; other improvement.

Research, Applications of. Some Applications of Research to Modern Foundry Practice, J. E. Fletcher. Engineer, vol. 140, no. 3652, Dec. 25, 1925, pp. 703-704, 6 figs. Author seeks to illustrate a few examples of type of work and method of attack used in applying results of research to current foundry practice. Paper read before Instn. Mech. Engrs.

Testing of Materials. Physical Testing of Foundry Materials, J. S. C. Primrose. Foundry Trade Jl., vol. 32, no. 487, Dec. 17, 1925, p. 506. Brief review of paper read before Lancashire Junior Section of Inst. Brit. Foundrymen; explains differences between proof tests, such as are applied to finished article, and specification tests employing test bars or coupons.

FOUNDRY EQUIPMENT

Mechanical Sand-Handling. Reducing the Cost of Production in Iron, Steel, Malleable and Brass Foundries, R. H. Heisserman. West. Machy. World, vol. 16, no. 10, Oct. 1925, pp. 418-419. Notes on substitution of mechanical handling for manual labor; sand-handling machinery; advantages of mechanical sand conditioning.

FUELS

Developments, 1925. Fuels and Combustion. Power, vol. 63, no. 1, Jan. 5, 1926, pp. 8-12. Coal, oil and other fuels, development in stoker field, trend in pulverized-coal burning and status of low-temperature carbonization of coal with by-product recovery.

Smokeless. Glasgow and Solid Smokeless Fuel. Indus. Chemist, vol. 1, no. 10, Nov. 1925, pp. 481-488, 12 figs. Description of Maclaurin plant at Dalmarnock Gas Works, Glasgow, and methods employed.

Smokeless Solid Fuel Conference, W. E. Davies. Gas. Jl., vol. 172, no. 3266, Dec. 16, 1925, pp. 723-724. Discusses coal-ash content, plasticity and coking, physical and chemical characteristics of coke, combustibility and reactivity test, principles of carbonization.

Testing Plant. Sensible Heat Distillation. Gas Jl., vol. 172, no. 3265, Dec. 9, 1925, pp. 654-656, 2 figs. Describes plant of Sensible Heat Distillation, Ltd., used as demonstration unit for mixing various kinds of carbonaceous material, from caking and noncaking coals and lignites to town sewage.

See also Coal; Oil Fuel; Pulverized Coal.

FURNACES

Protecting Metal Parts from Oxidation. Protecting Furnace Metal Parts from Oxidation, H. E. Weightman. Power Plant Eng., vol. 29, no. 24, Dec. 15, 1925, pp. 1276-1277. Process developed by author for treating metal parts, which consists in treating metals with slip made of aluminum-iron-titanium mixture with sodium-metasilicate; no spraying apparatus is needed.

G

GASOLINE ENGINES

Exhaust-Gas Analyses. Chemical Equilibrium in Gases Exhausted by Gasoline Engines, W. G. Lovell and T. A. Boyd. Indus. & Eng. Chem., vol. 17, no. 12, Dec. 1925, pp. 1216-1219, 4 figs. With purpose of getting further knowledge of combustion reaction, which occurs so speedily in gasoline engines, authors have closely examined number of exhaust-gas analyses, with interesting results, as outlined.

GEOLOGY

Economic. Economic Geology and the Mining Industry, H. C. Boydell. Inst. of Min. & Metallurgy—Bul., no. 254, Nov. 1925, pp. 1-12. Discusses inadequate geological control by mining companies in their operations, owing to absence of physical and chemical research directed to solution of existing problems of ore deposits and economic geology.

GRINDING MACHINES

Internal. Rivett Motor-Driven Internal Grinder No. 104. Am. Mach., vol. 63, no. 26, Dec. 24, 1925, pp. 1027-1028, 2 figs. For grinding small and accurate holes on production basis; machine is driven by two independent motors.

Roll. Large Roll Grinding Machine. Iron Age, vol. 116, no. 27, Dec. 31, 1925, p. 1805, 2 figs. Equipment for Carnegie Steel Co.'s Munhall plant has capacity for work 54 in. in diam. and 21 ft. long; four driving motors used.

GEARS

Ground. Characteristics and Use of Ground Gears, H. F. L. Orcutt. Engineering, vol. 120, no. 3126. Nov. 27, 1925, pp. 691-694, 2 figs.; also Engineer, vol. 140, nos. 3648 and 3649, Nov. 27, and Dec. 4, 1925. pp. 589-591 and 618-619, 4 figs. Characteristics, use, and research. (Abridged.) Paper read before Instn, Mech. Engrs.

Idler, Bearing Loads on. Bearing Loads on Idler Gears, F. W. Halliwell. Machy. (Lond.), vol. 27, no. 692, Dec. 31, 1925, pp. 461-462, 3 figs. Shows that reduction of 50 per cent or more in load can often be achieved by transposing idler gear from one side to other.

Internal. Internal Gears, H. Walker. Machy. (Lond.), vol. 27, no. 692, Dec. 31, 1925, pp. 455-457, 5 figs. Nature of internal interference; presents example showing that it is possible to obtain a 100 to 102 ratio without interference.

Normal Pitch. Normal Pitch the Index of Gear Performance, G. M. Eaton. Mech. Eng., vol. 48, no. 1, Jan. 1926, pp. 27-32, 13 figs.

Spur. An Investigation of the Efficiency and Durability of Spur Gears, C. W. Ham and J. W. Huckert. Univ. Ill. Bul., vol. 22, no. 47, July 20, 1925, 94 pp., 42 figs.

Teeth, Involute. Rolling and Sliding Contact in Involute Teeth, J. Cryer. Machy. (Lond.), vol. 27, no. 688, Dec. 3, 1925, pp. 289-290, 9 figs. Graphical treatment.

Teeth, Wear Experiments. Some Comparative Wear Experiments on Cast-Iron Gear Teeth, G. H. Marx, L. E. Cutter and B. M. Green. Mech. Eng., vol. 48, no. 1, Jan. 1926, pp. 33-36, 8 figs. Report of experiments made in laboratories of mechanical-engineering department at Stanford Univ.

Testing. Testing Spur and Helical Gears or Cutters. Machy. (N. Y.), vol. 32, 32 no. 5, Jan. 1926, pp. 382-383, 4 figs. Describes two machines used in tool room of Maxwell Motor Corp., Detroit, Mich., for determining accuracy of spur and helical gears and gear-shaper cutters; how test is made; using machine as comparator; checking spacing and concentricity of teeth; using optical micrometer.

Worm. Worm Gearing—Its Evolution and Manufacture, H. E. Merritt. Machy. (Lond.), vol. 26, nos. 675 and 676, Sept. 3, and 10, 1925, pp. 708-711 and 737-742, 24 figs. Features in practice of David Brown & Sons (Huddersfield). Sept. 3; Worm-gear materials. Sept. 10: Manufacture of worm; production of worm wheels.

H

HEAT CONDUCTIVITY

Calculation. Equation of Conduction of Heat, M. C. Gray. Roy. Soc. Edinburgh—Proc., vol. 45, part 3, 1925, pp. 230-244. Discusses differential equation of conduction of heat in three-dimensional space and its various solutions, including Forsyth's and series solution; solution of equation for 2 dimensions, integral-equations solution, Fourier's solution, etc.

HEATING, GAS

Efficiency. Relation Between Heating Value of Gas and Its Usefulness to the Consumer, E. R. Weaver. U. S. Bur. of Standards—Technologic Papers, no. 290, July 21, 1925, pp. 347-463, 51 figs. Critical reviews of available data regarding relative usefulness of gases of different heating value, confined almost exclusively to facts expressed in definite figures; direct determination of useful facts obtained by burning gas in various appliances, and statistics regarding relative amount of gas used before and after changes of heating value, etc.

HEATING, STEAM

VACUUM. Vacuum Pump Heating Systems, R. H. Anderegg and M. W. Ehrlich. Domestic Eng. (Chicago), vol. 112, nos. 5, 6, 7 and 8, Aug. 1, 8, 15 and 22, 1925, pp. 22-24; 18-20; 33, 35 and 37; and 20-22; 22 figs. Aug. 1: Working parts of single-case and two-case vacuum pumps of water-seal type. Aug. 8 Ratings and capacities of pumps; vacuum pumps are listed in terms of equivalent direct radiation and selected on basis of water and air capacity. Aug. 15: Installation and operation of vacuum pumps. Aug. 22: Describes some actual vacuum heating installations; how to apply pumps to problems of actual heating systems.

HIGHWAYS

MAINTENANCE. Administration and Location of State Highways, G. F. Syme. Pub. Wks., vol. 56, no. 12, Dec. 1925, pp. 428-434, 5 figs. Discusses organization of State highway departments; maintenance most important function from administrative point of view; field procedure of making location; qualifications of a locating engineer.

RESEARCH. Highway Research Develops Definite Objectives. Eng. News-Rec., vol. 95, no. 24, Dec. 10, 1925, pp. 960-961. Annual convention of Highway Research Board shows increasing co-ordination and definite planning indeveloping information on uncertain questions.

HYDRAULIC TURBINES

BLADES. The Graphical Determination of the Meridian Paths of Turbine Blades (Sur la détermination graphique des traces meridiennes des aubes des turbines), Eydoux. Académie des Sciences—Comptes Rendus, vol. 181, no. 2, July 15, 1925, pp. 69-70. If turbine be set in the flow for development of mechanical energy, calculation shows that tangential component of vortex does not enter into blade reactions; based upon Lorenz's differential equation for this motion, author describes graphical construction for given curves which show energy exchanges, these curves being in meridian plane owing to above condition.

HIGH-HEAD. Development of High-Head Hydraulic Turbines, Wm. M. White. Power Plant Eng., vol. 29, no. 24, Dec. 15, 1925, pp. 1262-1268, 8 figs. Changes are largely in bearings, details of construction and methods of speed control.

REACTION. World's Highest Head Reaction Turbine Plant, B. West. Tech. Eng. News, vol. 6, no. 4, Nov. 1925, pp. 146-147, 3 figs. Desribes 860-foot head Oak Grove station of Portland Electric Power Co., including discussion of reasons for the development.

HYDRO-ELECTRIC DEVELOPMENTS

PROGRESS, 1925. Activity in Field of Water Power. Power, vol. 63, no. 1, Jan. 5, 1926, pp. 20-24, 9 figs. New contracts of 1,000,000 hp. reported; propeller-type shows gains; increased efficiency renders development of many low-head sites commercially economical.

HYDRO-ELECTRIC PLANTS

NIAGARA. Water-Power Possibilities of the St-Lawrence and Niagara Rivers, H. B. Dwight. Tech. Eng. News, vol. 6, no. 4, Nov. 1925, pp. 144-145, 2 figs. Discusses technical, economical, and political aspects involved in development of 6,000,000-hp. project.

ONTARIO. Norman Dam Power Development, S. T. McCavour. Contract Rec., vol. 39, no. 49, Dec. 9, 1925, pp. 1158-1160, 6 figs. New dam and power house on western outlet of the Lake of the Woods; five units to be installed at present; details of construction methods.

I

ICE MANUFACTURE

ELECTRIC. Electricity in the Manufacture of Ice, D. W. McLenegan. Gen. Elec. Rev., vol. 28, no. 12, Dec. 1925, pp. 846-857, 16 figs. General advantages of electric drive, process of ice manufacture, plant equipment, air compressor; air-storage tanks, ammonia-compressor motor, transformers, ammonia condensers, ice scoring machines.

ICE PLANTS

DESIGN. Many Factors Influence Ice Plant Design, H. J. Macintire. Power Plant Eng., vol. 30, no. 2, Jan. 15, 1926, pp. 151-154, 1 fig. Discusses fundamental principles, showing their application by solution of typical problem in ice-plant design.

ELECTRICALLY DRIVEN. Performance Test of Electrically Driven Raw Water Ice Plant. Ice & Refrigeration, vol. 69, no. 6, Dec. 1925, pp. 365-368, 4 figs. Report of performance of plant of Fulton Ice Co., New York City, in which author describes operating conditions which made it possible to obtain high efficiency shown; much credit due loyalty and team work of employees.

HAZARDS. Ice Plant Hazards. South. Engr., vol. 43, no. 10, Dec. 1925, pp. 51-52. Causes of accidents and how to avoid them. Presented at 14th Annual Safety Congress, Cleveland.

INDICATORS

PRACTICAL OPERATION. Practical Operation of the Indicator, W. H. Wakeman. South. Engr., vol. 43, nos. 8, 9 and 10, Oct., Nov. and Dec. 1925, pp. 54-57, 49-53 and 53-56, 90 figs. Diagrams showing what indicator discloses as to what is taking place in engine cylinder; peculiar indicator diagrams and what was done to remedy matters.

INDUSTRIAL MANAGEMENT

BUDGETING. My Experience with Many Industries, H. I. Shepherd. System, vol. 48, no. 6, Dec. 1925, pp. 699-701, and 742 1 fig. Discusses experience in various industries, the budget as a tool of management; set-up and operation of budget.

INDUSTRIAL CONTROL. Production Control—A Simple System of Recording, W. J. Hiscox. Machy. (Lond.), vol. 27, no. 689, Dec. 10, 1925, pp. 335-336, 4 figs. Describes series of charts which will render efficient service to management of any factory where production is handled on large number of work orders, corresponding to actual sales requirements.

INDUSTRIAL ORGANIZATION

PLANT ORGANIZATION. The Organization of an Industrial Plant, J. Seton Gray. Machy. (N. Y.), vol. 32, no. 5, Jan. 1926, pp. 398-400. Supervision of production; time- and cost-keeping departments; store-keeping department; time study and planning department; employment, inspection and miscellaneous-shop departments; importance of teamwork.

INDUSTRIAL PLANTS

SANITARY SURVEY. How to Make a Sanitary Survey of Your Plant, C. L. Ferguson. Indus. & Eng. Chem., vol. 17, no. 12, Dec. 1925, pp. 1275-1277. Notes on cleanliness, drinking water, ventilation, lighting, exhaust systems, toilets, wash rooms, dressing and rest rooms, etc.

INLAND WATERWAYS

INDUSTRIAL DEVELOPMENT, AND. Seaport and Inland Waterways, S. A. Thompson, World Ports, vol. 14, no. 2, Dec. 1925, pp. 47-81, 3 figs. Compares conditions on the two sides of the Atlantic as to inland waterways, seaports and transportation, showing resemblances and differences; the place of inland waterways in industrial development, etc.

INSULATION, ELECTRIC

HIGH-VOLTAGE. High-Voltage Insulation, J. B. Whitehead. Elec. World, vol. 87, no. 1, Jan. 2, 1926, pp. 31-32. Co-operative research brings new facts to light; now considering 132-kv. cables as practicable; survey of experimental work and status of insulation breakdown theory.

INSULATION, HEAT

GAS MANUFACTURE, USE IN. Insulation, L. E. Cover. Am. Gas Jl., vol. 123, no. 27, Dec. 5, 1925, pp. 611-612 and 620, 2 figs. Its importance in manufacture and domestic and industrial use of gas.

INSULATING MATERIALS, ELECTRIC

DIELECTRIC LOSSES. Dielectric Absorption in Fibrous Insulating Materials, R. E. Marbury and E. R. Le Chait. Elec. Jl., vol. 22, no. 12, Dec. 1925, pp. 605-610, 10 figs. Operation of dielectric lag meter; residual voltage of unimpregnated condenser and of impregnated condensers; relation between dielectric absorption and a.c. losses.

INSULATORS, ELECTRIC

HIGH-TENSION. Porcelain for High Tension Insulators, K. H. Reichaw. Ceramic Soc.,—Trans., vol. 25, part 4, 1925, pp. 279-301, 7 figs. Discusses question as to value of high tension porcelain, and present state of manufacture; complaints as to breakdowns in operation and serious trouble due to faulty manufacturing of line insulators; difficulties of absence of porosity with a well glazed and non-granular fracture; rational composition, presenting of clay silica and felspar; dielectric strength; mechanical testing, etc.

INTERCHANGEABLE MANUFACTURE

WORK-HOLDING FIXTURES FOR. Work Holding Fixtures for the Manufacture of Interchangeable Parts, C. A. Handschin. West. Machy. World, vol. 16, no. 10, Oct. 1925, pp. 399-400 and 415, 3 figs. Examples of special fixtures; points in designing drilling and reaming fixtures.

INTERNAL-COMBUSTION ENGINES

CARBON DEPOSITION. Tests of Carbon Deposition in Internal Combustion Engines, D. R. Brooks. Soc. Automotive Engrs.—Jl., vol. 18, no. 1, Jan. 1926, pp. 48-52, 5 figs.

DOUBLE-EXPANSION. A Double Expansion Internal Combustion Engine. Gas & Oil Power, vol. 21, no. 242, Nov. 5, 1925, pp. 25-27, 5 figs.

PROGRESS, 1925. Progress of the Internal-Combustion Engine. Power, vol. 63, no. 1, Jan. 5, 1926, pp. 18-19, 5 figs. High-Speed oil engines; Diesel locomotive; large units; transformation of semi-Diesel; high and low-speed gas engines.

See also Airplane Engines; Automobile Engines; Diesel Engines; Gas Engines; Gasoline Engines; Oil Engines; Semi-Diesel Engines.

IRON CASTINGS

CLUTCH COUPLINGS. Clutch-Coupling Castings. Metal Industry (Lond.), vol. 27, no. 23, Dec. 4, 1925, pp. 537-539, 9 figs. Describes attempts to produce sound castings of this type, and successful methods finally employed.

IRON ORE

MAGNETITE. The Genesis of the Texada Island Magnetite Deposits, C.O. Swanson, Can. Dept. of Mines—Geol. Survey, no. 2066, 1925, pp. 106A-140A, 5 figs. Details of deposits in Texada Island including limestone, tonalite, porphyries; occurrance of recrystalization; gensis of all deposits formed by magnetic solutions in which the materials were concentrated by the crystalization of the intrusive.

IRRIGATION

DEVELOPMENTS. A New Idea in Drainage for the Irrigation Farmer, J. C. Marr. Agric. Eng., vol. 6, no. 12, Dec. 1925, pp. 306-307, 4 figs. Discusses sluicing or hydraulic methods of drainage, principle of which is similar to that of hydraulic mining and hydraulic method of constructing earthen dams, or displacement and conveyence of earthen materials by a rapidly moving stream of water, the farmer providing needed drainage facilities through expenditure of own time and energy rather than an outlay of captital.

L

LABOUR

EMPLOYMENT POLICY. A Systematic Scheme for an Employment Policy, Berger. Int. Labour Rev., vol. 12, no. 5, Nov. 1925, pp. 634-649. Outlines scheme for comprehensive employment policy which considers ordinary problem of filling normal vacancies in industrial employment from the available reserve of man power, and extraordinary problems of large-scale unemployment in periods of depression.

LATHES

MULTI-CUTTING. Multi-Cutting Lathes. Brit. Machine Tool Eng., vol. 3, no. 36, Nov.-Dec. 1925, pp. 329-335, 9 figs. Discusses possibilities of practice installing a standard machine tool modified to suit special work, instead of entirely special machine of new design.

LEAD ALLOYS

LEAD-ANTIMONY. The System Lead-Antimony, R. S. Dean, W. E. Hudson and M. F. Fogler. Indus. & Eng. Chem., vol. 17, no. 12, Dec. 1925, pp. 1246-1247, 2 figs. Solid solubility of antimony in lead at cutectic temperature; solubility of antimony in lead below eutectic temperature; age hardening of lead-antimony alloys.

LIGHT

PROJECTION. Studies in the Projection of Light, F. Benford. Gen. Elec. Rev., vol. 28, no. 12, Dec. 1925, pp. 866-872. Discusses sectional paraboloidal mirror and its properties for production of wide and soft-edged beam free from images used in out-door flood lighting and in studio illumination.

LIGHTING

STREET. Lighting Chicago's Residential Sections, J. T. Miller. Elec. World, vol. 86, no. 26, Dec. 26, 1925, pp. 1309-1311, 9 figs. Taking advantage of latest economic developnent to effect savings in construction, operation and maintenance, discourage crime and minimize traffic hazards.

Street Lighting from Utility Viewpoint, G. H. P. Dellmann. Elec. World, vol. 86, no. 24, Dec. 12, 1925, pp. 1203-1204, 2 figs. Benefits from lighting must be prime factor; general scheme should be adopted; non-ornamental lighting favoured; raising minimum standards.

LIGHTNING ARRESTERS

JOYCE. Lightning Arresters for Transmission and Distribution Circuits, E. E. Burger. Gen. Elec. Rev., vol. 28, no. 12, Dec. 1925, pp. 857-859, 4 figs. Economic consideration, and types of equipment best adopted to the several classes of service.

LIME

HYDRATED. Hydrated Lime as a Chemical Base, A. B. Searfe. Indus. Chemist, vol. 1, no. 1, Feb. 1925, pp. 38-41, 3 figs. Discusses lump lime versus hydrated lime, nature of hydrated lime, production, and mode of using.

LOCOMOTIVES

BRITISH DEVELOPMENT. The British Steam Railway Locomotive from 1825 to 1924, E. L. Ahrons. Engineer, vols. 139 and 140, nos. 3601-3650, Jan. 6-Dec. 11, 1925, pp. 2-4, 34-37, 66-68, 94-96, 124-126, 151-152, 178-181, 206-208, 232-233, 258-260, 288-290, 316-318, 344-346, 370-372, 398-400, 424-426, 452-454, 478-481, 506-507, 534-536, 562-564, 616-617, 642-644, 670-672, 698-701, 2-4, 28-29, 54-56, 80-82, 104-107, 132-133, 156-157, 180-181, 206-207, 232-233, 258-260, 284-286, 312-314, 338-339, 366-368, 394-395, 422, 452-453, 480-481, 508-510, 538-540, 570-571, 598-600 and 628-629, 314 figs. Traces gradual development during century. Jan. 9: Period 1828-31. Jan. 16 and 23: 1830-1837. Jan. 30 and Feb. 6: 1837-1841. Feb. 13, 20, 27, Mar. 6 and 13: 1841-1849. Mar. 20, 27, Apr. 3 and 10: 1849-1855. Apr. 17 and 24: 1855-1859. May 1: Locomotive performances, speeds and coke consumption, 1845-1859. May 8: Locomotives built by British firms for abroad (including those for Colonial and Indian railways). May 15, 22 and 29: 1860-1865. June 5 and 12: 1866-1869. June 19, 26, July 3 and 10: 1870-1875. July 17 and 24: 1876-1881. July 31: Train resistances and locomotive performances, 1855-1879. Aug. 7: Engines for Ireland and overseas, 1870-1879. Aug. 14, 21, 28, Sept. 4, 11, 18 and 25: Compound locomotives, 1882-1889. Oct. 2, 9, 16, 23 and 30: 1890-1900; articulated, steep gradient and miscellaneous locomotives. Nov. 6, 13, 20 and 27: 1901 to 1914. Dec. 4 and 11: 1914-1924.

COAL TRIALS. Locomotive Coal Trials on the Southern Railway, H. Holcroft. Engineer, vol. 140, no. 3651, Dec. 18, 1925, pp. 658-662, 4 figs. Result of series of trials in order to compare results of using typical South Wales and Yorkshire coals, to ascertain if any appreciable difference in coal consumption is made by passing Welsh coal through mechanical coaling plant, and, incidentally, to observe performance of new 4-6-0 type engines of "King Arthur" class.

DIESEL-ELECTRIC. Diesel Locomotive Development and Problems, L. Kniel. Diesel & Oil Engine Jl., vol. 1, no. 1, Nov. 1925, pp. 28-39, 18 figs. Details of design and construction; fuel consumption; transmission devices, electric drive, mechanical-gear drive, hydraulic drive and other transmission devices.

ELECTRIC. *See Electric Locomotives.*

OIL-ELECTRIC. Oil-Electric Locomotive Makes Record Run. Ry. Age, vol. 79, no. 26, Dec. 26, 1925, pp. 1190-1192, 5 figs. Travels 537 mi. in 28 hr. 45 min. with load of 377 tons on 473 gal. of fuel oil; built jointly by Gen. Elec. Co., Ingersoll-Rand Co. and Am. Locomotive Co. for Long Island R. R.

OIL-ELECTRIC VS. STEAM. Oil-Electric versus Steam Locomotives, W. W. Baxter. Ry. Rev., vol. 77, no. 24, Dec. 12, 1925, pp. 871-874, 4 figs. Operation in actual service indicates relative performance and cost of two sources of motive power.

THREE-CYLINDER. The Three-Cylinder High-Pressure Locomotive, H. N. Gresley. Instn. Mech. Engrs.—Proc., no. 4, May 1925, pp. 927-967 and (discussion), 968-986, 24 figs.

LUBRICANTS

MANUFACTURE. Using Oils and Greases for Industrial Lubrication, F. E. Gooding. Indus. Engr., vol. 83, no. 12, Dec. 1925, pp. 558-566, 4 figs. Discusses properties, sources of oil lubricants, blending and compounding; manufacture of lubricating greases; graphite and its action on scored bearings; effect of speed on charge of lubricant, etc.

LUBRICATING OILS

CARBON-RESIDUE TEST. The Carbon Residue Test for Lubricating Oils, W. M. Seaber. Indus. Chem., vol. 1, no. 2, Mar. 1925, pp. 79-80, 1 fig. Carbon residue test, known in United States as Conradson test, has certain drawbacks, chief of which is lack of control over temperature around crucibles; describes some of the results obtained, using an electric furnace whereby temperature can be controlled with limit of 5 deg. fahr.; it would appear that there is a distinct advantage over Conradson apparatus, using this method of heating oil, more concordant results being obtained.

REFINING. Lubricants, Lubrication and Insulating Oils, R. W. L. Clarke. Instn. of Petroleum Technologists—Jl., vol. 11, no. 51, Aug. 1925, pp. 337-342. Reviews literature on subject, including preparation, refining of oils, properties, oils and lubrication; insulating oils for transformers, etc.

M

MACHINE TOOLS

ANNUAL DIGEST, 1925. Tool Builders Introduce Machines for Higher Production, E. F. Ross. Iron Trade Rev., vol. 78, no. 1, Jan. 7, 1926, pp. 30-32 and 48, 8 figs. Recapitulation of machines tools and other equipment developed for machine-shop use and described in 12 monthly digests in this journal in 1925.

DEVELOPMENTS 1925. New Machine Tools. Machy. (Lond.), vol. 27, no. 690, Dec. 17, 1925, pp. 372-400, 61 figs. Details of lathes, chucking machines, drilling machines, milling machines, grinding and lapping machines, wheel lathes, etc. See also pp. 401-405, giving capacity list and summary of improved features.

Machine Tool Developments in 1925. Machy. (Lond.), vol. 27, no. 690, Dec. 17, 1925, pp. 363-371. Review of principal improvements in design.

PORTABLE. Portable Machine Tools. Machy. (Lond.), vols. 26 and 27, nos. 677, 678, 679, 680, 681 and 682, Sept. 10, 24, Oct. 1, 8, 15 and 22, 1925, pp. 769-782, 815-817, 1-4, 33-37, 83-89 and 97-100, 80 figs. Discusses more recent developments and describes their application; class of tools dealt with range from large duplex spindle milling machines, shaping, slotting, facing, boring and duplex spindle drilling and tapping machines, down to small electric and pneumatic hand tools such as drills and grinders; examples are included of practice in shipbuilding yard, locomotive-building and repair shop, heavy electrical machine shop, maintenance department of coal mine, power station, rubber factory, and motor-repair station.

SELECTION. Standard Machine Tools. Times Trade & Eng. Supp., vol. 17, no. 379, Oct. 10, 1925, p. 99. Discusses lathe and its derivatives, turret lathes and automatic lathes, drilling machines and gear-cutting machines; adoption of new machine tools and subsequent increase in output, especially in automobile industry.

MACHINERY

SAFETY DEVICES. Engineering Revision and Mechanical Safeguarding, E. W. Beck. Nat. Safety News, vol. 12, no. 6, Dec. 1925, pp. 9-12, 6 figs. General principles for mechanical safeguards; they should not interfere with operations, should be strong enough to withstand more than wear and tear, simple and easily accessible; daily inspection necessary; familiarity of workmen in operating them, etc.; gives examples.

MAGNESIUM

PROPERTIES AND MANUFACTURE. Magnesium: A Metal with a Future, L. P. Sidney. Chem. Age (Lond.), vol. 13, no. 334, Nov. 7, 1925, pp. 33-34. Relation to aluminum, properties and occurrence, process of manufacture, properties in fibrous condition, and use for castings.

MANGANESE STEEL

HEAT TREATMENT. Describes Results of Tests in Manganese Steel, Rob. Hadfield. Iron Trade Rev., vol. 77, no. 26, Dec. 24, 1925, pp. 1597-1598, 4 figs. Effect of special heat treatment; test results show that by appropriate heat treatment, manganese steel can be made hard and magnetic at same time. From paper read before French Congress of Chem. Industry, Paris.

MANHOLES

DANGEROUS. Gas Hazards in Street Manholes, S. H. Katz, E. G. Meiter and J. J. Bloomfield. U. S. Bur. of Mines—Reports of Investigation, no. 2710, Oct. 1925, 20 pp. Dangerous gases in street manholes and their principal sources; use of safety lamps on entering a manhole; tests for monoxide and explosive or inflammable gas mixtures.

METAL DRAWING

HEAVY SHEET STEEL. Examples of Heavy Sheet Steel Drawing, E. Sheldon. Am. Mach., vol. 63, no. 27, Dec. 31, 1925, pp. 1035-1038, 6 figs. Advantage taken of tendency of metal to thicken up, shells produced having wide variation in thickness of wall; drawing steel that is more than ¼-in. thick.

METALLOGRAPHY

ENGINEERS. Metallography for Engineers, W. Rosenhain. Metallurgist (Supp. to Engineer), Nov. 27, 1925, pp. 168-171, 7 figs. Failures and defects.

PHOTOMICROGRAPHS. Photo-Micrographs. Metallurgist (Supp. to Engineer), Dec. 25, 1925, pp. 184-187, 4 figs. Discusses fundamental question as to whether all etching reagents produce same pattern on a given specimen; describes examples which serve to show that all structures which can be developed on given surface by different reagents are closely correlated, and can be rightly regarded as different aspects of same structure; choice of magnification; interpretation of photomicrographs.

METALS

COLD WORKING, EFFECT OF. Effect of Cold Working on Endurance and Other Properties of Metals, D. J. McAdam, Jr. Am. Soc. Steel Treating—Trans., vol. 8, no. 6, Dec. 1925, pp. 782-836, 41 figs.

ENGINEERING AND SCIENCE IN METAL INDUSTRY. Engineering and Science in the Metal Industry, Z. Jeffries. Mech. Eng., vol. 48, no. 1, Jan. 1926, pp. 8-16, 15 figs. Growth of metal industries since 1885; selecting best metal or alloy for given purpose; factors governing properties of alloy; causes of hardness in steel; effect of science on metal industry.

FATIGUE OF. An Investigation of the Fatigue of Metals. Univ. Ill. Bul., vol. 23, no. 12, Nov. 23, 1925, 92 pp., 29 figs. Methods and apparatus used in investigation; concludes that at elevated temperatures a marked difference was found between ultimate tensile strength as determined by ordinary static tension tests and as determined by prolonged and retarded tension tests; of metals tested, those having high nickel content showed least falling off of ultimate tensile strength and proportional elastic limit as temperatures were increased, etc.

X-RAY EXAMINATION. X-Ray Examination of Inner Structure of Strained Metals, Iron Plastically Strained in Extension, Compression and Torsion, A. Ono. Kyushu Imperial Univ. College of Eng.—Memoirs, vol. 3, no. 6, 1925, pp. 267-286, 7 figs. Discusses crystal rearrangement as observed in X-ray examination of metals, plastically strained in extension, compression and torsion; also mechanism of crystal rearrangement and cost of strain hardening.

MICROMETERS

ULTRA. Valve Method of Measuring Small Motion, with Special Reference to Precise Recording of Sounds, Pressure-Variations and Vibrations, J. Obata. Tokyo Imperial Univ.—Report Aeronautical Research Inst., vol. 1, no. 11, Aug. 1925, pp. 305-319, 7 figs. Experiments carried out with view to apply methods of measuring small motion utilizing a generating circuit containing a triode to the precise recording of sounds, pressure-variations and vibrations; microphone and ultramicrometer used for this purpose.

MINERAL DEPOSITS

CANADA. Geology and Mineral Deposits of the East Central Manitoba Mining District, J. F. Wright. Can. Inst. of Min. & Metallurgy—Bul., no. 164, Dec. 1925, pp. 1146-1164, 9 figs. Discusses gold bearing quartz veins in the Eastern central Manitoba mining district, topography and geology, gold quartz deposits, copper deposits, etc.

Minerals Deposits of Hudson Bay Territory, R. C. Wallace. Can. Inst. of Min. & Metallurgy—Bul., no. 164, Dec. 1925, pp. 1165-1176. Mineral occurrences in Hudson Bay area, iron ores, native copper, copper-gold, mica, etc.; transportation and developments.

NICKELIFEROUS. Nickeliferous Mineral Deposit, Emory Creek, Yale Mining Division, British Columbia, C. E. Cairnes. Can. Dept. of Mines—Geol. Survey, no. 2066, 1925, pp. 100A-105A. Location and geology, genesis of nickeliferous deposits; assays, secondary sulphides, minerals, etc.

MINERAL RESOURCES

MANITOBA. Mineral Resources of Manitoba, R. C. Wallace. Can. Min. Jl., vol. 46, no. 52, Dec. 25, 1925, pp. 1171-1176, 6 figs. Discussion of minerals including amber, antomony, arsenic, building stone, cement rock, clays, coal, copper, gold, gypsum, kaolin, zinc and lead.

MINES

PERMISSIBLE EQUIPMENT. List of Permissible Mining Equipment. U. S. Bur. of Mines—Reports of Investigation, no. 2720, Nov. 1925, pp. 1-6. List of equipment tested and approved by U. S. Bureau of Mines up to Sept. 15, 1925, covers electric air compressors, coal drills, mining machines, mine pumps, room hoists, switches, electric cap lamps, flame safety lamps, etc.

MOMENTS

GRAPHICAL TREATMENT. Graphical Treatment of Moments, W. W. Padfield. Machy. (Lond.), vol. 27, no. 688, Dec. 3, 1925, pp. 293-295, 9 figs. Useful method for preliminary designing; shows that by means of moments many constantly recurring engineering problems may be solved simply and neatly.

MOULDING MACHINES

TYPES. Moulding Machines. Foundry Trade Jl., vol. 32, nos. 480 and 482, Oct. 29 and Nov. 12, 1925, pp. 370-372 and 403-408, 35 figs. Oct. 29: Early work on mechanical moulding; hydraulic machines. Nov. 12: Centrifugal casting; stripping plates; jolt machines; hydraulic moulding machines; built-up pattern plates.

MOULDING METHODS

STRICKLE MOULDING. A New Method of Strickle Moulding. Foundry Trade Jl., vol. 32, no. 485, Dec. 3, 1925, p. 474. New method of moulding invented by Sappin Frères, which obviates pulls occurring during stripping process when walls of casting are vertical or have not sufficient taper. Brief abstract from paper read before Franco-Belgian Foundry Congress.

MOTOR-BUS TRANSPORTATION

STREET RAILWAYS, CO-ORDINATION WITH. Can Motorcoaches Relieve Traffic Congestion? P. B. Harris. Soc. Automotive Engrs.—Jl., vol. 18, no. 1, Jan. 1926, pp. 33-34. After comparing some of major advantages of motor coaches and electric street cars in transportation service, author asserts that electric-railway companies believe that motor-coach lines have future as feeders, but that to be successful they must be operated by same companies that operate rail lines.

MOTOR BUSES

DEVELOPMENT. The Bus as a Mass Transportation Carrier, W. W. Harris. Engrs. & Eng., vol. 42, no. 12, Dec. 1925, pp. 321-323. Discusses possibility of bus as a carrier, in competition with street cars, railroads, taxis, etc.; increasing bus traffic in London; comparison of New York traffic; congestion of streets, and efficiency of the motor bus.

The Motorbus as an Adjunct to the Street Railway, R. H. Horton. Engrs. & Eng., vol. 42, no. 12, Dec. 1925, pp. 324-325. Discusses anormalous position of motor buses operating more cheaply in one locality and electric cars in another; major features to be considered being investment, depreciation, plttform labour and maintenance; conditions in Philadelphia.

GASOLINE-ELECTRIC. Operating Experience with Gasoline Electric Motorcoaches, R. H. Horton. Soc. Automotive Engrs.—Jl., vol. 17, no. 6, Dec. 1925, pp. 592-596. Results obtained in 5-months operation of fleet of 130 gasoline-electric single-deck pneumatic-tire and double-deck dual-solid-tire motor coaches by Philadelphia Rural Transit Co.; outstanding advantages realized in operation of this type of motor coach are enumerated; troubles that have been overcome.

N

NICKEL

ELECTROLYTIC. The Electrolytic Production of Nickel, A. N. Campbell. Metallurgist (supp. to Engineer), Nov. 27, 1925, pp. 167-168. Main factors which have hitherto prevented successful electrolytic production of nickel have now been indicated, and may be summarized as: (1) Imperfect removal of impurities from electrolyte; (2) poor electrical efficiency; (3) unsatisfactory nature of deposit. Systematic work may result in elimination of (1) and (3), but (2) must of necessity persist as long as insoluble anode, with consequent inevitable high cell voltage, is used.

NOZZLES

STEAM, DESIGN OF. Fourth Report of the Steam-Nozzle Research Committee. Instn. Mech. Engrs.—Proc., no. 4, May 1925, pp. 747-843, 31 figs. Deals with 12-deg. convergent impulse nozzles with thin and with thick blades; built-up type of impulse nozzle; test results of straight elementary nozzles; efflux angles of steam; superheat effect. Includes discussion.

O

OFFICE MANAGEMENT

Development. The Present State of the Art of Office Management, W. H. Leffingwell. Soc. Indus. Engrs.—Bul., vol. 7, no. 12, Dec. 1925, p. 10. Discusses management as the art of handling men, materials and machinery for purpose of producing certain desired results, measurement of work done and method of rating the various operations.

OIL ENGINES

Crankless. Tilting Thrust Blocks on Crankless Engines. Oil Engine Power, vol. 3, no. 11, Nov. 1925, pp. 649-650, 4 figs. Discusses application of swash plates in oil-pressure transmissions for converting reciprocating into rotary motion and vice versa, and gives example of its application to two-cycle airless-injection oil engine with four 7½ x 9-in. cylinders rated to deliver 100 hp. at 500 r.p.m.; also application to gas engines.

Two-Stroke. Some Tests on a Two-Stroke Cycle Oil-Engine, E. A. Allcut. Instn. Mech. Engrs.—Proc., no. 4, May 1925, pp. 819-881 and (discussion) 882-909, 21 figs. Tests made to investigate behaviour of engine under different loads, to ascertain extent of various heat losses and various efficiencies; as suitable oil calorimeter was not available for student and laboratory work, experiments described in appendices were undertaken with object of designing such a calorimeter.

OIL FUEL

Burners. Oil-Fired Cast-Iron and Steel Boilers Show High Combined Efficiency. Heat. & Vent. Mag., vol. 22, no. 12, Dec. 1925, pp. 71-74, 1 fig. Results of three series of tests, one with an A.B.C. burner, one with a Winslow industrial-type burner, and third with a Johnson burner.

Burning, Requirements for. Burning Fuel Oil, F. A. Rothwell. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 23-26, 5 figs. Discusses more important factors governing successful burning of fuel oil.

Methods Used in Burning Oil Fuel Under Boilers. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 26-30, 6 figs. Starting up, control of fuel and air, checks on performance, shutting down; storage and handling, special precautions.

Purification. Fuel and Lubricating Oil Purification Reviewed, L. H. Clark. Oil Engine Power, vol. 3, no. 12, Dec. 1925, pp. 700-702, 4 figs. Use of centrifugal machines for purifying oils; impurities of lubricating oils and their detrimental action on engines; drawbacks in purification of fuel oils and how to overcome them.

OPEN-HEARTH FURNACES

Acid Steel Melting. Acid Open Hearth Steel Melting Practice, R. Furness. Am. Soc. Steel Treating—Trans., vol. 8, no. 6, Dec. 1925, pp. 728-736 and (discussion) 736-738.

Basic Steel Melting. The Basic Open Hearth Practice, E. A. Whitworth. Am. Soc. Steel Treating—Trans., vol. 8, no. 6, Dec. 1925, pp. 739-744 and (discussion) 744-747. History of basic open-hearth steel-melting practice; furnace design; practice for high-grade carbon forging steel.

OXYACETYLENE WELDING

Copper. Autogenous Welding of Copper by the Oxyacetylene Process, A. Eyles. Am. Mach., vol. 63, no. 27, Dec. 31, 1925, pp. 1043-1045, 14 figs. Characteristics of copper, especially when in moltent state; fluxes not necessary; precautions to be taken in making sound welds; welded joints and their preparation.

P

PAPER INDUSTRY

Finland. The Pulp and Paper Industry of Finland, J. Matthews, Jr. Commerce Reports, no. 48, Nov. 30, 1925, pp. 520-522. Production regulated by trade associations; increasing output and export of pulp and paper; modern equipment of mills, etc.

PAVEMENTS

Repair Costs. Repair Costs of City Pavements, R. H. Simpson. Eng. World, vol. 27, no. 6, Dec. 1925, pp. 331-336, 7 figs. Discusses misleading character of cost figures, compares repairs costs for light and heavy traffic, for brick and asphalt pavements and develops diagrams.

PAVEMENTS, ASPHALT

Experimental. An Experimental Pavement, F. C. Lang. Minn. Techno-Log, vol. 6, no. 2, Nov. 1925, pp. 40-41, 2 figs. New types of construction employed in test pavement recently constructed through campus by state highway commission.

PAVEMENTS, BRICK

Salvage Value. The Salvage Value of Brick Pavements, A. S. Mirick. Min. & County Engineering, vol. 69, no. 5, Nov. 1925, pp. 245-248. Experience with brick pavements in various parts of Pennsylvania and West Virginia.

PEAT

Problems, Sweden. Peat and Peat Problems in Sweden, Sven Oden. Fuel, vol. 4, no. 12, Dec. 1925, pp. 505-527, 17 figs. Formation and constitution of peat; rational method of peat analysis proposed by author; utilization of peat; peat as fuel; economy of air-dried peat; pressing out peat water; theory of water removal by means of pressure; wet carbonization and low-temperature carbonization.

PIERS

Concrete. Extension of Concrete Pier No. 314 Navy Yard Charleston, S. C. G. S. Burrell. Pub. Works of Navy, Bul. no. 35, Oct. 1925, pp. 33-45, 8 figs. Details of rebuilding old pier, redriving piles; extension of pier, borings, piles spacing and testing, reinforcement of piles, etc.

PIPE LINES

Coolgardie, W. Australia. The Coolgardie Pipe Line in Australia, and Measures Taken to Correct Corrosion, F. F. Longley. New England Water Works Assn.—Jl., vol. 39, no. 4, Dec. 1925, pp. 421-444, 8 figs. Details of 350-mile pipe line; condition of corrosion and measures taken to minimize it; reduction of carrying capacity; de-aeration treatment, etc.

PLANERS

Roll Wabbler. Roll Wabbler Planer. Iron Age, vol. 116, no. 27, Dec. 31, 1925, p. 1807, 2 figs. Heavy travelling head machine, placed on market by Morton Mfg. Co., Muskegon Heights, Mich., accommodates rolls up to 56 in. in diam.

PLASTER

Gypsum. A High Strength Gypsum Plaster, M. L. Chassevent. Rock Products, vol. 28, no. 24, Nov. 28, 1925, p. 64, 1 fig. By working with water at a temperature too high for setting, a product resembling marble is said to be obtained. (Translated from Le Ciment, 1925, pp. 316 and 317.)

PLATINUM

South Africa. The Platinum Deposits of the Bushveld Igneous Complex, P. A. Wagner, S. A. Mining and Eng. Jl., vol. 36, part 2, Nov. 21, 1925, pp. 315-316. Classification of deposits and characteristics of the Dunite deposits, Merensky Horizon type and also Potgieterrust and those in upper part of the Norite Lopolith.

POLES, WOODEN

Preservation. How Pole Consumer Can Benefit Himself, H. S. Sackett. Elec. World, vol. 86, no. 25, Dec. 19, 1925, pp. 1245-1248, 3 figs. Economical utilization essential to perpetuate adequate supply of suitable pole timber; involves treatment, modified specifications, anticipation of wants and uniform inspection; new German timber-treating process claimed to be promising.

POTASH

Production. The Mineral Industry of the British Empire and Foreign Countries. Imperial Mineral Resources Bureau, 1925, 50 pp. Statistical tables of exports and imports for 21 different countries.

POWER

Equipment, European Developments. Power Equipment Developments in Europe, J. H. Blakey. Power Plant Eng., vol. 29, no. 24, Dec. 15, 1925, pp. 1281-1281, 2 figs. French-patented progressive-action friction clutch; rupture tests on steel stirrups carried out by Central Bureau of Normalization of Delft, Holland; mandrel for spreading ends of boiler tubes designed by German firm of Steinmüller; annealing of plates for electrical machines.

Power Show, New York City. Fourth Power Show Surpasses Predecessors. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 94-106, 5 figs. Pulverized-coal and combustion apparatus are centers of interest; steam turbines; centrifugal and reciprocating pumps; electrical equipment; furnace construction; valves and valve control; steam and vacuum traps; feedwater control; piping system and equipment; water heating and steam superheating; etc.

Progress, 1925. Year's Progress in Power Field Shows Many Marked Advances. Power, vol. 63, no. 1, Jan. 5, 1926, pp. 2-4, 3 figs. Results obtained from large new steam plants show remarkable reduction in fuel consumption; condensing steam station has operated on heat rate of 13,715 B.t.u. per kw-hr.; tests on hydro-electric units have shown combined overall efficiencies of 92 per cent for turbine and generator; improvements in furnace designs, etc.

PUBLIC UTILITIES

Public Works and Transport Congress. Public Works and Transport Congress. Engineer, vol. 140, nos. 3647, 3648 and 3649, Nov. 20, 27 and Dec. 4, 1925, pp. 540-542, 577-579 and 606-608, 2 figs. Nov. 20: Résumé of papers on sewage disposal, water supply, roads and bridges, etc.; see also Engineering, vol. 120, nos. 3126, 3127 and 3728, Nov. 27, Dec. 4 and 11, 1925, pp. 683-686, 714-715 and 749.

PULVERIZED COAL

Requirements for Burning. Requirements for Burning Pulverized Fuel, H. D. Savage. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 14-15. Economic results from pulverized fuel; coal-burning conditions made possible presage radical changes in plant design.

Systems. Pulverized Coal Systems of 1925, A. Scheffler. Power Plant Eng., vol. 29, no. 24, Dec. 15, 1925, pp. 1251-1254, 4 figs. Growth of method, typical results and new developments.

Unit System. Unit System for Powdered Coal are Successful, W. C. Heckeroth. Power Plant Eng., vol. 29, no. 24, Dec. 15, 1925, pp. 1254-1255, 3 figs. Ability to serve small and large plants, dependability and ability to use any fuel are factors.

PUMPS

Pit Sinking. Concrete Pump Pit Sunk as an Open Caisson, P. S. Nelson. Eng. News-Rec., vol. 95, no. 27, Dec. 31, 1925, pp. 1078-1079, 3 figs. Walls built on steel shoe; forms had exceptionally rigid design; water jets opening out of shoe proved ineffective; open-caisson operation recently carried out for new water-works station at Vicksburg, Miss.

PUMPING STATIONS

Automatic. Automatic Pumping Stations. Brown Boveri Rev., vol. 12, no. 12, Dec. 1925, pp. 251-261, 21 figs. Electrically driven centrifugal pumps used in connection with water supply for isolated dwellings, hotels, and large establishments, industrial and agricultural purposes, and whole towns, developed by Brown Boveri.

PYROMETRY

Methods. Pyrometry, J. L. Haughton. Metallurgist (Supp. to Engineer), Nov. 27 and Dec. 25, 1925, pp. 162-165 and 179-181, 9 figs. Notes on platinum-resistance, thermoelectric, and radiation pyrometry.

R

RADIOTELEGRAPHY

Reception. A New Directional Receiving System, H. T. Friis. Inst. Radio Engrs.—Proc. vol. 13, no. 6, Dec. 1925, pp. 685-709, 17 figs. Methods of combining the signal currents from different antennas in a directional receiving system; describes system by which all phase and amplitude adjustments are performed upon beating current imputs of a double detection receiver.

Short-Wave. Short-Wave Transmission Theory, E. V. Appleton. Wireless World, vol. 17, no. 26, Dec. 23, 1925, pp. 885-887. Refraction and absorption in the upper atmosphere; the heaviside layer and its action on short-waves; absorption of different wave lengths.

RAILS

Failure. An Examination into the Causes of the Failure of Steel Rails, E. A. Dancaster. Indus. Chemist, vol. 1, no. 9, Oct. 1925, pp. 441-448, 6 figs. Describes how examination of piece of rail is carried out, in connection with a series of investigations being carried out by author in conjunction with W. H. Shortt into microstructure of rails which have failed in service.

RAILWAY ELECTRIFICATION

Great Britain. Traction Motors and Substation Equipment for the Southern Railway. English Elec. Jl., vol. 3, no. 3, Oct. 1925, pp. 105-114, 12 figs. Details of electrification of first part of suburban lines of South-Eastern and Chatham Railway, operating on direct current at 660 volts, led to the trains by the conductor rail, running rail being used as a return; power in bulk from Deptford Station of London Electric Supply Corp. to railways; main distribution at Lewisham in the form ol three-phase, 25-cycle supply at 11,000 volt; motor equipment, rotary converters, switch gear, substations.

RAILWAY MANAGEMENT

Statistics, Value of. Statistics and Their Value in All Phases of Railway Economics, W. E. Symons. Ry. & Locomotive Eng., vol. 38, no. 12, Dec. 1925, pp. 354-355, 1 fig. Gives illustrations of great value of comparative statistics in all phases of railway ownership and operation.

RAILWAY MOTOR CARS

Gasoline. New Type Motor Rail Car Introduced, W. W. Baxter. Ry. Rev., vol. 77, no. 22, Nov. 28, 1925, pp. 807-809, 2 figs. All-steel construction with two engines driving both trucks employed in new unit for branch lines; built by Smalley Rail-Car Co. at Davenport, Ia. See also description in Ry. Age, vol. 79, no. 24, Dec. 12, 1925, pp. 1183-1185, 4 figs.

RAILWAY OPERATION

Economics. Economics of Railway Operation. Am. Ry. Eng. Assn.—Bul., vol. 27, no. 278, Aug. 1925, pp. 66-80. Report of committee covering method for determining allowance for maintenance-of-way expenses due to increased dues and increased investments, including items chargeable to roadbed and track accounts, also bridges and buildings.

RAILWAY TIES

LIFE MEASUREMENT OF. Life of Ties Measured by New Method. Eng. News-Rec., vol. 95, no. 26, Dec. 24, 1925, p. 1034. Diagram and table enable probable life of groups of ties to be determined from annual rate of renewal.

SUBSTITUTE. Report of Committee on Ties. Am. Ry. Eng. Assn.—Bul., vol. 26, no. 275, Mar. 1925, pp. 1009-1078, 17 figs. Report of Committee on making tests of substitutes ties, their design, rail fastening, insulation; results with copper-content steel; cross ties of foreign woods; testing woods.

RAILWAY TRACK

BALLAST CLEANING. Vacuum Cleaner Renovates Ballast on Pennsylvania. Ry. Age, vol. 79, no. 26, Dec. 26, 1925, pp. 1195-1196, 2 figs. Vacuum cleaner of such size and power that it is capable of lifting stone ballast and foreign matter embedded in it from track to cleaning chamber mounted on car has been employed in renovating ballast on Philadelphia division of Pennsylvania. See also description in Ry. Eng. & Maintenance, vol. 21, no. 12, Dec. 1925, pp. 495-496, 2 figs.

STRESSES. Special Committee on Stresses in Railroad Track. Am. Ry. Eng. Assn.—Bul., vol. 26, no. 275, Mar. 1925, pp. 1081-1245, 103 figs. Details of conduct of tests and production data; straight and curved tracks, stresses in rails, vertical and lateral stresses in curved track; test carried out in Chicago, Milwaukee and Eastern Rys.

RAILWAYS

CHANGING PROBLEMS AND I. C. C. Changing Problems of Railways and I. C. C., F. J. Lisman. Ry. Age, vol. 79, no. 26, Dec. 1925, pp. 1204-1006. Consolidation; motor buses and trucks; long and shorthaul clause; rates; valuation.

REAMERS

FLOATING CUTTERS. Adjustable Reamer with Floating Cutters. Engineering, vol. 120, no. 3129, Dec. 18, 1925, p. 779, 3 figs. Describes reamer brought out by D. Brown & Sons, Huddersfield; two short, diametrically opposed cutters of rectangular section are employed. See also Machy. (Lond.), vol. 27, no. 691, Dec. 24, 1925, pp. 422-423, 5 figs.

REFRACTORIES

SILICA. Silica Refractories, G. Weyman. Gas Engr., vol. 41, no. 596, Dec., 1925, pp. 256-257. Discusses origin of refractories, attack of dust, difficulties of binding, "after expansion", examination and microscopic structure.

RESEARCH

INDUSTRIAL. Industrial Picture Through the Focus of Research, M. Holland. Am. Welding Soc.—Jl., vol. 4, no. 11, Nov. 1925, pp. 12-17. Development of growth of research in industries, and the part governments, national research council, and other bodies are taking in it.

PURE-SCIENCE. The Vital Need for Greater Financial Support to Pure-Science Research, Herbert Hoover. Mech. Eng., vol. 48, no. 1, Jan. 1926, pp. 6-7. Points out that United States is backward in development of research in pure science; scientific work seriously impeded by lack of financial resources; need of adequate organized financial support to pure science recognized by leaders of industry.

RESINS

SYNTHETIC. Synthetic Resins in Industry. Indus. Chemist, vol. 1, nos. 1, 2 and 3, Feb., Mar. and Apr. 1925, pp. 10-13, 73-78 and 145-148, 15 figs. Manufacture and use of synthetic resinous condensation products of phenol-formaldehyde class, with special reference to their molding characteristics.

RIVERS

COLORADO. Slit and Channel Conditions in Colorado River Delta, S. L. Rothery. Eng. News-Rec., vol. 95, no. 27, Dec. 31, 1925, pp. 1068-1071, 9 figs. How deposition centributes to instability of channel; effect of flood scour on levees; Bescadero cut dependent on competent engineering maintenance; present condition threatens disastrous results.

RIVETED JOINTS

TESTS. Comparative Tests of Button Head and Countersunk Riveted Joints, J. B. Kommers. Univ. Wis.—Bul., vol. 9, no. 5, 59 pp. 10 figs. Method and apparatus for testing comparative strength of buttonhead and contersunk rivets, etc.; concludes that average ultimate shearing strength of countersunk joints is at least equal to that of buttonhead joints for lap, single-covered butt and double-covered butt joints; for lap joints diameter of rivet and thickness of plate seem to have little effect on ultimate shearing strength of rivets; deformation, and results of bending tests.

ROAD MACHINERY

ASPHALT MIXING PLANT. A Portable Asphalt Plant. Engineer, vol. 140, no. 3652, Dec. 25, 1925, pp. 700-701, 2 figs. Describes asphalt or bituminous-macadam mixing plant, by Marshall, Sons & Co., of Gainsborough, which are of American Cummer design, but entirely British-made.

ROADS

CONSTRUCTION AND MAINTENANCE, EUROPE. Highway Construction and Maintenance Problems in Europe and America, W. Calder. Surveyor & Mun. & Cty. Engr., vol. 67, nos. 1748, 1749, 1750 and 1751, July 17, 24, 31 and Aug. 7, 1925, pp. 61-62, 85-86, 99-100 and 120, 6 figs. An Australian road engineer's impressions. Effect of motor traffic; advantages of smooth road surfaces; foundations; tar-macadam; cold spray; clinker asphalt; Scottish roads; asphaltic or bituminous materials; cement concrete roads.

WEAR. Effect of Pleasure Traffic on Bronx Roads, L. G. Holleran. Pub. Wks., vol. 56, no. 12, Dec. 1925, pp. 425-427, 1 fig. Discusses effect of intense traffic of pleasure vehicles, using pneumatic and balloon tires, on asphalt block and bituminous concrete road surfaces.

ROADS, CONCRETE

CONSTRUCTION. Efficiency in Concrete Road Construction, J. I. Harrison. Pub. Roads, vol. 6, no. 9, Nov. 1925, pp. 194-202, 1 fig. Report of observations made on going projects on public roads of efficient production including stop watch studies.

ROCK DUST

PRODUCTION AND USE. Production and Use of Rock Dust, R. Reddic. Min. Congress Jl., vol. 11, no. 11, Nov. 1925, pp. 547-553, and 569, 9 figs. A discussion dealing with chemical and physical properties of rock dust, sources of supply, equipment required, and its production and use; rock dusting now recognized as a real factor in mine safety.

ROLLING MILLS

ELECTRIC DRIVE. Electrical Rolling Mills, D. W. Blakeslee. Iron & Steel Engr., vol. 2, no. 12, Dec. 1925, pp. 508-512, 17 figs. Discusses finishing mills, bar mills, rod mills, method of electric drive, power consumption, etc.

Selection of Electric Drives for Reversing Mills, L. A. Umansky. Iron & Steel Engr., vol. 2, no. 12, Dec. 1925, pp. 479-500, 21 figs. Shows how capacity of a contemplated reversing drive may be determined, what factors affect the size of the machines ,and how they affect it; how the terms "horsepower," "torque," ampere," etc., are related to each other in a reversing-mill equipment; gives new procedure for the rather simple calculations required and proves that these calculations very closely approach actual test results.

HIGH-SPEED COLD. The High-Speed Cold Rolling Mill. Engineer, vol. 140, no. 3652, Dec. 25, 1925, pp. 688-691, 2 figs. Author believes that, now that application of roller bearings has been proved to be successful with cold-rolling mill, greatest obstacle in way of adoption of high rolling speeds has been removed.

STEEL-ROLLING PRACTICE. The Theory and Practice of Rolling Steel, W. Tafel. Iron Trade Rev., vol. 77, nos. 12, 13, 14, 15, 16, 17, 19, 21, 23, 25 and 27, Sept. 17, 24, Oct. 1, 15, 22, Nov. 5, 19, Dec. 3, 17 and 31, 1925, pp. 677-679, 739-741, 824-825, 964-966, 1033-1036, 1143-1146, 1277-1280, 1404-1405 and 1434, 1530-1533 and 1651-1655, 65 figs. Important theories and rules of rolling; characteristics of rolling process; notch test; guides; excess over draft increases stress; roll diameter affects grip; roll-pass design.

S

SEMI-DIESEL ENGINES

IGNITION PLUG FOR. Ignition Plug for Semi-Diesel Engines. Engineering, vol. 120, no. 3130, Dec. 25, 1925, p. 817, 1 fig. Plug designed by Lodge Plugs, Ltd., Rugby, Eng., for igniting oil spray until some part of combustion chamber becomes sufficiently hot to maintain ignition.

SEWAGE DISPOSAL

NEW YORK. Wards Island for Treating New York's Sewage. Pub. Wks., vol. 56, no. 12, Dec. 1925, pp. 438-440. Sewage from three boroughs to be treated on northern part of this island of it can be recovered from state, to which it has been leased; outline of proposed plan.

SHAFT SINKING

LINING SIMULTANEOUSLY, AND. An Improved Device for Progressively Lining Shafts with Concrete Without Interfering with Sinking Operations, E. M. Roberts. Min. and Mech. Engrs., vol. 75, part 3, April 1925, pp. 125-130, 7 figs. Device for lining shafts with concrete simultaneously with shaft sinking, consisting of a platform or cradle moveable vertically in shaft, two concreting cylinders, an annular base, means for enabling the raising and lowering of cylinders as the shaft is being lined, means for adjusting diametrically concreting cylinders.

SHAPERS

GEAR-CUTTING ATTACHMENTS. Gear Cutting Equipment for Shaping Machines. Engineering, vol. 121, no. 3131, Jan. 1, 1926, pp. 11-14, 12 figs. Gear-cutting attachments introduced by Matterson, Ltd., Shawclough, Rochdale, in which sigle straight tool is employed; this tool is ordinary V-type.

SILICA BRICK

ONTARIO QUARTZITES FOR. Ontario Quartzites Available for the Manufacture of Silica Brick, E. S. Moore and G. B. Langford. Can. Min. Jl., vol. 46, no. 49, Dec. 4, 1925, pp. 1110-1112, 4 figs. Lorrain quartzite; results of laboratory tests on quartzites; microscopic characters of quartzites; fusion tests.

SOIL

LAND AND CLAY. Principles of Soil Mechanics, Chas. Terzaghi. Eng. News-Rec., vol. 95, nos. 19, 20, 21, 22, 23, 24, 26 and 27, Nov. 5, 12, 19, 26, Dec. 3, 17, 14 and 31, 1925, pp. 742-746, 790-800, 874-878, 912-915, 987-990, 1026-1029 and 1064-1068, 42 figs. Nov. 5: Phenomena of cohesion of clay. Nov. 12: Compressive strength of clay—Modulus of elasticity: Poisson's ratio. Nov. 19: Determination of permeability of clay. Nov. 26: Settlement and consolidation of clay. Dec. 3: Physical differences between sand and clay. Dec. 17: Electric behavior of sand and clay. Dec. 24: Friction in sand and in clay. Dec. 31: Future development and problems.

STANDARDIZATION

ELECTRICAL. Commercial Results of Standardization, M.D. Cooper. Wis. Eng., vol. 30, no. 2, Nov. 1925, pp. 27-28 and 56-58. Discusses practical results of standardization and shows its good effect, as an example quoting the Kaiser Vacuum Lamps selling in United States at 27 cts. and in England at 54 cts.

WELDING. Standardization of Hose Connections for Welding and Cutting Torches and Regulators. Am. Welding Soc.—Jl., vol. 4, no. 11, Nov. 1925, pp. 49-53, 2 figs. Details of standards approved by American Welding Society in Oct. 1925, and agreed to by various other associations.

STANDARDS

U. S. BUREAU OF STANDARDS REPORT. Annual Report of Director of the Bureau of Standards for Fiscal Year Ended June 30, 1925. U. S. Bur. of Standards—Miscl. Publications, no. 69, 1925, 41 pp. Details of its activity during fiscal year, covering weights and measures, electricity, heat and power, optics, chemistry, mechanics and sound, structural engineering, metallurgy, ceramics, simplified practice, building and housing, etc.

National Bureau of Standards. U. S. Bur. of Standards—Circular, no. 1, Oct. 29, 1925, 111 pp., 86 figs. Report on purposes and activities of Bureau of Standards and details of work carried out in scientific and industrial research, testing standards and specifications, simplified practice, etc.

STEAM

HIGH PRESSURES AND TEMPERATURES. High Steam Pressures and Temperatures. Power Plant Eng., vol. 30, no. 2, Jan, 15, 1926, pp. 131-133, 3 figs. High steam pressures and temperatures bring greater economy but limits are fixed by properties of materials available. (Abstract.) Report of Prime Movers Committee of N. E. L. A.

SPECIFIC HEAT AT HIGH PRESSURES. Graphical Representation of the Specific Heat of Steam at High Pressures, Schmolke. Mech. Eng., vol. 48, no. 1, Jan. 1926, pp. 63-64, 10 figs. Points out that with modern tendency toward commercial employment of high steam pressures, knowledge of thermodynamic properties—especially specific heat—of steam at higher ranges becomes of great importance; describes method of calculation. Translated from Wärme, vol. 48, Aug. 21, 1925.

STEAM ACCUMULATORS

INSTALLATION IN STEAM PLANT. Industrial Plant to Install Steam Accumulator. Power, vol. 62, no. 26, Dec. 29, 1925, pp. 1013-1014, 1 fig. New arrangement of steam lines in power plant; accumulator, which is of Ruths type, is designed to take care of all fluctuations in consumption of steam occurring during normal operation in any part of refinery; this will allow boilers to be operated at practically constant rating, which is expected to give much higher overall efficiency.

PRINCIPLE OF. Steam Accumulators, A. J. T. Taylor. Combustion, vol. 13, no. 5, Nov. 1925, pp. 275-277, 2 figs. A discussion of principle upon which they are based and of their importance to heat-using industries.

STEAM ENGINES

TYPES AND APPLICATIONS. The Steam Engine as a Factor in Industrial Power. Power, vol. 63, no. 1, Jan. 5, 1926, pp. 16-17. Special investigation shows trends in types and applications to industries; figures show steam engine holding its own.

STEAM GENERATORS

PULVERIZED-COAL-BURNING. Steam Generator of Unique Design Gives High Rating. Power Plant Eng., vol. 30, no. 2, Jan. 15, 1926, p. 157. Combustion Steam Generator, recently placed on market, combines recent developments of pulverized fuel, water-cooled furnace wall, preheated air and turbulent action in combustion space; practically all boiler surface is exposed to radiant heat.

STEAM POWER PLANTS

DESIGN DEVELOPMENTS. Power Station Design Continues to Progress, P. Junkersfeld. Power Plant Eng., vol. 29, no. 24, Dec. 15, 1925, pp. 1248-1250, 1 fig. Interconnection of generating stations presents new problems to designers: B.t.u. required per kw-hr. cut to 16,000 in 1925.

STEAM TRAPS

DESIGN. Theory Involved in the Design and Testing of Steam Traps, L. C. Price. Sibley Jl. of Eng., vol. 39, no. 7, Oct. 1925, pp. 382-385, 2 figs. Discusses classification, capacity and its calculation, dumping frequency, selecting traps for a given job.

STEAM TURBINES

DESIGN. Graphical Design of Steam Turbines, A. Oppitz. Mech. Eng., vol. 48, no. 1, Jan. 1926, pp. 60-61, 8 figs. Author attempts to apply to turbine design the comparatively newly developed method of applied mathematics, namely, nomography. (Abstract.) Translated from Archiv für Wärmwirtschaft, vol. 6, Oct. 1925.

Steam Turbine Growth Steady. Power, vol. 63, no. 1, Jan, 5, 1926, pp. 12-15, 4 figs. Large-capacity units; higher steam pressure and temperature; high-economy small units; continued refinements in design; large condensers and new designs installed; valves and piping show progress.

EFFICIENCY OF BLADING. The Efficiency of Reaction Blading. Engineering, vol. 120, no. 3129, Dec. 18, 1925, pp. 775-776, 1 fig. Refers to test results on Brown-Boveri steam turbine, described by Prof. Stodola in same journal, Oct. 2, 1925; and discusses figures somewhat more fully than was done in report; explanation of term, hydraulic efficiency.

OVERHAULING. Overhauling the Main Turbines at Connors Creek. Power Plant Engrs., vol. 30, no. 2, Jan. 15, 1926, pp. 135-136, 4 figs. All of turbines in Detroit Edison plant, which is about 10 years old, have been entirely overhauled and rebuilt.

STEEL

ALLOY. *See Alloy Steel.*

COLD-WORKED. Thermal Disturbances and Recrystallization in Cold-Worked Steels, V. N. Krivobok Am. Soc. Steel Treating—Trans., vol. 8, no. 6, Dec. 1925, pp. 703-720, 20 figs.

HIGH-SPEED. *See Steel, High-Speed.*

LOW-CARBON. Flow In a Low-Carbon Steel at Various Temperatures, H. J. French and W. A. Tucker. U. S. Bur. of Standards—Technologic Papers, no. 296, 1925, pp. 619-640, 11 figs.

MANGANESE. *See Manganese Steel.*

STAINLESS. Non-Corrosive Steels, F. R. Palmer. Tech. Eng. News, vol. 6, no. 3, Oct. 1925, pp. 102-104, 4 figs. Production and characteristics of stainless and rustless steels, their micrographic structures, hardening temperatures, etc.

STEEL CASTINGS

ELECTRIC. Some Metallurgical Points in Electric Steel Castings and Notes on Defects, F. A. Melmoth. Foundry Trade Jl., vol. 32, no. 489, Dec. 31, 1925, pp. 549-552.

STEEL, HIGH-SPEED

CHEMICAL COMPOSITION, EFFECT OF. Experiments with Nickel, Tantalum, Cobalt and Molybdenum in High Speed Steels, H. J. French and T. G. Diggcs. Am. Soc. Steel Treating—Trans., vol. 8, no. 6, Dec. 1925, pp. 681-699 and (discussion) 699-702, 5 figs.

STEEL, HEAT TREATMENT OF

METHODS AND APPARATUS. Heat Treating Methods and Apparatus, C. B. Bellis. Am. Soc. Steel Treating—Trans. vol. 8, no. 6, Dec. 1925, pp. 837-850, 9 figs.

PROPORTION TO TOTAL PRODUCTION. Proportion of Heat Treated Steel to Total Production, C. J. Stark. Am. Soc. Steel Treating—Trans., vol. 8, no. 6, Dec. 1925, pp. 721-727.

STEEL INDUSTRY

ANNUAL ANALYSIS, 1925. Fifth Annual Analysis Shows Steel's Use. Iron Trade Rev., vol. 78, no. 1, Jan. 7, 1926, pp. 11-14, 5 figs. Presents annual analysis for 1925 of finished steel among leading consuming groups; various aspects of year's business in analysis of shipments and consumption in accordance with classified groups; gross production of finished steel in United States in 1925 approximates 33,000,000 tons, greatest ever recorded; steel requirements of automotive industry contributed more than any other single element to building up of great market.

STEEL WORKS

ENGLAND. Messrs. Brown Bayley's Steel Works, Engineering, vol. 120, nos. 3111, 3113, 3116, 3117, 3119, 3123, 3124, 3125, 3127, 3129 and 3130, Aug. 14, Sept. 4, 18, 25, Oct. 9, Nov. 6, 13, 20, Dec. 4, 18 and 25, 1925, pp. 192-196, 256-258, 343-345, 374-376 and 450, 567-570, 619-621, 654-655, 702-703, 759-762 and 791-794, 139 figs. partly of supp. plates. Account of plant and manufacturing process of works in Sheffield. Eng.

STOKERS

OPERATION. Good Firing Requires Intelligent Appreciation of Functions of Stokers, R. S. Riley. Power Plant Eng., vol. 30, no. 1, Jan. 1, 1926, pp. 2-5, 2 figs. Points out that essentials of stoker operation are good equipment properly kept up, adequate records of results and attention to fuel bed, air supply and ash-pit conditions.

STREET RAILWAYS

CAR REPAIRING. Arc Welding Reduces Maintenance Costs, A. M. Candy. Elec. Ry. Jl., vol. 66, no. 25, Dec. 19, 1925, pp. 1072-1074, 9 figs. Equipment and facilities for welding in shops of Worcester Consolidated Street Ry.; welding booths are arranged in a row between overhauling pits and machine shop.

TRACK RECONSTRUCTION. Rebuilding Track Amid Traffic Congestion, C. A. Elliott. Elec. Ry. Jl., vol. 66 no. 25, Dec. 19, 1925, pp. 1063-1067, 15 figs. Particulars of new methods of track reconstruction adopted by Pacific Elec. Ry. because of increase in traffic congestion; special work is made up in advance; gangs comprise about 50 men; work is done in two nine-hour shifts; under favorable conditions one block of double track is rebuilt in 20 days; average rates of progress for various jobs are given.

SUBSTATIONS

CONTROL. Centralized Supervision of Automatic Substation System, R. J. Wensley. Elec. World, vol. 86, no. 25, Dec. 19, 1925, pp. 1259-1260, 2 figs. Describes supervisory control system designed and installed to operate both on Staten Island Rapid Transit Co.'s control system of substation converters and upon 33,000-volt transmission system of Staten Island Edison Co. supplying railway converters.

SPACING AND SIZE. Economic Spacing and Size of Substation, E. L. Sweet. Elec. World, vol. 86, no. 24, Dec. 12, 1925, pp. 1200-1202, 7 figs. Effect of substations on primary distribution costs; evaluation of losses and costs to secure minimum overall costs; use of general standard advocated.

SUPERPOWER

STATIONS. The Metallurgical and Chemical Industries in Relation to Super-Power Stations, E. K. Scott. Combustion, vol. 13, no. 6, Dec. 1925, -pp. 356-357. Discusses superpower problems in connection with Great Britain; an ideal superpower plant should provide factories with cheap industrial gas and electricity, supplying at same time low-temperature coke for house fires and making all by-products from coal.

SURVEYING

TRAVERSING, TAPES FOR. Use of 300- and 500-ft. Tapes for Survey Traversing, H. Rubey. Eng. News-Rec., vol. 95, no. 26, Dec. 24, 1925, pp. 1024-1029, 7 figs. Economy and speed increased; charts for slope corrections, vertical components, corrections due to temperature, pull and sag.

T

TELEPHONY

BELL SYSTEM. General Engineering Problems of the Bell System, H. P. Charlesworth, Elec. Communication, vol. 4, no. 2, Oct. 1925, pp. 111-125, 18 figs. Character and scope of problems involved in caring for growth and operations of Bell System; plant extensions to meet service requirements, necessity for advanced planning; analysis of engineering cost studies; discusses New York-Chicago toll cable and New York City telephone problem.

LOADED CIRCUITS. Irregularities in Loaded Telephone Circuits, Geo. Crisson, Elec. Communication, vol. 4, no. 2, Oct. 1925, pp. 98-110, figs. 14. Describes line irregularities in long-distance transmission; structure of coil loaded circuits which permit calculation of possibility of obtaining an assigned accuracy of balance between line and net work; gives formulae and results of calculations compared with measurements made on circuits of known accuracy of loading.

THERMOCOUPLES

TEMPERATURE MEASUREMENT AND CONTROL, FOR. Thermo-Couples—Their Use for Temperature Measurement and Control, P. M. Heldt. Automotive Industries, vol. 53, no. 26, Dec. 24, 1925, pp. 1056-1059, 5 figs. Characteristics of rare-metal and base-metal-type couples; methods of keeping temperature of cold junction constant or compensating for changes in it; special types for special uses; installation.

TOLERANCES

SYSTEM FOR ALLOWANCES AND. The Evolution of an Allowance and Tolerance System, T. Rapson. Machy. (Lond.), vol. 27, no. 688, Dec. 3, 1925, pp. 297-299, 7 figs. Description of inception, experiments and revisions, final results of which were put into operation as being most suitable for class of work produced, and conditions existing, in connection with manufacture of automobiles and internal-combustion engines for various purposes.

TRANSFORMERS

DEVELOPMENT AND APPLICATIONS. Power Transformers, C. E. Sisson. Eng. Jl., vol. 9, no. 1, Jan. 1926, pp. 3-12, 12 figs. Development of power transformers with some modern features and applications.

OILS. Methods of Testing Transformer Oils, H. C. Staeger. Indus. & Eng. Chem., vol. 17, no. 12, Dec. 1925, pp. 1272-1275, 2 figs. Outline of chemical constitution of oils followed by outline of type of reactions occurring under influence of elevated temperatures in presence of oxygen; several standard tests of insulating oils are critically reviewed; described BBC (Brown, Boveri Co.) test and claims it is most nearly representative of service conditions and as taking account of all phases of oil deterioration.

PHASE ANGLE OF CURRENT. The Phase Angle of the Current Transformer, E. G. Reed. Elec. Jl., vol. 22, no. 12, Dec. 1925, pp. 594-596, 6 figs. Phase angle for varying primary current; and for varying volt-ampere secondary load; effect of phase angle on power reading.

TAYLOR CONNECTION. Taylor Connection for Transforming from Three-Phase to Two-Phase, J. B. Gibbs. Power, vol. 62, no. 26, Dec. 29, 1925, pp. 1005-1006, 5 figs. Presents diagram of connection; comparison with other 3-phase to 2-phase connections, showing advantages and disadvantages.

TIE-IN. Tie-In Transformer Equipped with Load Ratio Control, M. H. Bates. Gen. Elec. Rev., vol. 28, no. 12, Dec. 1925, pp. 823-826, 4 figs. Describes various operating principles that have been incorporated in design of such transformers, and gives details of particularly large unit constructed along these lines.

TRANSPORTATION

RAILWAYS AND HIGHWAY CARRIERS. A Survey of the Bus and Truck Situation. Ry. Age. vol. 79, nos. 23 and 24, Dec. 5 and 12, 1925, pp. 1023-1028 and 1077-1082, 14 figs. Points out that highways competition is seriously affecting railways revenues; suggestions for solution of problem; what is being done by railways to meet competition of motor-bus and truck transportation. Information derived mainly from answers made by railway presidents throughout country to questionnaire. Dec. 12: Tendency toward adoption of highway carriers by railroads themselves.

TUBES

COLLAPSING PRESSURE. The Collapse of Short Thin Tubes by External Pressure, G. Cook. Lond., Edinburgh & Dublin Philosophical Mag. & Jl. of Sci., vol. 50, no. 298, Oct. 1925, pp. 844-848, 2 figs. Discusses mathematical investigation of collapsing pressure of short tubes by Southwell and others and gives results of tests carried out, showing very good arrangement between calculated and observed pressures.

TUNGSTEN

MINING AND USES. Report of Sub-Committee on Tungsten. Min. & Met. Soc. of Am., vol. 43, no. 6, Sept. 1925, pp. 84-105. Discusses tungsten minerals, mining and conversion of ore, manufacture and use of finished product; substitutes; geographical distribution of deposits; domestic sources of supply.

TURBO-GENERATORS

AIR COOLER FOR. Air Cooler for Turbo-Generators. Engineering, vol. 121, no. 3131, Jan. 1, 1926, pp. 28, 3 figs. Cooler of closed-circuit type, manufactured by Cole, Marchent & Morley, Bradford.

V

VANADIUM

PRODUCTION AND APPLICATIONS. Vanadium: Its Production and Commercial Applications, A. J. Ewins. Indus. Chemist. vol. 1, no. 1, Feb. 1925, pp. 3-4. Notes on occurrence and source; use in steel industry, and other uses; production.

VAPORS

PRESSURES. Pressure-Temperature Charts—Extended Ranges, Geo. Galingaert and D. S. Davis. Indus. & Eng. Chem., vol. 17 no. 12, Dec. 1925, pp. 1287-1289, 6 figs. It has been shown that empirical method of Cox of plotting vapor-pressure data was suitable for range of 0 to 300 deg. cent. in case of several vapors; it is shown in this paper that this method is applicable over very much greater ranges.

VENTILATION

AUTOMATIC VENTILATORS. New Tests of Automatic Ventilators, J. P. Calderwood and A. J. Mack. Heat. & Vent. Mag., vol. 22, no. 12, Dec 1925, pp. 49-53, 13 figs. Investigation of 22 commercial types, with comparative data on plain stationary, stationary siphoning, plain rotary and rotary siphoning types.

BUILDINGS. Is Present Ventilation Practice Wrong? F. M. R. Butler. Contract Rec., vol. 39, no. 50, Dec. 16, 1925, pp. 1182-1184.

UNIT SYSTEM. Ten Fundamentals of Unit Ventilation and Their Application, A. J. Nesbitt. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 31, no. 12, Dec. 1925, pp. 545-552, 5 figs. Ventilation of schools and other buildings by unit system designed by Hubbard; details of principal changes since 1908; use of by-pass damper; change in form; adaptation of air filters and successful application of polyphase a.c. motors.

VOLTMETERS

CREST. Crest Voltmeters and Their Characteristics, D. F. Miner. Elec. Jl., vol. 22, no. 12, Dec. 1925, pp. 571-577, 19 figs. The simple crest voltmeter; calibration; form of condenser used with crest voltmeter; rectifiers.

Engineering Index

This Index is prepared by the American Society of Mechanical Engineers.

In this department will be published from month to month the titles of current engineering papers with the authors and source and a brief extract of the more important. It is designed to give the members of The Institute a survey of all important articles relating to every branch of engineering profession.

PHOTOSTATIC PRINTS

Photostatic copies of the articles listed in this section, or others on engineering subjects, may be obtained from the Engineering Societies Library.

Price of each print (up to 11 by 14 in. size) 25 cents, plus postage. Where possible, two pages, up to 7 by 9 in. size, will be photographed on one print. Larger magazines require a print per page. Bills will be mailed with the prints.

The Library is also prepared to translate articles, to compile lists of references on engineering subjects and render assistance in similar ways. Charges are made, sufficient to cover the cost of this work. Correspondence is invited. Information concerning the charge for any specific service will be given those interested. In asking for information please be definite, so that the investigator may understand clearly what is desired.

The Engineering Societies Library is under the management of the United Engineering Society, which administers it as a public reference library of engineering. It is maintained jointly by the American Society of Civil Engineers; the American Institute of Mining and Metallurgical Engineers; the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. It contains 150,000 volumes on engineering and allied subjects, and receives currently most of the important periodicals in its field.

Orders and correspondence should be addressed to

Harrison W. Craver, Director,
Engineering Societies Library,
29 West Thirty-ninth Street. New York, N.Y.

A

AERONAUTICAL INSTRUMENTS

Altimeters. Behm Acoustic Sounder for Aircraft. Nat. Advisory Committee for Aeronautics—Tech. Memorandums, no. 346, Jan. 1926, 5 pp., 3 figs. on supp. plates. This sounder enables non-barometric determination of altitude by night or in fog which functions on acoustic principle of water sounder, the sound waves passing from airship to ground and return. Translated from German.

AERONAUTICS

Developments. Possible Lines of Aeronautical Development, R. F. Hall. Aviation, vol. 20, no. 7, Feb. 15, 1926, pp. 218-220, 14 figs. Development of compound wings; helicopter possibilities; reducing landing speed; additional wing attachments; vertical flight; construction; monocoque construction; metal-wing structures; airplane glider.

AIR

Pollution by Smoke. Measuring the Smoke Pollution of City Air, J. S. Owens. Analyst Jl., vol. 51, no. 598, Jan. 1926, pp. 2-18, 5 figs. Divides methods of measuring into those aiming at measuring deposit of impurity from the air and those dealing with impurity while suspended in the air; filtration of suspended matter, washing it out with water, electrical precipitation; measuring deposit; dust counters and other methods.

AIR COMPRESSORS

Electric Motors For. Power Drive Equipment for Air Compressors, G. Fox. Indus. Engr., vol. 84, no. 1, Jan. 1926, pp. 13-18, 8 figs. Type and capacity of motor required, control apparatus necessary and mechanical connection for coupling motor to compressor.

AIR CONDITIONING

Humidifying System. The Humidity Problem, A. C. Willard. Sheet Metal Worker, vol. 16, no. 24, Jan. 1, 1926, pp. 863-865, 2 figs. Fundamental requirements for successful humidification, cost of evaporating by electricity, gas, etc.

AIRCRAFT CONSTRUCTION MATERIALS

Dopes. Dopes and Their Application. Air Service Information Circular, vol. 6, no. 544, Nov. 1, 1925, 11 pp., 18 figs. Discusses composition, tests and storage of dope, a colloidal solution of cellulose acetate, and application with brush or by spraying.

Two-Cycle. Two-Stroke-Cycle Engines for Airplanes, J. Jalbert. Nat. Advisory Committee for Aeronautics—Tech. Memo., no. 347, Jan. 1926, 23 pp., 17 figs. Application of two-stroke engines to airplane after their adoption in automobiles; reduced heating; scavenging exhaust gases; intake, fuel consumption, alimentation, distribution, carburetion, idling speed, ignition; Laviator, C. F. A. and other engines. Translated from Aeronautique, July and Aug. 1925.

AIRPLANES

Airfoils. The Rolling and Yawing Moments of an Aerofoil in Straight Flight, H. Glauert. Aeronautical Research Committee—Report & Memoranda, no. no. 980, July 1925, 5 pp. Concludes that induced yawing moment can be reduced to some extent by use of tapered wings whose tip chord is less than half the central chord, but possibility of obtaining no yawing moment about wind axes depends on some device which introduces a profile yawing moment of the opposite sign to induced yawing moment.

Multiple-Engine. Multi-Engine Airplanes and Forced Landings, H. G. Smith. Aviation, vol. 20, no. 3, Jan. 18, 1926, p. 78. Points out that multiple engines insure greater reliability; one forced landing in 343,000 flights or one in 1400 years, a possibility.

Scale Effect. The Air Forces on a Model of the Sperry Messenger Airplane Without Propeller, M. N. Munk and W. S. Diehl. Nat. Advisory Committee for Aeronautics—Report, no. 225, 1925, 12 pp., 9 figs. Report on scale effect research made in wind tunnel of National Advisory Committee of Aeronautics with a 1/10 scale model of Sperry Messenger airplane with U.S.A.-5 wings showing that scale effect is almost confined to the drag.

AIRSHIPS

Mooring Towers. 210-Ft. Airship Mooring Tower at Detroit Airport, H. V. Thaden. Eng. News-Rec., vol. 96, no. 5, Feb. 4, 1926, pp. 202-204, 3 figs. With new system, dirigible lands passengers and freight at ground instead of at top of tower; bow held in sliding guide as ship is hauled down; anchor trucks restrain ship's hull.

ALLOYS

Aluminum. *See Aluminum Alloys.*

Brass. *See Brass.*

Viscosity. Viscosity of Alloys at High Temperatures (Contribution à l'étude de la viscosité des alliages à température élevée), J. Cournot and K. Sasagawa. Revue de Métallurgie, vol. 22, no. 12, Dec. 1925, pp. 753-763, 9 figs. Describes apparatus for determining rapidly and with sufficient accuracy speed of hot pouring and limits of viscosity at various temperatures.

ALUMINUM ALLOYS

Casting. The Casting of Aluminum Alloys. Chem. Age (Lond.), vol. 14, no. 342, Jan. 2, 1926, p. 3. Practical notes on process; preparation of alloy.

Commercial. Commercial Aluminium Alloys from the Users' Point of View, J. B. Hoblyn. Foundry Trade Jl., vol. 33, no. 480, Jan. 7, 1926, pp. 3-5, and (discussion), no. 491, Jan. 14, 1926, pp. 34-36. Investigation of how far results obtained experimentally from casting made under favorable conditions, were reproduced in practice; in author's belief, there is a future for heat-treated aluminum alloys in automobile construction; in stressed parts, castings, if heat treated, have very extensive field. (Abstract.)

Duralumin. *See Duralumin.*

Light Casting. Aluminum Alloys Develop Greater Commercial Applications, E. V. Pannell. Foundry, vol. 54, no. Feb. 1, 1926, pp. 105-107. Presents list showing average analysis and approximate physical properties of 67 alloys which are of more or less commercial value.

ALUMINUM

Properties and Uses. Aluminum — Its Strength and Lightness, R. C. Rowe. Can. Foundryman, vol. 17, no. 1, Jan. 1926, pp. 14-17, 4 figs. Malleability and ductility; origin of bauxite and its uses in abrasives; production of aluminum from alumina; uses of aluminum.

AMMONIA

By-Product. By-Product Ammonia in the United States, H. A. Curtis. Am. Fertilizer, vol. 63, no. 9, Oct. 31, 1925, pp. 33-36. Production of by-products, fixed nitrogen, production and distribution of ammonia nitrogen in United States, cost of manufacturing ammonia sulphate, ammoniates and fertilizers, etc.

APPRENTICES, TRAINING OF

Building, Trades. Apprenticeship in the Building Trades, D. L. Hoopingarner. Mech. Eng., vol. 48, no. 2, Feb. 1926, pp. 111-114. Problems of apprenticeship; economic and educational background; what is being done in apprenticeship training in building trades.

Craftsmen. The Training and General Position of the Craftsman, K. C. Appleyard. Foundry Trade Jl., vol. 33, no. 491, Jan. 14, 1926, pp. 28-30, and (discussion), no. 491, Jan. 14, 1926, pp. 28-30, and (discussion), no. 492, Jan. 21, 1926, pp. 51-52. Fundamentals and history of craftsman; present position and future development; social and psychological factors; aspirations of craftsman; discontent and progress; choosing apprentice; artisan training.

Railway. The Training of Railway Apprentices, M. Chouard. Ry. Engr., vol. 47, no. 552, Jan. 1926, pp. 7-10, 2 figs. Details of apprenticeship system developed by Paris-Orleans Railway, which has produced very good results and has greatly increased efficiency of the mechanical engineering staff.

AQUEDUCTS

Providence, R.I. Construction of Steel Portion of Providence Aqueduct, B. F. Snow. Eng. News-Rec., vol. 96, no. 4, Jan. 28, 1926, pp. 159-161, 5 figs. Nearly two miles of 66-in. steel pipe coated at trench side; collapse and restoration of 2200-ft of the line.

ARCHES

Concrete. The Design of a Symmetrical Hingeless Arch, A. C. Hughes. Surveyor, (Lond.), vol. 69, no. 1774, Jan. 15, 1926, pp. 51-53, 6 figs. Abutments of reinforced concrete or mass concrete; forces acting on abutment of arch; spandrel walls, calculations, etc.

Temperature Deformations in Concrete Arches, H. Cross. Eng. News-Rec., vol. 96, no. 5, Feb. 4, 1926, pp. 190-191, 2 figs. Crown deflections give basis for direct method of determining temperature effects by simple calculation.

AUTOMOBILE ENGINES

Crankcase-Oil Dilution. A Suggested Remedy for Crankcase-Oil Dilution, R. E. Wilson and R. E. Wilkin. Soc. Automotive Engrs.—Jl., 18, no. 2, Feb. 1926, pp. 163-170, 11 figs.

Design Trend. Higher Compression Ratios a Feature of This Year's Engines, P. M. Heldt. Automotive Industries, vol. 54, no. 2, Jan. 14, 1926, pp. 50-54, 11 figs. Better understanding of laws of heat flow in combustion chamber, aluminum-alloy pistons and improved fuel are factors contributing to trend; many gear-type oil pumps now outside crankcase.

Sleeve-Valve. Sleeve-Valve Engine Development, W. Ferrier Brown. Automobile Engr., vol. 16, no. 211, Jan. 1926, pp. 18-25, 14 figs. Outlines development of sleeve-valve engine and shows steady progress made with this type from its inception in 1908 to its present state.

Starting. Progress Report on Engine-Starting Tests. J. O. Eisinger. Soc. Automotive Engrs.—Jl., vol. 18, no. 2, Feb. 1926, pp. 147-152, 12 figs.

Steam Cooling. Cylinder-Temperature Control by Evaporation, A. G. Herreshoff. Soc. Automotive Engrs.—Jl., vol. 18, no. 2, Feb. 1925, pp. 153-159, 9 figs.

AUTOMOBILE FUELS

Equilibrium Boiling Points. Equilibrium Boiling Points, W. A. Whatmough. Indus. & Eng. Chem., vol. 18, no. 1, Jan. 1926, pp. 43-45, 2 figs. Equilibrium boiling points of motor fuels have been investigated by Barnard and Wilson, and, independently, by writer in connection with new system of dry-gas carburation, which involves boiling fuel before its admixture as dry gas with air.

Synthetic. Synthetic Motor Fuels—Has Europe Found the Formula? W. Ostwald. Automotive Industries, vol. 54, no. 3, Jan. 21, 1926, pp. 108-110. Author claims there is no longer any doubt as to chemists' ability to produce quality heat units from cheap materials and only question now is how it can be done to best advantage. Translated from Motorwagen.

AUTOMOBILES

Chassis Design. New Cars Reflect Tendency to Build Chassis Closer to Ground, H. Chase. Automotive Industries, vol. 54, no. 2, Jan. 14, 1926, pp. 54-57, 6 figs. Supplementary parts are fitted with greater care than formerly; centralized lubricating systems used on more models.

AVIATION

Aerial Navigation. Progress Necessary to Develop Aerial Navigation (Les Progrès Techniques sont nécessaires au développement de la Navigation Aérienne), E. Allard. Assn. des Ingenieurs sortis de l'Ecole Polytechnique de Bruxelles—Bul. Technique, vol. 21, no. 2, 1925, pp. 33-44, 5 figs. Records attained since Blériot crossed English Channel; problems of safety, economy, metals for airplanes, fuels.

Night Flying. Night Flying Experiments in Europe. Aviation, vol. 20, no. 6, Feb. 8, 1926, pp. 182-183, 1 fig. London-Paris airway lighted; experiments with neon lights and radio direction finding; fog difficulties.

B

BATTERIES

Standard Cells. Standard Electrical Cells, M. Eppley. Franklin Inst.—Jl., vol. 201, no. 1, Jan. 1926, pp. 17-46, 2 figs. Discusses cell made up of cadmium amalgam, solution of salt of cadmium, excess of salt of mercury to correspond to salt of cadmium and mercury; containers for standard cells; neutral solution and acid solution types, etc.

BEARINGS

Oil Film in. Charts for Studying the Oil Film in Bearings, Geo. B. Karelitz. Mech. Eng., vol. 48, no. 2, Feb. 1926, pp. 128-131, 5 figs. Presents charts which give designer or investigator a means of determining with sufficient accuracy the shape and pressures in oil film for bearings under different conditions.

BOILER FEEDWATER

Treatment. Fundamentals in the Conditioning of Boiler Waters, R. E. Hall. Engrs. Soc. of Western Penn.—Proc., vol. 41, no. 9, Dec. 1925, pp. 347-377, 14 figs. Relation of water softening to boiler-water conditioning; deposits resulting from evaporation or natural waters; mechanism of scale formation and means of obviating it; boiler-water sludges and steam-line deposits, control of suspended material and wet steam and non-condensible gases in steam.

Pure Feed Water, D. G. McNair. Power Engr., vol. 21, no. 238, Jan. 1926, pp. 23-25. Deaerators and their functions; evaporators; advantages of multiple effect; preheaters, coils and straight tubes.

BOILER FURNACES

Arches. Suspended Furnace Arches for Bagasse Furnaces. Int. Sugar Jl., vol. 27, no. 324, Dec. 1925, pp. 661-663, 2 figs. Discusses function of furnace arch, flat suspended arches, advantages of Liptak arches, their durability, etc.

Brown-Coal-Fired. Steam Raising Plant at Yallourn, Vic. Commonwealth Engr., vol. 13, no. 4, Nov. 2, 1925, pp 139-141, 3 figs. Details of John Thompson water-tube boilers fired with brown coal at power station of the Victorian Electricity Commission, each boiler guaranteed to evaporate 70,000 lb. of water per hour; test carried out with brown coal containing 48 per cent moisture showed maximum of 105,000 lb. per hour and efficiency of 77.3 per cent, stokers burning 98 lb. of coal per sq. ft. on grate area.

Combustion Control. Combustion Control System Reduces Labor. Blast Furnace & Steel Plant, vol. 14, no. 1, Jan. 1926, p. 47. Describes system which saved $4359.04 a year in wages, and also increased boiler efficiency appreciably.

European. Fuels and Furnaces in Europe, W. Trinks. Fuels & Furnaces, vol. 4, no. 1, Jan. 1926, pp. 19-30 and 36'22 figs. Developments noted by author on recent trip; high-temperature and low-temperature carbonization; liquefaction of coal; materials handling; heating furnaces; sheet furnaces; welding, atmosphere control, etc.

Oil-Fired. Systems for Burning Liquid Fuel. Southern Power Jl., vol. 44, no. 1, Jan, 1926, pp. 39-47, 18 figs. Design of coil burning furnaces, advantages and drawbacks of oil firing, circulation and heating of oil, types of oil burners, operating costs, etc.

Radiation in. Radiation in Boiler Furnaces, B.N. Broido. Mech. Eng., vol. 48, no. 2, Feb. 1926, pp. 133-137 and (discussion) 137-138, 4 figs.

Wall Design. Refractories for Boiler Furnace Walls, H. C. Thayer. Power Plant Eng., vol. 30, no. 4, Feb. 15, 1926, pp. 256-257, 4 figs. Designs of furnace walls which overcome difficulties due to expansion and contraction of firebrick under influence of temperature changes, etc.

BOILER OPERATION

Valve Control. Motor Control for Valves, C. J. Sittinger. Elec. World, vol. 87, no. 4, Jan. 23, 1926, pp. 201-202, 2 figs. Montaup Elec. Co. uses central control system for closing boiler valves at Somerset station; emergency system provided.

BOILER PLANTS

Fuel Measurement for Tests. Fuel Measurement for Boiler Tests, D. S. Frank. Power Plant Eng., vol. 30, no. 3, Feb. 1, 1926, pp. 200-201, 2 figs. Simple yet accurate apparatus for weighing coal or oil, constructed at small cost.

BOILER PLATE

Metallurgical Problems. The Metallurgical Aspects of Modern Boiler Practice, L. P. Sidney. Chem. Age (Lond.), vol. 14, no. 342, Jan. 2, 1926, pp. 2-3. Factors of problem; boiler pressures and temperatures; elasticity and viscous flow; determinations of flow; chromium and nickel in boiler plates.

BOILER TUBES

Failures. Why Boiler Tubes Burnt Out, Geo. C. Reinhard. Power, vol. 63, no. 2, Jan. 12, 1926, pp. 51-53, 3 figs. Removal of scale resulted in tube failure; scientific study made of conditions; trouble due to sulphur in oil.

BOILERS

Electrically Heated. Central Heating Plant by Means of Electric Boilers of Lyons Gas Co. (L'installation de chauffage central par chaudières électriques de la Compagnie du Gas de Lyon), D'Aubenton-Carafa. Electricien, vol. 56, no. 1384, Nov. 15, 1925, pp. 512-514, 4 figs. Design and operation of boilers heated by current during low load (mainly night time) calculated to maintain a temperature of +18 deg. cent. for 10½ hours per day with outside temperature at —10 deg. cent.; steam accumulators of 30 cu. m., one each boiler; pipe lines of 1600 m.

Fuel-Waste Estimation. Insufficient Data for Estimating Fuel Waste, H. D. Fisher. Power Plant Eng., vol. 30, no. 3, Feb. 1, 1926, pp. 218-220. Points out that fuel-gas temperature, soot on tubes and carbon in ash are entirely overlooked by F. C. DeWeese in his investigation of a poorly run boiler plant, described in Nov. 15, 1925, issue of same journal.

Internal-Combustion. The Internal-Combustion Boiler, O. Brunler. Inst. Mar. Engrs.—advance paper for mtg. Nov. 24, 1925, 6 pp., 5 figs. Details of internal-combustion boiler, principle of which is to maintain flame burning in water in order to produce steam; application to generator which can produce 11,000 lb. of steam-gas mixture per hour.

Locomotive. *See Locomotive Boilers.*

Water-Tube. *See Boilers, Water-Tube.*

BOILERS, WATER-TUBE

Oil-Fired. Handling Oil-Fired Water-Tube Boilers, Geo. H. Briggs. Power, vol. 63, no. 4, Jan. 26, 1926, pp. 130-131. Problems encountered; proper air regulation; damper control.

BOLTS

Manufacturing and Stocking. Manufacturing and Stocking Bolts in the Shop, E. Kennedy. Ry. Mech. Engr., vol. 100, no. 1, Jan. 1926, pp. 56-57, 2 figs. Notes on establishing a system for manufacturing and stocking of finished bolts.

BOREHOLES

Surveying. A New Instrument for Surveying Boreholes, J. S. Owens. Instn. Min. & Metallurgy—Bul., no. 256, Jan. 1926, pp. 1-18, 20 figs. Describes new instrument for surveying boreholes consisting of external water-tight casing which protects internal mechanism from injury; the latter is opened in two carrier tubes connected mechanically and electrically by means of bayonet joint which permits them to be withdrawn for adjustment, setting and charging; in one carrier tube clinometer and compass bowl are free to rotate on axis at right angles to the cradle pivot other carrier tube contains mechanism controlling consecutive exposures.

BRASS

Heat Treatment. Annealing, Tempering and Drawing of Some Industrial Nickel-Brasses (Le recuit, la trempe et le revenu de quelques laitons au nickel industriels), F. M. Ostroga. Revue de Métallurgie, vol. 22, no. 12, Dec. 1925, pp. 776-786, 16 figs. Concludes that it is always possible to secure hardening corresponding to annealed state of metal by means of tempering with or without drawing; hardness is the more pronounced the finer the new microstructure.

Ingot Production. The Production of Sound Brass and Copper Ingots. Metal Industry (Lond.), vol. 28, no. 1, Jan. 1, 1926, pp. 3-7. General discussion of practical problems at meeting of Birmingham and West Midlands Section of Inst. of Metals, dealing with mold dressings, mold materials, pouring temperatures and speeds, cooling rates, feeding, casting and melting equipment, manual skill, etc.; comparisons of British, European Continental and American practice.

Melting and Pouring. Melting and Pouring of Brass and Bronze, T. J. Bamford. Foundry Trade Jl., vol. 33, no. 493, Jan. 28, 1926, pp. 76-78. Utilization of scrap metal; aluminum as an impurity; using turnings and borings; melting furnaces. Includes discussion and author's reply.

BRASS FOUNDRIES

Tumblers for Castings. Tumblers for Brass Castings. Foundry Trade Jl., vol. 32, no. 488, Dec. 24, 1925, p. 256. Discusses use of tumbling barrel as cleansing factor; tumbling consists of filling or partially filling barrels with castings, cleansing material and sometimes liquid; shapes and materials employed in making tumblers; loading tumblers.

BRIDGE PIERS

Underpinning. High-Level Bridge, Newcastle-upon-Tyne: Underpinning and Repair of Foundations of River Piers, C. F. Bengough. Engineering, vol. 121, no. 3132, Jan. 8, 1926, pp. 43-44. Methods employed in underpinning foundations with concrete; excavation was carried out through shafts; concrete used in underpinning was 1:2:4 mixture. (Abstract.) Paper read before Instn. Civ. Engrs.

BRIDGES, CONCRETE

Arch. Bridge Reconstruction Work of the Ministry of Transport. Engineering, vol. 121, no.3136, Feb. 5, 1926, p. 157, 4 figs. partly on p. 172. Reconstruction of Muskham bridge over River Trent; new bridge consists of two skew arches, each of 100-ft. span over river, and two 25-ft. shore spans, which serve as flood openings; these are constructed as reinforced concrete girders.

Continuous Girder. Reinforced Concrete Continuous Girder Bridge Built in China. Eng. News-Rec., vol. 96, no. 4, Jan. 28, 1926, p. 149, 2 figs. Details of 11-span highway bridge, 616-ft. long at Shin Tai Hsien.

Floor Slabs. Wearing Surfaces for Concrete Bridge Floor Slabs, E. F. Kelley. Eng. News-Rec., vol. 96, no. 1, Jan. 7, 1926, pp. 26-27. Renewable surface desirable on reinforced concrete floors as protection from injury by tire chains.

BRIDGES HIGHWAY

Concrete. The Construction of the New Oswald-street Bridge, Glasgow, W. L. Scott. Engineer, vol. 141, no. 3655, Jan. 15, 1926, pp. 62-63, 7 figs. Deals with erection of structure, particularly construction of river and abutment piers and their foundations; supports for river pier, and abutment lintol beams, consist of circular reinforced concrete caissons.

Construction 1925. Highway Bridge Construction Activity in 1925. Eng. News-Rec., vol. 46, nos. 2 and 3, Jan. 14 and 21, 1926, pp. 79-83 and 122-124, 26 figs. Summary of state highway bridge construction by regions and states based on incomplete reports from several highway departments.

Impact Studies. Experimental Impact Studies on Highway Bridges, A. H. Fuller and R. A. Caughey. Iowa State College Agriculture & Mech. Arts—Official Pub., vol. 24, no. 30, Dec. 23, 1925, 61 pp., 45 figs. Details of 1925 work of co-operative project by U. S. Bureau of Public Roads, Iowa State Highway Commission and Engineering Experiment Station of Iowa State College to investigate the effect of impact; covers determination of observed stresses due to certain static and dynamic loads in steel floor systems and in some cases of truss members of five steel bridges with concrete floor slabs and seven steel bridges with plank flooring.

Loading. British Standard Unit Loading for Highway Bridges, J. M. Liddell. Engineer, vol. 141, no. 3657, Jan. 29, 1926, pp. 119-121, 12 figs. Explanation of charts. Description of unit loading; maximum stresses in plate girders and in framed girders; maximum pier reactions.

Melbourne, Victoria. Premium Design for Bridge over River Yarra, Melbourne. Civil Eng. Rec., vol. 2, no. 6, Dec. 15, 1925, pp. 196-200, 1 fig. Details of bridge 320-ft. long between inside faces of abutments on roadway of 75-ft. clear between kerbs and two 12-ft. sidewalks, with clear headway of 11-ft. above low water; competitive designs for Victorian Public Works Department.

BRIDGES, RAILWAY

Steel. Building Four-Track Steel Bridge Over Newark Bay: Two Types of Foundation. Eng. News-Rec., vol. 96, no. 5, Feb. 4, 1926, pp. 184-189, 7 figs. Bridge over Newark Bay built by Central Railroad of New Jersey, having high-level crossing of girder spans with two vertical lifts, replacing present low-level trestle with bascules; details of floating cofferdam and pneumatic piers.

Central of New Jersey Builds Remarkable Bridge. Ry. Age, vol. 80, no. 3, Jan. 16, 1926, pp. 217-222, 8 figs. Four-track structure across Newark Bay contains a mile of long girder spans and 4 double-track lift spans.

BUILDING CONSTRUCTION

FIREPROOF. Fire-Proofing the Bronx Terminal Market Building, F. W. Skinner. Brooklyn Engrs. Club—Proc., vol. 24, Oct., 1925, pp. 17-35, 13 figs. Construction equipment, methods, and operations for encasing exposed steel surfaces of floor beams, girders and trusses, with reinforced gunite; storing, conveying and mixing sand and cement for 12,000 cu. yd. of gunite; application of gunite, cement guns, etc.

BUSBARS

60-CYCLE FOR HEAVY CURRENTS. Carrying Capacity of 60-Cycle Busses for Heavy Currents, T. G. Le Clair. Am. Inst. Elec. Engrs.—Jl., vol. 45, no. 1, Jan. 1926, pp. 9-14, 9 figs. Paper is presented with idea of giving ready reference for determining bus-capacities without involved calculations; curves are given showing carrying capacity of a few types which are proposed as standards, and, in addition, a few curves compiled from tests showing distribution of current in busses to show necessity of this type of design; by a little careful study of these curves, average designer may quickly choose type of bus which will best meet his requirements for carrying capacity and allowable space.

C

CABLES, ELECTRIC

HIGH-TENSION. Dielectric Problems in High-Voltage Cables, P. Dunsheath. Instn. Elec. Engrs.—Jl., vol. 64, no. 349, Jan. 1926, pp. 97-125 and (discussion) 125-149, 63 figs. Deals with important problems of particular theoretical and practical interest at present time in connection with design, manufacture, and operation of high-voltage impregnated-paper cables; dielectric absorption; fundamentals of a.c. losses; "V" curve for loss and power factor; connection between a.c. and d.c. losses; rise of power factor with voltage; breakdown; assessment of cable quality; absorption calculations. Bibliography.

Testing High-Voltage Cables with D.C. After Installation, N. A. Allen. Elec. Communication, vol. 4, no. 3, Jan. 1926, pp. 184-195, 13 figs. Methods of producing high tension d.c., operation of Kenotron rectifier testing set, fault location, etc.; two-valve Kenotron can be used very efficiently for applying d.c. integrity tests to cables after installations, Kenotron outfit can be utilized for burning out faults sufficiently to permit making accurate localization tests. Bibliography.

IMPREGNATING. Methods of Impregnating Cables, H. W. Fisher. Elec. World, vol. 87, no. 4, Jan. 23, 1926, pp. 195-196, 4 figs. New developments in impregnation of high-voltage cable; advantages and disadvantages of practices used; newest scheme offers great possibilities.

CABLEWAYS

FUNICULAR. The Aiguille du Midi Funicular Aerial Line (Le funiculaire aérien de l'Aiguille du Midi), A. Bourgain. Nature (Paris), no. 2697, Dec. 12, 1925, pp. 373-380, 12 figs. Layout and constructon of line from Pèlerins to Paraz and finally to Midi (near Mount Blanc, Switzerland), of 3842-m. altitude, of which the first section has recently been opened to traffic; three-cable system; cars equipped with electric motors of 55 to 70 kw.

CAR COUPLERS

AUTOMATIC. Japanese Railways Adopt Automatic Couplers, S. Akiyama. Ry. Mech. Engr., vol. 100, no. 1, Jan. 1926, pp. 30-34, 6 figs. Final work of changing from screw and link type to automatic is completed in one day.

Vienna Tests New Coupler. Elec. Traction, vol. 22, no. 1, Jan. 1926, pp. 31-32, 4 figs. New system of automatic train and current coupling being tested in Vienna, Austria.

CAST IRON

ANALYSIS. The Rapid Determination of Structural or Constitutional Analysis, J. E. Fletcher and J. G. Pearce. Brit. Cast Iron Research Assn.—Bul. no. 11, Jan. 1926, pp. 17-20, 6 figs.

DIESEL-ENGINE. Cast Iron for Diesel Engines, A. Campion. North-East Coast Instn. Engrs. & Shipbldrs.—advance paper, for mtg. Jan. 22, 1926, pp. 201-216, 10 figs.

FACTORS AND PROBLEMS. Some Factors which Constitute Problems in the Iron Foundry, S. G. Smith. Foundry Trade Jl., vol. 33, no. 492, Jan. 21, 1926, p. 42. Stresses importance of freezing phenomena, volume changes, solid contraction, etc.; distortion is direct result of contraction; examples of effect of mass on shrinkage; importance of correct sand control and of adequate liquid metal in risers to accomplish proper feeding. (Abstract.)

GRAPHITE IN. Graphite in Pig and Cast Iron. Metal Industry (Lond.), vol. 28, no. 2, Jan. 8, 1926, pp. 39-40, 1 fig. Discusses importance of effect on graphite of temperature to which iron is raised during smelting and remelting; refers to some of principal researches on subject, more particularly recent work of Piwowarski; importance of subject in connection with suggested reforms of pig-iron grading.

GRAY, LIQUID SHRINKAGE OF. Liquid Shrinkage in Grey Iron, J. Longden. Foundry Trade Jl., vol. 33, no. 494, Feb. 4, 1926, pp. 85-92, 17 figs. Existing theories; defects due to what is known as Leonard effect; influence of dissolved gases; experimental data; influence of temperature on castings; graphite in molten cast iron; influence of length of cooling range; influence of slow pouring; filtering cast iron; rod feeding; chills and denseners; feeding heads.

GRAY, STRUCTURE OF. Compares Gray Iron Structure, Wm. Campbell. Foundry, vol. 54, no. 4, Feb. 15, 1926, pp. 148-149, 5 figs. Comparison between structure of gray iron cast in sand molds and cast-iron permanent molds cooled by oil. Abstract of report.

PEARLITIC. Pearlitic Cast Iron (La fonte perlitique), B. Buffet and A. Roeder. Société Industrielle de Mulhouse—Bul., vol. 91, no. 9, Nov. 1925, pp. 622-634, 14 figs. Discusses qualities of good gray iron, machinable cast iron, pearlitic and steeled cast iron, graphitization, testing and uses.

SUPERHEATING. The Superheating of Cast Iron. Metallurgist (Supp. to Engineer, vol. 141, no. 3657), Jan. 29, 1926, pp. 15-16, 1 fig. Review of two papers by Piwowarski, published in Stahl u. Eisen, Aug. 27 and Dec. 3, 1925.

CASTINGS

ECONOMICAL PRODUCTION. Cutting Down Waste on Castings, A. A. Wood. Iron Age, vol. 117, no. 7, Feb. 18, 1926, pp. 487-488, 2 figs. Reducing amount of metal and thus minimizing machining operations successfully practised in many plants; in author's belief, excess finish is economic waste; large savings in plant of Warren Webster & Co., Camden, N. J., in cutting down patterns. (Abstract.) Paper read before Philadelphia Foundrymen's Assn.

MACHINES FOR HOLLOW. Casting Machines for Production of Hollow Castings such as Tubes, (Machine à couler pour la fabrication de pièces de fonte à noyaux, telles que les tubes, etc.) Métallurgie et Construction Mécanique, nos. 50 and 51, Dec. 10 and 17, 1925, pp. 1675-1679 and 1715-1719, 13 figs. Details of machine in which formation of mold and core and their assembling is carried out automatically; machine after producing the core places it accurately in the mold produced simultaneously.

CEMENT, PORTLAND

PROGRESS. Twenty-one Years' Progress in the Portland Cement Industry, A. C. Davis. Concrete & Constructional Eng., vol. 21, no. 1, Jan. 1926, pp. 69-77, 6 figs. Discusses progress in manufacture, improvements in quality, increase in fineness and strength, rapid-hardening, aluminous cement, testing, etc.

CENTRAL STATIONS

BUDGETING OPERATION. Budgeting Central-Station Operation, H. P. Liversidge. Elec. World, vol. 87, no. 4, Jan. 23, 1926, pp. 189-191, 1 fig. Points out that budgets help keep balance among three dominating factors, engineering, financing and commercial activities; outlines their scope; details of their formulation and operation; measurement of success.

CONTROL BOARDS. Power Station Control Boards, E. Zeuthen. Elec. Jl., vol. 23, no. 1, Jan. 1926, pp. 4-9, 7 figs. Details of advance in design for Toronto power station and Boardman substation of Ohio River Edison Co.; making switching practically fool-proof by suitable interlocking, facilitating real supervision by limiting panel equipment to essential instruments, segregating switchboards, etc.

CHAIN DRIVE

SILENT. Silent Chain Drives on Industrial Equipment, F. E. Gooding. Indus. Engr., vol. 84, no. 1, Jan. 1926, pp. 8-12, 8 figs. Discusses application in driving compressors, blowers and fans, conveyors, pulverizers, etc.

CITIES

ENGINEERING IN. Engineering in the Small City, A Survey. Eng. News-Rec., vol. 96, no. 2, Jan. 14, 1926, pp. 76-78. Suggested improvements in administration of engineering services in the city under 100,000 population, based on editorial study from coast to coast.

CLAY

BENTONITE. The Minerals of Bentonite and Related Clays and Their Physical Properties, C. S. Ross and E. V. Shannon. Am. Ceramic Soc.—Jl., vol. 9, no. 2, Feb. 1926, pp. 77-96, 2 figs. Occurrence and structure, mineralogy and chemical composition, optical properties.

COAL

ASH. Coal Ash and Clean Coal, R. Lessing. Royal Soc. of Arts—Jl., vol. 74, nos. 3817 and 3818, Jan. 15 and 22, 1926, pp. 182-197 and 205-218, 13 figs. Reviews treatment of coal at collieries, showing that every step in operations is closely bound up with problems for solution of which a knowledge of its mineral constituents and chemical and physical properties is indispensable; distribution of mineral matter in coal, chemical method of coal getting, clearing and washing process, sampling, etc.

CARBONIZATION. The Case for Low Temperature Carbonization in America Today, H. W. Brooks. Combustion, vol. 14, no. 1, Jan. 1926, pp. 46-54, 3 figs. Compares American and European conditions, concludes that lower temperature carbonization lends itself better to dividend-paying possibilities in America than by-product coke oven methods on account of lower operating and investment costs, higher oil and richer gas yields, and production of finely divided easily ignitable coke, etc.

HEATING VALUE. A Simple Method for Determining Heating Value of Solid Fuels (Einige einfache Verfahren zur Bestimmung der Heizwertes fester Brennstoffe), H. Winkelmann. Brennstoff- u. Wärmewirtschaft, vol. 7, no. 24, Dec. 2, 1925, pp. 477-482. Method of taking samples approved by V. D. I. (Assn. of German Engrs.) and others; determining water content and ash content; describes von Jüptner process of calculation in which one gram of finely pulverized fuel is put into a platinum crucible and after determining moisture content, is heated until no more combustible gases escape.

PULVERIZED. *See Pulverized Coal.*

SEMI-COKING. Low-Temperature Semi-Coking Benefits Coal, R. D. Hall. Coal Age, vol. 29, no. 3, Jan. 21, 1926, pp. 112-114, 1 fig. Toledo plant manufactures amalgam; Rhode Island field prepares to produce carbonized product; charring coal dust in suspension is new venture.

COAL HANDLING

PAPER MILLS. Coal Handling and Boiler Operation at Northern Paper Mills, H. W. Gochnauer. Mfg. Industries (Mgmt. & Admin.), vol. 11, no. 1, Jan. 1926, pp. 23-24, 5 figs. Methods and equipment employed.

COKE MANUFACTURE

METHODS. The Manufacture of Coke of the Most Suitable Qualities for Domestic and Industrial Purposes, W. W. Townsend. Gas Jl., vol. 173, no. 3269, Jan. 6, 1926, p. 31. Selection of coals, washing at colliery or gas-works, blending, retorting and quenching in thin layers.

COLD STORAGE

PLANTS. Modern Warehouse of Terminal Refrigerating & Warehousing Co. Ice & Refrigeration, vol. 70, no. 1, Jan. 1926, pp. 118-122, 12 figs. Describes combined cold-storage and ice-making plant: details of structural features; insulation; refrigerating system, etc.

COLUMNS

CRITICAL LOAD. The Theory of Columns, Jas. J. Guest. Engineering, vol. 121, no. 3136, Feb. 5, 1926, p. 186, 2 figs. Author describes method by which he obtains Eulerian critical load.

CONCRETE

FIELD, STRENGTH OF. Effect of Manipulation on Strength of Field Concrete, G. W. Hutchinson. Eng. News-Rec., vol. 96, no. 6, Feb. 11, 1926, pp. 246-247, 1 fig. Tests show that concrete of constant visible quality varies according to amount of work given placing.

READY MIXED. Ready Mixed Concrete Easily Sold in Birmingham, Ala., W. E. Barker. Eng. News-Rec., vol. 96, no. 7, Feb. 18, 1926, pp. 282-283, 3 figs. Mechanical features, testing and inspection, and business methods of plant selling concrete that utilizes blast furnace slag for aggregate.

RESEARCH. Researches in Concrete, W. K. Hatt. Purdue Univ. Eng. Dept.—Bul., vol. 9, no. 11, Nov. 1925, 102 pp., 30 figs. Survey of research work on occasion of the 100th anniversary of invention of Portland cement, comprising expansion and contraction, strength of dry and wet hardened concrete, extensibility, elasticity, plastic flow, permeability, fatigue, heat transmission, fire resistance of concrete, non-rusting of steel, reinforcing steel and bond, effect of age, amount of mixing water, time of mixing, field and laboratory tests. Bibliography.

WATER PERMEABILITY AND ABSORPTION. Relation between Water Permeability and Water Absorption of Concrete, E. Anderson. Indus. & Eng. Chem., vol. 18, no. 1, Jan. 1926, pp. 17-18, 1 fig. Describes water-absorption and water-permeability tests for concrete; results of experiments indicate that there is, in general, no direct relation between per cent water absorption of cement mortar specimen and its water permeability or water tightness; recommends that for determination of water permeability of concrete some method be employed which directly measures this property.

CONCRETE BLOCKS

TESTING. A Method of Testing Concrete Blocks, H. G. Lloyd. Structural Engr., vol. 4, no. 1, Jan. 1926, pp. 3-14, and discussion 15-16, 2 figs. Discusses consistency of portland cement and method of determination; ingredients used in concrete, grading, percentage of water, method of preparation of blocks, crushing tests and crushing strength, comparison of weight and strength, etc.

CONCRETE CONSTRUCTION, REINFORCED

DESIGN. Reinforced Concrete in Relation to Present-Day Design, A. E. Richardson. Concrete & Constr. Eng., vol. 21, no. 1, Jan. 1926, pp. 37-46, 7 figs. Discusses necessity for co-operation between architect and engineer; traditional methods and materials; development of steel and concrete, possibilities of reinforced concrete; and gives various examples.

CONCRETING

COLD-WEATHER. Aids to Cold-Weather Concreting, H. L. Mahaffy. Contract Rec., vol. 40, no. 5, Feb. 3, 1926, pp. 88-89, 1 fig. Details of convenient method of determining temperatures of concrete in place.
Winter Concrete Must Be Kept Warm, A. M. Bouillon. Ry. Eng. & Maintenance, vol. 22, no. 1, Jan. 1926, pp. 10-13, 5 figs. Heating of aggregates and water should be followed up with precautions against freezing in forms.

CONDUITS

INSTALLATION AND USES. The Installation and Uses of Conduit, J. E. Housley. Power, vol. 63, no. 2, Jan. 12, 1926, pp. 58-59, 1 fig. Discusses kinds and types of conduit, roughly divided into rigid and flexible classes; methods of installation.

CONVERTERS

SYNCHRONOUS. Synchronous Converters and Synchronous Motor-generator Sets Compared for Industrial Service, W. B. Snyder. Gen. Elec. Rev., vol. 29, no. 2, Feb. 1926, pp. 115-117, 3 figs. A balanced analysis of inherent characteristics of both sources of direct-current power, to enable proper selection; discusses first cost and efficiency, power-factor, power contract, power supply, direct-current load, etc.

CORROSION

PROBLEMS. Meeting of German Corrosion Committee. Metal Industry (Lond.), vol. 28, no. 3, Jan. 15, 1926, pp. 53-55 and 66. Summarized translations of papers presented at meeting of German Official Committee for Metal Protection (Reichsausschuss für Metallschutz), as follows: Tin Plating and Lead Plating, M. Schlötter; Determination of Quality of Zinc Coatings, H. Bablik; Influence of Thermal and Mechanical Treatments upon Resistance of Aluminum to Corrosion, W. Wiederholt; Corrosion of Condenser Tubes, E. Goos; Cathodic Polarization of Metals, E. Liebreich.

COUPLINGS

SHAFTING AND MACHINES, CONNECTING. Types of Couplings for Connecting Shafting and Machines, S. Rice. Belting, vol. 28, no. 1, Jan. 1926, pp. 29-30. Discusses flange, sleeve, clamp, compression, cut-off and flexible coupling, general construction and service to which each is adapted.

CRANES

ELECTRIC DERRICK. Electric Derrick Crane. Engineering, vol. 121, no. 3136, Feb. 5, 1926, pp. 108-109, 6 figs. Crane of level-luffing type made by Anderson-Grice Co., Carnoustie, Scotland.

FULL-ARCH. Cranes Increase Pier Capacity over 300 Per cent. Eng. News-Rec., vol. 96, no. 3, Jan. 21, 1926, pp. 118-119, 2 figs. Full-arch cranes of 10 to 20-ton capacity built for New York Central Railroad at Weehawken, N. J., to handle boxed automobiles for export.

JIB DESIGN. Notes on the Design of Crane Jibs, F. G. Fiegehen. Mech. World, vol. 79, no. 2037, Jan. 15, 1926, pp. 48-50, 4 figs. Detailed discussion of design.

CRUSHERS

GYRATORY. The Development of the Gyratory Crusher, H. W. Weimer. Rock Products, vol. 29, no. 2, Jan. 23, 1926, pp. 38-41, 5 figs. Discusses rock crushing machinery, use and applications, size of crushers, capacity, power requirements, erecting and operating.

CUPOLAS

AIR-BLAST CONVEYANCE TO. The Conveyance of Air-Blast to Cupolas and Forced-draught Furnaces, W. J. May. Mech. World, vol. 79, no. 2036, Jan. 8, 1926, pp. 28-29, 6 figs. Discusses air propelling and distributing.

CUTTING METALS

OXYGEN LANCE. Cutting Salamanders and Heavy Masses of Iron with an Oxygen Lance, E. E. Thum. Blast Furnace & Steel Plant, vol. 14, no. 1, Jan. 1926, pp. 18-20, 1 fig. Outlines methods whereby large masses or blocks of iron or steel may be cut to handling size; oxygen lance consists essentially of steel pipe, passing a stream of pure oxygen; operation of lance; application to drilling of salamanders, breaking up spills and ladle skulls, and cutting ingots and heavy metal masses.

CUTTING TOOLS

LUBRICATION AND COOLING. Cutting, Grinding and Rust Prevention, J. A. Maguire. Can. Machy., vol. 35, no. 1, Jan. 7, 1926, pp. 26-27. New method of holding oil in a cutting emulsion in suspension with water, thus avoiding rust, keeping point of tool cooler, and lengthening its life.

STARTING. Starting Cutting Tools, F. Horner. Can. Machy., vol. 35, no. 4, Jan. 28, 1926, pp. 13-16, 8 figs. Devices used to insure accuracy and prevent damage;; special starting tools; eccentric cuts; use of loose bushings, etc.

D

DAMS

CONCRETE. Bulding America's Largest Dam, W. B. West. Sibley Jl. Eng., vol. 39, no. 9, Dec., 1925, pp. 419-422 and 428-429, 5 figs. Details of Wilson dam, largest concrete dam for hydro-electric development in U.S.A., containing 1,000,000 cu. yds. of concrete; data on electric equipment of Muscle Shoals Nitrate plant.

EARTH-FILL. Construction Methods on Alouette Dam. Contract Rec., vol. 40, no. 3, Jan. 20, 1926, pp. 46-49, 7 figs. Details of plant and procedure in building an earth-fill dam, 1000 ft. long and 63 ft. high, which forms a storage reservoir for the Alouette power development in British Columbia.

FAILURES. Failure of Dam in Wales Due to Washout Under Foundation. Eng. News-Rec., vol. 96, no. 1, Jan. 7, 1926, pp. 12-13, 5 figs. Concrete footings not carried to depth required by plans; poor concrete; lack of engineering supervision.

WATER PRESSURES. Tests of Water Pressures Under Brule River Dam. Eng. News-Rec., vol. 96, no. 7, Feb. 18, 1926, pp. 274-275, 4 figs. Dam of Peninsular Power Co., near Florence, Wis., has pipes from foundation to downstream face, fine cracks in bedrock prove practically watertight.

DIE CASTING

DEVELOPMENTS. Diecasting Industry Makes Progress, J. S. Gullborg. Foundry, vol. 54, no. 2, Jan. 15, 1926, pp. 48-49. Material used in early days of industry: use of stronger and more ductile material as industry grew larger; modern machines; proper filling and ventilating of dies. (Abstract.) Address before Chicago Foundrymen's Club.

DIES

CONSTRUCTION OF. Construction of Sheet Metal Tools, C. E. Stevens. Forging—Stamping—Heat Treating, vol. 12, no. 1, Jan. 1926, pp. 18-25, 10 figs. Details of die construction.

DIESEL ENGINES

GENERATOR DRIVE. Flywheel-Type Generators for Oil Engines. Oil Engine Power, vol. 4, no. 2, Feb. 1926, pp. 76-79, 8 figs. Rotor of generator supplants flywheel, reduces generator and overall cost, saves outboard bearings.

INDUSTRIAL USE. Industrial Use of the Diesel Engine, M. Rotter. Power Plant Eng., vol. 30, no. 4, Feb. 15, 1926, pp. 263-264. Consideration of Diesel installations involves efficiency, cost of fuel and lubrication, maintenance and fixed charges.

DIRECTION FINDING

EXPERIMENTAL RESULTS. Radio Direction Finding. Aviation, vol. 20, no. 4, Jan. 25, 1926, pp. 109-110. Results of experimental work reported by E. Sibley, Superintendent of Radio Air Mail Service.

DREDGES

HYDRAULIC. High Power Hydraulic Dredge for General Contracting, J. M. Allen. Eng. News-Rec., vol. 96, no. 5, Feb. 4, 1926, pp. 196-197, 1 fig. Speed-up gear gives high runner velocity with slow speed engine; frame barge gives mobile discharge.

DURALUMIN

HEAT TREATMENT. The Effect of Heat Treatment on Some Mechanical Properties and on the Microstructure of Duralumin Sheet, Rob. J. Anderson. Am. Metal Market, vol. 33, no. 12, Jan. 19, 1926, pp. 4-6 and 16. Brief abstract of results of extensive investigation on constitution, heat treatment and microstructure of duralumin, Thesis presented to Mass. Inst. Technology.

E

EDUCATION ENGINEERING

ELECTRICAL. Report of Conference of Teachers of Electrical Engineering, Held at Schenectady, N.Y., June, 17, 1925, L. A. Hawkins. Eng. Education—Jl., vol. 16, no. 5, Jan. 1926, pp. 378-388. Discusses research as an aid in teaching.

ELECTRIC CONDUCTORS

SINGLE. Properties of the Single Conductor—New Fundamental Relations, C. Hering. Am. Inst. Elec. Engrs.—Jl., vol. 45, no. 1, Jan. 1926, pp. 31-39, 7 figs. In opinion of writer, proofs, deductions, and discussion herein presented, will show that new system of treatment of electrical problems can be based on single-straight conductor, as distinguished from that based on Maxwell complete circuit; not to replace latter system but to supplement it, and to test correctness of parts of it; single-conductor system leads to some new and useful results, and shows that term self-inductance has been used in dual sense and that distinction should be made analogous to that between resistance and reactance.

ELECTRIC CURRENTS, ALTERNATING

ANALYSIS. Alternating Current Analysis, R. D. Mershon. Am. Inst. Elec. Engrs.—Jl., vol. 1, Jan. 1926, pp. 43-45, 4 figs. Analytical method of solving a.c. problems, requiring simple algebra only.

ELECTRIC FURNACES

AUXILIARIES. Auxiliary Equipment for Electric Furnaces, J. D. Keller. Fuels & Furnaces, vol. 4, no. 1, Jan. 1926, pp. 49-56, 17 figs. Discusses wiring diagrams, control and safety switches, relays and fuses, for resistor-type furnaces.

BRASS-MELTING. Melting Brass by Electricity. Elec. News, vol. 34, no. 2, Jan. 15, 1926, p. 25, 1 fig. National Bronze Co., Montreal, install 175-kva. electric furnace; excellent central-station load; one of few used for this purpose in Canada.

HARDENING. Magnetic Indicator is Designed to Control Hardening Furnace Temperatures. Automotive Industries, vol. 54, no. 3, Jan. 21, 1926, pp. 104-105, 3 figs. Describes Wild-Barfield automatic hardening furnace manufactured in London, Eng., equipment consists of electrically heated furnace and control panel electrically connected thereto; latter consists of magnetic indicator which produces musical sound until steel ceases to be magnetic, which is considered correct temperature for quenching.

HEAT BALANCE OF. Balance of Electric Furnaces (Le bilan des fours électriques), A. Levasseur. Société Française des Electriciens—Bul., vol. 5, no. 48, Aug. 1925, pp. 738-771, 13 figs. Electric, calorific and electrothermal efficiency; consumption of electrodes; induction, resistance and arc furnaces; power factors; advocates more rational study of furnaces and abandonment of mere empiricism.

HEAT-TREATING GEARS. Gears Heat Treated Electrically. Iron Age, vol. 117, no. 6, Feb. 11, 1926, pp. 401-402, 2 figs. Normalizing and hardening in automatic furnaces; compensating action of heat and large savings are features.

HIGH-TEMPERATURE. High Frequency Electric Induction Furnaces for very High Temperatures (Fours électriques à induction à haute fréquence pour très hautes températures), Ribaud. Jl. de Physique & Radium, vol. 6, no. 9, Sept. 1925, pp. 294-299, 5 figs. Describes two models of furnaces which may be used up to 3000 deg. cent., with linings of porous charcoal of very low heat conductivity; may be used for burning or melting refractories, and for reactions in a gaseous atmosphere, etc.; provided with optical pyrometers.

OSCILLATING. The Oscillating Electric Furnace, Nolly System (Four Electrique oscillant, système de Nolly). Jl. du Four Electrique, vol. 34, no. 17, Dec. 1, 1925, pp. 230-232, 2 figs. Furnace used by Société Métallurgique de St-Béron, for melting reduction and refining, a combination of several electrodes replacing usual silica arch; cooled by circulating water; advantages, etc.

ELECTRIC LOCOMOTIVES

SAFETY DEVICE FOR. Safety Device for Electric Locomotives. Elecn., vol. 96, no. 2488, Jan. 22, 1926, pp. 88-89, 3 figs. New device used by Rhaetian Railways in Switzerland, developed by Brown Boveri, which operates only when locomotive is in motion, and if then only after it has covered a certain distance which can be regulated as desired; action of device commences after driver releases his hold of push button.

ELECTRIC MOTORS

CONTROLLERS. Tendencies in Electric-Motor Control Installations, J. E. Housley. Power, vol. 63, no. 4, Jan. 26, 1926, pp. 134-135, 4 figs. Attention is called to practices that should be avoided in controller installations and examples are given of methods for mounting motor-control apparatus that makes foi flexibility and safety in operation and maintenance.

ELECTRIC MOTORS, A. C.

INDUCTION. Polyphase Induction Motors with Double Squirrel-Cage Windings, C. W. Kincaid and D. F. Alexander. Elec. Jl., vol. no. 1, Jan. 1926, pp. 15-19, 10 figs. Discusses high starting-torque and short time running, low starting torque and continuous running and high starting torque and continuous running at full load; characteristics of rotor windings, etc.

Synchronous. Effects of Changing the Load on a Synchronous Motor. J. M. Cunningham. Power, vol. 63, no. 3, Jan. 19, 1926, pp. 99-102, 5 figs. Discusses effect on power factor of power system when load on synchronous motor is varied, and at what load on motor will corrective effect on system's power factor be greatest.

ELECTRIC MOTORS, D. C.

Band Losses. Motor Band Losses, T. Spooner. Am. Inst. Elec. Engrs.—Jl., vol. 45, no. 1, Jan. 1926, pp. 14-17, 3 figs. Shows that motor-band losses are of appreciable magnitude, sometimes sufficiently large to be detrimental to cooling of machine; losses are shown to be due chiefly to change in radial component of flux as band passes by pole tip; for average bands, about 15 per cent of losses (hysteresis and eddy) are due to tangential flux in bands; shows typical set of curves for calculating hand losses.

Types. Characteristics of Direct-Current Motors, R. W. Owens. Elec. Jl., vol. 23, no. 1, Jan. 1926, pp. 37-43, 10 figs. General d.c. motor with bracket type bearings, crane type motor and mill type motor; enclosed intermittent ratings, windings, speed adjustment, etc.

ELECTRIC RAILWAYS

Equipment. Developments in Electric Equipment in 1925, W. D. Bearce. Ry. Rev., vol. 78, no. 1, Jan. 2, 1926, pp. 63-65, 5 figs. Railroads augment existing facilities by additions of many new cars and locomotives; oil-electric locomotives; steam-road electrification; city and suburban systems; gas-electric buses; automatic railway substations.

ELECTRIC TRANSMISSION LINES

Over-Compounded Voltages. Transmission Systems with Over-Compounded Voltages, H. B. Dwight. Am. Inst. Elec. Engrs.—Jl., vol. 45, no. 1, Jan. 1926, pp. 25-30, 2 figs. Gives methods of calculating transmission line with transformers, first with over-compounded generator voltage and constant receiver voltage, in which case diagram is a circle, and second, with over-compounded voltage at both generator and receiver, in which case diagram is an ellipse; discusses advantages and limitations of using over-compounded voltage.

Towers. Towers, H. S. Brubaker. Elec. Light & Power, vol. 4, no. 2, Feb. 1926, pp. 25-27, 14 figs. Unusual designs and methods of construction including 5 tower structure of the West Penn Power Co. at Logans Ferry with length of span of 2250 ft., and other types.

ELECTRIC WELDING, ARC

Automatic. Welding Automatically by Electricity. Can. Mfr., vol. 46, no. 1, Jan. 1926, p. 6, 1 fig. Automatic electric welder which may be used for quantity production and for repair work; cost data.

Structural Steel. Structural Steel Welding on a Commercial Basis, H. P. Egan. Am. Welding Soc.—Jl., vol. 5, no. 1, Jan. 1926, pp. 51-58, 7 figs. Details of two-story buildings of Peerless Automobile Sales Co., Canton, Ohio, in which 95 tons of structural steel are entirely welded, both in shop fabrication and erection.

ELECTRIC WIRING

Conductivity Tests. Conductivity Tests of Wires and Cables, H. M. Friend. Elec. World, vol. 87, no. 3, Jan. 16, 1926, pp. 151-152. Describes simple, fairly accurate and quickly computed method of measuring conductivity used by writer for past 4 years.

ELECTRICAL INDUSTRY

Development. Some Developments in the Electrical Industry During 1925, J. Liston. Gen. Elec. Rev., vol. 29, no. 1, Jan. 1926, pp. 13-69, 104 figs. Survey of signal advances made during 1925 covering turbines, supercharges, marine equipment, main and industrial haulage, electric railways, waterwheel generators industrial motor control and motor application, arc welding, radio, transformers, lightning generator research, automatic stations, outdoor stations, switching houses, lighting, etc.

ELECTRICAL MACHINERY

Heating Curves. Parameters of Heating Curves of Electrical Machinery, V. Karapetoff. Am. Inst. Elec. Engrs.—Jl., vol. 45, no. 1, Jan. 1926, pp. 40-42. Points out that for thermal purposes an electrical machine cannot be considered as single body, since stator consists of two metal bodies (winding and core) between which there may be considerable heat interchange, and that rotor is also such a composite body; differential equations of heat flow in a combinational body are established and solved; stator winding is thermally determined by its heat capacity and its heat dissipation coefficient, and so is stator core.

ELEVATORS

Passenger. A Notable High-Speed Elevator Installation, C. R. Callaway and E. D. Harrington. Gen Elec. Rev., vol. 29, no. 2, Feb. 1926, pp. 84-96, 14 figs. Details of elevators in Equitable Life Assurance Society's building; variable-voltage or Ward-Leonard control and its advantages; car-speed regulation; electrical and mechanical equipment, safety devices, roping, etc.

Safeguarding. The Safeguarding of Lifts, R. Lister. Engineering, vol. 121, no. 3132, Jan. 8, 1926, p. 61. Summary of chief items in elevator specification to be examined from point of view of safety.

EMPLOYMENT MANAGEMENT

Analyzing Employee Attitudes. Analyzing and Rebuilding Employee Attitudes, J. F. Sherman. Indus. Mgmt. (N. Y.), vol. 71, no. 1, Jan. 1926, pp. 1915. The constructive, negative neutral types of workers; finding and winning the natural winner; points out that there is in modern industry a place for a specialized science of man engineering— analysis and measurement of attitude or motive factor, and rebuilding of it along constructive lines.

ENAMELS

Weathering of Lacquer. Accelerated Weathering as Applied to Lacquer Enamels, H. A. Nelson. Can. Chem. & Metallurgy, vol. 10, no. 1, Jan. 1926, pp. 11-13. Present state of general work on accelerated weathering; testing lacquer enamels; comparison of accelerated tests with outdoor exposure tests, and results of recent investigation on lacquer enamels carried out in laboratory of the New Jersey Zinc Co.

ENGINEERING

Science, Relation to Advancement in. The Advancement of Engineering in Relation to the Advancement of Science, A. E. Kennelly. Mech. Eng., vol. 48, no. 2, Feb. 1926, pp. 102-108, 7 figs. Definition of engineering; engineering in early times; points out that manufacture on large scale is virtually engineering itself; tendency of present engineering age toward accuracy of reasoning and precision of thought; tendency for world leadership to rest mainly upon science and its applications.

ENGINEERS

Industrial Opportunities. Opportunities for Engineers in Industry, J. O. G. Gifibonf, Mech. Eng. vol. 48, no. 3, March 1926, pp. 261-262. Necessity of advising preparatory-school and engineering-college graduate about the duties, opportunities, and responsibilities of engineer, so that he may make more intelligent choice of his profession.

EXPLOSIVES

Applications. Notes on Explosives, E. Godfrey. Can. Inst. Min. & Metallurgy—Bul. no. 165, Jan. 1926, pp. 95-109, 5 figs. Discusses various applications for mining tunnel driving, roadmaking, submarine work, clearing land of stumps, etc.; drilling, tamping and blasting operations.

F

FANS

Starting and Stopping. The Effect on the Ventilation Current of Stopping and Starting a Main Fan, R. A. H. Flugge-de Smidt. Chem., Met. & Min. Soc. of S. Africa, vol. 26, no. 5, Nov. 1925, pp. 110-114, 2 figs.

FEEDWATER HEATERS

Locomotive. A Locomotive Feed-water Heater. Engineer, vol. 141, no. 3654, Jan. 8, 1926, p. 53, 2 figs. Combined feedwater heater and pump specially suited for service on locomotives, manufactured by Worthington-Simpson, of Newark-on-Trent.

FLIGHT

Path of Airplane, Determining. Photographic Time Studies of Airplane Paths, A. G. Von Baumhauer. Nat. Advisory Committee for Aeronautics—Tech. Memorandums, no. 345, Jan. 1926, 10 pp., 5 figs.

FLOW OF AIR

Measurement. The Practical Measurement of Air Flow, E. Ower. Domestic Eng. (Lond.), vol. 45, no. 11, Nov. 1925, pp. 229-231, 3 figs.; and vol. 46, no. 1, Jan. 1926, pp. 3-9, 15 figs.

FLOW OF LIQUIDS

Orifices. Experiments on Contraction of Jets of Liquids (Esperienze sulla contrazione delle vene liquide), F. de Marchi. Annali dei Lavori Pubblici, vol. 58, no. 8, Aug. 1925, pp. 689-731, 15 figs. Discusses flow of liquids through 4 orifices, 3 of which were provided with short internal tubes in addition, and studies variation in jet, develops formulas for coefficients of flow, of contraction and of velocity; effect of viscosity.

FORGING MACHINES

High-Duty. National High-Duty Forging Machine. Am. Mach., vol. 64, no. 6, Feb. 11, 1926, pp. 257-258, 4 figs. Improvements in line of forging machines of Nat. Machy. Co., Tiffin, O.

FORGINGS

Steel, Hard Spots on. Hard Spots on Steel Forgings, J. D. Gat. Blast Furnace & Steel Plant, vol. 14, no. 2, Feb. 1926, pp. 74-78, 15 figs.; also in Forging—Stamping—Heat Treating, vol. 12, no. 1, Jan. 1926, pp. 2-7, 15 figs. Summary of careful investigation of phenomena connected with these formations.

FOUNDATION

Bearing-Power Tests. Bearing-Power Tests on Deep Caisson Foundations, R. L. Waring and C. T. Morris. Eng. News-Rec., vol. 96, no. 3, Jan. 21, 1926, pp. 109-112, 8 figs. American Insurance Union building in Columbus founded on hard clay 90-ft. below ground where borings indicated limestone; clay strength measured and bearing areas proportioned accordingly.

FOUNDRIES

Cost Methods. Describes a British System of Finding Foundry Costs. T. Smith. Foundry, vol. 54, no. 4, Feb. 15, 1926, pp. 151-153, 7 figs. Describes methods which are not hypothetical but illustrative of practice in large British iron and steel foundry.

Economics. Foundry Economics, J. Wolstenholme. Foundry Trade Jl., vol. 33, no. 493, Jan. 28, 1926, pp. 74-75. Cost of casting and part it plays in analyzing cost of engineering products; cost of molding and coremaking; piece work. (Abstract.) Paper read before Junior Instn. Engrs.

Management and Costs. Foundry Management and its Effect on Foundry Costs, Wm. J. Barretts. Am. Foundrymen's Assn.—reprint no. 498, for mfg. Oct. 6, 1925, pp. 6-14. Measuring management; comparison of iron and steel foundries; failures amoung foundries; measuring management in industry; successful operation through a cost system; underbidding without cost guidance; casting and cupola charging; costs as guidance in securing new equipment and as a guide in making sales.

Fuels. *See Coal, Lignite; Oil Fuel; Pulverized Coal.*

FURNACES, ANNEALING

Regenerative Gas-Fired. Regenerative Gas-Fired Furnaces, A. Harvey and H. W. Jackson. Metal Industry (Lond.), vol. 28, no. 1, Jan. 1, 1926, pp. 9-13, 6 figs. Equipment at new French non-ferrous works, for melting and annealing copper and brass alloys; crucible producer-gas-fired melting furnace for brass.

FURNACES, GAS

Selas. Gas Furnaces Applied to the Steel Industry, S. A. Sears. Machy. Market, nos. 1309, 1310, 1311 and 1312, Dec. 4, 11, 18 and 25, 1925, pp. 21-22, 19-20 and 22, 4 figs. Discusses theories on fuels and combustion; characteristics of gas as fuel.

FURNACES, INDUSTRIAL

Radiant-Heat. Radiant-Heat Furnaces. Engineering, vol. 121, no. 3134, Jan. 22, 1926, pp. 106-108, 7 figs. Typical examples of Krupp radiant-brick furnaces, employing principle of surface combustion, which are made for practically all industrial heating processes, such as reheating, forging, welding, annealing tempering, hardening, metal melting, etc., as well as for use in connection with manufacture of glass and pottery; any kind of clean gas can be used as fuel.

G

GALVANIZING

Testing Thickness of Coatings. Methods for Testing the Thickness of Zinc Coatings, H. Bablik. Metal Industry (Lond.), vol. 28, no. 2, Jan. 8, 1926, pp. 33-35, 2 figs.

GAS ENGINES

Otto. The Use of Gas engines (Warun nitch wieder Gasmotoren?), Schäfer. Gas- u. Wasserfach, vol. 68, no. 50, Dec. 12, 1925, pp. 783-785. Otto four-stroke engine and its fifty years of existence; proposes that all liquid fuel should be reserved for engines used in locomotion, but gas should be used for stationary engines. See also comment by Elvers, pp. 785-786.

GASES

Combustion of. The Processes of Combustion as a Foundation for the Industrial Uses of Gas, F. Plenz. Gas World, vol. 84, no. 2166, Jan. 23, 1926, pp. 81-82. Concludes that for high temperature excess of either gas or air should be avoided; hydrogenous gases give highest temperatures, their use requires a good burner and gas-air mixture must be passed in at high velocities to obviate back firing. Translated from Gas- und Wasserfach.

H

HEATING, ELECTRIC

Industrial. Status of Industrial Electric Heating. Elec. World, vol. 87, no. 4, Jan. 23, 1926, pp. 197-200, 5 figs. Rapid progress in applications to varied industries; increased production and better quality output attained in numerous installations; central stations beginning to appreciate load-building possibilities.

Panel. Electric Panel Heating, E. M. Bussy. Elec. Rev., vol. 98, no. 2510, Jan. 1, 1926, pp. 3-4, 2 figs. Discusses panel-heating system in Cinema de Paris, in London, which has 34 standard panels on auditorium ceiling, etc.; units are 6 ft. by 3 ft. by 1⅛ in. fixed on surface of ceiling and finished with suitable molding following general lines of decoration.

HEATING, HOT-AIR

Gravity System. Temperature Conditions Existing, in the Rooms of a Residence Heated by a Gravity Warm Air System, V. S. Day. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 32, no. 2, Feb. 1926, pp. 73-78, 5 figs. Data and conclusions of study of temperature conditions existing in various rooms of residence of National Warm Air Heating and Ventilating Assn. at Illinois Univ.

HEATING, HOUSE

Combination Air and Water System. Combination Heating System, A. M. Daniels. Sheet Metal Worker, vol. 16, nos. 24, 25 and 26, Jan. 1, 15 and 29, 1926, pp. 866-868 and 885, 912-915 and 950-951, 7 figs. Data to enable furnaceman to design and instal properly combination warm-air and hot-water heating system; location of radiators, size of pipes to serve radiators; two-pipe up-feed direct-return system; over-head down-feed system with single riser.

Fuel Savers. Tests of Household Fuel Savers and the Economical Use of Coal, F. G. Hechler. Pan. State College Eng. Experiment Station—Bul., no. 34, Oct. 1925, pp. 5-35, 10 figs.

HIGHWAYS

Planning. What Comprises the Ideal Highway? S. W. Campbell. Contract Rec., vol. 40, no. 1, Jan. 6, 1926, pp. 9-10. Improvements in recent years, construction of pavements, drainage, resistance to traffic.

Relocation. Highway Relocation Practice in Pennsylvania, W. W. Crosby. Eng. News-Rec., vol. 96, no. 6, Feb. 11, 1926, pp. 232-233, 1 fig. Procedure followed in line rectification when road construction is required by wear or traffic, (Abstract) Paper presented before Am. Road Bldrs' Assn.

Widening and Thickening. Widening and Thickening California Paved Roads, R. M. Morton and N. A. Bowers. Eng. News-Rec., vol. 96. no. 1, Jan. 7, 1926, pp. 6-11, 12 figs. Contains two articles as follows: General Methods and Costs, by R. M. Morton; Construction Methods and Plant, by N. A. Bowers.

HYDRAULIC TURBINES

Coupling. Methods of Coupling Hydraulic Turbines (A propos de méthodes d'accouplement des turbines hydrauliques), R. Thomann. Bul. Technique, vol. 51, no. 24, Nov. 21, 1925, pp. 289-293, 3 figs. Discusses two turbines of 600 and 720 r.p.m., respectively, when to replace the smaller by the larger, when to couple them, how to proportion supply water for each when coupled, determining optimum of coupling, etc.

High-Speed. High-Speed Turbines for the Berne Hydro-Electric Power Station. Engineering vol. 121, no. 3133, Jan. 15, 1926, pp. 74-76, 10 figs. Details of turbines constructed by T. Bell & Co., Kriens, Switzerland, with specific speed of 970 r.p.m.; efficiency of turbines is 85 per cent as compared with 75 per cent of old Jonval turbines.

Kaplan. The Kaplan Turbine. Engineering, vol. 121, no. 3135, Jan. 29, 1926, pp. 152-154, 7 figs. Details of 10,000-hp. Kaplan turbine at Lilla Edet power station, Swede; distinguishing characteristic of Kaplan type of propeller turbine is that vane angle is variable, runner being constructed on lines of screw propeller with feathering blades.

Racing. Racing of Turbines at Fixed and Variable Head (Note sur l'emballement des turbines sous chute fixe et sous chute variable), L. Barbillion. Electricité & Mécanique, no. 7, July-Aug. 1925, pp. 7-7 to 7-14, 6 figs. Discusses action of regulator in limiting speed, curve of speeds attained by turbines, relation between curve of angular acceleration and that of speed; comparison of speeds attained at a given moment witb fixed and with variable head, etc.

Reaction. Efficiency Test on High-Head Reaction Turbine. Eng. News-Rec., vol. 96, no 1, Jan. 7, 1926, pp. 18-19, 1 fig. Oak Grove unit on Portland system shows 90 per cent efficiency at 35,000 hp. under 882-ft. effective head.

HYDRO-ELECTRIC DEVELOPMENTS

British Columbia. Development at Bonnington Falls, B. C. L. A. Campbell. Can. Engr., vol. 50, no. 3, Jan. 19, 1926, pp. 141-144, 7 figs.

Ontario. Hydro-Electric Power Commission of Ontario, Canada. Australasian Elec. Times, vol. 4, no. 9, Sept. 27, 1925, pp. 597-601, 9 figs. Compares developments of Australia with those of Ontario; trend of energy prices; Niagara, St. Lawrence and other systems.

HYDRO-ELECTRIC PLANTS

Operation. Hydro-Electric Operating Economies, A. R. Haynes. Elec. Light & Power, vol. 4, no. 2, Feb. 1926, pp. 21-24 and 102. Features of operation as effecting water savings in governing hydro-electric station having considerable storage.

Suggestions Regarding Hydraulic Plant Operation, L. F. Harza. Power Plant Eng., vol. 30, no. 4, Feb. 15, 1926, pp. 268-270, 1 fig. Parallel operation with steam plants.

I

IMPACT TESTING

Notched-Bar Tests. An Application of the Two-Testpiece Method of Notched Bar Impact Testing, Metallurgist (Supp. to Engineer, vol. 141, no. 3657), Jan. 29, 1926, pp. 14-15. Review of work by M. Moser in Stahl u. Eisen, vol. 45, 1925, p. 1879, in which he describes applications of two-specimen method of impact testing, and gives results of analysis of large number of tests made by this method.

INDUSTRIAL MANAGEMENT

Cost Control. The Effectiveness of Cost for Controlling Waste, T. D. Nevins. Soc. Industrial Engrs.—Bul., vol. 8, no. 1, Jan. 1926, pp. 3-6. Discusses importance of costs in prevention of waste by analyzing expenses, and budgeting, and gives typical cases.

Engineer's Relation to. Relation of the Engineer to Management, H. Diemer. Professional Engr., no. 1, Jan. 1926, pp. 5-7 and 11. Discusses gradual isolation of engineer as technical specialist, industrial engineering, and its limits, management engineering, budgeting and forecasting in business analogous to designing and planning, etc.

Financial and Industrial Investigations. Scope of Financial and Industrial Investigations, A. Andersen. Mfg. Industries (Mgmt. & Admin.), vol. 11, no. 1, Jan. 1926, pp. 17-22. Conditions and sources of data; place of financial investigation; place of appraisal; differences between external and internal investigations; data from appraisal, legal, research and accounting data; use of balance sheets; relative importance of data.

Hand and Machine Labour. Hand Labour and Machinery as Producers, R. Polleys Mfg. Industries (Mgmt. & Admin.), vol. 11, no. 1, Jan. 1926, pp. 11-12. Comparative advantages and formulae for cost calculations.

Inventory Control. The Control of Inventory Through the Scientific Determination of Lot Sizes, H. S. Owen. Indus. Mgmt. (N. Y.), vol. 71, no. 1, Jan. 1926, pp. 12-16, 5 figs. Specification or groundwork from which all control records originate.

Modern Methods. New Fields for Modern Management, W. Clark. Am. Mach., vol. 64, no. 7, Feb. 18, 1926, pp. 285-287, 1 fig. Contrast between old-fashioned and modern shops; development of sales quotas and various types of budgets; typical administrative control chart.

Production Control. An Effective Production Control System, J. J. Swan. Mfg. Industries (Mgmt. & Admin.), vol. 11, no. 1, Jan. 1926, pp. 39-43, 15 figs. Employed in manufacture of automatic printing presses.

Standard Practice Instructions. Standard Practice Instructions, P. M. Atkins. Am. Mach., vol. 64, no. 1, Jan. 7, 1926, pp. 23-27, 5 figs. Necessity for handling on explicit instructions for routine work; example worked out for details handled by balance of stores clerk.

INDUSTRIAL ORGANIZATION

Personnel, Choice of. Judging Organization and Personnel A. Andersen. Mfg. Industries, vol. 11, no. 2, Feb. 1926, pp. 113-117. Broad and detailed tests on organization; organization balance; relations of organization and personnel; functions of committees; personal statistics; personnel qualifications and analysis; vital importance of personnel.

INDUSTRIAL TRUCKS

Electric. Electric Trucks in the Locomotive Repair Shop, H. J., Payne. Ry. Elec. Engr., vol. 17, no. 1, Jan. 1926, pp. 21-23, 7 figs. Practice of one railroad indicates that this equipment fills definite need; work done by elevating platform trucks; saving on chip removal.

INSULATION, HEAT

Buildings. Advantages of Heat Insulation in Hotels, Apartment Houses, and Private Residences, R. H. Heilman. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 32. no. 1, Jan. 1926, pp. 37-52, 12 figs. Discusses various types of insulating materials and gives data helpful to heating engineer in selecting and directing use of suitable heat insulation.

INSULATING MATERIALS, ELECTRIC

Transformers. Herkolite Insulating Materials in Transformers, V. M. Montsinger and W. S. Moody. Gen. Elec. Rev., vol. 29, no 2, Feb. 1926, pp. 102-108. 9 figs. Discusses paradoxical requirements which insulation must meet and describes a new insulating material which is extremely dense, strong and hard, yet elastic enough not to break under short-circuit stresses; it is readily machined and will take high polish when necessary.

INTERNAL-COMBUSTION ENGINES

British Show, Olympia. The Shipping, Engineering and Machinery Exhibition. Automobile Engr., vol. 16, no. 211, Jan. 1926, pp. 2-11, 28 figs. Notes on exhibits in internal-combustion-engine section.

Fuels. Fuels for High-Compression Engines, S. W. Sparrow. Oil & Gas Jl., vol. 24, no. 34, Jan. 14, 1926, pp. 118-122 and 184-190, 13 figs. Discusses characteristics with reference to preignition and detonation; compression ratio and preignition; methods of measuring detonation, etc.

Steam Cooling. Evaporative Cooling, H. C. Harrison. Soc. Automotive Engrs.—Jl., vol. 18, no. 2, Feb. 1926, pp. 195-200, 5 figs.

Supercharging. Supercharging Internal-Combustion Engines, C. R. Short. Soc. Automotive Engrs.—Jl., vol. 18, no. 2, Feb. 1926, pp. 185-194, 23 figs.

See also Automobile Engines; Diesel Engines; Gas Engines; Oil Engines.

IRON

Corrosion. Tbe Nature of the Protective Film of Iron, T. Fujihara. Am Electrochem. Soc.—advance paper, no. 1, for mtg. Apr. 22-24, 1926, pp. 1-8, 9 figs. Discusses phenomena connected with formation of protective film or membranes when drops of water are placed on a polished iron surface.

Protective Coatings. Note on the Protection of Iron by Cadmium ,H. S. Rawdon. Am. Electrochem. Soc.—advance paper, no. 3, for mtg. Apr. 22-24, 1926, pp. 21-30, 3 figs. Results of qualitative experiments with specimens of steel and iron, in each of which a plug of anotber metal was inserted and immersed in dilute sodium-chloride solution; zinc and cadmium behaved alike in preventing corrosive attacks of iron.

IRON AND STEEL

Bibliography. Review of Iron and Steel Literature for 1925, E. H. McClelland. Blast Furnace & Steel Plant, vol. 14, no. 1, Jan. 1926, pp. 49-51, also Forging—Stamping—Heat Treating, vol. 12, no. 1, Jan. 1926, pp. 15-17. Classified list of more important books, serials and trade publications during year, with few of earlier date, not previously announced.

IRON AND STEEL

World Capacity. World Iron and Steel Capacity. Iron Age, vol. 117, no. 1, Jan. 7, 1926, pp. 22-24, 2 figs. Equipment for 108,000,000 tons of pig iron, and how it is subdivided geographically; equipment for 117,000,000 tons of ingots and castings and its subdivision.

IRON CASTINGS

Cleaning. Cleaning Gray Iron Castings, E. H. Trick. Foundry, vol. 54, no. 2, Jan. 15, 1926, pp. 71-72, 4 figs. Methods and machinery used to handle castings from shakeout to warehouse in Southwestern plant making varied work.

Light. The Production of Light Grey-Iron Castings, D. McQueen. Foundry Trade Jl., vol. 33, no. 492, Jan. 21, 1926, pp. 53-54. Main considerations in iron for light castings are that it should be fluid so as to run thin castings and also soft, as large percentage of castings have to be drilled and some polished; influence of manganese and carbon; sulphur in light castings; mis-run castings; sands for light work; molding methods. (Abstract.)

Road Rollers. Making a Motor Road Roller, B. Hird. Foundry Trade Jl., vol. 32, no. 488, Dec. 24, 1925, pp. 527-529, 12 figs. Methods and equipment employed in making casting for hind roller of a Barford Perkins motor road roller; these castings weigh from 3 to 6 tons; molding in box for bottom part; coremaking.

IRON METALLURGY

Developments, 1925. Ferrous Metallurgy in 1925, H. M. Bolyston. Iron Age, vol. 117, no. 1, Jan. 7, 1916, pp. 46-50, 1 fig. Technical developments in steel, iron and alloys; contributions of research; progress in heat treatment; improved testing; improved testing equipment; foundry problems; blast-furnace design and operation; open-hearth furnace; rolling mills, etc.

J

JETTIES

GRAIN. The Design, Construction and Operation of a Grain Jetty at the Port of Vancouver, British Columbia, H. W. Frith. World Parts, vol. 14, no. 3, Jan. 1926, pp. 43-65, 9 figs. Jetty 930 ft. long and 56 ft. wide, accommodating two vessels on west side and one on east side, berths being dredged 35 ft. at low water; construction and method of placing cribs; superstructure and conveying equipment, etc.

L

LACQUERS

TESTS. Durability of a Colored Lacquer Containing Various Resins, H. A. Gardner. Paint Manufacturers' Assn. of U. S. Sci. Section—Circular, no. 252, Oct. 1925, pp. 168-173, 2 figs. Details of tests to determine effect of various resins; durability of brush lacquer, with results tabulated.

Physical Tests on Lacquers, H. A. Gardner and H. C. Parks. Paint Manufacturers' Assn. of U. S., Sci Section—Circular, no. 253, Nov. 1925, pp. 174-194, 4 figs. Tests to determine physical properties, including tensile strength and elongation of films, roof-exposure tests; cold-water test, baking, bending, etc., together with composition of lacquer.

LEAD ORES

EASTERN CANADA. Lead and Zinc in Eastern Canada, F. J. Alcock. Min. & Metallurgy, vol. 7, no. 230, Feb. 1926, pp. 51-56, 4 figs. Ores may be grouped under three divisions depending on their character and origin; (1) Ores of Appalachian region; (2) ores of Grenville region; and (3) calcite-barite veins of Ontario and Quebec. Published with permission of Director of Geol. Survey of Canada.

LIGHTING

FACTORIES. Illumination and Industrial Welfare, A. F. McBride. Illum. Eng. Soc. —Trans., vol. 21 no. 1, Jan. 1926, pp. 61-69. Regulations affecting welfare of industrial workers with particular emphasis on importance of adequate industrial illumination and its relation to efficient production, improved safety conditions, better eyesight and health.

LIGHTNING ARRESTERS

AUTOVALVE. Theory of the Autovalve Arrester, Jos. Slepian. Am. Inst. Elec. Engrs.—Jl., vol. 45, no. 1, Jan. 1926, pp. 3-8, 12 figs. Discusses advantage of valve-type arresters for high-voltage, power-system protection.

LOCKS

CONCRETE. Lockport Lock Construction Plant, Illinois Waterways. Eng. News-Rec., vol. 96, no. 6, Feb. 11, 1926, pp. 228-231, 6 figs. Locks consists of parallel gravity-section walls, 938-ft. long. 110-ft. apart and 66-ft. high, having left of 41-ft., cableway handles 7-yd. bucket.

LOCOMOTIVES

DIESEL-ENGINED. Clutch Drive Locomotive of 1600 HP. Oil Engine Power, vol. 4, no. 2, Feb. 1926, pp. 82-93, 2 figs. Direct-drive Diesel locomotive now being built at Krupps to specifications of American railroad; drawbar pull 40,000 lbs., high speed 49.75 m.p.h.; mechanical transmission throughout, avoiding electric or hydraulic intermediary systems.

TYPES. Three New Locomotive Types in '25, C. B. Peck. Ry. Age, vol. 80, no. 1, Jan. 2, 1926, pp. 47-49, 3 figs. All demonstrate that capacity possibilities of single-unit driving wheelbases have not been exhausted; 2-8-4 type built by Lima Locomotive Works; 4-10-2, three-cylinder, built for Southern Pacific; and 2-10-4 type, for Texas & Pacific, built by Lima Locomotive Works.

LUBRICATION

CUTTING TOOLS. Importance of Lubrication in Working of Metals (Importance de la lubrication, dans le travail d'usinage des métaux), J. Jacquet. Arts et Métiers, vol. 78, no. 61, Oct. 1925, pp. 407-411, 3 figs. Use of cutting compound for increasing speed of cutting and experiments carried out.

JOURNAL. A Graphical Study of Journal Lubrication, H. A. S. Howarth. Mech. Eng., vol. 48, no. 2, Feb. 1926, pp. 131-132 and (discussion) 132-133, 3 figs. Continues investigation of journal lubrication reported to Society under same title in 1923 and 1924; presents friction curves for central and offset partial bearings whose curvature radius exceeds that of journal; characteristics of fitted partial bearings are studied, including their varying capacities and friction.

M

MAGNESIUM ALLOYS

ELECTRON. The Alloy Electron, W. Schmidt. Metal Industry (Lond.), vol. 28, no. 6, Feb. 5, 1926, p. 130. High-magnesium alloy first introduced to public by Chemische Fabrik Greisheim-Elektron in 1909; review of developments, especially since end of war; physical and mechanical properties; casting in green sand; facility of working.

MALLEABLE CASTINGS

ANNEALING. Malleable Iron (La Malléable), M. Guedras. Fonderie Moderne, vol. 20, Jan. 1926, pp. 4-6. Discusses oxidizing cementation known as annealing, its chemical and thermal aspects; use of Ardennais furnace in France; formation of skin due to oxidation.

METALLURGY

BIBLIOGRAPHY. A Carefully Prepared List of Books on Metallurgy and Allied Subjects. Forging—Stamping—Heat Treating, vol. 12, no. 1, Jan. 1926, pp. 45-47.

METALS

DRAWING PROPERTIES. Some Attempts to Measure the Drawing Properties of Metals, Wm. S. Montgomery, Jr., and E. R. Enders, Jr. Mech. Eng., vol. 48, no. 2, Feb. 1926, pp. 119-124, 2 figs. Results of series of tests made with idea of ascertaining whether or not measurable properties bear any relation to drawing properties of metals.

HIGH TEMPERATURES, RESISTANCE TO. The Use of Metals at High Temperatures, W. Rosenbain. Metallurgist (Supp. to Engineer, vol. 141, no. 3657), Jan. 29, 1926, pp. 2-4, 2 figs. Discusses manner in which materials are exposed to high temperatures and mechanism of their resistance under these adverse conditions.

STRENGTH. The Effect of Tension on the Transverse and Longitudinal Resistance of Metals, P. W. Bridgman. Am. Soc. Arts & Sci.—Proc., vol. 60, no. 8, Oct. 1925, pp. 423-449, 1 fig. New experimental method for measuring change of resistance in a metal under tension with direction of flow at right angles to tension; results of measurement on aluminum, gold, copper, silver, platinum, iron, nickel, etc.

THIN TRANSPARENT FILMS OF. Thin Transparent Films of Metal. Metallurgist (Supp. to Engineer, vol. 141, no. 3657), Jan. 29, 1926, p. 6. Describes process worked out by C. Müller at the Reichsanstalt at Charlottenburg, who has succeeded in making excessively thin films of nickel, copper, etc., which are continuous and sufficiently strong to be reasonably handled; they can even be soldered or welded together to form thermocouples; they are also transparent.

MINERAL RESOURCES

BRITISH COLUMBIA. Mineral Resources of the Lardeau and Trout Lake Mining Divisions of British Columbia, N. W. Emmens. Can. Min. Jl., vol. 47, nos. 1 and 2, Jan. 1 and 8, 1926, pp. 5-8 and 36-38, 5 figs. Lardeau and Trout Lake section and its resources of gold, silver, lead and zinc.

NON-METALLIC, CANADA. Non-Metallic Minerals of Canada, Sir S. Brunton. compressed Air Mag., vol. 31, no. 1, Jan. 1926, pp. 1485-1489, 5 figs. Discusses large fields of non-metallic resources, including abrasives, arsenic, barytes, clay, coal, fluorspar, graphite, etc.

MORTARS

STRENGTH TESTS. Report of Committee on Materials of Construction, M. O. Witbey. Eng. Soc. Wis., Seventeenth Annual Report, 1925, pp. 109-121, 1 fig. Results of strength tests on mortars for masonry construction cured in cold and warm temperatures at the materials testing laboratory of the University of Wisconsin; concludes that freezing is detrimental to the strength of mortars, used in brick laying, etc.

MOTOR BUSES

BRISTOL. The Latest Bristol Production. Motor Transport (Lond.), vol. 42, no. 1091, Jan. 25, 1926, pp. 115-117, 7 figs. Latest model by Bristol Tramways & Carriage Co. for single-deck bodies with 32 seats; 4-cylinder mono-block engine with detachable head; wheelbase, 16 ft.; overall length, 25 ft. 6 in.

MOTOR TRUCKS

CHASSIS SUSPENSION. Chassis Suspension for Industrial Vehicles. Motor Transport (Lond.), vol. 42, no. 1092, Feb. 1, 1926, pp. 129-131, 6 figs. Recent improvements in design; effect of imperfect suspension; suiting the spring to its load, spring lubrication, etc.

N

NATURAL GAS

CANADA. Natural Gas in 1923 and Petroleum in 1923, R. B. Harkness. Ontario Dept. of Mines—33rd Annual Report, vol. 33, 1925, 112 pp., 12 figs. Discusses changes and improvements in service, extension of gas lines, price of manufactured and natural gas, leakage, exploration work, etc.; oil at base of Trenton limestone, drill cuttings, yield of oil wells in 1923, price of oil, refining operations, etc.

ENERGY CONTAINED IN. Energy Contained in Petroleum Gas, S. F. Shaw. Min. & Metallurgy, vol. 7, no. 229, Jan. 1926, pp. 9-10. Notes amount of oil that could be lifted by natural gas if 100 per cent efficiency were obtained and efficiencies actually obtained in use of this gas.

O

OIL

BIBLIOGRAPHIES. Recent Articles on Petroleum and Allied Substances, U. S. Bureau of Mines, Dec. 1925, 31 pp. List of recent articles on geology and origin, development and production, transportation, and storage, refining and refineries, etc.

OIL ENGINES

COLD-STARTING. Blackstone Spring-Injection Cold Starting Engine. Elec. Times, vol. 69, no. 1786, Jan. 7, 1926, pp. 12-13, 2 figs. Details of improved oil prime mover developed by Blackstone & Co. of Stamford, in which air compressor and hot-bulb attachment of cylinder bead is replaced by mechanical injection device together with completely water-cooled cylinder head; injection device having a low-pressure fuel-measuring pump, high-pressure fuel-injection pump and spring-loaded fuel-injection valve, etc.

15,000-B.HP. A Large Double-Acting Oil Engine. Engineer, vol. 141, no. 3657, Jan. 29, 1926, p. 134. Details and tests of 9-cylinder, double-acting 2-cycle 15,000-b.hp. oil engine built under license form M.A.N. Co., Ausgburg; claimed to be largest unit yet constructed; it will be employed for driving 10,000-kw. alternator at Neuhof Electricity Works, Hamburg.

OIL FUEL

BURNERS FOR. Burning of Fuel Oil, E. T. Keenan. Southern Power Jl., vol. 44, no. 1, Jan. 1926, pp. 36-38, 4 figs. Discusses analysis of liquid fuels; how fuel oil is burned, methods of atomizing, selection of type of burner, etc.

TESTING. Modern Test Methods for Fuel Oil, W. D. Campbell. Nat. Engr., vol. 30, no. 2, Feb. 1926, pp. 57-60, 1 fig. Instructions for handling bomb calorimeter in making tests and precautions to be taken to insure accuracy, how to determine acid and sulphur content, how to calculate results.

OSCILLOGRAPHS

TRANSIENT PHENOMENA, FOR STUDY OF. Study of Time Lag of the Needle Gap, K. B. McEachron and E. J. Wade. Am. Inst. Elec. Engrs.—Jl., vol. 45, no. 1, Jan. 1926, pp. 46-52, 7 figs. Describes oscillograph used by authors and discusses method of operation; tests were made with a wave which was nearly perpendicular, reaching its maximum in about one microsecond; such a wave was obtained by discharge of condenser through suitable circuit; gives oscillogram which shows wave front used; results of tests in which this wave front was applied to gaps; shows that with any given gap setting and sparkling voltage time lags vary through wide limits; also that, for same voltage, increased gap settings mean increased lag.

OXYACETYLENE WELDING

HOSE CONNECTION FOR EQUIPMENT. Standard Hose Connections for Welding Equipment. Am. Mach., vol. 64, no. 6, Feb. 11, 1925, p. 253. Reference-book sheet for holding and fastening devices.

P

PAVEMENTS, ASPHALT

DESIGN. Design of Bituminous Pavements, H. W. Skidmore. Eng. & Contracting (Roads & Streets), vol. 64, no. 6, Dec. 2, 1925, pp. 1229-1233, 2 figs. Discusses method of designing mixtures for asphalt pavements and gives examples.

PAVEMENTS, CONCRETE

CONSTRUCTION. How to Stop Cement Overrun in Pavement Construction, R. E. O'Connor. Muni. & County Eng., vol. 70, no. 1, Jan. 1926, pp. 19-26. Specifications, methods and equipment used in construction, cause of overrun, inundation, effect of grade, selection of forms, etc.

PIGMENTS

LITHOPONE. Lithopone Making Rapid Progress in Plant Industry, C. F. Beatty. Chem. & Met. Eng., vol. 33, no. 1, Jan. 1926, pp. 27-28. Zinc pigments finding increasing outlets in rubber, plastics, printing inks, pottery glazes, abrasives and oil cloth.

PIPE, CAST-IRON

BRONZE WELDING. Effect of Heat of Bronze Welding on Cast Iron Pipe, A. R. Lytle. Am. Welding Soc.—Jl., vol. 5, no. 1, Jan. 1926, pp. 28-50, 35 figs. Discusses theories that depend on structural changes occurring in cast iron due to heat of application of bronze; cast-iron welding of sand-cast and centrifugally cast pipe; bronze welding of the same, etc.

CENTRIFUGALLY CAST. Making Cast Iron Pipe Centrifugally, F. Grossmann. Foundry, vol. 54, no. 2, Jan, 15, 1926, pp. 58-59. Description of the de Lavaud machine and its operation; advantages of centrifugal process.

PNEUMATIC MACHINERY

LUBRICATION. Lubrication of Pneumatic Machinery. Lubrication, vol. 12, no. 1, Jan. 1926, 12 pp., 25 figs. Lubrication of air tools on pneumatic machinery; design, construction and operation of drills, riveters, hoists, their operating conditions, lubrication requirements, cleanliness and methods of cleaning.

POWER

DEVELOPMENTS, MISSISSIPPI VALLEY. Power Developments in the Mississippi Valley, S. Insull. Power Plant Eng., vol. 30, no. 4, Feb. 15, 1926, pp. 250-253. Resources of Middle West; development of interconnected power systems; power outlook for future.

POWER FACTOR

CALCULATION. Calculation of Power Factor for Electric Energy rates (Calcul du facteur de puissance co-intervenant dans les tarifications d'énergie électrique). Electricien, vol. 56, no. 1386, Dec. 15, 1925, pp. 559-561, 4 figs. Methods of direct calculation, by trigonometric functions, by graphs, by curves, etc.

CORRECTION. Power-Factor Correction, Its Imports to the Power User, M. A. Hyde. Iron & Steel of Can., vol. 9, no. 1, Jan. 1926, pp. 10-11. Various types of corrective equipment, synchronous motors, synchronous and static condensers, etc.

MIDWEST POWER CONFERENCE, CHICAGO. Midwest Power Conference Meets All Expectations. Power, vol. 63, no. 6, Feb. 9, 1926, pp. 211-218. Review of papers presented at conference held in Chicago from Jan. 26 to 29, 1926, discussing power developments in Mississippi Valley; water power and interconnection; changing viewpoints in turbine practice; combined operation of steam and hydraulic systems; electric-power development in Chicago district; by-product processing; boiler-water conditioning; industrial-plant design; turbine testing; first aid and power for coal mines; oil and gas power; etc.

POWER SHOW, CHICAGO. Chicago Power Show Arouses Great Interest. Power Plant Eng., vol. 30, no. 4, Feb. 15, 1926, pp. 282-294, 35 figs.

POWER TRANSMISSION

SHAFTING. Using Steel Forms for Supporting Lineshafting, P. L. Pyribil. Indus. Eng., vol. 84, no. 1, Jan. 1926, pp. 19-25, 14 figs. Erection of lineshafts in mill-type steel and concrete buildings, with particular attention to provisions for easy anchorage of mechanical equipment and to facilitate future changes in layout.

PRESSES

PUNCH, DIE SETS FOR. Standardized Die Sets for Punch-Press Work, F. H. Colvin. Am. Mach., vol. 64, no. 6, Feb. 11, 1926, pp. 245-249, 19 figs. How standardization of sets makes it possible to use modern production methods and to secure accurate results at low cost.

PROSPECTING

METHODS. Swedish Electric Prospecting Methods, H. Lundberg, K. Sunberg, and J. Eklund. Can. Min. Jl., vol. 47, nos. 2 and 3, Jan. 8 and 15, 1926, pp. 29-32 and 51-52, 2 figs. Potential methods based on investigation of distribution of potential in electrical field by tracing equipotential curves between different points; electromagnetic methods based on causing current to flow in ore body and then examining disturbances in electromagnetic field caused by it; magnetic seismic, gravity methods and interpretation.

PULVERIZED COAL

BOILER FIRING. A Critical Analysis of Pulverized Fuel for Small Boiler Plants, A. A. Fette. Nat. Engr., vol. 30, no. 2, Feb. 1926, pp. 65-67. Discussion of bin or storage system; drying of coal; problems of pulverized-coal plant; comparison with stokers; cost data of pulverizing and stoker systems.

Notes on Powdered Fuel, W. Lulofs. Elec. Times, vol. 69, no. 1787, Jan. 14, 1926, pp. 35-38, 3 figs. Discusses reduction of excessive air for combustion to limit supply to that which is theoretically necessary, and its consequent advantage in decreasing heat losses due to reduction of quantity of unnecessary air heated and saving of heat units because smaller quantity of gas can be reduced by boiler to a lower temperature before reaching the chimney.

Powdered Fuel, W. Lulofs. Combustion, vol. 14, no. 1, Jan. 1926, pp. 40-43, 1 fig. Discusses pulverized coal firing combined with mechanical stoking resulting in decreased efficiency and steam production and increased adaptability for varying load.

CARBONIZATION. Carbonization of Pulverized Fuel at Low Temperature, S. McEwen. Combustion, vol. 14, no. 2, Feb. 1926, pp. 107-110, 2 figs. McEwen-Rune process of pulverization of coal to be carbonized and its elevation to top of an internally heated tower; powdered fuel is caused to fall down this tower in form of a cloud meeting in its downward passage and upward current of hot inert gases.

PUMPS

HYDRAULIC. A New Hydraulic Pump. Engineer, vol. 141, no. 3654, Jan. 8, 1926, pp. 52-53, 1 fig. New design brought out by West Hydraulic Eng. Co.; it is of vertical type, and one of its outstanding features is provision made for lubricating running parts.

PUMPS, CENTRIFUGAL

HYDRODYNAMIC THEORY. The Hydrodynamic Theory of Turbines and Centrifugal Pumps, B. Eck. Engineering, vol. 121, nos. 3134 and 3135, Jan. 22 and 29, 1926, pp. 98-101 and 125-127, 21 figs. Author has succeeded in deducing exact solution for one particular case of turbine or pump problem, that in which turbine has but a single vane; from this he has derived approximate expressions applicable to practical turbines or centrifugals having multiple vanes.

PYROMETERS

INDICATING AND RECORDING. Indicating and Recording Pyrometers, P. M. Heldt. Automotive Industries, vol. 54, no. 3, Jan. 21, 1926, pp. 94-99, 9 figs. Their design and operation; potentiometer principle; automatic cold-junction compensation; checking against standard cell; automatic signaling device; automatic inking arrangement.

R

RADIOTELEGRAPHY

ATMOSPHERICS. The Present Status of Radio Atmospheric Disturbances, L. W. Austin. Wash. Acad. Sciences—Jl., vol. 16, no. 2, Jan, 19, 1926, pp. 41-46, 5 figs. Discusses uncertainty of our knowledge concerning atmospheric disturbances, origin of rumbling disturbances or grinders, connection between intensity of disturbances and position of sum; effects of thunderstorms, etc.

RADIOTELEPHONY

BROADCASTING. Some Studies in Radio Broadcast Transmission, R. Brown, D. K. Martin and R. K. Potter. Bell System Tech. Jl., vol. 5, no. 1, Jan. 1926, pp. 142-213, 50 figs. Discusses radio transmission tests from station 2XB in New York City to outlying field stations, to study fading and distortion of radio signals under night time conditions; concludes that fading can be quite sharply selective as to frequency, wave interference is probable cause; quality distortion may result from dynamic instability of transmitter.

RECEPTION. Progress in Radio Receiving During 1925, Dr. A. N. Goldsmith. Gen. Elec. Rev., vol. 29, no. 1, Jan. 1926, pp. 70-77, 19 figs. Reviews year's progress in receiving circuits, receivers, vacuum tubes, power supply devices and power amplifiers, etc.

RAILS

FAILURE. An Examination into the Causes of the Failure of Steel Rails, E. A. Dancaster. Ry. Engr., vol. 47, no. 552, Jan. 1926, pp. 21-27 and 33, 7 figs. Series of investigations into microstructure of rails which have failed in-service, showing that in sound rails fracture is close to the end, generally passing through fishbolt holes; failure in flawed rail is due to pipes, transverse cracks, blowholes, or excessive segregation.

SPECIFICATIONS. Report of Committee on Rail. Am. Ry. Eng. Assn.—Bul., vol. 27, no. 283, Jan. 1926, pp. 473-629, 70 figs. Revised specifications for spring washers; rail failures; effect of various bolt tensions on mechanical strength of joints; effect of welding in changing structure of rail; standard specifications for manufacture of open hearth-steel girder rails of plain, grooved and guard types.

RAILWAY ELECTRIFICATION

FACTORS AFFECTING. Factors Affecting Electrification, A. G. Oehler, Ry. Age, vol. 80, no. 1, Jan. 2, 1926, pp. 50-51, 1 fig. Points out that new conditions have been introduced which may influence future development.

RAILWAY MANAGEMENT

ACCOUNTING. Report of Records and Accounts. Am. Ry. Eng. Assn.—Bul., vol. 27, no. 281, Nov. 1925, pp. 245-284. Gathering and recording data for keeping up to date valuation records of property; feasibility of reducing number of forms and simplifying those retained; comparison of daily and monthly time and material reports.

FORECASTING REVENUES. Forecasting Railway Revenues, J. E. Slater. Ry. Age, vol. 80, no. 2, Jan. 9, 1926, pp. 187-192, 11 figs. Methods worked out by New Haven to assist in budgeting of expenses.

RAILWAY MOTOR CARS

GASOLINE-ELECTRIC. High Capacity Gas-Electric Car for the Seaboard. Ry. Age, vol. 80, no. 4, Jan. 23, 1926, pp. 273-275, 6 figs. Dual power plant and four motors permit high-speed operation with greater hauling capacity.

The Reading Gas-Electric Rail Car, T. H. Murphy. Ry. Age, vol. 80, no. 2, Jan. 9, 1926, pp. 168-170, 4 figs. Car is controlled from either end and can also be used in multiple-unit operation. See also Ry. & Locomotive Eng., vol. 39, no. 1, Jan. 1926, pp. 17-19, 1 fig.

RAILWAY OPERATION

STATISTICAL DATA. Traffic, Earnings and Expenses, M. O. Lorenz. Ry. Rev., vol. 78, no. 1, Jan, 2, 1926, pp. 41-45, 2 figs. Résumé of comparative statistical data pertaining to railway operation.

TRAIN CONTROL. Train Control Progress in 1925, J. H. Dunn. Ry. Age, vol. 80, no. 1, Jan, 2, 1926, pp. 115-119. Twenty-four divisions completed under first order and two under second; Interstate Commerce Commission has made two final results.

RAILWAY SIGNALING

A. R. A. REPORT. Report on Signals and Interlocking. Am. Ry. Eng. Assn.—Bul., vol. 27, no. 281, Nov. 1925, pp. 315-351, 1 fig. Automatic train control; signals for highway-crossing protection; requisites for automatic signals for highway crossing protection.

AUTOMATIC EQUIPMENT, 1925. An Active Year in Interlocking and Signal Construction, J. H. Dunn. Ry. Age, vol. 80, no. 1, Jan. 2, 1926, pp. 97-104, 3 figs. More equipment placed in service during 1925 than in any year since 1914; statistical data on automatic signaling completed in 1925 and contemplated for 1926.

RAILWAY TIES

PRESERVATIVE TREATMENT. Systematic Protection of Ties Effect Marked Economies, E. F. Robinson. Ry. Age, vol. 80, no. 2, Jan. 9, 1926, pp. 175-180, 3 figs.; also Ry. Eng. & Maintenance, vol. 22, no. 1, Jan. 1926, pp. 15-21, 4 figs. Timber-preserving plant at Bradford, Pa., of Buffalo, Rochester & Pittsburgh Ry.; methods employed; air seasoning; native hardwoods prove most satisfactory.

SPECIFICATIONS. Report of Committee on Ties, Am. Ry. Eng. Assn.—Bul., vol. 27, no. 283, Jan. 1926, pp. 687-732, 9 figs. Specifications for cross-ties, switch-ties, dating nails; making ties for service records; extension of service test records for furnishing information for study of economics of ties; adherence to specifications; substitute ties.

RAILWAY TRACK

REINFORCED-CONCRETE SLAB. Building a More Permanent Track, F. H. Alfred and P. Chipman. Ry. Eng. & Maintenance, vol. 22, no. 1, Jan. 1926, pp. 4-8, 4 figs. Reinforced-concrete slab is suggested to support rails; marked savings anticipated.

RELAYING MACHINE. Railway Track-Relaying Machine. Engineering, vol. 121, no. 3134, Jan. 22, 1926, pp. 102-103, 24 figs. partly on supp. plates. Machine designed and patented by A. W. Bretland, is adaptation to track laying, of system of block laying, long standardized in pier and harbor work. See also description in Engineer, vol. 141, no. 3655, Jan. 15, 1926, pp. 75-77, 9 figs.

SPECIFICATIONS. Report of Committee on Track. Am. Ry. Eng. Assn.—Bul., vol. 27, no. 283, Jan. 1926, pp. 631-686, 25 figs. Proposed revised specifications for steel tie plates and for soft-steel track spikes; specifications for gros filler sections and for wooden handles for track tools; effect of brine drippings on track appliances; canting rail inward and taper of tread of wheel; railway renewals; tie plates, etc.

RAILWAY YARDS

A. R. A. REPORT. Report of Committee on Yards and Terminals. Am. Ry. Eng. Assn.—Bul., vol. 27, no. 282, Dec. 1925, pp. 353-388, 6 figs. Joint use and operation of passenger terminals; scales; freight-yard design; mechanical means for controlling movement of cars in hump yards.

REDUCTION GEARS

TYPES. Gears for Speed Reduction. Power, vol. 63, no. 5, Feb. 2, 1926, pp. 181-183, 8 figs. Types of gear drives; applications in power plant.

REFRACTORIES

PROPERTIES. Refractories, M. C. Booze. Fuels & Furnaces, vol. 4, no. 1, Jan. 1926, pp. 41-44 and 71-72. Discusses consumption, life, selection and testing of refractories; improvement of properties, recent developments.

REFRIGERATING MACHINES

HIGH-SPEED. Modern High Speed Refrigerating Machines, G. W. Daniels. Cold Storage, vol. 29, no. 334, Jan. 21, 1926, pp. 9-12. Advantages and disadvantages of low speed and high speed; construction of valves, suction pipes and passages, lubrication, balancing, etc.

REFRIGERATING PLANTS

CORROSION. Corrosion in the Refrigerating Industry, W. G. Whitman, E. L. Chappell and J. K. Roberts. Ice & Refrigeration, vol. 70, no. 1, Jan. 1926, pp. 46-51, 11 figs. Reports submitted to committee on corrosion of Am. Soc. of Refrig. Engrs., covering general principles of corrosion, corrosion in condenser systems and in brine systems. Bibliography.

EFFICIENCY. Limits of Refrigerating Plant Efficiency. V. J. Azbe. Ice & Refrigeration, vol. 70, no. 1, Jan. 1926, pp. 33-40, 8 figs. Also Power, vol. 63, no. 4, Jan. 26, 1926, pp. 138-139, 4 figs. Discusses that part where power is applied to compress ammonia to produce refrigeration and factors which determine range through which ammonia is to be compressed.

HEAT BALANCE. Heat-Balance in a Refrigerating Plant, W. S. Huntington. Refrigeration, vol. 38, no. 1, Jan. 1926, pp. 44-46, 2 figs. Attempts to construct a heat-balance diagram; discusses freezing tank, tank insulation, daily storage, ratio of refrigeration and ice tonnage, distribution of refrigerating cost in cents per dollar expended.

HEAT LEAKAGE. Heat Leakage in the Refrigerating Plant, W. H. Huntington. Power, vol. 63, no. 3, Jan. 19, 1926, pp. 96-97, 1 fig. Chart showing leakage from bare and insulated tanks; permits calculation for most efficient thickness of covering.

INSULATION. The Insulation of Cold Stores. Ice & Cold Storage, vol. 29, no. 334, Jan. 1926, pp. 3-5, 4 figs. Discusses question of insulation of refrigerating installations as affecting machinery. piping and buildings, and gives results of experiments and experience. Translated from Sulzer Techl. Rev.

REFUSE DISPOSAL

DESTRUCTORS AND TIPS. Disposal of Refuse at Destructors and Tips. Surveyor, (Lond.), vol. 69, no. 1773, Jan. 8, 1926, pp. 31-32. Relative cost of systems, operating refuse destructor or closing it down and diverting all refuse to tips.

RESEARCH

INDUSTRIAL. The Adminstration of Industrial Research, E. R. Weidlein. Indus. & Eng. Chem., vol. 18, no. 1, Jan. 1926, pp. 98-101. General absence of scientific research methods in chemical technology led to formulation in 1906 of Indus. Fellowship System of Mellon Inst.; review of gradual development; scope of research management; definition of research organization; principles of research laboratory management; functions of organization; selection; selection of research men.

ROADS

STRENGTHENING AND WIDENING. The Economics of Strengthening and Widening of Pavements, W. H. Connell. Am. Highways, vol. 5, no. 1, Jan. 1926, pp. 10-17, 8 figs. Discusses traffic capacity of roads and traffic data, strengthening and widening in Pennsylvania, economic thickness and surfacing, etc.

ROADS, CONCRETE

CONSTRUCTION. Efficiency in Concrete Road Construction, J. L. Harrison. Pub. Roads, vol. 6, no. 11, Jan. 1926, pp. 241-250, 1 fig. Report of observations made on going projects by Division of Control, Bureau of Public Roads, covering efficiency of equipment, proper use of stock pile and modern steel bins, cement handling inefficient, subgrade practice recommended, finishing method, etc.

ROADS, GRAVEL

ASPHALT SURFACING. Gravel Roads Cheaply Surfaced with Asphalt. Eng. News-Rec., vol. 96, no. 1, Jan. 7, 1926, pp. 14-17, 11 figs. Michigan is covering old gravel roads with sheet asphalt at a cost of about a dollar a yard; reports and cost records.

ROOFS

SLATE SURFACE ASPHALT-PREPARED. United States Government Master Specification for Slate-Surfaced Asphalt Prepared Roofing and Shingles. U. S. Bur. Standards—Circular, no. 285, Nov. 17, 1925, 6 pp. Rag roofing felt saturated and coated on both sides with asphalt and surfaced on the weather side with granulated slate of similar material, methods of inspection and testing, packing and marking.

ROLLING MILLS

CONTINUOUS. Ford Merchant Mill in Operation. Iron Age, vol. 117, no. 3, Jan. 21, 1926, pp. 197-201, 8 figs. First unit of new steel works is 14-in. motor-driven continuous mill: unusual features.

S

SAFETY

ENGINEERING. The Problems and Functions of a Safety Engineer, K. C. Monroe. Am. Mach., vol. 64, no. 5, Feb. 4, 1926, pp. 197-198, 2 figs. Selection of proper safety devices; co-operation of employees most necessary for establishment of safe practices; safety bulletins and accident records.

SEWAGE DISPOSAL

PERCOLATING FILTERS. The Cost of Sewage Disposal Works in Relation to Volume and Strength of Sewage, L. F. Mountfort. Surveyor, (Lond.), vol. 69, no. 1772, Jan. 1, 1926, pp. 305, 1 fig. Use of percolating filters for final stage of purification, suggests an approximate method of ascertaining rapidly variation of cost in relation to strength of sewage.

SLUDGE, HEAT DRYING. The Heat-Drying of Sludge at the Baltimore Sewage Works, C. E. Keefer. Eng. News-Rec., vol. 96, no. 6, Feb. 11, 1926, pp. 238-240. Plant for converting sludge into fertilizer shut down after 6½ years operation by company under contract with city.

SHAFTS

CRITICAL SPEEDS. Determination of Critical Angular Velocity (La Détermination des Vitesses angulaires critiques), F. H. Van den Dugen. Assn. des Ingénieurs de l'Ecole Polytechnique de Bruxelles—Bul. Technique, vol. 21, no. 1, 1925, pp. 1-15, 3 figs. Discusses formulation of integral equation, phenomenon of resonance, various methods of calculation, and examples: physical properties of critical speed, stabilizing speeds; problems with several parameters.

DIAGRAMS. Shaft Diagrams, J. R. Hurford. Power, vol. 63, no. 2, Jan. 12, 1926, pp. 59-61, 5 figs. Presents charts constructed by author to solve formula proposed by A. L. Jenkins for shaft made of ductile material.

SPRINGS

RING. The Ring Spring, O. R. Wikander. Mech Eng., vol. 48, no. 2, Feb. 1926, pp. 139-143, 8 figs. Characteristics and advantages of type of compression spring consisting of assembly of alternate inner and outer rings, each coating with adjacent ones along conical surfaces; design formulae and illustrative calculation.

STEAM

CHARTS AND TABLES. Progress Report on the Development of Steam Charts and Tables from the Harvard Throttling Experiments, J. H. Keenan. Mech. Eng., vol. 48, no. 2, Feb. 1926, pp. 144-151, 9 figs. partly on supp. plate.

RESEARCH. Progress in Steam Research. Mech Eng., vol. 48, no. 2, Feb. 1926, pp. 151-160, 19 figs. Reports presented at session on Progress in Steam Table Research, Dec. 2, 1925, as follows: Report of Executive Committee of Steam Table Fund; Report on Progress in Steam Research at the Bureau of Standards, N. S. Oshorne and H. F. Stimson; Report on Progress in Stéam Research at Massachusetts Institute of Technology, L. B. Smith; Notes on Steam-Research Work Carried out at Harvard University, R. V. Kleinschmidt; Temperature Scale and Pressure Standard Employed in M. I. T. Steam-Research Measurements, F. G. Keyes; Progress Made in Technique of Computing a Steam Table from the Harvard Data, H. N. Davis; Comparison with the Formulations, R. C. H. Heck. These reports are supplementary to those published in same journal, Feb. 1924 and Feb. 1925.

STEAM ACCUMULATORS

RUTHS. Ruths Steam Accumulators (L'accumulateur de vapeur Ruths), H. Schrenk. Revue Universelle des Mines, vol. 8, no. 6, Dec. 15, 1925, pp. 347-361, 16 figs. Details of examples of applications in coal mines, central stations, and metallurgical works.

STEAM ENGINES

DEVELOPMENT. Conversion of Reciprocating Steam Engines to Combined Steam and Internal Combustion Engines. Diesel & Oil Engine Jl., vol. 2, no. 1, Jan. 1926, pp. 13-18, 6 figs. Discusses invention by Cox and Lagergreen with the object of improving economy of the old steam power plant of ship and to provide the vessel with such power as to make it independent as to the kind of fuel at the ports of call, giving a cost ratio of 1 to 5 in favor of the converted engine.

STEAM POWER PLANTS

RESEARCH. Bureau of Mines Aids Power Plant Practice. Power Plant Eng., vol. 30, no. 4, Feb. 15, 1926, pp. 246-249, 7 figs. U. S. Government station at Pittsburgh conducts intensive research in combustion, feedwater treatment and refractory problems.

STAND-BY STATIONS. Recent Refinements in Power-plant Auxiliary Apparatus and Operating Methods. Southern Power Jl., vol. 44, no. 1, Jan. 1926, pp. 1-10, 13 figs. Discusses stand-by steam stations of various electric power plants for generating electric energy during summer and method of operation.

STEAM TURBINES

SMALL. A New Line of Small Turbines, R. R. Lewis. Power, vol. 63, no. 5, Feb. 2, 1926, pp. 178-180, 4 figs. Describes series of small turbines developed by Gen. Elec. Co. to meet demand for small units of refined design.

STEEL

BENDING STRESSES, EFFECT OF. Safe Loads and Endurance of Steels under Repeated Pending Stresses. Engineering vol. 141, no. 3657, Jan. 29, 1926, p. 130. Review of article by V. Prever and E. Balma, published in Ingegneria, giving results of number of alternating bending-stress tests on series of 42 steels comprising wide range of compositions and including several nickel and nickel-chromium-tungsten steels with varying carbon contents.

HIGH TEMPERATURES, EFFECT OF. Behavior of Steel at Elevated Temperatures, O. A. Knight. Forging—Stamping—Heat Treating, vol. 12, no. 1, Jan. 1926, pp. 36-40. Comprehensive report covering behavior of cold-drawn mild steel at elevated temperatures; experiments discusses were confined to tensile tests.

STEEL CASTINGS

ELECTRIC. Discussion on Mr. Melmoth's Paper on "Some Metallurgical Points on Electric Steel Castings and Notes on Defects." Foundry Trade Jl., vol. 33, no. 490, Jan. 7, 1926, pp. 13-15. Discusses contraction in wheel castings; liquid contraction; actual contraction determined; cost of electric steel castings; fluidity and light emission; shape of risers.

STEEL, HIGH-SPEED

MANUFACTURE. Making High Grade Steel, J. A. Coyle. Iron Trade Rev., vol. 78, nos. 4 and 6, Jan. 28, Feb. 11, 1926, pp. 261 and 268-269, 3 figs., and 397-399, 1 fig. Jan. 28: Production of high-speed steel, and difficulties met with; chemical analyses of typical tool steels. Feb. 11: History of heat, with full information on analyses, practice, etc.

STEEL WORKS

BETHLEHEM STEEL WORKS. Modernization at Bethlehem's Lackawanna Steel Works. Iron Age, vol. 117, nos. 1 and 6, Jan. 7 and Feb. 11, 1926, pp. 40-45 and 404-410, 25 figs. New coke ovens, blowing engines, two structural mills and scrap plant, rebuilt openhearth furnaces and blooming mill; extensive electrification.

SUPERHEATERS

PRINCIPLE OF. Getting Added Power from Waste Heat, F. Juraschek. Indus. Mgmt. (N. Y.), vol. 71, no. 1, Jan. 1926, pp. 55-59, 5 figs. Discusses use of superheaters.

SURVEYING

INSTRUMENTS. The Owens Bore-Hole Alignment Indicator. Engineering, vol. 121, no. 3133, Jan. 15, 1926, p. 87, 3 figs. Surveying instruments designed by J. S. Owens and constructed by C. F. Casella & Co., London.

T

TELEPHONY

AUTOMATIC. How Dial Impulse Directs Automatic Switching, F. J. Dommerque. Telephone Engr., vol. 30, no. 1, Jan. 1926, pp. 34-36, 8 figs. Explains principle underlying impulse sending by aid of dial type for step by step system represented by Strowger type of switching, and for power drive system represented by panel type machine switching system of the Western Electric.

CARRIER SYSTEM. Carrier Telephone System Installed Between Sydney and Melbourne, F. A. Hubbard. Elec. Communication, vol. 4, no. 3, Jan. 1926, pp. 153-160, 8 figs. Details of new carrier system installed on an existing 600 lbs. per mile copper circuit between two cities whcih are nearly 600 miles apart by circuit route, providing three telephone channels for simultaneous telegraph and telephone operations, carried out under supervision of Bell Telephone Laboratories.

INDUCTIVE INTERFERENCE. Two International Conferences and the Inductive Interference Problem, S. C. Bartholomew. Post Office Elec. Engrs.—Jl., vol. 18, Jan. 1926, pp. 370-380. Review of international conferences on large electric high tension systems, third session in Paris and conference of International Advisory Committee on long distance telephony; protection of telephone lines against absorbing influences from strong currents at bigh tension power installations.

TERMINALS, RAILWAY

ST. PAUL, MINN. The Saint Paul Union Depot, G. H. Wilsey. Minn. Federation Architectural & Eng. Soc.—Bul., vol. 11, no. 1, Jan. 1926, pp. 11-50, 17 figs. Design and construction of new Union Station, electrical and mechanical equipment, platforms, trains sbed and tracks, elevators and ramps, subways, engine terminals, machine sbops, etc.

TERRA COTTA

PRODUCTION. Monograph and Bibliograpby on Terra Cotta, H. Wilson. Am. Ceramic Soc.—Jl., vol. 9, no. 2, Feb. 1926, pp. 94-145, 1 fig. Discusses terra cotta classes, mining, handling and mixing; drafting and plaster work; pressing and finishing; drying; slips, glazes and spraying; color work; kilns and firing, etc., Bibliography.

TESTING MACHINES

UNIVERSAL HORIZONTAL. Universal Horizontal Testing Machine. Engineering, vol. 121, no. 3133, Jan. 15, 1926, pp. 85-86, 3 figs. Details of 100-ton macbine made by A. J. Amsler & Co., Scbaffhausen, Switzerland, designed for making tensile, compression and transverse bending tests.

POWER FOR. Power for Textile Mills, Cbas. T. Main. Mech. Eng., vol. 48, no. 2, Feb. 1926, pp. 125-127 and (discussion) 127-128. Survey of possibilities of production of power by water and steam and of purchase of electric current, with conclusions as to plans to be followed by various types of mills.

TRANSFORMERS

EFFICIENCY. Transformer Efficiencies, A. Stingant. Elec. Times, vol. 69, no. 1786, Jan. 7, 1926, pp. 5-7, 3 figs. Explains by means of calculations and curves significance of statement tbat maximum transformer efficiency occurs at a load on which iron loss is equal to copper loss.

TRANSPORTATION

RAILWAY AND MOTOR-VEHICLE. Bus and Truck Operation Should Be Co-ordinated. Ry. Age, vol. 80, no. 3, Jan. 16, 1926, pp. 231-233. Abstracts of papers presented before Am. Road Bldrs.' Assn., as follows: Highway Transportation Problems, C. H. Markham; Coördination of Steam Railway and Motor-Vehicle Transportation, F. H. Alfred.

TUNNELLING

MOFFAT TUNNEL COLO. Will Hole Through Moffat Tunnel in July 1926, C. A. Betts. Eng. News-Rec., vol. 96, no. 7, Feb. 18, 1926, pp. 284-285, 1 fig. Notes on construction progress and conditions to date, construction being more than three-fourths finished.

V

VALVES

AIRPLANE-ENGINE. Internal Combustion Engine Valves, M. Mahoux. Iron Age, vol. 117, no. 5, Feb. 4, 1926, p. 339. Results of Frencb investigation to determine alloy steels best fitted to meet severe conditions; discussion of exbaust valves for airplane engines. Translated abstract form Revue de Métallurgie.

MANUFACTURE. Making Valves for Many Purposes, R. G. Skerrett. Compressed Air Mag., vol. 31, no. 1, Jan. 1926, pp. 1499-1504, 22 figs. Describes plants and equipment of the Cbapman Valve Mfg. Co. at Indian Orchard, Mass.; especially equipment using compressed air.

VENTILATION

BUILDINGS. Tbe Neutral Zone in Ventilation, J. E. Emswiler. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 32, no. 1, Jan. 1926, pp. 1-16, 8 figs. Explains relation between position of neutral zone and motive heads arising from temperature differences available for causing a flow, and shows bow idea of neutral zone is helpful to a better understanding of ventilating problems, particularly bow it may be applied advantageously in ventilating large factory buildings by natural means.

TEXTILE MILLS. Ventilation of Textile Mills, C. L. Hubbard. Textile World, vol. 49, no. 1, Jan. 2, 1926, pp. 75-79, 5 figs. Discusses theory of ventilation, pure air depending upon physical conditions rather tban on chemical composition; humidity control, air movement, removal of dust and odors.

VOLTAGE REGULATION

REGULATORS. Operation of Counter-E.M.F.-Type Voltage Regulator, F. A. Byles. Power, vol. 63, no. 5, Feb. 2, 1926, pp. 171-174, 4 figs. Notes on proper protection of generators; putting regulator in and out of service; parallel operation of generators; main control and relay magnet adjustments; operation of regulating motor.

W

WASTE UTILIZATION

METHODS. The Problem of Industrial Waste Disposal, C. M. Baker. Cornell Civil Engr., vol. 34, no. 1, Oct. 1925, pp. 3-4. Discusses metbods of disposing of sewage and factory effluents; results of improper handling on public bealtb and comfort, fish, livestock, etc.; classification and analysis of different wastes; treatment and by-product recovery.

WATER FILTRATION

PLANTS. Water Filtration and Softening as Applied to Clay Products Plants, H. M. Marsh and W. J. McLelland. Contract Rec., vol. 39, no. 49, Dec. 9, 1925, pp. 1161-1163, 4 figs. Filtering and softening installation at plant of Don Valley Brick Works; fuel losses caused by scale; zeolite water softening system.

RAPID SAND. Rapid Fine Sand Filtration, H. W. Blaisdell. Am. Water Works Ass.—Jl., vol. 14, no. 6, Dec. 1925, pp. 581-597, 3 figs. Discusses filtering capacity of dry, wet or wasber consolidated sand; Montreal filtration plant, construction and testing; concludes tbat when rapid fine sand filtration is more generally understood, its use sbould increase, for cost of installation and operation is less than one-half tbat of filters now in use.

WATER MAINS

LAYING. Sterilizing a Main Laid in Polluted Ground Water, W. W. Brush. Water Wks. Eng., vol. 79, no. 1, Jan. 1, 1926, pp. 9-10 and 48, 3 figs. Discusses problem of laying pipes under leaking sewers in Rockaway, N.Y.

WELDING. Welding A Cracked 48-incb Cast Iron Pipe Under 20 Feet of Earth, W. W. Brusb, Am. Water Works Assn.—Jl., vol. 14, no. 6, Dec. 1925. pp. 550-562, 5 figs. Details of preliminary work and welding work to repair crack from the inside of pipe, operation being completely successful.

WATER PIPES

INTAKE LINE. Building a Large Intake Pipe Line in Lake Michigan, C. R. Knowles. Ry. Eng. & Maintenance, col. 21, no. 12, Dec. 1925, pp. 488-489, 5 figs. Unsual construction required to meet wave action and settlement of future embankment.

WATER POLLUTION

SEWAGE, BY. Analytical Study of the Waters of Antietam Creek, T. C. Schaetzle. Md. State Dept. Health—Bul., vol. 1, no. 2, Sept. 1925, pp. 105-141, 11 figs. Determination of degree of pollution of inland water courses by untreated and sewage, with special reference to relation of biological growths in stream to cbemical cbanges taking place therein.

WATER POWER

CANADA. Surface Water Supply of Canada, Atlantic Drainage (South of St. Lawrence River). Dominion Water Power & Reclamation Service (Canada)—Water Resources Paper no. 45, 1925, 108 pp. 1 fig. Hydrometric data on Nova Scotia, New Brunswick, Prince Edward Island, and miscellaneous measurements; meteorological data, precipitation and evaporation.

HYDRAULICS, APPLICATION OF. The Principles of Hydraulic Power, F. Johnstone-Taylor. Power House, vol. 18, nos. 19, 20, 21, 22, 23 and 24, Oct. 5, 20, Nov. 5, 20, Dec, 5 and 20, 1925, pp. 19-20, 94 19, 27-28, 23-24 and 19-20, 28 figs. Explanation of their application to power generation. Deals with flow of water in pipes and channels, effect of friction on flow, effect of inertia of water columns and application of safety devices to overcome it, power of water and measurement of flow and hydraulic gradient.

WATER SUPPLY

LAWRENCE, MASS. Lawrence Water Supply, Investigations and Construction, M. Knowles, M. Mansfield and P. Nugent. New England Water Works Assn. —Jl., vol. 39, no. 4, Dec. 1925, pp. 345-369, 2 figs. Discusses growth and population, original water works and tbeir various periods of development, needs of increased supplies, emergency constructions; types of filters, etc.

RATES. Effect of Water Rates and Growtb in Population upon per Capita Consumption, L. Metcalf. Am. Water Wks. Assn.—Jl., vol. 15, no. 1, Jan. 1926, pp. 1-21, 7 figs. Discusses determination of growth of population, increasing water 1-21, 7 figs. Discusses determination of growtb of population, increasing water consumption, per capita, decrease of per capita consumption witb increase in rates, etc.

SURFACE, CANADA. Pacific Drainage, British Columbia & Yukon Territory. Can. Dept. of Interior—Water Resources Paper, No. 47, 1925, 192 pp., 2 figs. Detail of stream flow data for year ending Sept. 30, 1924 covering Nanaimo, Fraser, Tbompson, Columbia, Kootnay, Kettle, Okanagan, Similkameen and other rivers.

VICTORIA. Supplying Water to an Area of 10,000 Square Miles, Commonwealth Engr., vol. 13, no. 4, Nov. 2, 1925, pp. 132-136, 5 figs. Details of Wimmera-Mallee scheme of domestic and stock water supply to 12,000 farm boldings in area of 11,000 sq. mi. witb 5,000 miles of channel distributing water, also supplies 31 towns.

WATER TREATMENT

CHLORINATION. Tbe Sensitivity of the Ortho-Tolidine and Starch-Iodide Tests for Free Chlorine, A. M. Buswell and C. S. Boruff. Am. Water Works Assn.—Jl., vol. 14, no. 5, Nov. 1925, pp. 384-405, 1 fig. Shows that both tests are equally sensitive, each giving positive test for 0.005 p.p.m. of excess Cl in a 50-cc. Nessler tube at room temperature; ortho-tolidine test becomes less sensitive in lower temperature, starcb-iodide test more so; behavior in presence of nitrites, iron, organic compounds, etc.

METHODS. Progress in the Purification of Water Supplies, N. J. Howard. Contract Rec., vol. 39, no. 52, Dec. 30, 1925, pp. 133-138, Advantages of double filtration, sedimentation of turbid waters pipe incrustations, goiter control, chlorination, standards for purity, etc.

WATT-HOUR METERS

CONNECTIONS. Checking the Accuracy of Watt-Hour Meter Connections, W. F. Walsb. Power, vol. 63, no. 6, Feb. 9, 1926, pp. 206-208, 12 figs. Points out some of the likely connection errors and methods of detecting them.

WELDING

ELECTRIC. *See Electric Welding, Arc.*

OXYACTEYLENE. *See Oxyacetylene Welding.*

RODS. Western Company Manufactures New Type Welding Rods, Miles C. Smith. West. Machy. World, vol. 16, no. 11, Nov. 1925, pp. 452-453, and 459, 9 figs. Describes self-hardening welding rod and "Stoodite," made by Stoody Co. of Southern California; latter is product of electric furnace and is claimed to be, after it bas been welded on, hardest known metallic substance.

STAMPINGS. Stampings Assembled by Welding, L. S. Love. Iron Age, vol. 117, no. 2, Jan. 14, 1926, pp. 123-127, 13 figs. Jigs facilitate operations and assure alignment to close limits, in one case to 0.0005 in.; press work at times more economical.

WELDS

PIPE JOINTS. Welds Made Stronger than tbe Welded Material, H. A. Woodworth. Power Plant Eng., vol. 30, no. 2, Jan. 15, 1926, pp. 149-151, 3 figs. Tests on ordinary welds show bow tbey fail; metbod by wbich welds were made that tested stronger than body of material.

WOODWORKING

TECHNICAL TRAINING IN. Technical Training in Woodworking, Thos. D. Perry. Mech. Eng., vol. 48, no. 2, Feb. 1926, pp. 108-110. Summary of replies to questionnaire sent to 750 public schools, colleges, and universities by Wood Industries Division of Am. Soc. Mech. Engrs.

X

X-RAYS

RÖENTGEN. Industrial Application of Röetgen Rays, P. W. Priestley. Indus. Chemist, vol. 1, no. 7, Aug. 1925, pp. 331-336, 10 figs. Discusses x-ray generation, Röentgen rays, photographic properties of x-rays, and application.

Engineering Index

This Index is prepared by the American Society of Mechanical Engineers.

In this department will be published from month to month the titles of current engineering papers with the authors and source and a brief extract of the more important. It is designed to give the members of The Institute a survey of all important articles relating to every branch of the engineering profession.

PHOTOSTATIC PRINTS

Photostatic copies of the articles listed in this section, or others on engineering subjects, may be obtained from the Engineering Societies Library.

Price of each print (up to 11 by 14 in. size) 25 cents, plus postage. Where possible, two pages, up to 7 by 9 in. size, will be photographed on one print. Larger magazines require a print per page. Bills will be mailed with the prints.

The Library is also prepared to translate articles, to compile lists of references on engineering subjects and render assistance in similar ways. Charges are made, sufficient to cover the cost of this work. Correspondence is invited. Information concerning the charge for any specific service will be given those interested. In asking for information please be definite, so that the Investigator may understand clearly what is desired.

The Engineering Societies Library is under the management of the United Engineering Society, which administers it as a public reference library of engineering. It is maintained jointly by the American Society of Civil Engineers; the American Institute of Mining and Metallurgical Engineers; the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. It contains 150,000 volumes on engineering and allied subjects, and receives currently most of the important periodicals in its field.

Orders and correspondence should be addressed to

Harrison W. Craver, Director,
Engineering Societies Library,
29 West Thirty-ninth Street. New York, N.Y.

A

AERONAUTICS

British Development, 1925. Aeronautics in 1925. Engineer, vol. 141, nos. 3653 and 3654, Jan. 1 and 8, 1926, pp. 10-12, and 32-35 and 44, 25 figs. partly on supp. plates. Account of work undertaken during past year by British firms engaged in aeronautical industry. Jan. 1: Civil aviation; British military and civil airplanes. Jan. 8: Military and civil airplanes; helicopters; airships.

AIR COMPRESSORS

Centrifugal. Study of Centrifugal Compressors (Etude sur les compresseurs centrifuges), C. Charton. Revue Universelle des Mines, vol. 9, no. 3, Feb. 1, 1926, pp. 110-137, 28 figs. Determination of speed of compression; distribution of speed in runners; shape of blades; diffusers; power absorbed by compressors; cooling, etc.; characteristics of types of compressors; use of compressors in mines, steel works, navy yards, etc.

The Heat-Balance Method of Testing Centrifugal Compressors, M. G. Robinson. Mech. Eng., vol. 48, no. 3, Mar. 1926, pp. 256-259 and (discussion) 259-260, 5 figs.

Rotary Compressors (Comment réaliser élégamment la suralimentation dans les moteurs à grande vitesse). Revue de l'Ingenieur, vol. 23, no. 1, Jan. 1926, p. 14, 1 fig. Compressor designed by Cozette particularly for use in supercharging highspeed internal-combustion engines, but suitable for other purposes as well.

AIR CONDITIONING

Aerozon System. The Aerozon Air-Conditioning System. Cold Storage, vol. 29, no. 335, Feb. 18, 1926, pp. 80-81, 2 figs. This unit consists of metal casing, with adjustable conical front nozzle and is provided with central atomizer so that combined air and water jet can be projected through front nozzle.

Carrier System. Air-Conditioning in Modern Industry. Cold Storage, vol. 29, no. 335, Feb. 18, 1926, pp. 75-79, 3 figs. Application of Carrier system, which can control any temperature within 1 deg. fahr. over range extending from zero to 300 deg., and humidity within 2 per cent.; details of hygrostat or humidity-control instrument in this system and Carrier centrifugal refrigeration.

Developments. Air-Conditioning and Cleaning, A. G. Clausen. Cold Storage, vol. 29, no. 335, Feb. 18, 1926, pp. 71-73. Notes on air-borne pests; temperature and humidity; vapor pressures; hygrometric tables; humidifier spray units; air drying; refrigeration; hot climates.

AIR COOLING

Buildings. Refrigerated Air is Cooling Buildings and Increasing Use of Coal, R. D. Hall. Coal Age, vol. 29, no. 6, Feb. 11, 1926, pp. 221-223, 6 figs. Use of refrigerated air in cafes, restaurants, dance halls, amusement palaces and hospitals.

AIR FILTERS

Developments. Air Filters Protect Equipment, W. B. Spooner. Iron Trade Rev., vol. 78, no. 9, Mar. 4, 1926, pp. 573-575, 3 figs. Damage to internal-combustion engines, turbo-generators, mill motors and air-cooled transformers by dust is prevented by passing air through cellular structures coated with sticky fluid; description of unit.

AIRPLANE ENGINES

Air-Cooled. Installation Problems on Radial Air-Cooled Engines, A. H. R. Fedden. Roy. Aeronautical Soc.—Jl., vol. 30, no. 182, Feb. 1926, pp. 83-111 and (discussion) 111-127, 26 figs. Remarks applying particularly to 9-cylinder single-row air-cooled radial.

The Advent of the Radial Air-Cooled Engine, W. L. LePage. Aviation, vol. 20, no. 8, Feb. 22, 1926, pp. 257-259, 1 fig. Great possibilities for air cooling; type supplements rather than competes with water-cooled engine.

Specifications, American and British. American and British Aero Engine Specifications. Automotive Industries, vol. 54, no. 7, Feb. 18, 1926, p. 327. Tabular data arranged alphabetically according to makes.

AIRPLANES

Airfoils. On the Pressure Distribution Round Certain Aerofoils of High Aspect Ratio, D. M. Wrinch. Roy. Aeronautical Soc.—Jl., vol. 30, no. 182, Feb. 1926, pp. 129-142, 12 figs. Records types of pressure-distribution curves obtained in a set of simple sections when characteristics of small camber, rounded leading edge and thin trailing edge found in all airfoils so far used, are retained.

Report on Aerofoil Tests at National Physical Laboratory and Royal Aircraft Establishment. Aeronautical Research Committee—Reports and Memoranda, no. 954, May 1925, 46 pp., 5 figs. Tests made in England on airfoil model.

Tests on an Aerofoil with Two Slots Suitable for an Aircraft of High Performance, F. Handley Page. Flight, vol. 18, no. 4, Jan. 28, 1926, pp. 48a—48d, 4 figs. Results of series of tests on airfoil fitted with front and rear slots; rear slot formed between portion of plane aft of rear spar and forward portion of flap; measurements of lift, drag, rolling and yawing moment.

The Effect of Sweep Back and Sweep Forward on an Airfoil, P. M. Lyons. Air Service Information Circular, vol. 6, no. 547, Jan. 25, 1926, 6 pp., 5 figs. Test to determine aerodynamic characteristics of U. S. A.-35 airfoil as result of sweeping tip section backward and forward with respect to root section.

Bending Moments. Bending Moments Obtained Graphically, M. Watter. Aviation, vol. 20, no. 8, Feb. 22, 1926, pp. 254-256, 2 figs. Graphical method of determining allowable stress in uniform section members.

Wind-Tunnel Tests. Wind Tunnel Test of Six Horizontal Tail Surface Designs Having the U.S.A.-47 Airfoil Section, P. M. Lyons. Air Service Information Circular, vol. 6, no. 511, Jan. 25, 1926, 4 pp., 5 figs. Test to determine effect of plan form and elevator size on aerodynamic characteristics.

Wing Flap Test of a DH-4B Wind Tunnel Model, P. M. Lyons. Air Service Information Circular, vol. 6, no. 552, Jan. 25, 1926, 9 pp., 12 figs. Test to determine aerodynamic characteristics of this model as affected by adjustable wing flaps.

Wings. A Study of Wing Weights, C. J. Rowe. Air Service Information Circular, vol. 6, no. 541, Oct. 1, 1925, 17 pp., 13 figs. Detail weights of various structural parts of wings and relation of these parts to whole; calculation of formula by E. P. Warner, based upon knowledge of gross weight of airplane, wing area, aspect ratio, etc.; and formula by F. S. Barnwell, requiring knowledge of only wing area and chord.

AIRSHIPS

Bracing. An Experimental Investigation Into the Properties of Certain Framed Structures Having Redundant Bracing Members, A. J. S. Pippard and G. H. W. Clifford. Aeronautical Research Committee—Reports & Memoranda, no. 977, Sept. 1925, 12 pp., 10 figs. Continuation of earlier experimental work on hexagonal braced tube, three bays in length, fitted in present case with solid keel; experiments show that with efficient bracing in plane of applied load system, stresses tend quickly to become independent of arrangement of that system and with additional bracing elsewhere a much quicker equalization of stress is produced.

ALLOY STEELS

Airplane-Engine Valves. Influence of the Thermal Zone of Working on Selection of Steels for the Valves of Airplane Engines (Influence de la zone thermique de travail sur la sélection des aciers pour soupapes de moteurs d'aviation), C. Grard. Académie des Sciences—Comptes Rendus, vol. 181, no 26, Dec. 28, 1925, pp. 1143-1145. Most suitable alloy examined was steel containing 0.4 per cent. carbon, 2.5 per cent. silicon, and 12 per cent. chromium, quenched in air at 1200 deg. and reheated to 900 deg.; valves made of this alloy retained their original polish and texture after continuous operation for 50 hours.

ALLOYS

Aluminum. *See Aluminum Alloys.*

Elastic Properties. Elastic Properties of Alloys: Variation with Composition (Propriétés élastiques des alliages: Variation en fonction de la composition chimique), P. Chevenard and A. Portevin. Académie des Sciences—Comptes Rendus, vol. 181, no. 21, Nov. 23, 1925, pp. 780-782, 2 figs. Presents curves for elastic properties of annealed carbon steels and gold-silver alloys; modulus of elasticity varies almost linearly with composition, both in alloys of two structural constituents and also in solid solutions, this being confirmed for alloys of copper with zinc, aluminum or nickel; on other hand, elastic contraction is always much less than that of pure metals.

Lead. *See Lead Alloys.*

Magnesium. *See Magnesium Alloys.*

Nickel. *See Nickel Alloys.*

ALUMINUM

Cast-welding. Cast-Welding Aluminum. Machy. (N.Y.), vol. 32, no. 7, Mar. 1926, p. 572. Process of repairing broken castings by cast-welding or burning on.

ALUMINUM ALLOYS.

Aluminum-Copper. Equilibrium Relations in Aluminum-Copper Alloys of High Purity, E. H. Dix, Jr., and H. H. Richardson. Am. Inst. Min. & Met. Engrs.—Trans., no. 1534-E, Feb. 1926, 21 pp., 5 figs. Investigation undertaken because of discrepancies in previously published results and to establish metallography and constitution of aluminum alloys free from contaminating impurities which have hampered earlier investigators.

Quenching of Light Aluminum-Copper Alloys Containing More than 5 Per Cent. of Copper (Sur la trempe des alliages légers aluminium-cuivre renfermant plus de 5 pour 100 de cuivre), L. Guillet and J. Galibourg. Académie des Sciences—Comptes Rendus, vol. 181, no. 26, Dec. 28, 1925, pp. 1107-1108. Tabulation of data on hardness and electric resistivity of castings containing 7 to 45 per cent. copper, after quenching and subsequent reheating.

Aluminum-Manganese. Sand-Cast Aluminum-Manganese Alloys, S. Daniels. Indus. & Eng. Chem., vol. 18, no. 2, Feb. 1926, pp. 125-130, 14 figs. Composition and characteristics of aluminum alloys to which manganese is added.

Aluminum-Silicon. Aluminum-Silicon Alloys (Contribution à l'étude des alliages aluminum silicium), A. Petit. Académie des Sciences—Comptes Rendus, vol. 181, no. 20, Nov. 16, 1925, pp. 718-719. Records influence of various metals and alloys on physical properties of aluminum-silicon alloys.

Castings. Aluminium-Alloy. Permanent-Mould Castings, Rob. J. Anderson. Foundry Trade, Jl., vol. 33, nos. 494, 495 and 496, Feb. 4, Feb. 11 and 18, 1926, pp. 93-94, 105-108 and 125-128, 13 figs. Feb. 4: Permanent-mold and semi-permanent-mold casting process; die-casting process; sand founding. Feb. 11: Advantages and disadvantages in comparison with sand and die castings. Feb. 18: Uses and field of application; specific kinds of castings produced in permanent molds.

Copper-Rich. The Copper-Rich Aluminum-Copper-Tin Alloys, D. Stockdale. Inst. Metals—advance paper, no. 14, for mtg. Mar. 10-11, 1926, 27 pp., 49 figs. Investigation of number of ternary alloys.

Piston. Effect of Reheating on the Al-Cu-Ni-Mg and the Al-Cu-Fe-Mg (Piston) Alloys, S. Daniels. Am. Inst. Min. & Met. Engrs.—Trans., no. 1519-E, Feb. 1926, 26 pp., 24 figs. Deals with these piston materials when tested at room temperature after having been reheated both in sand-cast and in quenched and artificially aged condition to various temperatures and different periods of time up to 50 hours.

Sand-Cast. Modification and Properties of Sand-Cast Aluminum-silicon Alloys, R. S. Archer and L. W. Kempf. Am. Inst. Min. & Met. Engrs.—Trans., no. 1544-E, Feb. 1926, 39 pp., 30 figs. Result of work bearing on control of modifying process, and of investigation of effects of alloy composition with respect to silicon and iron.

AMMONIA COMPRESSORS

Efficiency. Factors Affecting Ammonia Compressor Efficiency, J. H. H. Voss. Power, vol. 63, no. 9, Mar. 2, 1926, pp. 334-335, 2 figs. Presents G. Lehnert's 14 indicator diagrams showing mistakes in design, maintenance or operation. (Abstract.) Paper presented before Nat. Assn. Practical Refrig. Engrs.

AQUEDUCTS

Hetch Hetchy, San Francisco. San Francisco Bay Crossing of Hetch Hetchy Aqueduct. Eng. News-Rec., vol. 96, no. 11, Mar. 18, 1926, pp. 434-438, 10 figs. Methods used in laying flexible 42-in. pipe on channel bottom and in building bridge over shallows and large pier between channel and bridge sections.

AUTOMOBILE ENGINES

Turbine. Internal Combustion Turbines. Autocar, vol. 56, no. 1581, Feb. 5, 1926, pp. 207-208, 3 figs. Design evolved by Paris engineer and submitted to French government; possibilities of such an engine for both car and aviation service.

AUTOMOBILE FUELS

Tetraethyl Lead. Report of Surgeon General's Committee on Tetraethyl Lead. Indus. & Eng. Chem., vol. 18, no. 2, Feb. 1926, pp. 193-196, 2 figs. Methods used, results and conclusion.

AUTOMOBILE INDUSTRY

World Statistics. 4,608,331 Cars and Trucks Now in Use Outside U.S. Automotive Industries, vol. 54, no. 7, Feb. 18, 1926, pp. 255-258. Gain of 26.8 per cent. over last year; total in world 24,452,267, representing 14.5 per cent. increase over 1925; world registration of cars and trucks, alphabetically listed; statistics of North and South America, Europe, Asia, Africa and Oceana.

ARCHES

Concrete. Progress Report of the Special Committee on Concrete and Reinforced Concrete Arches. Am. Soc. Civil Engrs.—Proc., vol. 52, no. 3, March 1926, pp. 136-145. Report of Conneaut (Ohio) and Danville (Ill.) bridges; pier movements, skew arches; theoretical and laboratory investigations; forecast of work still to be done.

ARMATURES

Rewinding. Rewinding Railway Armatures, J. M. Zimmerman. Elec. Ry. Jl., vol. 67, no. 8, Feb. 20, 1926, pp. 315-316, 2 figs. Descriptions, functions and location of armature rewinding insulation, core insulation and banding material will help repairman to do better job.

ASBESTOS

Uses. Asbestos—Non-Conductor of Heat, R. C. Rowe. Power House, vol. 19, no. 4, Feb. 20, 1926, pp. 26-29,4 figs. Points out that uses of asbestos are varied, but depend mostly on its remarkable heat-resisting qualities, although it is used in soaps and for other purposes; production in 1924.

AVIATION

Beacons. The Air Service Radio Beacon. Aviation, vol. 20, no. 10, Mar. 8, 1926, pp. 331-332, 3 figs. Unique method of aiding aerial navigation, developed by Radio Laboratory at McCook Field, Dayton, O.

Design Tendencies. Aviation at the Beginning of 1926 (L'aviation au début de 1926), C. Martinot-Lagarde. Technique Moderne, vol. 18, no 4, Feb. 15, 1926, pp. 103-110, 9 figs. Recent developments as to arrangement of engines, water and air cooling; power increase, compression, speed of revolution; new ideas as to most powerful engines; air screws and their control; engines of high performance; accessories, etc.

Development. High Spots in Aviation Development, J. F. Boyle. Soc. Indus. Engrs.—Bul., vol. 8, no. 2, Feb. 1926, pp. 15-24. Brief history of aviation; safety factor; comparison with Europe; air-cooled engines; light planes; 10 years' development; high-altitude flights; supercharger; bombing and racing airplanes; high speeds; propellers; future of commercial aviation; safety of airships.

B

BALANCING MACHINES

Vertical. Olsen-Lundgren Vertical Balancing Machine, no. 3, Am. Mach., vol. 64 no. 10, Mar. 11, 1926, pp. 417-418, 1 fig. Machine brought out for balancing flywheels, pulleys, clutch parts, disks and bodies that are easily handled on vertical spindle.

BEAMS

Reinforced Concrete. Bond and Anchorage in Reinforced Concrete Beams, T. D. Mylrea. West. Soc. Engrs.—Jl., vol. 31, no. 1, Jan. 1926, pp. 11-31, 30 figs. Shows fallacy of placing too much reliance upon hooks which have decided tendency to split concrete.

BELTING

Tension Ratio. The Tension Ratio and Transmissive Power of Belts, C. A. Norman. Mech. Eng., vol. 48, no. 3, Mar. 1926, pp. 240-245, 9 figs. Points brought out in discussion of annual-meeting paper presented by C. A. Norman.

BLASTING

Ditch. Largest Blast Ever Made in Canada, E. Godfrey. Contrat Rec., vol. 40, no. 7, Feb. 17, 1926, pp. 140-143, 11 figs. How course of river was diverted with 205,479-lb. of explosives; details of intricate piece of construction work in connection with Isle Maligne development.

BOILER EXPLOSIONS

Gas-Fired Boilers. Explosion in the Flues of a Gas-Fired Boiler (Rauchgasexplosion in Kesselzügen), V. Hundertmark. Glückauf, vol. 61, no. 51, Dec. 19, 1925, pp. 1634-1635, 1 fig.

BOILER FEEDWATER

Conditioning. Boiler Water Conditioning, R. E. Hall. Gas Age-Rec., vol. 57, no. 8, Feb. 20, 1926, pp. 255-257. Results of 4 years' research on boiler-water conditioning with special reference to high operating pressure and corrosion (Abstract.) Paper presented at Midwest Power Conference.

Oil Elimination. Oil Elimination. Eng. & Boiler House Rev., vol. 39, no. 7, Jan. 1926, p. 342, 1 fig. Describes Paterson oil eliminator with fluxograph flow recorder and feed tank.

BOILER FURNACES

Draft. Mechanical Draught. Eng. & Boiler House Rev., vol. 39, no. 7, Jan. 1926, pp. 334-335, 3 figs. Notes on Prat system for boiler house.

Pulverized-Coal-Fired. Powdered Coal at Ashley Street Station, E. H. Tenney. Power, vol. 63, no 11, Mar. 16, 1926, pp. 404-407, 7 figs. Experiences with eight boilers equipped with unit pulverizers, water-cooled furnace walls and radiant-type superheaters at St. Louis station.

Pulverized Coal, Radiation from. Radiant Heat, E. G. Ritchie. Combustion, vol. 14, no. 3, Mar. 1926, pp. 170-175, 6 figs. Its significance in relation to pulverized-coal furnace design.

Radiation In. Radiation in Boiler Furnaces, G. A. Orrock. Mech. Eng., vol. 48, no. 3, Mar. 1926, pp. 218-220, 2 figs. Radiant-heat data on locomotive and water-tube boilers fired with various fuels, and development therefrom of simple formula that permits of results being predicted with considerable degree of accuracy.

Screenings as Fuel. Loads of 200 Per Cent. Rating Carried with Screenings as Fuel, J. E. Kilker. Combustion, vol. 14, no 3, Mar. 1926, pp. 169-170. Survey provides definite, reliable and unbiased performance data in Ewing Avenue, St. Louis, and other plants.

BOILER OPERATION

Chain Grate and. Notes on Boiler and Chain Grate Operation, J. T. Ruddock-Eng. & Boiler House Rev., vol. 39, no. 6, Dec. 1925, pp. 273-274 and 277-278, 1 fig., and nos. 7 and 8, Jan. and Feb. 1926, pp. 340-341, and 388-390. Dec. 1925: Deals only with solid fuels; notes on combustion, ignition point, air for combustion, heat values and weights involved in combustion. Jan.: Practical values for coal and oil; arches and brickwork. Feb.: Side sealing with minimum supply of air; growth of cast-iron links; wet coal.

BOILER PLANTS

Equipment. New Boiler Equipment at the Interborough Rapid Transit Co.'s Fifty-Ninth Street Power Station, H. B. Reynolds, J. M. Toggart and R. S. Lane. Mech. Eng., vol. 48, no. 3, Mar. 1926, pp. 246-250, 4 figs. New boilers operating at normal high load of 300-per cent. rating and supplying steam to 35,000-kw. turbines now in place will develop a capacity of approximately 7000 kw.; stokers are of Taylor HC7 type, 7 retorts and 37 tuyeres long; hand and automatic controls, boiler meters, economizers, etc.; test results.

BOILERS

Corrosion. Sidelights on Scale and Corrosion. Power, vol. 63, no. 10, Mar. 9, 1926, pp. 362-364, 6 figs. How calcium-sulphate crystals entangle calcium carbonate; simple experiment shows effectiveness of sodium hydroxide in preventing corrosion.

Locomotive. *See Locomotive Boilers.*

Scale Removal. Eliminating Boiler Scale by Agfil Process, D. A. Gardner. Power, vol. 63, no. 7, Feb. 16, 1926, pp. 261-262, 2 figs. Process invented in Europe has been in use for 3 years; apparatus consists of 3 pieces, a thermopile, vibrator and ammeter.

Stoker-Fired. Stoker-Fired Boiler Unit Develops High Efficiency. Power. vol. 63, no. 11, Mar. 1o, 1926, pp. 398-399, 3 figs. Interesting departures from usual practice are believed to be principal causes contributing to efficiency of 83 per cent. under normal plant conditions at plant of Brown & Sharpe Mfg. Co., Providence, R.I.

Waste-Heat Boilers in Steel Mills, F. H. Wilcox and J. C. Hayes. West Soc. Engrs.—Jl., vol. 31, no. 1, Jan. 1926, pp. 1-10, 5 figs. Shows that designs must be different from those used with furnaces; records of economy which have been established; use of these boilers with internal-combustion engines offers promising fields for further study.

Water-Tube. *See Boilers, Water-Tube.*

BOILERS, WATER-TUBE

Heat Transmission in. Heat Transmission in Water-Tube Boilers, C. F. Wade. Combustion, vol. 14, no. 3, Mar. 1926, pp. 163-164, 3 figs. Author believes that considerable improvement is possible in conduction stages of gas passages, in fact to possible extent of relieving radiation section from some of heavy duty now being imposed upon it; with this end in view he has devised system ot water-tube boiler construction in endeavor to get maximum possible duty from all parts of boiler alike.

BONUS SYSTEMS

Practical Application. Bonus Systems in Practice, C. F. Wade. Eng. & Boiler House Rcv., vol. 39, no. 7, Jan. 1926, pp. 325-326. Application of systems to boiler-house operators.

BORING MILLS

Side-Head. 42-inch Side-head Boring Mill. Machy. (Lond.), vol. 27, no. 693, Jan. 7, 1926, pp. 478-479, 3 figs. Important development by Webster & Bennett, Coventry.

BRAKES

Power. Power Brake Investigation Now Making Rapid Progress. Ry. Age., vol. 80, no. 6, Feb. 6, 1926, pp. 377-380, 6 figs. Progress made by Am. Ry. Assn. in investigation of power brakes and power-brake, operating appliances for freight trains of 100-car test rack located at Purdue Univ., Lafayette, Ind. See also account by H. A. Johnson in Ry. Rev., vol. 78, no. 7, Feb. 13, 1926, pp. 320-305, 5 figs.

Testing. Poser Brakes Tested at Purdue. Ry. Mech. Eng., vol. 100, no 3, Mar. 1926, pp. 151-154, 6 figs. Investigation by Am. Ry. Assn., of power brakes and brake-operating appliances for freight trains on 100-car test rack located at Purdue University, Lafayette, Ind.

BRASS

Mixing For Billets. Mixing Brass for Billets, W. J. Pettis. Metal Industry (N.Y.), vol. 24, no 3, Mar. 1926, p. 99. Ingenious, quick and practical method for controlling zinc contents of 60-40 brass.

Zinc Oxide in. Determination of Zinc Oxide in Brass, B. S. Evans and H. F. Richards. Inst. Metals—advance paper, no. 4, for mtg. Mar. 10-11, 1926, 7 pp., 1 fig. Method worked out in attempt to account for presence of certain inclusions in samples of brass.

BRASS FOUNDRIES

Methods and Equipment. From Prison Bakery to Brass Foundry, R. Micks. Can. Foundryman, vol. 17, no. 2, Feb. 1926, pp. 9-10, 3 figs. Methods and equipment of foundry in Hamilton, Ont.

BRIDGE ERECTION

Construction Methods. Use Novel Methods in Building Bridge Substructure. Ry. Age, vol. 80, no. 15, Mar. 13, 1926, pp. 795-799, 7 figs. Foundation work of unusual character and scientific methods of proportioning concrete are noteworthy features of Newark Bay projects.

BRIDGES, CONCRETE

Arch. Concrete Arch Bridge at Donner Summit, Calif. Eng. News-Rec., vol. 96, no. 9, Mar. 4, 1926, pp. 357-358, 5 figs. Bridge roadway curved on 360-ft. radius with 7-per cent. grade; new route replaces 20-per cent. grades.

BRIDGES, HIGHWAY

Cantilever. Large Cantilever Planned for Mount Hope Toll Bridge. Eng. News-Rec., vol. 96, no. 11, Mar. 18, 1926, pp. 438-439, 1 fig. Span of 1200 ft. recommended for Rhode Island bridge; trusses to have three chords.

BRIDGES, HIGHWAY

Impact Studies. Final Report of the Special Committee on Impact in Highway Bridges. Am. Soc. Civil Engrs.—Proc., vol. 52, no 3, Mar. 1926, pp. 442-453, 9 figs. Determination of observed stresses due to certain static and dynamic loads in steel floor systems, and in some cases of truss members of five steel bridges with concrete floor-slabs and seven steel bridges with plank flooring.

BRIDGES, RAILWAY

Anchorage. Anchorage and Bearing Details of Rigolets Bridge; L. & N. R.R. Eng. News-Rec., vol. 96, no. 7, Feb. 19, 1926, pp. 288-289, 3 figs. Removable anchor bolts facilitate landing spans on piers; oil boxes for roller bearings; bottom laterals.

Plate-Girder. Longest Ballasted-Deck Plate-Girder Bridge; E.J. & E. Ry. Eng. News-Rec., vol. 96, no. 8, Feb. 25, 1926, pp. 328-331, 5 figs. Girders 126 ft. 10 in. long; one end supports adjacent span; bridge with track complete erected on carriages and rolled into place; cranes remove old truss span.

Wooden. Report of Committee VII—Wooden Bridges and Trestles. Am. Ry. Eng. Assn.—Bul., vol. 27, no. 284, Feb. 1926, pp. 829-912. Commercial names for lumber and timber cut from principal species of softwoods; American lumber standards for softwood lumber; standard grades of red cedar shingles; softwood factory and shop lumber; structural grades of lumber and timber and method of their derivation; specifications for structural joist plank, beams, stringers and posts; structural grades and reference code; coded specifications for structural grades; notes on tables of working stresses; safe loads for wooden columns; value of treated timber in wooden bridges and trestles. See also (Abstract) in Ry. Age, vol. 80, no. 14, Mar. 12, 1926, pp. 775-778, 1 fig.

BRIDGES, SUSPENSION

Bear Mountain, Hudson River. The Design and Construction of the Bear Mountain Bridge Over the Hudson River, H. D. Leopold, Bklyn. Engrs. Club—Proc., vol. 24, Part 2, Jan. 1926, pp. 14-26 and (discussion) 27-30, 10 figs. Design and methods of erection of very long, high level suspended span having special anchorages, towers and floor construction; details of cable making, erection of structural steel and adjustments of anchorages and cables.

BRONZES

Brittle Ranges. The Brittle Ranges of Bronze, W. L. Kent. Inst. Metals—advance paper, no. 9, for mtg. Mar. 10-11, 1926, 8 pp., 4 figs. Brittle ranges of bronze containing up to 25 per cent. of tin have been investigated in both cast and annealed alloys by carrying out Izod impact tests at temperatures up to 700 deg. cent.; it was observed that limit of solid solubility of tin and copper is greater than had been supposed.

Properties. Physical Properties of Engineering Materials. Power Engr., vol. 21, no. 240, Mar. 1926, pp. 101-102, 3 figs. Effect of high temperatures and heat treatment on bronze corrosion.

BUSBARS

Tubular. Selection of Tubular Bus Material, J. V. Wall. Elec. World, vol. 87, no. 6, Feb. 6, 1926, pp. 299-302, 1 fig. Mechanical characteristics essential to selection; tables showing deflections, carrying capacities and other characteristics of tubular buses; test results made available.

C

CABLES, ELECTRIC

Ducts for. Chicago Ducts Ready for 132-kv. Cable. Elec. World, vol. 87, no. 7, Feb. 13, 1926, pp. 351-353, 4 figs. Will allow tying stations inside and outside city by high-voltage circuits without usual number of costly intermediate transformations; will also increase cable capacity six-fold, reduce line drop and loss and incidentally improve power factor.

Insulation. Experiments on Cable Insulation, E. G. Gilson. Elec. World, vol. 87, no. 6, Feb. 6, 1926, pp. 297-298. Laboratory tests on insulating compounds used in high-tension paper-insulated cables show effect of temperature in forming voids; methods devised to neutralize temperature changes.

Telephone. The Technics of Long-Distance Telephone Cables, E. Zopf. Eng. Progress, vol. 7, no. 1, Jan. 1926, pp. 17-20, 13 figs. Latest progress and plants.

CANALS

Problems. The Problem of the Canals, J. Eaglesome. Inst. Transport—Jl., vol. 7, no. 1, Nov. 1925, pp. 38-48. Pre-canal period; suggested lines of development; rates and wages; use of waterways; future of canals.

CARS

Hot-Box Lubrication. A Good Record on Lubrication and Hot Boxes. Ry. & Locomotive Eng., vol. 39, no. 2, Feb. 1926, pp. 53. Large increase in car mileage and reduction in number of hot boxes on Delaware, Lackawanna & Western.

CAST IRON

Corrosion. Corrosion of Cast Irons in Sulphuric Acid of Varying Concentration (Etude comparée de la corrosion des fontes dans l'acide sulfurique à divers degrés de concentration), G. Delbart. Académie des Sciences—Comptes Rendus, vol. 181, no. 21, Nov. 23, 1925, pp. 786-788. Loss in weight of different kinds of cast iron in sulphuric acid has been determined, concentration varying from 1.6 to 92.6 per cent. total SO; phosphoric or impure cast irons are more rapidly attacked than pure or malleable cast irons, difference being greatest for dilute acids; cast irons are more rapidly attacked than cold-drawn steel in dilute acid, but in concentrated oleum results are comparable, and cast irons may even be better.

Grain Growth. Further Comments on the Growth of Cast Iron at High Temperatures Brown Boveri Rev., vol. 13, no 2, Feb. 1926, pp. 58-59, 1 fig. Results of latest chemical research on structure of different substances and its application to graphitic iron.

CASTING

Problems. Some Iron Foundry Problems, J. G. Pearce. Metal Industry (Lond.), vol. 28, no. 7, Feb. 12, 1926, pp. 160 and (discussion) 161. As effective way of showing value of research knowledge in explaining difficulties met with in everyday practice, author quotes number of practical examples dealing chiefly with structural constitution of faults concerned. (Abstract.) Paper read at Manchester Assn. of Engrs.

CASTINGS

Macrostructure. The Interpretation of the Macrostructure of Cast Metals, R. Genders. Inst. Metals—advance paper, no. 6, for mtg. Mar. 10-11, 1926, 21pp., 14 figs. Deals with influence of factors which need to be taken into consideration to bring interpretation of macrostructure of non-ferrous alloys into line with that of steel; in steel ingots, commonly known regular distribution of different types of macrostructure to be due largely to relatively low conductivity of metal and resulting low rate of solidification; ingot may be considered as having solidified from volume of liquid metal of uniform temperature; where thermal conductivity of cast alloy is high, solidification is rapid, occurring concurrently with pouring; macrostructure is also partly governed by physical characteristics of alloy.

Transverse Testing. A Home-made Transverse Testing Machine, Vallishe. Foundry Trade Jl., vol. 33, no. 495, Feb. 11, 1926, p. 109, 1 fig. Details of construction and how to use machine; points out that results of this transverse test should be invaluable to many foundries; by use of it satisfactory mixing for certain classes of castings may be determined.

CATALYSTS

Industrial Application of. Principles and Methods of Catalytic Investigation, H. S. Taylor. Can. Chem. & Metallurgy, vol. 10, no. 2, Feb. 1926, pp. 35-38. List of more important industrial catalytic reactions classified as to type of reaction and type of catalyst; form of catalyst and catalyst support materials; reactions at boundaries of phases and problem of promoter action.

CEMENT

Research. Progress Report of the Special Committee on Cement. Am. Soc. Civil Engrs.—Proc., vol. 52, no. 3, Mar. 1926, pp. 210-222, 1 fig. Recommendations of committee.

CEMENT MILLS

Electric Drive. Application of Electrical Equipment to Operations of a Cement Mill, R. H. Rogers and A. C. Turnbull. Can. Chem. & Metallurgy, vol. 10, no. 2, Feb. 1926, pp. 27-29, 6 figs. Discusses new plant of Natl. Cement Co. of Montreal; quarrying and crushing operations, grinding equipment, kiln operation, storage and reclaiming system, etc.

CENTRAL STATIONS

Australia. The Morwell-Yallourn Power Project. Power, vol. 63, no. 10, Mar. 9, 1926, pp. 373-374, 3 figs. New 62,500-kw. steam plant, located at Australian coal fields, burns brown coal running up to 60-per cent. moisture; chain-grate stokers, return arches and waste-heat driers are employed.

Chicago. Electric Power Development in the Chicago District, Wm. S. Monroe. Mech. Eng., vol. 48, no. 3, Mar. 1926, pp. 292-293. (Abstract.) Paper read before Midwest Power Conference, Chicago.

Toronto, Ont. Toronto Station Designed for Base Load, J. H. Wells. Elec. World, vol. 87, no. 7, Feb. 13, 1926, pp. 354-356, 4 figs. Boilers use pulverized fuel; house turbines operate with automatic heat balance; unit-type control for main generators and auxiliaries.

CHAIN DRIVE

Application. Application of Chain Drives. Power, vol. 63, no. 7, Feb. 16, 1926, pp. 258-259, 8 figs. Various types of link belts and silent chain drives and how they are used in power plant.

CHIMNEYS

Capacity. How to Figure the Capacity of Chimneys, J. G. Mingle. Power, vol. 63, nos. 7, 8 and 9, Feb. 16, 23 and Mar. 2, 1926, pp. 247-248, 288-289 and 332-333. Feb. 16: Fundamental draft equation. Feb. 23: Factors determining area or diameter of chimney. Mar. 2: How to calculate draft requirements and design of chimney of minimum cost.

Design. The Importance of Proper Chimney Design, J. G. Mingle. Combustion, vol. 14, no. 3, Mar. 1926, pp. 166-168. Factors influencing design; theory for economical determination of chimney size.

CITY PLANNING

Street Planning. Arterial Street Planning in Cities, E. S. Taylor. Roads & Streets, vol. 65, no. 3, Mar. 3, 1926, pp. 145-146. Experiences in Chicago. (Abstract.) Paper before Am. Road Bldrs. Assn.

CLAY

China. Developing China Clay Deposit in Ontario, H. S. Hancock, Jr., Eng. & Min. Jl.—Press, vol. 121, no. 11, Mar. 13, 1926, pp. 441-442, 1 fig. Deposit of china clay of unusual purity is being developed on east bank of Mattagami River.

CLUTCHES

Magnetic. Magnetic Clutches. Power Engr., vol. 21, no. 240, Mar. 1926, pp. 99-100, 2 figs. Principles of operation and application.

COAL

Ash Composition. Relation of Ash Composition to the Uses of Coal, A. C. Fieldner and W. A. Selvig. Am. Inst. Min. & Met. Engrs.—Trans., no. 1529-F, Feb. 1926, 13 pp. Nature and composition of coal ash; sulphur forms in coal and coke, iron forms in coal; gas and cooking coal; coal for steam purposes; pulverized coal; manufacture of water gas; domestic use.

Briquetting. Effect of Sulfur in the Briquetting of Sub-bituminous Coal, H. K. Benson, J. N. Borglin, and R. K. Rourke. Indus. & Eng. Chem., vol. 18, no. 2, Feb. 1926, pp. 116-117, 1 fig. Attempt was made in preliminary way to modify structure of Tono (Wash.) coal, so that its fuel values and its form and structure alike enhance its commercial use; results of tests and conclusion.

By-Product Processing. The By-Product Processing of Coal, H. W. Brooks. Mech. Eng., vol. 48, no. 3, Mar. 1926, pp. 233-239, 13 figs. Methods of by-product processing and converting coal into more valuable forms; carbonization of coal; complete gasification; high and low-temperature carbonization; typical low-temperature retorts.

Carbonization. Relation of Origin and State of Carbonization of Coal to Problems of Low-Temperature Carbonization, S. W. Parr. Am. Inst. Min. & Met. Engrs. —Trans., no. 1543-F, Feb. 1926, 6 pp., 2 figs. Types of coal; conditions of carbonization.

Distillation. Suggested Method of Estimating the Quantity of Heat Required for the Distillation of Coal, N. E. Rambush. Fuel, vol. 5, no. 1, Jan. 1926, pp. 12-16. By application of well-known physical laws it is possible to estimate heat required for distilling bituminous coal accurately enough for practical purposes; relation between liquor of decomposition, its temperature range of formation and internal heat of decomposition at such temperature does not yet seem to have been subject of reliable research; distillation heat required for certain coal depends principally upon design of apparatus and carbonization process used.

Spontaneous Combustion. Application of Gas Analysis to the Detection of Heatings, C. E. Morgan. Iron & Coal Trades Rev., vol. 112, no. 3022, Jan. 29, 1926, pp. 175-178, 2 figs.: also Colliery Guardian, vol. 131, nos. 3396 and 3397, Jan. 29 and Feb. 5, 1926, pp. 251-252 and 316-318, 2 figs.

Thermal Decomposition. The Initial Decomposition of Coal by Heat, M. J. Burgess and R. V. Wheeler. Fuel, vol. 5, no. 2, Feb. 1926, pp. 65-68, 1 fig. Experiments on thermal decomposition of Lancashire coking coal, showing that, whereas gases removed under vacuum up to 200 deg. cent. appeared to be occluded gases, character of gases evolved between 270 and 300 deg. pointed to their being products of decomposition of coal substance.

COAL HANDLING

EQUIPMENT. The Mechanical Handling of Coal, G. E. Titcomb. Black Diamond, vol. 76, no. 6, Feb. 6, 1926, pp. 140-141 and 147, 6 figs. Special types of equipment developed for different purposes; trend is toward larger units; economies effected by huge machines.

SYSTEM. The Installation of a Coal Handling Screening and Storing System at the Nassau Works of the Brooklyn Union Gas Co., L. S. Stiles. Bklyn. Engrs' Club—Proc., vol. 24, part 2, Jan. 1926, pp. 31-53, 19 figs. Brings out engineering features; operation of plant; construction details.

COAL INDUSTRY

BITUMINOUS. Report of Coal and Coke Committee. Am. Inst. Min. & Met. Engrs.—Trans., no. 1540-F, Feb. 1926, 16 pp., 11 figs. Capacity and over-development; growth of items of costs; fuel for railroads; past and future fuel production in United States.

COAL MINES

WASTE TREATMENT. Colliery Waste and Its Treatment, S. H. North. Colliery Eng., vol. 3, no. 24, Feb. 1926, pp. 87-89. An examination of existing conditions and possible methods of improvement.

DIRT DISPOSAL. A method of Mine Dirt Disposal, G. E. Stewart. Colliery Eng., vol. 3, no. 24, Feb. 1926, pp. 65-67, 3 figs. System developed by author in which simple cantilever, suitably braced, is substituted for elaborate built-up headgear.

SUBSIDENCE. Report of Subcommittee on Coal Mining to Committee on Ground Movement and Subsidence. Am. Inst. Min. & Met. Engrs.—Trans., no. 1546-F, Feb. 1926, 65 pp., 33 figs. Considers effects of subsidence under following heads: (1) those due to squeezes, or subsidence where pillars have not been withdrawn; (2) those in upper seams, due to mining seams beneath them; (3) those due to mining by room and pillar system; (4) those due to mining by longwall system.

COAL STORAGE

BITUMINOUS COAL. Design of Stores for Bituminous Coals, G. Gardiner. Gas Jl., vol. 173, no. 3273, Feb. 3, 1926, pp. 283-288, 8 figs. Considers proper method of storing coal, and describes design for ideal coal storage plant. Paper read before Junior Gas Assn. See also Gas World, vol. 84, no. 2168, Feb. 6, 1926, pp. 121-125, 3 figs.

COILS

WINDING. Some Mechanical Principles in Coil Winding. Machy. (Lond.), vol. 27, no. 694, Jan. 14, 1926, pp. 502-508, 11 figs. Their application for small coils for electrical and wireless purposes.

COLUMNS

BATTEN-PLATE. Batten-Plate Columns: Their Status and a Design Theory, R. Fleming and W. H. Weiskopf. Eng. News-Rec., vol. 96, no. 10, Mar. 11, 1926, pp. 412-414, 9 figs. American and European attitudes; faults in tests of Am. Ry. Eng. Assn.; proposed method of calculation.

STEEL. Progress Report of the Special Committee on Steel Column Research. Am. Soc. Civ. Engrs.—Proc., vol. 52, no. 3, Mar. 1926, pp. 146-209, 17 figs. Relation of strength of relatively short columns to elastic properties of metal; tabular data on relation of strength of short columns to yield point of metal; mill and laboratory tests for elastic limit; comparison of tensile and compressive useful limit points; results of tests on columns of all lengths and showing integral action; effect of various details of strength of columns.

COMBUSTION

CONTROL. Automatic Combustion Control, H. W. Hollands. Eng. & Boiler House Rev., vol. 39, no. 8, Feb. 1926, pp. 375-376. Discusses problems of control. (Abstract.) Paper read before Elec. Power Eng.'s Assn.

CONCRETE

CURING. Studies of Curing Concrete in a Semi-Arid Climate, C. L. McKesson. Eng. News-Rec., vol. 96, no. 11, Mar. 18, 1926, pp. 452-453, 2 figs. Use of substitutes for water curing justified where no water can be had; seven days' water curing sufficient.

FROZEN. How to prevent and to Restore Frozen Concrete, A. M. Bouillon. Eng. News-Rec., vol. 96, no. 10, Mar. 11, 1926, pp. 408-410, 2 figs. Effect of frost upon freshly made concrete with suggestions on how to discover and restore frozen concrete.

CONDUITS

WATER-SUPPLY. The Queen Mary Reservoir Conduit. Engineer, vol. 141, nos. 3657 and 3658, Jan. 29 and Feb. 5, 1926, pp. 131-133 and 142-145, 19 figs. Details of aqueduct or conduit which is to convey water from reservoir to various works of Metropolitan Water Board, where it will be treated before being distributed; arrangement of gage basin; method of constructing conduit; method employed for excavating trench and putting in conduit.

CONTRACTING

CONTRACTING. Standard Construction Contracts. Am. Soc. Civil Engrs.—Proc., vol. 52, no. 3, Mar. 1926, pp. 225-241. Standard agreement for engineering construction; standard general conditions.

CONVERTERS

ROTARY. A Rotary Converter Experience, J. Simpson-Tyler. Power Engr., vol. 21, no. 240, Mar. 1926, pp. 105-106. Discussion, in simple terms, of steps taken to improve operation of unstable machine.

SYNCHRONOUS, VS. MOTOR GENERATORS. Synchronous Converters Versus Motor Generators, C. O. Mills. Power, vol. 63, no. 10, Mar. 9, 1926, p. 364. Studies question of which is more economical to use for converting alternating into direct current for industrial loads.

CONVEYORS

FACTORY. Controlling Production Mechanically, Wm. F. Bailey. Factory, vol. 36, no. 2, Feb. 1926, pp. 262-265, 340, 342, 344, 346, 348 and 350, 14 figs. Details of conveyor system designed and laid out at plant of Hoover Co., North Canton, O., to permit accurately timed dispatch of stock from central stores and control department to machine and assembly operations, handling of active stock in course of manufacture with minimum amount of physical labor, cutting down number of inspectors required, use of ceilings as trucking aisles, eliminating 75 per cent. of trucks, etc.

MACHINE-HOUR RATE SYSTEM. New Cost Basis for Material Handling, F. E. Moore, Mfg. Industries, vol. 11, no 3, Mar. 1926, pp. 169-170, 4 figs. Modified form of machine-hour rate system applied to conveyors.

COOLING TOWERS

DESIGN. Design of Cooling Towers (Considerations générales sur les tours réfrigeration: éléments de calcul et essais), J. Vassiliere-Arlhac. Revue Générale de l'Electricité, vol. 19, no. 1, Jan. 2, 1926, pp. 22-29, 9 figs. Presents theoretical examination of problem of cooling towers, which leads to graphical and mathematical method of dimensioning such towers for given amount of water and desired temperature gradient; an actual example reduces writer's formulas to concrete facts; recommends employment of electrical remotely indicating thermometers as means to gain permanent control of power performance of these towers.

COPPER
