Power Transformers

Development of Power Transformers with some Modern Features and Applications

C. E. Sisson, M.E.I.C.

Transformer Engineer, Canadian General Electric Company, Limited, Toronto, Ont.

Paper read before the Montreal Branch, The Engineering Institute of Canada, April 23rd, 1925.

In presenting a paper on Power Transformers it has occurred to me that it might be sufficiently interesting to justify our starting with the first transformers and rather hurriedly follow their development or evolution up to the present time before calling attention to some of the more important modern features and applications of this type of electrical apparatus.

Early Use of Electricity

The first practical use of electricity was that of the battery used in telegraphy. Volta produced the battery in 1800 although it was not put to practical use until about forty years later. In 1830 Faraday in Europe and Hendry in America discovered the principle of electro magnetic induction which gave rise to the dynamo and later the transformer. Generators were at first built as direct current units and used principally for series arc lighting, under the Brush, Thompson-Houston, Wood and other systems. This system was, of course, only applicable for street lighting due to the high voltage which had to be employed. Efforts were made to find a different type of lamp from the arc and Edison succeeded in producing his incandescent lamp in 1879. In 1882 he started in New York the first central station in existence in which he used the parallel direct current system.

As the system grew and the demand for electric light increased the amount of copper necessary to carry the current became excessive and so the scheme became somewhat limited in its application. Its scope was, however, greatly extended by the development and adoption of the three wire system.

Series Transformer System Introduced

Alternating current generators had been built but only for low voltage, and were used on the multiple system of lighting. Those interested in the work were, therefore, confronted with the limitation of the multiple system due to the restricted area it could cover on the one hand, and the danger in using the series system due to high voltage on the other. About 1884 Mr. Goulard, a French engineer, invented a system among the component parts of which was what he termed "secondary re-generators" and what we to-day would call series transformers. The distributing line was carried through the area to be supplied and when a service was to be provided a "secondary re-generator" was installed, usually indoors, the primary of which was connected in series with the line and the secondary carried through the house or shop to be supplied. Each transformer had to be built to suit the demands of the service, the turns on the primary being varied with the amount of current to be taken off, while, of course, the voltage varied with the current used.

This scheme was introduced into England and America about the same time, the transformers used in America being first imported from Europe. Of course, this system was subject to a number of objections and handicaps, among them being the fact that it required a high voltage and the necessity for a constant current in the line. The high voltage was objectionable due to the lack of familiarity with the problems of insulation while the constant current had to be maintained by hand control. There was also the difficulty that if one transformer burned out the whole system was put out of commission.

Parallel Transformer System

About this time Mr. William Stanley became associated with Mr. George Westinghouse and was assigned the problem of studying the improvement of electric lighting. He first devoted his energies towards develop-

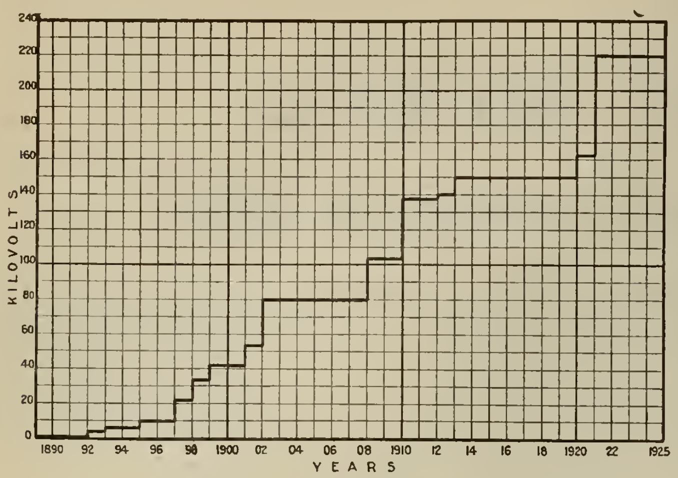

Figure No. 1.—Maximum Transmission Potentials Growth Since 1888.

ing the self-regulating feature of the generators but later concentrated his efforts on and finally produced the parallel or constant voltage transformer such as is employed to-day. The scheme which was proposed was to connect a transformer across the two wires of the system so that if the transformer got into difficulty it would not interfere with the successful operation of its neighbours. By many this was regarded as impracticable as it was feared that such a connection would short circuit the system or that the leakage or exciting current would prove too great a waste to permit of anything like a reasonable efficiency.

However, Mr. Stanley had discovered during his experimenting that coils with an alternating current flowing in them developed a counter e.m.f., and had in fact suggested the use of coils to replace lamps in the multiple series low voltage systems that had been employed to some extent. He spent the winter of 1885-1886 working on this multiple transformer and by the spring of 1886 had it in operation on the first multiple alternating current system using transformers in the world. This installation was at Great Barrington, Mass., and was the beginning of what has been a very rapid development in the transmission and distribution of electricity.

The original Stanley transformer is now in the possession of the American Institute of Electrical Engineers in New York City. This transformer had a voltage ratio of 500:100, was built for a frequency of 133 cycles and was of the natural air cooled type.

An Early European Installation

Higher voltages were employed in Europe earlier than in America, a great deal of the pioneer work in England being done by Dr. Ferranti. In about 1889 there were installed, in a station about six miles from London, generators wound for 10,000 volts and transformers for "stepping down" from this voltage at the London end of the line. A group of 10,000—2500 volt transformers were installed in London in 1891, and were still in service in 1921, although no doubt they had received some repairs in the meantime. These units were natural draft cooled as were all Transformers built even for some time afterwards.

Air Blast Transformers Used

However, with the development of larger generators the capacity of transformers had to be increased and the necessity for artificial cooling was soon experienced. The forced draft apparatus or air blast type was the next step in the development, this artificial cooling permitting greater electrical capacity to be taken from the same size of unit and thereby decreasing the cost of manufacture and improving the efficiency.

Oil Insulating and Cooling

With the increase in voltage, however, the necessity for other than dry insulation arose and it was not long before the use of oil in connection with transformers was adopted, the value of same as an insulating and cooling medium commending it against prejudices of those who had visions of the destruction of whole plants due to the inflammability of the oil.

Water-Cooled Units Adopted

As the losses in the core and coils of a transformer vary as the cube of the dimensions and as the radiating surface of these parts, as well as of the tank, vary as the square of the dimensions, soon the problem of providing sufficient surface to transfer the heat gathered by the oil to the surrounding air became difficult and expensive, so that artificial means of cooling the oil immersed apparatus was required and was developed in the water-cooled transformer in which water was circulated through pipes immersed in the oil, or in the forced oil cooling in which the oil was carried away from the transformer to a cooling medium such as water and returned to the transformer in a closed system.

Increase in Voltage

The increase in capacity and voltage of transformers has, of course, been necessitated by the increase in length of transmission systems and the development of larger generating stations located at strategic points, often quite remote from the point or points at which it is desirable to use the energy. A curve is shown in figure No. 1, giving the increase in potential for which transformers have been built.

It is somewhat interesting to note that this increase has been fairly gradual and as the demand for electric energy increases and the necessity of developing water powers more remote from their centres of population arises, transmission at voltages of 220,000 and over will quite likely be employed much more than was dreamed of but a few years ago. If you extend the curve shown in figure No. 1 say to 1935, it will be noted that you

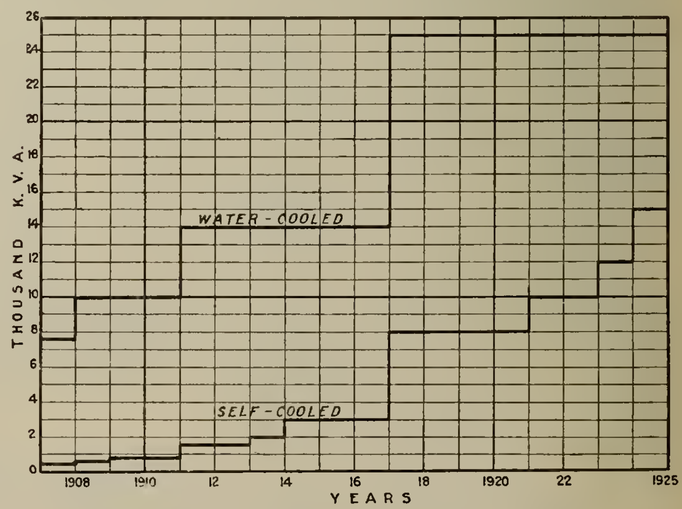

Figure No. 2.—Growth of Transformer Units.

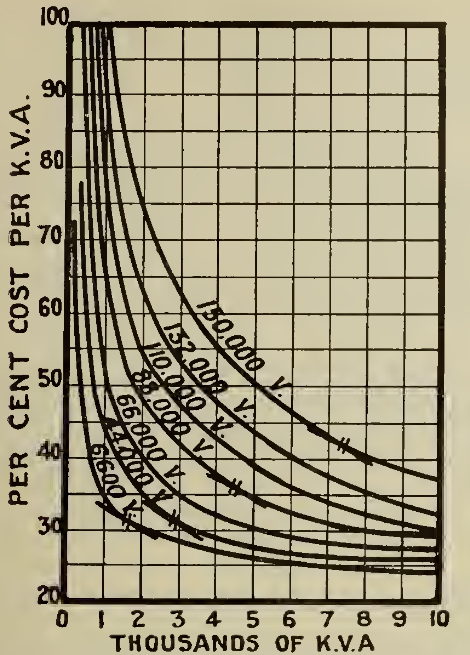

Figure No. 3.—Relative Costs per kv.a. of Transformers of Various Voltages.

obtain a voltage of approximately 300,000 volts, which is quite within the realm of possibility; although, if we are to follow what seems to be an established practice of using voltages which are a multiple of eleven, the next step will probably be 330,000 volts.

Growth in Capacity

It is equally interesting to note the increase in capacity of transformers built. In 1887 a 9-kv.a., transformer was built having a voltage of 1,000, and was used on a transmission line of about one-half mile. In 1890 an effort was made in America to transmit a few kilowatts several miles. In 1892, the largest transformer which had been built in America was a 30-kv.a., which had a voltage of 5,000. Figure No. 2 shows the growth of transformers since 1906, and up to the present time, on this continent. It will here be noted that there is a fairly continuous increase in capacity and if we project this curve we soon come to a rating of 40,000 or 50,000 kv.a., which is quite probable, and in fact quite essential if we are to employ high voltages and wish to keep the efficiencies of a transformer bank up and the cost down.

As the cost per kilovolt-ampere of high voltage transformers increases with the voltage but decreases within reasonable limits with the capacity, and as the efficiency increases with the capacity, the natural tendency will be toward larger units.

Relation Between Capacity, Cost, Voltage and Efficiency

It may be interesting to here reproduce a couple of curves showing how the cost and efficiency of transformers vary with the voltage and capacity. Figure No. 3 gives the relative cost per kilovolt-ampere of different sizes with different voltages. These curves were plotted for self-cooled transformers but are equally representative of water-cooled units. The point on the curves where there is a rapid upward turn indicates the capacity below which it is uneconomical to go.

Thus we see that the smallest 66,000-volt transformer that should be adopted in order to avoid undue costs is approximately 3,500 kv.a. At 110,000 volts, this point is found to be 5,000 to 6,000 kv.a., while at 150,000 volts the smallest economical size is about 7,500 kv.a. Although not included in the curve the smallest 220,000-volt unit that will keep below the point where the cost per kilovolt-ampere increases rapidly is about 10,000 kv.a. It is, of course, quite appreciated that it is not always possible to keep above these economical points indicated but in many cases if a small quantity of power is to be taken from a high voltage system it will be found more economical to use a small unit on a second transformation rather than to build it with a higher voltage.

The advantage of higher efficiency is also of extreme importance in determining the size of transfoimer to be installed as will be appreciated from figure No. 4. This gives the efficiencies of a number of sizes of 110,000-volt transformers demonstrating the decided advantage in the larger units.

Comparison Between Water- and Self-Cooled

The relative development of water- and self-cooled transformers within the last few years, as built by one American manufacturer, is shown in figure No. 2. It will be noted that while the self-cooled unit is of smaller capacity, the rate of growth of this type has been very marked due to certain advantages inherent in this design. There are a number of factors which will affect the decision as to whether self- or water-cooled transformers should be installed. For instance the water-cooled will in general be cheaper as to first cost, as will be seen from figure No. 5, which gives the cost of water-cooled units compared with self-cooled. This curve must be regarded as merely showing the trend in costs and should not be used for any specific combination of frequencies, voltages, etc. As the size increases, the advantage of the artificial cooling becomes more pronounced.

However, the cost of water, and in some cases pumps to supply it, must also be taken into the calculation as well as the supervision of the artificial cooling if the amount of water used is to be kept as low as possible. It might be well to call attention to this curve at the smaller capacity end. It will be noted that there is very little difference in the cost between self- and water-cooled transformers at about 400 kv.a., and when the cost of water, piping, etc., is taken into

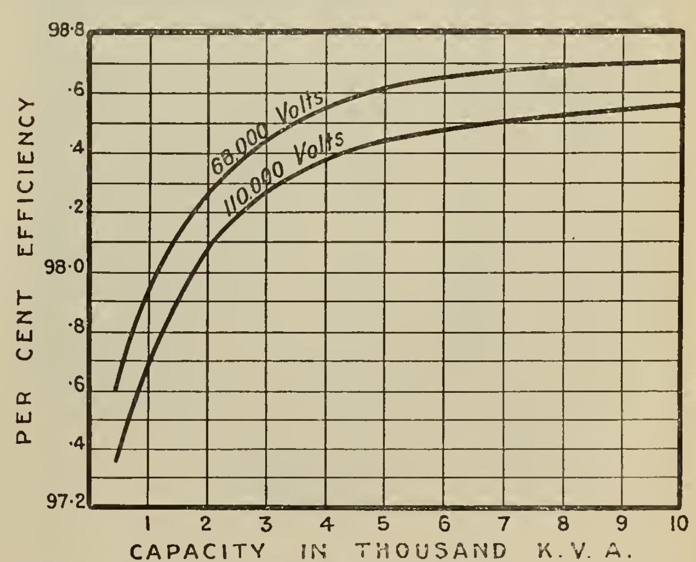

Figure No. 4.—Efficiencies of 66,000 - and 110,000-volt Transformers of Various Capacities.

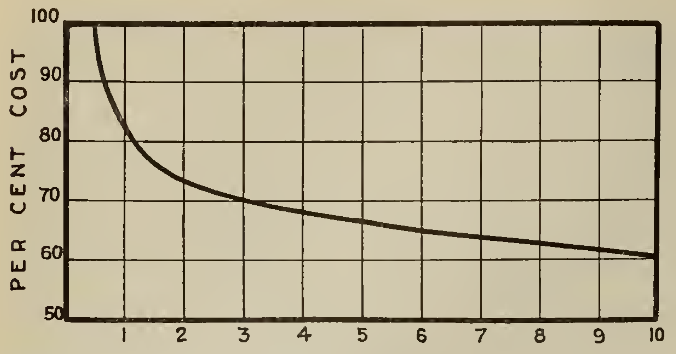

Figure No. 5.—Water-Cooled Transformer Cost in Percent of Self-Cooled Transformer Cost.

consideration the self-cooled unit has the advantage at these small sizes. The self-cooled unit is practically self-contained and will operate with but little attention and may be placed in an unattended station or sub-station, where it will receive only occasional oil test and general inspection. It is, of course, better suited for automatic stations where the problem of water supply may be forgotten.

The heat generated in the so-called self-cooled transformer is carried off by the natural means of convection and radiation into surrounding air. Means must be provided for exchanging this air sufficiently often to insure against its becoming unduly heated. If the transformer is located in a room or building, means must be provided to exhaust and supply air through ventilating openings or through doors and windows, otherwise the air must be cooled by coming in contact with the walls. Neglecting to provide the proper cooling of indoor air may lead to greatly shortening the life of the apparatus due to overheating of the insulation or the sludging of the oil.

Ventilating Self-Cooled Indoor Installations

The volume of air necessary may be determined from the specific heat of air at the temperature agreed upon. At 40° C. (the standard ambient temperature adopted by the A.I.E.E.), the specific heat of air is approximately .0088 watt hours per cubic foot per degree centigrade; so that for each kilowatt loss there are required 1,900 cubic feet of air per minute per degree centigrade rise. A 5° rise of room temperature over the incoming air is usually selected as a practical limit and by using the equation covering the theoretical velocity of a column of heated air, we find that, for rooms with heights varying from 10 to 35 feet, we require an opening area varying from 1.96 to 1.05 square foot per kilowatt loss.

If the room or vault is made only large enough to accommodate the transformer some allowance for friction should be made before using these figures and in order to play safe it might be well to double them. On the other hand, if the room is large in proportion to the transformers there will be considerable heat storage available to carry the apparatus over periods of peak load, while at the same time the larger the room the larger will be the cooling effect of the walls, doors and windows. In general, with the average type of building and the usual load cycle, it would probably be found sufficient to allow 1.5 square foot for each of inlets and outlets per kilowatt loss at full load. In arranging openings, the inlets should be near the floor level so as to bring the cool air to the bottom of the transformer and the outlets as high above the apparatus as the construction of the building will permit in order to increase the height of the air column.

It will be noted, however, with a bank of three 5,000-kv.a. transformers having an efficiency of 98.5, installed indoors with a roof 30 feet above the floor, the theoretical area of the air inlets and outlets to carry full load losses at 5° C. will be 250 square feet. If full load is to be carried for considerable period at least double this amount should actually be provided or say ten openings, each 7 feet square, at the floor and the same at or in the roof.

Outdoor Self-Cooled Units

These figures show that the proper place for a large self-cooled transformer is outdoors where the restrictions in the flow of air may in general be forgotten. As an alternative it may be found advantageous to provide artificial draft for the transformer chamber, when the transformer can no longer be termed self-cooled.

Two types of large self-cooled transformer tanks have become of general use, one consisting of external

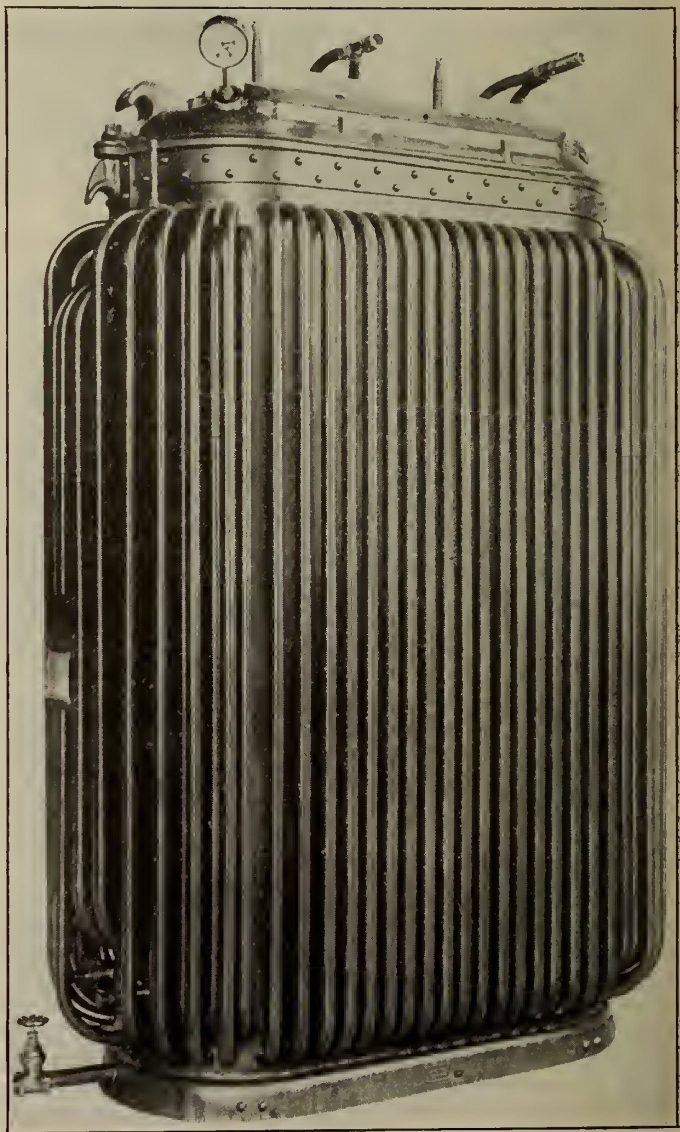

Figure No. 6.—1,000-kv.a. Single-phase Core Type Transformer with Combination Water- and Self-Cooled Radiator Tubes.

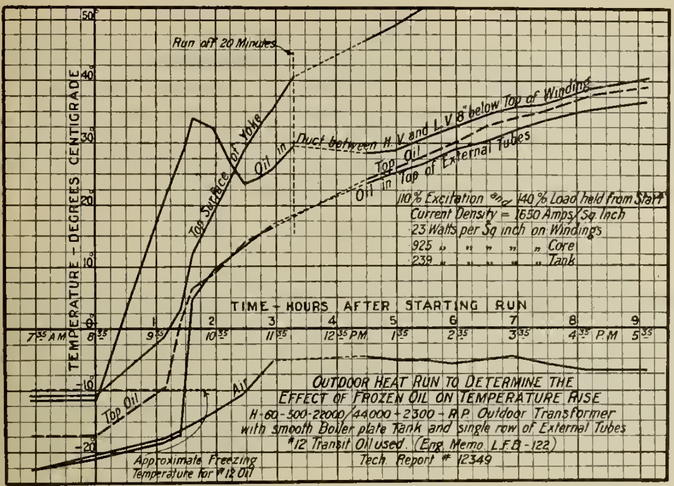

Figure No. 7.—Outdoor Heat Run to Determine the Effect of Frozen Oil on Temparature Rise.

tubes connected to the tank at the top and bottom as shown in figure No. 6, the other having its necessary surface provided by the addition of pressed steel radiators as shown in figure No. 8.

The practice of installing a transformer indoors but locating the cooling radiators outdoors has been used in a number of instances. The radiators are arranged in a double bank mounted on two large manifolds connected to the top and bottom of the tank. The whole is mounted on a truck which permits the assembled parts to be moved as a unit. Another installation recently described in the *Electrical World* has the radiators placed on the roof of the station and the transformer piped to same through an expansion tank.

Some doubt has existed in the minds of many as to the effect that extremely cold weather might have on the oil in transformers with the external cooling features. An experiment was made with a 500-kv.a., unit which had been exposed to a temperature of approximately 20° C. below zero for some time and was then loaded by applying 110 per cent voltage and 140 per cent load. Figure No. 7 shows a summary of the results obtained. It will be noted that the oil between coils, where we might expect the highest temperatures, kept well within a safe limit. No extreme temperatures were found and the transformer soon went merrily on its way with the oil circulating freely.

Outdoor Water-Cooled Units

Of recent years, due to the increase in the size of all units and the attending cost of housing same, the practice of installing water-cooled units outdoors has been finding increasing favour. This was at first considered an unwarranted risk in our climate on account of the anticipated danger from the freezing of the water used for cooling. However, there are a number of outdoor water-cooled stations in Canada which have passed through the last winter without any trouble having been experienced with the water. One of these is on the New Brunswick Hydro-Electric Power Commission's system, a number are in Toronto and western Ontario and two in northern Ontario on the system of the Hydro-Electric Power Commission of Ontario. The ones in northern Ontario are located near Port Arthur and have been subjected to the extreme weather conditions experienced in that vicinity. In the case of the installations in Toronto and western Ontario the only precaution taken to protect the water piping was to lag them heavily with sheet cork. However, it was considered advisable to adopt more elaborate precautions in the case of the Port Arthur units. These transformers were equipped with a housing over the cooling water piping, the cold water feed pipes receiving a certain amount of heat from the warmer water in the discharge pipes. It was also deemed advisable to locate a small heater at the lower end of this housing.

The water piping for all these units enters the transformer on the side of the tank. It would be much more simple and convenient to have the pipe carried through a tunnel or passage to a point beneath the transformer and have them enter the transformer tank through the bottom. There will be a certain amount of natural heat in the tunnel and if necessary a small heater sufficient to insure against trouble could readily be added.

Forced Oil-Cooled Systems

A means of cooling which has been in use in Europe perhaps more than in America is the so-called forced oil-cooled system, which has been used in place of the water-cooled system having the cooling coils within the transformer, and has been regarded with considerable favour for outdoor installations. The insulating and cooling oil is carried from the transformer to a cooler which may be placed at any convenient distance or location where the water will be protected against excessive cold. The cooler may either consist of a series of pipes in the tail race of the power station or an enclosed device where the oil is brought in fairly close contact with cooling water.

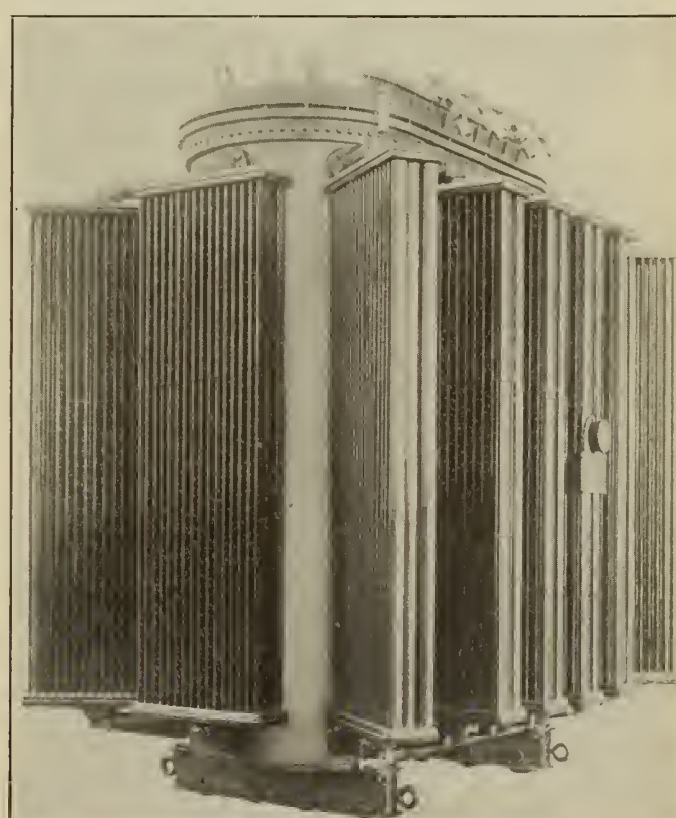

Figure No. 8.—5,000-kv.a. 25-Cycle Combination Self- and Water-Cooled Transformer with Radiators.

These artificial coolers can be conveniently located in the basement of the station or at some place where they are out of the way and at the same time insured against danger from freezing. This type of transformer will be slightly more expensive than the so-called water-cooled unit. It is possible that as the size of transformers built increases this forced oil cooling system may be more generally adopted, the oil circulating system permitting of the permanent installation of oil purifying equipment.

Combination Water- and Self-Cooled Transformers

A combination of water- and self-cooled transformer has been used to advantage in many instances and should, we believe, be found to recommend itself in many installations, particularly in many parts of Canada where we encounter a fairly cold climate during certain parts of the year. Figure No. 8 shows a 5,000-kv.a., transformer conservatively built for 35° rise at a normal load as a water-cooled unit and which will carry a substantial overload without undue heating and will also carry full load as a self-cooled unit with a rise not exceeding 55° C., which with an ambient temperature such as is experienced at the point of installation still keeps the ultimate temperature down to conservative point determined on by the operating company. This construction also permits of the apparatus carrying a fair percentage of its normal load even with a high ambient temperature and should work to advantage should there be considerable variation in the load demanded. With this construction, therefore, we are in a position either to secure some compensation for the extreme climate in which we have chosen to live or some economy in the use of water in case of the load demand dropping off periodically.

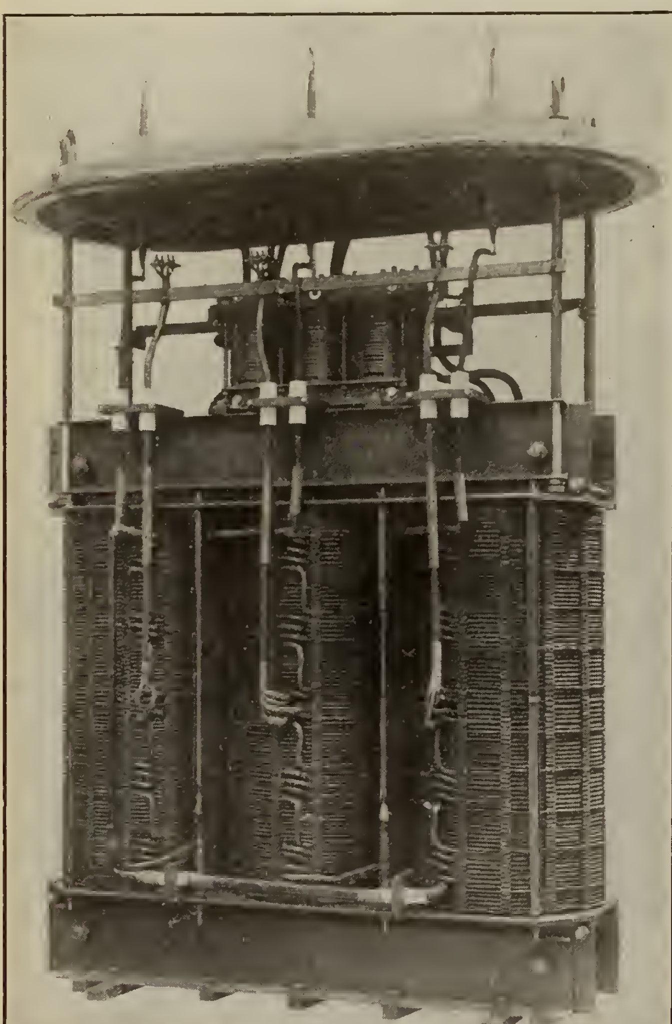

Figure No. 9.—5,000-kv.a. 25-Cycle Transformer with Interleaved Disc Core and Coils.

Smaller Sizes Require Careful Designing

We have allowed ourselves to be lead into a discussion of the different methods of cooling and their relation to the location or type of installation. However, we naturally find ourselves interested in the development of the size and voltage of this type of equipment, and consequently the questions of the means of cooling and where we are going to locate the equipment force themselves upon us.

On the other hand the improvement of the smaller sizes of transformers must not be overlooked if we are to better the efficiency, reliability and economy of our systems as a whole. In fact some of these features force themselves before our attention, as for instance, as the capacity of our systems increases the amount of power behind a small transformer becomes in comparison practically unlimited, and designs must be such that short circuits on the line or other extremely heavy sudden demands of power will not give rise to such severe mechanical strains as to distort the windings.

These forces should be so distributed and the several parts of the apparatus so supported as to resist any tendency to move. It is only of recent years that the magnitude of these forces had been fully appreciated and designing engineers familiarized themselves with same in order to be able to calculate accordingly. Thus the transformer designer must be a better mechanical engineer than was the case earlier in the art. Figure No. 9 shows a three-phase unit having its windings thoroughly supported by rows of insulating spacers and rigidly braced by means of substantial steel members.

Alloy Steel

The vital parts or features of a transformer are the core, the windings, the insulation and the means of cooling. The discovery of alloy steel for the magnetic circuit has been one of the greatest contributions made to the economic and efficient development of transformers. Steel is now produced which has a loss per pound of one-half of what was obtained with the advent of silicon steel and infinitely better than what the first manufacturers were compelled to use. Some interesting discoveries of other iron alloys have recently been made and we are hopeful of laying hold of something permanent and practical in this line ere long. The use of silicon or other elements in steel has a tendency to render it hard and somewhat brittle. While mechanical work upon it, of any sort, has the same effect. It is, therefore, desirable that the laminations of the core should be carefully annealed to remove all strains after all mechanical work such as shearing, piercing, etc., has been completed. Silicon steel of the better grade now employed is practically non-aging.

Winding

Copper is, of course, the universal metal used in the winding of almost all electrical apparatus. We have come to regard the conductivity of copper as a fixed and unalterable characteristic. However, we know that the addition of an extremely small percentage of certain substances will reduce its electrical conductivity very materially so great care is required to keep the copper pure. Improved methods of annealing copper have been developed and we trust more reliable means of rolling and drawing it so as to insure against those fatal enemies burrs, splinters, etc., for which it is now found necessary to inspect before the conductor is covered with its insulation, may be found.

Insulation

Transformers are essentially insulation apparatus and the development of insulating materials and the proper application of them has been vital to the possibility of producing transformers to meet the ever increasing demand for higher voltages. Characteristics of insulation and the most advantageous method of applying the same present a very wide and promising field for careful investigation.

It is rather interesting to note that the first insulation employed in the construction of transformers was paper, and by a more or less curious cycle the manufacturers of the highest voltage transformers to-day employ paper to a very large extent although it now receives very carefully thought out treatments to improve its dielectric qualities. In the early days, especially when air cooled transformers were employed to a great extent and even after the introduction of oil, it was the practice to wrap the coils with a number of wrappings of some textile material and fill the same with an insulating varnish or other compound applied by brushing. This had the evil effect of blanketing the windings unduly and in the case of the oil insulated units it interfered with the proper dissipation of heat by means of the oil.

Every effort is now made to insure that the oil which serves the dual purpose of an insulator and cooling medium, comes as close to all parts of the winding as possible. The winding should, therefore, be thoroughly broken up and positive access of the oil to all parts of the coils insured. This is equally important from a point of view affecting the condition of the oil as well. Improvements have been made in the quality of the insulating oil offered to the trade but it has not been possible to produce an oil which will not sludge to some extent. This objectionable feature can be remedied to a large extent but only at considerable cost. Care should therefore be taken to insure that not only the windings but also the cores, especially those of greater size, are carefully opened up to insure against excessive temperatures at any points. Figure No. 9 shows a modern transformer in which a thorough ventilating of the parts is insured.

Oxidation of Oil

In selecting an insulating oil probably the characteristics that should receive first consideration are its tendency to oxidize or sludge. Almost any oil can be brought to a high dielectric strength by cleaning and drying, while a safe fire point and degree of viscosity is not so difficult to obtain, but it is expensive to produce an oil that will not sludge readily.

Conservator Tanks

The most effective method of preventing the oxidation of oils is to keep oxygen away from the oil particularly when warm. This is effected by means of the use of a conservator which forms an expansion chamber in which the oil is comparatively cool and has a comparatively small surface exposed to the air. This is connected to the highest point of the transformer cover by means of a pipe not too large in diameter to permit too free a flow of warm oil into the conservator tank. The connecting pipe enters the conservator tank a short distance above the bottom of the tank. This expansion chamber should have sufficient capacity to take care of the expansion of the oil in the main transformer due to variation in its temperature as affected by changing loads. The transformer tank proper is completely filled with oil. The oil in the conservator being comparatively cool is very much less subject to oxidation than the warm oil in the transformer and should any slight oxidation take place the sludge will collect in the conservator tank.

This filling of the transformer tank proper has the additional advantage of insuring against the development of excessive pressures due to an explosion of arc gases and air. The mixture of oil vapours and air is not explosive in the usual sense, but an arc beneath the oil may evolve such gases as hydrogen, carbon monoxide and methane which are fairly readily explosive when mixed with air in the proper proportion and under the proper conditions. The proper conditions require a temperature of about 550° C. in the air space, which will never be found under normal conditions but may arise by the failure in a transformer, especially if exposed arcs are produced. The complete elimination of the transformer "air space" therefore reduces the contact between air and oil, decreases sludging and very materially reduces pressure hazard.

Pressure Relief Vents

However, a pressure may be generated in the transformer tank by the development of a fault in the apparatus which evolves gases so quickly that relief cannot be obtained through the comparatively small pipe leading to the conservator. Such a pressure may reach a magnitude sufficient to do mechanical damage to the tank or cover. To insure against this a pressure relief vent is provided such that a sudden rise in the internal pressure will shatter a diaphragm placed across the pipe sufficiently high above the cover as to prevent the outpouring of the oil due to the head in the conservator.

When these relief vents were first adopted diaphragms were made of metal which when pressure was created were dished outward and had their strength very materially increased due to their shape, preventing release of the pressure and in one or two cases causing damage to the tank. A fragile material is now employed and since its adoption the writer has no record of this relief vent not functioning in a way that protected the tank.

Inert Gas Cushion and High Pressure Tanks

Another method recently developed is to fill the upper part of the tank with an inert gas which does not provide an explosive mixture with air and which affords a cushion effect against increased pressure. This arrangement requires a device for admitting an inert gas at low pressure from a higher pressure supply or a means of deoxidizing the air as it passes into the tank through a chamber provided with a special material having this deoxidizing ability.

Some operating companies in wishing to make assurance still more sure in addition to the conservator and pressure relief vent use a tank and cover designed to withstand a hydrostatic pressure of from 25 to 150 pounds per square inch. Figure No. 10 shows such a transformer. Its tank was tested with a pressure of 150 pounds per square inch.

Changing Ratio of Transformers

Taps in transformer windings are always a source of weakness and danger. However, they are evils which appears to be necessary and everyone has past from the stage of enduring to that of embracing them. Among the many serious objections to taps was the inconvenience and danger in changing tap connections when necessary.

The first and most simple method of changing ratio was to bring the various leads outside the transformer case and use any pair which gave the desired ratio. These taps were necessarily located at the ends of the winding.

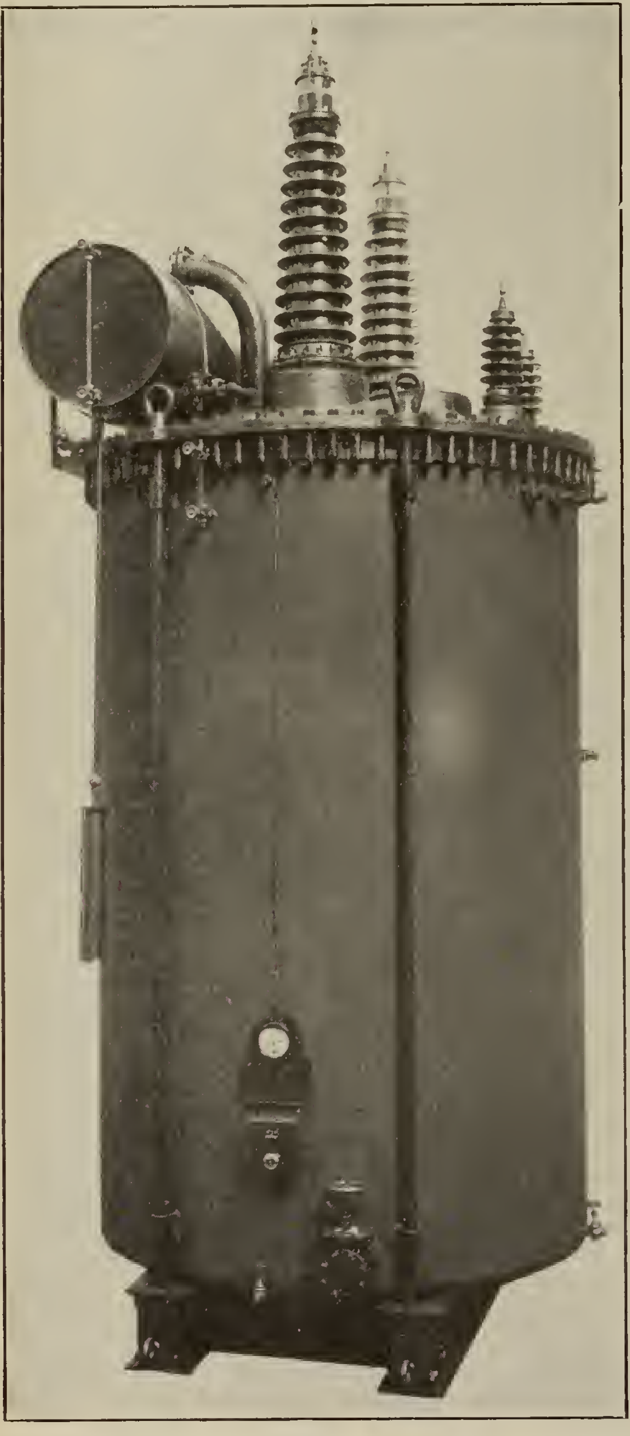

Figure No. 10.—High Voltage Water-Cooled Transformer in Round Steel Tank and with Conservator.

The next step was to use a connection board inside of the tank to which all the leads and taps were brought. Only the line leads were brought through the cover and they could be connected to any desired terminal on the connection board. It was later found necessary to put the connection board under oil due to the increase in voltage. It was soon found to be desirable to locate the tap leads near the centre of the winding in order not to interfere with the heavier insulation placed on the ends turns. The taps were then brought through a multi-conductor lead to the top of the transformer so as to be conveniently reached through the handhole in the cover.

To make the change in the ratio necessitated removing the handhole cover and either lowering the oil or working in what was sometimes found to be uncomfortably hot oil. It was felt that a device for changing the connections more quickly and more comfortably would justify itself and in response to this demand a device called a ratio adjuster was produced. It was first employed on small units but has been more recently developed so as to take care of practically all voltages and currents capacities.

The operating handle of this device was first placed just inside of the cover but the next natural step in the development was to bring the operating handle out through the cover so that the change could be made in a very short time. This arrangement has been provided on a number of outdoor transformers as well as on those for indoor service.

In the case of very large units it was considered unduly awkward to climb to the top of the transformer in order to make adjustment and an operating mechanism consisting of a hand wheel, operating shaft and the proper gears has been employed. Thus the connections can be made from the floor.

In selecting this tap changing device due consideration should be given to the positiveness of operation of the mechanism. This is best insured by having the device self-contained so far as the actual connections are concerned and the movement from one point to another positive. The carrying capacity of the apparatus should be sufficient to take care of short circuit currents and should also be built to withstand practically full line voltage between points.

Changing Taps on Loaded Transformers

Up to this time, the question of changing taps only when the apparatus was not under load has been considered. A demand has existed for some time for a device which would change the ratio when the transformers were loaded. The first attempt to meet this demand was an arrangement in which all taps were brought out of the tank to a quick brake dial switch arranged with reactance which would limit any arcing between contacts. However, this contrivance was limited to a very small capacity and therefore did not meet the general demand.

In order to take care of the larger capacities, transformers were designed connected delta-delta and provided with taps on the ends of the windings. By means of switches outside the transformer one corner of the delta could be opened and closed again upon the tap desired, the load being carried by the other two units in open delta. This operation was repeated for each transformer.

Later transformers were built using parallel "Y" connected circuits, the line ends of the phases being brought outside the tank to two solonoid operated three-phase oil switches. The whole mechanism was controlled from one point by means of a hand wheel mounted on

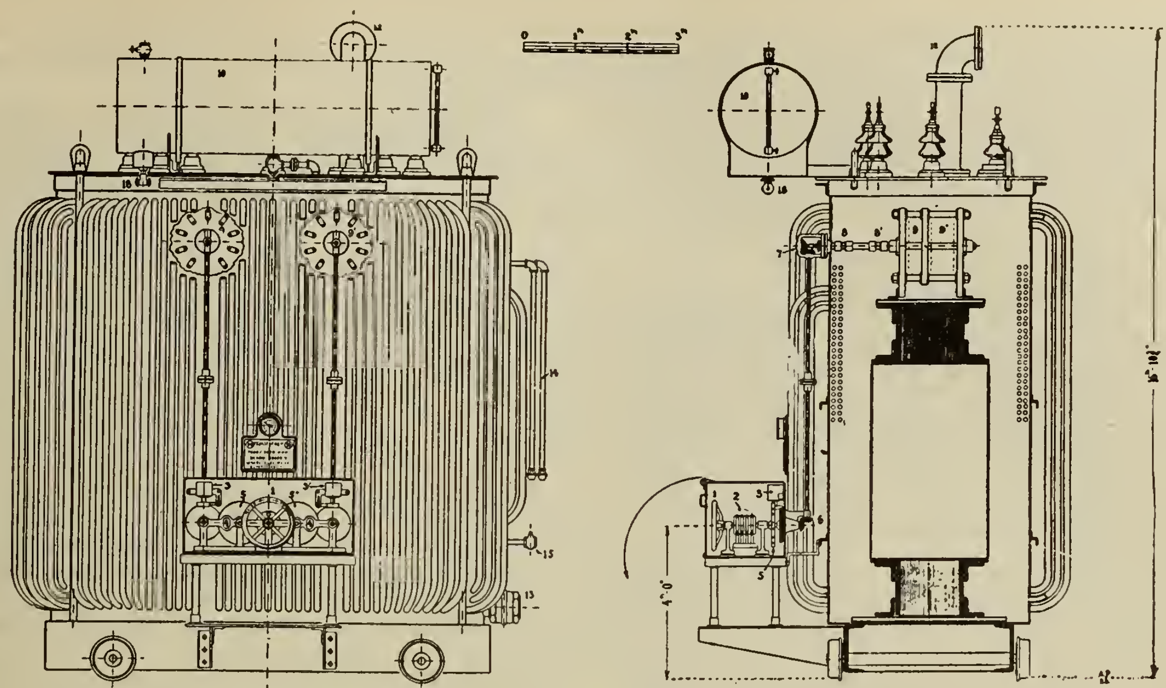

Figure No. 11.—Arrangement of Tap Switching Mechanism when Installed on Transformer.

the side of the tank. In operation one of the parallel circuits was opened by means of one of the oil switches, the position of its ratio adjuster changed one point, and the winding again connected in circuit. The other parallel circuit was then opened, its ratio adjuster brought to a corresponding position, and the circuit closed. This cycle was repeated until both circuits were on the desired tap.

Of course, one circuit carries the entire current during the time the other circuit is opened and a circulating current will flow while the two adjusters are not on the same tap. The circulating current is limited by the inherent reactance of the transformer. Introduction of external reactances in order to limit the circulating current was a further step in the development. This arrangement of tap switching mechanism is shown in figure No. 11; while the diagram showing the sequence of operations of the tap switching mechanism is shown in figure No. 12.

In larger high-voltage units, where it may be desirable to keep the power units free from taps, the regulating part of the equipment may be separated from the other winding and provided by means of a regulating transformer having windings for the regulating operation and being connected by means of oil circuit breakers and reactors so that the ratio can be raised or lowered in very much the same manner as described above. These regulating transformers can be placed either in the centre of the delta winding, at the end of the delta winding or at the neutral end of a "Y" connected bank. If closer regulation is required than can be obtained by the use of taps additional equipment in the form of regulators may be employed to this end.

Some of the installations made have employed a driving motor for more or less automatic operation, while others have been manually operated.

220,000-Volt Transformers

So far as transformers are concerned we have passed into the use of 220,000-volt transmission with but very little stir. No entirely new features have been introduced and the same standard practices as have been employed for some time on high voltage transformers have been maintained. As a matter of economy all the present 220,000-volt systems are operating with a grounded neutral. Considerable economy was, therefore, effected by arranging the transformers to take advantage of this feature by economizing in the insulation at the end of the winding which was connected to the ground. This did away with the necessity of a second high voltage lead.

The terminal connected to the line is connected to the middle point of the winding and the two legs of the high tension winding connected back and forth so as to keep the voltage between coils near each other at a safe low limit, the upper and lower halves of the winding being connected in multiple. This brings the upper and lower ends of the winding to ground potential and permits the winding being located much closer to the core than would be otherwise possible.

The question might naturally arise as to why the economy effected by this arrangement of grounded neutral should not be extended to other voltages. As a matter of fact it has been employed in two or three installations

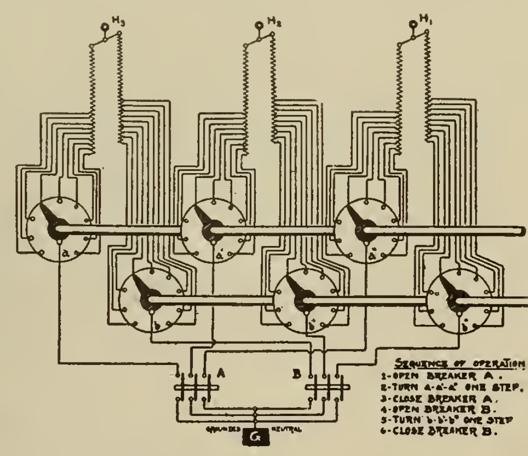

Figure No. 12.—Diagram Showing Sequence of Operations of Tap Switching Mechanism.

with which the writer is familiar. The percentage of economy will, of course, depend upon the voltage and capacity of the units. For instance a greater percentage of saving would be obtained by the use of this system in connection with a 5,000-kv.a., 110,000-volt transformer than with a 10,000-kv.a., 110,000-volt unit. The percentage of saving in a 10,000-kv.a., 220,000-volt would also be greater than with a 10,000-kv.a., 110,000-volt.

Three-Winding Transformers

The growth of transmission systems has not only increased the voltage and capacity of transformers but has in a number of cases developed high voltage networks that must be tied together in order that power may be interchanged between them. In some cases three sections operating at different voltages are tied together at one bank of transformers. This requires a three-winding transformer which requires careful designing in order to allow the proper interchange of load and at the same time maintain satisfactory regulation.

It is desirable at times in tying two systems together that the phase positions should be kept identical and at the same time a neutral connection provided. In this case both windings will be connected star or "Y", and in order to take care of the third harmonic component of the exciting current it is desirable to add a third winding which will be connected in delta and which is generally referred to as a tertiary winding. The capacity of this winding will be controlled by the short circuit load which it has to carry in case a fault develops in the transformer.

In extensive high voltage systems a problem which presents itself is that of voltage regulation which is taken care of usually by means of synchronous condensers. The voltage for these condensers is quite often obtained from the transformer bank and in many cases by means of a third winding. These three-winding transformers, while proving a decided economy both in space and cost of equipment, present some rather interesting problems in design. One complicated determination is that of the reactance between different windings. There have not been very many of these transformers installed in Canada as yet. A couple of such banks are in existence although of comparatively small capacity.

The changes which have taken place in transformer construction have, of course, been very largely called for due to requirements met with in the development of our large generating and transmitting systems and the extension of the application of electricity to a vast number of industries. As to what the future will demand in this connection we cannot, of course, definitely predetermine but since transformer manufacturers have been able to meet almost all demands in the past we are confident that the transformer designer will not be found wanting when further demands are made upon him.

No. 1-B Colliery of the Dominion Coal Company, Limited

A Description of the New Colliery of the Dominion Coal Company Limited, at Glace Bay, N.S., which Contains Features New to Coal Mining Practice in that Province.

A. L. Hay, A.M.E.I.C.
Asst. Mining Engineer, Dominion Coal Company, Limited, Glace Bay, N.S.

Paper read before the Cape Breton Branch, The Engineering Institute of Canada, August 29th, 1925.

No. 1-B colliery, located at Glace Bay on the well-known Phalen seam, is the latest addition to the coal mines of the province of Nova Scotia. A great deal of interest has been shown in the development of this mine, for the following reasons: It was the first-fruits of the merger of the two large coal producing companies of Cape Breton — the Dominion Coal Company and the Nova Scotia Steel and Coal Company. It is not a new mine in the strictest sense of the word, but rather an outgrowth of an old mine, known as Dominion No. 1. Its capacity is greater than that of any other mine in the province. It is entirely submarine, except for the fact that the shaft itself is located on land. Certain innovations have been introduced new to the hitherto accepted mining practice in Nova Scotia.

It will be noted from figure No. 1 that the Sydney coalfield consists of a series of basins, divided by anticlinal folds and named from east to west as follows: Morien, Glace Bay, New Waterford, and Sydney Mines. While New Waterford and Sydney Mines are usually spoken of as two basins, in reality there is one basin only. The synclinal fold of this basin is approximately under and parallel to Sydney harbour.

It will be noted on the same map that the seams are continuous for the most part throughout the field. The Blockhouse seam in the Morien Basin is the same as or at least corresponds to the Harbour seam at Glace Bay, the Victoria at Waterford, and the Main seam at Sydney Mines. Some of the seams, while easily correlated throughout the basins, change somewhat in their physical and chemical characteristics.

The workable seams and those of present proved economic value in Glace Bay are, beginning at the top: Hub, Harbour, Phalen, Emery and Gardiner. The vertical interval between the Hub and Gardiner is 1420 feet.

The Phalen and Harbour seams have been worked extensively, as their quality and physical characteristics are such as to make them attractive economical propositions. Other seams have been proved, such as the Boutilier and Back Pit, which lie between the Harbour and Phalen. Their thickness and quality are such that they are not considered to-day as being of any real importance. There is no doubt, however, that these seams will eventually be worked and millions of tons of coal from them drawn through No. 1-B shaft.

In 1893 a shaft was sunk at Dominion No. 1. In 1900 another shaft was sunk at what is now known as Dominion No. 2. The object of these two shafts was to afford entrance to win all the coal held under lease by the Dominion Coal Company in this section of the field. (See figure No. 2.) All coal to the dip of the barrier was allocated to Dominion No. 2 and the balance to Dominion No. 1.

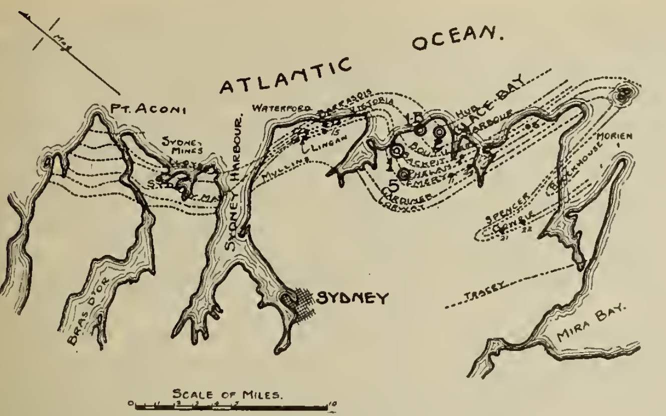

Figure No. 1.—Map of Sydney Coal Field.

In 1914 considerable difficulty began to be experienced in maintaining satisfactory ventilation. This condition had developed gradually, but as the airways became lengthened, the difficulty was accentuated. Increasing the ventilating pressure resulted in very heavy leakage losses without improving the ventilation to any appreciable extent. The cost of opening up these airways and building concrete stoppings was considered prohibitive.

The distance a miner was compelled to walk from the shaft to his working face was in some cases upwards of two miles. When it is remembered that a miner's work is usually quite strenuous, it can be seen that the time and energy expended in walking four or five miles a day underground was unprofitable to both the miner and the company. The roadways in years gone by had not always been developed with the end in view of ultimately making them haulageways for the transportation of men, with the result that a very heavy expenditure would have to be made if these roadways were to be built at this late date.

Another point that was being given serious study at this time was the desirability of establishing an additional escapeway from No. 2 colliery against the possibility of a disaster, such as a fire or explosion. At that time there were three entries into No. 2 mine. One of these entries was via No. 5 colliery. As this latter colliery was rapidly reaching the point of exhaustion, it was deemed advisable to provide another escapeway.

With these objects in view: — improving the ventilation of No. 1 mine; reducing to a minimum the length of walk for the miners of No. 1 colliery; and providing an additional escapeway for the miners of No. 2, it was decided to sink a shaft to No. 1 mine as close to the working face as possible and build a branch line from the S. & L. Railway for the transportation of men on the surface.

It will be seen from figure No. 2 that the seam had been worked out entirely under the land and also for a very considerable area under the sea. The narrow strip which formed the boundary between Dominion Nos. 1 and 2 collieries still remained intact and afforded the only suitable site for a shaft. This explains why the shafts are located within fifty-five yards of the sea cliff, which has an average erosion of eight inches per year.

A circular shaft was sunk and completed as a man shaft and return airway in 1921. The shaft was 670 feet deep and 12 feet in diameter. It was lined with brick for a distance of 213 feet from the surface and below this point was lined with concrete. For a time the shaft was quite wet, due to seepage of sea water. Holes were therefore drilled through the concrete lining and cement grout pumped in under pressure. This practically eliminated the leakage and the shaft to-day is dry.

The long haul necessary to win the coal from the outward limits of the Dominion Coal Company area to Dominion No. 1 shaft was adding very considerably to production costs. On the other hand the limited tonnage available from this area would not justify the cost of sinking a coal shaft and erecting a new surface plant. The economical mining limit was being approached rapidly when the merger was consummated. This completely changed the aspect of things, since it gave access to a large area of coal held under lease by the Nova Scotia Steel and Coal Company, seawards of the Dominion Coal Co.'s. leasehold. (See figure No. 2.) Under these circumstances, it was considered advisable to sink a coal shaft near the air shaft which was the only possible site. The advantages of such a proposition are obvious: the length of haul would be reduced nearly two miles; maintenance of compressed air line and intake airway would be reduced by two miles; a modern and more economical screening and surface plant would be erected; and production would be doubled.

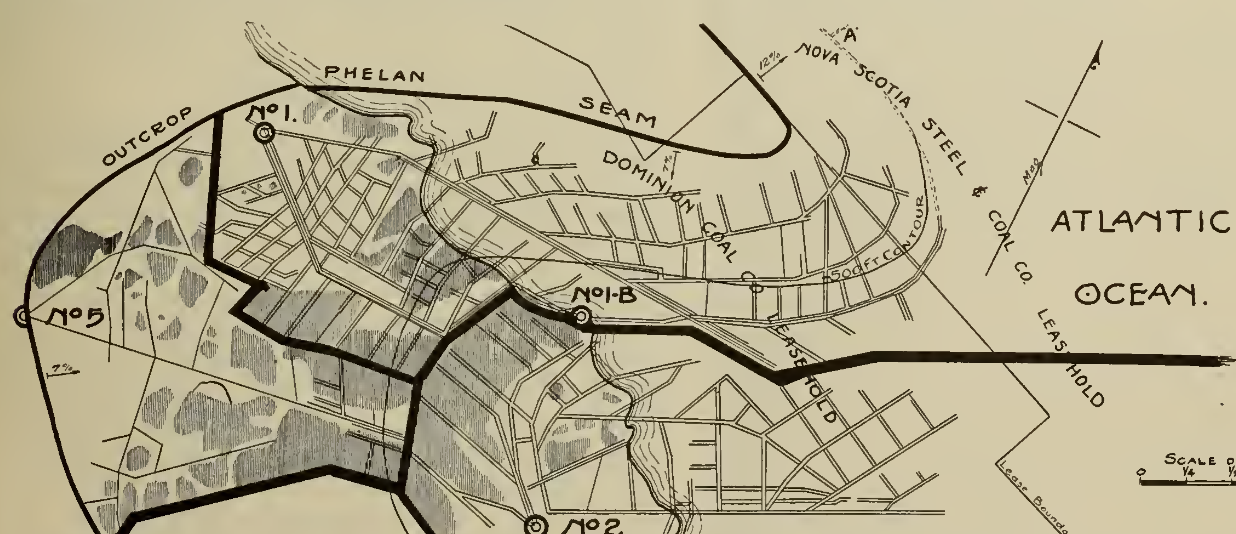

Figure No. 2.—Map Showing Section of Coal Field Held Under Lease by the Dominion Coal Company Limited.

The shaft was located July 30th, 1921, and sinking operations commenced the following month. As already stated the location was restricted within certain narrow limits, which hampered the layout to some extent, both on the surface and underground, but particularly underground.

Since the life of this colliery is estimated at a minimum of 126 years, it was judged to be true economy to give every structure the character of permanence and this has been the dominant note throughout.

The coal shaft is 670 feet deep and 31 feet 2 inches by 13 feet 4 inches in the clear. The shaft collar is of concrete and extends 32 feet from the surface. Below this point the shaft is timbered with 8 by 10-inch buntons and wall plates, and 6 by 10-inch posts, placed at 6-foot intervals, sheathed skin-tight, with 3-inch pine lagging. At 36-foot intervals an additional set of timbers was put in, hitched into the shaft wall for additional support. The shaft timbers are mortised in such a manner that all are interlocked, obviating the use of nails or spikes. All the timber used in the shaft has been treated with creosote. A shaft ring about 230 feet from the surface drains the water off the shaft into a pipe and the shaft is comparatively dry.

There are three compartments to the shaft. Two of these, each 11 feet 3½ inches by 12 feet, are used for hoisting coal and are fitted with double steel guides of 85-pound rail section. The third compartment, 6 feet 3 inches by 12 feet, is used as a pipeway. At the present time there is one 12-inch air line, one 14-inch cast iron water discharge column and a 3-inch water supply pipe.

There is a rock tunnel, 5 by 8 feet, driven from the north end of the shaft at a point 34 feet below the surface to the face of the cliff. The mine water, 1250 g.p.m. is discharged through the 14-inch shaft column to this drift, whence it flows into the sea at a point 9 feet above mean sea level.

At the west side of the shaft and at a point 112 feet above the shaft bottom, an opening, 8 by 15 feet, has been made into the Back Pit seam. Connection is made through a tunnel having an inclination of 55° with the workings of No. 1-B. This serves as a return airway for the colliery.

Shaft Bottom

At the site of the shaft, workings had already been developed without regard to the requirements of a new mine. Consequently in the layout of the pit bottom, the roads in existence had to be utilized whether of suitable grade or not. This necessitated very heavy rock grading. The amount of rock blasted to meet the requirements of standage exceeded 8,000 cubic yards. The pillars in the vicinity of the shaft were very small and the rock blasted from the roadways for height and grade was used to fill the open spaces, thus reinforcing the coal pillars and arresting the process of coal pillar disintegration.

Due to the fact that the shaft was sunk close to the workings of No. 2 colliery, where all the coal had been extracted, there was a possibility of a movement of the overlying strata in the vicinity of the shaft. Any such movement would prove disastrous to the colliery, consequently special precautions were taken to prevent this. For this reason the approach to the shaft, for a distance of 48 feet on either side, was secured by fabricated steel sets, roof, floor and side members being tied together. The roof members vary from 17 feet to 23 feet in length and are 18 inches in depth, with flanges of 11½ inches. The floor members are 12-inch I-beams with 5½-inch flanges. The vertical members are 8-inch H-beams, except in the immediate vicinity of the shaft, where 10-inch H-beams are used. Concrete walls were erected along the sides of the opening, into which the vertical steel supports were bedded and concrete filling arched between the roof members. To give further support, concrete walls were carried for a distance of 600 feet from the shaft. These walls vary from 12 inches to 15 inches in thickness, depending on the roof members they carry and on the condition of the pillars contiguous to them. The roof throughout the roadways of the pit bottom standage is supported by 10-inch steel H-beams of Bethlehem section. The walls of the empty and full roads inbye the point where concrete walls were built were lined with rock from the excavation of the roads and the nearby ventilation tunnel, and were given a face of gunite. The main objects here were the preservation of the coal pillars and the prevention of the forming of coal dust from the crumbling of the ribs, the coal itself being quite friable.

Movement of Output

By referring to figure No. 3, the movement of the output may be readily understood. Trips of 50 or more cars are hauled by trolley locomotives through the main turnout "A" to the standage "AB". The gradient of this standage is 9/10 per cent, favouring the load. The locomotive uncouples at "B" and runs through the run-around track.

The trip is spragged and moves slowly to point "C", where a motor driven creeper chain engages the car axle and hauls the cars to an elevation which permits a gravity run to the shaft bottom. One man is employed at "B" to uncouple the cars and operate the chain. At "C" there is an automatic switching device, which operates to throw the switch points after the passage of two cars. At "D" two automatic switches throw the points alternately. In this way cars are fed to the shaft bottom on four tracks.

Near the shaft the cars are held by a car stop, which is operated by the seating of the descending coal cage. As soon as the cage comes to rest, stops in the cage itself are released and at the same time the car chocks in the full road are thrown open. The cars next to the cage, brought to rest on a 4 per cent grade, move forward by gravity and bump the empties off the cage. The entry of the full cars throws the pit bottom and the cage chocks into service. This automatic caging arrangement is known as the Nolan Cager. Two cars are caged side by side simultaneously and similarly two empties are pushed out on the empty tracks.

By means of a very simple automatic chocking device the cars are regulated to a single track. One car has a clear track to the empty standage, while the second car is retarded by a chock 8½ feet from the shaft. When the first car has travelled 30 feet, the wheel of the car engages with the lever arm of the retarder and releases the second car.

The cars run by gravity to point "E". At this point a creeper chain, similar to the one on the full road, engages the car axle and hauls the car to an elevation sufficient to deliver it to the level empty standage. The cars are coupled at this point and a motor driven pusher pushes the trip forward. The locomotive picks up the trip at "A" and hauls it into the inside workings.

There is a locomotive repair shop close to the pit bottom which has two stalls with pits and is equipped with a crane. Here repairs can be readily effected.

The grades throughout, in the vicinity of the pit bottom, are designed to take care of a constant stream of cars, that is to say, between the full and empty creeper chains the grades are sufficiently great to permit a box to start readily from rest and move forward its own length only and this without excessive jar or shock. If there is any delay in delivering coal from the mine to the pit bottom and hoisting is continued until all cars are removed, between the two creeper chains, it is evident that cars released at the full creeper chain knuckle will acquire a very considerable momentum before reaching the shaft.

As designed, three men are sufficient to handle 2,500 tons in 8 hours, that is, one man uncoupling and running the full road creeper, the motor for this having a remote control, one man signalling the shaft hoist and one man coupling the empties and operating the empty creeper.

Pumping

To centralize the pumping of Nos. 1 and 5 collieries, the combined water growth of which is 1,200 gallons per minute, it was decided to impound the water in one main lodgment near No. 1-B shaft, advantage being taken of existing barriers for this purpose. The make of water at No. 1-B itself, being less than 30 gallons per minute, is allowed to drain through two 2¾-inch boreholes driven through the barrier to No. 2 Mine. This mine is naturally dry, and very little of the water entering through these boreholes has to be pumped as the ventilating current takes up a considerable portion of it.

The pump room is located in an old chamber which was later excavated to a height of 14 feet and the ribs reinforced with 12-inch concrete walls. The roof is supported with 85-pound rails set at 9-inch centers and lagged with brick.

The pumping plant consists of two 3-stage Sulzer centrifugal pumps, each direct connected to a 400-h.p., 2,200-volt motor, running at 1,500 r.p.m. Each pump has a delivery of 1,250 g.p.m., against a head of 630 feet. There is a third pump of the reciprocating type, motor driven, which pumps the water from the shaft sump into the suction of the Sulzer pumps.

An ell of the pump room contains the switch gear and step-down transformers for the lighting of the pit bottom and the operation of the car haul motors. A split of fresh air, conducted through a 12-inch wrought iron pipe from the main aircourse, ventilates the pump room.

Development

As already mentioned, a very large area of coal is allocated to this mine. It is difficult to say just where the economic limiting line exists, but it is reasonable to assume that as the years go by and advances are made in engineering practice, this limit will be further seawards.

By referring to figure No. 2, it will be seen that the contour of the seam swings through an arc of 115 degrees, as it turns around the anticline separating the Glace Bay and Waterford basins. While the shaft is located in the Glace Bay basin, it is apparent that the bulk of the coal to be drawn to No. 1-B shaft will be from the Waterford basin. The seam is 7 feet thick, clean coal, and is suitable for metallurgical purposes.

By means of cross-measures drifts from No. 1-B workings overlying and underlying seams will eventually be won.

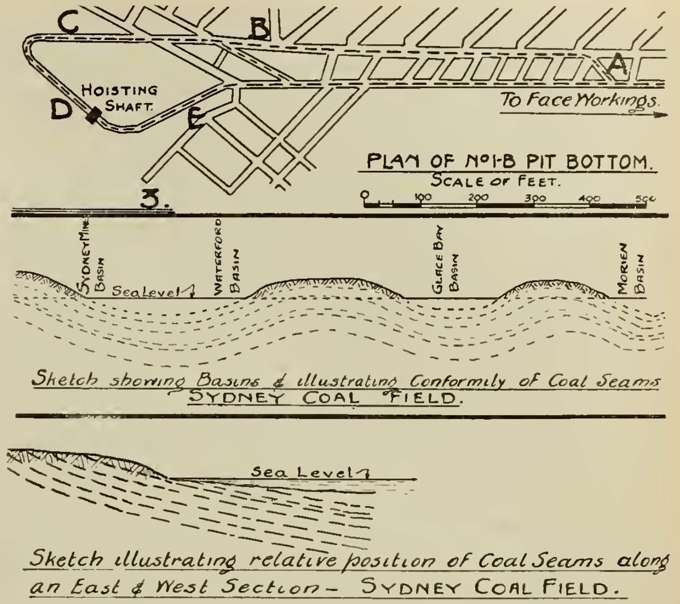

Figure No. 3.—Plan of No. 1-B Pit Bottom with Sketches Illustrating Conformity of Coal Seams and Relative Position of Coal Seams Along an East and West Section-Sydney Coal Field.

The tonnage of coal recoverable from these seams from a boundary line considered within the present economical limit is: Hub, 18 million tons; Harbour, 27 million; Phalen, 43 million; Emery, 22 million; Gardiner, 30 million; or a total of 140 million tons. With an output of 2,500 tons per day and continuous operation, i.e., 280 days per year, the Phalen and Upper seams alone will make the life of the colliery 126 years. If the lower seams are added, the life of the colliery will be 200 years.

The Phalen seam only is being worked at the present time. The main development at present is a haulage way which follows approximately the contour of the seam from the shaft bottom. At present the face of this roadway is 2.3 miles from the shaft. It will continue to drive along the contour until it reaches the western barrier, 4.3 miles distant from the shaft. This barrier is the eastern limit of an area reserved for development from North Head, Lingan.

At a point one mile from the barrier it is proposed to develop deeps on the full dip of the seam for a distance of at least two miles. The length of face between the barrier of the reserved area and No. 2 colliery is three miles. As this is considered too great a length of face tributary to one deep, a second set of deeps will be started shortly at point "A" and driven parallel to No. 2 barrier. This will take care of one mile of producing face. By the early winning of these deeps, the output of the mine can be easily maintained while the long development to and of the farthest deeps is being prosecuted.

The system of mining is pillar and room. This is the only system feasible within present cover limits, where 56 per cent of the coal is left to support the sea bottom. As the cover increases to the dip, a point will be reached where all the coal may be safely extracted. This may be done by removing the pillars formed by first operation or by longwall. Hydraulic stowing has been suggested for this seam, replacing the coal by sand, crushed slag and other refuse. This, however, is not considered economically feasible at the present time.

Until recently rooms have been developed 20 feet wide with crosscuts, at intervals of 75 feet, 12 feet in width. This has been the standard practice in all the collieries of the Phalen seam for the last twenty or more years. Recently a slight change has been made, the rooms being reduced in width to 16 feet and the crosscuts increased in width from 12 feet to 16 feet.

The same percentage of extraction is maintained and the rooms are so spaced that there is always a crosscut cutting face to each room. This change, slight as it is, has many advantages, the most important of which is a concentration of workings 100 per cent greater than obtains at present. It also results in a safer working condition at the face, improves the ventilation and makes it easier for the miner and loader. One-third of the present producing faces are working under the new system. It will require about eighteen months to make the system effective throughout the entire mine.

The coal is cut by air driven Ingersoll Rand radial coal cutter machines. These machines are comparatively light, weighing 391 pounds, and are easily moved. They are capable of undercutting seventy-five tons or more per machine per day, although the average perhaps does not exceed fifty tons.

For some time the company has had under consideration the installation of another type of mining machine, viz., the Arcwall chain machine. The machine weighs five tons and is equipped with either an electric or turbine-air drive. This machine will cut the coal in one-fifth the time of the radial cutter. On the other hand, it is much more difficult to move from place to place. This is particularly true of the turbine-air machine.

The electric driven Arcwall machine is undoubtedly an advance over our present coal cutter, but the introduction of electric current to the working face presents its own difficulties, as there is always the possibility of ignition of gas or dust from electric sparking. These machines are equipped with explosion-proof motors, but the cables leading to the machines have been known in several instances to be responsible for the ignition of gas.

To minimize the dangers from the use of electric current at the face, it has been proposed to use water to lay the dust and prevent its ignition and also to use stone dust to prevent the propagation of flame originating in a gaseous atmosphere. In the writer's opinion there is no doubt that electric coal cutting can be made reasonably safe if proper precautions are taken to offset possible dangers.

Electric coal cutting is coming more and more to the front in the coal mines competing against Nova Scotia. We must either adopt modern methods and take advantage of every reasonable means to produce cheaper coal or be relegated to the discard in the economic struggle.

At the present time air is compressed at Dominion No. 1 colliery and transmitted through an 8-inch main to No. 1-B workings. This is supplemented by a compressor of 3,000 cubic feet capacity at No. 1-B shaft. In the course of eighteen months, No. 1 colliery will be exhausted and either additional compressor capacity will be required at No. 1-B or electric coal cutters will be introduced.

Transportation

The coal is loaded at the working face into cars of two tons capacity. The dimensions of the cars are: height, above rail, 3 feet 8 inches; inside length, 8 feet 8 inches; between buffers, 10 feet 3 inches; width, 4 feet 4¾ inches. The rail gauge is 36 inches, wheels are 16-inch tread diameter and are equipped with Timken roller bearings. The cars are built with solid ends and require a complete revolution to empty them. As a result they are comparatively dust proof. The cars are hauled by horses from the producing face to room landings, an average distance of 1,300 feet.

Trips of seventeen cars are made up on the landings and lifted by a 15- by 16-inch Ingersoll Rand air hoist and lowered through a headway to the main landing. Three headway trips, or fifty-one cars, constitute a normal main haulage trip. Two headways are in operation at the present time, the average output from each being 750 tons.

Each air hoist is so designed that it is a combined hoisting and compressing engine. When hoisting, it offers all the advantages of an efficient hoist. When lowering, the design permits of air being compressed into the main pipe-line, with good efficiency.

The rope speed is controlled by the amount of air compressed and is at all times under control of the operator. By the movement of a lever, more or less air is compressed, thus governing the speed of the rope, thereby effecting a direct saving in energy that is usually absorbed by friction brakes.

Its operation from hoisting to lowering or compressing is automatic. The hoist is equipped with friction brakes for emergency. A compressor discharge valve is placed in a by-pass to insure automatic passage of the compressed air and to prevent the return of the compressed air when hoisting or with the throttle valve open.

Coal from the dips is hauled in 13-car trips from room landings by means of main and tail rope motor driven hoists. There are two of these hoists in operation, each driven by a 150-h.p. motor, at 2,200 volts. The coal is hauled from the main landings to the shaft bottom by three 13-ton, 240-h.p., d.c., Goodman trolley locomotives. The line pressure is 250–275 volts. These locomotives have a draw-bar pull of 6,500 pounds on a level grade, at a speed of eight miles per hour. The wheels, 33 inches in diameter, have cast iron centres with steel tires 2¾ inches thick, the tread being 3 inches wide, and the wheel base 66 inches. Each locomotive has two 120-h.p. geared motors, centrally hung, of the open type. There is a controller of the open drum type at each end of the locomotive.

Three of these locomotives provide ample margin in handling the total output from the present workings. It is estimated that the main haulage can be extended another 5,000 feet without additional locomotives.

The system of main haulage at most collieries, both here and on the main land, is plane rope, endless rope, or a modification of these. It is true that Jubilee colliery, Sydney Mines, had some years ago introduced storage battery locomotives for the main haul, which in this case was very short. Also about twenty years ago, compressed air locomotives were introduced in Nos. 2 and 9 collieries to meet a somewhat similar condition as that existing in No. 1-B to-day. While these locomotives did the work, they were far from economical and in time were discarded.

About twenty-five years ago, a trolley locomotive was used in No. 1 mine for comparatively short level hauls. Whether or not it was considered economical in those days, it is certain that it was operated without regard to the possible dangers arising from a dusty road.

At No. 1-B, owing to the changing direction of the contour, it was not considered feasible to work this mine with rope haulage with any degree of success. To meet this curvature condition, it was necessary to install locomotive haulage of some kind.

The merits of storage battery and trolley locomotives were discussed fully. It was felt that for long runs, such as will be the case in this colliery, that trolley locomotives would be the more economical. This decision led to special precautions being taken to prevent dust or gas ignition. It also necessitated the widening and increasing of the height of the roadway. The roadway as originally developed was 7 by 10 feet. It was necessary to increase this to 8 by 20 feet, giving it a finished clearance of 6 feet 6 inches by 18 feet. This clearance holds good, except for a distance of 1,000 yards between the shaft turnout and the assembly yard, which is laid with single track. Upwards of 14,000 tons of coal and 16,000 cubic yards of rock had to be excavated in preparing this roadway. The ruling grade is one-half of one per cent against the load.

The coal, of course, was loaded out to the surface, where it had a market value. The disposal of the stone, however, was a more difficult problem. All openings adjoining the roadway itself were stowed with excavated rock. Although there were numerous vacant chambers to the rise of the parallel roadway, these could only be used to a limited extent, as this latter place was the chief coal road of No. 1 colliery and intensive development work was being carried on at the same time as construction.

Stone packwalls were built along both ribs of the haulage way. These walls varied in thickness from 1 foot to 4 feet, depending on the road alignment. This absorbed about 6,000 cubic yards of excavated material. Where the rock was of a sandy nature it was crushed to a size suitable for road ballast. Apart from a small section at the pit bottom, all excavated material was disposed of as outlined above.

The packwalls were given a coat of gunite, 1 of cement, 3½ of sand. This bonded the walls, closed the crevices and reduced to a minimum irregularities where coal dust might lodge. The walls prevented spalling of the coal ribs, which would have created a very serious dust menace.

The roof, which consists for the most part of soft shale is supported by rail beams, 60 pounds to the yard where the span does not exceed 12 feet, and 85-pound and 100-pound rails where the span exceeds this. A number of 6-inch H-beams, rolled by the Dominion Iron and Steel Company, were also used. These, however, although of proper section were found to be too soft and 100-pound rails are now used exclusively. The rail booms are supported by black spruce props imbedded in the packwall. Considerable lofting is necessary over the steel booms as the roof deteriorates due to the changing temperature.

In the extension of the main haulage, now under construction, straight concrete walls 8 inches thick are erected on either side and these support the rail beams. To prevent the falling on the roadway of small pieces of stone from the roof between the beams, skin-tight lagging between rails has been resorted to.

The track rails are 60 pounds to the yard, laid on ties 6 inches by 6 inches by 5 feet, spaced at 30-inch centres. The rail is perhaps on the heavy side, but it makes a good substantial track for main line, which must serve for many years. The rails are bonded with copper bonds at each rail joint and cross-bonded at 200-foot intervals. At intervals of 2,500 feet, the track rail is grounded to the main air pipe on the parallel road. The tracks are laid at 8-foot centres and as the locomotives are 5 feet 2 inches in width, this gives a clearance of 2 feet 10 inches between passing locomotives. This is ample to permit centre supports if these should become necessary. There is a clearance of 1 foot 11 inches between the locomotives and packwall on the low side and 2 feet 11 inches on the high side. The high side is used as a walkway by workmen and officials, whose duties take them on the haulageway during operations. In addition to the clear space of 2 feet 11 inches, there are manholes established at 100-foot intervals as a further safety measure.

The trolley wire is hard drawn copper, 4/0, B. & S. gauge, fastened to insulators, secured to the roof beams. It is offset 6 inches east from the low side rail and supported at a height of 6 feet 4 inches above it. There is a feeder cable carried close to the packwall on the low side of the roadway. The drop at the end of the line does not exceed 45 volts.

Considerable sparking was experienced when operations commenced. This has been very much reduced by fixing the trolley wheel so that it makes a sliding contact.

The 300-k.w., C. G. E. motor generator set, which supplies direct current to the trolley system is located 4,600 feet from the shaft bottom in the same chamber as the motor driven deep hoists. A 4/0, 3-conductor, paper insulated, lead covered, armored cable, 2,200-volt, is carried from the air shaft along the intake airway to the motor generator set. The generator is driven by a synchronous motor, 750 r.p.m.

Throughout the entire length of the roadway, stone dust has been used freely to neutralize as much as possible the combustible coal dust. Coal spillage is cleaned regularly from the roadbed. In spite of this, quantities of small coal accumulate and are ground by traffic into dust. Coal dust is also swept off the top of full cars in motion. The combined velocity of the inbye air and the outward bound car creates a very strong current and at places produces a cloud of dust to the rear of the moving trips. Steps are being taken now to spray the loaded cars with water at the main landings, which will help this condition materially. The roadway is examined daily and samples of dust taken at frequent intervals. The degree of fineness is determined and the combustible matter present ascertained. It is aimed to keep the combustible dust below 25 per cent, although as high a percentage as 45 might be considered safe. The stone dust is derived from George's River limestone, crushed by a Bradley pulverizer, to pass 85 per cent through a 200 mesh.

Ventilation

The mine is ventilated by a 5- by 10-foot Sirocco forcing fan, connected by a Morse silent chain drive to a 400-h.p., Canadian General Electric synchronous motor. The fan is designed to deliver 300,000 cubic feet of air at 6 inches w.g. At the present time the fan delivers 90,000 cubic feet with a w.g., of 3.8 inches, running at 183 r.p.m. There is a standby, 20 by 42 inches Dixon steam engine connected to the fan shaft by a rope drive. The air is delivered through a staple pit, 11 feet 4 inches by 13 feet, and 40 feet deep, to a drift 74 feet from the circular shaft, to which it is connected. It will be recalled that this airshaft was sunk prior to the merger and before such a large development was contemplated. As a consequence, while the shaft is of ample dimensions for the requirements of the next ten or twelve years, nevertheless at some future date when the quantity of air required is considerably greater than it is to-day, a much larger shaft will be needed. When the larger air shaft is completed, a rock drift will be driven through to the staple pit and the ventilation diverted. The fan is amply big for all future demands.

As the air shaft is equipped with hoisting cages and is used during coal hoisting periods by officials and also for the lowering of certain materials, it was necessary to build an air lock at the shaft mouth. This consists of two chambers, each 17 feet 4 inches square. The section immediately over the shaft extends to a height of 33 feet 10 inches above the surface. The roof is pierced with two small openings for the passage of the hoist ropes. The height of the outer chamber is 11 feet 4 inches. Between the two chambers there is a ¾-inch steel raising door, 10 feet by 8 feet 6 inches, with a trap door 6 feet 6 inches by 2 feet. The outer door is a double one, 8 feet 6 inches by 6 feet, with a trap door inset. The air enters the shaft at a point 43 feet below the surface. At a short distance from the shaft bottom, the air is split into two main airways. These run parallel to the main haulage for a distance of 2,200 feet. At this point a connection is made with the main haulage road. One airway is continued to the face, the main haulage serving as a second main intake also. It is necessary that trolley haulage be operated only on intake air.

To prevent short circuit of the air to the coal shaft, an air lock was established on the main road, the doors being set 1,250 feet apart. This distance enables the motor trip to pass through the air lock without any appreciable reduction in speed. The doors are of wood, 7 feet 4 inches by 6 feet 5¾ inches, bedded in concrete. A smaller door, 6 feet 5¾ inches by 2 feet 6 inches, is set opposite the travelling way.

The total pressure on the main door is nearly 700 pounds. It is customary for the trapper, (when the locomotive is approaching), to open the small door and equalize the pressure on both sides of the main door before attempting to open the latter.

The leakage is sufficiently great to ventilate thoroughly the haulage road from the air lock to the shaft. The air is split into five separate ventilating currents, so that the return air from each working section passes directly into the main return airway. The main return air divides itself naturally between No. 1 shafts and No. 1-B coal shaft. At some future date the return to No. 1 shaft will be closed off, in which case all the return air will make its exit through No. 1-B coal shaft via the dumb drift. The area of the airways leading to the shaft and the shaft itself is sufficiently great to do this without adding undue resistance to the air.

It will be recalled that one object of the circular shaft was to provide an escapeway for the workmen in No. 2 colliery, in case of a disaster cutting off No. 2 mine shafts. Shortly after the circular shaft was sunk, a passage was driven between Nos. 1 and 2 collieries, 140 feet in length and 6 by 8 feet in section. In this passageway, doors were erected which effectively separated the ventilating currents of the two mines. These doors are referred to as "explosion doors". It is hoped, in the event of an explosion in either mine, that the doors may withstand the force of the blast and provide an escapeway for survivors.

There are four doors, located in pairs, two doors being hung on one frame. The distance between frame centres is 15 feet 9 inches. The frames are heavily constructed of cast steel and each is securely fastened into a heavy reinforced concrete ring. They are 23¼ inches thick on the bottom and 18 inches thick at the top, leaving room between the doors for a man when the doors are shut. The battered frame insures the door being shut by their own weight. The door opening is 2 feet 6 inches by 5 feet 6 inches. The doors are also of cast steel 1¼ inch thick, heavily ribbed and further strengthened by having their outside surface convex. The bearing surfaces between doors and frames are machined so that there is no air leakage between the mines. The door hinges are equipped with grease cups and open easily. The perimeter of the passageway between doors and for a distance of 5 feet on the outer ends is lined with concrete. A 4-inch pipe with a trap drains the water from No. 1-B into No. 2 colliery.

This colliery is designed to hoist 2,500 tons per 8-hour shift. It was officially opened June 20th, 1924. The maximum output raised in any one shift until the cessation of work due to the labour situation was 3,048 tons, on December 8th, 1924.

Marketing Nova Scotia Coals

A Suggested Investigation and Educational Campaign to Promote the Wider Use of these Fuels

H. A. Hatfield.

Maritime Representative, Babcock-Wilcox and Goldie-McCulloch, Limited

Paper read before the Maritime Professional Meeting of The Engineering Institute of Canada, at Halifax, October 8th, 1925.

According to Bulletin No. 630, published by the Mines Branch, Department of Mines, at Ottawa in 1925, the bituminous coal used in Canada in 1923 was, in round numbers, 29,600,000 short tons, of which the United States supplied 17,300,000, Great Britain 269,000, and all Canada about 12,000,000 tons. Out of this western Canada mined about 7,500,000, and Nova Scotia a little over 4,000,000 tons, of which approximately 1,250,000 went to Montreal and its vicinity.

Our mines can produce, (approximately), 7,000,000 tons, and to keep them working continuously we have to find a market along the St. Lawrence for an additional 3,000,000 tons. In the year referred to, Quebec and central Ontario used 16,400,000 tons of soft coal and 4,800,000 tons of anthracite, so it should not be difficult when we have the information needed by coal users and stoker manufacturers, to find a place in that market for all the coal Nova Scotia can produce.

Our coal is used successfully at many steam plants in the Maritime Provinces and in and around Montreal. Moreover, it is handled with all types of stoker equipment. In the Montreal district, competition with foreign fuels is close, so that users must get satisfactory results or they would not buy our coal.

Without doubt our furnace designs and firing methods can be improved by studying the plants which use the million odd tons of coal shipped up the St. Lawrence each year. On the other hand, by studying our coals we shall be able to furnish more reliable information about them, and the stoker manufacturers would be in a better position to supply the proper equipment to burn them.

To engineers in the coal fields the problem of keeping our mines busy is of great importance. One difficulty in keeping the Nova Scotia mines working is, that on account of winter interruption of St. Lawrence shipments, continuous operation means piling coal at the mines. The argument usually offered against the success of any such plan is that it costs too much to pile and reclaim the coal. That the cost of piling coal without proper facilities is high cannot be disputed. But figures from several large central power plants in the United States show costs varying from 15 cents to 25 cents per ton, where the work was done with drag scrapers or electric cranes.

In this part of Canada the cost has been 45 cents to 65 cents per ton, because the coal is usually dumped from the cars and spread by hand, and reclaimed in the spring with a locomotive crane. It is probable that after a thorough study of the problem of storage, and after installing the proper equipment, the cost could be cut to 30 cents per ton or less.

Moreover, our piled coal should have a better chance in the Montreal market, for it has been the experience of several large coal users in that city that Nova Scotia coal which has been piled for several months gives better results in a furnace designed for eastern American coals than our freshly mined coal. A reason for this is given in Bulletin No. 97, issued by the University of Illinois. The coals tested at Urbana had analyses very much the same as those from our Nova Scotia mines. It is explained that freshly mined coal has a large capacity for absorbing oxygen, which combines chemically with both the organic combustible and the iron pyrites present while the coal lies in the pile. When these constituents become saturated the coal does not give up its heat units as readily as fresh mined coal. On account of this characteristic, such coal is thought to have lost a large part of its heat, when as a matter of fact, it may have the same number of heat units, but a different rate of combustion. The difference can be off-set by a stronger draft, which will speed up the burning or oxidation process and a corresponding increase of efficiency will result. The correctness of this theory is borne out by the results shown in the following table, which is taken from page 37 of the University of Illinois Bulletin No. 97.

Table No. 1,—Results of Boiler Tests with Mission Field Fresh Coal and with Weathered Coal after Six Years in Storage.

Fresh Mission Field Coal			Weathered Coal			
Test No.	Boiler h.p. developed	Efficiency of boiler furnace and grate per cent	Test No.	Coal and county tables (5 to 10)	Boiler h.p. developed	Efficiency of boiler furnace and grate per cent
10	554.0	63.96	20	Nut—Sangamon	568.5	64.50
11	569.6	61.21	21	Screenings—Sangamon	557.2	63.05
12	572.7	60.67	22	Nut—Williamson	727.1	65.98
13	589.0	69.87	23	Screenings—Williamson	509.6	60.04
14	555.9	64.75	24	Nut—Vermilion	655.0	64.20
15	506.6	65.50				
16	644.0	60.84				

It is to be noted that the over-all efficiency of the weathered coal averages quite as high as that of the fresh screenings. The general summary covering the behaviour of weathered coal in steam generation after six years of storage, as set forth in Bulletin No. 78 of the University of Illinois Engineering Experiment Station, is as follows:

"1. Burning weathered coal is largely a question of correct handling and ignition. Under these circumstances it gives as good results as fresh screenings.

"2. Weathered coal required a little thinner fire and more draft than fresh screenings.

"3. When using weathered coal the fuel bed should not approach any nearer to the water-back than from 4 to 6 inches, otherwise trouble with clinker is experienced.

"4. Practically as high capacity was obtained with weathered coal as with the other coals used, and, if anything, the fuel bed requires less attention."

The bulk of the coal used in Montreal and district comes from Pennsylvania and West Virginia mines, and has a smaller percentage average volatile than our coals. It can be burned in a lower furnace because the flames are shorter, but it requires more draft. When our coals have been stored, they should be better suited to these conditions, but we have to find out if all kinds can be stored and the exact results with each.

If we are to supply all the Eastern Canadian market, it is necessary to teach the consumer the business of buying in the early summer and storing properly. Some large steam coal users understand this now, and it is not difficult to deal with them because they realize the loss if their plant shuts down for want of coal. But the majority of plants take chances on strikes and other troubles because they are able to get coal from the United States and England as well as from Nova Scotia.

Probably the next objection offered will be that there is a great chance for loss due to the coal heating while in the pile. This difficulty has been overcome by spreading the coal so that the larger pieces do not separate from the fine stuff. Each layer of the pile is rolled as it is spread, so that the whole pile is packed thoroughly from top to bottom, and the circulation of air is eliminated. One method of keeping the pile from scattering is to build a sealed wall on each side and one end. Unless the wall is used the loose coal at the sides of the pile must be carefully gathered up. This trimming can be done by the locomotive crane operator with his bucket. It is a factor in favour of coal that has been piled at the mines that it is very unlikely to give further trouble by heating. Buyers who have had trouble on this account should be glad to get stored coal when informed of this fact, and taught how to fire it and what draft to give it.

For the purpose of studying the plants using our coal and the requirements of each consumer in our prospective market, the Nova Scotia government might well send out a man who would visit all the steam plants in eastern Canada and obtain such data as:—The quantity of coal used in each plant; its characteristics; how it is fired; pounds burned per square foot of grate; draft at boiler damper; type of boilers; pounds of water evaporated per pound of coal.

While the field man is collecting information about the market, it is proposed to get experimental data about the various coals at the Nova Scotia Technical College, Halifax. By working in close co-operation it should be possible to settle questions of furnace design so that eventually the field man can advise each coal user as to the coal best suited to the particular requirements of his plant.

The field man would necessarily be a combustion engineer, well grounded in steam engineering generally, for in plants already established he would have to talk "shop" with the operating staff in order to get the correct information about their equipment and requirements, and to interest them in such a way as to lead to orders for Nova Scotia coal. He would keep in touch with all new work and advise power plant designers of the best Nova Scotia coal available for their particular purposes and the best type of furnace in which to burn it. He should be prepared to talk, and take opportunities to address meetings of engineers and manufacturers, in order to develop interest in the product of our coal mines.

Keeping in touch with new work is particularly important, for business gained that way will induce other concerns to build their new furnaces to burn our coal efficiently. Also it amounts to something each year. This year, for instance, one company has already built boilers for eastern Canada which will use between 325,000 and 350,000 tons of coal per year. If any of these consumers have arranged to buy foreign coal and have built their equipment to burn it, rather than our local coals, it will be just that much more difficult to get them to try our coal and to find one that will be satisfactory.

It is equally important that the field man be enthusiastic over the work and well posted on handling our coals, for he will have to explain and demonstrate to the users how to pile it and how to burn it. He will have to explain the effect of weathering while in storage, and prove that a stock of coal at the consumers plant is cheap insurance against shut-down. Fortunately, as explained before, there are good engineering reasons why Nova Scotia coal that has been piled is to be preferred by the consumer in Montreal and vicinity. The field man can get proof of this from the plants he visits.

It is necessary to put a man in the field who can answer every argument, because the coal users in our prospective market have an idea that all our Nova Scotia coals are high in ash and sulphur and they cannot expect good results from them. The information available in government reports has not controverted this idea. Take for instance the report of J. B. Porter, M.E.I.C., R. J. Durley, M.E.I.C., and others who made an "Investigation of the Coals of Canada with Reference to their Economic Qualities". This report of six volumes is deemed a classic, and is found in all technical libraries of any size. But these boiler tests were made about 1910, and since that time we have changed our ideas as to what quantity of water a pound of coal should evaporate. Table 8, on page 41 of that report, shows that the equivalent evaporation per pound as fired of the coals from this district averaged about 7.3 pounds. They used a Babcock and Wilcox boiler for their tests, which was set so that the front of the grates were 24 inches from the tubes. If a boiler set as high as the Babcock and Wilcox at the Nova Scotia Technical College, Halifax, had been used to test these coals, it is likely that the evaporation would have been at least two pounds greater per pound of coal fired. Therefore, although we can admire the work of any man who could get even such good results with a furnace built for hard coal, we should obtain and send out information which will prove that the furnace used for those tests was not high enough for any Nova Scotia coal to show to the best advantage.

The Mines Branch bulletin, from which we quoted in the first paragraph of this paper, says on page 14:

> "The coals of Nova Scotia vary greatly in character, some being high in ash, low in sulphur, and vice versa — others high in both ash and sulphur, and others low in both. The fusibility of the ash also varies."

This variation is looked upon as a disadvantage, whereas it might well be considered the opposite, because it means we can supply coals suitable for other purposes than for boiler fuel.

Even the steam coal market requires several kinds of coal, for in general we need to supply one grade for hand firing, one for chain grates, and another for underfeed stokers. The majority of the plants in Canada use small horizontal return tubular boilers. Of these the greater number are not equipped with stacks or fans to give sufficient draft, so they cannot use a poor grade of coal, or slack coal of any kind where the boiler is operated at rating. The chain grate type of stoker handles high ash coals to advantage and this is the grade which should be supplied to plants where they are installed. The underfeed stoker was designed for coals such as those from the eastern American mines, which have only about two-thirds the volatiles that our coals contain, and an ash with a high fusing point, so we should furnish plants where they are installed with such a grade.

It is not as though Nova Scotia were being asked to undertake something entirely new. The province of Alberta has done a great deal of work along similar but more elaborate lines. The Scientific and Industrial Research Council of Alberta has done much to gather the necessary information. The Alberta government, working through its Trade Branch, went directly after a bigger market for the sale of their coals. One move was to give each coal a trade name so that the buyer would be sure to get the same kind every time he asked for it by that trade name. Books of instruction on firing stoves, heating furnaces and small steam boilers, were printed and scattered all over Canada. These books were written in non-technical language so that any man could understand them. For the users of power boilers, Prof. C. A. Robb prepared a report on the "Combustion of Coal for the Generation of Power". In Winnipeg and other cities the firing of Alberta coals was demonstrated in furnaces of various types.

In this campaign they increased their market in the west for all kinds of coal and practically drove American anthracite out of the prairie provinces. They also made a very strong attempt to introduce Alberta fuels into Ontario against American competition. In fact, they might have been supplying that market to-day if freight rates could have been arranged.

We have a much better chance to get the Ontario market than Alberta has, for our coal can be carried a great part of the distance by water, and it can be arranged to take it westward from Montreal in the grain boats so that they will not go up the lakes empty. It would be difficult for Alberta to make regular deliveries in the fall because the railroads give grain shipments preference over everything else at that time when most householders are buying their winter stock of coal. Moreover, the cars used for coal would return empty so the railroads would only get one freight. By-product coke made from our coal can be supplied more cheaply, so that the actual cost for household and heating purposes during the year should be considerably less than if hard coal were used.

Part of our work in Nova Scotia is to find out how the data collected by other coal mining districts applies to our coals. We know we can get better efficiency with a horizontal return tubular boiler which is set well above the grates, but we do not know what the distance between the grates and shell should be for the greatest all-around efficiency. There is a good chance to make the necessary tests at Halifax. The horizontal return tubular boiler in the Mechanical Engineering Department of the Nova Scotia Technical College could be set so that the furnace is 10 feet high. It would then be fired from a movable platform, which could be raised or lowered as desired and by arranging the grates so that they could be set at any required distance from the shell, the efficiency at various heights of settings could be ascertained and the most economical setting determined.

The Babcock and Wilcox boiler in the same college is 12 feet to tube door, which is considered to be a good height for a hand-fired boiler. It could easily be arranged to raise and lower the grates to find out how that will effect the efficiency. The boiler can be stoker fired and later on it might be policy, both for the information that can be gained about our coals, and for the sake of students who want instruction in boiler testing, to install various types of stokers one after the other and make a series of tests with them. The meters and other equipment for boiler testing which is part of the mechanical engineering course, will, of course, serve for the coal tests.

In the field at the rear of the Technical College there is plenty of room to put all the bins necessary to store any coal which is to be subjected to tests to find out the effect of weathering.

After considerable study of the problem, the writer is of the opinion that in order to market more coal, we have to do two things immediately:

First, get more information useful to the coal users, so that they will know how to build furnaces and firing equipment which will make more steam for the dollar spent in the product of our mines than they will get from any other fuel.

Second, put one or more men in the field to see that such information is applied so that coal sales result.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOL. IX JANUARY 1926 No. 1

Queen Alexandra

We record with deep regret the death of H. M. Queen Alexandra, which took place on Friday evening, November 20th, 1925.

The Toronto Meeting

The admirable policy of holding the Annual General and General Professional Meetings of *The Institute* in different large cities of the Dominion leads this year to Toronto, to which city the Annual General Meeting of *The Institute*, will be adjourned, after convening, in accordance with the By-laws, at Headquarters on Tuesday, January 26th, 1926; assembling at the King Edward Hotel, Toronto, on Wednesday, the 27th.

In accordance with the programme published elsewhere in this issue, the Annual General Meeting will be followed as usual by the General Professional Meeting, and it is gratifying to note that this year a particularly varied and important programme of papers will be presented for discussion.

In the Civil Engineering Section, water supply, sewerage systems and questions in connection with concrete will be discussed, while the Mechanical and Electrical Sections will consider matters connected with steam power plant design and operation, and European practice in electrical transmission engineering.

The general session which follows has an equally diversified programme, and the papers of the concluding session on the Fuel Problem in Canada will be particularly timely.

The Toronto Branch has displayed its well known activity and capacity for organization, and in laying out the programme has not omitted to allow time for recreation and visits. It is expected that there will be a large attendance of members from outside points, for whose benefit arrangements for reduced railway fares have been made with the Canadian Passenger Association.

All signs point to a successful meeting.

Special Railway Rates for the Toronto Meeting

DIRECTIONS FOR MEMBERS ATTENDING

Buy ordinary one way first-class ticket to Toronto. When doing so ask ticket agent for Standard Convention Certificate, (C. P. A. Form 24). On arrival at the King Edward Hotel deposit your certificate at the Registration Booth, for endorsation and validation, for which twenty-five cents is charged.

Before leaving Toronto obtain your validated certificate. This will entitle you to purchase a one way continuous passage ticket for your return trip at one half the ordinary rate.

It is necessary that one hundred and fifty certificates be validated in order that this plan may be effective.

Dates on which Standard Convention tickets can be obtained are as follows:

From points in British Columbia—Jan. 22nd to 26th inclusive.

From points in Alberta and all points West of Armstrong and Fort William, Jan. 23rd to 28th, inclusive.

All points East of and including Armstrong and Fort William, Jan. 23rd, to 29th, inclusive.

The return trip from Toronto must be commenced before midnight on February 2nd, 1926.

Portrait of the Late Peter Alexander Peterson

The gallery of portraits of Past-Presidents of *The Insiitute* at Headquarters has been enriched through the kindness of Mrs. P. A. Peterson, who has presented to *The Institute* a portrait of her late husband painted by Robert Harris, R.C.A.

The Council has expressed its appreciation of Mrs. Peterson's liberality and has directed that the painting be hung in the room in which Council meets.

Annual General and General Professional Meeting

King Edward Hotel, Toronto

January 27th, 28th, and 29th, 1926

PROGRAMME

(Subject to Revision)

Wednesday, January 27th.

9.00 a.m. Registration at King Edward Hotel. (Members register in Foyer, Second Floor; Ladies in Room 225).

10.00 a.m. Annual Business Meeting, in Banquet Hall.

1.00 p.m. Luncheon in Pompeian Room, at which the Mayor of Toronto will deliver an address of welcome. Complimentary to visiting members and visiting ladies.

2.30 p.m. Resumption of business meeting. Address of retiring President and presentation of Charter to Toronto Branch. Inauguration of incoming President.

5.00 p.m. Reception tendered by the Toronto Branch, on Parlor Floor for guests, members and ladies, (complimentary to all).

8.00 p.m. Smoker in the Crystal Ballroom, (complimentary).

Thursday, January 28th.

Professional Meeting, Civil Engineering Section

9.15 a.m.

Banquet Hall. Chairman, George A. McCarthy, M.E.I.C.

Deterioration of Concrete in Alkali Soils—Prof. C. J. Mackenzie, M.E.I.C., and Prof. T. Thorvaldson, University of Saskatchewan.

Design of East York Sewers and their Construction by Contract and Day Labor—R. O. Wynne-Roberts, M.E.I.C., consulting engineer, Toronto, and Grant R. Jack, A.M.E.I.C., township engineer.

The Water Supply of the Border Cities—William Gore, M.E.I.C., consulting engineer, Toronto, and J. B. Clark Keith, A.M.E.I.C., chief engineer, Essex Border Utilities Commission.

Reduction of Flexural Stresses in Fixed Concrete Arches—J. F. Brett, A.M.E.I.C., designing engineer, Montreal Water Board.

Professional Meeting, Mechanical and Electrical Engineering Section

9.15 a.m.

Room under Balcony of Ball Room. Chairman, Prof. R. W. Angus, M.E.I.C.

Steam Power Plant Design—Prof. A. G. Christie, Johns Hopkins University.

Generation of Explosive Gases in Electric Water Heaters and Boilers Operating on Alternating Current with Submerged Electrodes—Prof. J. W. Shipley, University of Manitoba and A. Blackie, National Testing Laboratories, Ltd., Winnipeg.

European Transmission Practice—A. E. Davison, transmission engineer, Hydro-Electric Power Commission of Ontario.

2.30 p.m. Inspection of new Hillcrest shops of the Toronto Transportation Commission.

Trips of inspection to certain other plants or works under consideration by the Committee will be organized, should they be found practicable.

2.30 p.m. Ladies will visit the Art Gallery and Hart House, University of Toronto.

5.00 p.m. Ladies will be entertained at tea at Government House.

7.30 p.m. Annual Banquet of *The Institute* in the Pompeian Room.

8.00 p.m. Theatre party for ladies.

Friday, January 29th.

Professional Meeting, General Session

9.15 a.m.

Pompeian Room. Chairman, George T. Clark, A.M.E.I.C.

The Influence of the Modern Highway—W. A. McLean, M.E.I.C., Consulting Engineer, Toronto.

Some Phases of Industrial Relations—Homer E. Niesz, Manager, Industrial Relations Department, Commonwealth Edison Co., Chicago, and President, Western Society of Engineers.

1.30 p.m. Ladies Luncheon, Y.W.C.A., McGill St.

Professional Meeting, General Session

2.30 p.m.

Pompeian Room. Chairman, A. D. LePan, A.M.E.I.C.

The Fuel Problem in Canada—Lesslie R. Thomson, M.E.I.C., consulting engineer, Montreal.

Methods of Fuel Production—J. L. Landt, consulting engineer, Buffalo.

Methods of Fuel Consumption—John Blizard, research engineer, Power Specialty Co., New York.

8.45 p.m. Supper-Dance, Crystal Ballroom.

Amendments to By-Laws

The report of the Legislation and By-laws Committee for 1925, which includes proposals for a number of important changes in certain By-laws, was submitted to the Council of *The Institute* at the regular meeting held on November 17th, 1925.

The report, together with suggestions from councillors, and from the Board of Examiners and Education, was then fully considered, discussed, and adopted.

In accordance with the By-laws the amendments proposed are herewith submitted to the membership and will come before the Annual Meeting for discussion. After such discussion the changes will in due course be submitted to the corporate membership for vote by letter ballot, as required by the By-laws. Particulars of the proposed changes follow:—

Section 8. Amend paragraph two to read:—

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

Section 9. Amend paragraph two to read:—

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

Section 10. Amend to read:—

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

Section 16.

Line 13: Delete all words after "for their approval" to end of paragraph, and insert: "He, or in the case of his absence or inability to act, the Treasurer, together with any one member of the Finance Committee, shall have authority on behalf of *The Institute*, to draw, accept, sign, make and agree to pay all or any bills of exchange, promissory notes, cheques and orders for the payment of money."

Section 17. Amend paragraph two to read:—

He shall attend meetings of Council and shall prepare and present annually to the Council in time for the Annual General Meeting a financial statement, as of the 31st December, of the affairs of *The Institute*. He shall furnish from time to time such other reports as may be prescribed.

Section 30. Amend to read:—

On the admission of a candidate, he shall be notified by the Secretary and he shall then be entitled to the privileges of membership. Membership shall date from the date of admission.

NOTE:—This amendment to Section 30 seems desirable in order to agree with a recent decision of Council proposing that the entrance fees of applicants shall accompany their applications for admission. This will involve a re-arrangement of the admission forms, the present forms A and D being replaced by a new one containing the essential provisions of both. See also the proposed amendments to Sections 33 to 36.

Section 32.

NOTE:—In accordance with the recommendations of the Legislation and By-laws Committee and the advice of counsel, it is proposed to delete the matter now printed on pages 22 and 23 of the Year Book, following immediately after the Code of Ethics, and to embody the essential features of this material in an amended Section 32.

Section 32. Amend to read:—

Expulsion and Discipline

(*a*) The Council shall have the right to expel from *The Institute* any corporate or non-corporate member who may be convicted by a competent tribunal, of felony, embezzlement, larceny, misdemeanour, or other offence which in the opinion of the Council renders him unfit to be a member. Such expulsion shall be effected by causing the name of such member to be erased from the register of members, and such member shall not be entitled to receive previous notice of such expulsion, but upon such expulsion shall be notified in writing by the Secretary to that effect.

(*b*) If, in the opinion of Council, any corporate or non-corporate member be guilty of a breach of the Code of Ethics adopted by *The Institute*, or have acted in a manner unbecoming to a member of *The Institute*, or in a manner detrimental to the character, reputation or interests of *The Institute*, or adverse to the objects of *The Institute*, the Council may discipline such offending member by:

1. Censuring such member in writing by letter addressed to him by the Secretary or by having such member appear in person before the Council for the purpose of receiving such censure, or;
2. Suspending the membership of such member for such length of time as the Council sees fit, or;
3. Causing the name of such member to be erased from the register and thereby expelling him from *The Institute*.

Any enquiry or investigation with a view to disciplining a member as aforesaid, may be instituted by the Council at any time by its own action, or upon the complaint in writing of any member or members, addressed to the Secretary, who shall submit the same for consideration to Council at its next meeting, and such enquiry and investigation shall be conducted in such a manner and to such extent and at such time or times as the Council may in its absolute discretion decide. No verbal or anonymous complaint against any corporate or non-corporate member shall be considered or acted upon by the Council. If the Council be of the opinion that any complaint is trivial and not of sufficient gravity or importance to justify an enquiry, the Secretary shall notify the complaining member to that effect, and the Council shall not be obliged to take any further action in regard thereto and no further record shall appear in the minutes.

No disciplinary action as aforesaid shall be taken by Council unless the same has been approved by the affirmative vote of at least three-fourths of the members of the Council present at a meeting specially called for the purpose of considering the same, and at which at least twelve members of the Council are present. Should the complaining member or offending member be a member of Council, he shall not act as a member of Council at any such enquiry or vote on any matter relating thereto.

Any member, whose conduct or action is to be made the subject of enquiry with a view to disciplinary action as aforesaid, shall be entitled to be notified by the Secretary by registered letter addressed to his last known place of residence and specifying the nature of the charges against him, and before any such disciplinary action is taken by Council, such offending member shall be given a fair opportunity of being heard by Council, either by appearing in person before it, or, subject to the approval of Council, by submitting to the Council a sworn statement in writing addressed to the Secretary.

If the Council, after holding an enquiry, decides to take disciplinary action, the same shall be duly recorded and the offending member notified in writing thereof by the Secretary.

Section 33. Amend the first two lines to read:—

The entrance fees, payable at the time of application for admission to *The Institute*, shall be as follows:

New *Section 34.* Present Section 37 to be renumbered Section 34 and amended to read:—

Section 34. All annual fees shall be due and payable on the first of January for the calendar year then commencing, at which time a bill for the sum shall be mailed to each member, in accordance with the following Schedules of Fees:—

Present *Section 34* to be renumbered Section 35 and amended to read:—

Schedules of Fees

Section 35. The annual fees payable by Montreal Branch Residents shall be as follows:—

		If paid on or before March 31st.
Members	$14.00	$13.00
Associate Members	11.00	10.00
Juniors	7.00	6.00
Students	2.00	1.00
Affiliates	11.00	10.00

The annual fees payable by all other Branch Residents shall be as follows:—

Members	$11.00	$10.00
Associate Members	9.00	8.00
Juniors	5.00	4.00
Students	2.00	1.00
Affiliates	11.00	10.00

The annual fees payable by Branch Non-Residents and Non-Residents shall be as follows:—

Members	$ 9.00	$ 8.00
Associate Members	7.00	6.00
Juniors	4.00	3.00
Students	2.00	1.00
Affiliates	11.00	10.00

Honorary Members shall be exempt from annual fees.

In accordance with the above schedules, if paid on or before March 31st of the current year, a deduction of one dollar will be allowed on the annual fees of all grades.

Section 35. Present Section 35 to be renumbered Section 36 and amended to read:—

Section 36. Members elected after the thirtieth day of June shall be liable for only one half of the annual fees for that year, with a deduction of fifty cents if paid within one month of notification of admission.

Present *Section 36* to be renumbered Section 37.

Section 38. Amend the first paragraph to read:—

The Secretary shall notify any members whose fees become in arrears. No members shall be considered in arrears for any year until after the thirty-first day of March of that year. On the first day of January next following, six per cent per annum shall be added as interest on the subscriptions in arrears, and the same sum shall be added on the first day of January of each year until the said arrears are paid. No member who is in arrears after June thirtieth shall have the right to vote, nor shall he receive the publications of *The Institute.*

Section 52. Amend to read:—

Each Branch shall be managed by an Executive Committee which shall include:—

(*a*) A chairman, secretary and treasurer, and not less than three other members, all to be known as elected members and to be ballotted for by all members of the Branch entitled to vote at Branch elections.

(*b*) Those members of Council resident within the jurisdiction of the Branch, to be known as ex-officio members, and

(*c*) The immediate past-chairman and the immediate past-secretary of the Branch, to be known as members emeriti, these latter to be members for only the year immediately following their term of office.

Section 53. Delete the second paragraph beginning "The chairman" and ending "election".

Highway Development in Canada

The trend of the development of highways in relation to motor transportation has recently been the subject of addresses delivered to several Branches of *The Institute,* and is a matter of active public interest at the present time.

It will be dealt with in a timely paper to be presented at the forthcoming General Professional Meeting in Toronto, and is treated in a brief but comprehensive manner in Bulletin No. 7, recently issued by the Highway Branch, Department of Railways and Canals.

It is a commonplace to say that the progress and development of the country are intimately bound up with its transportation systems, and of these the network of improved highways and subsidiary roads which is gradually covering the country has perhaps the closest contact with the life of the general public. An idea of the magnitude of the financial questions involved may be gleaned when it is pointed out that in the open southern sections of Canada no less than 220,000 miles of earth roads remain unimproved. These alone involve an ultimate expenditure exceeding two hundred million dollars.

Since 1919, when the Canada Highways Act was passed, the primary highway systems in all provinces have been developed along definite lines, under the guidance of the Provincial Highway Departments, and with the co-operation of the Highways Branch of the Dominion Government. Federal contributions to Provincial Highway Funds during this time have aggregated approximately twenty million dollars ($20,000,000.), and the length of the main trunk and market roads, approved as being eligible for this aid, amounts to nearly twenty-five thousand miles.

The profound influence of highway development upon the daily life of the people has been manifested in many directions, among which, to cite only a few instances, may be named the rise and rejuvenation of villages located on primary highways; the improvement in rural education, resulting from the possibility of consolidating and thus improving rural schools; the marked reduction which has taken place in the cost of hauling farm produce to the shipping point, and the knowledge of their own country which is being obtained by the thousands of Canadians who use our newly developed highway systems for tourist purposes.

Members who were at the Banff meeting in July last were particularly impressed by the constant stream of cars, Canadian as well as American, entering and leaving the automobile camping ground close beside the E.I.C. camp.

The dissemination of authentic information on highway questions is an important function, not only of interested bodies like *The Engineering Institute of Canada,* the various Provincial Motor Leagues, and the Canadian Good Roads Association, but also of the Federal and Provincial Highways Departments.

OBITUARIES

William R. Butler, M.E.I.C.

Members of *The Institute* will read with regret of the death in England, of Professor W. R. Butler, M.E.I.C., for many years professor of civil engineering and architecture at the Royal Military College, Kingston. The late Professor Butler was born in England in 1852. He graduated from Kings College, Windsor, N. S., with the degree of Bachelor of Engineering in 1879. From 1880-1881 he was engaged as assistant engineer under Messrs. Watson, Smith and Watson of London, England on construction of the Swindon, Marlborough and Andover Railway. Coming to Canada again in 1881, he was elected professor of engineering at Kings College, Windsor, N. S., which position he held until he was appointed professor of civil engineering and architecture at the Royal Military College. Kingston, in 1897. Professor Butler retired from the Royal Military College in 1915 and returned to England where he remained until his death. The late Prof. Butler had been a member of *The Institute* since its inception, having been admitted as Member on January 20th, 1887.

Richmond Hersey Cushing, M.E.I.C.

Sincere regret is expressed at the death of Richmond Hersey Cushing, M.E.I.C., former city engineer of St. John, N. B., which occurred at his home in West St. John on December 7th, 1925. The late Mr. Cushing was born in St. John, N. B. on May 8th, 1854. After finishing his grammar school course in St. John he studied Civil Engineering at the Massachusetts Institute of Technology from 1871-1875.

During the years 1880-82 he was engineer of the Grand Southern Railway, now called the Shore Line, between West St. John and St. Stephen. He then joined the staff of the European and North American Railway, in Nova Scotia, being located on the Oxford-Pugwash branch in 1882 and the Patterson Pt. Pictou Branch the following year. In 1884 he was located in Prince Edward Island on the Cape Traverse Branch and the next year was employed with the Intercolonial Railway. In 1886 he did considerable work for the Moncton-Buctouche Branch line and during 1887 was construction engineer on the Pictou-Truro line. In 1888 he commenced his duties as Chief Engineer of the Oxford-New Glasgow Railway and continued in their service until 1893. On the completion of this line he moved to the state of Maine and was employed as construction engineer on the Bangor and Aroostook Railway, until 1899. During the two years following he resumed work with the I. C. R. being located in St. John, and it was during this time that he was engineer on the construction of the I. C. R. elevator and conveyor system, Long Wharf, and other terminal facilities.

RICHMOND HERSEY CUSHING, M.E.I.C.

In April 1901 he was appointed Director of Public Works of St. John continuing these duties for six years, during which time he superintended extensive improvements to the harbour, water-works, ferry, sewerage system, etc. In 1908 he was appointed Division Engineer on the Transcontinental Railway, being in charge of the construction of this line between Moncton and Edmundston, N. B. On the completion of this work in June 1913 he was employed until December 1913, on the Ocean Terminals at Halifax.

During the next five years he superintended the construction of several large dock improvements in and around St. John. In March 1921, he began his duties as right-of-way and claims agent for the New Brunswick Electric Power Commission and continued in their employ until the time of his death.

Referring to the death of Mr. Cushing the St. John Globe in its editional column, under the heading "A Public Loss" says in part:

"Much of the active life of R. H. Cushing, C. E., was given to the public service and most faithfully and loyally did he serve the public. As engineer in the Department of Public Works of the city he had an important part in planning and carrying to completion much of the harbor development work, particularly at West Saint John."

Major H. Graham Starr, A.M.E.I.C.

It is with regret that we record the death of Major H. Graham Starr, A.M.E.I.C., which occurred at Christie Street Hospital, Toronto, on Wednesday, December 9th., 1925. The late Major Starr was born at Maple, Ontario, on August 14th, 1883. He received his early education at Royal Military College, Kingston, from which he graduated in 1905, and the same year he was field draughtsman with the Canadian Pacific Railway Company. Three years after he was engineer in charge of the Gowganda and Montreal River Mines Limited. In 1909 he rejoined the Canadian Pacific Railway Company on the staff of the right-of-way department; the following two years he was with the Kettle Valley Railway, first as assistant locating engineer and later as resident engineer. He enlisted for overseas service in 1915 in the 84th Infantry Battalion, C.E.F., with which he was lieutenant. He later received his captaincy and was appointed adjutant in November of that year. He went overseas with the unit in June, 1916, and served with distinction in France and was wounded and invalided home in March 1918. The late Major Starr was admitted to *The Institute* as Student on January 11th, 1906, and was transferred to Associate Member on May 13th, 1913.

PERSONALS

T. M. S. Kingston, S.E.I.C., is located in Buffalo, N.Y., with the E. P. Muntz Company, engineers and contractors.

R. H. Cratchley, Jr. E.I.C., has accepted a position as draughtsman-designer with the Consumers Gas Company of Toronto.

J. D. Peart, A.M.E.I.C., of the Northern Electric Company has been transferred by the company from Montreal to their Winnipeg office.

F. H. Job, Jr. E.I.C., is located at Pittsburgh, Pa., on the engineering staff of the Koppers Construction Company. Mr. Job was for some time structural draughtsman with the Hamilton Bridge Works, Hamilton, Ontario.

C. F. Phipps, S.E.I.C., who graduated from McGill University in 1924, since which time he has been with the North Shore Power Company at Three Rivers, Quebec, has been moved to Shawinigan Falls, Quebec, with the Shawinigan Water and Power Company.

K. H. Smith, M.E.I.C., has resigned as chief engineer of the Nova Scotia Power Commission with which he has been connected since its inception. Mr. Smith's future plans are not sufficiently matured to warrant any statement at the present time.

Major Geo. A. Walkem, M.E.I.C., of Vancouver, formerly vice-president of *The Institute*, who has been nominated for the presidency of *The Institute* for the coming year, was elected president of the Association of Professional Engineers of the Province of British Columbia at the annual meeting in Vancouver this month.

Donald G. Robertson, Jr. E.I.C., who, since graduating from Queen's University in 1924, has been with the Southern Canada Power Company in connection with the construction of their power development at Hemmings Falls, Drummondville, Quebec, has joined the engineering staff of the Riordon Pulp Corporation at Temiskaming, Que.

S. C. Wolfe, A.M.E.I.C., is located at Detroit, Michigan with the C. O. Barton Company, general contractors. Mr. Wolfe was, for a number of years with Messrs. Lockwood Greene and Company of Canada, Limited, as office engineer in charge of design, draughting, and all office work on contracts, payments and records. He was also for a time engaged in contracting work in Montreal.

Thos. H. Winter, Jr.E.I.C., of St. John's, Newfoundland, who has, until recently, been located at Corner Brook, Newfoundland has joined the government engineering staff at St. John's. Mr. Winter is a graduate of Kings College, Windsor, Nova Scotia, and of the Nova Scotia Technical College, from which he received the degree of B.Sc., in 1923. At Corner Brook he occupied the position of chief assistant to engineer in charge of pipe line and forebay construction with the Sir W. G. Armstrong, Whitworth and Company Limited.

Institute Members on Hydrographic Surveys

The following members of the Canadian Hydrographic and Tidal and Current Surveys of the Marine Department have recently returned from a successful season's work in carrying on the charting of the coastal waters and trade routes on the Atlantic and Pacific seaboards, the headquarters at Ottawa and Victoria,—R. J. Fraser, A.M.E.I.C., in charge of the Survey Steamer "Cartier" and the Gulf of St. Lawrence transatlantic route; M. A. MacKinnon, A.M.E.I.C., and Norman Wilson, A.M.E.I.C., both connected with the same survey; J. L. Foreman, A.M.E.I.C., engaged in charting work along the coasts of Nova Scotia. H. D. Parizeau, A.M.E.I.C., of the Victoria Branch of *The Institute*, who has been charting for the past eight months with the Survey Steamer "Lilloett" on the Pacific, has laid up his vessel and is wintering at Victoria. Chas. A. Price, A.M.E.I.C., in charge of the automatic gauge division of the Hydrographic Surveys, has returned from a season's tour of inspection of gauging stations from Quebec to Port Arthur. H. W. Jones, M.E.I.C., in charge of the Atlantic tidal division, has recently completed two years' tidal work on the currents of the strait of Canso, and returned to Ottawa.

E. H. James, A.M.E.I.C., Enters Partnership

A. D. Swan, M.E.I.C., consulting engineer, Montreal, has announced that he has taken E. H. James, A.M.E.I.C., into partnership.

Mr. James has been resident engineer on the design and construction of new harbour works at Vancouver, B.C., during the last six years to the value of about ten million dollars, the work consisting of reinforced concrete piers, a drydock and the railway and vehicular bridge across the harbour. Mr. James previous to this has had extensive experience in dock and harbour, bridge and foundation work, including foundations under heavy air pressure, and has also had valuable experience in connection with arbitrations and legal proceedings involving engineering.

For the time being the name of the firm will remain as before.

A. D. Swan has had thirty years' experience in the design, construction and management of large public works. Many years ago Mr. Swan was resident engineer in charge of the design and construction of the new wet dock and graving dock at Avonmouth, England.

Mr. Swan was assistant chief engineer to the Montreal Harbour Commissioners from January 1909 to May 1913, and supervised the design and construction of new harbour works there during that period. In 1912 he reported on the general conditions and future development of the port of Vancouver, B.C., and prepared plans for same for the Dominion government and has since that time been continuously interested in work there. He was appointed consulting engineer to the Harbour Commissioners in February, 1914, and designed and supervised construction of the Ballantyne pier and other works.

Mr. Swan was one of a commission of three engineers appointed to select a site for a new drydock at Levis, Quebec. He was consulting engineer to the contractors for the new harbour works at Halifax, N.S., also at St. John, N.B., and other ports. During 1914, he was engaged by an English company to select sites, report on and prepare plans and estimates for three harbours and railway terminals on the west coast of South America. He prepared plans for new wharves and shipping facilities for handling pulp and paper at Newfoundland. He designed and constructed the drydock piers and basin for Canadian Vickers, at Montreal. He was retained as consulting engineer and prepared plans for a proposed new drydock at Halifax for Wm. Beardmore and Company, Glasgow.

For the last four years Mr. Swan has been consulting engineer for the contractors on the construction of the large new drydock at Esquimalt, B.C. He designed and supervised the construction of the new drydock works at North Vancouver, B.C., and is consulting engineer for the new drydock at St. John's, Nfld., now under construction.

He was consulting engineer and prepared designs for new wharves for the International Paper Company at Three Rivers, Quebec, and prepared complete schemes for new harbour development on behalf of the Marine and Fisheries Department at Three Rivers.

He was consulting engineer for a large railway and traffic bridge across the harbour at Vancouver, B.C., for the Burrard Inlet Tunnel and Bridge Company, Ltd., and has been engaged on many arbitrations and legal cases concerning dock works in different countries.

Harold S. Johnston, M.E.I.C., Appointed Chief Engineer

Harold S. Johnston, M.E.I.C., who has recently been appointed chief engineer of the Nova Scotia Power Commission, is a graduate of McGill University, from which he received the degree of B.Sc., and since graduating, has had extensive experience in hydro-electric development work in the provinces of Ontario, Alberta and Nova Scotia.

Mr. Johnston is a native of Gananoque, Ont., where he was born in 1885 and where he received his early education. Following graduation from McGill University in 1909, he was assistant engineer on the hydro-electric development at Nipissing, in the following January taking a similar position on the 19,500 h.p. plant for the Calgary Power Company and after four years with this company, he became engineer and superintendent of construction for the Department of the Interior on the installation of water mains and the design and installation of intake works in connection with storage propositions for the Department of the Interior and the Calgary Power Company.

HAROLD S. JOHNSTON, M.E.I.C.

In March, 1920, Mr. Johnston was appointed hydraulic engineer for the Nova Scotia Power Commission, associated with K. H. Smith, M.E.I.C., chief engineer, to whose activities the Nova Scotia Power Commission may be said to owe its existence, and from which same activities and his great executive abilities, the province of Nova Scotia has so much benefited.

Mr. Johnston has been intimately associated with the development of the Commission, and is responsible for the design and construction of the 5,550-h.p. and 6,580-h.p. Malay and Ruth Falls developments of the Sheet Harbour system, and other considerable hydro-electric developments in general.

Through the resignation of Mr. Smith, Mr. Johnston now becomes chief engineer, and will be most ably assisted by J. F. Lumsden, M.E.I.C., formerly electrical engineer, who has been appointed assistant chief engineer.

It is believed that an era is opening for Nova Scotia which will be marked by an increasing industrial development, in one department of which development at least,—the pulp and paper industry,—the Nova Scotia Power Commission may be expected to play a considerable part through the development of the province's hydro-electric resources. Mr. Johnston, therefore, enters upon his increased responsibilities, with a full sense of the foundation laid by the former chief engineer, and a belief that there will be increasing benefit to the province in the Commission's activities.

EMPLOYMENT BUREAU

Situation Vacant

TRANSITMAN

Wanted transitman for logging operations, technical graduate, single, under thirty, healthy, a worker experienced on bush surveys winter and summer, willing to learn logging operations and French. For such a man a well known company offers fine future. Apply box No. 149-V.

Situation Wanted

DESIGNING AND CONSTRUCTION ENGINEER

A.M.E.I.C., age 39, with extensive experience in design and construction of power transmission, mine and smelter installations, pulp and paper mill design estimating and sales of structural steel, desires position, full details of experience will be supplied on request. Apply Box No. 201-W.

ELECTIONS AND TRANSFERS

At the meeting of Council held on December 22nd, 1925, the following elections and transfers were effected:

Member

DARLING, Edward, B.Sc. (McGill Univ.), pres. and gen. mgr., Darling Bros. Ltd., Montreal, Que.

Associate Member

DICKENSON, George Newton, Brevet Capt., R.C.E., asst. works officer, Military District No. 6, Halifax. N.S.

Juniors

CUSHING, Richmond Hersey, Jr., transitman, N.B. Electric Power Commission, St. John, N. B.

GRAY, Maxim Theodore, i/c of constrn. engr. with Geo. C. Diehl Inc. of Buffalo, at Williamsville, N. Y.

Transferred from the class of Student to that of Associate Member

BIGGAR, Percival Elliot, B.Sc. (McGill Univ.), consltg. on development work to Attendu Engines (England), on loan from Eastern Engineering Company, Montreal, Que.

MAHAFFY, Herbert Laurence, B.Sc. (McGill Univ.), acting chief of inspection dept., J. T. Donald & Co. Ltd., Montreal, Que.

McCLINTOCK, George Arthur, B.A.Sc. (Univ. of Tor.), engr. for Keasberg & Mattison Co., Bell Asbestos Mines Dept., Thetford Mines, Que.

Transferred from the class of Student to that of Junior

BARRETT, Andrew Grant, B.Sc. (Queen's Univ.), field engr. for Canadian Johns Manville Co., Asbestos, Que.

CHISHOLM, Joseph Donald, B.Sc. (McGill Univ.), elect'l. design office, Nfld. Power and Paper Co. Ltd., Corner Brook, Nfld.

COPPING, Allan Blythe, B.Sc. (McGill Univ.), technical asst. to sulphite supt., paper mill technical work, tech. service dept., DeGrasse Paper Co., Pyrites, N. Y.

CRAWFORD, Robert Eric, B.Sc. (McGill Univ.), estimator, paper machinery and hydraulic turbines, Dominion Engineering Works, Montreal, Que.

GUSCOTT, Alfred George, B.A.Sc. (Univ. of Tor.), design and constrn. of water mains, sewers and sidewalks, Town of Leaside, Ont.

LESLIE, Roy Campbell, B.A.Sc., M.A.Sc. (Univ. of Tor.), dftsman., Canadian Bridge Co. Ltd., Walkerville, Ont.

WRIGHT, Joseph Agar, instr'man. on constrn., of Dunblane-Mower Branch, C.N.R., 162 Arlington Street, Winnipeg, Man.

The following students were admitted:—

ARCHAMBAULT, Ubald, 317 de l'Epée Avenue, Outremont, Que.
BOISMENU, Roméo, 419 De St. Valier, Montreal, Que.
CAMPAIGNE, Evan William, Niagara House, Niagara Falls, Ont.
COSTIGAN, James Percival McDougall, 494 Grosvenor Avenue, Westmount, Que.
DUCHASTEL de MONTROUGE, Leon A., 640 Dunlop Avenue, Outremont, Que.
HELWIG, Gerald Vincent, Strathcona Hall, Montreal, Que.
HUTTON, John Robert, 31 Carlton Street, Halifax, N. S.
JOHNSON, Edward Laurence, Strathcona Hall, Montreal, Que.
LALONDE, Jean Paul, 656 de l'Epée Avenue, Outremont, Que.
MATHIEU, Albert, 662 Cadieux, Street, Montreal, Que.

Effect of Size and Shape of Test Specimen on Compressive Strength of Concrete

Data of interest to those engaged in the testing of concrete will be found in Bulletin 16 of the Structural Materials Research Laboratory, Lewis Institute, Chicago, "Effect of Size and Shape of Test Specimen on Compressive Strength of Concrete" by Harrison F. Gonnerman. The report is reprinted from the 1925 Proceedings of the American Society for Testing Materials.

Tests were made on 1755 concrete specimens at ages of 7 days to 1 year in a study of the compressive strength of:

(1) Cylinders 1½ to 10 inches in diameter, 2 diameters long.
(2) Cylinders 12 inches long, 3 to 10 inches in diameter.
(3) Cylinders 6 inches in diameter, 3 to 24 inches long.
(4) Cubes, 6 and 8 inches.
(5) Prisms, 6 by 12 and 8 by 16 inches.

The relative strength of the different forms of specimen was compared with the strength of 6- by 12-inch cylinders from the same concrete.

ANNOUNCEMENT OF MEETINGS

Information may be secured from the secretaries of the various Branches, whose addresses will be found under "Officers of Branches" on page 2 of *The Journal.*

LETHBRIDGE BRANCH:—

Secretary-Treasurer, N. H. Bradley, A.M.E.I.C.

Jan. 9th. Illustrated address on "Technical Education in the Province of Alberta" by A. G. Carpenter.
Jan. 23rd. Illustrated address on "Architecture" by H. M. Whiddington.
Feb. 6th. Address on "Some Phases of the Art of Communication", by A. M. Mitchell, of the Alberta Government Telephones.
Feb. 20th. Address by E. Stansfield, M.E.I.C., of the Research Council of Alberta.

CALGARY BRANCH:—

Secretary-Treasurer, G. P. F. Boese, A.M.E.I.C.

Jan. 6th. Annual Dinner. Entertainment arranged by G. H. Patrick, A.M.E.I.C.
Jan. 28th. Address on "Hydro-Electric Operation Problems" by G. H. Thompson, A.M.E.I.C.
Address on "Turbine Rating Calgary Power Plant" by G. H. Whyte, A.M.E.I.C.
Feb. 9th. Address on "Winnipeg River Power" by C. H. Attwood, A.M.E.I.C.
Feb. 18th. Address on "The Present State of Oil and Gas Development in Western Canada" by S. J. Davis, A.M.E.I.C.
Mar. 2nd. Address on "Beet Sugar" by C. R. Wing.
Mar. 6th. Annual Meeting.

ST. JOHN BRANCH:—

Secretary-Treasurer, W. J. Johnston, A.M.E.I.C.

Jan. 21st. Address on "Radio Direction Finding" by Lt.-Commander C. P. Edwards, O.B.E., A.M.E.I.C., Dept. of Naval Service, Canada.
Feb. 19th. Address on "The Interconnection of High and Low Pressure Turbines" by J. D. Garry, A.M.E.I.C., N.B. Telephone Company.
Mar. 18th. Address on "Aerial Surveying" by A. M. Narraway, A.M.E.I.C., Topographical Surveys Branch. Illustrated.
Apl. 15th. Address on "The Elements of Photography and Correct Colour Rendering" by Prof. E. L. Harvey, M.A., University of New Brunswick.

OTTAWA BRANCH:—

Secretary-Treasurer, F. C. C. Lynch, A.M.E.I.C.

Jan. 14th. Annual Meeting of the Local Branch.
Jan. 21st. Annual Ball, Chateau Laurier.
Feb. 11th. Address "The Founders of Modern Science" by Dr. L. E. Parizeau, of Montreal.

VICTORIA BRANCH:—

Secretary-Treasurer, E. P. Girdwood, M.E.I.C.

Jan. 13th. Address on "Highways on Vancouver Island" by H. M. Bigwood, A.M.E.I.C., and W. P. Beaven, A.M.E.I.C.
Feb. 10th. Address on "Earthquakes" by F. Napier Denison, Supt., Dominion Meteorological Service.
Feb. 17th. Address on "World Flight" by Colonel Brome.
Mar. 3rd. Address on "Manufacture of Cement" by J. H. McIntosh, Jr., British Columbia Cement Co., Bamberton, B.C.
Mar. 9th. Address on "Logging Railways" by C. F. Cooke, A.M.E.I.C.
Mar. 31st. Address on "Pacific Great Eastern Railway" by Thos. Kilpatrick, Manager, Pacific Great Eastern Railway.
April 14th. Address on "Fraser Canyon Section" by Patrick Philip, M.E.I.C., Chief Engr., Dept. of Public Works, Prov. of B.C.
April 17th. Visit to Canada Cement Company, Bamberton, B.C.

MONTREAL BRANCH:—

Secretary-Treasurer, C. K. McLeod, A.M.E.I.C.

Jan. 7th. Address on "Features of Design and Construction of Isle Maligne Station," by W. S. Lee, M.E.I.C.
Jan. 14th. Address on "The Effect of Personnel on Industry", by R. A. C. Henry, M.E.I.C.
Jan. 21st. Address on "Some Problems in Connection with Construction Work at Lake Kenogami.
Jan. 28th. Address on "Pulp and Paper Industry", by H. S. Taylor, M.E.I.C.
Feb. 4th. Student Papers.
Feb. 11th. Address on "Pulverized Fuel" by H. G. Barnhurst, Advisory Engineer, Fuller Lehigh Co.
Feb. 18th. Address on "The History of the Locomotive", by W. A. Newman, Engineer Locomotive Design, C.P.R.
Feb. 25th. Address on "Outside Plant Construction of the Bell Telephone Co. of Canada", by W. H. Winter.
Mar. 4th. Address on "Paper on Metallurgy", by Messrs. Roast and F. Newell, M.E.I.C.
Mar. 11th. Address on "Vancouver Narrow Bridge" by E. H. James, A.M.E.I.C.
Mar. 18th. Symposium of Municipal Papers.
Mar. 25th. Address on "The South Shore Bridge", by P. L. Pratley, M.E.I.C.
April 1st. Address on "Synchronous Converters", by E. B. Shand, Westinghouse Company.
April 8th. Symposium of paper on Cost Accounting.
April 15th. Address on "Hemmings Falls Development", by J. S. H. Wurtele, M.E.I.C.
April 22nd. Address on "Television", by Dr. L. E. Pariseau.
April 29th. Address on "Belgian State Railways", by Mr. Van Bruyssel.
May 6th. Address on "Penal Conditions in Canada", by Col. R. de la B. Girouard.

The Association of Professional Engineers of the Province of British Columbia

ANNUAL MEETING

The Sixth Annual General Meeting of the Association of Professional Engineers of the Province of British Columbia opened on December 5th, 1925, at the Hotel Vancouver, Vancouver, B.C., with a well attended luncheon, at which an interesting address was given by Mr. Campbell Sweeny on the Early History of Engineering in British Columbia. Mr. Sweeny, as an old resident of British Columbia, dealt with the experiences of the early days, commencing with the first passage over the continent on foot, approximately seventy years ago. He brought out the fact of the separation between this part of the country and the eastern parts of Canada due to the Prairies and the mountain barriers further westward, and told how the first overland party left Fort Garry and made the passage by the Yellowhead Pass.

Later, a party of Royal Engineers came under the leadership of Colonel Newton, and many evidences of their work remain to this day. Following the Royal Engineers other men took up development of communications, and the Cariboo and Kootenay trails were opened, while further explorations were undertaken with a view to establishing railroad connections with the eastern parts of the country. This latter project, however, was the subject of long continued argument, but was eventually made one of the terms of confederation; and British Columbia entered confederation with a definite promise from the Central Government at Ottawa for the construction of a Transcontinental Railway.

This railway project was the subject of much controversy, and Alexander MacKenzie when Premier brought forward strong claims for the development of the various water routes with rail connections to form a continuous chain across Canada. This would have involved steamship lines to the end of the chain of Great Lakes, with further connections by way of the various great rivers and short isolated sections of rail, a project which by no means met with the approval of the residents of British Columbia. Shortly after this Sir John A. MacDonald returned to power as Premier, the construction of a Transcontinental Railroad was actually decided upon, and definite explorations and surveys were commenced with this complete scheme in view. Many engineers whose names have since become famous were connected with the project—Sanford Fleming being in charge, and having Collingwood Schreiber, Marcus Smith, H. J. Cambie, M.E.I.C., and many others as colleagues and associates. The original surveys for the line entered British Columbia by way of the Yellowhead Pass, a route which has always been admitted to be the best available, both from the view of construction costs and the lower operating costs offered by the easy grades of that pass. The Canadian Pacific Railway, however, was formed at about this time to undertake the construction of the road, and for reasons satisfactory to those in charge of the company, it was eventually decided to get as far south as possible, and the Kicking Horse Pass was selected as the route. The entry to this Pass is comparatively easy, but the great difficulty found in developing this route was in getting down out of it on the western side, and in the crossing of the Selkirk Range. For a considerable time the Selkirks offered an almost insuperable barrier. However, a route was at length found by Major Rogers and Walter Moberly through the Pass now known as Rogers Pass.

The speaker then outlined the rapid changes that followed the connection of the Western Coast of Canada by rail with the Eastern Cities, and dwelt on the opening up of the mining districts; the utilization of water power, both in the interior and on the coast; and the marvellous commercial development which has occurred in the Vancouver area as the terminal of the railways, favoured as it is with such a fine harbour as Burrard Inlet.

In concluding his address Mr. Sweeny paid a graceful tribute to the part played by the engineering fraternity in all these developments.

The Annual Business Meeting of the Association, which was held in the afternoon was presided over by Mr. Patrick Philip, M.E.I.C., Deputy Minister of Public Works of British Columbia, President of the Association. Mr. Philip in his opening address welcomed the out-of-town members and gave a general résumé of the work of the Association

Association of Professional Engineers of B.C.,— Officers and Council for 1925.

Sitting — Left to Right:

A. S. WOOTTON, M.E.I.C.; Engineer, Board of Park Commissioners;

FRANK SAWFORD, Member of Council 1923 and 1924; Vice-President of Council 1925; Consulting Electrical and Mechanical Engineer;

E. G. MATHESON, M.E.I.C.; First President of Association (1920), Member of Council 1921, 1922, 1923, 1924, 1925; Professor of Civil Engineering University of B. C.; Consulting Engineer;

J. F. FREW, M.E.I.C.; Consulting Engineer; Designing Plant Engineer; Vice-President 1926;

PATRICK PHILIP, M.E.I.C.; Member of Council 1923; Vice-President 1924; President 1925; Deputy Minister and Chief Engineer, Public Works Dept. (B. C.);

E. A. WHEATLEY, Capt. — M.C.; A.M.E.I.C., Registrar and Secretary-Treasurer.

Standing — Left to Right:

G. S. ELDRIDGE, M.E.I.C.; Engineer of Way, B.C. Electric Railway Co., Vancouver, B.C.

C. A. BANKS, Consulting and Metallurgical Engineer, representing the Selukwe Gold Mining & Finance Co. of London; Managing Director British Canadian Silver Corporation, Ltd.; President and Managing Director B.C. Silver Mines, Ltd.

J. MUIRHEAD, M.E.I.C.; Chief Inspector Electrical Engineering, Provincial Government; Member of Council 1921, 1922, 1923, 1924 and 1925; now Consulting Engineer, 630 Birks Bldg., Vancouver, B.C.

Absent:

E. E. BRYDONE-JACK, M.E.I.C.; Member of Council (1923 and 1925); President of Association 1924; Supervising Engineer, Department Public Works Canada, Western Provinces.

W. L. UGLOW, Ph.D.; Member of Council 1924-1925; Professor Mineralogy and Petrology, University of B.C.

Council during the past year. He referred especially to the Secretary's visit to centers in the interior of British Columbia, and to his attendance at the Western meeting of *The Engineering Institute of Canada* at Banff. He drew attention also to the very responsible duties of the Council and urged the membership to use care in their choice of those who are to fill the places of the retiring Council. He also reviewed the various amendments to the Engineering Act which have been passed through the Legislative Assembly during the past year, and extended the thanks of the Association to Mr. Geo. A. Walkem, M.L.A., M.E.I.C., a member of the Association, for his work as sponsor of the amendments.

The visit of R. J. Durley, M.E.I.C. Secretary of *The Engineering Institute of Canada*, was also referred to and Mr. Philip stated that there was a very happy tendency towards closer co-operation between the Association and *The Engineering Institute*. The Secretary has been authorized to attend a joint meeting of the Professional Associations early in the coming year. It is hoped that a closer co-operation between the various corporations throughout Canada will result from this conference.

The President also spoke of the good work done during the year by the Business Committee. He believed that the prospects for the future of the profession were now very encouraging and urged especially that all traces of professional jealousy between engineers should disappear and that all should work amicably together.

Kindly reference was made to late Colonel T.H. Tracy, M.E.I.C., and late H. M. Burwell, M.E.I.C., whose deaths occurred during the year.

Following the President's address, Captain E. A. Wheatley, A.M.E.I.C., Registrar of the Association was called upon to make his report.

Captain Wheatley stated that 1925 had been a memorable year in the history of the Association. The first four years of its operation had required great courage and persistence, but it was felt that at last something had been really accomplished, that the tide had turned, and that the Association was now on the way to more satisfactory recognition.

Captain Wheatley referred especially to the amendment to the Engineering Act which had recently been obtained, which, from a legal standpoint, had definitely changed the status of the profession.

As regards the Business Committee, with the new system of weekly meetings, it was now possible to get important business through in from two to three weeks, with the result of a great improvement in the general efficiency of the Association's operations.

The work of the Employment Department had been very successful during the year and he called upon the members to assist him in this branch of the Association's work by sending in enquiries and notifications of vacancies at as early a date as possible in the season.

In a forecast of the work which will require the attention of the 1926 Council, Captain Wheatley mentioned the forthcoming meeting of representatives of all the Professional Engineering Associations of Canada. A considerable amount of work was outlined also as coming before the Legislation Committee. This will include suggested amendments to the Electrical Inspection Act; the Interpretations Act; the Railway Act and to the Engineering Profession Act. Certain changes in the administration of the Association were brought forward as desirable, particularly the suggestion that members of Council should be elected for terms of two or three years, with an annual election,— thus only a part of the Council would retire annually, so that the Association would not suffer the loss of experience of the members of Council by a complete change in personnel each year as may easily be the case under the present system.

Captain Wheatley referred especially to the growth of what he called "Professional Consciousness" among the membership, which he described as the guidance of personal action by a sense of duty to the profession as a whole. The construction of the Pacific Highway, which is one of the largest pieces of work in hand at present in British Columbia, was cited as a special instance of this. Throughout this work, from location onwards, the entire project has been under the direction of qualified professional engineers, and those in charge of the work have not failed to draw the attention of the authorities in a tactful manner to the great advantages resulting from this careful supervision.

Great encouragement has also been given to students and engineers-in-training, for whom employment has been found, and who have expressed pleasure and satisfaction with the work of the Association on their behalf.

Following these two addresses, there was a general discussion of various subjects of interest, including the work of the Legislation Committee; questions of annual fees; qualifications for membership; and reciprocity with other associations. An official announcement was made of the elections for the ensuing year, — the elected members for the Council to be as follows:

President	— Geo. A. Walkem, M.E.I.C.,
Vice-President	— J. F. Frew, M.E.I.C.,
Council	— Chas. Brakenridge, M.E.I.C.,
	J. D. Galloway;
	G. S. Eldridge;
	A. S. Wootton, M.E.I.C.

The meeting concluded with a vote of thanks to the President and members of the outgoing Council, and to the Registrar.

The Electric Audiphone

The advances made in telephony during the past few years have been remarkable, not only for the distances spanned, but for the variety of uses to which audio-electrical science has been turned.

The telephone engineer has now turned his ingenuity to correcting subnormal hearing, and has promised a device which will enable the deaf to communicate responsively with their more fortunate fellows.

The appliance, in a general way, resembles the amplifier familiar to the radio fan, and is known technically as the Northern Electric Audiphone.

It is an electrical circuit, employing vacuum tubes with transformers designed for the audible frequencies. The apparatus, together with the required dry-cells, is packed into a small carrying case, in appearance like the box-type kodaks.

A microphone, hardly larger than a fifty-cent piece, built on the principles of the microphones used in broadcasting stations, serves to gather the sound and transmit it to the amplifier.

From the amplifier, the amplified sound is carried by a silk-covered wire to an ear-piece of novel design, molded from a plaster cast to fit exactly the crypt or small cavity of the ear. This renders it inconspicuous since it dispenses with usual head-band, and also, by its close contact with the ear excludes sounds other than those picked up by the microphone.

For those whose hearing is not so deficient as to require a high degree of amplification, a similar instrument is being made without the vacuum tubes and electric batteries.

At present there are only a few demonstration models of the instrument in existence, but if present plans mature, production on a commercial scale will begin in Montreal in the near future.

Abstracts of Papers read before the Branches

The New Diesel Electric Car

C. E. Brooks, Chief of Motive Power,

Canadian National Railways, Montreal, Que.

Ottawa Branch, November 26th, 1925.

Mr. Brooks referred to vicissitudes attendant upon railway transportation in these days. "In building railways," he said, "it is not always possible to go through the largest seats of population, or to follow the most favourable routes, owing to difficulties of land conformation."

One of the results referred to by Mr. Brooks was the springing up of bus lines between small towns and villages half a mile or so from the railroad. "These lines operate as long as it pays them, and then drop out of business, leaving local branch lines to handle the traffic. I do not think that the general public understands just what this sort of thing means to a railway. "The legislation which permits such companies, some of which I have referred to as wild-cat organizations, always is exceedingly busy in prosecuting the railways for any slight breach of regulations," Mr. Brooks complained. "There is no doubt that for general purposes most of our trains to-day are over-manned. Unit cars would solve this problem in many instances, and labor must realize the necessity of adopting this form of economy."

Mr. Brooks outlined some measures adopted to meet adverse considerations. He referred to criticism, much of it unjust, levelled at steam operation, particularly by those interested in electric engines. He admitted disadvantages of steam as a mode of transportation; loss of thermal heat, limitations of boilers, inability to carry around sufficient power to meet all hindrances.

As to a storage battery car, he referred to loss of time, which could not be avoided without serious damage to the expensive batteries.

The next attempt was an experiment with gasoline engines. Much had been accomplished by these, useful and efficient gasoline units having been employed with striking success in different places. Inability, however, on the part of the ordinary crews to handle efficiently these intricate gasoline electric units had brought about their gradual elimination.

Difficulty was also experienced with inferior quality and too high price of gasoline. In parts of the United States residual oils had been used with a certain amount of success.

A commission also was sent to Sweden, where it was found that the Diesel electric equipment had been successfully used. Here, however, it was discovered that too great weight proved a handicap. This formed the subject of investigation, and useful research work was done and had satisfactory results.

Mr. Brooks referred to encouraging results of the tests performed with Diesel cars. In spite of optimistic press reports, he did not think that the public yet were fully alive to the possibility of the cars. Much adverse criticism, most of which was unfair, had been published and the optimism warranted was not yet apparent.

"We have been able to cut down the cost of fuel to one-quarter of that under the old steam and coal method," he said: "The test recently completed was not with a view to publicity, but as an endurance test, purely and simply. We felt that if over that 2,900 miles we could demonstrate its practicability then the general public must be convinced."

Mr. Brooks quoted figures to show the relative cost of operating expenses of the steam engine with coal fuel and the new type of car, and these showed a tremendous saving; in addition to which Mr. Brooks explained that the staff could be reduced to an efficiency limit.

"Our experience has taught us," Mr. Brooks said, amidst laughter, "that the general public will stand a lot of vibration on the highway and even in their homes, but if they encounter it on the railroad there is the very devil to pay right away."

In conclusion, Mr. Brooks spoke optimistically of the future of the electric cars, and thanked the president and members of *The Engineering Institute* for the opportunity given him to explain the working advantages of the new type of car. He also expressed the opinion that, did the public understand the magnitude of the problem being tackled by the C.N.R. in a matter which concerned them so closely, they would be more helpful with sympathetic suggestions and constructive criticism than they had been in the past and less ready to heap abuse on the heads of the railroad officials.

Mr. A. B. E. Chorlton, representing Messrs. Beardmore, the designers of the new engine, then addressed the meeting. At the outset, he passed an eloquent tribute on the ability and public spirit of Mr. Brooks.

"You will find," Mr. Chorlton prophesied, "that the development in these cars proceeds far more rapidly than you dream of. Success has been so noteworthy that their future is assured."

Mr. Chorlton gave the credit of original discovery of the system of feeding and ignition which resulted in the modern engine to an Englishman named Akroyd Stewart, whose constant volume explosive cycle engine was really the forerunner of the new engine, although it was termed the Diesel engine. Development of the Akroyd Stewart car, however, was slow and it was only towards the end of the war that its value and practicability was established.

Operation and Maintenance of Lethbridge Northern Irrigation Project

P. M. Sauder, M.E.I.C., Project Manager,

Lethbridge Northern Irrigation District, Lethbridge, Alta.

Calgary Branch, November 26th, 1925.

In his remarks Mr. Sauder referred to a few statistics of the project, stating that there were 104,000 irrigable acres in all, 48,000 of which were irrigated up to the present. The water is taken from the Old Man river and delivered to the Keho reservoir, which latter has proved its worth as a balancing factor in the system on several occasions of excessive flood conditions. The dam at this headwork is 6½ feet high by 524 feet in length, and is constructed on a gravel bed. The main canal is designed to carry 800 cubic-feet per second, including losses by seepage and evaporation. The land is covered by 18 inches of water in an irrigating season, and the velocity of the flow in the main canals is 2.75 feet per second.

He dealt with his subject in a concise manner following out the different points from construction to operation very clearly. He referred to the concrete headgates with their "Stony" sluicegates which can be operated by one man; also the two river crossings of wooden stave syphons, 10½ feet in diameter, 3,000 feet and 950 feet long.

He then described the manner in which the district was served through main canals, branch, secondary, and distributing, comprising in all 600 miles of canals. There are 1,526 small wooden drops, and 1,196 delivery gates for farmers, 3,500,000 f.b.m. of lumber, 25 tons of nails, 50 tons of metal.

With reference to finance, he stated that 30-year bonds were issued by the province amounting to $5,400,000 yielding six per cent, also $140,000 short term debentures, to get this project under way.

There were three methods of delivering water, namely: continuous, rotation, and demand delivery. The work was designed for a rotation method which however generally entailed a supply on demand. He claimed that a fall irrigation assists materially in relieving an excessive load in June and July the following year, also that the problem of adequate drainage was a most serious one facing irrigationists to-day.

He detailed the organization and working of the system in full, and related the importance of literally selling irrigation to the farms, and would urge the governments to assist in every way possible in the matter of irrigated lands.

Modern Views on Matter, Energy and Radiation

Dr. J. C. McLennan, Professor of Physics, University of Toronto, Toronto, Ont.

Toronto Branch, November 26th, 1925.

Before the time of Dr. Black, the Scotch physicist, (1728-99), the general conception of matter, said Dr. McLennan, was summed up in the phrase "solid and continuous"; but to account for expansion under the influence of heat Dr. Black propounded the theory of discontinuity, i.e. that the component particles moved farther apart under the influence of heat. John Dalton (1766-1844) a man far ahead of his time, from these beginnings developed the atomic theory, which, with the theory of the Conservation of Energy, became the basis of physics and chemistry during the nineteenth century and was further developed by Lord Kelvin, Helmholtz and others.

Research work during the last twenty years had however caused the view to be held that even atoms were not solid, but were themselves the aggregates of large numbers of infinitely smaller corpuscles revolving at great speed in orbits about their common centre of mass like the planets of the solar system around the sun; and MASS was therefore but a quality or form of ENERGY, in the same way that sound, heat, light, electricity, magnetism, gravity, etc., were qualities or forms of energy. Conversely, all forms of ENERGY have MASS, the relation between them being $E = Mc^2$, where E = energy, M = mass, and c = the velocity of light, so that $E = M x 9 x 10^{20}$, i.e. a very LITTLE matter is equivalent to ENORMOUS energy.

Slides were shown indicating the relationship between the 92 known kinds of atoms that make up our universe, and outlining atomic numbers, molecular velocities, gas viscosities, etc., and it was shown that whereas the atomic weight of hydrogen is 1.008, that of helium is exactly 4.0. It was believed that four hydrogen atoms combined to make one helium atom, and since 1.008 x 4 = 4.032 there was a loss of mass in the transformation of .032, and a release of energy of $0.032xc^2$. As a matter of fact, there were certain stars, (whose temperature was well above 20,000 degrees), that showed the hydrogen spectrum, with a very faint helium spectrum, which suggested a "factory" where hydrogen was being converted into helium, the released energy being converted into heat. The explosion when hydrogen and oxygen united to form water was also, it was believed, due to lost mass; the lost mass being infinitesimally small, and unmeasurable.

As illustrating the almost inconceivable reservoir of energy in the atom, Professor McLennan gave the following examples:—

If one gram of hydrogen were turned into light, and the light absorbed as heat by lake Ontario, 200,000 tons of water would be raised in temperature one degree.

One ounce of hydrogen would heat 6,000,000 tons of water 100 degrees.

Professor McLennan, (if *he* disappeared), would heat four cubic miles of lake water to boiling point.

All engineering was founded on physics said Dr. McLennan. James Watt was at one time an assistant of Dr. Black, and put the physicists's theory of matter to practical use in the steam engine; the electrical engineer had done the same with the discoveries of Faraday. How many engineers to-day were following modern discoveries in energy and radiation? There were vast possibilities in these discoveries, and it needed the engineer to put them to practical use.

Ontario's Great Mining Northland

Hon. Chas. C. McCrea, Minister of Mines, for Ontario
Toronto Branch, November 19th., 1925.

ONTARIO'S GREAT MINING NORTHLAND.

Ontario's gold production, said Mr. McCrea, is to-day twice that of Mexico, more than half that of the combined United States, and equivalent to one ounce for every 6.8 ounces produced in the Transvaal; but whereas production in the Transvaal is declining, Ontario's production is rapidly increasing. The development of Ontario's gold mines dates from the discovery of the Porcupine gold field in 1909; previous to that year there was general disbelief that gold would ever be found in commercial quantities in Ontario, owing to the failure of previous developments. In fifteen years an industry has been built up that last year produced gold amounting to twenty-five million dollars, and that is expected to produce this year, thirty million dollars, and next year thirty-five million dollars.

Many engineering problems are involved, and some of the workings are now from 2,000 to 3,000 feet deep. If our geologists are correct, we shall eventually have shafts from 6,000 to 7,000 feet deep, and to ensure the safety of the miners, the Ontario government last year sent to South Africa, (where such depths are quite common), to obtain information as to the best methods of deep mining.

Silver mining in Ontario dates from 1903, when the Cobalt silver field was discovered. Since the fall of 1903, silver has been shipped to the value of 253 million dollars, and dividends paid amounting to 91 million dollars.

Nickel mining dates from 1883 when the Sudbury field was discovered. This field was at first worked for the copper without much commercial success, but the introduction of nickel-steel alloys, and the great demand for alloys during the Spanish-American and subsequent wars, put the industry on its feet. The increasing use of nickel for peace purposes has opened up a growing market for the nickle produced.

Mr. McCrea stated that no man could measure the future of the mining industry. If investments were wisely placed on the advice of competent engineers great results might be expected. Though the hardships were undoubtedly many, he did not know of any other field of activity which offered such scope and opportunity for young men, particularly graduates from our Canadian Universities. It was the duty of every Canadian to make Canada something more than a "back-yard from which materials might be drawn and fabricated in the United States."

The Annual Meeting

CORRESPONDENCE

A Field Method for determining Moisture Content and Bulking of Sand

Toronto 2, Ont., November 7, 1925.

The Editor,
The Engineering Journal,

Dear Sir:

Now that the water cement ratio theory is being applied to concrete mixes it seems to me that anything bearing on the application of this theory in the field is of possible interest to engineers. In working in the field one of the chief difficulties that has occurred is to determine quickly the quantity of water contained in the damp sand on the job and to determine the bulking of this sand due to its moisture content.

Of course, this can be done by measuring and weighing a quantity of wet sand, drying it, and measuring and weighing again, but to do this every day and change the mix accordingly is very defficult and tedious. Accordingly various quicker and more or less rough methods have been used by different engineers in the field. The following method seems to give more accuracy than most of them and to be easy to apply in the field; it is the result of a good deal of experimenting during the past season:

PRELIMINARY EXPERIMENT

Take a measure made of galvanized iron and containing, say 1/5 cubic foot and stand it inside a pail. Pour into the measure 80 fluid ounces of water measured by means of a graduated flask such as is used by photographers. Pour dry sand into the water until the measure is full, jarring the measure and pail from time to time so as to bring the water up to the surface. (If the water all soaks up into the sand before the measure is full, add more, but 80 ounces is usually found to be enough for 1/5 cubic foot of sand.) When the measure is full of inundated sand, jar it again and give it a little time for all the superfluous water to come to the surface, tip the whole apparatus a little to run all this water off into the pail, then remove the measure, pour all the overflowed (dirty) water from the pail into the flask and note its volume. If this be, for instance, 5 ounces and we began with 80, we know that it takes 75 ounces to inundate 1/5 cubic foot of this particular sand.

A precaution to be remembered is that one must always pour the sand into the water; never pour the water into the sand.

DETERMINATION OF BULKING

Fill the 1/5 cubic foot measure with the sand damp and loose. Empty this sand out on to a sheet of table oilcloth and keep it. Place the measure in the pail and pour into it the amount of water (e.g. 75 ounces) determined by the preliminary experiment. Pour the 1/5 cubic foot of damp sand into this water slowly and jar it as before. When it has a level surface under the water measure its volume by getting the depth from the top of the measure to the surface of the sand with a foot rule at various points. As the volume of the inundated sand is practically the same as that of dry tamped sand, this gives us the bulking of the damp sand.

DETERMINATION OF MOISTURE CONTENT

Continue adding more damp sand until the measure is full and measure the overflowed water precisely as in the preliminary experiment. This overflowed water will be the water originally contained in the sand (moisture content).

Suppose for instance, the sand were found to bulk 20 per cent and to contain 9 fluid ounces of water to the 1/5 cubic foot, (dry tamped measure), and that our mix is 1:3:4.

Instead of using 3 cubic feet of sand we must use 3 plus 20 per cent of 3 = 3.6 cubic feet, and the quantity of water per bag of cement that we should use if the sand were dry must be reduced by an amount calculated as follows: nine fluid ounces in 1/5 of a cubic foot equals 45 per cubic foot or 135 per bag, (3 cubic feet sand per bag). Divide this by 154 to bring it to Imperial gallons and we get 0.88 gallons.

The foregoing method saves all weighing and all evaporation after the preliminary experiment. Of course, the preliminary experiment must be repeated for each new type of sand, but, so long as the character of the sand on the job is constant, we need only make the determination for bulking and moisture and this can be done in fifteen minutes every morning. The method seems to be accurate within about 4 or 5 ounces of water per cubic foot and this error is negligible in practice.

Yours truly,
G. M. STEWART, A.M.E.I.C.

BOOK REVIEWS

The Theory and Design of Structures

Ewart S. Andrews, Consulting Engineer.
Demy 8vo.; 640 pages, fourth edition.
Price 13s. 6 d. Chapman & Hall, London.

The first edition of this book, it will be remembered, appeared some seventeen years ago. The present volume, like its predecessors, is intended for use in the class room and by practitioners in engineering offices as well. Graphical and analytical methods are both employed, the one best adapted to the problem in hand being apparently the one selected in any given instance. A feature of the book is the large number of illustrative problems scattered throughout the text intended to elucidate the related reading matter.

The author is on firm ground when, in his effort to meet the views of the practical man who scorns theory entirely, he asserts that it must not be forgotten that if theory be used at all, the best theory should be employed. Practical rules for use in designing, he states, are not necessarily sound simply because the structures resulting therefrom fulfil their function. In other words, correct theory considers all the facts in which case there can be no conflict between theory and practice.

The thing that impresses the reader perhaps more than anything else is the tremendously large field that the book attempts to cover. Within its covers one finds graphic and analytical statics, mechanics of materials, theory of framed structures, together with a treatment of each of suspension bridges, arches, masonry structures, reinforced concrete, retaining walls, dams and foundations. In consequence some of the discussions are very brief. To this last statement, however, the treatment of the beam and column, to cite two cases only, are exceptions.

The terminology is in places different from what we on this side of the Atlantic are accustomed to. One finds "core", "cleat connections", "notch" and "parallel flanges" where "kern", "beam connections", "cope" and "parallel chords" respectively would here be more familiar terms.

The book, like others by the same author, is well written, is sound in theory and although extended in its scope, apparently fills, judging by its reception in the past, an important place as a text for students and designers.

Peter Gillespie, M.E.I.C.

Tables for Reinforced Concrete Floors and Roofs

R. Travers Morgan with a foreword by E. Fiander Etchells, Past President of the Institution of Structural Engineers.
Demy 8vo.; 97 pages. Price 10s. 6d. Chapman & Hall, London.

This book is intended primarily for the busy man. It includes some 69 tables each giving the make-up in respect to thickness, and size and spacing of reinforcement, of a reinforced concrete slab capable of supporting an assumed live load, stated in pounds per square foot, across the various spans likely to be met with in ordinary construction. The tables are divided into three classes, the first pertaining to freely supported slabs and the second and third to slabs continuous at one and at two ends respectively. In the construction of the tables, bending moment coefficients of 1/8, 1/10 and 1/12 for the respective classes as above have been employed. Working stresses have been taken as 16,000 lb. per sq. in. for steel and 600 for concrete. As these are somewhat lower than those to-day generally favoured on this side of the Atlantic, the usefulness of the tables is somewhat lessened for American designers. Reference, however, is exceedingly simple and can be made very quickly. It is, for example, a matter of only a few seconds to ascertain that a 7-inch slab reinforced with ½-inch round rods spaced 4¾ inches centre to centre is one method of carrying a live load of 200 lb. per sq. ft. freely supported, over a span of ten feet. In addition to this, there are for the same problem, thirteen alternative solutions more or less desirable from which to select. To the American designer, it seems odd to find tables figured for live loads of 168, 224 and 336 lb. per sq. ft. The British "stone" of 14 lb. is doubtless the explanation of this.

A brief exposition of the theory of the reinforced concrete slab is given in the introduction.

The book is well gotten up, the press-work and binding being of excellent quality. For designers working under British specifications and for others also, but to a less extent perhaps, the book will be a valuable vade mecum.

Peter Gillespie, M.E.I.C.

BRANCH NEWS

Border Cities Branch

F. Jas. Bridges, Secretary-Treasurer.

The annual meeting of the Border Cities Branch was held Friday evening, Dec. 11th, in the Prince Edward hotel, Windsor.

After partaking of a splendid dinner the reports of the various committees were read. A. E. West presented the report of the Membership Committee and showed a net increase of 27 members or 30 per cent. The reports of the Papers and Entertainment Committee was presented by W. B. Pennock, Jr.E.I.C., The inactivity of the Advertising Committee was told of by W. J. Fletcher, A.M.E.I.C., F. Jas. Bridges, A.M.E.I.C., presented the reports of the secretary and the treasurer.

The meeting was then thrown open for nominations and election of officers for the year 1926. The result of the voting is as follows.—Chairman, A. J. M. Bowman, Vice-Chairman, L. McGill Allan, Secretary-Treasurer, W. H. Baltzell, Executive, Harvey Thorne, J. J. Newman, A. E. West. The ex-officio members of the Executive are J. Clark Keith, A.M.E.I.C., F. J. Bridges.

Entertainment for the evening was provided by two coloured entertainers who sang and recited many numbers which were well received.

Calgary Branch

G. P. F. Boese, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch-News Editor.

Members of the Calgary Branch gathered at the board of trade rooms Thursday evening, to listen to an address delivered by P. M. Sauder, M.E.I.C., of Lethbridge. The subject of Mr. Sauder's address was "The Operation and Maintenance of the Lethbridge Northern Irrigation Project"; a subject about which he is competent to speak, as he has been intimately connected with the project from its inception, both as division engineer on construction and now as manager. At the commencement he referred particularly to his renewal of acquaintance with members of the Calgary Branch of which he was a charter member.

As soon as Mr. Sauder was on his feet several of his classmates of early days at Toronto University gave him a welcome with the old college yell!

An abstract of Mr. Sauder's paper appears on another page of this *Journal.*

A. L. Ford, M.E.I.C., was in the chair, and thanked the speaker for a splendid paper. P. J. Jennings, M.E.I.C., proposed a vote of thanks and claimed that the paper might almost be taken as a treatise on the subject.

New members introduced during the evening were Lt.-Col. Parks engineer for the railway board; Lt.-Col. J. P. B. Dunbar, A.M.E.I.C., engineer for military district No. 13, and C. C. Ross of the federal mines branch.

On December 8th, a joint meeting of the members of this branch of *The Institute,* the Association of Professional Engineers of Alberta, and the Institute of Mining and Metallurgy took place. Commencing with a dinner at which some eighty persons sat down the programme consisted of a talk by the chairman, Professor R. W. Boyle, M.E.I.C., on "Natural Resources", and an address with lantern slides by Dr. F. A. Wyatt, professor of soils at the University of Alberta. Interspersed between these items were some humorous songs and community singing.

Natural Resources

Prof. Boyle mentioned that it was such meetings as this that did a great deal of good in furthering a better fellowship among engineers of the various societies. In his talk he dwelt in a general way on the natural resources of not only our own but every country from the point of view of an engineer. He grouped them into four classes:—

1. Nature's supplies of air, sunlight, and the earth's crust.
2. Reproducible resources, forests, fish, animals for clothing, and food animals.
3. Unreproducible resources, minerals, oil, gas.
4. Permanent resources, but limited.

He stressed his idea that there must be a rise and fall of industrialization, which in time must peter out and decay.

Alberta, he claimed had a super excellence of class one, including a wonderful soil, but systematic surveying and research must be carried out in regard to the latter. Conservation should be carried out by a more general use of bricks in building, thereby saving our timber.

In regard to class two, this showed a comparatively slow rate of production. The development of natural resources should not mean extermination. The consumption should not exceed the yearly supply of any one natural resource. If it does we should turn to suitable substitutes.

In class three he enumerated metals, coal, petroleum, and gas. Minerals and oil are being imperatively brought more in demand on all sides year by year. Mining, he said, is a wasting industry, as there is only one crop, and the most spectacular resource under this heading is that of petroleum. Petroleum makes history he declared, and the world is now being ransacked, especially by England and the United States, for new petroleum fields and is in the midst of a great experience concerning questions of supply. At present, he claimed, the supplies can only last a short time, relatively; we shall then have to turn attention to shales and sands for our oil supplies, and then at great cost.

In his reference to class four, namely, water power, he stated that here we have a great source of power, but the question will arise as to who really owns this resource. Most likely it will become the property of the people. Soil is an indestructible resource, but can very well be wasted. He claimed that this material is the maker of history, also, and the cause of wars and existence of people, adding that the supply will never again be equal to the demand. Eventually the soil must limit the world's population. Immigration, due to the over-saturation of the soils in proportion to the population, will take place from densely populated countries to Africa and North and South America. He believed that in thirty or forty years time immigration to Canada will have to be restricted. He also stated that this province will some day be a great workshop, when the population increases to the necessary point of about 1,000,000 people. It is obvious by the right plan for people all the world over to live near the productive soil areas, and as capital becomes saturated, like the people in any country, capital must emigrate. He surprised his audience by stating that to-day some three thousand million dollars of United States money was invested in Canada, and aptly concluded with the remark that the greatest resource of this country was its people.

Testing Alberta Soils

Dr. Wyatt gave a resume of the work being done by his department at the University in connection with soil surveys, tests, and research work. He referred to the co-operation existing between the university, the topographical branch of the Dominion government, and the province, the latter supplying the funds for carrying out the work. He claimed that we were twenty years behind the times in this work, in that it should really have been done before the homesteader arrived to take up the land. He produced samples of various soils, dividing them into heavier varieties such as clays, and lighter varieties such as sands, the proportion of which constituted the difference in the nature of the soils as we commonly know them. He explained the methods adopted in gauging the different classes varying from gravel to the finest sand forming the clays. These ranged from twelve grains per inch placed end to end, up to 5,000 particles per inch. He claimed that the soil of the western prairies was as good as anywhere else, all that was needed was the necessary water. His statistics showed that for every inch of rainfall on three of the large grain growing areas of Southern Alberta the returns in bushels per acre were practically identical. A very surprising though true statement. These results were gleaned from published results spread over a period of eighteen years.

Votes of thanks to both Prof. Boyle and Dr. Wyatt were suitably voiced by R. Mackay, A.M.E.I.C., and W. H. Snelson, A.M.E.I.C., and thanks proffered by the chairman to Dr. Wyatt for his able address. Mr. Snelson emphasized the great importance of this soil survey and investigation work and a proper understanding by the farmer of the nature and water-holding capacity of the soil on his holdings.

A pleasant evening was concluded by the thanks of Prof. Boyle to the Calgary committee, consisting of J. F. McCall, (chairman), G. H. Morton, A.M.E.I.C., Floyd K. Beach, A.M.E.I.C., and R. Mackay, A.M.E.I.C., for the splendidly arranged programme.

Cape Breton Branch

D. W. J. Brown, Jr.E.I.C., Secretary-Treasurer.

On Friday, October 2nd, Mr. Durley visited the Cape Breton Branch on his way to the Halifax Professional Meeting. The Executive had the pleasure of dining with Mr. Durley in the evening, after which a smoker was held at the branch rooms, where the members had an opportunity of meeting our new Secretary for the first time, and *Institute* matters of general interest were discussed.

Marketing of Cape Breton Coal

H. A. Hatfield, Maritime Representative of Babcock-Wilcox and Goldie McCulloch, Ltd., addressed a large meeting on the evening of November third, on the subject of the "Marketing of Cape Breton Coal". This paper was previously read by Mr. Hatfield at the Halifax Professional Meeting and will probably appear later in *The Journal.* The speaker suggested ways of increasing the sale of Maritime coal by means of making public reliable data concerning the different grades, and outlined a plan for procuring this data and making it available for the use of coal consumers. The subject seemed to hit those present in the right place, almost all taking part in the discussion that followed. The following motion, by W. S. Wilson, A.M.E.I.C., seconded by J. R. Morrison, A.M.E.I.C., was unanimously passed, "That the Cape Breton Branch of *The Engineering Institute of Canada* endorse Mr. Hatfield's suggestions outlined in his paper that the government of Nova Scotia take the necessary steps to bring users and producers of Nova Scotia coal into closer touch to their mutual advantage, with the prime object of increasing sales of Nova Scotia coal. To this end this branch offers what help it may be able to give."

Annual Meeting

The next gathering was the annual meeting, which took the form of a dinner, held in the Oddfellows' hall, Sydney, on the evening of December 8th. About thirty-five members and guests were present at this meeting, which opened at seven-thirty, when the chairman, S. C. Mifflen, A.M.E.I.C., asked the scrutineers to count the ballots for election of officers. While this was being done, the secretary read the annual report, which was adopted as read. The result of the ballot was that W. C. Risley, M.E.I.C., was elected chairman, and J. J. McDougall, M.E.I.C., of Sydney Mines, and J. R. Morrison, A.M.E.I.C., of Sydney, were elected as committeemen.

Mr. Mifflen, after a short address, in which he thanked the members for their co-operation during his term of office, and expressed the pleasure which he had derived in carrying out his duties as chairman, resigned the chair to Mr. Risley.

Mr. Risley assured the meeting of his appreciation of the honour being paid him and of his desire to make every effort possible to increase the benefit derived by the members of the branch. An excellent dinner was then served by the ladies of Rebekah Lodge, Sydney, interspersed with choruses, after which the following toast list was honoured:

The King, The Chairman.
Sister Societies, J. H. Fraser, A.M.E.I.C.
Response E. C. Hanrahan, Esq., Sec'y Nova Scotia Mining Society.
The Institute, J. J. McDougall, M.E.I.C.
Our Guests, A. L. Hay, M.E.I.C.
Response, Col. J. A. McDonald.

The speaker of the evening was Mr. H. J. Kelly, general manager, Dominion Iron and Steel Company, who spoke on "The Engineering Profession", stating to what great degree the operating man is dependent on the engineer and how necessary the engineer is to the successful carrying on of any industry.

A coloured orchestra provided entertainment in the way of popular musical numbers and vaudeville stunts. One of the orchestra inadvertently stepped on the toes (or rather the "cocoanut"), of another and they immediately clinched. Bill Wilson and Charlie Ross manfully separated the combatants in an effort to maintain the peace. "Razzers" being unobtainable, two pairs of gloves were produced and "Charlie" refereed a couple of rounds until honour was satisfied.

Many individual vocal efforts were well rendered and applauded, but the feature of the evening was the spirit with which (or should I say "by"), everybody joined in the choruses. They went in with both feet and raised the roof. The chairman even found difficulty in getting a motion of adjournment through as the wee sma' hours approached.

London Branch

E. A. Gray, A.M.E.I.C., Secretary-Treasurer.

Motor Trip

A motor trip was held to Stratford, on Saturday, October 24th. The party of twenty members, on arrival at the Stratford city hall, were met by City Engineer A. B. Manson, M.E.I.C. The locomotive repair shops of the C.N.R., city sewage disposal plant, and waterworks plants were inspected and proved most interesting to those present.

Following dinner at the Queen's Hotel, the party adjourned to the Chamber of Commerce rooms where speeches were delivered by General Superintendent of Motive Power, Roberts, Ald. Mone, Commissioner Garner, and City Engineer Manson. Chairman Mille extended to the speakers a vote of thanks on behalf of those present for the many kindnesses shown them.

Regular Meeting

The regular monthly meeting was held in the board room of the Public Utilities Commission, on Wednesday, November 25th. After the consideration of routine business, the subject "The desirable radius in rounding street intersections, (curb radius), was informally discussed, the consensus of opinion being that the radius was entirely dependent upon local conditions."

A dinner meeting was held in the drafting room of the Public Utilities Commission, Wednesday, December ninth.

Diesel Engines

Following the dinner, Chairman W. C. Miller, A.M.E.I.C., called on Mayor-elect J. M. Moore, M.E.I.C., who delivered a most interesting address. The paper "Diesel Engines", by E. V. Buchanan, M.E.I.C., was presented by V. A. McKillop, B.A.Sc., owing to the illness of Mr. Buchanan, the paper proved most instructive and interesting as Mr. Buchanan has investigated the subject personally both in America and Europe. Considerable discussion ensued following the reading of the paper.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
Stanley A. Neilson, A.M.E.I.C., Branch News Editor.

Stress Analysis by means of The Photoelastic Method.

Dr. P. A. Heymans, professor in the Physics Department of the Massachusetts Institute of Technology, read a paper on the above subject before the Montreal Branch on November 19th, 1925.

After an introduction in which he derived equations for the principal stresses in a structure under load, Prof. Heymans went on to tell of some of the applications of the theory of photoelasticity.

Celluloid models are used and the specimen to be tested is placed in the path of a beam of polarized light. Under different stresses a variety of colour combinations are observed. A simple specimen is first tested under known loads and a calibration thus obtained. Sections of unsymetrical form or with holes in them are then tested and the colour combinations obtained give a measure of the distribution and intensity of the stresses set up.

Prof. Heymans showed some slides illustrating work that had been done on gear pinions. Some interesting theories were developed in the laboratory relative to the shape of the fracture of gear teeth when subjected to destruction, either by being driven too tightly on a tapered shaft, or, by being overloaded by repeated heavy blows on the side of one of the teeth. These theories were fully borne out when full sized specimens, in metal, were tested under the conditions named.

Two interesting examples, the deck of an airplane mother ship, and, the structure of the illfated dirigible, the Shenandoah, were also dealt with.

Dean H. M. Mackay, M.E.I.C., took part in the discussion which followed, telling of some of the work done in the McGill laboratories where mirror extensometers were used to measure the strain produced by various loads. Prof. E. Brown, M.E.I.C., brought up the question of specimens composed of two materials with different moduli of elasticity such as reinforced concrete.

Dr. L. E. Pariseau, with a few well chosen words, in which he referred to Prof. Heymans' enviable war record, proposed the vote of thanks which was tendered to the speaker by the chairman, F. P. Shearwood, M.E.I.C.

Prior to the meeting the Executive of the branch entertained Prof. Heymans at dinner at the University Club.

Aviation and Modern Engineering Practice

Possibilities in the future development of aerial work, especially with reference to Canada, were described by Wing Commander E. W. Stedman, O.B.E., on November 26th, 1925 during the course of an address on "Aviation and Modern Engineering Practice," to the members of the Montreal Branch.

Exploration, surveying, transportation of goods and passengers, geological work, fishery patrols, city planning, commercial photography, railway surveys, timber cruising, plant "dusting", forest fire protection, and fire fighting were among the tasks now undertaken by aircraft, and big developments were ahead.

The address was illustrated by a large number of aerial and other photographs, showing various phases of the use of aircraft, many of which were of un-exampled beauty, and brought forth spontaneous applause from the members present.

Another statement, that was warmly greeted by the audience, was that in which he said that the Vickers "Vedette", specially designed by Canadian Vickers and produced at their Montreal works was the finest seaplane of its size in the world.

In the transportation of passengers and goods by aircraft, ground organization, such as aerodromes, beacons, signals, was just as necessary as good air organization, he continued. Good aerodromes were needed for the aeroplane just as much as good roads for the automobile, and this meant such an expenditure that it seemed the future of aerial transportation was intimately connected with the railroad and steamship business.

After describing the operation of the United States night and day air mail and the development of the "air taxi" service in Europe, Commander Stedman turned to aviation in Canada. He referred to the work done by the Quebec Dominion Air Exploration Company, for several industrial firms and to the survey of the watershed of the Hamilton river in northern Quebec, where the use of aircraft resulted in the transportation of 12,000 pounds of goods into the heart of the country, thus eliminating 24 portages, one of which was 10 miles in length, and doing in three weeks the work that had previously taken three months. By this means also the usual losses attendant on canoe transportation of goods were all avoided.

With a series of photographs taken from the air Commander Stedman showed how the camera could help the surveyer by giving the details of huge stretches of country in one photograph that could otherwise only be obtained by weeks of toil. In the United States, city surveys were being done by aircraft and city tax revisions were being governed by the photographs in some cases. Aerial photographs also showed the lay-out of industrial plants, city traffic, harbour works, water power developments, and flood control work. The aerial photograph was being used in railway surveys, in timber cruising, in ascertaining the various types of timber in a district, and in connection with the developments of factories, bridges, dams, wharves and piers. He also showed "without comment" five photographs of the Port Nelson terminal of the Hudson Bay Railway. No ice was visible in the pictures but the general impression gathered was one of deadly desolation.

After telling of the aeroplane's work in fighting the boll weevil pest in the cotton growing regions of the United States, the speaker went on to deal with the forest fire protection work now being done in various parts of Canada.

Prof. J. B. Porter, M.E.I.C., Dr. R. A. Ross, M.E.I.C., and Mr. Wilson, the secretary of the Air Board, took part in the discussion that followed. The question of an air harbour for Montreal was discussed and it was suggested that it might be opportune for the Montreal Branch to go on record in this connection. It was pointed out by J. L. Busfield, M.E.I.C., however, that the matter of establishing an air harbour was really a commercial business and not one in which the branch had any concern.

The vote of thanks was proposed by Dr. H. T. Barnes, A.M.E.I.C., and tendered to the speaker by the chairman, P. S. Gregory, A.M.E.I.C.

Students Evening

The evening of December 3rd, was given over to the Student Section of the Branch; the entire proceedings being in their hands. It was unfortunate that the weather man was not kind for the Students acquitted themselves nobly.

Scientific Principles Applied to Dwelling House Construction

The above title was rather formidable for the very clear and precise paper which H. A. Gauvin read. He first described the general problem of heating houses and pointed out where and how the largest part of the heat was lost.

He then told of a series of tests which had been made at the University of Saskatchewan, Saskatoon, in which model houses built to different specifications were heated by electricity throughout two winters. Some interesting tables were prepared showing the relative cost of heating the various types.

Mr. Gauvin then went on to describe in detail the construction of a number of houses built according to the ideas which had been developed. The house is essentially a frame structure, stucco on the exterior, plaster on the interior but with the space between filled with some insulating material such as mineral wool, shavings, or best of all granulated cork.

Automatic Control for Railway Substations

E. Gray-Donald, S.E.I.C., was the second speaker and read a very interesting and instructive paper which described in detail the function of the new substation which the Toronto Hydro-Electric Commission have recently installed in North Toronto.

Mr. Donald's paper is among those entered for Student's Prizes.

J. F. Rutherford, A.M.E.I.C., moved the vote of thanks which was tender to the speakers by the Chairman F. E. Winter, S.E.I.C.

J. L. Busfield, M.E.I.C., chairman of the Branch, complimented the Students on the excellence of the papers, and on the manner in which the whole meeting had been conducted.

Transmission Towers

Transmission Towers was taken as the subject of a lecture given by C. M. Goodrich, M.E.I.C., to the members of the Montreal Branch, on December 10th. Mr. Goodrich, who is designing engineer and manager of the transmission tower department of the Canadian Bridge Co., has had twenty years' experience in designing and fabricating all types of transmission towers and radio masts for erection in all parts of the world, which enabled him to give a particularly interesting talk, illustrated with lantern slides.

Pictures of towers and poles, both four square and triangular, conveyed a clear impression of the various forms that he had previously described. At the same time the defects and advantages of each were shown up and pointed out. Mr. Goodrich tinged all his explanations and anecdotes with a quiet humor that added greatly to the pleasure derived from his comprehensive address.

Towers in Canada were the chief subject for his photographs, although several other portions of the globe were shown.

The chairman for the evening was G. A. Wallace, A.M.E.I.C.

Annual Meeting

On December 17th, 1925, the annual meeting of the Montreal Branch, was held; J. L. Busfield, M.E.I.C., the retiring chairman, conducting the meeting.

The minutes of the last meeting were read and adopted after which Mr. Busfield gave his address, the report of the year's activities. As this report will be published in the February issue of *The Journal* no comment will be made on it here.

K. B. Thornton, M.E.I.C., moved the adoption of the report with fitting remarks. Prof. H. T. Barnes seconded the motion of adoption.

The report of the scrutineers was then read, the following being successful in the last election.

Chairman: C. J. DesBaillets, M.E.I.C.

Vice-Chairman: C. V. Christie, M.E.I.C.

Members of the Executive Committee: A. Duperron, A.M.E.I.C., A. R. Ketterson, A.M.E.I.C., J. A. McCrory, A.M.E.I.C.

The meeting was then thrown open for general discussion and some interesting suggestions were made.

Each of the incoming executive were then called upon to say a few words. Both Mr. DesBaillets and Professor Christie assured the members of the branch that they would do their best to try and keep up the good work which the retiring executive had done.

Messrs. McCrory, Ketterson and Duperron in turn moved a vote of thanks to the Publicity Committee, the Reception Committee and the Press respectively.

Geo. R. MacLeod, M.E.I.C., spoke of the fine work of the branch secretary, and K. B. Thornton, M.E.I.C., eulogized the retiring chairman's attainments.

The meeting then adjourned for refreshments which were served by a number of the Students under H. Massue, A.M.E.I.C., the Chairman of the Reception Committee.

Prior to the meeting Mr. Busfield entertained the outgoing executive at dinner.

Future Meetings

The programme of meetings for the spring term of 1926 is given on another page of this issue. The members will note that the branch is fortunate in obtaining some very eminent and well known speakers. Messrs. Henry Lefebvre, Newell, Pratley, Wurtele, Dr. Pariseau and Col. Girouard need no introduction. The mere mention of their names as authors is a guarantee of an interesting evening.

W. S. Lee, M.E.I.C., who is to talk to us on January 7th, is the chief engineer and vice president of the Duke interests. He is perhaps best known in Canada by his work in the Isle Maligne district.

H. S. Taylor, M.E.I.C., is well known as an engineer, specializing on pulp and paper plants. One of his most interesting recent works has been in connection with the Eddy Company at Ottawa.

W. A. Newman of the C. P. R., has specialized in the design of locomotives and is an outstanding authority.

E. B. Shand, is a McGill graduate, who has made a name for himself with the Westinghouse Company, with whom he is connected in a consulting capacity.

Dr. Van Bruyssel is a special representative in this country of the Belgian State Railroad, his paper will give us some very interesting facts with reference to the experience of government owned railroads in Europe.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

This month the activities of the Branch were confined to a single dinner meeting held at the Welland Inn., St. Catharines. A good attendance was more than rewarded by having the pleasure of meeting R. J. Durley, M.E.I.C., and also of listening to a most instructive address by Professor C. R. Young, M.E.I.C., of the University of Toronto.

The Art of Bridge Building

Professor Young spoke on the subject of the art of bridge building and his lantern slide illustrations of notable—and remarkable—bridges undoubtedly emphasized the development which has taken place during the last century. One of the most interesting features was the comparison between American and European ideals, tending to show that the latter were the more inclined to boldness and individualism in their design.

Mr. Durley was on his first official trip as general secretary of *The Institute.* He spent the day with us and was given glimpses of the work on the New Welland ship canal and the hydro-electric power house at Queenston. Much of his time however was taken up in asking rather searching questions as to the activities of the branch and as to the feeling of its members on matters affecting the welfare of *The Institute.*

Engineers are discovering that the present stage of construction work on the ship canal is worthy of study. Lately a number of prominent Quebec engineers have paid us a visit, notably O. O. Lefebvre, M.E.I.C., chief engineer of the Quebec Streams Commission and de Gaspé Beaubien, M.E.I.C., and J. L. Busfield, M.E.I.C., consulting engineers of Montreal.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The New Diesel Electric Car

"A minute quantity of fuel oil,—less than one drop in volume,—is injected into each of eight cylinders and exploded,—or burnt,—144 times every second in the newly developed oil-electric car which recently made such a successful transcontinental trip of 2,000 miles without the engine being once stopped."

This was the practical explanation given members of the Ottawa Branch of *The Engineering Institute* at their luncheon at the Chateau Laurier on November 26th, by C. E. B. Brooks, chief of motive power of the C.N.R. Montreal, and by Mr. A. B. E. Chorlton the inventor, of the outstanding success from economical and serviceable standpoints of the new so-called Diesel electric car, which, it was stated, will revolutionize railway transportation, will effect extraordinary economy, and will solve many of the most difficult problems which have confronted railway officials in the past.

Noise and vibration, the chief existing difficulties, were stated by Mr. Brooks to be rapidly nearing elimination, whilst Mr. Chorlton explained that the fuel, being slow burning and being injected into the cylinder at the end of the stroke was exceedingly safe, and that power and length of continuous service had been achieved by lightness of construction, which enabled the expert manufacturers to build an engine which weighed less than 12 pounds per unit of horse-power instead of 200 or 300 pounds per horse power, as did the old type of engine.

The steel superstructure of the Diesel cars which have stood such conspicuously successful tests was all manufactured by the Ottawa Car Company and so the Capital City shares in the glory of the new achievement.

"We are in the midst of an experiment, and it is difficult to talk at such a time, said Mr. Brooks. But on pressing invitation of Mr. Craig, and other officers of your association, and also because many incorrect rumours have been given publicity, I decided to brave the somewhat difficult task of talking to an audience in this seat of oratory."

A. E. Macallum, M.E.I.C., chairman of the Ottawa Branch was in the chair. There was an excellent attendance and both speakers received warm ovations, the cleverness of the discovery and the courage with which it had been put into practical use eliciting unbounded admiration from a group of scientific men who understood the value of the new discovery. An abstract of Mr. Brooks' paper appears on another page of this *Journal.*

The Ascent of Mount Logan

How a slender willow wand probably saved the lives of the expedition attempting the ascent of Mount Logan, second highest mountain on the North American continent, situated in the extreme southwestern corner of the Yukon Territory, was told on the evening of December 8th, by H. F. Lambart, B.Sc., D.L.S., A.M.E.I.C., before a joint meeting of the Ottawa Valley Graduates' Society of McGill University, and the Ottawa Branch of *The Engineering Institute of Canada.*

At four o'clock on the afternoon of June 23rd, the climbing party of eight attained what was thought to be the summit of the huge mountain, only to find that the real peak was three miles farther on across a thousand-foot valley, said Mr. Lambart, who was second in command of the expedition.

After a brief stay at the final summit, where record was left of the magnificent achievement and a flash of motion picture taken with the compact miniature camera, the party commenced the return to their supplies at their last camp. At midnight they were unable to find the return trail, so burrowed into the snow, being saved from probably fatal frost bites by a heavy fall of snow. As it was, all suffered frozen hands and feet that made their position, together with their weakened condition, due to the rarified atmosphere, very perilous.

To find the return trail that led down to their last camp and provisions, the willow wands that were placed every hundred feet to mark the trail after winds and snow had obliterated it, had to be located. Bundles of these had been carried in the ascent to guide the party as they proceeded, but had given out as they neared the goal.

"It looked as big as a telegraph pole, and very welcome," said Mr. Lambart, in speaking of the finding of the first willow wand that led them back to safety.

Mount Logan is 19,850 feet high, said Mr. Lambart, and not only is the highest mountain in the Dominion of Canada, but is the highest in the British Empire with the exception of some in the Himalayan chain. It is a colossal mass, probably the largest in the world, covering an area of 100 square miles at the 10,000-foot level.

Though visible from the sea as a distant ridge beyond the great coastal ranges, it was not observed nor named until 1891 when an expedition attempting the ascent of Mount St. Elias, in that region, saw the outline of the king of peaks in the distance. To the east of Mount Logan in the Yukon is an area 60 miles square, said the speaker, which is quite unknown to man, an unmapped chaos of mountains and glaciers.

No expedition ever attempted a similar task with better equipment, said Mr. Lambart, paying tribute to certain local firms that had contributed, and to the topographical maps supplied them by the Topographical Surveys from material collected by the International Boundary Survey of 1913.

"Andy" Taylor, one-time citizen of Ottawa, who acted as trail guide to the party, was warmly referred to by Mr. Lambart, who said that the members probably owed their success, if not their lives, to the judgment, sagacity and work of this veteran.

Mr. Lambart did not speak of the personal hardships or experiences of the members of the party to any extent. Of the climbing party of eight, two were forced to return as the more difficult sections of the ascent were reached.

The meeting was under the joint chairmanship of A. F. Macallum, M.E.I.C., chairman of the Ottawa Branch, and Dr. J. T. Basken, chairman of the Ottawa Valley Graduate's Society of McGill University.

Economic Phases Entering into the Adjustment of Vehicular Traffic to Steam Railways

R. A. C. Henry, M.E.I.C., director of the Bureau of Economics, Canadian National Railways, delivered an address on some economic phases entering into the adjustment of vehicular traffic to steam railways before a large and representative gathering of members of the Ottawa Branch, and men connected with transportation, at the Chateau Laurier, December 15th.

The speaker was introduced by A. F. Macallum, M.E.I.C., chairman of the local branch, and outlined in a comprehensive manner the various modes of transportation, their operating cost and the important part they played in the economic life of the nation.

He stated that the transportation of people and commodities was a vital factor in the economic structure of Canada and the United States, much more so than in other countries owing to the long distances involved. Figures were submitted bearing on the operating cost of electric, steam and motor vehicle transportation, which brought to light the fact that the cost per mile of electric freight and passenger transportation was 30 cents, and the cost of steam freight and passenger transportation was 14 and 30 cents respectively.

He pointed out that it was difficult to compare the cost of steam and electric transportation with motor vehicle transportation owing to the lack of standardization in the latter field, but $25 to $30, per diem would approximately cover the operation of a five-ton truck. It was apparent that Mr. Henry considered that operators of vehicular traffic had distinct advantages over those engaged in other modes of transportation, as they did not pay for the upkeep of roads, had terminals furnished them gratis, and were more elastic in their range of operation.

From the viewpoint of the tourist, busses provided greater scenic attractions than the electric railway, especially when speed was not considered a serious factor. Mr. Henry considered that trucks were of great advantage operating beyond a three-mile limit and in the vicinity of terminals and that they should be fostered in these spheres. At the same time, he felt that the time had arrived when vehicular traffic should operate under regulations somewhat similar to those pertaining to steam and electric transportation systems, that is, they should have uniform regulations to ensure continuous service and should contribute to the upkeep of roads and other facilities they are at present using without expenditure on their part. Instances were cited where considerable damage was done by trucks operating on roads only suited in their present shape to ordinary automobile traffic.

Mr. Macallum, on behalf of the Ottawa Branch, extended a vote of thanks.

Mr. Charles O'Reilly, during the course of the luncheon, rendered some much appreciated selections on the piano.

Peterborough Branch

Paul Manning, A.M.E.I.C., Secretary.
W. E. Ross, A.M.E.I.C., Branch News Editor.

Annual Banquet

The Peterborough Branch held their annual banquet on the evening of Tuesday, November 24th, at the Empress hotel, when members and friends to the number of eighty gathered around the festive board spread by host Graham.

Among the guests were Sir Alex Bertram, M.E.I.C., treasurer of *The Institute;* Professor H. E. T. Haultain, M.E.I.C., R. J. Durley, M.E.I.C., general secretary; Fraser S. Keith, M.E.I.C., W. H. Munro, M.E.I.C., F. S. Lazier, M.E.I.C., and others.

A. L. Killaly, A.M.E.I.C., chairman of the branch, presided in his usual cheery manner, making everyone feel at home; and in welcoming the guests and proposing a toast to them, paid a particular tribute to Sir Alex Bertram as the able financial head of *The Institute.*

In proposing the toast to *The Institute*, Mr. Killaly declared that a hard task had been set him to follow in the footsteps of the seven capable past presidents of the branch who had preceded him. He said in part that he had hopes that his own efforts would be judged with charity and paid tribute to the good work of his predecessors in office.

Sir Alex Bertram spoke briefly in reply, and indulged in some reminiscences of his early associations with Peterborough which go back as far as thirty-five or forty years ago. In referring to *Institute* affairs, Sir Alexander rather deprecated his own activities, stating that he had been treasurer for a number of years and could not understand why he could not be allowed by this time "to go and sit on the shelf and watch affairs from there." He spoke of the excellent services rendered *The Institute* by Fraser S. Keith, M.E.I.C., during his tenure of office as general secretary and lauded the members of the financial committee for their good work.

Mr. Durley also spoke in reply to the toast to *The Institute* opening his remarks by stating that in making his first bow to Peterborough Branch, he was somewhat subdued to find that he was addressing captains of industry and other high officials in the world of affairs, stating that he felt something like a lion in a den of Daniels. He paid a tribute to the work of his predecessor in office, stating that this was the first opportunity on which he had been able to express that sentiment in Mr. Keith's presence. In taking over the secretaryship he found that he had a highly trained and organized staff for which all credit was due to Mr. Keith. Mr. Durley said that he was at present making a survey of conditions in Canada, and stated that there were twenty-four autonomous and largely self-governing branches, which were capable of dealing with local conditions, and he emphasized the fact that this autonomy carried with it the responsibility of encouraging the growth of *The Institute* by securing new members, stating that the onus of increasing the membership rests entirely with the branch committee.

During his remarks, Mr. Durley said that in his opinion there should be some modification in the method of sending or interchanging papers between branches, and suggested a central agency for this purpose. He also spoke in reference to the relationship with young members, which relationship, he stated, should be improved.

Professor H. E. T. Haultain, M.E.I.C., replied to the toast to "Professional Engineers", but, as he had previously stipulated that he would only speak for one minute, his remarks were brief. Notwithstanding his self-imposed time limit, he succeeded in that time, in characteristic vein, in replying to the toast and also in conveying the good wishes of the Toronto Branch.

F. S. Lazier, M.E.I.C., conveyed the greetings of the Niagara Peninsula branch and complimented the Peterborough organization on the enthusiastic spirit of their meetings.

W. H. Munro, M.E.I.C., who is an old resident of Peterborough, now connected with Vickers Limited, amused the "banqueteers" when he stated that he was a reversal of the usual order of things, in that instead of being an Englishman making good in Canada, he was a Canadian Engineer who had at least succeeded in making a living in England.

The toast to the "Sister Professions" was replied to by the Reverend J. W. Gordon and Mr. V. J. McElderry, who replied for the Ministry and the profession of law respectively.

Other speakers were, R. B. Rogers, M.E.I.C., E. R. Shirley, M.E.I.C.; R. L. Dobbin, M.E.I.C., all of the local branch, and Mr. F. H. Dobbin, a non-member, but a close friend and always welcome guest at branch affairs.

The irrepressible "Sextette" were, as usual, in evidence, and perpetrated a couple of alleged musical numbers in which they took liberties with members and guests with the utmost impartiality, although the victims appeared to enjoy it. The "Sextette" consisted of Paul Manning, A.M.E.I.C., A. B. Gates, A.M.E.I.C., L. Dickieson, A.M.E.I.C., T. E. Gilchrist, A.M.E.I.C., and J. H. Johnson Jr., E.I.C., with Mr. I. McKenzie at the piano.

Reclamation of Lands in Western Canada

A regular meeting was held on Thursday, December 10th, in the Chamber of Commerce, when E. L. Miles, M.E.I.C., county engineer, and superintendent of roads for the county of Victoria gave a paper on the above subject.

A. L. Killaly, A.M.E.I.C., was in the chair, and in opening the meeting expressed the pleasure of the branch in having a paper from a branch member and reminded those present that Mr. Miles was eminently qualified to speak on the subject which he had chosen, since he had spent some ten years engaged in engineering work in the west, five years of which were in private practice and five years with the Department of the Interior.

Mr. Miles, in his introductory remarks, said that the presentation of a paper on the subject of the reclamation of western lands before a branch in this part of the country might seem somewhat superfluous, but that a knowledge of the necessity for, and the operation of some of the departments at Ottawa, with respect to the civil service and national development might not be amiss in these times.

He pointed out that the Department of the Interior might very appropriately be termed the Department of Research and Science, and briefly outlined the scope of it's activities. Referring particularly to the "Water Powers Branch" the speaker said, that this branch has as one of its subdivisions the Reclamation Service which covers all irrigation and drainage projects and developments. The two terms drainage and irrigation, being inseparably connected under the heading of reclamation as the term is applied to land.

Mr. Miles referred to the power of the Department by virtue of the "Irrigation Act" of 1894 for the North West Territories and "The Act Respecting Irrigation" of 1906, and described fully how these acts were administered by the department for the benefit of the two prairie provinces. Speaking of irrigation it was mentioned that in India over 40,700,000 acres are under irrigation, the largest area in the world; in the United States, in 1920, a total area of 19,191,716 acres were under irrigation; Argentine has 1,000,000 acres, and Japan about 7,000,000 acres under irrigation. In Canada, we have 50,000,000 acres of land in Alberta and Saskatchewan that need irrigation, but much of this area is too high and rough for practical irrigation, therefore, the actual irrigable area is 4,000,000 acres.

The speaker quoted figures indicating the actual areas irrigated by the various projects and the cost thereof, and speaking particularly of the western section of the Canadian Pacific Railway, Department of National Resources, which has an area of 122,000 acres irrigated, at a cost of about $16.000,000. he stated that according to the 1923-1924 report 10,050,000 bushels of wheat were harvested from this area, with a value of 71 cents per bushels to the farmer or a total value of $7,135,-500.

There was a very good attendance of members and friends at this meeting and the lively discussion, and the many questions which Mr. Miles was called upon to answer at the conclusion of his address were clear evidence of the interest and appreciation which his address had evoked.

E. R. Shirley, M.E.I.C., formally condensed this into a vote of thanks which was very heartily endorsed by all present.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

A meeting of the Saint John Branch of *The Engineering Institute of Canada* was held on the evening of November 19th, 1925 at the New Brunswick Telephone Company building and was addressed by K. H. Smith, M.E.I.C., of Halifax speaking on the subject of World Power Conference-Scandinavian Tour. The address was illustrated by a large number of very fine slides showing water power and scenic views of several European countries, W. R. Pearce, M.E.I.C., was chairman of the meeting and tendered a vote of thanks to Mr. Smith on motion of Geoffrey Stead, M.E.I.C., and G. G. Murdoch, M.E.I.C.

On December 11th, 1925, the members of the Branch, were addressed by Gordon Kribs, M.E.I.C., on "The Calculation of Short Transmission Lines". This paper had been recently read at Maritime Professional Meeting at Halifax in October but some of the members had not previously heard it. A number of slides were shown on the screen in explanation of various points brought out in the paper W. R. Pearce, M.E.I.C., presided and a vote of thanks to Mr. Kribs was moved by Geoffrey Stead, M.E.I.C., and F. P. Vaughan, M.E.I.C.

The papers of Mr. Smith and Mr. Kribs have been previously published in *The Journal*.

A resolution of condolence was passed by the branch at the death of R. H. Cushing, M.E.I.C., and a copy ordered to be forwarded to the family of the late Mr. Cushing.

Toronto Branch

C. B. Ferris, A.M.E.I.C., Secretary-Treasurer.
J. W. Falkner, A.M.E.I.C., S. G. Salman, A.M.E.I.C.,
Branch News Editors.

The regular weekly meetings have been of particular interest this month on account of the variety of the subjects dealt with by outstanding men.

Ontario's Great Mining Northland

It was a great pleasure to welcome on November 19th, the Hon. Chas. S. McCrea, minister of mines for Ontario, and a speaker of authority on the present mining developments in Ontario's northland. An abstract of Mr. McCrea's paper is given in this issue of *The Journal*.

At the close of Mr. McCrea's address, moving pictures were shown of typical Ontario gold, silver, and graphite mines, and illustrating in detail the underground workings of a gold mine and the process of recovery of gold from the ore.

Modern Views on Matter, Energy and Radiation

Dr. J. C. McLennan, professor of physics, University of Toronto, addressed the branch on November 26th, and held members spellbound for over an hour while he described in language that all could understand the revolutionary changes which the last two decades have seen in our conception of matter, energy, and radiation. The meeting was held in the Physics Auditorium of the University of Toronto to enable suitable apparatus to be used, and to accommodate the large number of members who wished to be present. An abstract of Dr. McLennan's address appears elsewhere in this issue.

Geneva

After hearing of such strife and turmoil in the breast of an atom, post-war Europe would almost seem peaceful!

At the monthly luncheon on December 3rd, the branch had the pleasure of welcoming Sir Robert Falconer, president of the University of Toronto, as their guest. Sir Robert had not long returned from Europe, and gave the members present a delightful word picture of that beautifully situated city,—Geneva, and the work being done there by the League of Nations. Ideally located for ease of access from all the European capitals, hospitable to all who visited her, intellectually second only to Paris as a centre of French culture, yet unprejudiced and open minded as regards international politics, Geneva was pre-eminently suited to be the headquarters of the League; and the unseen and unheralded work done there during past years had made possible the more spectacular news-items of the Dawes plan, and of Locarno. Canadians should be exceedingly proud, said Sir Robert, of their representation at Geneva; and of such men as Senator Dandurand, Chairman of the Annual Assembly, and Sir Herbert Ames, Treasurer of the League.

The closeness with which Sir Robert's address was followed was an indication of its great interest to those who had the good fortune to be present.

Brazil

On December 10th, an open meeting was held, addressed by F. J. Mulqueen, of the Brazilian Traction Company, and many members of the general public, as well as students from the University of Toronto, availed themselves of the invitation to be present.

Mr. Mulqueen's address was profusely illustrated with lantern slides, and surveyed the early history of the country, and its present geographical, economical, and sociological character. Although lacking coal and oil, Brazil has become a country of great possibilities, and is to-day in an analogous position economically to that of the United States fifty years ago.

Members present were specially interested in details of the large modern hydro-electric generating stations and transportation systems, controlled by the Canadian company with which Mr. Mulqueen is connected, and which supply Rio de Janeiro and Sao Paulo with light and power; and excellent slides were shown of these magnificent cities and the surrounding country. Mr. Mulqueen had evidently gone to great trouble in the preparation of his address, and that it was much appreciated was shown by the numerous questions put to him at the close, and the evident desire of members to hear still more of this republican neighbour to the south.

Standards of Admission and Grades of Membership

On Thursday, December 17th, a meeting was held at Hart House, devoted to the discussion of standards of admission and grades of membership in *The Institute;* Professor T. R. Loudon, M.E.I.C., being in the chair. While the attendance was not as large as had been expected, members had the great pleasure of welcoming R. J. Durley, M.E.I.C., the general secretary of *The Institute*.

J. A. Knight, A.M.E.I.C., led the discussion, and explained that a letter had been received from the Saskatchewan Branch in March, 1925, stating that "members of that branch felt that the present system of classifying members was not satisfactory". A committee had been studying the matter, and on their recommendation, that evening had been set apart for discussion.

Mr. Knights' first question was: "Are our standards of membership high enough?" and by comparing the standards of admission and grades of membership in the E. I. C. and kindred societies, he showed that the E. I. C. requirements were higher than those of many other societies, and that members were justified in accepting them as being satisfactory. In only one instance might an objection be raised,—that was, to the maximum age limit of thirty-three years for Juniors.

As regards the interpretation of the by-laws there was however in one case a wide divergence of opinion—as to the meaning of the term "Professional Responsibility". Some engineers held that when a man was in a position where he might be asked to do original design or layout work, he was in a position of professional responsibility. Others felt that unless a man were *personally responsible* for the safety and efficiency of the engineering project on which he was working, he was *not* in a position of professional responsibility. Then again, as regards the term "responsible charge", was the designing engineer, the resident engineer, or the chief engineer the responsible party; or were they all responsible? Although these were minor difficulties, it would be a good thing if a uniform interpretation could be secured throughout *The Institute.*

Mr. Knight felt that our real troubles were chargeable against ourselves, and not to the constitution, and that we should try to develop more "esprit de corps" by (1) Assuming responsibility in the affairs of the society; (2) Attending and taking an interest in the branch meetings; (3) Offering CONstructive, but not DEstructive criticism of *The Institute,* and *The Journal,* and (4) contributing to the engineering literature of Canada, instead of to the literature of some other country.

Each corporate member of the society, said Mr. Knight, is liable to be named as sponsor by some applicant for admission or transfer, and at such times the reputation of *The Institute* is in his hands, since the members of Council can only rely on the recommendations of the five sponsors, and the local branch executive. The reputation of *The Institute* was established by its members, and one inferior member might do more to lower that reputation than many worthy members. If there was the slightest doubt as to an applicant's qualifications, give the society the benefit of the doubt—not the applicant. The applicant could apply again, but it was a serious if not impossible step for *The Institute* council to cause a member to revert to a lower grade.

The discussion which followed was taken part in by George T. Clark, A.M.E.I.C., Professor C. R. Young, M.E.I.C., George A. McCarthy, M.E.I.C., R. B. Young, A.M.E.I.C., A. C. Oxley, A.M.E.I.C., R. O. Wynne-Roberts, M.E.I.C., and William Storrie, M.E.I.C., following which refreshments were served in the Great Hall.

Mr. Durley was then called upon, and in humorous and yet serious vein gave a summing up of the whole discussion from the point of view of the general secretary. Members present were particularly interested to hear that the only reason that the transactions were not now being issued was a financial one, and that the Council were anxious to resume their publication when they were able.

Victoria Branch

E. G. Marriott, A.M.E.I.C., Secretary-Treasurer.

Ascent of Mt. Logan

An audience of about four hundred people, assembled on November 24th, 1925 in the Chamber of Commerce auditorium, heard the history of one of the great adventures of the age when they listened to Colonel W. W. Foster's narrative of the Mt. Logan expedition successfully carried through in May and June this year.

Colonel Foster told the story in the simplest possible language, without any rhetorical flourishes. But it was tremendously impressive, the very absence of elaborate description leaving the listener's imagination freer play with the facts.

Col. Foster hurriedly sketched the history of the Mt. Logan expedition from the inception of the idea in 1913 down to the carrying out of Capt. McCarthy's reconnaissance in 1924, and the final achievement in the early summer of the present year. A chart, photographs and his own unembellished narrative furnished an excellent description of the surrounding country and approach to the ice-girt mountain. Generous tribute was paid to the reconnaissance party last year, when Colonel Foster said that he attributed the success of the enterprise to the work of Capt. McCarthy and the packers who had gone in then and established supply bases in readiness for this year's expedition.

The main party left Seattle in the latter part of April this year, on May 6th, reached Cordova, Alaska, and on May 12th, started up the Chitina river.

Early in the proceedings the expedition experienced the difficulty of travelling over moraine, at first carrying heavy packs which they gradually reduced as they realized the disadvantage of weight. Within ten miles of the point selected for their main camp they came upon the main cache established the previous year, and from here supplies were relayed to the base. Weather conditions had to be studied continually. The day at that latitude was from twenty-two to twenty-three hours long. Great variations of temperature were experienced at 8,000 feet altitude, from which the main climb began. On the snow the temperature might be about freezing point, and four or five feet above one's feet the temperature would be eighty or ninety degrees.

Up to May 31st, when they established their base camp at the foot of Mt. Logan, the weather had been beautiful throughout, and the schedule had been strictly adhered to. But difficulties were to present themselves later. A deep cleft between Mt. King and Mt. Logan was not anticipated, photographs taken from a distance having represented this as a continuous shoulder.

Colonel Foster described the feeling of the explorers when they came to what it was feared was an impasse, but from which Mr. McCarthy found an exit through the fortunate discovery of a narrow gateway through a mountainous block of ice. The weather, hitherto friendly, became violently stormy at this last difficult point in the expedition, and at that great altitude, where nearly all of the climbers experienced some difficulty in the mere act of breathing, they were weather-bound for four days, dense snow clouds cutting off the light. This fact, coupled with the great velocity of the wind, made it dangerous to attempt climbing. They began to suffer fromfrostbite. June 16th, they were still some distance from the summit, and felt that the situation was rather desperate. The temperature had dropped to 25 below zero, there was only food at this point for another twenty-four hours, so the frost-bitten members were sent down to Col camp. Captain McCarthy and Colonel Foster made a rush for what they thought was the summit of Mt. Logan, only to find that they had made a mistake. After eighteen days from their camp they were still four miles from the highest peak, well-nigh exhausted. They returned to the King Col camp once more. Two other attempts had to be made before they finally attained their objective.

The summit of Mt. Logan offered little room for description, being a narrow plateau about three feet in width and seventy feet long. Such a terrific wind was blowing that they had to lean on their ice-picks in order to keep a foothold. The strain of the twenty-three days' climb had proved almost too much for them; they were suffering from fear of delusions, delusions of comfortable homes and barns which became so insistent during the descent of the mountain that Colonel Foster himself was half-prompted to stop and tell a spectre of his imagination that it was very bad weather in which to paint a barn.

Still they encountered storms and terrific cold. Without tents and unable at one point to make any progress owing to the gale, they cut holes in the ice and huddled together in these for twelve hours. One member of the party, unable to walk because of frostbite, had to be carried, which made the descent still more tedious and difficult. It took them six days to get down from the summit of the mountain to the camp at King Col. There were hardships still ahead of them, even then, but a fine spirit was shown even by the worst sufferers. One man with feet so badly frozen that the bone protruded, walked a distance of fifty miles without complaint. Twice they discovered that their caches had been rifled by bear.

Even after reaching the river their troubles were not at an end. Two rafts were built to take them down to McCarthy. One accomplished the eighty-eight miles in safety; the other one, on which Captain McCarthy and Colonel Foster travelled, was swept away a short distance from its starting point, and it took them five or six days to make the remaining seventy miles on foot.

"This expedition was not just for the purpose of climbing Mt. Logan," said Colonel Foster in conclusion, indicating something of the valuable information which it had given to science through its disclosure of meteorological conditions, geography, geology and the fauna and flora of the country. All this was adding to the store of human knowledge. The expedition, moreover, was carried out in a spirit of adventure which was a characteristic of the Anglo-Saxon race, a spirit which had been greatly responsible for the building of the Empire.

This idea was emphasized by Mr. Ford and Mr. Lindley Crease in the vote of thanks which they accorded the speaker at the conclusion of the proceedings. G. B. Mitchell, chairman of the local branch, presided.

Joint Luncheon of the British Columbia Professional Engineers

On November 19th, the Victoria Branch held a joint luncheon meeting with the Association of Professional Engineers of British Columbia. At this meeting the principal speaker, F. A. Wheatley, A.M.E.I.C., registrar of the professional association, gave a very interesting address on the work of the Association.

The
Annual General
and
General Professional Meeting
will be held in
Toronto, January 27th, 28th, and 29th, 1926

Preliminary Notice

of Applications for Admission and for Transfer

December 19th, 1925

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in January, 1926.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council, shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering with special reference to the branch of engineering in which he has been engaged. This examination may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the first year in such a course, shall be required to pass an examination in the following subjects: geography, history, (that of Canada in particular), arithmetic, geometry, euclid (books I, IV and VI), trigonometry, algebra up to and including quadratic equations.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed successfully an examination equivalent to the final examination of a high school or the matriculation of an arts or science course. He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination equal to that prescribed for admission to the grade of Junior in the foregoing section and he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BENNETT—STEWART GORDON, of 121, Spadina Rd., Toronto, Ont. Born at Toronto, Ont., May 20th, 1892. Educ., B.A.Sc., Univ. of Toronto, 1914 one term Oxford University; four summers with Dept. of Public Wks., Toronto; 4½ yrs., Capt. Royal Engineers; then with Canadian Johns-Manville Co., acoustical engr., until Nov. 1919, when taken on staff of Faculty of Applied Science and Engr'g. Univ. of Toronto; 1920, lecturer in commercial engr'g., and asst. secretary; 1921 to date, lecturer and secretary, University of Toronto, Toronto, Ont.

References: C. H. Mitchell, P. Gillespie, T. R. Loudon, H. E. T. Haultain, A. D. Campbell, F. A. Gaby, A. H. Harkness, C. S. L. Hertzberg.

BERRY—EDWARD WILSON, of Ottawa, Ont. Born at Fermoy, Ireland, Aug. 26th, 1881. Educ., Hon. Grad., S.P.S., Toronto, 1910; D.L.S.; 1908 (summer) township outline, Ontario; 1909 (summer) asst. topogr., geological survey; 1920 (May-Dec.), articled pupil, D.L.S.; 1911-12, D.L.S. asst. to C. F. Miles, Inspr. of Surveys; 1913-14, asst. to T. H. Plunkett, D.L.S., base line surveys; 1912-13, surveys of township outlines and misc. surveys in Northern Manitoba; 1914 to date, i/c precise levelling parties except for two years overseas; at present, surveys engr., Grade 3, Geodetic Survey of Canada, Ottawa, Ont.

References: E. P. Bowman, R. H. Montgomery, W. H. Norrish, W. C. Murdie, O. Inkster, F. B. Reid.

BURKET—LESLIE HOWARD, of 165, Bedbrook Ave., Montreal West, Que. Born at Montreal, Que., July 5th, 1889. Educ., private tuition; 1904 to date, with Dominion Bridge Co., as follows:—1904-08, dftsman. in drawing office; 1908-13, checker, checking drawings of all kinds of steel structures; 1913-15, squad leader i/c of drawings of buildings and bridges; 1915-23, designing office, making designs of highway and railway bridges, hotels, office bldgs., apartments, theatres, churches, mill bldgs., transmission towers, water tank towers, oil tanks, electric signs, etc.; Sept. 1923 to date, i/c city designing office, superintending design of all building structures, Dominion Bridge Co., Ltd., Montreal, Que.

References: F. P. Shearwood, P. L. Pratley, LeRoy Wilson, D. C. Tennant, Jas. Robertson, L. R. Thomson.

CONNOR—HERBERT ARTHUR, of Calgary, Alta. Born at Winnipeg, Man., Sept. 28th, 1900. Educ., 1 yr. Arts and Science, Univ. of Alberta; 1920-22, chainman, C.N.R., Edson Divn.; 1923 rodman, and 1924 to date, rodman, C.N.Rlys., Edson and Calgary Divisions.

References: W. S. Fetherstonhaugh, H. W. Tooker, H. A. Bowden, A. J. Gayfer, C. V. Hope.

COOTE—JAMES ALEXANDER, of Pointe Claire, Que. Born at Oakville, Ont., July 25th, 1882. Educ., B.Sc. McGill Univ. 1914; Previous to and during college course, engrg. work as follows: 2 years, Westinghouse shops; 6 mos. switchboard operation; 2 or 3 years electr'l. constrn.; 1916 to date, mech'l. dept., McGill University, Montreal, as follows: 1916-17, demonstrator; 1917-23, lecturer and 1923 to date, assistant professor.

References: H. M. MacKay, C. M. McKergow, A. R. Roberts, C. V. Christie, C. J. Desbaillets, C. S. Saunders.

CRAIG—STEPHEN E., of Toronto, Ont. Born at Brampton, Ont., Jan. 31st, 1882. Educ., B.A.Sc., University of Toronto, 1911. 1911-12, d'ftsman, Dom. Bridge Co.,Lachine1;912-14, mech. supt., Ritchie & Ramsay, New Toronto, i/c of machinery, small power plant and pumping station; 1914-16, inspr., bridges and tanks, C.N.R.; 1917-19, chief inspr., representing Internat. Shipbuilding Co. at Detroit and Rochester, and Manager, Hamilton District for Canadian Inspection Co.; 1919-24, district mgr., for Canadian Inspection Co.; 1924-25, asst. laboratory engineer for H.E.P.C. of Ont., and at present, asst. laboratory engr., i/c of inspectn. of all materials of construction except concrete, H.E.P.C. of Ont.

References: W. P. Dobson, R. B. Young, R. J. Marshall, W. D. Walcott, C. P. Disney, Thos. Taylor, Fred. Newell.

DOBIE—ROBERT, of Peterborough, Ont. Born at Osnabruck, Ont., June 16th, 1863. Educ., Norman School, Milton, Ont. Tech. School, Grand Trunk Ry., Montreal; 1880-1895 — 5 years ap'ticeship, locomotive shops, 3 years ap'ticeship, dfting office, G.T.R.; 2 years firing locomotive express, then back to shops for 2 years. Afterwards in dfting office for 3 years; 1895-1900, chief dftsman., Royal Electric Co., Montreal; this company purchased by Can. Gen. Elec. Co. 1900-03, mech'l. supt., when transferred to same position in Peterborough. Still occupying position as mech'l. supt., Can. Gen. Elec. Co., Peterborough, Ont.

FOR TRANSFER FROM CLASS OF ASSOCIATE MEMBER TO MEMBER

JAMES—EDWARD HENRY, of 416 Phillips Place, Montreal, Que. Born at Farnham, Surrey, England, Dec. 30th, 1886; Educ., Assoc., City and Guilds Inst., London, Eng., 1906; Assoc.M.Inst.C.E. 1913; 1907-09, dfting., design and erection of steel bridges and structures, A. Handyside & Co., Derby, Eng.; 1909-10, dfting, estimating and design of temporary works, Easton, Gibb & Son, Ltd., Rosyth, Scotland; 1910-13, with same company i/c of sinking monoliths, entrance and main outer wall of basin, H. M. Dockyard, Rosyth; 1913-14, with Foundation Co., Ltd., Montreal, asst. supt., at Little Current, Ont., on rly. terminals and timber docks, Bear River, N.S., on bridge foundations; 1914 (Aug.-Nov.) on design of extension of No. 1 Elevator, Montreal, with J. S. Metcalf Co., Ltd.; 1914-19, overseas, Lieut.; 1919-20, with A. D. Swan, M.E.I.C., i/c of design of Ballantyne Pier, Vancouver, and a graving dock in Vancouver; 1920-25, res. engr., i/c of all work in B.C. for Mr. Swan; at present partner with A. D. Swan, M.E.I.C., Consltg. Engr., Montreal.

References: A. D. Swan, H. Holgate, F. P. Shearwood, H. Rolph, W. J. Bishop.

LEFEBVRE—JOSEPH ALEXIS, of Vallee Street, Beauport, Que. Born at Maskinonge, Que., August 1st, 1884. Educ., Polytech. School; Passed exam. Can. Soc. C.E. 1915; Previous to 1915, supt. of gravelling branch, and from 1915 to date, head of district, Roads Dept., Province of Quebec, responsible for road constrn., mtce., repair and traffic supervision.

References: A. Fraser, J. O. Montreuil, A. Larivière, A. B. Normandin, R. Savary, T. E. Rousseau, C. C. Piché, I. Vallée.

MILLS—THOMAS STANLEY, of Ottawa, Ont. Born at Kingston, Ont., Jan. 26th, 1889. Educ., B.A. 1910, B.Sc. (C.E.), (Honours), 1911, Queen's Univ.; D.L.S. 1915; 1910, res. engr., highway constrn., Niagara River Blvd.; 1911, res. engr., water supply constrn., St. Thomas, Ont.; 1913, asst. city engr., Prince Albert, Sask.; 1914, prin. asst., misc. surveys on D.L.S. in B.C., Alta. and Sask.; 1915, asst. engr., 1916-18, acting head office engr., 1919, acting chief highway engr., 1920 to date, asst. chief engr., Dominion Parks Branch, Dept. of the Interior, Ottawa, Ont.

References: J. Murphy, S. S. Scovil, J. M. Wardle, J. H. Marshall, G. H. Herriot, G. F. Horsey.

STERNS—FRANK ERNEST, of St. Catharines, Ont. Born at Charlottetown, P.E.I., Dec. 15th, 1879. Educ., M.Sc., McGill Univ., 1903. 1902-03, demonstrator, McGill Univ.; 1903-05, dftsman., C.P.R., Montreal; 1905-06, dftsman., Robins Conveying Belt Co., N.Y.; 1906 (May-Aug.) designed and detailed a travelling dock crane for Locomotive & Machine Co., Montreal; 1906-07, 8 mos. leading dftsman., and 6 mos. res. engr., on constrn., with Henry Goldmark, Consltg. Engr., Montreal, on improvements to plant of Canadian Locomotive Co., Kingston, Ont.; 1907-12, asst. engr., design of lock gates, etc., Panama Canal; 1912-13, asst. engr., Welland Ship Canal; 1913-17, designing engr., genl. and detail design of locks, dams, weirs, etc.; 1917-18, design'g. reinf. concrete barges and ships with J. L. Weller, Cons. Engr., St. Catharines, and Cummings Structural Concrete Co., Pittsburgh; 1918-19, prin. asst. engr., with Henry Goldmark, New York, design of lock gates, etc., for Inner Harbour Navigation Canal, New Orleans; May 1919 to date, designing engr., design structures and equipment, Welland Ship Canal, St. Catharines, Ont.

FOR TRANSFER FROM CLASS OF JUNIOR TO HIGHER GRADE

LANCTOT—JEAN JACQUES, of 9, Haldimand, Quebec, P.Q. Born at Montreal, Que., Oct. 20th, 1891. Educ., McGill Univ. and Ecole Polytechnique de Montréal, enlisted before completion of course; admitted by exam. to Corp. of Professional Engrs., Quebec, 1923; 1913 (summer) asst. to E. A. Evans, C.E., estimate of cost of constrn. of projected rly. (North Rly.) between James Bay and Nottaway Village; 1914 (summer) asst. to C. E. Lemoine, L.S., surveys of rivers and lakes in Northern Abitibi; 1915 (summer) testor and inspr. of steel and tools, Ross Rifle Factory of Quebec; 1916 (summer) asst. to J. Fortin, C.E., constrn. hydro-elec. power on Ha Ha River for Chicoutimi Pulp & Wood Co.; 1917-19, R. F. Corps.; 1920, gen. supt. of roads constrn., etc., Provincial Building & Engr'g. Co. of Montreal, and also for P. C. Costo et Frère, contracting firm of Montreal; 1921, road inspectn., for Ministry of Roads, Prov. of Quebec; 1921 to date, divnl. engr., for Ministry of Roads, Prov. of Quebec, Quebec, P.Q.

References: A. Fraser, J. A. Lefebvre, A. B. Normandin, A. Larivière, T. E. Rousseau, F. X. Ahern, J. M. H. Cimon.

PRIEUR—HENRI, Apt. 3, 173 St. Joseph Boulevard, Montreal, Que. Born at Montreal, April 17th, 1893; Educ., 1 yr. and 7 mos. Polytechnic School. Private study. Admitted to Corpn. of Prof. Engrs. of Quebec by Exam. 1925; 1911-12, rodman, field work, dftsman., municipal works, with Boucher & Demers; 1912, instr'man., chief of staff on surveys, etc., with Austin & Chapdelaine. (Sept.) rodman, dftsman., sewer dept., City of Montreal; 1914 to date, with the City of Montreal — 1914-18, northern divn., asst. engr. on sewer constrn. and design, and 1918 to date, asst. engr., sewers branch.

References: deG. Beaubien, G. R. MacLeod, E. Fusey, J. G. Caron, H. A. Gibeau.

TURNBULL—AUBREY ARNOLD, of 40, Crown Street, St. John, N.B. Born at Digby, N.S., Aug. 30th, 1896. Educ., B.Sc., N.S. Tech. Coll., 1922, engr'g. course Dalhousie Univ.; 1916-19, Lieut., 4th Batt. Can. Machine Gun Corps.; 1920 (summer) with res. engr., on hydro-elec. development, St. Margaret's Bay, N.S.; 1921 (summer) instr'man., on hydrographic and power surveys in the Provinces of Nova Scotia, New Brunswick and Prince Edward Island, for Dom. Water Power Branch; 1922-23, telephone engr. student, and 1924 to date, plant engr., with The New Brunswick Telephone Co.

Automatic Gauge Division of Hydrographic Office

The engineering profession in general, and more particularly those parties seeking precise information in regard to water surface elevations, of the Great Lakes and St. Lawrence river, for scientific investigations, water power developments and navigation interests, especially during the present low stages of the waterways, should be acquainted with the following facts,—namely, that there is an Automatic Gauge Division, of the Canadian Hydrographic Office, whose special province it is to obtain and record precisely the hourly fluctuations in the levels of the Great Lakes and St. Lawrence waterways.

In 1906 the work of recording in a reliable and systematic manner the hourly levels of water surfaces of the Great Lakes during the season of navigation was begun in a small way by establishing self-registering gauges at three locations,—one at French River Village, one at Collingwood, and one at Toronto.

The results, from this small start, proved so gratifying that urgent requests, for further and more extensive data of the same nature provided by the preliminary investigation, came from scientists and engineers along the whole fifteen hundred miles of the waterways extending from Quebec harbour to Port Arthur. Since 1906 the work has expanded and has covered forty-eight locations between Quebec harbour and Port Arthur. At present there are thirty-eight gauging stations maintained, thirty-two of which are operated during the entire year because of the demands for precise information in connection with special ice and hydraulic investigations by both Canadian and international commissions. Although this special work has become of international scope its administration remains entirely under the Canadian Hydrographic Office.

During the present year there was inaugurated the issuance of a monthly bulletin to all interested parties on both sides of the international border. This bulletin, issued before the 10th of each month, gives the mean elevation, of each of the Great Lakes, and the St. Lawrence river at Montreal, for the preceding month as computed by hourly readings from automatic gauge records. A further feature of the bulletin is comparative statements of the then reported stages, of water levels, to similar data since 1860.

Requests for information of the above nature should be addressed to, Captain F. Anderson, M.E.I.C., chief hydrographer and director of Tidal and Current Surveys; or to The Canadian Hydrographic Office, Department of Marine and Fisheries, Ottawa.

The Trend of Steam Power Plant Development

A. G. Christie,
Professor of Mechanical Engineering,
The John Hopkins University, School of Engineering, Baltimore, Maryland.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

Introduction

One of the remarkable developments of the past decade has been the improvement in the economy of steam power plants, particularly of the large central stations. This is made evident by noting the performance of typical American plants of 60,000 k.w., and higher. Stations put in service in 1915 required about 20,000 B.t.u. per kilowatt hour of net station output while some of those initially operated in 1925 required only 15,000 B.t.u. per kilowatt hour. This represents a decrease of 25 per cent in coal consumption in ten years. While further gains are still possible, other factors which have increased in relative importance, particularly increasing fixed charges, may delay any great decrease in coal consumption. Much interest is manifested in power station development both for central stations, and for industrial plants and any discussion of the trend of development is helpful and stimulating in inducing further study of possible economies. The trend presented in the following paragraphs is based on present progress and on probable developments and has been written largely with Canadian conditions in mind.

The uses of electric power are increasing at a rapid rate. The records of growth of any public service system indicate the expansion in power demands. For instance, your Hydro-Electric Power Commission of Ontario had a load of 77,000 horse power in 1914. In 1924 the Commission was distributing 700,000 horse power, including exported power. Canada has abundant good coal supplies only in Nova Scotia, Alberta, and British Columbia. Coal must be imported or shipped to other districts and is high in price. Fortunately in many sections water powers, with quite steady flow are available for the cheap development of hydro-electric power, and most of these have been put to use. In certain parts there are few sites capable of cheap development that are not utilized. Furthermore, your hydro-electric systems have developed sharp load peaks of a relatively few hours duration per year due largely to lighting loads. These low-load-factor peaks can be carried by developing expensive water power sites which remain idle during the rest of the year, and which consequently involve high fixed charges on the power system as a whole. Steam stand-by stations can often be built for much less than an equivalent hydro-electric plant and long transmission line, and in consequence thereof with lower fixed charges per kilowatt-hour. Several of the large hydro-electric power systems of California and of the southeastern states have found it advisable to install steam stand-by stations for contingencies, peak loads and low water periods. It is quite probable that low-cost stand-by steam stations for similar purposes will soon fill an economic need in Canada.

Load Factor

Load factor has a great influence on steam station design. It may be expressed in several ways as daily, monthly or annual. The influence of each of these on costs is not always well understood. These influences may be stated briefly as follows:

(a) Daily load factor and the form of load curve affect fuel costs.
(b) Monthly load factor affects labour and fuel costs.
(c) Annual load factor affects fixed charges.

All of these influences must receive careful consideration in the plant design. It also follows that careful studies must be made of expected load conditions throughout the life of the plant in order to estimate accurately the value of these various load factors.

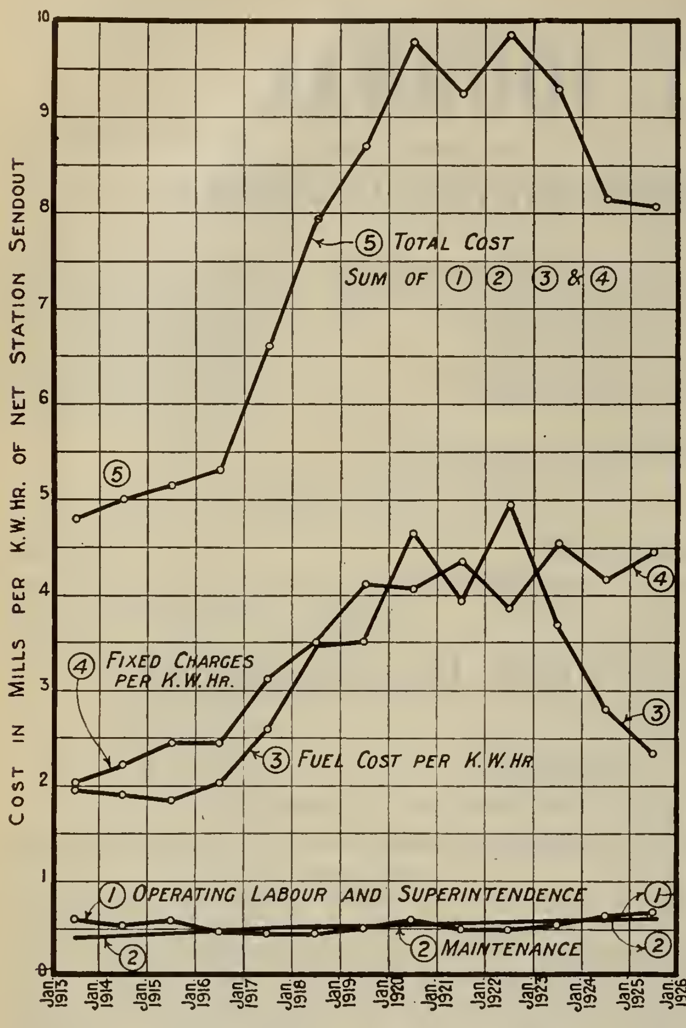

Figure No. 1.—Trend of Operating Costs and Fixed Charges for Typical Stations of 60,000 k.w. Capacity and Higher, Plotted against Date of Initial Operation of Stations.

High annual load factors will warrant considerable refinement and higher investment costs to secure the increased station economy. On the other hand, very low annual load factors warrant only a low cost station because fixed charges constitute a larger item in power costs while fuel costs in such cases are relatively lower. Engineers have in the past been prone to use too high values of annual load factor for the useful working life of machinery. Much special equipment has been installed the use of which was not economically justified by the actual operating life of that part of the plant. The actual relations between load factor and working life have been fully discussed.* The relation of load factor to plant design is now better understood and fewer mistakes are made than in earlier designs. However, certain so-called "base-load plants" are still being built, although it is evident that these can only remain base-load plants until some newer and more economical equipment is installed. The art of steam power plant design is still developing rapidly and it is reasonable to expect that further progress will be made. In such a case, the life of a station on base-load cannot be long, when supplying power to growing communities.

*"Obsolescence a Factor in Power Plant Design", Peter Junkersfeld, *Power*, June 12th, 1923.

The cost of power includes items for fuel, maintenance, operating labour and fixed charges. The trend of these separate items of cost and of total cost is shown in figure No. 1, which is reproduced from the 1925 Report of the Committee on Power Generation of the American Institute of Electrical Engineers. These curves indicate a definite upward trend for fixed charges while fuel cost shows a downward trend due partly to the increasing efficiencies of the newer stations and partly to reduced coal prices. The last points on the curves indicate that fixed charges are almost double fuel costs per unit of output. These considerations indicate that the foremost problem confronting designers to-day is the reduction of initial investment in the plant so that the trend of the curves for fixed charges and for total cost may be turned downward. This desire to reduce fixed charges should have a modifying effect on the trend of steam station design, particularly in endeavours to secure increased output out of standard designs of equipment and to reduce building volume.

Location of Steam Stations

The steam station should naturally be located as near the centre of load as possible to cut down distribution losses and fixed charges. It is seldom so placed on account of other factors that enter the problem. For instance, much cheaper and more land may be favourably located at another place where the saving in first cost will overbalance the capitalized additional transmission losses. Modern steam turbines require enormous quantities of cooling water in their condensers so that a waterside location is necessary. Cooling towers are used only when natural supplies of water are unavailable. The plant must be easily accessible from trunk lines of railroads to assure steady coal deliveries, particularly in the winter months. It is also desirable to provide if possible for water delivery of coal. Coal unloading devices and ample coal storage must be provided. Much coal enters Canada in the summer and is stored for winter use. Means must be provided to cheaply store and reclaim this coal even when frozen or covered with snow. Central Canada gets most of its coal from Pennsylvania. It would be in the interests of Canada's National economy to furnish as much as possible of this coal from Nova Scotia by boat through the proposed St. Lawrence Deep Waterways. In certain cases the disposal of ash introduces problems. Central station location will thus be influenced by suitability and cost of land, available water supply, coal handling and storing facilities.

Local conditions may favour the addition of a central heating load to a stand-by steam power station. This service would ensure the steady and economical operation of the boiler house and the presence of an active operating force throughout the winter. The short demands for electric power during peak loads on the system, could be met in considerable part by forcing the boilers to higher ratings. The heating service would bear a proportionate part of the fixed charges of the boiler plant. This would prove one effective way to lower fixed charges on the electrical output of such stations.

Theoretical Factors in Steam Station Design

The design and selection of steam station equipment is governed by two factors which have been most effective in securing high efficiency. These are the utilization of the available heat head and the heat balance.

A certain amount of energy is thermodynamically available for work when steam is expanded from steam line pressure and temperature to the given exhaust

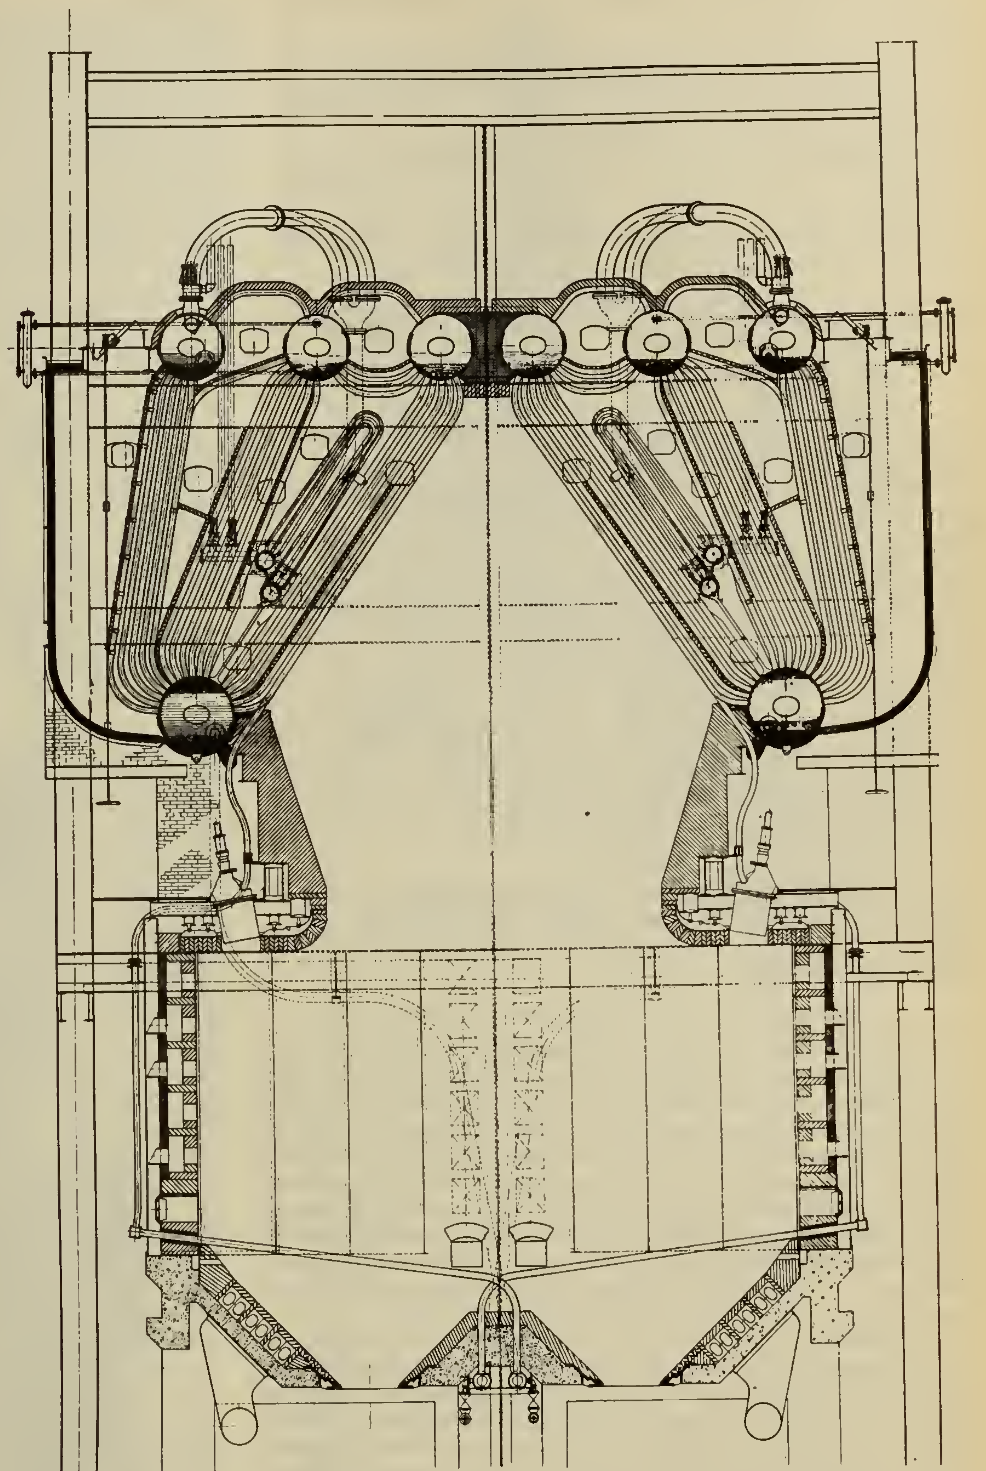

Figure No. 2.—Section of Duplex Stirling Boiler and Furnace at the Lake Shore Station, Cleveland Electric Illuminating Company, Cleveland, Ohio.

Heating surface in boiler 30,600 sq. ft.; in water screen, 835 sq. ft.; in superheater 4,520 sq. ft. Furnace volume above water screen, 26,000 cu. ft. Each boiler has an economizer of 22,080 sq. ft.

pressure. The greatest amount of this available energy should be converted into useful work in the station. The main turbines are the most efficient elements in a central station. If heat head alone were considered, then all energy transformations should take place in them and all auxiliaries should be driven by electric power from the main generators. In practice this ideal is modified by such considerations as first cost, increasing efficiency of small steam turbines, reliability against shut-down, and space requirements. Such equipment as steam-driven boiler feed pumps for starting up the station and for stand-by reserve, steam-driven circulating pumps for reliability, and steam-jet air pumps for low cost and small space requirement, are examples of departures from the ideal maximum utilization of heat head. In all new stations such departures will be closely scrutinized and must be amply justified before they are incorporated in the plant design. Heat head has been fully discussed in another paper.*

The heat balance is more comprehensive than heat head utilization. It implies a study of the plant design as a whole so that the greatest economical amount of

*"The Utilization of Heat Head", A. G. Christie, *Power*, Dec. 2nd, 1924.

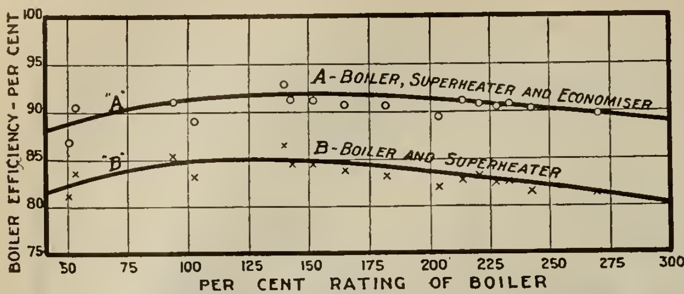

Figure No. 3.—Test Efficiencies of Various Ratings of 30,600 sq.ft. Boiler, Lake Shore Station, Cleveland Electric Illuminating Company, Cleveland, Ohio.

(a) Boiler, Superheater and Economizer. (b) Boiler and Superheater.

heat energy in the coal may be delivered as electric power to the feeders leaving the station. Due regard must be given to costs of obtaining such performance and all gains must be balanced against the increased cost of securing such improvements. This study has to do not only with the utilization of available heat head but also with economical boiler operation and with the economy and reliability of all auxiliary services necessary in the plant such as condenser operation, feed water heating, pump and other auxiliary drives, coal handling and preparation, and all other services. Heat balance studies have resulted in the use of higher steam pressure and temperatures, reheating of steam, powdered coal, air preheaters, bleeder heaters for feed water, evaporators, and the various systems of electric drives for auxiliaries. Improvements in station performance can still be secured by careful heat balance studies.

The modern trends of steam station design may be defined as attempts to apply these two theoretical principles, viz., conservation of heat head and economical dollar heat balance.

Steam Pressure and Temperatures

The first steam central station started in New York, in 1882, carried 120 pounds steam pressure with no superheat. By 1920 steam pressures had risen to 300 pounds and steam temperature to 700° F. Rapid advances have been made in the last five years so that there are several stations in the United States with pressures between 550 and 600 pounds. A 1,200-pound boiler is going into operation in one station, while in England an experimental boiler with 3,200 pounds steam pressure has been in operation. Steam temperatures have however increased only to 750° F.

The writer has for several years urged the desirability of increased steam temperature, and demonstrated the economic possibilities of higher temperatures in a recent paper.* Increased steam temperature involves increased expense only in the superheater, the main steam header and valves, and in the early stages of the turbine. Higher boiler pressure requires increased expense for all equipment from the boiler feed pump practically to the turbine exhaust.

The steam consumption will be decreased by either higher steam pressure or higher temperature and smaller pumps, boilers, superheaters, piping, and condenser equipment will be required. Such decreases will offset a portion of the increased expense due to higher pressure or temperature. The net increase of fixed charges on this more expensive equipment must be balanced against the reduction in fuel costs at the assumed annual load factor before one can decide whether it will pay to go to the higher pressure or temperature. At the present time power plant designers look to the metallurgists to develop steels suited for higher temperatures than 750° F. Some hold that carbon steels can be safely used. Others think that there is hope in the chrome steels, for these oxidize slowly. In the meantime the general tendency is towards higher pressures, although eventually higher temperatures than 750° F. will also be used. Boilers for 425 pounds are now made in standard sizes, 600 pounds is being used and some 1,200-pound plants may be in operation in the United States within a few years.

Structural Features of Design

Building and foundations may account for one-fifth to one-third or more of the total cost of the plant. These afford much room for competent design as they are more controllable on a given site with given requirements than steam or electrical equipment. These facts are among the least appreciated and least understood by central station managers and often by designers as well.

Many variables such as size and shape of available ground, soil and flood conditions, circulating water supply and levels, rail service, etc., are encountered with every power house site. It is seldom, if ever, possible to build

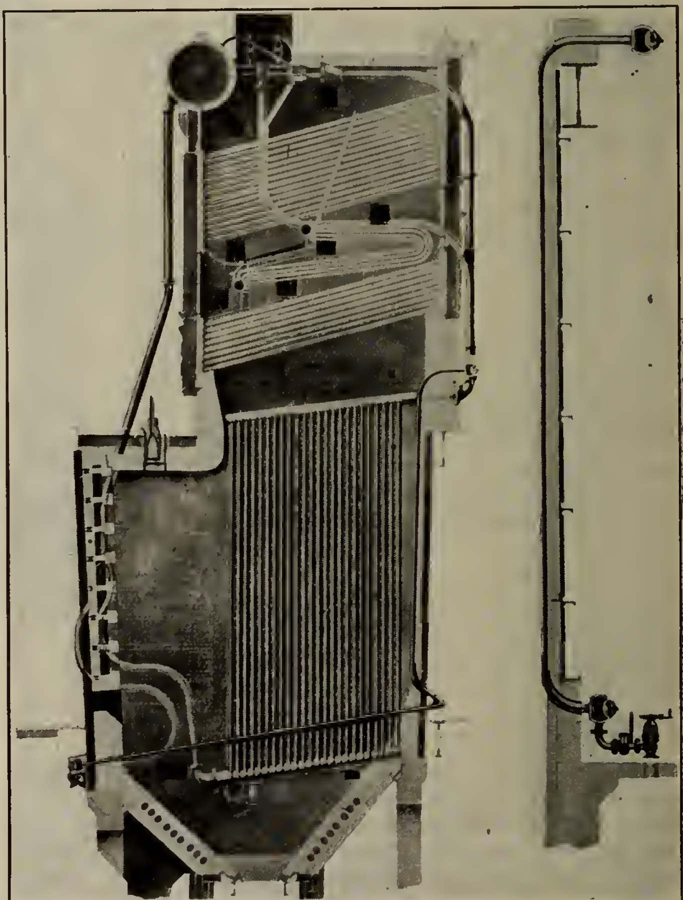

Figure No. 4.—Phantom Section through Boiler No. 11 and Furnace at Cahokia Station, Union Electric Light & Power Company, East St. Louis, Ill.

Heating surface in Babcock and Wilcox cross-drum boiler 18,010 sq. ft.; in water screen and fin-tube side walls 1,888 sq. ft.; furnace volume above water screen 13,500 cu. ft.; furnace for pulverized coal firing. Section of fin-tube side walls also shown.

*"Higher Pressures or Higher Temperatures", A. G. Christie and D. C. Turnbull, Jr. Report of Prime Movers Committee, National Electric Light Association, on Higher Steam Pressures and Temperatures, July, 1925.

two power plants in different locations from the same design. The arrangement of apparatus depends on whether the location is on a small city site or in the country where plenty of land is available and also on the foundation conditions at the two locations. It is generally necessary to restrict the floor area in the city location on account of the cost of land, while in the country, if good soil for foundations is available, the plant may be spread over considerable ground. Each of these types requires different structural design. Skilful arrangement of equipment is necessary to reduce building costs in any large measure.

Volume is the more generally accepted unit for the comparison of plant designs. Much thought is now devoted to studies of means to reduce power plant volume. Breechings have been placed on the roofs of boiler houses to reduce their roof heights. Fans and even air preheaters may also be placed above the roof if no other space is available. Efforts will be made to reduce furnace volumes with powdered coal which would tend to reduce the volume of the boiler house. Considering boiler plants as now built, there appear to be possibilities of further developments in design and of reduction in total volume and cost of the structures.

Turbine room height and width are fixed by the requirements of the condenser and its auxiliaries, and by the clearances necessary to lift covers and remove rotors from turbines and generators. The turbines may be placed end-to-end or cross-wise in the turbine room and the possibilities of each plan must be carefully studied. The usual arrangement is to place the turbine on steel or concrete foundations above the condenser with the axes of turbine and condenser at right angles to one another. The height of the turbine room cannot be greatly reduced when this arrangement is used. It has been suggested that vertical condensers would permit reductions in roof height and lessen turbine room volume.

Much of the electrical equipment formerly housed inside the building is now placed outside and this has decreased building expense. It is sometimes possible to find room in the lay-out for engineers' offices, laboratories, emergency bed-rooms, wash rooms, a lunch room, locker rooms, store rooms, machine shop, and pipe shop, by utilizing otherwise unoccupied space.

Inside ornamental brick facings together with outside architectural elaboration involve added first cost. The trend now is towards simple plain low-cost designs and in some cases reinforced concrete has been used in place of structural steel and brick. Much money may be needlessly spent on the station structure and careful study of this feature can often effect large savings in total plant cost.

Boilers

Modern boiler plants have four outstanding characteristics, namely, increased boiler size, high ratings in operation, new furnace designs and automatic control.

Boilers with 30,600 square feet of heating surface and 835 square feet additional in the water screens, are in operation at the Lake Shore station of the Cleveland Electric Illuminating Company, Cleveland, Ohio, one of which is shown in figure No. 2. This is fired with pulverized coal as shown. Formerly 20 feet was considered the limiting length for straight water tubes for boilers. Boilers with 24-foot and 25-foot tubes are now in service and longer tubes are quite probable as these provide increased furnace volume and increased low-cost heating surface, both of which are necessary for high ratings. There is a definite trend towards larger and fewer boilers in power stations.

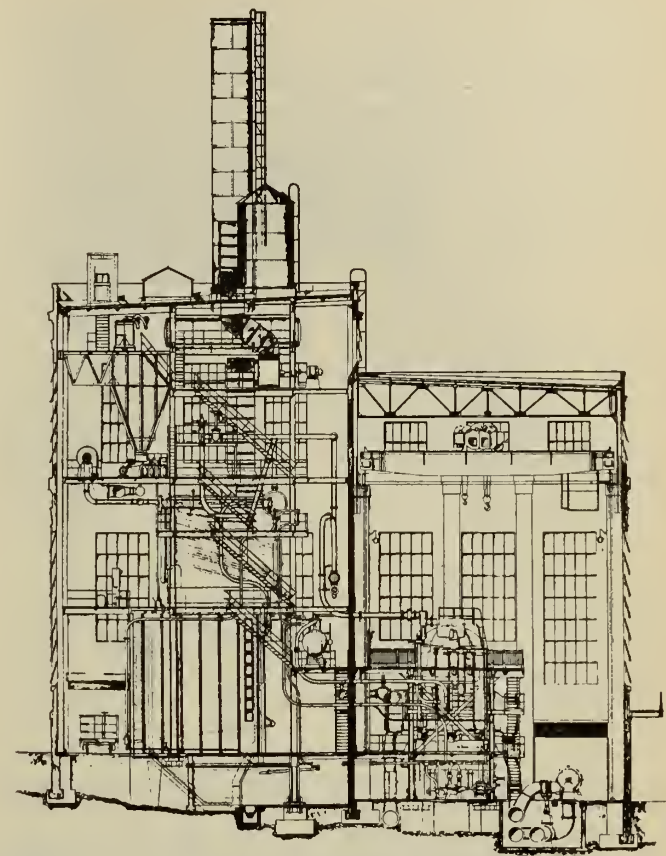

Figure No. 5.—Cross-section of Holtwood Steam Station of the Pennsylvania Water and Power Company, Holtwood, Pa.
Two 12,500-k.w. turbines; three boilers with 14,050 sq. ft. heating surface; pulverized coal furnaces with induced draft with provision for air preheaters to be added later.

Increased boiler ratings are now possible through improved furnace designs which produce higher efficiency over a wide range of load. Figure No. 3 shows the combined boiler, superheater, and economizer efficiencies as found by tests on the boiler illustrated in figure No. 2. This curve is remarkably flat over a wide range of load. Few boilers are now operated continuously at ratings above 300 per cent. Air preheaters tend to flatten the boiler efficiency curve so that operation at peak-load at much higher boiler ratings than 300 per cent does not require much sacrifice in fuel economy.

The motive in developing boilers for high ratings is largely a matter of investment costs. The cost of furnace and setting, air preheater, and forced and induced draft fans, will be increased when high ratings must be carried. The plant as a whole can operate with fewer boilers installed and these increased auxiliary costs are small compared with the costs of complete additional boiler plant. High boiler ratings therefore tend to lower the first cost of plant and are often justified on this basis for the given load conditions.

These higher ratings are only possible with improved furnace designs. Powdered coal has been successfully applied to boiler firing within the last few years. General statements on the relative cost of pulverized coal systems and stokers are dangerous to make because other factors must be considered besides the mere item of first cost of this equipment alone. When all factors are considered the differences in cost become small and may favour either system depending on local conditions. Unit pulverizers are, under the same conditions, less costly than

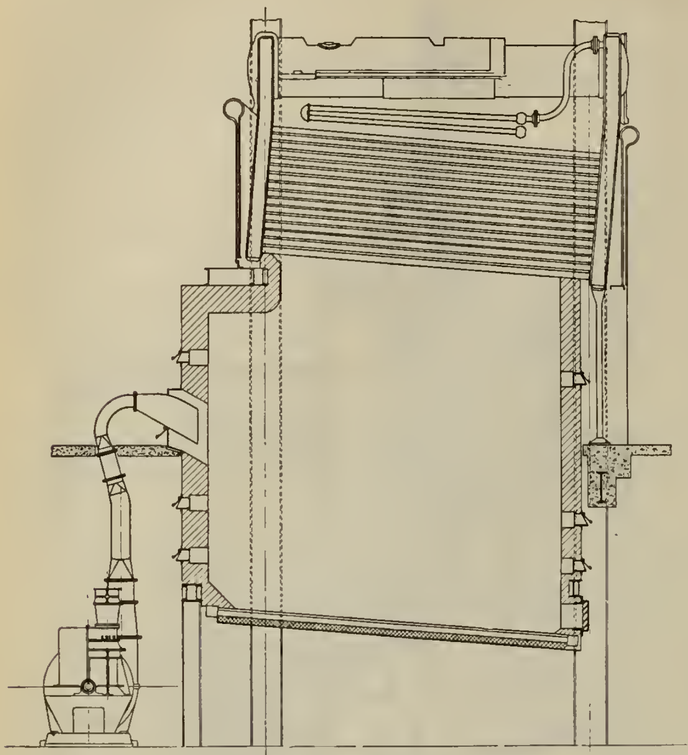

Figure No. 6.—Arrangement of Boiler, Furnace and Unit Pulverizer for Boiler No. 19 Ashley Street Station, Union Electric Light and Power Company, St. Louis, Mo.

Heating surface in Edgemoor boiler 5,580 sq. ft.; refractory faced Bailey side walls and Bailey bottom with cast iron facing; heating surface of Bailey side wall and bottom 789 sq. ft.; furnace volume 5,230 cu. ft.

central pulverized coal systems. Powdered coal equipment requires more auxiliary power than stokers. On the other hand, it gives a higher efficiency over a wider range of boiler ratings and is more independent of the grade of coal than the best stokers. Powdered coal more nearly approaches test efficiency in daily operation and has lower stand-by losses and lower maintenance costs than stokers. These factors have warranted its installation in many stations. The use of pulverized coal is a new art and is developing rapidly. Improvements in pulverizer design and in furnaces, should all tend to lower first cost and increase simplicity and efficiency. The use of pulverized coal is increasing and it must be given serious consideration in designs of new plants.

When powdered coal was first used, it was soon found that solid walls of the best grade fire-brick would not always stand the increased furnace temperatures. Air-cooled brick side walls were tried with considerable success with certain good coals, while with other coals the spray of liquid ash on these side walls, particularly of ash high in iron, caused the walls to wash badly and resulted in rapid erosion of the fire bricks. Studies of furnaces* indicated that the benefits of the radiant heat developed in the flame were not fully realized when brick walls were used. It was suggested that the furnace be wholly enclosed by water-cooled walls to absorb the greatest possible amount of radiant heat. Figure No. 4 shows such a furnace setting in the Cahokia station of the Union Electric Light and Power Company of Illinois. Water-cooled walls of the fin-type are provided for both sides and rear walls as shown, with a water screen above the ash-pit. A detail of the side wall construction is also shown.

With water-cooled furnaces, the entering air should be preheated and furnished in slight excess, (10 to 15 per cent), over theoretical requirements. This combination of water-cooled furnace walls and an air preheater seems in practice to offer the most economical combination. The rates of heat absorption by radiant heat in the water-cooled furnace walls are so great, — from 40,000 to 75,000 B.t.u. per square foot per hour, — that much of the heat generated in the furnace will be transmitted to the boiler in this way. Future boilers may be built *around* the furnace rather than entirely *above* it. These may be radically different in design from present types, will probably have less heating surface per unit of performance and hence should cost less than present day standard designs.

Some refractory lining seems to be required in certain furnaces such as those burning pulverized coke or anthracite. This may be of the standard air-cooled brick-and-tile design, now in use in some pulverized coal plants, or may consist of a refractory lining on water-cooled walls. Figure No. 5, is a cross-section of the Holtwood station of the Pennsylvania Water and Power Company, where furnaces with air-cooled side walls were installed to burn either a good grade of powdered bituminous or powdered anthracite coal. This station is interesting as it is one of the newest of the steam stand-by stations to a water-power development. It straddles the dam at McCall's Ferry, Pa. Two 12,500-k.w., turbines, with condensers, regenerative feed water heating, evaporators, pumps, etc., have been installed together with three 14,050 square feet Babcock and Wilcox cross-drum boilers, one of which is a spare. These boilers operate at 385 pounds pressure and for the present at 560° F. steam temperature, but this will be increased later. Induced draft fans furnish the draft. The turbines are designed to float on the system at peak load and to carry loads in excess of the hydro plant capacity. They may at times be motored during fluctuations in load. This plant has been in satisfactory operation for several months.

It is not always economical to entirely supersede an old station which may be favourably located. Such stations generally have stokers with small furnaces and hence operate at relatively low boiler efficiencies. Increased boiler ratings, reduction in smoke, and at the same time increased efficiency have been secured by rebuilding such furnaces for powdered coal. Figure No. 6 shows such a rebuilt furnace under a 5,580 square feet boiler at the Ashley Street station of the Union Electric Light and Power Company, St. Louis, Mo. This is equipped with a Simplex Unit Pulverizer of 8,000 pounds per hour capacity. Increased boiler ratings, less smoke, and greatly improved boiler efficiency resulted from this change.

References have been made to preheated air. Wherever the cost of coal warrants the saving of a portion of the heat in the flue gases leaving the boiler, air preheaters or water economizers should be installed. From a heat balance point of view for the whole station, the lowest heat consumption would be expected by the use of stage bleeding of the main turbine to heat the feed water and of air preheaters to recover some of the losses in the flue gas from the boilers. Preheated air raises furnace temperature and greatly increases the rate of radiant heat emission which results in increased boiler efficiency.

*"The Influence of Radiant Heat on Furnace Design", A. G. Christie, *Power*, May 29th, 1923, also, "Boiler Furnaces for Pulverized coal", A. G. Christie, *Mechanical Engineering*, August, 1925.

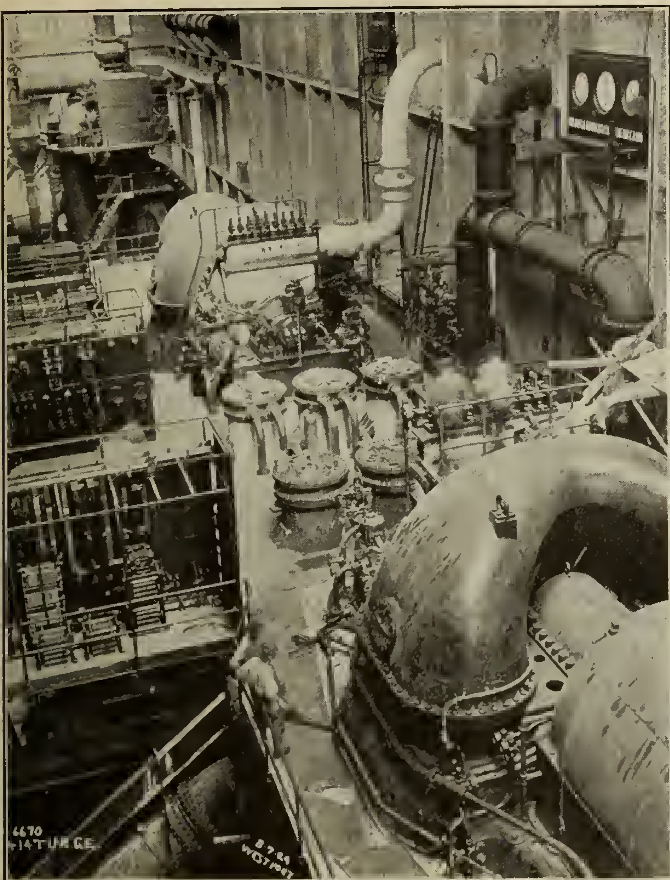

Figure No. 7.—Interior View of Westport Station of the Consolidated Gas, Electric Light and Power Company of Baltimore.

Boilers cannot be operated at high ratings on natural draft unless very high chimneys are provided. Where ratings over 250 per cent are desired, induced draft fans are generally necessary. These assume large proportions when very high ratings are desired. Forced draft fans are needed where air preheaters are used. Considerable study must be devoted to the best choice of number and size of fans for these purposes and to their arrangement and location. The fan builders should do further development work in order to produce smaller-sized fans for this purpose.

Ample light should be furnished to all parts of the boiler room. Cleanliness is an essential requirement and provisions for keeping the whole plant clean, particularly the boiler room and pulverizer room, should be incorporated in the design.

Powdered fuel firing lends itself admirably to full automatic control for which several systems have been developed. These control systems have maintained the average daily boiler efficiency on varying loads within a few per cent of test efficiency. Such performance should warrant their consideration in all new stations.

These and other developments to be described indicate that a high order of intelligence is needed in the operators of a modern boiler plant.

Feed Water

Careful study is now given to the treatment and heating of boiler feed water. Surface condensers are generally installed with all large steam turbines and the condensate, being pure distilled water, can be returned to the boiler as feed water. Troubles with boiler corrosion and oxidation of blading in steam turbines, have been traced to the presence of free oxygen in solution in the feed water. Hence the feed is de-aerated and kept in a closed system out of contact with air on its way to the boiler. De-aeration may be accomplished in the condenser itself or in separate de-aerator-heaters specially provided for this purpose. De-aeration accomplishes two results: it removes the undesirable oxygen and other gases from the feed water and this results in higher vacuum in the condenser.

Make-up water should be supplied from evaporators after such preliminary chemical treatment as the raw water may require. Low pressure evaporators are used to conserve heat head and may be single or multiple effect, depending on the source of steam and the heat balance arrangement. The heat balance is generally planned so that the condensate from the main condenser serves as cooling water in the evaporator condenser and thus returns the evaporator heat to the boiler.

The most efficient method of heating feed water is by means of steam, bled at several stages from the main turbine. This provides progressive heating by steps with steam whose heat head has been most economically utilized. The heaters are of the closed type, generally horizontal, and may be located either under the turbine or elsewhere as desired. Vertical closed heaters of the hair-pin type, first used at the Westport station of the Consolidated Gas, Electric Light and Power Company of Baltimore, are of a later design. Figure No. 7 shows this installation in the centre of the picture. The advantages claimed for these heaters over horizontal heaters are lower first cost and greater accessibility. While it is desirable to heat the feed entirely with bled steam, every other source of waste heat in the plant should be utilized in heating feed water. Such waste heat may be recovered from the steam-jet air pumps, steam leakage from main turbine glands, the evaporator condenser, any steam driven auxiliaries and in some cases, the main turbo-generator cooling air and cooling oil.

Centrifugal pumps for boiler feed are generally provided with one steam driven pump for starting up and for emergency service while the others are motor-driven. Only steam-driven pumps have been installed in some new stations to secure lower first cost and greater reliability. These pumps may be provided with automatic control. The feed to the individual boilers is usually governed by automatically controlled feed water regulators.

Steam Turbines

The capacity of individual turbines has increased rapidly during the last few years. Units of 30,000 k.w., are common and turbines with outputs of up to 60,000 k.w., are in daily operation. A 75,000-k.w. turbine has been ordered for the Crawford Avenue station, Chicago, and an 80,000-k.w. unit for Hudson Avenue station, Brooklyn.

The capacity of individual turbines depends on the size and character of the connected load, and the nature of other generating units available on the system. Large units with no spares may be installed in a new station if older stations on the system can serve as stand-by and absorb the load should a generator in the new station be out of service. A new station built solely for stand-by service to an hydro-electric plant may also have no spare units. A central station for public utility service and also for industrial plants, where load must be carried

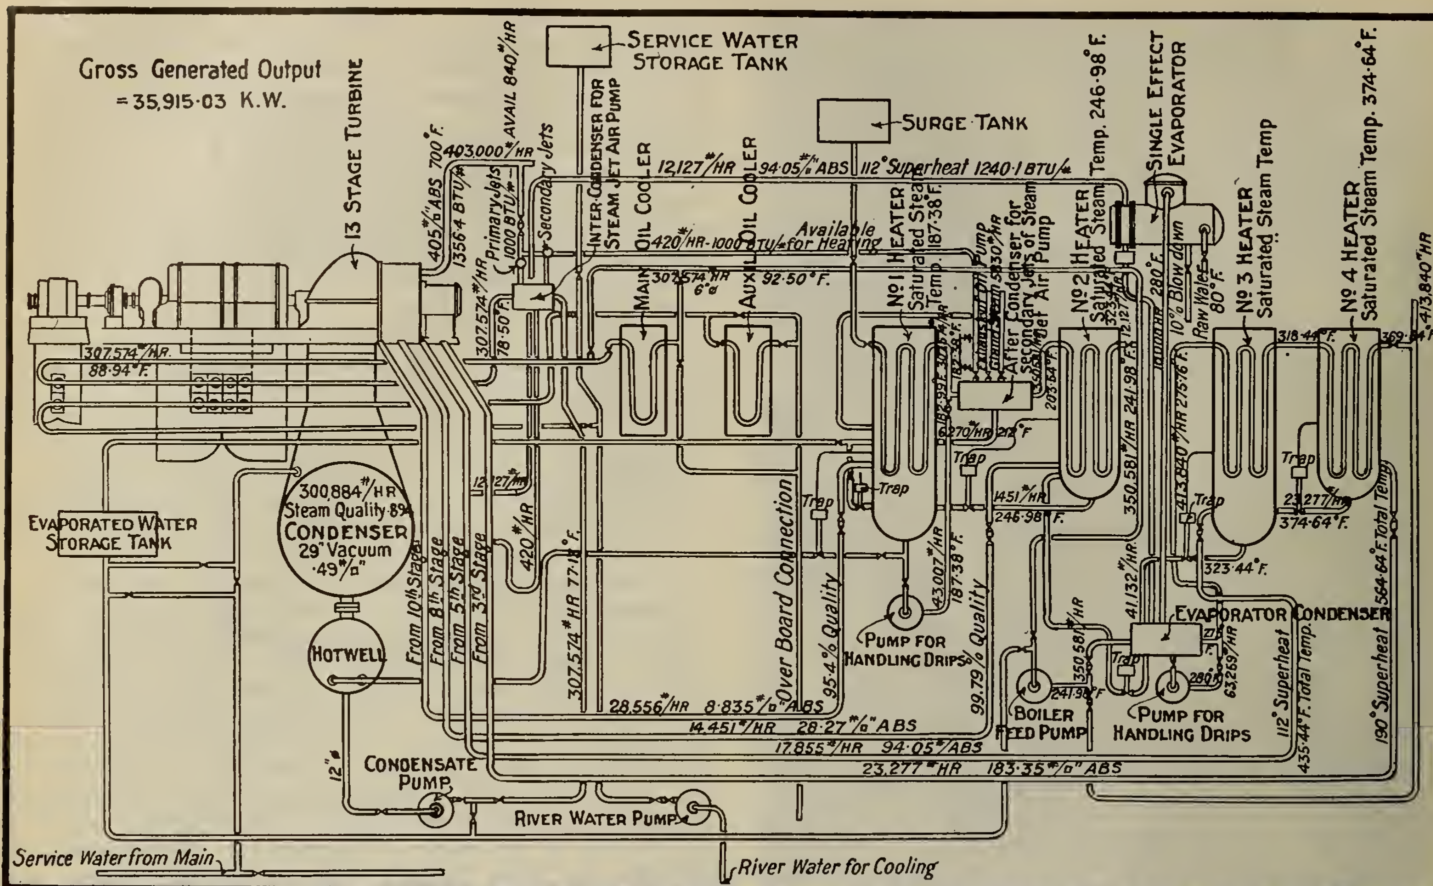

Figure No. 8.—Flow Sheet Showing the Heat Balance Arrangement and Bleeder System for the New Gould Street Station of the Consolidated Gas, Electric Light and Power Company, Baltimore, Md., for a Total Generator Output of 35,915 k.w.

Main generator rating 35,000 k.w.; auxiliary generator 1,200 k.w.; exciter 250 k.w. G.E. turbine with 13 stages; 390 lb. gauge and 700 deg. fahr. at throttle; 29-inch vacuum; 1,800 r.p.m.

continuously, should have one spare unit above the maximum load demand.

Steam turbines have been developed to a high degree of efficiency and reliability. Refinements in design permit some further gains, which, however, will come slowly. The largest turbines show only slight improvement in steam economy over the medium sized units. When steam expands in a condensing turbine, it becomes wet at a certain stage and the efficiency of the remainder of the turbine is decreased by the moisture in the steam. If the initial superheat can be materially increased, or if the steam can be re-superheated when it has expanded almost to the saturated condition, the deleterious effect of moisture in the turbine will be removed, the efficiency increased and the steam consumption lowered. To reheat between stages the steam must be carried back to a reheating superheater in the boiler. This additional complication, together with resultant boiler and turbine control problems, have made engineers reluctant to adopt reheating except where unusual base load conditions prevail and where high pressures are used.

As feed water is quite generally heated by steam bled from various stages of the turbine, less steam is delivered to the condenser. The limit of steam turbine output is the quantity of steam that can be passed through the longest permissible low pressure blades with a given leaving loss. Assuming this capacity is attained in a turbine with extraction bleeding, additional kilowatts can be secured from the steam bled off at earlier stages by proportioning all stages to the actual steam flow. This design may give 10 to 15 per cent increased output over non-bleeding performances with the same steam flow to the condenser, and is probably the cheapest way to secure additional turbo-generator capacity. Figure No. 8 shows the heat balance system for the new Gould Street station of the Consolidated Gas, Electric Light and Power Company, Baltimore, where the 35,000-k.w., turbine is designed in the manner just described. The condenser will contain only 30,000 square feet of cooling surface.

The nuisance of steam leakage at the turbine glands has been stopped by the use of water glands on both ends of the shaft. In some new designs of impulse turbines, the steam leakage at the high pressure gland is to be returned to one or more of the lower stages of the turbine. This will simplify both turbine and plant design, and will improve turbine performance slightly.

Closed air-cooled circuits are standard on turbo-generators with closed-type fin-tube coolers to remove the heat losses. This system lessens the danger of fire in turbo-generators, lessens the noise in turbine rooms and provides a neat compact design. These coolers along with the oil coolers may have condensate as the cooling medium with a slight gain in station economy, or may be cooled by raw circulating water if this is clean. Electrical engineers are now considering the use of hydrogen or other gases instead of air for cooling turbo-generators. Tests with hydrogen indicate that generators can be safely operated with practical elimination of the fire hazard. Windage and other losses are so decreased that the generator capacity may be increased about one-third with the same heat losses as with air. Increased generator capacity at low first cost may be obtained by the use of hydrogen provided no other difficulties develop.

The trend is still towards increased size in steam turbines, and single units of 100,000 k.w., may be expected within a reasonable time. Turbines are bled to heat feed water at two, three or four points, depending on the cost of coal and load factor. In some base load plants reheating is employed.

Condensers

Surface condensers are used where possible with large turbines as they produce a higher vacuum, require less auxiliary power than jet condensers, and also provide pure condensate for boiler feed. These may be single- or multi-pass, depending on whether there is an abundant or limited supply of cooling water. Developments are largely confined to improvements in tube spacing which will make all the cooling surface equally accessible to the exhaust steam and will cause this steam to sweep in straight lines towards the air cooler section. Improved performance, with reduced tube surface and hence lessened first cost, has been reported as a result of these changes. Formerly much trouble was experienced with split condenser tubes and with failure from other causes. These have not been entirely overcome but considerable improvement has been made in the art of manufacturing these tubes.

In some cases the character of the cooling water due to foulness, acidity or other causes, prohibits the use of surface condensers. Jet condensers must then be used and special provision must be made to treat all the raw feed water.

Some condensers act as de-aerators. The make-up water is warmed and sprayed into the steam space in the top of the condenser. This causes all gases to flash out and they are removed by the air pump. Where closed feed systems are used, a hot-well receiver of several thousand gallons capacity is added to the condenser to serve as a reservoir on the feed system.

Steam jet air pumps are favoured on many installations due to their cheapness, their simplicity, the high vacuum attainable and the small space requirements. The condensate passes through the inter- and after-condensers of these air pumps and recovers the heat in the steam used by the jets. Reciprocating dry vacuum pumps may in some cases make a lower steam demand on the boilers and may produce higher vacuum than with steam jets. These advantages are offset somewhat by high first cost, large space requirements, and generally higher maintenance.

Close study is now given to the probable source of the coldest available circulating water and intakes should be designed to utilize the bottom strata of water.* Such great quantities of water are handled in large central stations that careful study must be given to small details of design of intake and discharge tunnels, and suction and discharge piping, in order to keep the hydraulic losses at a minimum. Draft tube designs on the condenser discharge have been used to recover the leaving velocity head and thus lower the pumping head on the circulating pumps. These improvements reduce the power input to the circulating pumps. Care should also be taken to spread the cooling water in a thin surface layer at the outlet of the discharge tunnel so as not to cause any intermixing with the cold bottom strata of the water supply.

*"Lake Waters for Condensers", A. G. Christie, *Mechanical Engineering*, October, 1925.

Auxiliary Drives

The prime requisite of an auxiliary drive is reliability; high efficiency is a secondary consideration. Formerly steam driven auxiliaries were considered the most reliable but improvements in electrical machinery and in sources of electric auxiliary power have made the electric drive the favorite in many new stations.

Auxiliaries may be divided into two general classes. Those that are absolutely essential for the continuous operation of the station, such as boiler-feed pumps, powdered coal feeders or stoker drives, condenser auxiliaries, unit pulverizers when used, draft equipment, and exciters; and those that may be subject to interruption with no serious effect on operation such as coal handling and pulverizing equipment for storage systems, service pumps, air compressors, etc. The first class, if electrically driven, must secure power from a source not subject to line interruptions. House turbines of efficient design, often operating condensing, are used in some plants. In others, auxiliaries are supplied with power from the main unit through an auxiliary bus, with an automatic throw-over to a spinning house turbine in case of trouble. Another plan is to connect an auxiliary transformer to the main generator inside the switch gear and reactance coils, and to furnish auxiliaries with power from this transformer.

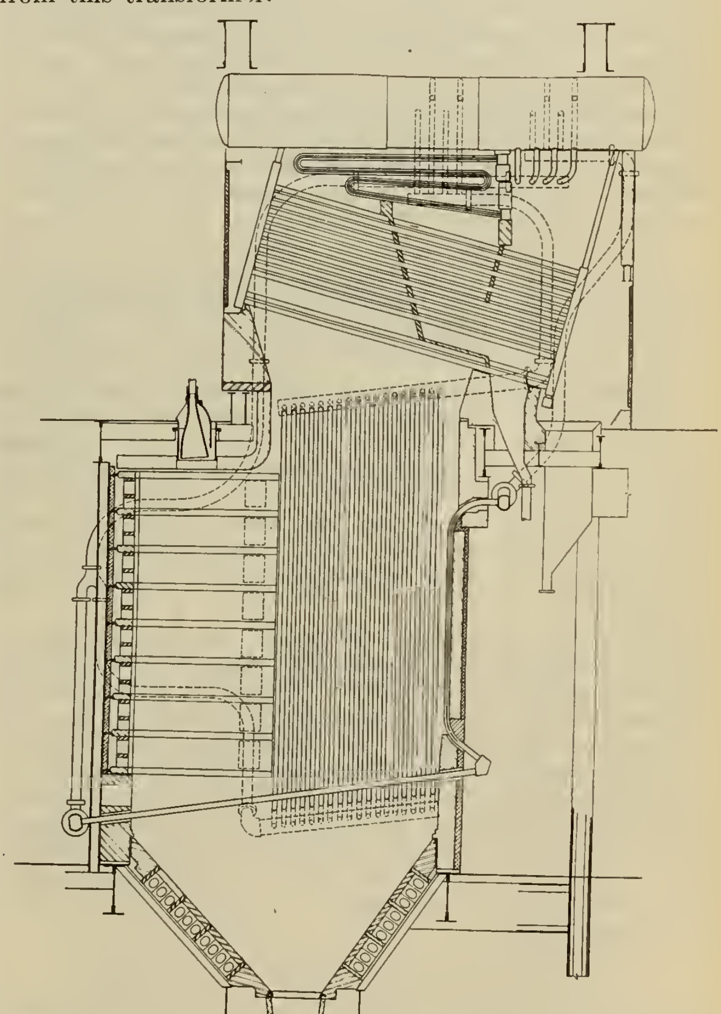

Figure No. 9.—Cross-section of Boiler and Powdered Coal Furnace for a Canadian Paper Company.

Heating surface in boiler 10,160 sq. ft.; in fin-tube water-screen 1,201 sq. ft.; furnace volume above water-screen 8,200 sq. ft.

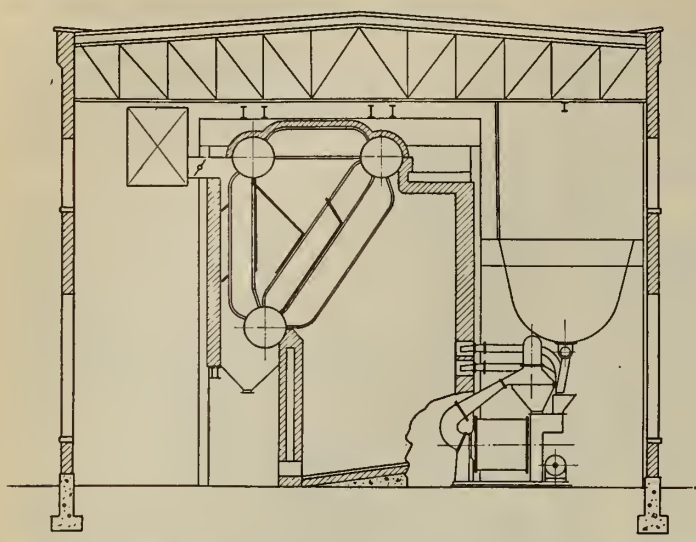

Figure No. 10.—Arrangement of Boiler, Furnace and Unit Pulverizer in the Boiler House of a Canadian Industrial Plant.

Heating surface in boiler 7,000 sq. ft.; furnace volume 4,450 cu. ft.

Still another plan is to provide an auxiliary generator driven by the main turbine and placed beyond the main generator. This provides cheap auxiliary power but is subject to shut down if the turbine should trip out from over-speed. A low cost stand-by non-condensing house turbine may be provided for starting up and emergency service. There is a wide difference in practice on this matter of auxiliary drive for normal and emergency operation.

Some designers prefer to install duplex sets with both turbine and motor drive for all essential auxiliaries. Improvements in the efficiency of small turbines tend to encourage such installations. All essential auxiliaries will be steam driven in one of the newest large stations.

The design of turbines of sizes used for house service is being further developed so that their efficiency will be only a little below that of the main units. This will lead to the use of more house turbines and since these operate at nearly constant load, it has been suggested that a portion or all of the feed water heating be done by steam bled from them rather than from the main units. This has some advantages with variable load conditions.

Methods of auxiliary drive, the use of full-voltage starting motors, means of providing variable speed to the various auxiliaries, and first cost and maintenance of auxiliary equipment, are all receiving much study and undergoing development. An arrangement which meets the requirements of one station may not be satisfactory in another plant. Hence the multiplicity of schemes. At present the electric drive with the auxiliary turbine is widely used. It is improbable that any one system will ever become predominant and that different plans will always be used to meet the conditions that exist in various plants.

Steam Stations for Industrial Plants

The preceding discussion refers specifically to large central stations. Many industrial plants require a steam station to furnish steam for heating or process work or for power. The use factor of such equipment may be quite high in which case refinements in design would be warranted that could not be justified with a low use factor.

While the same general tendencies prevail in industrial plant design as in central stations, the former lag behind partly due to the fact that the industrial steam plant is a secondary part of the whole works and partly because less efficient operating management and personnel are available in the small plant than in the large electric works. The management of large industries can often effect considerable savings by the reconstruction of their power plants and the employment of skilled operators.

Increasing boiler pressures, larger boilers of the water-tube type, pulverized coal or more modern stoker equipment, and large condensing or non-condensing steam turbines, now characterize the equipment of the larger industrial plants. There appears to be a tendency in European industrial plants where process steam is required, to use even higher steam pressures than in central station practice. Greater heat head is made available for power production by the use of these higher pressures before the steam is exhausted into the heating system. A careful analysis of this use of higher steam pressure has been presented in a recent paper.*

Small plants are usually built with little or no thought given to fuel economy. Owners would save money by engaging competent engineering advice before building such small plants.

Figure No. 9 shows a cross-section of a boiler and furnace for the new boiler plant of a Canadian paper company. The Lopulco pulverized coal firing system will be installed, with a central pulverizing plant using steam dryers and located near the wharf, some 1,200 feet away from the boilers. This plant is designed to burn any available coal, including Nova Scotia coals with low-fusing ash.

Figure No. 10 shows a cross-section of an addition to the boiler room of another Canadian industrial plant consisting of one 700-h.p., boiler to be initially operated at 130 pounds gage pressure, but built for 350 pounds gage. A superheater to provide 700° F. steam temperature will be added later. A Fuller-Bonnot unit pulverizer will furnish powdered coal to the solid wall combustion chamber. Secondary air will be admitted through a hollow bridge wall. No water screens will be used on this plant. The unit will operate at 250 per cent rating with peaks up to 300 per cent. An old economizer now in place will be used to heat the feed water.

Central pulverized coal systems may be justified in new industrial steam plants with many large boilers. New plants with a few boilers may employ unit systems for pulverized coal. Much must still be done to improve and further develop unit pulverizers to reduce outage, maintenance costs and depreciation, and to provide suitable mixing burners.

Steam Accumulators

The recent development of high pressure accumulators has directed the attention of engineers to the possibilities of this equipment. In large central stations, the principle of conservation of heat head together with the flat boiler efficiency curve over wide ranges of load, do not leave much opportunity for accumulators to effect savings. Another situation prevails in the process work of industrial plants particularly where widely fluctuating steam demands are common. Heat head is then of less importance than heat capacity. These accumulators seem to have possibilities in such plants, particularly when stokers with limited furnace volumes have been installed.

*"The Value of Higher Steam Pressures in the Industrial Plant", W. F. Ryan, presented at December 1925 Meeting of A.S.M.E.

Low Temperature Carbonization and Other Processes

Wide interest is apparent in low temperature carbonization processes as a means of furnishing a smokeless substitute for anthracite coal and of providing valuable by-products. These processes consist essentially of heating bituminous coal or lignite at temperatures not in excess of 1,200° F., and thereby driving off the rich gas and the light oils which, not being exposed to high temperatures, contain portions suitable for use in automotive engines. The coke residue contains sufficient volatile matter to kindle readily but burns without smoke. It can be used either for domestic purposes or for pulverized fuel The power plant engineer is interested in these processes as a means of furnishing him cheaper fuel through the sale of by-products.

Although many processes have been invented and several are in advanced stages of development, none are in full commercial operation. It is probable that a few of these will be worked out so that they may be incorporated in future plant design. The problem is quite fascinating and interest has been intensified by recent developments in closely related fields which will undoubtedly affect low temperature carbonization methods. Bergius has developed a process for the complete hydrogenation of coal into oils. Patart makes synthetic methanol out of water gas. Fischer hydrogenates the tar oils of the low temperature carbonization process into light motor fuels. He has also developed a synthetic process to convert the water gas made from the coke residue into a new motor fuel called "Synthol", which consists of a mixture of oils and alcohols. These foreign developments have started intensive research work at many places. One cannot predict what ultimate effect low temperature carbonization and these other processes will have on power plant design.

Electrical Equipment

This paper has been planned to discuss the steam power station up to the generator terminals only. Much could be written on the electrical side of the steam station design, particularly with reference to the type of switch gear to be used, the isolation of the phases, outdoor switching, protective devices and systems for maintaining auxiliary power supply. Types of motors for auxiliary drive and means of throwing these from one bus to another bus in case of a failure of power supply, could also be discussed at length. Such discussion would unduly lengthen this paper and since electrical equipment is so much dependent on distribution requirements, it will not be further considered.

Closure

The present trends of steam plant development are briefly presented in the preceding paragraphs. There may be differences of opinion among engineers in regard to the interpretation of these trends. Furthermore, the art of steam power plant design is still undergoing rapid change and the trend of development may be quickly modified by new thoughts on power production. This whole discussion indicates that one can look hopefully for better fuel economy and lower power costs from new steam power stations.

The author wishes to express his indebtedness to McClellan and Junkersfeld, Inc., New York, to the Consolidated Gas, Electric Light and Power Company of Baltimore, and to the engineers of these two companies for the use of their data and designs and for their assistance in the preparation of this paper.

Generation of Explosive Gases in Electric Water Heaters and Boilers

An Investigation of the Generation of Explosive Gases in Electric Water Heaters and Boilers Operating on Alternating Current with Submerged Electrodes.

J. W. Shipley,
Assistant Professor of Chemistry, University of Manitoba, Winnipeg, Man.
and
A. Blackie,
National Testing Laboratories, Winnipeg, Man.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

The complete demolition of an electric boiler together with the wrecking of the house in which it was installed drew attention to the possibility that the explosion causing this damage might have been due to an accumulation of hydrogen and oxygen within the system, the gases being generated by the electrolysis of water. An inspection of several similar installations discovered the fact that gases of an inflammable and explosive nature were being generated within the heating system.

Gases Generated from Service Heaters

Samples of gases were secured from two water heaters, the first a 550-volt, single-phase, 60-cycle installation. This heater was discharging gas continuously from the air relief valve at the rate of 10,000 cc. per day. The following analysis is typical of the gas collected from this heater:—

Carbon dioxide	10.4 per cent
Oxygen	1.4 "
Hydrogen	49.8 "
Nitrogen	38.4 "

This gas was found to be inflammable and when mixed with 70 per cent of air was explosive. Three months later this heater was found to be generating gas of a similar composition and at about the same rate.

The second heater was a 220-volt, single-phase, 60-cycle installation operating intermittently. Gas at the rate of 2,000 cc. per 24 hours of operation was being generated by this heater. The composition of the gas was as follows:—

Carbon dioxide	4.7 per cent
Carbon monoxide	0.6 "
Oxygen	1.0 "
Hydrogen	54.5 "
Nitrogen	39.2 "

This gas was inflammable and when mixed with air was explosive. Samples of gas collected during a period of three months had a similar composition and the rate of generation was approximately the same.

TABLE No. 1,—Electrolytic Gases Generated by a 60-Cycle Alternating Current

Electrodes	Iron	Iron	Carbon	Carbon	Copper	Copper	Lead	Zinc	Aluminum	Nickel	Platinum
Voltage	220	110	220	110	220	110	110	110	110		
Percentage composition of generated gases: Carbon dioxide	1.6	6.6	17.5	14.6	0.6	1.3	0.8	2.2	0.2	Explosive gases generated.	Hydrogen and oxygen generated in equivalent proportions.
Oxygen	18.4	21.1	3.2	5.0	1.2	3.2	1.3	5.4	7.6		
Hydrogen	35.2	39.2	66.2	61.7	97.2	83.6	85.9	71.4	89.5		
Nitrogen	44.8	21.8	0.4	12.7	1.0	11.9	12.0	21.0	2.7		
Carbon monoxide			6.5	6.0							
Hydrocarbon gases			6.2								
Explosion	vio	lent	ign	ites	ign	ites	ignites	ignites	violent		violent
Approximate electrode surface exposed sq. cm	180	180	105	105	75	75	180	180	180	180	8
Ccm. of gas collected in 24 hours	200	400	no record	no record	no record	no record	115	186	6000	no record	no record

Note:—It was impossible to determine the current density as the electrode chamber was in continued surge with respect to the immersion of the electrodes due to the automatic control of this type of heater.

Electrolysis by Alternating Current

Experiments on the generation of gases in this type of water heater were conducted in small model heaters designed to allow for the removal and exchange of the electrodes. Figure No. 1 indicates the apparatus used, and table No. 1 contains the observed results for various electrodes.

These experiments established without any doubt that single-phase, 60-cycle, alternating current of either 110 or 220 volts would generate gases in aqueous electrolytes and that these gases were generally of an explosive nature. The aqueous electrolyte used was water from the domestic supply of the city.

Gases Generated by Alternating Current

It is apparent from the composition of the gases generated that their nature depends upon the composition of the electrodes used in the experiments. The metals evolved very little, if any, hydrocarbon gases whilst the carbon electrodes gave a considerable percentage of these gases. During the process of electrolysis, the electrodes were all attacked with the exception of the platinum. The carbon electrodes were mechanically disintegrated and the copper almost completely dissolved. Metals capable of oxidation absorbed the oxygen generated by electrolysis forming oxides of the metal. This was particularly observed in the case of copper, lead and aluminum where an oxide or hydrated oxide appeared as a deposited sludge in the generator. This absorption of oxygen accounts for the low percentage of oxygen and the high percentage of hydrogen in the gases collected.

Oxygen also combines with the iron electrodes, but absorption is slower than in the case of the metals mentioned above. The automatic control of this type of heater permits the water to be evacuated into an expansion tank. Here atmospheric gases are redissolved, and on the electrode chamber of the heater cooling below the boiling point of water it is refilled with this aerated water which is degassed with rising temperature adding a fresh supply of oxygen, nitrogen, and carbon dioxide to the gases in the electrode chamber.

Effect of Lowering of the Electrical Resistance upon the Rate of Generation and Composition of Gases

It was deemed desirable to determine what the effect upon the generation of gases might be if the nature of the electrolyte was changed by the addition of certain salts. The following were the salts chosen for this experiment as they were those that if it were possible to inhibit the generation of gases might be expected to do so: magnesium sulphate; sodium dichromate; potassium permanganate; sodium nitrate; sodium bicarbonate; sodium phosphate; sodium cyanide.

The addition of these salts to the water in the electrode chamber in every instance increased the rate of generation of gases enormously. This rapid generation was largely due to the lowering of the resistance and the consequent increase of the flow of current through the electrolyte.

Relation of Grounding Shell to Generation of Gases

Since all service installations are surrounded by an electrically grounded metal shell in electrolytic contact with the electrodes through the electrolyte, (tap water), the experimental generators just described were provided with metal sleeves electrically grounded. In the case of the iron electrodes the generation of explosive gases was increased nine-fold by the introduction of the grounded shell rising from 25 cc. in 12 hours to over 200 cc. evolved in the same time.

To simulate more closely the type of heater employed in service a small cast iron model was prepared and operated on the 220-volt circuit with a watt meter in series. A typical analysis of the gas generated within this diminutive heater is as follows:—

Carbon dioxide	13.0 per cent
Oxygen	11.6 "
Hydrogen	30.0 "
Nitrogen	45.4 "

This gas exploded when an electric spark was passed through it.

It was found that the rate of evolution of gas depended upon the spacing of the electrodes, the relation of the electrodes to the shell, the current flowing, the temperature of the electrolyte and the depth of immersion of the electrodes. Moreover the composition of the gas was also a function of the manner of operation of the system that is the surge between the electrode chamber, the radiating system and the expansion tank. The majority of these variables are interdependent and consequently the evaluation of the rate of evolution becomes very complicated. The maximum evolution appears to take place just below the boiling point.

Water-cooled electrodes, (economically impracticable), prepared by using as electrodes iron pipes with water flowing through them, generated explosive gases both upon the electrodes and the metallic sheath. Electrodes of different types of iron such as cast iron, mild steel and high carbon steel affected the composition of the gases but little.

Large Experimental Heater

A service heater of the standard size used for domestic heating purposes was installed and operated for two months. The installation was provided with a thermometer inserted into the electrode chamber, a recording ammeter, a watt meter and a water gauge glass showing the fluctuations in water level within the heater. Gases were generated within the heater and the following is a typical analysis of the gas generated with a minimum surge throughout the system.

Carbon dioxide	3.3	per cent
Oxygen	3.7	"
Hydrogen	42.6	"
Nitrogen	50.4	"

On passing an electric spark through this gas a slight explosion occurred.

When the method of operating this heater was changed so as to produce a surging effect that is an evacuation of the water from the heater into the expansion tank and a refilling on condensation of the steam, a gas of the following composition was obtained:—

Carbon dioxide	12.8	per cent
Oxygen	2.6	"
Hydrogen	34.5	"
Nitrogen	50.1	"

This was non-explosive until the carbon dioxide was removed.

Generation of Gases outside the Electrode Chamber

The volume of gases generated in the electrode chamber of this system was not nearly so large as collected from service installations elsewhere. A chance remark from one of the operators that "air" was collecting in the cooling system led to the installation of a collection valve on the radiator and more gas was removed at this point than from the electrode chamber itself. Its composition was similar to that evolved from the electrode chamber.

The generation of gases by electrolysis at points relatively far removed from the electrodes will take place wherever the chemical decomposition potential of the electrolyte in contact with the metallic conductor is lower than that on the electrodes themselves. The generation of gases may be expected anywhere on the metallic installation system in contact with the electrolyte.

This discovery of the generation of gases outside the electrode chamber nullified the possibility of relating the evolution of gas to the recorded electrical measurements.

Explosiveness of Gases

The explosiveness of the gases collected from the experimental heaters and service installations varied in proportion to the inert gases present and with the oxygen content. The analyses of 22 gases are listed in table No. 2 arranged in order of increasing oxygen content. It will be noticed that in sample 7 the oxygen content is only 4.2 per cent and the hydrogen 5.2 per cent. This mixture gave but a slight explosion but all mixtures containing a higher percentage of oxygen and hydrogen exploded violently.

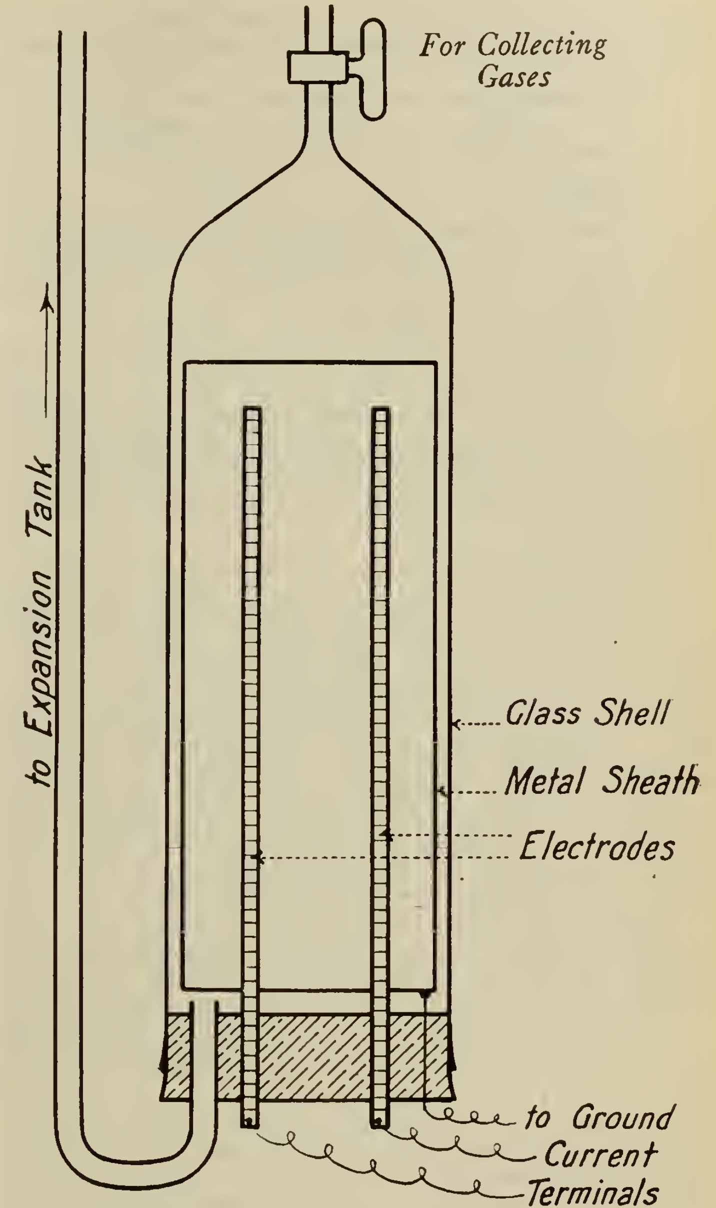

Figure No. 1.—Small Cast Iron Experimental Electric Water Heater.

Electric Steam Generators

While conducting this investigation gas was observed bubbling through water contained in the cup of an air valve attached to a steam radiator on the floor of the building in which the experimental water heater was installed. On applying a match to the bubbles a sharp detonation occurred as each bubble broke. The radiators

(Explosive = X, Non-explosive = —).

of this building are provided with steam from an electric steam generator in the basement operating on 2,200-volt, a.c., 60-cycle current.

Two litres of gas were collected from this radiator which on analysis gave the following composition:—

Carbon dioxide	0.6 per cent
Oxygen	32.4 "
Hydrogen	66.0 "

On being informed that several of the radiators on the top floor of the same building were "air locked" a sample of gas was removed from one of the cold radiators and analyzed. It contained the following:—

Carbon dioxide	0.4 per cent
Oxygen	30.8 "
Hydrogen	69.2 "

It will be observed that the proportions of hydrogen and oxygen in these two samples are approximately those obtained by the electrolysis of water and also they occur in proportions that would give an explosion of maximum violence.

Explosiveness of Gases in Relation to Steam

A sample of the explosive mixture taken from the radiator mentioned above was placed in a wide eudiometer tube over mercury with water in contact with the gas. The temperature was raised to 250° F. and the gas permitted to remain in contact with the water for one hour. The pressure on the mercury manometer registered a little over two atmospheres. On passing an electric spark through the mixture a violent explosion occurred completely wrecking the apparatus. This explosion was with 25 cc. of the gaseous mixture saturated with water vapor at a temperature corresponding to the boiling point of water under two atmospheres pressure.

The accumulation of gases in radiators or other cooling parts of a system provided with steam from an electric boiler must be considered extremely hazardous.

The explosiveness of such gaseous mixtures is determined by the proportions of hydrogen and oxygen present. The amount of water vapour present in the gases within the electrode chamber of a water heater depends upon two factors, the quantity of other gases present in the chamber when ebullition begins and the hydrostatic pressure under which the system operates. When only a small quantity of permanent gases are in the electrode chamber the depression of the water is secured by the generation of an almost equal volume of water vapour to the liquid displaced but as the chamber comes to contain more and more of the permanent gases a smaller volume of water vapour is required to depress the electrolyte. With several of the gaseous mixtures listed in table No. 2 even if the chamber were only partially filled with such a gas the amount of water vapour generated in depressing the water from off the electrodes would not sufficiently dilute it to prevent an explosion were an arc to form when the water receded from one or the other electrode.

Several determinations were made and the possibility demonstrated of exploding gaseous mixtures secured from the gases listed in table No. 2 and under the conditions of water vapour saturation and pressure described above.

Finally a small experimental heater with the electrodes inserted from the top and without any vent being provided for the generated gases was set up and permitted to operate under a small hydrostatic pressure and low electrolytic resistance. The surging effect was very pronounced until a considerable volume of gas collected in the electrode chamber. After about an hour's operation the generator blew up wrecking the whole apparatus. As the explosion was accompanied by a flash presumably it was caused by the formation of an arc when the electrolyte was depressed from off one electrode. The explosion took place while the heater was operating over water close to the boiling point.

Venting of Gases

The accumulation of gases in the electrode chamber of service heaters has been recognized by the installation of automatic valves. Such valves are frequently set to operate open up to approximately 214° F. when they close and remain closed at all temperatures above this. But the heaters actually operate under a head of pressure as high as an additional atmosphere at which pressure steam is generated and recondensed at 250° F. Consequently the temperature of the electrode chamber never drops to that at which the valve is supposed to open and the accumulated gases cannot be vented.

Such valves are also liable to become clogged by the accumulation of iron rust carried into them by the surging water of the electrode chamber. Such valves were frequently found to vent the accumulated gases only after vigourous tapping.

It is extremely hazardous to rely upon the automatic venting of the chamber gases and all installations of such water heaters should be provided with a water gauge glass whereby the accumulation of gases retained within the electrode chamber could easily be detected.

Explosion Hazards

Dantsizen and Horstkotte* carried out a series of determinations for the General Electric Company on the evolution of hydrogen by a 3-phase 60-cycle 6,600-volt electric boiler. They found 1.3 per cent hydrogen and 18.0 per cent oxygen in the permanent gas content when the boiler began generating steam and after several hours operating 4.4 per cent hydrogen and 20.5 per cent of oxygen were obtained. They determined the hydrogen content of the steam from a fuel fired boiler and found it to be 0.0003 cubic feet of hydrogen per each cubic foot of water evaporated while the generation of hydrogen by the electric boiler was 0.002 cubic feet per each cubic foot of water evaporated or seven times as much.

They conclude as follows: "The generation of hydrogen in an electric steam boiler will be approximately proportional to the amperes input, but whatever the current input the same volume of hydrogen might accumulate in a heating system if it were supplied with steam from a fuel fired boiler this being merely a question of time. However, since no destruction of heating systems has been attributed to hydrogen from fuel fired boilers it is reasonably safe to assume that the same performance might be expected with steam from an electric steam generator."

The generation of hydrogen is not the dangerous feature connected with electric steam generators but the generation of equivalent amounts of hydrogen and oxygen forming on the condensing of the steam an explosive mixture of the first magnitude. This in conjunction with the possibility of having such a mixture under certain conditions of boiler design adjacent to electrodes where an arc might form is the principal hazard so far as the boiler is concerned but another and greater hazard is the accumulation of these gases in radiators and other traps far removed from the generator.

The richness of the explosive mixture is much enhanced if the generator operates on condensate for this

Pulp and Paper Magazine of Canada, 22, 1251-2 (1924).

would contain but little dissolved gases from the air. Systems operating on raw water will dilute the explosive gases by the degassing of the water.

A cubic foot of raw feed water at atmospheric pressure and 68° F. contains about 183 cc. of dissolved oxygen and 340 cc. dissolved nitrogen. According to Dantsizen and Horstkotte a cubic foot of water on being generated into steam in an electric boiler produces 0.002 cubic feet of hydrogen or 57 cc. and 28 cc. of oxygen would also be generated from the same quantity of water. Consequently a cubic foot of raw water would produce 608 cc. of gas, (neglecting the CO_2), containing 57 cc. of hydrogen or over 9 per cent of the total volume. This quantity of hydrogen in air is above the border line of explosibility. Dr. Von Schwartz,* giving 7 per cent of hydrogen in air as the lower limit for explosibility when subjected to electrical ignition.

At a temperature of 180° F. which was the temperature of the feed water used by Dantsizen and Horstkotte the content of dissolved air at atmospheric pressure would be reduced from 523 cc. per cubic foot of water to one third this amount or 174 cc. and the proportion of hydrogen on generating steam would increase to 24 per cent in the residual gases from the condensate. It is evident from this calculation that these experimenters must have had dilution with atmospheric gases from another source than that dissolved in the feed water.

Granting an evolution of 0.002 cubic feet of hydrogen per cubic foot of water evaporated in an electric boiler of the exposed electrode type, the possibility for the accumulation of a dangerously explosive mixture is largely a function of the gaseous content of the feed water.

Summary

Electric Water Heater

(1) Gases of an explosive nature are generated in water heaters operating on bare submerged electrodes using 220- or 110-volt, 60-cycle, a.c. The nature of the gases depends upon the material of the electrodes. Carbon electrodes give hydrogen, oxygen, carbon monoxide, carbon dioxide and hydrocarbon gases. Aluminum electrodes as would be expected, generate hydrogen and oxygen most vigourously, the oxygen being largely fixed as hydrated oxide of aluminum. Iron electrodes produce hydrogen and oxygen with possibly a little carbon dioxide. The oxygen is largely fixed in the electrode chamber as hydrated oxide of iron.

(2) The gases accumulating in the system are due to three causes:

(a) Degassing of the water;

(b) The action of the water on iron producing hydrogen; and

(c) Gases generated by the electrolysis of the water by alternating current.

*"Fire and Explosion Risks," Von Schwartz, page 33.

Frequent surging of the water from the expansion tank into the electrode chamber brings in dissolved atmospheric gases. Nitrogen and carbon dioxide dilute the explosive gases but oxygen enhances the possibility of an explosion.

(3) The rate of generation with fixed electrodes is largely a function of the electric current flowing and the temperature. Apparently a larger volume of hydrogen is generated near the boiling point than the temperature co-efficient of the conductivity of the electrolyte will account for.

(4) Gases may be generated by the electric current in other parts of the system outside the electrode chamber. This is due to the intimate contact of the electrolyte with the whole metallic system and to the practice of electrically grounding the shell.

(5) Steam in so far as it dilutes the gases reduces the explosiveness. The range of explosibility of hydrogen and oxygen mixtures is too great however to permit of the presence of steam in the gases generated always preventing the possibility of an explosion. Gases generated by the 220-volt, 60-cycle current using iron electrodes in a water heater exploded in the presence of steam when fired by an electric spark.

(6) The gases generated may be ignited by an electric spark. The danger of ignition is greater with heaters provided with electrodes entering from the top. Whenever the electrolyte is depressed so that one of the electrodes is completely bared an arc will be produced. Other conditions may also arise within the electrode chamber causing the production of a spark.

(7) The explosive nature of the gases generated in this type of domestic heater makes reliance upon automatic venting extremely hazardous and since the generation of gases is a function of the alternating current electrolysis of water all types of heaters in which the passage of the electric current through the water within the heater is possible can only be operated in the expectancy of having explosive gases generated.

Electric Boilers

Electric boilers operating on a.c., with bare submerged electrodes, generate equivalent quantities of hydrogen and oxygen, and these are carried out of the electrode chamber with the steam, accumulating wherever the steam is condensed. If raw water is used in the boiler these explosive gases will be diluted with the gases of the atmosphere dissolved in the feed water, if condensate be used the accumulation will more nearly approximate a mixture of hydrogen and oxygen of the maximum explosibility.

Explosive mixtures of hydrogen and oxygen were found in "air locked" radiators and escaping from the air valve of radiators provided with steam generated by an electric boiler operating on 2,200-volt, a.c., 60-cycle current.

An explosion hazard exists at those parts of a system provided with steam from electric boilers wherever there is a possibility of gases accumulating from the condensate.

European Engineering Practice in Production, Transmission and Use of Electrical Energy

A. E. Davison,
Transmission Engineer, Hydro-Electric Power Commission of Ontario.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

The Hydro-Electric Power Commission of Ontario arranged that a representative from the engineering staff attend the International High Tension Conference at Paris during June of 1925, with instructions to study such engineering and construction conditions in Europe as interested the Commission. This paper is a brief and cursory review of some of the more interesting features of this study.

Seeing is believing. It is very excellent practice on the part of administrations interested in the generation and distribution of electrical energy and in engineering matters generally to arrange that technical men shall have an opportunity from time to time to study developments and efforts of other engineers in the advancement of the art. Such an opportunity was afforded the writer during the year of 1925. Being identified largely with the transmission of electrical energy, such works naturally received the most attention. However, the feature which seemed to be most in evidence was the extent to which the efforts of the engineering profession are modifying the life of the human race generally. Reference was made recently in the press to an opinion that the primary element of disturbance and unbalance in British labour conditions is the reduction in the demand for coal. This may appear on the surface to be largely the result of economic conditions. However, an analysis will reveal in most cases that these conditions are the result of the efforts of engineers to minimize the amount of labour involved in the construction and operation of various works and processes. From the time of making an inspection of the oil fired boilers and enclosed steam turbines to the extent of 79,000 h.p., on the Mauritania, where some 150 stokers have been released, to that of observing on the return journey, the efforts, of calèche drivers of Quebec and of the horse-drawn cab owners of Montreal, to avoid being superseded by the 20 to 40 seat char-à-banc, there was one continued story of the relief of labour for other purposes on account of the efforts of engineers. The most remarkable examples are the electrification of state railways in those countries where coal is not generally available and the superseding of steam by internal combustion engines especially for marine work. These are referred to later in this paper.

First Impressions of Great Britain

On arriving in Great Britain, an opportunity was afforded to visit, among other engineering plants, the Perelli General Works at Southampton and to discover, as seemed to be the case throughout Europe, that most of the electrical engineering trades were quite busy. This company has samples of the joint used for the underground single-phase cable which is operating on the continent at 130 kv., and is, with the various laboratories and test rooms which are available, prepared to manufacture underground cables at voltages of 33 kv. and greater. This is common practice in England at the present time.

The small electric trams of this comparatively small city are typical. Two men are employed to operate the cars and at terminals automatic "Y" 's are installed in the overhead and track in such a way that it is not necessary for the crew to give any attention whatever to reversing and turning of the car. This is a considerable improvement so far as the comfort and convenience of the crew is concerned.

Transmission lines are not as much in evidence in England as they are on the continent of Europe and in America generally. In explanation of this, there are some calculations available by English engineers to indicate that coal can be transported from mine mouth to point of use cheaper than it can be transmitted as electricity after being developed at the mine.

Through Northern France

In the northern part of France considerable development is evident during the last seven years. Numerous concrete pole lines are operating at from 30 kv., to 60 kv., both single and double circuit, and there is a system of steel tower lines tying these lower voltage lines together in the Boulogne district. The concrete poles have a greater cross-section than is found in other countries. They are frequently of a sort of "A" frame construction with a cross-section at the ground line of approximately 9 by 20 inches. The total weight is reduced somewhat by placing circular or other holes through the pole so as to give the appearance of a ladder.

There are numerous cement mills served in this district as well as general manufacturing and public services in the various municipalities. The towns of the war zone are being restored very slowly indeed. A trip through such towns as Arras indicates that the electrical works, pole lines, railway depots, etc., have been restored, but many domestic buildings have neither been restored nor completely razed. Considerable more or less temporary electrical overhead work appears to exist still in some of these towns.

The International High Tension Conference

At the High Tension Conference, there was an opportunity to meet engineers from all parts of the world. The Japanese were very much in evidence and appeared very anxious to carry back to their own country all information and data they could possibly make use of.

There were some 27 countries represented by 226 foreign delegates. Twenty-three of these came from Russia and five from Australia. Some 304 members attended from France. Ninety-nine papers were presented. Of these 37 were printed in English and French, 36 in French only and 26 in English only. All of the discussions were carried on in either of these two languages.

With the preponderance of French delegates, the greater part of the discussions and papers was supplied by them. Speaking generally of the discussions, representatives from Sweden, from the Strassburg section of France and from Austria-Hungary appeared to take more than an ordinary part. These representatives spoke fluently in both French and English.

The development of the use of electrical energy in rural districts received considerable attention. In Sweden there is a tendency just now to curtail development of new districts and give attention to the addition of new customers to existing lines. About 70 per cent of the possible rural customers in Sweden have already been served with distribution lines; not all of these however

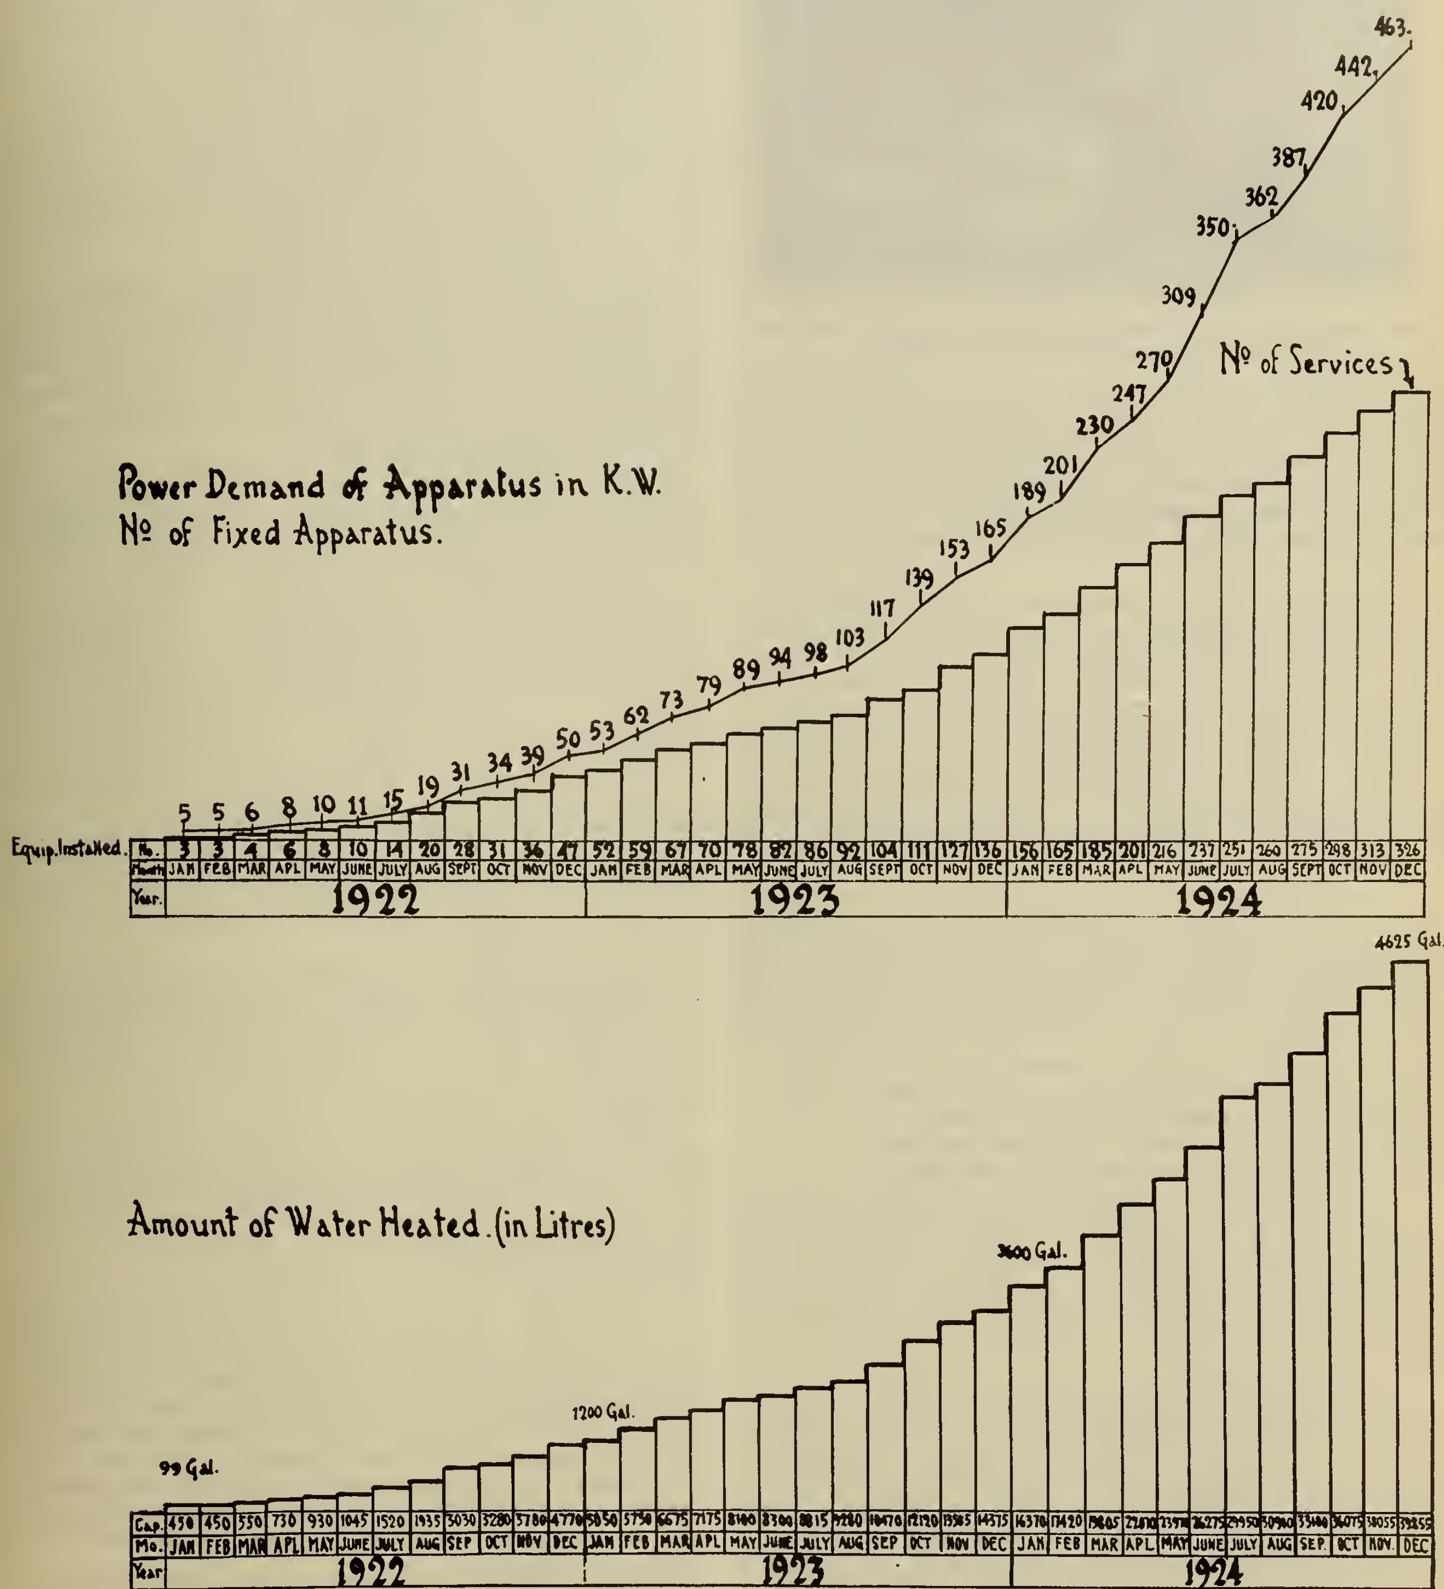

Figure No. 1.—Electricity in Strassburg—Utilization of Off-Peak Power in Hot Water Accumulators.

Figure No. 2.—General View of Plant of the Société Savoisienne de Construction Électrique Aix Les Bains.

are connected. The price is from 10 to 12 cents per unit. There is, of course, an agitation to have the rate for power in rural districts the same as it is in some of the cities. Matthews of England says consumption estimates should be based on the acreage of tillable land. He suggests 140 units per acre. He has found 200 different uses on the farm for electricity.

When combustion engineering was receiving attention, it was not difficult to get a considerable discussion regarding the merits of unit systems of steam generators as compared with the central systems. In the case of the unit system, it is necessary to grind coal at the time of peak load and this energy is often a considerable percent of the total revenue producing energy. Centralized systems for generation are therefore fundamental for low load power plants. Two papers were available on this subject and considerable attention is to be given the matter in subsequent conferences.

Tap switching of transformers under load was discussed by a number of the delegates. Some estimates and statements of costs were 7 per cent of the cost of the transformers, others were as high as 20 per cent. The Swedish engineers suggested four taps at 2½ per cent as being the most desirable. Mr. Semenza, representative from Italy, made a very fine suggestion in this connection. He recommends administrative control of load rather than the design of expensive, and otherwise superfluous, equipment to take care of voltage variations or other objectionable conditions due to low load factor.

Standardization of frequencies appears very desirable in Europe. It was mentioned that some fairly large electrical districts operate with three different frequencies with more or less overlapping, much as occurs within the municipality of London. Co-ordinations of this sort, would evidently improve conditions in all countries, and particularly in Europe.

The viewpoint of the continental engineers came out while discussing reactances, relays and other equipment which are frequently installed as safety and insurance features, and in order to have continuous service. Inferentially they admit comparatively numerous outages and frequent use of breakers. They asked the question—"Is all this extra equipment worth while?"—"Would it not be better to replace the contacts of the breakers a little more frequently and make more use of the breakers under load?"

There was plenty of evidence at the conference that insulating oils and gases for electrical equipment are still in the development stage. Catalysts were discussed extensively. A number of the manufacturers were anxious to standardize on at least two grades of oil as they felt that if this were not done some fairly large producers might be eliminated. The characteristics of the insulating oils produced in Russia were reflected in the remarks by representatives from that nation. They were anxious to establish one only high class specification and they did not agree with specifications regarding low temperature and freezing as found in many specifications. Representatives from America were asking for low viscosity especially for outdoor work. Some reference was made to the successful use of kerosene in this connection. The discussion was quite too varied to indicate that any decisions by agreement were possible.

An attempt was made by the Belgian representatives to introduce international rules for high tension overhead and underground. While there were national rules submitted which we understand in some cases have been made law, it was the consensus of opinion of a special committee that no attempt should be made just now to provide international standards.

Metal clad switch gear was brought before the meeting by Messrs. Gregory and Clothier. These papers brought out considerable discussion. Continental engineers evidently were not quite prepared to adopt such apparatus, although it was evidently quite popular in Great Britain.

The relative merits of enclosed and outdoor stations were reviewed by French representatives. The practice of using outdoor equipment in Alpine regions has not as yet passed the experimental stage. Twelve to eighteen feet of snow were considered as quite too strenuous weather conditions for outdoor electrical equipment.

From a description of the various high tension interconnected systems in France, it was evident that standard practice is to minimize the use of protective devices, and apparatus. The sky wire is generally carefully earthed. The neutral is frequently provided with a switch of about the same rating as the line switches. Scarcely any other protection is evident.

Tar and tar products appeared to predominate in the various recommendations and discussions regarding rust-proofing, although in practice galvanizing is used extensively. Some are using aluminum paint on galvanized material after they have been in contact with salt-laden atmospheres for five or six years.

There is no evidence at the present time of an agreement on suitable tests for dielectrics and especially for porcelain insulation as used on high tension lines. It is expected that there may be an agreement as regards national specifications in some of the European countries during the next year.

Similarly in the case of paper-insulated lead covered cables, there is evidence of a considerable search for a more satisfactory method of testing for the estimation of the life of the materials under load. Some of the manufacturers are submitting further evidence regarding the effect which the time element of tests has upon the value of tests for dielectrics. It would appear very advisable to test such apparatus and materials for a considerable length of time at the rated current in conductors involved, and at pressures which will be some multiple of the normal voltage

Glass insulators received some attention as they are being used extensively in France. Some think that glass will presently be generally competitive on account of comparatively low cost; however, some of the difficulties in annealing must be solved before the use becomes general.

The discussion of the effect of transients in the electrical circuits, led by Mr. Faccioli, was probably the most highly technical of the session. The effectiveness of equipment for the relief of surges and over-potentials, and analysis of the nature of these disturbances and their reproduction was reviewed. It followed rather closely the arguments which have been presented on various occasions in meetings of some of the American Institutions.

The economics of the distribution of electricity was the subject of a study and report by a representative from Holland who is using satisfactorily a rate making system which has given good service in England for some time. He finds that the rate zone for profits to companies is very limited,—that is, it is very easy to get the rates sufficiently high to reduce the consumption and thereby the profits. The Dutch Company charge rates of the order of 25 cents per unit for the first 130 hours and 5 cents thereafter. They figure their cost at the switchboard as 16 cents per unit whereas cost at the consumer's premises is 22 cents. One speaker stated that heat accumulators for domestic purposes were in use successfully and that the night rate for this class of consumption was 2 cents per kw. hour. This use of heat accumulators is probably the best example of a number of different efforts to improve very objectionable load factors in some of the electrical systems of Europe.

The Dutch representatives submitted some very interesting photographic records of electrical accidents and accident prevention methods. A set of these slides might be used very effectively in educating the staff of large electrical operating organizations.

At the final session of the conference, resolutions which had been discussed more or less tentatively up to that time, were submitted and passed as follows:—

(1) It was decided that national committees should be formed in all countries for co-operation in the development of the distribution of power at extra high tensions and allied undertakings much as has already been done in Great Britain with very satisfactory results.

(2) Instructions were issued for an enquiry and review of the production of power and the methods of utilization of various fuels throughout the world. This report was to be submitted to the Fourth Conference.

(3) It was decided that an international bureau of statistics should be organized by which it would be possible to establish in all countries uniform statistics of production, transmission and distribution of electric power in such a way as to make an analysis and comparison of the data from an economic standpoint.

(4) An effort will be made to co-operate with the International Electrotechnical Commission in establishing more satisfactory specifications and tests for insulating oils.

(5) It was decided that action upon the tests and specifications, including those for impact, on vitreous insulators should be deferred until the 1927 meetings. Similar action was decided upon in connection with specifications and proposed regulations for co-ordination of communication and power circuits when paralleling one another.

Electrical Industry in Europe

Throughout France and Italy the electrical industry appeared to be flourishing. Practically all of the plants which were manufacturing apparatus for electrical purposes were adding floor space. In many cases they were actually doubling manufacturing facilities. Electrical loads by districts were increasing at the rate of 15 per cent or more per annum. The development appears to be largely for the requirements of the French internal trade.

The factory of the Société Savoisienne de Constructions Electriques of Aix Les Bains under the management of Mr. Odier is an example of this development. This factory was opened January 1st, 1925, and is still being developed and extended. It is associated with the French electrical manufacturing group and produces transformers almost exclusively. Apparently this comparatively mountainous district was chosen for the plant in order to secure the best labor conditions possible in the republic.

The policy of taking over trunk lines and interconnected systems of railways by the state and of electrifying these, appears to be the outstanding economic development at the present time in Europe.

This policy is only getting established and confirmed in France, whereas in Italy, Switzerland and Sweden, very great expenditures are being made at the present time in electrifying railways systematically. In general a. c. motive power is being used. Mercury arc rectifiers are being installed on the Midi and some other privately owned railways in France. All of these countries excepting France have, of course, practically no coal and have considerable hydro-electric energy still available for transportation purposes.

Development of this sort has apparently been deferred in Germany on account of the war and latterly because the railways are evidently being used extensively to produce revenue for reparations purposes.

In Germany, they have under way extensive revisions of important pin type transmission lines, evidently operating at about 60 kv. This revision usually involves changing over the type of construction to suspension insulators so as to increase the operating voltage. In a number of cases new and larger conductors are being installed.

Concrete poles, as in France and Italy, are very much in evidence throughout Germany, and to some extent in Sweden where they have been used largely in the construction of a tie line designed to operate ultimately at 220 kv. This particular line is operating at 130 kv. at the present time.

The development of propeller type and Kaplan water wheels is receiving much attention in Czecho-Slovakia, Switzerland and especially in Sweden. This comparatively recent development will have avery considerable effect upon the efficiency and flexibility of low head plants. Some engineers venture the opinion that this type may be used in units as large as 30,000 horse power or more for heads up to 30 feet. The largest units projected at the present time are 10,000 horse power. An inspection was made of the progress of this work which will be put in operation in 1926, at the Lilla Edet plant of the Board of Water-Falls, Sweden.

A remarkable development in mechanical engineering which is affecting business conditions in Sweden, Great Britain and Italy, among other countries, is the Diesel engine. Some one million horse power for marine purposes is under contract at the present time with one company and its licensees. This type of primary producer is used somewhat in the electrical field and may at any time, as first cost is reduced, become an active competitor in the production of power for industrial purposes, as it has already in marine and land transportation.

The Fuel Problem in Canada

Lesslie R. Thomson, M.E.I.C.,
Consulting Engineer, Montreal.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 29th, 1926.

The Problem

The essence of the fuel problem in Canada can be stated in a few words and figures as follows:

	1922	1923	1924
Total consumption of coals in Canada in millions of tons........................	26	36	29.5
Total Canadian coal consumed in millions of tons..............................	12.5	15	12.5*
Differences supplied by importation from United States and Great Britain in millions of tons......................	13.5	21	17.0

The extraordinary fact in connection with these figures is that Canada, importing these tremendous quantities of coal, possesses the second largest coal reserves of any country in the world, as shown by the following table:

Coal reserves Reserves in millions of short tons (2,000 lbs.)				Special analysis of Canadian reserves			
Class	Canada	United States	Whole world		East	West	Total
Class "A" Anthracite or allied coals...	2,380	21,692	547,524	Actual		745	
				Probable		1,635	
				Total		2,380	2,380
Classes "B and C" Bituminous coals..........	312,593	2,154,984	4,201,044	Actual	2,411	29,723	
				Probable	8,466	271,993	
				Total	10,877	301,716	312,593
Class "D" Sub-bituminous coal and lignite.	1,043,192	2,053,524	3,303,535	Actual		422,234	
				Probable	28	620,930	-
				Total	28	1,043,164	1,043,192
Grand total..	1,358,165	4,230,200	8,052,103				1,358,165

United States possesses 52 per cent of world reserves
Canada " 16 per cent of world reserves
Of Canada's resources 77 per cent are in form of sub-bituminous and lignite coals Class "D"

NOTE:—These figures are taken from *Coal Reserves of World*, by McInnes, Dowling and Leach.

The amount of money involved when purchasing this coal may be taken roughly to be at least ninety millions of dollars annually. This money can be looked upon to some extent as being lost to Canadian industry.

While the problem can be stated thus very briefly, the solution is not by any means so easy to enunciate; and it is an open question whether any solution that is satisfactory to all parts of Canada can be reached immediately.

The Solution of the Problem

The solution of the fuel problem of Canada involves the consideration of a number of interdependent factors, and due weight must be given to each of these. The factors involved are geographical distribution of coal consuming communities and coal producing areas; transportation; basic relation of increased markets for Canadian coal on its selling price per ton; cost of production in various coal areas; proximity of United States coal areas; and other similar factors.

*Strikes occurred during this year.

There are two main questions that must be discussed before any permanent solution can be proposed:

1st. The actual situation in Canada in regard to location of coal, centre of gravity of consumption, size of markets in fixing selling price, magnitude of imports and consumption, and other similar factors.

2nd. Certain economic aspects of Canadian mining, in relation to mining elsewhere.

The writer proposes to discuss these two matters in sequence.

Actual Situation in Canada

The knowledge of the actual fuel situation in Canada need not be to-day in any state of ambiguity. The work of the Dominion Fuel Board since its inception has been of very great value in calling the attention of the Canadian public to the salient features of the Canadian fuel problem. Their reports are available to the public.

The subject has been further explored by a large Committee of *The Engineering Institute of Canada*, appointed in April, 1923, and presenting a final report in September, 1924. As the writer proposes to base the first portion of his paper upon the findings of that Committee, it seems desirable to record some facts concerning it. The membership was represented as follows:

From the Western region..	4
From the Central region (acute fuel area............................	18
From the Eastern region..	3
	25

All these were members of *The Engineering Institute of Canada*. All were more or less directly connected with the study, use, or application of fuel. None had any particular connection that would prejudice a consideration of the problem from the point of view of Canada as a whole. The result of their deliberations was in the main unanimous except on one or two slight points, and these were not serious enough to warrant a minority finding. Hence the considered opinion of such a Committee, reached without haste and without undue delay, would seem to warrant a further publication, at least as a basis for consideration and discussion of those new facts brought to light during the fifteen months that have elapsed since the report was prepared.

The reasonableness and accuracy of the findings and recommendations of that Committee are emphasized further by the fact that to the best of the writer's knowledge only one public exception was taken to the findings — that by the North Alberta branch of the C.I.M.M.

As a basis, then, for renewed discussion, the subject of fuel for Canada can be divided into the following heads:

I) Sources of fuel for Canada:
(a) Eastern Region (b) Western Region (c) Central Region.
II) Substitutes for American anthracite.
III) Possibility of utlization of Alberta coals in Ontario, and general Alberta situation.
IV) Miscellaneous matters.

These divisions will serve as guides for the orderly presentation of the whole discussion, and the writer next submits the digest of findings and recommendations of the Fuel Committee of the E.I.C. as presented in September, 1924.

Digest of Findings and Recommendations of the E. I. C. Fuel Committee

Sources of Fuel for Canada

(*a*) *Findings.*

1. That for the purpose of a discussion of fuel problems, Canada may be divided into three regions: the boundaries of which cannot be regarded as rigidly determined.
   - (i) Western: From British Columbia coast to Winnipeg.
   - (ii) Central: Ontario and approximately as far east as Montreal.
   - (iii) Eastern: Montreal to Atlantic coast.
2. That it is reasonable to expect that the Eastern and Western regions of Canada can be made generally self-supporting in the matter of coal for household and power purposes.
3. That the Central region must be dependent chiefly upon the importation of American coals, except insofar as Canadian coals can penetrate into competitive areas in the extreme east and west of the region.
4. That it is unreasonable and uneconomic to expect Alberta coals to compete in the Central region with American coals under present conditions.
5. That the apparent economic substitutes for American anthracite are: metallurgical coke, British anthracite and, to a lesser degree, briquettes.
6. That the work of the Dominion Fuel Board is of the very greatest benefit to Canada and that it should be encouraged in every way.

(*b*) *Recommendations.*

The committee recommended:

1. That the governments, federal or provincial, institute an inquiry into the real cost of moving coal.
2. That each province consider the advisability of establishing, with the authority of provincial legislation, standards of quality and regulations governing delivery of coal.
3. That a national fuel policy be only embarked upon after recommendations are received from the Dominion Fuel Board.
4. That Alberta operators concentrate their efforts on the production of high grade bituminous coals for power purposes in Western Canada and the United States rather than on any non-economic efforts to ship their low grade coals to Ontario.

Discussion of Findings

The writer proposes to discuss these recommendations and findings in sequence, with a view of pointing out what changes have occurred during the last 15 months.

In the opinion of many, the ideal solution of the fuel problem of Canada will be reached only when Canada is self-supporting from the point of view of supply of coal for household and power requirements. This solution is a counsel of perfection, as no country in the world has ever reached such a position, with the possible exception of the United States. In other words, except in time of war, that coal will reach the consumer which in the long run is most economic. The writer feels therefore that this ideal solution does not lie within the realm of the practicable.

The division of Canada into three fuel areas seems to be reasonable. It must be emphasized that the boundaries where these regions meet are not and cannot be sharply defined. They vary, too, from season to season.

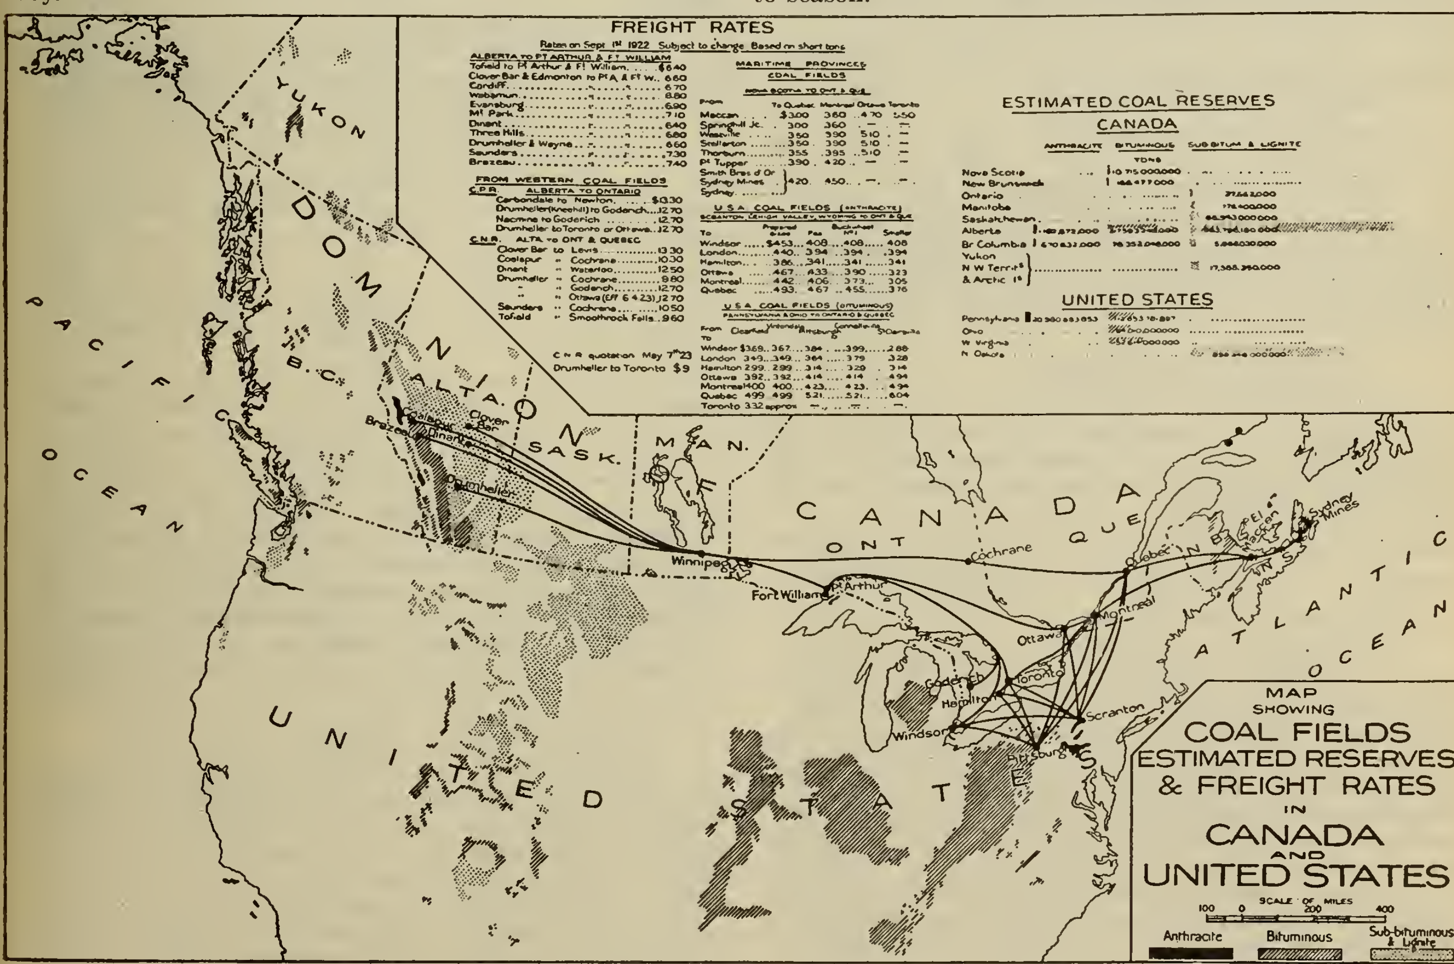

Figure No. 1.—Coal Fields, Estimated Reserves and Freight Rates in Canada and United States.

Coming next to a consideration of the sources of fuel for Canada, reference must be made to the fuel map appearing herewith. Figure 1.[⊕] A careful study of this map will give the reader a clear grasp of certain of the essential features of the Canadian fuel problem.

Eastern and Western Regions

All coal requirements of the Eastern region, both for domestic and power purposes, can be supplied on an economic basis from the Nova Scotia and New Brunswick fields. No foreign importations are essential for the complete and successful solution of the fuel problem of this region, even under present conditions.

Similarly coal for household purposes in the western region can be supplied economically from purely Canadian sources. The fields of Saskatchewan, Alberta and British Columbia can meet all foreign competition with untreated coal; and there is the further possibility of carbonized lignite briquettes supplying a portion of the demand. In a broad way it may be stated also that the power requirements of the Western region can be met from Canadian sources. This statement is subject to some correction in the case of Winnipeg, where American bituminous coals are being used to a certain extent. The threat of Alberta competition, however, has had the effect of keeping down the price in Winnipeg of American steam coals. These steam coals reach Winnipeg by a short rail haul from the head of the Lakes. In many cases the selling prices are so low that it is felt that this trade is purely a "dumping" one. In the meantime the Winnipeg consumer is getting the benefit. The magnitude of this trade can be gauged as follows:

	1922	1923	1924
Importation of Bituminous coal from U. S. into Manitoba in thousands of short tons	75	112	143
Total consumption of bituminous and lignite coals in Manitoba	760	890	878

Acute Fuel Area

The central region, or the "acute fuel area", is the crux of the real fuel problem. Here is the great coal consuming area, and here is the one large area of Canada where no coal is found. The problem falls into two divisions:

(a) household requirements;

(b) power requirements.

The magnitude of the difficulty can be judged by the following figures, giving the annual importation of coal into the acute fuel area of Canada, averaged over the 5-year period 1920-1924:

Anthracite...... 4,144,000 short tons—mainly for household purposes

Bituminous......14,030,000 short tons—mainly for power purposes

Total imported 18,174,000 short tons.

The household requirements of this area are not small. The great majority of the consumers are accustomed to and, in the main, still demand a luxury fuel — anthracite. As there is no anthracite available in Canada, the raw fuel to satisfy the demand must be imported either from the United States or Great Britain. *The Engineering Institute* Committee found that "acceptable untreated coal for household purposes in the acute fuel area cannot be supplied economically from Canadian sources under present conditions". In this opinion the writer still concurs. When considering power requirements the central region can hardly be considered as a single area, owing to the fact that its eastern portion (Montreal) has direct water access to the seaboard mines of Nova Scotia. Hence the Montreal district can be looked upon as being a fair market for Nova Scotia coals for power purposes, — largely due to the fact that under large contracts the Nova Scotia operators can lay down their coal f.o.b. dock Montreal at such small transportation charges. This has been due to thorough organization of shipping routes and first class unloading facilities in Montreal. When attention is turned, however, to the general manufacturing region of Ontario, it is practically impossible for the Canadian coal to compete, say, at Toronto with the American bituminous coals. The reasons for this will be touched upon in the second portion of this paper.

[⊕]Permission to use this map has been given courteously by the Dominion Fuel Board, Ottawa; 1925.

In 1924, the E.I.C. Committee found that "For power purposes in all but the Eastern section of the acute fuel area, it is quite hopeless to expect Canadian coals to compete with American coals." Since then the only marked change in the situation is the imposition of a Canadian duty of 50 cents a ton on bituminous slack, and the Canadian Government subvention on Nova Scotia coals of 1/8 cent per ton mile for points beyond Montreal. This duty makes the Canadian duty on all American bituminous coals uniform. The American coal roads are either meeting or will meet this duty by a shifting of freight rate on fine sizes.

The following table gives a quick grasp of the broad features of the situation. The figures are only general and are submitted more for comparison than any other purpose.

Approximate Cost of Coal in Toronto.

	Cost at pit head of R. of M. per net ton	Freight to Toronto per net ton	Duty net ton	Degradation and handling charges say	F.O.B. Toronto net ton
	$	$	$	$	$
American Bit.-Penn. or W.V.	2.25	3.50	.50	1.00	7.25
Nova Scotia	4.75	2.00 about (all water plus transfer Montreal)		1.00	7.75
Alberta	4.00	6.00 (experimental rate actually below cost)		1.00	11.00

A glance at the figures supplies the reason why Canadian coals can *not* compete at Toronto under present conditions. Quality for quality they cost more. If conditions, such as national sentiment, as reflected in tariffs or bonuses alter materially, a corresponding change may take place in marketing conditions. It is fair to point out also that in the foregoing table a very low freight rate has been assumed between Nova Scotia and Toronto.

Substitutes for American Anthracites

As above noted, Canada has been importing annually into the acute fuel area about 4¼ millions of tons of American anthracite. One of the major fuel problems before the country to-day is to discover if there are any feasible and economic substitutes. The necessity for such a search lies in the increasing cost of American anthracite, a lowering of its quality, the small quantity now left in the mines, and the not improbable imposition by the American Government of an embargo upon its exportation. The following are the possible alternatives:

(i) The development in the use for household purposes of metallurgical coke.
(ii) Importation of increasing quantities of Welsh and Scotch anthracites.
(iii) Possible development of briquetting industry using imported British or American anthracite fines as raw material.

The first two mentioned substitutes for American anthracite are extremely important while the latter is not quite so hopeful. But the increased use of any substitute, especially any increase in the use of coke and British anthracite, decreases our dependence on a single source of supply of a necessary commodity. In the past we have been almost at the mercy of the American anthracite operators. Be they as considerate as possible, this complete dependence is not wise.

The coke figures are interesting. In 1924 about 325,000 tons of coke were consumed for domestic purposes in the acute fuel area. For the first 9 months of 1925, over 300,000 tons have been sold for domestic use, and indications are not wanting that in the year 1925 about half a million tons of coke will be consumed. This indicates a healthy and, it is to be hoped, a permanent growth in the use of this substitute. As in other cases, the consumer must be educated in the methods of firing and burning coke, which are very different from corresponding methods for anthracite. The advantages of the coke over bituminous coal are obvious. It is a clean, smokeless fuel, provides a steady heat, and under proper draft control can be burned at higher efficiencies than coal. For domestic heating, metallurgical coke (by-product) is a better fuel than gas-house coke. This superiority is not so evident in the analyses as it is in the handling and burning qualities. The metallurgical coke is more solid, less brittle and less friable than gas-house coke, and is altogether a superior class of fuel. Plants are now in operation at Sydney and Hamilton.

Another important substitute is British anthracite. Welsh and Scotch anthracites have made impressive inroads on the former American monopoly. The figures are:

	1922	1923	1924	1925
Imports of British anthracites in short tons..	180,000	262,000	273,000	499,000 (11 months)

These British coals have penetrated into Nova Scotia, New Brunswick, Prince Edward Island, Quebec and Ontario, though about 75 per cent of the amount imported is consumed in the district of Montreal. It is quite probable that the captured part of this market has been lost to the American anthracite operators, though even this part of an attractive market will not be relinquished without a hard struggle. Price adjustments and grading qualifications will be made undoubtedly by the American operators to meet the British competition. But the low ash content and fine burning qualities of the British fuel are gaining and retaining many former markets.

Possibility of Alberta Shipments to Ontario

The effort to ship Alberta coals to Ontario under present conditions seems to be more of a political rallying cry than a serious economic proposal. The figures published by the E.I.C. fuel committee showed that such shipments were not feasible on purely business grounds, and the writer has not observed any serious criticism of the accuracy of the figures submitted. A brief digest of the fundamental economic difficulties will not be out of place: Alberta mining costs are high, due to the lack of co-operation among Alberta operators, the very short mining season in certain of the mines, high wages of the operatives, the mining difficulties encountered and the general over-development of the mining industry. The result of these conditions is obvious when coal costs at pitmouth in Alberta from $4.00 upwards, while coal at least as good in the American bituminous area costs from $1.90 upwards. Of course it can be pointed out with justice that the American prices are low at the present time due to a variety of causes which will be touched upon later.

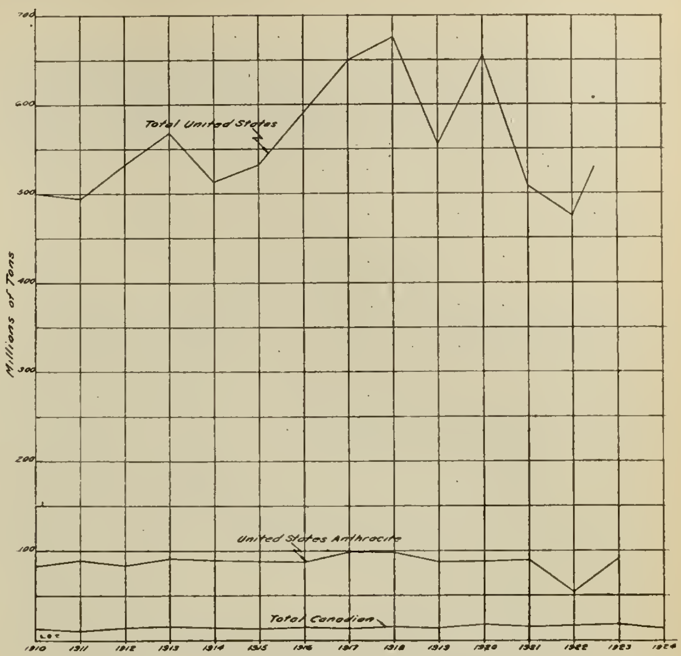

Figure No. 2.—Coal Production — North America.

Transportation is another stumbling block to this traffic. The basic fact is that first quality American coals can be put into Toronto with a haulage of only a few hundred miles as against eighteen hundred miles from A berta. Here geography is fighting against Alberta sales in Ontario. Even if the freight rate were produced to $6.00 — admittedly below cost — the coals can not compete on an economic basis as the following table will show:

	Cost at mine per net ton	Freight	Duty	Degredation and handling	Total per ton Toronto
	$	$	$	$	$
American low volatile bituminous coals. $2.25 to $4. take higher figure	4.00	4.00 (purposely high)	.50	1.00	9.50
Alberta coals $3.75 to $5.75: take low value.	3.75	6.00 (experimental rate —) below cost		1.00	10.75

In the foregoing table every possible advantage has been given to Alberta coals, yet they cannot compete in Toronto with American coals that, even at the worst, are quite as good as Alberta coals. The writer has often seen figures comparing the selling price in Ontario of Alberta and American anthracite coal — to the advantage of the former. But it is *not* with American anthracite that Alberta coals would have to compete ultimately. It is with the low volatile American bituminous coals. Nothing is gained in the long run by not

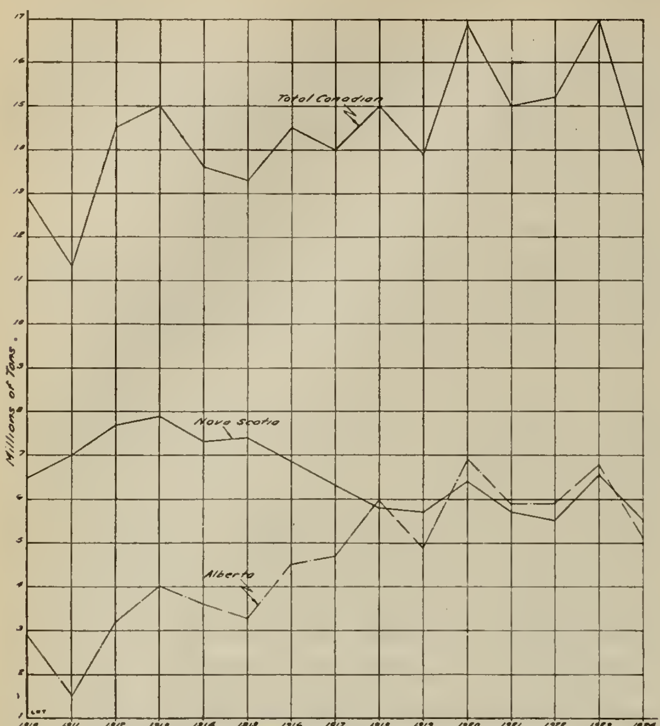

Figure No. 3.—Canadian Coal Production.

facing these facts fairly. If for national reasons the Dominion decides to become self-supporting so far as coal is concerned, then such a position can only be reached by tariff or bonuses in favour of the Canadian operators (Alberta and/or Nova Scotia), with, however, the necessary corollary that manufacturing costs in Canada would be increased.

Miscellaneous Matters

A solution of the fuel problem in the acute fuel area will be advanced by a co-ordinated policy of water power and fuel power development. As the use of water power increases coal will be released for heating purposes. In the congested centres also, central heating and steam plants will be conducive to more efficient utilization of coal both for power and heat.

For off-season heating, peat offers a desirable substitute for imported coal, and the writer wishes to record a word of appreciation of the work accomplished at Alfred by the Peat Committee financed by the Federal and Ontario governments. This is now being put upon a commercial footing, through the efforts of E. V. Moore.

As the use of oil for fuel in the industrial plants is very small relatively, the writer does not include oil in this discussion. There are certain cases, however, where special load factors or other local conditions justify the use of oil. One difficulty is that no firm price can be obtained for future deliveries of oil in quantity.

The use of oil as a household fuel is often very advantageous, especially when the owner is willing to pay a little more in operating costs and fixed charges for the cleanliness and convenience of oil firing.

Another subsidiary factor in the domestic field is the development of special grates with or without small blowers to enable the householder to burn small sizes of anthracite. The growth of these installations will result in an improvement in general fuel economy.

The foregoing constitutes a brief resumé of the fuel problem as it exists in Canada to-day. A successful solution from Canada's point of view is somewhat obscure. A few general observations must be considered however:

Is it reasonable to expect a Canadian consumer to pay more for a Canadian coal than he would for an American coal of equal quality, or to pay an equal amount per ton for a lower grade of Canadian coal? The result of such action is to increase immediately manufacturing costs, and ultimately selling price. The writer has never observed any tendency among the Canadian manufacturers to accept any such limitation, and believes that it is not wise to confuse patriotism with bad economics. Therefore, the general doctrine may be laid down that the coal that should be consumed in any given area is the coal that under normal operation of economic forces will reach there at lowest cost per ton grade for grade. This may be laid down as an economic axiom.

There has been some talk also of forcing the railways to move coal for less than cost on the grounds of an "all-Canadian policy". This paper is not the proper forum at which to discuss such a view, but the writer believes that it is unsound and pernicious from the points of view both of patriotism and economics.

What, then, can be done to solve this problem? Coal at the ends of our country — coal needed in the middle, while vast quantities of American coal are in close proximity to our centre of gravity of consumption.

Immediate Steps

The writer ventures to suggest that the following steps be taken:

That the federal government set on foot an enquiry into the actual cost of moving coal in train load lots and in steamer lots in order to place this matter beyond the realm of half-informed controversy. This duty might be discharged with propriety by the Railway Commission of Canada, but that its findings be not made public without including in the final figure proper allowance for overhead, depreciation and profit. Any other course of action might seriously prejudice the whole question of a long haulage movement of coal.

For example, the real cost of moving coal by water from Montreal to Toronto should be examined. In many cases the 14-foot draught vessels coming down to Montreal with grain return absolutely empty to Lake Ontario. A ballast cargo of coal to Toronto might be shipped very economically. The purpose of this suggestion is to get at the facts of the case in order that the

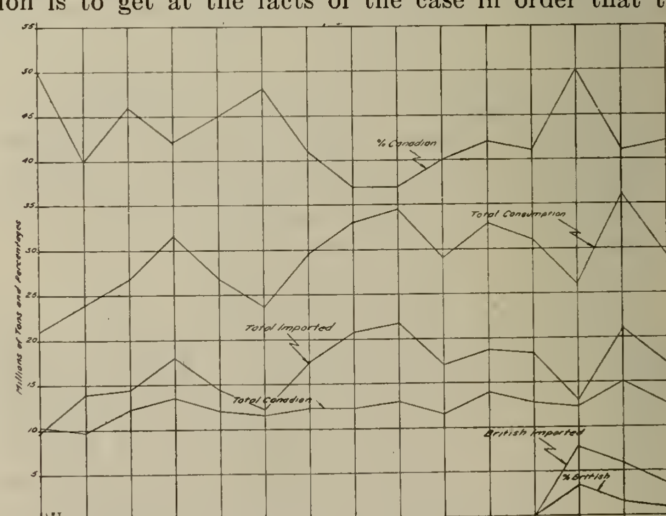

Figure No. 4.—Annual Consumption of Coal in Canada.

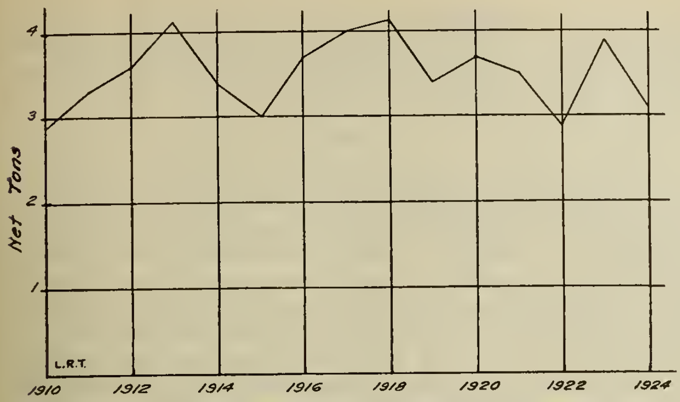

Figure No. 5.—Canadian Consumption per Capita per Year.

government may be able to assess accurately the amount of assistance required to place Alberta and Nova Scotia coals into Ontario on a competitive basis.

The writer now submits verbatim certain of the remaining detailed recommendations of the E.I.C. Committee. In these recommendations he concurs:

"Your committee recommends to Council that the federal government be urged to take appropriate action in order that each of the provinces concerned should adopt after discussion standards of quality and regulations governing delivery of coals. Until this is done, the public in their purchasing of coal will not be protected in any way.

"Your committee recommends that the Council place on record with the federal government its appreciation of the valuable work at present being undertaken by the Dominion Fuel Board, that the government be urged to prosecute this work vigourously and, further, that any so-called national fuel policy should only be adopted after receiving recommendations and reports by the Dominion Fuel Board.

"Your committee recommends that Council go on record as opposing any tendency to force the railways to haul commodities at less than cost except in times of national peril; and further recommends that, if for national reasons it be desirable to have Ontario become a market for Alberta coals, the Council urge upon the federal government the wisdom of bringing about such a result by subsidies or tariffs, rather than by imposing non-economic operation on the transportation systems.

"Your committee recommends that the Alberta operators be urged to concentrate their efforts on the production of the high grade coals for supply to the Western region rather than on the shipment of their low grade coals to Ontario."

Summary

The problems of the Eastern and Western regions are in a fair way to be solved successfully. The central region fuel problem is being attacked. One can see now the extension of the use of coke and British anthracites. This relieves a portion of our market from absolute dependence on one single source of supply. If the steps be taken as recommended, then will the information and facts be available on which a same and economic solution of the problem can be based. What is wanted are facts — not boosting speeches about "our glorious and illimitable coal deposits". Then and then only will a truly national fuel policy be possible.

Certain Economic Aspects of Canadian Mining

The mere possession of large coal mines and mining areas, even if of first quality, does not imply necessarily that it is economic to mine them. The questions of mining economics and mining costs are intimately bound up with the questions of geographical location, shipping costs, marketing costs, and foreign competition. Any attempt to solve the mining or fuel problem without giving due weight to these features is certain to prove abortive. Therefore time spent in studying the Canadian mining problem from a detached point of view will prove not unprofitable.

The writer proposes to divide this elementary introduction to the subject into the following heads:—

I Scale of coal industry in North America — See figures Nos. 2 and 3.

II Canadian consumption — See figures Nos. 4 and 5.

III Costs of a comparative character — See figure No. 6.

IV Comparative efficiency — See figures Nos. 7, 8 and 9.

V Transportation problem.

VI Summary.

Scale of Industry

Figure No. 2 shows graphically the magnitude of the coal industry of the North American continent. It will be noted that the scale of the United States production of coal is five hundred to six hundred millions of tons. The Canadian production is of the scale of fifteen millions, while Nova Scotia and Alberta are each producing in the neighbourhood of five millions of tons. It is interesting to note also the convergence of the lines of the Nova Scotia and Alberta productions. (See figure No. 3). From this it can be seen that, as an economic factor on this continent, Canada produces but 3 per cent of the total coal used, and Nova Scotia and Alberta each less than 1 per cent. At this point it should be noted that Nova Scotia is capable of producing another two million tons per annum without any further capital expenditure of magnitude. Alberta is also able to produce much greater tonnage if markets could be secured.

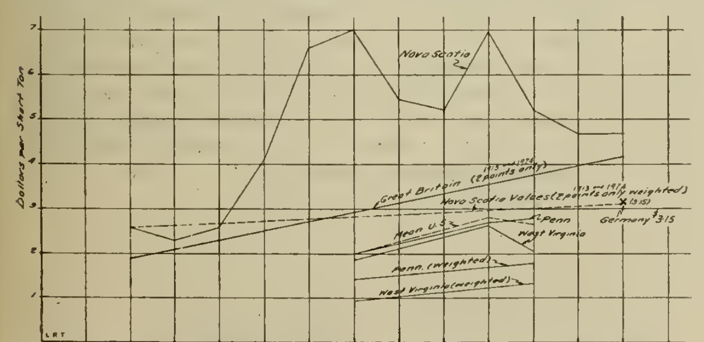

Figure No. 6.—Selling Price of Coal per Net Ton for Run of Mine of Pithead.

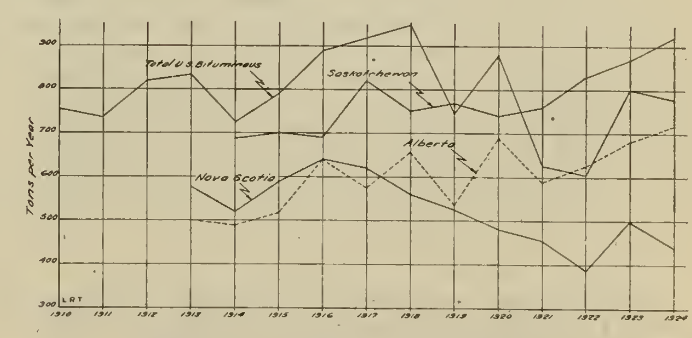

Figure No. 7.—Output per Man per Year.

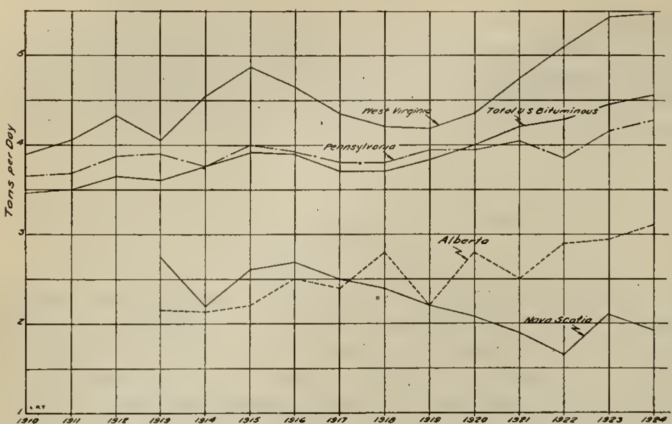

Figure No. 8.—Output per Man per Day.

It can be stated that in a broad way, values of coal quality for quality in North America are established by the United States conditions and not by the Canadian mines. It is impossible for the tail to wag the dog. Therefore one should accept with considerable caution the oft repeated statement that the threat of the penetration into Ontario of Nova Scotia coals has the effect of reducing the selling price in Ontario of American coal. While it is possible that the American operators would regard Ontario shipments* as dumping shipments, and thus reduce their Ontario selling cost to capture some or all of the market, it does not seem probable that, in the absence of competition, the price in Ontario of American coals could ever be artificially boosted, in view of the large number of independent and competing American operators. The difference between this situation and the presence of American coals in Winnipeg is very interesting. In Winnipeg the total of American shipments is small enough to be controlled and "dumped" whenever desired. Also it is only 10 per cent to 15 per cent of the Canadian coal supplied. Of course, it may be emphasized again that within political boundaries the price of coal or any other commodity can always be determined artificially by tariffs.

Consumption

The total annual consumption of coal in Canada is running pretty steadily since 1913 in the neighbourhood of thirty millions. (See figure No. 4.) The per capita consumption may be taken to be 3½ tons, which figure has also been maintained very steadily. (See figure No. 5.) Reverting now to the total consumption, it can be noted that the curve (see figure No. 4) of imports is *always* above the curve of Canadian coal consumed, showing that since 1910 Canada has always imported more coal for consumption than she has produced from her own mines. This idea is expressed in percentages at the top of the chart. To state it in another way, Canadian production has never exceeded 50 per cent of Canadian requirements. Practically all the imported coal is from the United States — the only other source of import being Great Britain. The curve of Britain coal imports from 1921 is shown and the percentage of this British coal to total consumption is also shown. The figure in 1922 was 3 per cent, while in 1924 only about one per cent of our consumption was supplied by Great Britain. This figure of one per cent will be slightly larger in 1925, due to the increased use of British anthracite. If the consumption of British anthracite in Canada be expressed relative to our anthracite requirements, the figure will run a little over 10 per cent this year.

Costs

The writer is well aware that cost figures may be very misleading, and the cost curves shown in this paper are not submitted with any feeling of absolute accuracy or finality. They are taken from official sources and compiled as nearly as may be to illustrate relative conditions. The writer emphasizes therefore that it is the inclination of the various lines to the horizontal that is of interest. The vertical position of the lines is of less importance than their relative positions and respective tangents. The costs per ton are in each case the selling price of run-of-mine coal f.o.b. pit head per short ton, unless noted otherwise. The general inclination of the average United States line is upwards between 1918 and 1921, but from then to 1923 it is downwards or horizontal. Especially interesting is the remarkable drop in the West Virginia field, which is one of the principal bituminous fields which compete with Canadian coals in the acute fuel area. Coming now to Nova Scotia coals, the curve of prices (see figure No. 6) is one made by the Montreal selling prices run-of-mine adjusted for freight, Nova Scotia fields to Montreal by water. Whereas in 1913 the cost was $2.60, the cost in 1924 was $4.70. It is a very interesting fact to notice that the average curve of British prices f.o.b. mines Great Britain (2 points only spotted)* has practically the same tangent as the line joining the 1913-1924 Nova Scotia prices. It will be observed that the average tendency then of British mines and Nova Scotia mines is steadily upwards in scale of dollars. Both Nova Scotian operators⊕ and British operators feel that this condition is a temporary one only, and that with better labour conditions, extended markets, and other special difficulties removed prices will again turn downwards. Against this opinion Great Britain and Nova Scotia each have nearly all their coal in deep mines, and often thin seams. The logical result is more expensive mining as time goes on. A reasoned opinion on this point is very difficult to submit owing to the difficulty of obtaining the confidential information necessary to form a judgment. If one were to assume that the wholesale commodity index of the United States Bureau of Labour is a fair guide on coal values, it is possible to form an estimate of the intrinsic value of these various prices already quoted, namely: $2.60 for 1913 and $4.70 for 1924. The curve of these corrected values is plotted on figure No. 6, and it will be seen that coal in 1925 is valued a little higher than it was in 1913. The United States selling prices per ton decreased in dollars but in terms of commodity value they have risen somewhat. These value curves are all marked "weighted". As another indication of the world marketing price, the German figure for corresponding grades of bituminous coal at pit head is equal to $3.15 per short ton. This is based on the gold mark. The order of selling prices to-day is: — United States, Germany, Great Britain, Nova Scotia.

---

*Ontario shipments from United States are about 3 per cent of the total United States production — and about 6 per cent of the production of the Pennsylvania, Virginia and Ohio fields.

*Average costs Great Britain — 1913 — 8/10
1924 — 19/1½

⊕It is only fair to note that the Nova Scotia price has receded since 1922.

Comparative Efficiency

The efficiencies of mining and of management are reflected to some extent in the costs already touched upon. The writer also desires to examine the apparent efficiency from the points of view of output per man per year, and output per man per day. The presence of too many men in the mines, too few working days in the year, ca'canny, or other disadvantageous principles, soon makes its appearance in statistics of this character.

The examination of the output per man per year of Great Britain and the United States show that in 1886 the two countries were not far apart. (See figure No. 9.) By 1910 the output per man per year in the United States fields was about 600 long tons, while the corresponding figure in Great Britain had fallen to 270 long tons. This remarkable increase in United States figures was due to the introduction of mining machinery, good thick seams, easy and workable mines, and other favourable factors. The British have deep mines, often bad seams, increasing number of men necessary for ventilating and handling, and other difficulties. Coming now to the years 1910 to 1924 there has been a drop in the United States bituminous output per man per year, but it is still very far above the British and Canadian figures. (See figure No. 7.) This drop has been due to changing labour conditions, shorter hours, etc. It is to be noted also that the Saskatchewan and Alberta figures were on a slight upgrade until 1921, when, due to rapid extension of Western Canadian markets, the output per man per year moved up comparatively quickly. During these years the condition of the Nova Scotia industry is of interest. From 1916 to 1922 there was a steady decline in Nova Scotia of output per man per year and the mean of the whole curve shows a falling tangent.

An even more illuminating condition is supplied by the figures for output per man per day. Figure No. 8 shows the coal produced per man per day. Here again there is a steady increase in West Virginia, Pennsylvania, and the total United States bituminous fields. Each of these tangents is positive. There is a steady increase also in Saskatchewan and Alberta. But the ominous fact appears that there is a steady fall in the output per man per day of the Nova Scotian fields. It is only fair to point out, however, that in 1924 Nova Scotia showed a big increase over 1923, and that the Nova Scotia operators have had difficult problems to face in connection with disorganized conditions, labour troubles, etc. As already observed it is not just to single out any one year, but the general tendencies of these lines are of real importance, and illustrate fundamental economic trends in the industry. It will be noted that the Nova Scotia and Alberta figures on output per man per day are much lower than any of the American fields — and this difference is not sporadic but is consistent. It is open to doubt if they are as far apart in fact as they appear. Some difference in assumption of the divisor may account for this. But in any event, the writer emphasizes the inclination of the lines — not their vertical position.

Transportation

The cost of transportation of coal to Ontario from Alberta or Nova Scotia is one of the real fundamentals of the Canadian problem. It is obvious that with reduced costs of haulage Alberta coals can move farther to the east and Nova Scotia coals can penetrate further westwards into Ontario. An analysis of transportation costs is obviously outside the scope of this paper, but certain points may be raised.

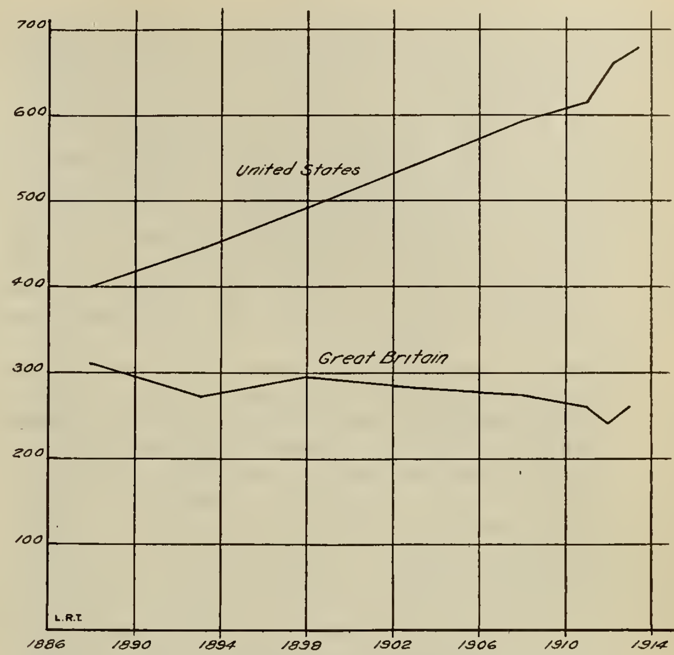

Figure No. 9.—Output per Year per Man in Long Tons.

The Canadian freight rate structure is at once delicate and intricate. In the main the freight rates are purely empirical, and no pleasing generalities, such as comparative rates per mile on various commodities, are able to solve the problem. On the other hand, the Railway Commission has in hand at the present time a complete investigation and revision of Canadian freight rates. Representations to them of glaring abuses or of commercial discrimination will be received most carefully, and will have great weight in clarifying the whole matter. A single example of one of the minor difficulties that Nova Scotia coal meets in order to penetrate into the eastern portion of the acute fuel area is the fact (touched on before) that the 14-foot grain carriers moving westbound Montreal to Port Colborne (passing Toronto) are practically always empty of heavy freight. The coal rate westbound quoted under the present lake freight structure makes it impossible for the Nova Scotia operators to compete in Toronto with American coals. If, however, a special rate were conceded with the object of getting some freight rather than none, it is possible that under certain circumstances Nova Scotia coals could make an impression in Toronto. The difficulty appears to be that this special westbound lake coal rate cannot be granted without prejudicing the whole question of the grain rates on the Great Lakes. It is obvious that we have here a very delicate point, and the writer quotes this example merely as one instance of how intricate the question of coal transportation is when looked at from a detached but responsible point of view.

In closing this section the writer would call attention to the fact that never before has the Canadian public been so well aware of the fact that in their ultimate analysis coal and transportation are national problems, and that the present is an opportune time to discuss the question of coal transportation in a non-partisan spirit.

Summary

To present briefly any condensed summary of the economic factors of the Canadian fuel problem is very difficult. Canada, roughly speaking, is a strip of country three thousand miles long and perhaps fifty to one hundred miles wide. At the two extremities there is abundance of good coal. At the centre there is none whatever thought it is just at this point that the centre of gravity of coal consumption lies. In close proximity are the finest bituminous mines in the world. As already pointed out these American mines during a period of years, have had a steady increase in the output per man per day. The Alberta fields cannot possibly compete, and the Nova Scotia fields have a decreasing output per man per day. The American fields have decreasing costs per ton pit head — the Nova Scotia fields have a far higher cost and possibly increasing prices. This is the very essence of the problem.

The writer believes, for reasons already outlined, that a complete Canadian supply for Canadian needs is from a purely economic point of view almost hopeless. On the other hand, if the people of Canada desire to reach an independent fuel position irrespective of economic law, it can be done by means of tariffs and bonuses. Before taking such an important step, however, it is essential that the facts of the situation be collected, collated carefully, and their real import understood. In this connection the real cost of moving coal should be known. It should also be understood *why* Nova Scotia prices are moving *upwards* — i.e. as a general tendency over a period of years — and outputs per man per day downwards when during the same space of time the American bituminous fields of similar types of mines are going through diffeient cycles. The public anxiety towards the Nova Scotian situation is reflected by a corresponding disquietude in England over a similar state of conditions obtaining in the British mines.

If part of the low prices and increasing outputs of the American mines are due to a cycle of disorganization, unfair competition and overdevelopment in these fields, then some estimate should be made of the amount of price adjustment to be expected, and the time when it will take place, in order to assess the amount of assistance to be granted to the Canadian areas. To the best of the writer's knowledge there has never been a time in Canada when so much interest is being shown in the question of fuel and a national fuel policy. The public, the miners, and the operators are all agreed that the matter is one of national importance and not merely a dispute as to wages and living conditions. The origin and the outcome of strikes, the protracted negotiations, etc., are no longer the sole concern of the disputing parties, but are of infinite importance to the future of this Dominion, for fuel is undoubtedly one of the basic facts of our civilization. The spirit of a sincere desire to solve this formidable problem has been born in a new atmosphere of national feeling, and in this atmosphere alone will a satisfactory solution be found. The order of the solution is beyond question:—

1st, What are the facts?

2nd, What is the real import and explanation of the facts when gathered?

3rd, The initiation of a national policy based on the facts.

To this work Canada should devote her finest and best ability. Nothing less will meet successfully so grave a situation.

In closing this paper, the writer wishes to acknowledge gratefully the assistance given him in the preparation of certain material by A. J. P. Walter, B.Sc., Dawson Research Fellow in Mining, McGill University, Montreal.

Fuel Preparation and Treatment

A Statement of the Present Situation Regarding Fuel Carbonization

J. L. Landt,

Consulting Engineer, Buffalo, N.Y.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 29th, 1926.

We are generally familiar with the various methods of preparing fuel and its utilization, and the remarkable strides made in recent years in their technical and commercial development. Washing and de-ashing, de-volatilizing, mixing, blending, etc., are of interest in certain fields, but are unlikely to become commercially important so long as we have available, at reasonable prices, large quantities of good coal.

During the past few years, a considerable amount of interest has been shown, both from technical and commercial standpoints, in the low and high temperature carbonization of coal.

Interest in low temperature carbonization is mainly due to the fact that a very high yield of tar and tar oils is obtained by this method of distillation, varying from 15 to 30 gallons per ton of coal as compared with 8 to 12 by high temperature carbonization.

Low temperature tar is a thin fluid or oil containing large proportions of paraffin bodies from which gasoline, fuel, and lubricating oils may be obtained. So far motor fuel has not been successfully produced, but if inferior bituminous coals and lignites can be made to yield these products, they will become of increasing economic importance. It is reported that the brown coals of Germany are giving satisfactory results, but this fact is of little interest in this country, because the commercial success of any system capable of general application is rendered more complex by the wide differences that exist between different coals. Low temperature carbonization is intimately bound up with the constitution of the coal to be treated. For example, coal contains resinous and cellulosic substances derived from resins and gums or from cellulosie of the original vegetation. Resinous substances have low melting points, yield large quantities of liquids on distillation, which consist chiefly of paraffins, napthenes, olefines, leaving a pitch which acts as a binding material for the char. The cellulosic or humic compounds are infusible and yield small quantities of liquids, which are generally phenolic in character. Sulphur, nitrogen, etc., are also present, making coal a very complex material.

Low temperature carbonization, (450 to 550 degrees C.), reduces the rate of transmission of heat through the charge. For this reason about four or five inches is the maximum depth of material that can be treated in stationary charges within economical limits of time. If the material is agitated during carbonization, poor char results. Hence, capital outlay is increased owing to increase in units, space required, maintenance and labor costs. Any free space left at the top of the coal increases the amount of air left in contact with coal. Those systems carbonizing at low temperatures with excessive air space above the coal usually produce a friable powdering mass of char. Brown coals or lignites in Germany have been submitted to a form of complete gasification in producers of modified Mond type, giving a tar resembling low temperature tar, but as the temperature of the exit gases evolved is high, the tars resemble more nearly high temperature tar. Products of distillation in this case are kept separate from those of combustion, and hence the temperature of the distillation products does not rise above the decomposition point. High yields of tar oils are obtained, which yield upon rectification motor fuel, fuel oils, lubricating oils, solid paraffin wax, ammonia, benzine, etc., yet it is the cost of such products, which is of vital interest. Cheap labour and other costs may offset any possible advantage we might have on this continent, especially when we are required to compete with high grade quantity produced products.

The distillation of coal at low temperature has created considerable public interest, but it is unfortunate that such publicity has been taken advantage of by some promoters, because there has been no developments along low temperature lines on this continent, or possibly in Europe, which would justify the statement that any of the various processes have passed from experimental stages, to commercial success.

It is believed today by many that the yields of by-products from low temperature processes are so much more valuable than those derived from high temperature processes, that the returns would immediately put low temperature carbonization processes ahead of all others. The low temperature processes have had considerable difficulty in finding markets for their products, for the reason that practically no markets existed for certain of the oils, and when an attempt was made to put them on the market in quantity, they were found to fetch about the same price per gallon as the tar made in the modern by-product coke oven. The quantity of tars derived from low temperature carbonization is in excess of those from the coke oven, and hence a greater return is shown on the balance sheet. This one item, however, may be offset by other considerations, such as the much larger quantity of saleable gas produced by the coke oven, the higher ammonia yields, etc. If the same economical rules which govern modern by-product coke companies, also apply to low temperature processes, the establishment of the latter as a commercial success may prove somewhat difficult. In general, coke must be sold at a considerably higher price than that of the raw coal from which it is made, and unless the yields of by-products in the low temperature carbonization processes very greatly exceed those of the coke oven, any scheme which has as its object the treatment of coal for the removal of by-products and the use of the coke or semi-coke as boiler fuel, may labour under severe difficulties.

With the exception of coke breeze, which is a so-called waste product from the high temperature processes, coke is unable to compete with bituminous coal as a fuel for power plants.

Furthermore, there is a great deal of discussion regarding the value of coke produced by the high temperature processes versus that produced by the low temperature process. In general, however, with proper equipment, we do not believe that low temperature coke is inherently superior to by-product coke even for domestic purposes.

We now arrive at the crux of the situation with regard to low temperature carbonization coke as a possible domestic fuel for Canada. If we must treat or briquette the product before it is suitable for the market, we have added to the cost of the product. Careful study has shown that there are few, if any, satisfactory briquetting processes in existence. Hence, where we have to double process a fuel to render it suitable for the market, we have made the cost excessive. At this point it would be, perhaps, well to point out also that the high temperature carbonization process leaves much to be desired, especially in the preparation of fuel for domestic purposes. In the past, it has been the custom to market coke rejected from the metallurgical screens and by sizing, place it on the market as domestic fuel, without regard to its physical characteristics. There are only very few modern by-product coking plants on this continent which start out with the primary idea of making domestic fuel, and studying the structure of the coke produced, from this standpoint. This idea, however, is very rapidly becoming recognized, and attempts to make domestic coke hard and dense have met with more or less success. There is still room for much improvement.

The advocates of one form or another of fuel carbonization, express commercial rather than scientific differences of opinion; hence the question of relative efficiencies of various processes is not of primary importance. There have been many reasons put forward for the use of low temperature carbonization, and of all of these, the most important is the commercial value of the products after processing. These products must also show a reasonable margin of profit after meeting cost of production, overhead expenses, etc.

From the standpoint of conservation, when it is well known that the world's supply of known fuels is rapidly diminishing, it is necessary to find new means for utilizing them more efficiently, and hence economically. This is the attractive feature of low temperature carbonization, and it is not our purpose to discourage additional and original research along these and other lines by those who have the capital and inclination to promote the general welfare. It is only because of the fact that the high temperature carbonization process has been established so successfully over a period of years, that the word of warning is sounded, when one is considering investment of money in new projects.

Considerable interest has been created in the scientific world by the production of "methanol" and "synthol", which may be described respectively as synthetic methyl alcohol and a mixture of liquid hydro-carbons. There are several ways of extracting, or obtaining oils from coal, as follows:

Extraction of solvents (1/2 of 1 per cent) non-commercial.

Low temperature distillation (4-10 per cent).

Hydrogenation of coal (10 to 45 per cent).

Combination of gases produced from coal with coal.

Hydro-carbons from carbides.

Fischer estimates that one ton of coke should produce in the neighborhood of 350 gallons of methyl alcohol. This figure, of course, has never been reached to date, and is entirely a theoretical one.

By subjecting coal held in oil to certain high temperatures and pressures in an atmosphere of hydrogen a mixture of liquid fuel results. One-third water gas and other fuels such as the higher alcohols and ketones are combined by using gas and steam catalytically, and the resulting product is known as "synthol". However, these fuels, methanol and synthol, have a lower calorific value than benzol, but may become increasingly important. The results have apparently been so promising with the meagre information at hand, that it would appear that the trend of scientific investigation will turn from the field of low temperature distillation to the new fields of synthesis of gases.

Carbonization of coal aims to raise to a higher point the value of the products and the availability of the heat units. However, the case of so-called "low grade fuels", such as shale or peat, leads to the belief that it is, at present, commercially unsound to attempt to increase their value by carbonization. Only as the higher grades of fuel increase in price, will the inferior fuels become of commercial importance.

It is not the purpose of this paper to discuss in detail, the various ways and means of carrying out low or high temperature carbonization. In the case of the latter, these methods are fairly well known, but in the case of the former, there are some technical problems which are of scientific and commercial interest. Where coal is exposed in thin layers, having been crushed, to the action of heat, a char is produced, which requires, or may not require, further treatment. Other processes are those in which the coal is stirred, which tends to break up the lumps of coke when formed and produces a friable coke, which must be processed before using for domestic fuels. The use of coking, or non-coking coals influences and makes the design of the retort difficult. The question of internal and external heating of the coal is also of prime importance.

We now arrive at the point where we can perhaps point out a commercially successful means of utilizing the low temperature process, and that is, in connection with the generation of power. Neither the by-product coke oven, nor the gas retort, offer many indications of success in the carbonization of non-coking coals. Here low temperature carbonization may prove of value in that the recovery of the valuable by-products will be accomplished, and at the same time, produce a fuel which is suitable for power generation, in a form which will not require further processing. Certain experiments have achieved results which indicate that non-fusible coals will coke much faster than fusible coals, as it is possible to drive the gases and oil vapours from the coal at a much faster rate.

It may eventually prove that this increase in capacity will offset other charges, and we will have gained in more efficient utilization of the material at hand. The foregoing is, of course, based on the assumption that the char will be used in pulverized fuel systems, where the power plant consumes enough fuel per day to warrant a large installation of the low temperature carbonizing process. Thus from the two angles which have been discussed in this paper, it would appear that there is room for both the high and low temperature process in Canada,—the former for the production of suitable domestic fuel at lowest possible cost, and the latter for the production of power under the same relative conditions, and yet attaining that which has never been accomplished,—the saving of valuable ingredients which have heretofore gone to waste up the stacks of many power plants.

For the purpose of comparing the two systems, the yields of the by-product coke oven and of low temperature carbonization are given. The yields are those per ton of coal carbonized, and those for the coke oven are actual results, while those for the low temperature carbonization process are the summary of the claims of various advocates of low temperature.

By-Product Coke Oven		Low Temperature Process
26-30 lbs	ammonia as sulphate	13-15 lbs.
8-12 gals	tar	20-30 gals.
3-3.5 gals	benzol or motor spirit	3- 4 gals.
10,000-12,000 cu. ft. 500-600 B.t.u's	total gas	6,000-7,000 cu. ft. 600-650 B.t.u's.
6,000,000	B.t.u's total in gas	4,000,000

It will be noted that advocates of low temperature carbonization recognize that the ammonia yield is such that at present prices, and cost of installation, its recovery is hardly worth while. Recent figures available indicate that for equal capacities the cost of a low temperature carbonization plant would be slightly less than that needed for high temperature carbonization. However, when reprocessing is necessary, or the by-products are to be made suitable for the market, the capital cost becomes greater for plants of equal capacity.

As before noted, the tar yield in the low temperature process is about three times that of the high temperature process, and the yields of motor spirit as such, are about equal. Great claims are made by advocates of the low temperature process of the value of the high B.t.u., gas produced. The fact is, however, that this question is entirely open to discussion, as the absolute quantities available for sale are not definitely known in the case of low temperature carbonization. Gas men for years have been fighting for reductions in the B.t.u. standard, and they could only secure this concession when it was proved that within limits, the lower B.t.u., gas could be utilized just as efficiently as high B.t.u. gas.

Granting that the cost of carbonizing one ton of coal by either the high or low temperature process is about the same, and assigning known values to the by-product, we still find that the balance is in favour of the coke oven at present. This is borne out by the experience of those who attempted to establish low carbonization on a commercial basis. This situation may change when the market is developed, and the value of low temperature by-products proven and recognized.

The Principles of Combustion and Heat Transfer as Applied to Steam Generation

John Blizard,
Research Engineer, Power Specialty Company, New York.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 29th, 1926.

While the exact laws governing the combustion of fuel, and the transference of heat to the water in a boiler from the gases and fuel bed are unknown, sufficient is known to enable engineers to design boiler plants to give overall thermal efficiencies as high as 90 per cent. To obtain efficiencies as high as this the fuel must be almost completely burnt and the gases cooled to a temperature well below that of the steam in the boiler of an ordinary power plant or factory.

It is proposed here to review first some of the factors involved in burning coal, then to consider methods of cooling the gaseous products of combustion.

Combustion of the Coal

The methods of burning coal may be subdivided into two parts:—

1. That of burning it in suspension in air.
2. That of burning it on a grate.

Powdered Coal

When the coal burns in suspension as in a powdered coal furnace its upward velocity is less than that of the air and it is this motion largely which enables it to burn with the desired rapidity. Its rate of descent through still air depends on its density, shape and size. If the particles are similar in shape and extremely small the terminal velocity will be proportional to the square of their linear dimensions, and when very large to the square root of their linear dimensions. With ordinary powdered coal, as used commercially, crushed so that the bulk of it passes through a 100-mesh screen the terminal velocity is proportional approximately to the linear size of the particle, and a particle with a mean diameter of one-hundredth of an inch falls with a velocity of about 1.4 feet per second.

The powdered coal is admitted to a furnace in either a horizontal direction or vertically downwards and usually it is mixed with about one-third to one-fifth of the air required to burn it, since this mixture ignites and burns more readily than one comprising all the air required for combustion. The remaining air is admitted later in such a way as to impart as much turbulence as possible to the particles of coal.

On entering the furnace the coal should be exposed to radiation from the flame itself to enable it to ignite readily. Once ignited it will burn completely if it is sufficiently finely ground, and enough air and combustion space are provided. The actual space required varies to some extent with the size of the largest particles of coal. The larger the particles of coal the greater their downward velocity relative to the stream of gases passing up the furnace and consequently the longer they will remain in the furnace. The rate at which the particles burn probably is proportional approximately to their velocity relative to the gases and to their surface, and is thus roughly proportional to their mass. But obviously the greater rate of combustion and slower speed of the particles through the furnace cannot enable them to burn to completion as rapidly as smaller particles. In ordinary boiler plants coal is ground so that about 90 per cent of it passes through a screen of 100 meshes to the inch, and about 1½ pounds of coal are burned per hour in one cubic foot of combustion space.

If the combustion space is too small, particles of coal are carried through the furnace and up the stack, and little or no carbon monoxide is produced. In attempting to burn powdered coal in the furnace of a Scotch marine boiler over 20 per cent of the fuel was carried through the boiler and lost, while on only one of five tests did the carbon monoxide exceed 0.2 per cent.

The great advantages of burning powdered coal lie in the ease with which the flow of air and fuel can be adjusted to the load, and the completion of combustion of the coal without an excessive ratio of air to coal.

Burning Coal on Grates

When coal burns on a grate the process of regulating its combustion is much more complicated than with powdered coal. Not only is the fuel bed far less homogeneous and more massive than a flame of powdered coal, but any troubles with clinker affect at once the flow of air and consequently the efficiency. The process of combustion in a fuel bed has been studied by Kreisinger who showed that the fuel bed acts principally as a gas producer and a gas retort. Only about one-half the chemical energy of the coal is liberated by combustion in the fuel bed, the remainder remaining latent as carbon monoxide, and hydrocarbons. Thus the gases leaving the surface of a fuel bed a few inches thick may contain as much as 30 per cent combustible matter and have no free oxygen present to burn it. This means that of the air necessary for complete combustion only one-half can be supplied through the grate, and therefore the other half must be supplied above the fuel bed. Thus the rate of supply of air beneath a fuel bed governs merely the rate of gasification of the coal, and the combustion can be completed only in the combustion space above the bed of fuel.

In the light of the above experiments, one may inquire why the loss caused by combustible gases in a boiler plant is not greater than it is, and various experiments have been carried to find out whence comes the air to burn these gases.

Tests on a Domestic Boiler

A series of tests carried out at the Bureau of Mines on the fire-pot only of a small domestic boiler, with no supply of air above the bed of fuel, showed that when burning anthracite and coke the heat lost by not burning carbon monoxide was never over 5 per cent of the calorific value of the fuel. But when burning a high volatile coal the loss caused by combustible gases leaving the fuel bed varied from 2 per cent just before the time for re-charging the fire-pot with coal to as high as 50 per cent after charging the fire-pot. This high loss could not be ascribed

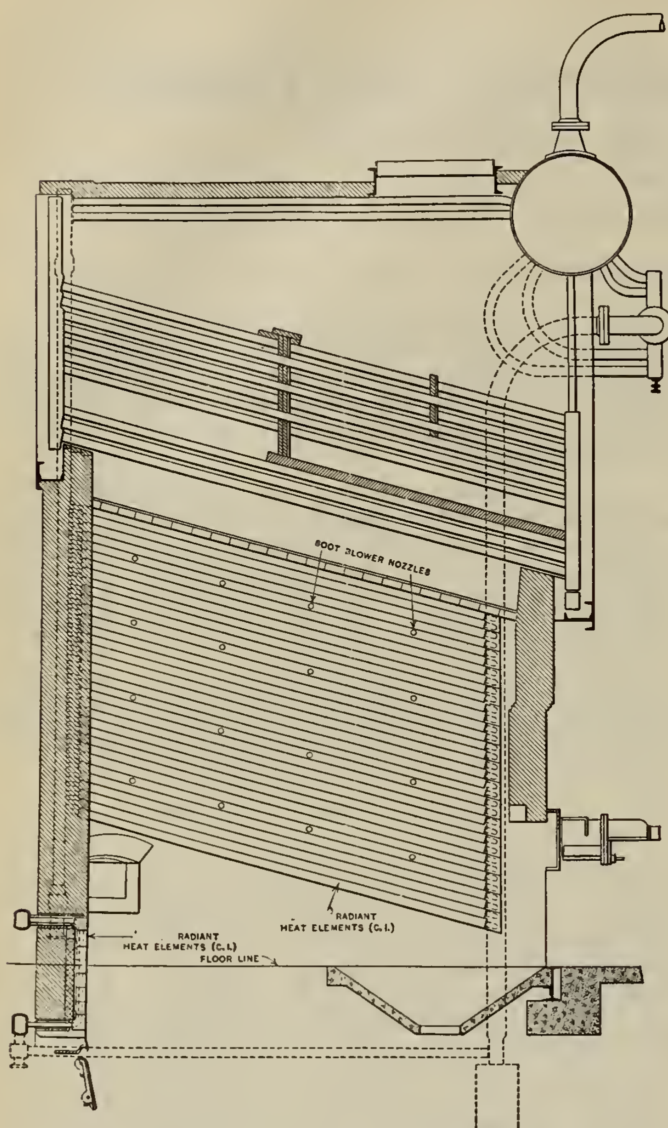

Figure No. 1—Boiler in the Power Plant at Zilwaukee, Mich., of the Consumers Power Company—Stoker Firing.

entirely to a deficiency of free oxygen above the fuel bed since at practically all times sufficient free oxygen was present to consume the combustible gases. Actually then, in a small domestic furnace sufficient oxygen finds its way around the edges of the fuel bed to complete the combustion of the combustible gases when burning anthracite and coke and for the most part in sufficient quantities to burn the gases rising from a fuel bed of bituminous coal. The thermal efficiency of the fire-pot alone of a domestic furnace was found to be 51 to 59 per cent when burning anthracite or coke, and about 33 to 40 per cent when burning bituminous coal. It was shown also that in any ordinary domestic boiler, admitting air continuously through slots in the fire door, reduced the efficiency with anthracite and coke, and on the average had little effect on the efficiency with bituminous coal. The temperature of the products of combustion leaving the fire-pot of the furnace of a domestic boiler are so low, at all ordinary rates of combustion, that the combustible gases do not ignite once they have left the incandescent fuel bed. The overall efficiency of a domestic furnace with anthracite or coke ranges from about 60 to 70 per cent, and the loss by combustible gas does not usually exceed 3 per cent, so that there is not as great a field for improvement by redesigning the boiler to enable the combustible gas to be burnt as there is when burning bituminous coal, when the efficiency may be as low as 50 per cent. If a domestic boiler is to be designed to burn bituminous coal with a better efficiency some arrangement will have to be made to mix supplementary air with the combustible gases before they have left the top of the fuel bed. Certainly there is ample scope for materially improving upon the efficiency of the ordinary domestic furnace when burning bituminous coal.

Tests on a Hand-Fired Grate

The difficulty of burning the gases rising from the fuel bed of a commercial steam boiler, with its higher rate of combustion, is less than with a domestic boiler because the temperature at which the gases leave the fuel bed of the commercial boiler are considerably higher. But the area of the grate is now larger in proportion to its periphery, so that any air admitted above the fuel bed has to travel a greater distance to burn the combustible gases rising near the centre of the grate.

Some interesting tests to determine the composition of the products of combustion were carried out by the Bureau of Mines on a marine water-tube boiler, and the first two or three tests showed considerable combustible gases at the base of the stack, while flames were observed frequently in the up-take. This condition was ameliorated by admitting suitable quantities of air over the fuel bed at the front and back of the grate.

When air is admitted over the grate to burn the gases rising from the grate it is desirable to mix the air with the gases as rapidly and as near to the fuel bed as possible. It happens frequently that the loss from combustible in the gases leaving a boiler is not very great, but that the secondary air mixes so slowly with the combustible gases that the gases continue to burn in their passage through the boiler. This means that much heat is generated by combustion too late to enable it to be cooled by the heating surface near the furnace and accordingly, the temperature of the flue gas is very high. For example, in a series of tests to determine the relative values of coke anthracite and bituminous coal, for generating steam in a low pressure cast iron boiler of 815 square feet of heating surface, the bituminous coal gave a thermal efficiency of only 67 per cent, while coke and anthracite gave efficiencies of about 78 per cent. The lower efficiency with bituminous coal was caused by the much higher temperature of the flue gases, which in turn was shown to be caused by prolonged combustion.

A striking example of the presence of combustible in the gases leaving a fuel bed was shown by the composition of samples of gas taken from the furnace and combustion chamber of a Scotch marine boiler. Here it was found that the contents of combustible gases leaving the fuel bed was as high as 14 or 15 per cent of the total volume of gases, but that in passing over the bridge wall at a high velocity these gases mix so rapidly with the air from the front of the grate, that the combustible is rapidly burned. This illustrates also the desirability of causing the gases and air to pass over a bridge wall or some constricted area to enable the free oxygen to mix rapidly with the combustible gases. One may notice also that although the furnace and combustion chamber of a Scotch boiler are bounded entirely with water-cooled surface, this did not prevent rapid and complete combustion of the combustible gases; and this shows that it is not essential for high efficiency to have a furnace lined with refractory material. This is borne out by the high efficiency of the Scotch marine boiler which was about 76 per cent when fired by hand with coal, and over 80 per cent when fired by oil.

Combustible Gases with Stoker Firing

When firing coal with a stoker, the fire is carried gradually across the furnace so that the fuel bed contains less and less combustible matter as it approaches the dump plate or other receptacle for the ash. In the main portion of the fuel bed, combustible gases are given off from the fuel bed and where the fuel bed becomes thin, free oxygen finds its way through the fuel bed. The furnace must be large enough and so constructed that the free oxygen passing through the thinner portions of the fuel bed may mix with the combustible gases before they have travelled far. The two principal stokers used in modern power plants are underfeed and chain-grate stokers. The underfeed stoker differs from the chain-grate in that on the under-feed stoker the coal is continuously agitated so that fissures occur in the fuel bed through which free oxygen may pass. With the chain-grate stoker little or no free oxygen finds its way through the main body of the fuel bed. The composition of the gases leaving a forced draft chain-grate stoker burning small anthracite has been determined by Mumford and he showed that above the rear end of the grate where the fire is thin the gas consists mostly of air, while towards the front of the grate a large proportion of carbon monoxide is present. Thus with a chain-grate some means must be provided to permit the free oxygen leaving the rear part of the stoker, to be employed usefully in burning the carbon monoxide rising from the front part of the stoker. This mixture of the oxygen and gases may be effected by a rear arch which causes the free oxygen to be brought forward and mixed with the combustible gases.

When burning a free burning bituminous coal on a chain-grate stoker the combustible gases have been burned by air injected through the front arch and the passage of free oxygen through the rear of the stoker has been reduced by installing a rear water box, whereby a thicker bed of fuel is maintained at the back of the grate.

With the modern multiple retort underfeed stoker, no arches are installed, though with these stokers, it is not unusual at high ratings to find gases burning above the tubes of the boiler in the first pass. Were it practical to construct and maintain arches over an underfeed stoker the gases could be burned probably at all times within the furnace; but were this done the radiation from the fuel bed to the tubes of the boiler would be reduced and probably at ordinary ratings the efficiency would not be improved by an arch.

If some form of constriction through which these gases pass from these stokers is to be used, the constriction and furnace should be composed entirely of water-cooled surface which absorbs radiation. On passing through this constriction the combustible gases and air would be mixed well and burn rapidly after passing through the constriction. This constriction would give also tolerable assurance that any free air admitted over the fuel bed would be used and undoubtedly enable operators to regulate better the composition of the gases. It would also reduce somewhat the temperature of the flue gas. But these heroic measures would not be justified when operating boilers at ordinary ratings, and would be justified only at high ratings if it then eliminated the delayed combustion of the gases. Thus in modern furnaces delayed combustion is tolerated though it is one of the factors reducing the rating at which a boiler may be operated with fair efficiency; and since delayed combustion reduces efficiency mainly by increasing the temperature of the flue gas, this tendency may be offset by installing more heating surface in the boiler proper, or in an economizer or air heater.

The foregoing shows that one of the principal obstacles to be overcome before a high efficiency is maintained in a stoker or hand fired boiler, is that involved in supplying the combustible gases rising from a fuel bed, with the least amount of air to burn them, and while this is done with stokers so that very high efficiencies are attained, the composition of the gases varies with the clinker formation, thickness of fuel bed and other factors somewhat difficult and laborious to control.

These difficulties have been instrumental in increasing the use of powdered fuel for firing boilers which may be fired with the requisite air by automatic control. It is true that stokers too, may be put under automatic control, but not to the same extent that powdered coal may be.

Efficiencies have been obtained with stokers which are as high as those obtained with powdered coal but in general the loss of combustible with stokers is greater and the flue gas loss is greater.

It is not intended here, to discuss at length the relative merits of powdered coal and stokers, since anyone contemplating installing a boiler plant must consider both in reference to his particular plant. The prospective purchaser must decide whether the additional cost of

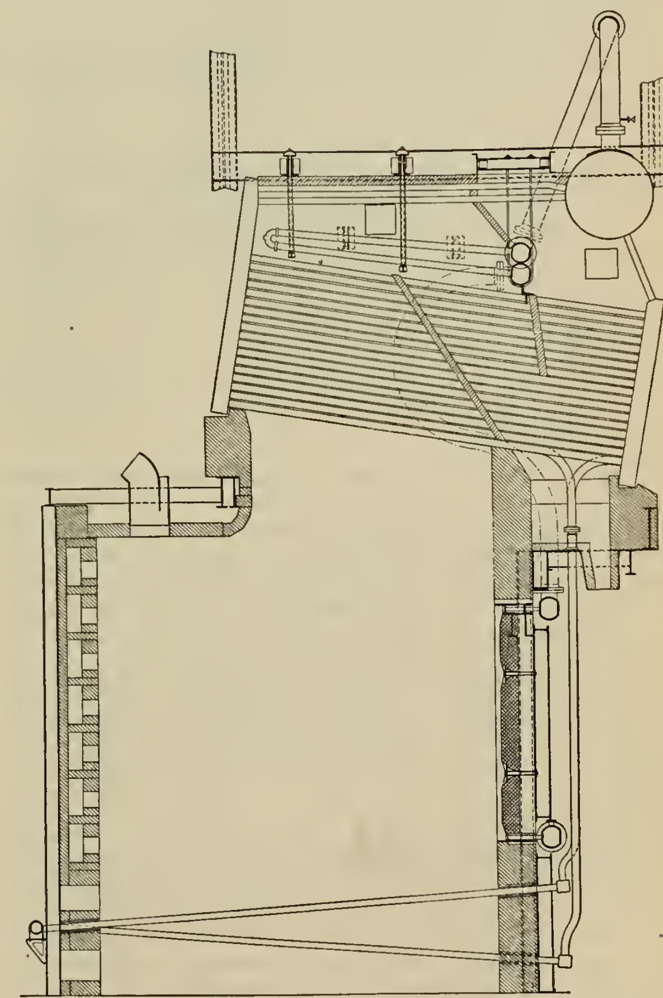

Figure No. 2.—Boiler in the Power Plant of the St. Paul Gas Light Company Limited, St. Paul,—Powdered Coal Firing.

installing and operating the equipment for burning powdered coal will be offset by the higher efficiency and convenience when using powdered coal.

In modern power plants in which a coking coal is burnt, the stoker generally used is a long underfeed stoker with clinker grinder, and the full length of the boiler tubes are exposed to the furnace. When the coal is free burning a forced draft chain-grate stoker is commonly used. This stoker has a set of separate air compartments across the stoker to control the relative rates of combustion of the fuel as it passes through the furnace. It is used also for the small sizes of anthracite. All ordinary commercial coal can be used in powdered form.

Transfer of Heat

The heat generated by combustion is transferred to the water and steam by radiation, convection and conduction. In the furnace the principal method of transfer is by radiation, and the rate of transfer may be as high as 70,000 B.t.u. per square foot of heating surface per hour or over two boiler horsepower. The magnitude of this may be appreciated better when it is realized that when a boiler operates at 200 per cent. of its rated capacity the mean rate of transfer amounts only to about 7,000 B.t.u. per square foot per hour or about one-tenth of the rate by radiation in the furnace. The radiation comes from the fuel bed and from the flame. It increases with the rate of combustion of the fuel and decreases when the ratio of air supplied to combustible burned increases.

There is no evidence to show that the walls of furnaces should not be composed of heating surface and thus increase the absorption of heat by radiation. The tests on the internally fired Scotch boiler referred to earlier give no evidence that the cool walls impede combustion and it is not uncommon today, to find furnaces, the walls of which are composed mostly of heating surface. Figure No. 1, shows such a furnace, the walls at the side are composed of tubes on to which cast-iron blocks are shrunk, and through the tubes water circulates, in fact the tubes form a part of the boiler. On the rear wall is a superheater, which is not shown in figure No. 1, but a similar superheater is shown in figure No. 2. It consists of a series of vertical wrought steel elements of rectangular section, which are connected by nipples to the inlet and outlet steam headers.

The advantages of installing heating surface instead of brickwork in the furnace of a boiler are many. The upkeep of the brickwork which the wall replaces, is eliminated, the upkeep of what brickwork remains is reduced since the temperature of the furnace is reduced, and heat transferred by radiation involves no loss of momentum to the gases, and consequently no equivalent loss of draft.

The radiation from the flame and fuel bed is absorbed by the heating surface on which it impinges; it is then transferred through the metallic walls of the boiler tubes, superheater or water walls by conduction and finally it is transferred to the water or steam by conduction and convection.

Since the conductivity of iron or steel is of the order of 300 B.t.u., inches, per square foot, hour, degree Fahr. the drop in temperature across a slab of steel one inch in thickness will be 200°F when transmitting 60,000 B.t.u., per square foot per hour. Even this temperature head of 200° can have little effect on the transfer, and this may be seen by the following simple computation. Let us suppose that if there were no drop in temperature through a heat absorbing wall, the wall would be at a temperature of 600°F. and that actually the wall is so thick that the outer temperature is 800°F. Then if we suppose that the outer wall radiates as a black body, the radiation per square foot per hour from the wall at 600° will be 2,150 B.t.u. and from the wall at 800°, it will be just twice as much, that is 4,300 B.t.u. Thus a difference of 200° in the temperature of the wall reduces the net heat absorbed by 2,150 B.t.u. per hour or by less than 4 per cent. of the total absorption. The temperature head required to transfer the heat from the inner wall to the water in the boiler tubes or water walls is very small, and this head can be kept low in a superheater by maintaining a high rate of flow of steam.

After the gases have left the furnace they are cooled to some extent by radiation to the boiler heating surface, but in the main, they are cooled by transferring heat from the hot gases by convection and conduction to the walls of the tubes of the boiler.

Both latter modes of transfer are caused by a movement of the gas itself in a direction normal to the heating surface and thus normal to the general path of the gases. When the transfer is by convection, small masses of gas in the form of eddies move to and fro across the main stream and when the transfer is by conduction the transfer takes place by the individual motion of the molecules themselves. At the walls of the heating surface the gas is stationary; and near the wall, the rate of flow is lower than in the main stream and is laminar. Near the wall where the flow is laminar, the heat is transferred across the layer in laminar flow solely by conduction and the rate of flow depends upon the thickness of the layer, the difference in temperature at the boundaries of the layer and on the conductivity of the gas. In the main stream where the velocity is higher and the flow turbulent the heat is transferred to the stream in laminar flow by convection. Thus the transfer of heat from a stream of gas to the metallic boundary separating the gas from the water in a boiler, depends upon many factors. They are, the temperature, size, shape and roughness of the channel in which the gas flows and the viscosity, conductivity, temperature, density, and velocity of the gas. Usually it is found sufficiently accurate to assume that the rate of transfer of heat is directly proportional to the difference between the mean temperature of the gas and of the mean temperature of the wall and of the channel; and to assume that the rate of transfer of heat per unit area of the wall is a function only of the mass flow of the gas.

The usual form of equation used is:—$R = a + bF$ where R is the B.t.u. transferred from the gas per square foot of area of the boundary, per hour, per degree difference in temperature between the gas and boundary; F is the mass flow in 1,000 pounds per square foot of free area per hour and a and b are constants. The value of a is about 2 and b varies from 0.75, which may be used for fluids flowing through a tube, to 1.4 for fluids flowing at right angles to tubes as in a boiler.

An example of an equation which takes account of more variables, is that of Weber which is for gases flowing through a pipe of diameter d inches: $R = 0.68\ (F^{.8})\ (T^{.5})\ (c)\ (M^{-.3})\ (d^{-.2})$. Where T is the mean absolute temperature of the gas in degrees Fahr., c its specific heat and M its molecular weight. This becomes for $T = 460 + 500$; $c = .24$; $M = 29$; and $d = 3$, $R = 1.8F$.

All experiments on the transfer of heat show that the rate of transfer per unit area increases as the rate of flow of the gas increases and that other conditions being the same, a small tube, whether the gas flows inside or outside, absorbs more heat per unit area than a large tube though this effect becomes less marked as the product of the mass flow and diameter of the cylinder increase. Thus by increasing the rate of flow we may use less surface to obtain the same efficiency as with a larger surface and lower rate of flow. In a boiler this may be done by increasing the number of baffles. But the resistance to flow increases approximately as the square of the rate of flow, so that we have to decide whether it is more economical to install a large amount of heating surface or to expend more energy on moving the gases at a higher velocity across the smaller surface.

Economizers and Air Heaters

It is obviously impossible to reduce the temperature of the gases passing through a boiler below that of the temperature of the water in the boiler, which in modern power plants is not less than 400° F. But if the boiler is to be operated at a high efficiency the gases should be reduced to temperatures below 400°F and in many plants the gases are discharged to the stack at temperatures below 300°, so that the sensible heat lost by the flue gas does not exceed 5 or 6 per cent. These low temperatures can be attained by letting the gases preheat either the air for combustion or the feed water. Usually these heaters are designed so that the gas and air, or gas and water flow in opposite directions. This principle enables economizers to heat the feed water to a temperature higher than that at which the gases leave the economizer.

In deciding upon the extent to which economizer or air heater surface should be installed, one should carefully consider a boiler, economizer and air heater as a unit for cooling the gases. Obviously the air heater or economizer has the advantage of the greater temperature head between the flue gas and fluid to be heated, which means that if the same rate of heat transfer per unit area of heating surface per degree temperature difference between the flue gas and fluid to be heated can be maintained in the boiler, economizer and air heater, then one square foot of heating surface in an air heater for heating the air to a moderate degree will cool the gases more than one square foot in an economizer. In the same way one square foot of economizer heating surface is of more value than that of a boiler. But while rates of heat transfer per degree temperature difference in an economizer, may, by suitable design, be made greater than that in a boiler; the rate of transfer in an air heater is usually low.

This relatively low rate of transfer in an air heater is caused by the resistance to the transfer of heat from the wall of tube or plate to the air, being much greater than that to the water in a boiler or economizer where the resistance to flow of heat from the wall to the water is negligible.

Further, while the temperature head at the cool end of a counter flow air heater may be two or three times that at the cool end of an economizer, yet air is heated through many more degrees of temperature than water so that at the hot end the difference between the temperature of the gas and water in the economizer may be twice that of the gas and air in an air heater.

When an economizer can be installed it is preferable to an air heater, but the tendency to go in for heating feed water to a high temperature, by bleeding steam from several stages of the turbines, makes the adoption of air heaters in these plants as auxiliaries to economizers, essential if high efficiency is to be maintained.

Differentiation of the Action of Acids, Alkali Waters and Frost on Normal Portland Cement Concrete

C. J. Mackenzie, M.E.I.C.,
Dean of Engineering, University of Saskatchewan, Saskatoon, Sask.
and
Dr. T. T. Thorvaldson,
Professor of Chemistry University of Saskatchewan, Saskatoon, Sask.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

For the past three years an intensive research into the effect of alkali ground waters on concrete has been carried on under the auspices of a Committee of *The Engineering Institute of Canada* with the financial support of the National Research Council, The Canada Cement Company, The Canadian Pacific Railway, and the three Prairie Provinces.

As has been stated many times, this Committee decided to undertake a research of a fundamental nature and not one guided by empirical methods. Up to the present time a great deal of work of value has been done and a brief review of the first published paper will be found in the November, 1925, issue of *The Engineering Journal* of Canada. From this review it is hoped engineers may obtain a general idea of how the work is being conducted and how it is progressing, and that they will again note how research of a fundamental nature not only throws light on the problem of immediate concern but always explains and illuminates problems that were not even thought of when the work was started. It will be seen that the above mentioned research, which was started primarily to examine the action of alkali ground waters on Portland cements, has already led to conclusions about the setting of cements, the effect of leaching waters, the effect of different kinds of alkali solutions, and it is hoped that by the methods developed in connection with this research and the data obtained, it will be possible in the near future to explain many matters in connection with the character of Portland, high alumina and other cements that will have far reaching scientific and practical effects. Such experiences indicate the wisdom of attacking in a scientific manner even problems that are essentially practical in nature. Fundamental scientific research provides the capital for applied science and if we merely live on the interest and do not add capital, we as a country cannot progress.

As a review of the purely scientific aspects of the research has appeared recently in *The Journal* of *The Institute*, it is proposed to submit to this meeting a brief account of some practical applications, and show how findings, made incidentally in connection with the research on alkali disintegration, have not only allowed us to make valuable field diagnoses, but have thrown considerable light on the action of acid solutions on cement.

It is common knowledge that concrete is attacked both by sulphate, (alkali), waters and acid waters; it is also known that poorly made and porous concretes may be disintegrated by the mechanical forces of expansion due to alternate freezing and thawing. In some cases of disintegration the cause can be well established by an inspection of the local conditions, but in others it remains a matter of conjecture whether the destruction has been due to acid action, alkali action, frost action or a combination of these.

This article has for its purpose: — (1) The presentation of a chemical procedure evolved by one of the authors for determining from a chemical analysis of disintegrated concrete whether the cause has been acid action, alkali action or frost action; (2) the description of an interesting case in a western city upon which one of the authors was asked to report, where cases of acid action, alkali action and frost action were all found in one sewerage system and of how the procedure mentioned above was applied and of how some chemical studies threw light on various phases of acid disintegration.

Chemical Procedure for Determining the Cause of Disintegration

The procedure for differentiating between alkali (sulphate) acid and frost disintegration of concrete by chemical analysis described below was evolved from, and has been used for some time in connection with, a larger research, and as much confusion has existed in the past due to the fact that in many cases of disintegration there has been serious disagreement as to the cause, a description of the chemical studies made in evolving the chemical procedure referred to above will be given, in order that those interested may realize the reliability of the method.

Chemical analyses were made of various samples of concrete which had been disintegrated by known agencies and a few typical examples are given below.

Samples

A. *Sulphate Action.*
- No. 1. Softened concrete removed from the outside of an aqueduct in contact with sulphate water, below level of frost action.
- No. 2. Softened concrete removed from blocks in contact with soil which contained a soil solution very high in sulphates; no evidence of frost action.

B. *Frost Action.*
- No. 3. Disintegrated concrete from a parapet of a bridge in Saskatoon, Sask., exposed only to weather action.
- No. 4. Disintegrated concrete from large concrete pipe in Saskatoon, Sask., exposed only to weather action.

C. *Acid Action.*
- No. 5. Portland cement mortar disintegrated by a very dilute solution of hydrochloric acid.
- No. 6. Neat Portland cement disintegrated by a dilute solution of sulphuric acid (¼ per cent).

Treatment of Samples

The cement material was loosened as far as possible from the aggregate, the former was pulverized, leaving any grains of sand intact, and the portion which passed a 40-mesh sieve used for analysis. This sample was ground fine, dried at 360° C. and determinations were made on the dried sample for loss on ignition, silica, iron oxide, alumina, lime and sulphate.

It is evident from table No. 1 that chemical analysis distinguishes clearly between concretes disintegrated in the three ways. Thus the sulphate (SO_3) content distinguishes clearly between sulphate action and frost

TABLE No. 1,—Results of Analysis
(Expressed in per cent of sample dried at 360° C.)

Group No.	Loss on ignition	Silica SiO_2	Iron oxide and alumina (Fe_2O_3 and Al_2O_3)	Lime CaO	Sulphate SO_3	Chloride Cl
A–1	11.25	29.25	11.15	25.10	9.65	
A–2	13.50			31.80	11.90	
B–3	9.90			27.05	0.59	
B–4	12.15	40.10	12.45	22.40	0.86	
C–5	2.55	81.25	9.90	2.35	——	4.28
C–6	0.84	22.25	10.55	28.35	39.40	——

action. A number of analyses of weathered concrete all gave a SO_3 content below 0.86 per cent while as a rule the value was much lower. Three samples of concrete from aqueducts carrying fresh water gave values between 0.2 and 0.4 per cent. In any case it is safe to say that the SO_3 content would never rise above that of the original cement unless it is subject to sulphate action.

The residue from cement disintegrated by acids evidently varies with the acid used, and thus the interpretation of the analytical results is not such a simple matter. The evidence however enables one to come to definite conclusions as follows:

(a) Loss on ignition after drying at 360° C. is very small. The reason is that the acids attack first the hydrated and carbonated materials of the cement, so that very little firmly held water or carbon dioxide remains.

(b) Presence of the acid radicle in the disintegrated cement indicates the specific acid causing the disintegration. This is the case even when the calcium salt of the acid is soluble as in No. C–5 above.

(c) When the calcium salt of the acid is soluble the lime is removed almost completely, while the residue is largely silica.

It may appear that there is a difficulty in distinguishing between sulphate action, ("alkali" water) and action of sulphuric acid, on account of the large amount of SO_3 present in both instances. Such is not the case. In the residue from disintegration with sulphuric acid the ratio of lime to SO_3 is but slightly greater than that for calcium sulphate, namely, 7 of lime to 10 of SO_3, while in cement residues from neutral sulphate action the proportion of lime is much higher. When the residue from H_2SO_4 disintegration is leached with water, lime and SO_3 are removed in chemically equivalent proportions and a residue low in calcium and high in silica is obtained similar to No. C–5. Thus, ultimately, if the acid is very dilute and the disintegrated cement is thoroughly washed by a stream of water the product has a low loss on ignition, is high in silica and low in lime.

Acid disintegration is a purely surface phenomenon, the material beneath being perfectly sound; it thus presents a characteristic physical appearance and can usually be identified, but it should be remembered that in the case of disintegration of a very rich and dense concrete by alkaline sulphate water the action also proceeds superficially and may thus resemble in physical appearance typical acid disintegration.

It is rare in practice to find combined acid and frost disintegration or any uncertainty as to which of these factors has been the cause of failure of concrete, but it is very common in the western plains to meet cases of combined sulphate and frost action, and many cases have occurred where the evidences of frost action have led authorities in the past to doubt the existence of alkali action, and even to make the absurd claim that all so-called alkali disintegration of concrete was really the result of weather action on inferior concrete.

Most concrete failures near the surface of the ground, have the appearance of frost action. This is due to the fact that the final disruption of the concrete usually is due to frost, while the real cause may be the weakening due to sulphate action, in the absence of which frost would have been permanently withstood. In such cases the information given by chemical analysis of the disintegrated concrete is most valuable and may be considered conclusive. Two cases will be cited as typical of what has been found many times.

SAMPLE D–1: *Disintegrated concrete from experimental blocks in surface soil.* The ground water contained about one per cent of sulphate calculated as SO_3. Disintegration was evidently due to sulphate action but there was also evidence of breaking down by frost.

SAMPLE D–2: *Disintegrated concrete from a partially disintegrated irrigation structure.* The soil in contact was heavily charged with sulphates, but the appearance of the structure suggested frost action.

Analyses showed that the calcium content was normal in each case, but the SO_3 content was 5.3 per cent in D–1 and 3.2 per cent in D–2. It will be noticed that while the concretes D–1 and D–2 represented failures as advanced as concretes A–1 and A–2, the SO_3 content of the former, while well over the normal, was well under the latter. The concrete of D–2 was made under careful supervision according to specifications and was of excellent quality as shown by other unaffected portions of the structure not exposed to sulphate water but exposed to extreme wind and weather conditions. It seems safe to conclude then that the real reason for disintegration was weakening due to the action of sulphates, with a secondary acceleration of failure due to frost.

One may also further conclude that whenever the sulphate content of concrete rises materially above the quantity which can be accounted for by the original sulphate content of the cement there is evidence of harmful sulphate action and disintegration is likely to be accelerated through frost action: a critical value for SO_3 content of one per cent is suggested tentatively, as in a large number of analyses of normal concretes according to the above procedure no SO_3 content over 0.86 per cent has yet been found.

INVESTIGATION OF A PARTICULAR CASE IN SASKATCHEWAN

The practical problem which suggested this article, and to which the results of the above study were applied, was an investigation of certain cases of concrete disintegration that had occurred in a city in Saskatchewan. The most serious case was the erosion in a large reinforced concrete storm sewer which received the effluent from an industrial plant and also for a few weeks per year a limited amount of storm water. The normal flow in this sewer was a relatively small quantity and averaged 6 inches to 12 inches in the bottom of a 6-foot sewer; the disintegration occurred only over the surface wetted by the normal flow. It was known that the effluent from the industrial plant was acid at times, but in view of the fact that concrete disintegration had also occurred at several places in the sewage disposal plant, which did not receive the effluent from the storm sewer, it was felt that a thorough

Figure No. 1.—Storm Sewer Invert Showing Reinforcing Rods Bared by Concrete Disintegration and Erosion.

study should be made to prove the cause of decay, especially as the financial responsibility for repairs rested with the company if necessitated by the effluent from its plant.

TABLE No. 2,—ANALYSES OF CITY WATER SUPPLY

	Parts per million			
	Analysis of Mixed Supply		Supply from Pump Well	
	I	II	III	IV
Date of analysis	21–9–20	28–10–24	21–9–20	28–10–24
Alkalinity ($CaCO_3$)	404.3	391.8	478.2	464.9
Calcium (CaO)	233.1	201.2	263.2	237.9
Magnesium (MgO)	112.1	38.6	130.6	52.7
Sulphates (SO_3)	239.0	257.6	394.1	302.4
Chlorides (Cl)	16.0	6.0	16.0	8.0
Total solids by evaporation	1049.	900.	1185.	1065.

NOTE:—The water supply is a mixture of well and spring water. The relative proportions vary somewhat throughout the year. The analysis of the supply from the pump well gives the upper limit of concentration.

The raw water supply from the city contains a high percentage of sulphate as shown by table No. 2, and as the water from the industrial plant was of a similar quality it was suggested that possibly this was a factor, but a careful examination of the concrete sanitary sewers in the city showed that no action whatever had occurred in them and as no other liquid in appreciable quantities was discharged into the storm sewer it appeared that any action taking place in the storm sewer was caused by the effluent from the industrial plant referred to It was learned that from 1916, when the sewer was first put into use, until 1923 a very considerable amount of damage was done, the concrete having been eroded quite generally along the area of flow to a depth as great as 2 inches, baring the reinforcement at places, as shown in figure No. 1. The action was typical of acid action, i.e.

4-(B)	Sept. 18	B	5.00 p.m.	nil

the gradual dissolving away of the cementing material with exposure of sand and gravel particles, but with no softening of the remaining concrete. In 1923, before the report referred to above was made, extensive repairs had been made and figure No. 2 shows how these were distributed. It will be noted that over fifty per cent of the repairs were made in the first third of the length and that the third nearest the outlet contained only about eight per cent of the repairs. The general distribution of these repairs was taken as an indication of the rate of disintegration along the pipe from outlet to inlet. After the time of flow in the sewer from inlet to outlet had been calculated and checked by floats, a series of tests were made of the acidity of the liquid as it passed "A", (inlet), and of the same liquid as it passed "B", (outlet), three hours later.

Table No. 3 shows four sets of analyses which are typical of many made, and on figure No. 2 these results are plotted and the points joined by dotted lines to indicate how the acidity of the sewage decreases from inlet to outlet. Whether this decrease follows a straight line or curve is not material to our conclusions. The point it is desired to make is that dotted lines (1) (2) (3) (4), of figure No. 2 which indicate in a general manner the acid conditions existing along the sewer line for variations in the concentration of the influent, explain why decay is more rapid at the inlet end than at the outlet, i.e. the acid is used up in combining with the cement and in some cases until it is all neutralized. It cannot be determined how uniform decay would have been throughout the length of the pipe had the incoming sewage at all times been of a sufficient acid concentration to prevent neutralization before it reached the outlet. It can be deduced, however, that in cases such as the one under review, where an industrial plant is discharging an effluent that varies from a neutral to a highly acid solution, any attempt to prevent trouble by reducing slightly the concentration of the acid content will likely have little effect on the portion of the sewer near the inlet, although action near the outlet may be materially retarded. Another interesting point to note is that permanent repairs by tile liners laid over the first portion only, where disintegration is most marked, would merely shift the area of intense action towards the outlet end of the line.

When a concrete surface is exposed to an acid solution the layer of acid in immediate contact with the concrete reacts with the calcium aluminates and calcium silicates forming the calcium and aluminum salts of the acid; this action is very rapid and for the layer in immediate contact may be considered instantaneous. Thus a neutral layer composed of a dilute solution of the calcium salt of the acid is formed at the boundary between the solution and the concrete and for further action to take place the acid molecules must normally diffuse through this layer. This protective layer is further increased by the inert material of the concrete remaining after solution of the cement particles. If the liquid is moving rapidly over the surface of the concrete, this adhesive layer will be torn away and fresh acid will be brought continually in contact with fresh concrete and the erosion will be greatly speeded up. It will readily be seen then that acid disintegration is a function of both the strength of the acid solution and the eroding effect of the moving liquid on the surface of the concrete. It was found that, in the sewer mentioned above, erosion was most marked where the velocity of the liquid was greatest, and that the underlying concrete was hard and sound. The secondary effect of erosion by rapidly flowing water was strikingly illustrated at several points where a small trickle of water entered the large sewer; these small streams entered the large pipe about half way up and dropped rapidly to the normal flow line below, it was noticed that above the flow line there was no action but that a furrow deeper than the surrounding erosion was caused where this falling water passed over the surface acted upon by the acid of the sewage.

At several points along the sewer depressions had occurred in the pipe line with the result that pools of slow-moving liquid of varying depth were formed; it was found that at these places no apparent action had occurred over the bottom of the pipe, but a slight action was noted over a small area at the water line. There were deposits in the bottom of the pipe at these depressions, which subsequent chemical analysis proved to be the products of acid-disintegrated concrete. It was at first suggested that the absence of any signs of action on the bottom of the pipe could be accounted for by the absence of the eroding effect of flowing water. It was felt, however, that on this assumption a slight softening or action would have been noticed. A chemical study was made in the laboratory, the results of which explain conclusively the phenomenal action of dilute acid solutions in such comparatively quiet pools. A few typical results of this study are presented below.

Two hemispherical earthenware jars, each 15 inches in diameter and 4½ inches in depth, were filled with a

Figure No. 2.—Distribution of 1923 Repairs Between "A" & "B" and Change in Acidity of Sewage as it Flows from A to B.

solution of sulphuric acid of about 500 p.p.m. Eight cement briquettes were arranged along the sides of the jar as shown in figure No. 3. In 3–A the briquettes were placed at the top of the jar near the surface, while in 3–B they were placed at the bottom of the jar. Samples of the liquid were removed at intervals from points (a) at the top and (b) at the bottom of the jars and the concentration of the acid determined. Table No. 4 gives the results.

The above results are very interesting, and it will be noted that when the briquettes were at the top, the concentration at the bottom decreased much more rapidly than at the top, although by the laws of diffusion the reverse should be the case. It will also be noted that when the briquettes were at the bottom the concentration also decreases much more rapidly at the bottom than at the top, but that it took 10 days to arrive at the same condition in the vessel as was arrived at in one day when the briquettes are at the top. It will be seen then that if the entire vessel were lined with cement, approximating the condition of a depression in a sewer pipe, and if the dilute acid solution were moving slowly, the concentration at the top would be many times that at the bottom and consequently practically all the acid action would occur along a narrow line at the surface of the liquid. This is what was found in the actual case above mentioned.

The theoretical explanation of this phenomenon is as follows: When dilute acid solutions act on the concrete at the sides of a sewer a solution of the calcium salt is formed, which is heavier than the original acid solution; this neutral solution therefore tends to sink along the walls to the bottom and fresh acid solution takes its place in contact with the concrete at the water line, while the neutral solution protects the lower portion of the sewer against action of the acid. In addition the inert solid products of the decomposition at the water line tend to sink and cover the floor of the pipe with a thick sluggish layer of protective neutral liquid.

While in the above case of the large storm sewer a physical examination alone provided conclusive evidence that the deterioration was caused by acid action, the fact that a chemical analysis of the products of disintegration, which settled out in the depressions, proved beyond doubt that such was the case, would be very valuable evidence in case of a dispute.

Three other cases of concrete disintegration, however, were found in the sewage disposal plant of the same city, where it was impossible to state definitely from a physical inspection alone, what caused the decay. In these cases an application of the principles outlined in part one of this article allowed definite conclusions to be drawn, and further, led to some interesting conclusions as to the lower limit of sulphate concentration in an effluent or water which may cause sulphate disintegration of good quality concrete under certain conditions.

The sewage disposal plant consists of preliminary sedimentation tanks, percolating filters and final settling basin; the plant treats the domestic sewage only; the effluent from the storm sewer, that was affected, does not pass through the disposal plant.

The filters are of the circular type. Open underdrains radiate from the centre and discharge into a gutter which encircles the filter; the drains are made of the same grade of concrete as the floor on which they rest. The underdrains were badly disintegrated at the outer end where they emerged from the filter bed, the concrete was soft and badly crumbled, and the exact cause could not be determined from an inspection alone. Experiences elsewhere suggested that the disintegration might be acid action due to the formation of H_2S from sewage of high sulphate content, with the subsequent formation of sulphurous or sulphuric acid; the disintegration also resembled alkali action. The curb on the outside of the gutter surrounding the filter was also badly shattered, and the appearance suggested frost action.

Samples of the disintegrated concrete from the drains (E1) and the curb (E2) were analyzed and by applying the principles set forth in the first part of this article, to the analytical results as shown in table No. 5 definite and reliable conclusions were drawn.

TABLE No. 5,—Analysis of Samples E1 and E2

Sample	Loss on Ignition	Lime (CaO)	Sulphate (SO_3)
E1	18.10	26.0	5.9
E2	14.45	25.0	1.9

In both samples E1 and E2 the high SO_3 content indicates sulphate action. The content in E1 is probably high enough to account for complete disintegration under conditions where a part of the calcium sulphate formed is removed by the water. Sulphate action was probably contributory to the failure of E2, the final cause being frost action.

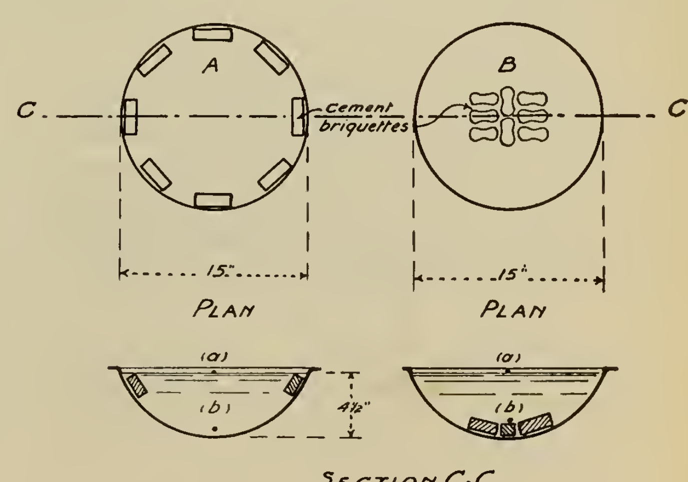

Figure No. 3.—Plan and Section of Jars A-B.

But the sulphate content of the city water as shown in table No. 2, while considerable, does not reach the limit usually considered dangerous to concrete structures. Several analyses of this water gave total dissolved solids of about one-tenth of one per cent, and sulphate content expressed as parts per million SO_3 as varying between 300 and 400 parts per million. Expressed as sodium sulphate the maximum is about 700 parts per million or well below a concentration of one-tenth of one per cent. Analysis of the sewage effluent after passing through the filter under consideration gave total solids of a little over 1000 parts per million and a sulphate content of about 300 parts (SO_3) per million. Thus while it may be mentioned that sample E2 was in contact with the soil and might have gained sulphate from the soil solution, the only source from which sample E1 could obtain sulphates was the effluent with its total sulphate content, calculated as sodium sulphate, of from 500 to 700 parts per million.

As mentioned before these drains, (E1), rested on a concrete base made of the same material, which showed no evidence of disintegration. The effluent flows through the openings in the drain so that the liquid covers the base completely but wets only the lowest fraction of an inch of the drain. The greater portion of the drain is thus exposed directly to the atmosphere while the base is continually wetted by the flowing liquid. It is evident that capillary forces cause a layer of the effluent to cover the exposed surface of the drain and that evaporation will take place from the whole surface of the drain not covered by the flowing liquid. The liquid film covering the exposed portion of the drain or permeating the same thus increases its concentration and may finally become a highly concentrated solution of sodium sulphate while the liquid in contact with the base of the drain and in contact with the concrete base on which the drain rests can never reach a concentration higher than that of the effluent. It would follow from such an explanation of the failure observed in the filter beds referred to above that only the tile at the outer surface of the bed, i.e. those which are in contact with freely circulating air, and therefore air which is not usually saturated with water vapor, should show signs of disintegration and the tile underneath the bed where the air is constantly saturated and no evaporation takes place should be intact.

Since writing the above and in accordance with our request the city engineer has had an examination of the tile made and reports: "We found that the interior blocks appear quite sound and in many cases the second block from the outside was found quite firm although the outside block adjoining it was in a crumbled condition." This is an interesting practical confirmation of the view outlined above. Thus it is evident that while a solution containing 500 parts of sodium sulphate per million, (a concentration commonly found in drinking waters in the West), may be harmless to good concrete immersed in it, (such as the concrete base in this case), the same concrete partly immersed, (here the drain), may disintegrate just above the water line, and that the lower limit of sulphate concentration which may thus cause disintegration depends on how favorable the conditions are for evaporation from the concrete just above the water level.

It may be mentioned that concrete foundations in sulphate soils usually show the greatest disintegration just around the upper limit of soil moisture, i.e. at the point where the soil moisture continually evaporates. Also that concrete walls and floors of basements which are in contact with sulphate ground water on the outside, sometimes show sulphate disintegration on the inside of the basement walls, while action is not so evident on the outside. Here the walls and floor are permeable to the dilute sulphate solution, and, while the original concentration of sulphate is not great enough to cause serious harm evaporation takes place on the inside of the walls, and the sulphate accumulates until the concentration is high enough to cause disintegration. In such a case the action can be stopped by painting the floor and walls inside with some material impermeable to water vapor so as to stop evaporation.

The third case of disintegration at the disposal plant was noted in the concrete columns which supported the roof over the sedimentation tanks. These columns rested on the side and partition walls of the tanks and their bases were within a foot or so of the water level in the tank. Several of these columns were badly eroded near the base to a depth of several inches. In appearance the damaged columns looked very much like those found disintegrated by alkali ground water in many buildings in the West, but a chemical analysis showed that the disintegrated cement was of the constitution of normal cement, which indicated that there had been no alkali or acid action to any extent. On inspection it was noticed that all of the columns eroded were situated either in front of doors or around the outside walls which were not sealed against the wind. It will be seen that this case was one of extreme frost action. Under normal winter conditions the atmosphere immediately above the tanks is moist and comparatively warm, the base of the columns becomes saturated and then, when there occurs a wind with a temperature anywhere down to 40° below zero, it is easy to see what happens to the nearest column when a door is opened, and to the columns on the windward wall through which air will filter freely.

To summarize: There has been presented in the above paper a description of an actual case where concrete disintegration caused by the three different agencies of alkali water, acid water and frost occurred in one sewerage system, in which conditions were such that failure could have been attributed to any two of three causes. There has been presented the chemical methods developed and adopted to determine definitely the cause of disintegration in each case, and this method of differentiating, by chemical analysis of disintegrated concrete, between alkali action, acid action and mechanical decomposition as found in frost action, will be appreciated as an important and practical contribution by those who have been confronted with the difficult problem of placing the responsibility for failure of normal concrete under conditions of uncertain exposure.

Design of East York Sewers and their Construction by Contract and Day Labour

R. O. Wynne-Roberts, M.E.I.C.,
Consulting Engineer, Toronto, Ont.
and
Grant R. Jack, A.M.E.I.C.,
Engineer, Township of York, Toronto, Ont.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

The Township of East York is one of several municipalities which are situated on the borders of the City of Toronto. It occupies a length of about four miles along the north-east boundary of that city. The natural slope of an area of about 1,000 acres in the centre and the west end of the township is south-westwards towards the city, and about 500 acres in the east slope in the opposite direction. For many years efforts were made to obtain outlet facilities into the city sewers, but in 1923 the city authorities definitely decided this was impracticable. The township council thereupon submitted the matter to the ratepayers, who by a large majority declared in favour of proceeding with an independent scheme of combined sewers.

The portion of the township which was urgently in need of sewers lay south of the Don river and this was divided into three sewer areas, known as Todmorden, Greenwood and Danforth Park, each area approximately 500 acres in extent.

The most pressing need was in Todmorden where the houses were subject to flooding by surface water in the spring, and the subsoil in places was wet and treacherous, and the engineers' first efforts were bent to design a scheme for this sewer area and Greenwood.

At first it was thought desirable to find an outlet for Todmorden and Greenwood on the west side, but sufficient land for a disposal site was not available, nor was the estimated cost of the same attractive. In the meantime the trustees of the Davies Estate offered the township a parcel of land on the Don river, 24 acres in extent, on the north side of Todmorden and Greenwood areas, which gift was accepted by the township council. Consequently the final sewer scheme for these areas was designed with an outlet on the north, whereas the slope of the district was southwest. This necessitated designing and constructing about 2½ miles of the trunk sewers in tunnel, ranging from 15 feet to 72 feet in depth from the ground surface to the invert of the sewer.

The Danforth Park sewer area has a superficial slope towards the north, and the first scheme considered for this district was that of concentrating the outfall works on the above mentioned 24 acres of land. It was found more advantageous, however, to locate the Danforth Park works in close proximity to the area, thus obviating the construction of an expensive trunk sewer which would be required to connect the area to the Don River works. Moreover, it will be necessary in the future to provide sewers and plant for additional subdivisions of about 1,000 acres, and these will then discharge at the Danforth Park works, for which about 16.9 acres of land have been acquired, but only a portion of which can be made available, owing to the uneven nature of the land.

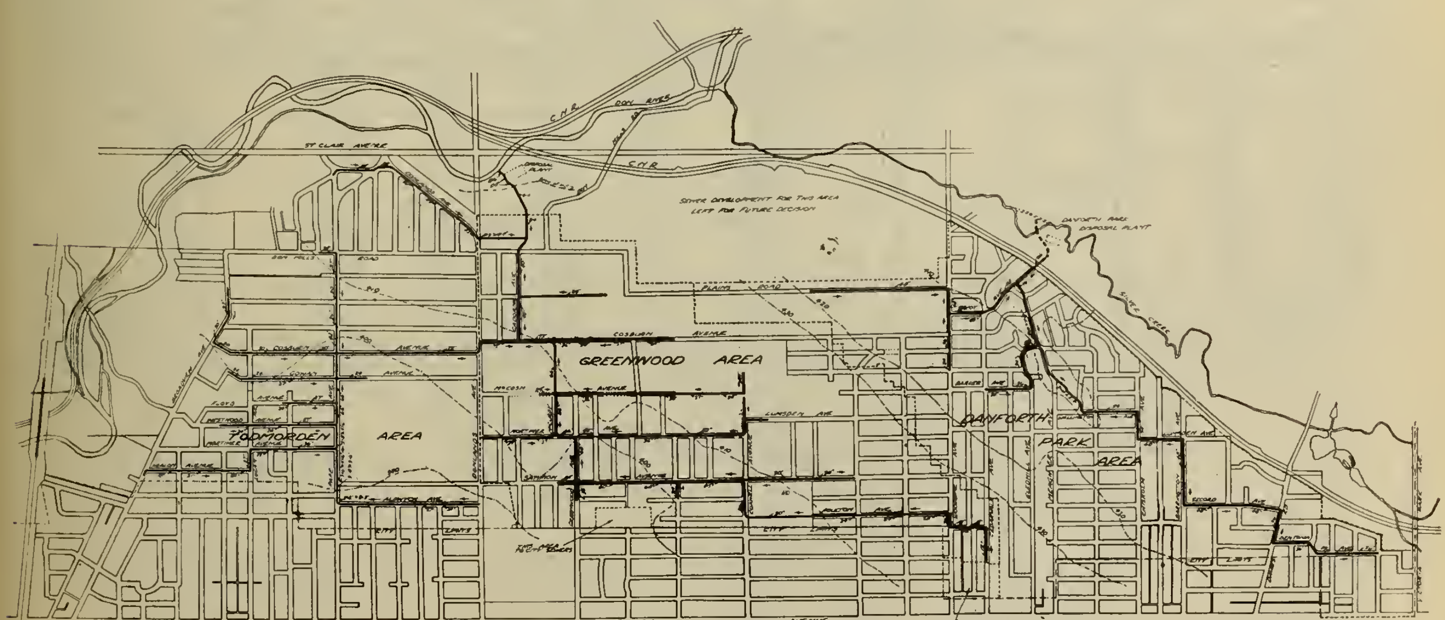

Figure No. 1.—Township of East York—Trunk Sewers, Twenty-seven Inches in Diameter and over, in Todmorden, Greenwood and Danforth Park Areas.

Sewer Design

Having decided on the general policy, it was necessary to formulate a basis of design of sewers. What is known as the "rational method" has been adopted by many authorities, but care has to be taken in its application, otherwise excessive capacities will be provided. Incidentally, it may be argued that the term "rational" is a misnomer. The many modifications suggested by different engineers indicate that it is not truly rational, that is, it is not always reasonable unless great care is taken in the selection of the factors. The term synthetical would be much more appropriate as this method of designing sewers consists in building up the system by making a whole out of parts. It is desirable that engineering terms should be precise and suggestive.

Before describing the synthetic method which was utilized in the design of East York sewers, it is advisable to deal with the matter of run-off. After much study and enquiry, a curve representing the rainfall intensity was adopted, which curve conforms to the equation

$$I = \frac{15.2}{t^{0.586}}$$

where, — "I" is intensity in inches per hour, which also practically equals cubic feet per second per acre, and "t" is the duration of a storm expressed in minutes.

It will take too much time in this instance to discuss the subject of rainfall intensity in Ontario, Quebec and certain eastern states of America. Suffice it to state that whilst there are some considerable differences in various cities, the intensity curve adopted for East York was from 3 to 15 per cent lower than the average for twenty-four cities.

It is evident to all engineers that only a portion of a rainfall reaches the sewers and this proportion depends upon several factors, such as the proportion of impermeable

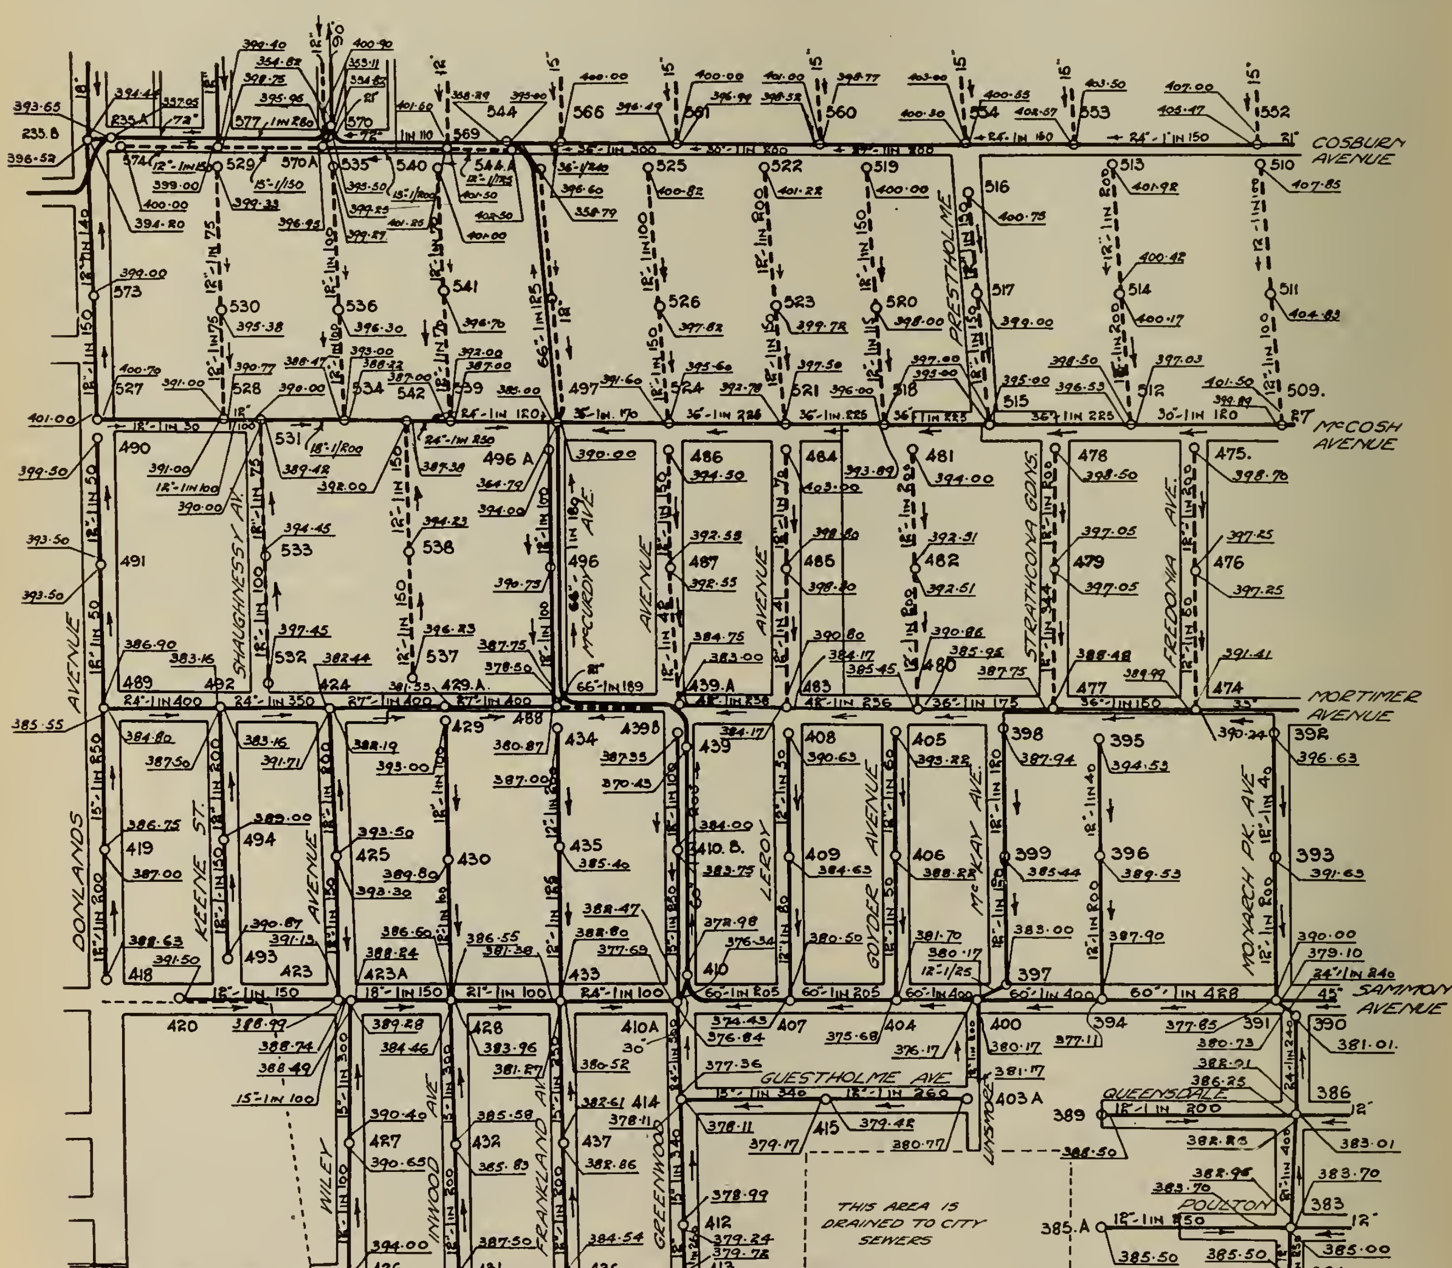

Figure No. 2.—Portion of Key Plan of Greenwood Area.

Figure No. 3.—36-inch Brick Sewer in Open Cut.

area to that permeable, the shape and slope of an area, the time to be allowed for the storm water to enter the sewers, and other details.

Although the average rainfall intensity differed but slightly, the factors used in the above mentioned cities to calculate the run-off were much more varied, and before adopting any proportion for run-off in East York, numerous computations were made and graphs were plotted. Raymond's zone principle, as described in his paper, Fruhling's graphical method, Coleman's summation curves as described in his book on "Hydraulics Applied to Sewer Design", and other methods were applied to ascertain by each method what would be considered as the maximum run-off. In the final analysis, the results obtained from the various methods were comparable, and as Raymond's zone principle was less laborious to calculate than the others, it was adopted.

The following summary indicates the run-off in cubic feet per second-acre. The average run-off given below is the average of the calculations as made in about twenty cities, and the East York run-off is that obtained by the zone principle.

Time in minutes	10	20	30	40	50	60	70
Average run-off c.f.s. per acre	1.15	0.98	0.82	0.72	0.62	0.56	0.50
East York	0.93	0.78	0.68	0.60	0.54	0.49	0.47

Montreal and Rochester, N.Y., engineers are designing sewers on a basis of a lower run-off than that mentioned for East York.

The time assumed in East York for the entry of storm water into the sewer in the Todmorden and Greenwood areas was eight minutes. In the Danforth Park area, where a sandy and gravelly soil obtains, sixteen minutes were allowed. The time allowed in other towns and cities varies from 3 to 20 minutes.

If it is feasible to have overflow outlets into recipient waters of sufficient capacity to be capable of oxidizing putrescible matters, the size of sewers can be modified and regard should be paid to any such conditions when comparisons are made.

Attention is here drawn to a very interesting paper by Mr. J. G. Caron, A.M.E.I.C., on a "Consideration of Rainfall and Run-off in connection with Sewer Design in the Montreal District", which appeared in June, 1925, issue of *The Engineering Journal* and which deals with some of the points discussed herein.

Having decided upon the run-off, the next business was to apply the same, and the synthetic method was used. The length of every sewer between street intersections, the area draining to the same, and other particulars were ascertained and entered on a sheet, of which the following is a copy containing a specimen of the calculations. (see table A).

Figure No. 4.—36-inch Segmental Block Sewer in Open Cut.

These sheets were filed in sequence in book form and a key plan of the area drawn. From these sheets plans and profiles of any sewers can be prepared in any order, with an assurance that the ultimate scheme will be co-ordinated, comprehensive and complete.

It will be noted that by the synthetic method, the whole system of sewers is designed in small sections commencing at the point most remote, and following downstream to the outfall. In this manner every street is provided with a sewer sufficient for its need, and every trunk sewer is ample to convey the maximum flow due to a storm of a duration equal to the time it takes for the sewage to reach any specific point.

The following is a copy of a small portion of the general sewer maps. It will be observed that each sewer has information as to invert elevations, diameter, grade, number of manholes, etc.

Sewer Construction

As has already been indicated, the construction of the main trunks was largely in tunnel. The majority of the trunk sewers built in open cut served also as "service" sewers, that is, provision was made for the house connections. At intervals of 25 feet, stub house connections were made to the trunk sewer and, encased in 6 inches of concrete, were carried up to within 12 feet of the ground surface. From this point, as required, the township works department lay the private drain to the house.

In the construction of the sewers, the township council at the outset decided that local labour and materials should be used. The percentage of local labour has risen steadily from 25 per cent in the first tunnel contract to 95 per cent in the case of contractors, but has always been 100 per cent in contracts awarded to the township works department. Minimum wages, both for labour and teams, were set by the council. Local bricks are used in the construction of sewers, except in the case of the lower half of the inner linings where approved shale bricks are employed.

With regard to excavation, it has been necessary to close sheet and brace every trench in open cut work. The majority of contractors used compressed air picks and shovels, loading the material into buckets which were hoisted from the trench and removed by a carrier on rails to another point on the work, where the excavated materials was used as a backfill. In the case of tunnels very considerable difference in strata was encountered. On a large proportion of the work compressed air, with gauge pressures from 6 to 23 pounds, had to be used on account of the wet material in the crown. On the Pape Avenue sewer, the contractor used 15 pounds of air to hold the crown of the sewer, but at the same time, was forced to employ large charges of dynamite to remove the material in the invert. Considerable difficulty, owing to the character of the soil, was experienced in retaining the compressed air, with the result that the air often escaped some distance away from the jobs. In another instance where the job was carried out under compressed air, whilst the crown was maintained reasonably dry, the bottom was too wet to permit the construction of the brickwork. The contractor, with the consent of the engineers, adopted the flying arch method, that is, building the crown and haunches supported by longitudinal timber, and on completion of a length of this work then the invert was inserted.

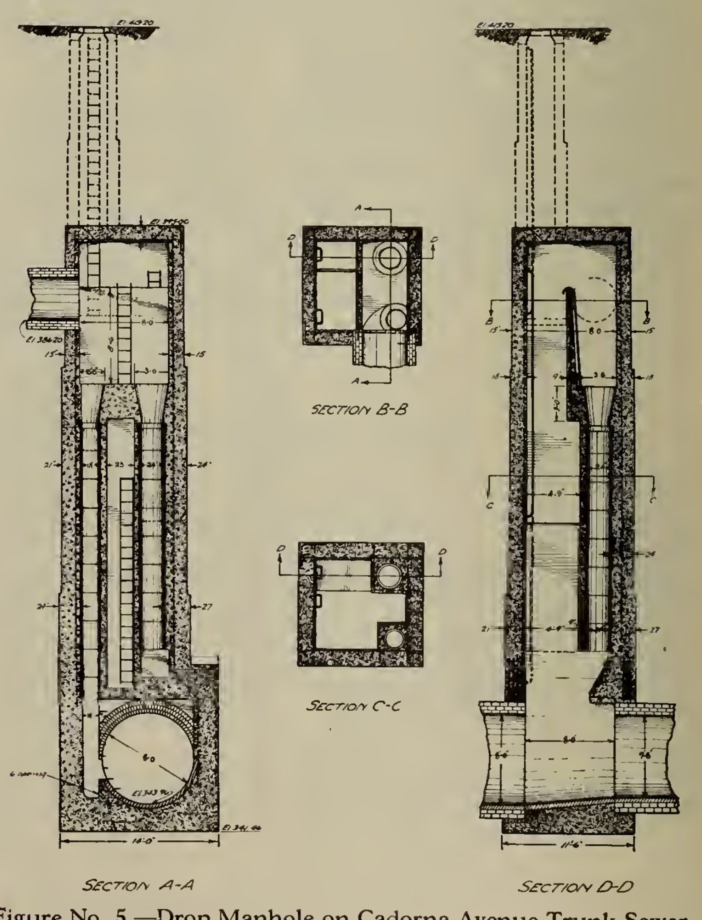

Figure No. 5.—Drop Manhole on Cadorna Avenue Trunk Sewer.

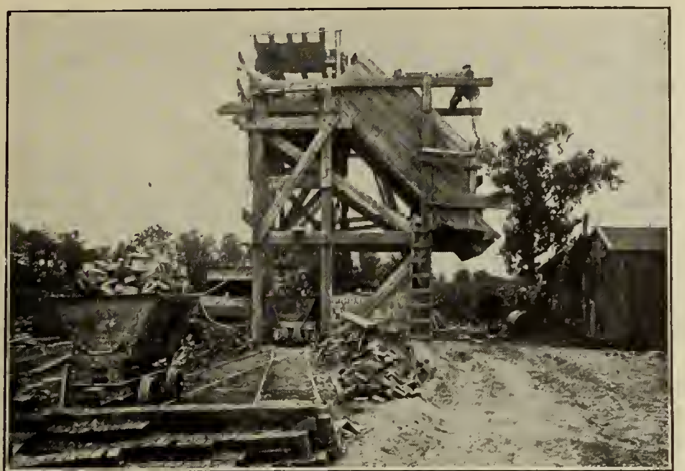

Figure No. 6.—Head Works at Drop Manhole Seventy-two Feet to Invert, Cadorna Avenue Tunnel Sewer.

The Meagher Avenue trunk sewer, which is now in course of construction near the proposed Danforth Park outfall works, is being built in a valley containing wet soft material. This has necessitated piling for about 1,500 feet in length of the sewer. The piles, three to a bent, are about 3 feet apart, and in some places are driven to 38 feet below the surface. In better ground they are only 20 feet deep. The piles are capped by

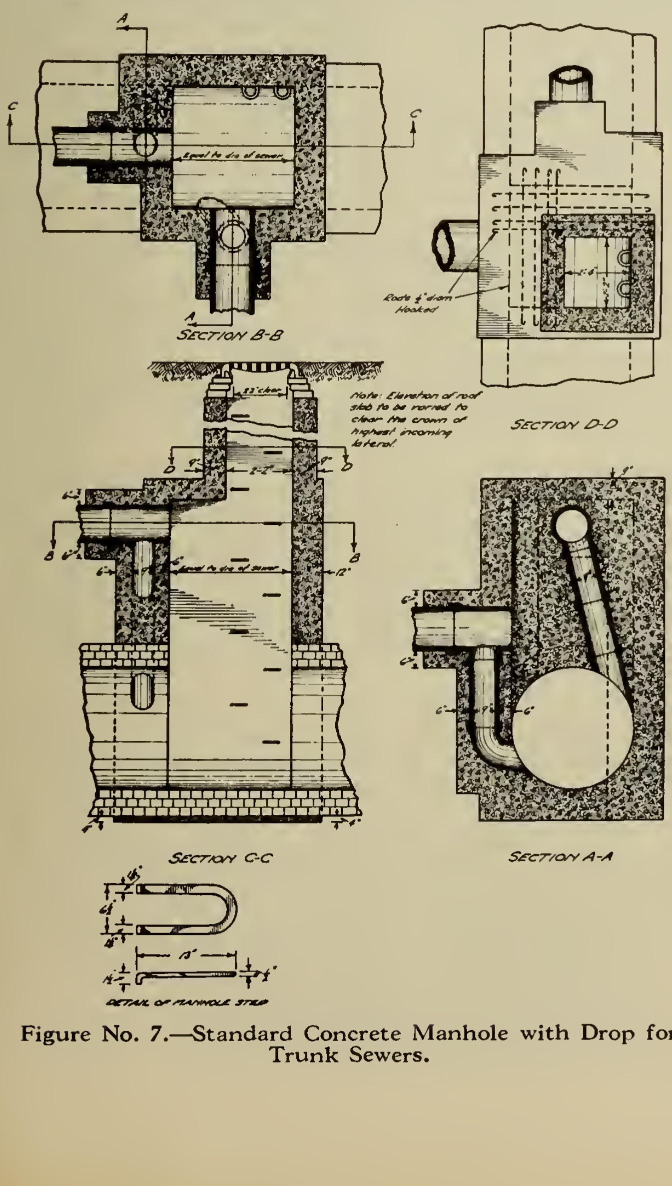

Figure No. 7.—Standard Concrete Manhole with Drop for Trunk Sewers.

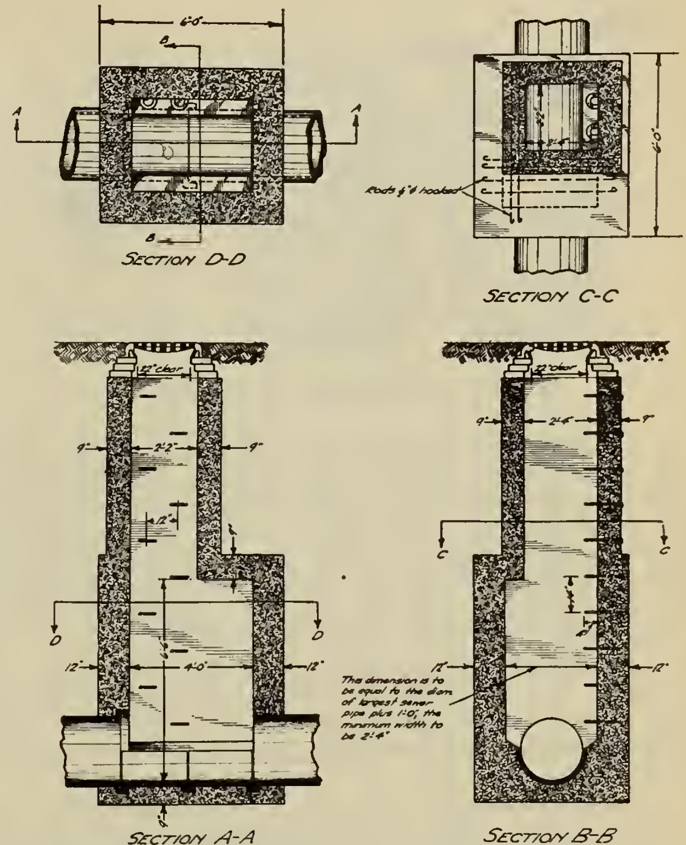

Figure No. 8.—Standard Concrete Manhole without Drop for Lateral Sewers.

8- by 8-inch timber on which is laid a 3-inch decking, and on this will be constructed an egg shaped concrete sewer 3 feet 10 inches by 5 feet 9 inches. There will be a fill in this valley of about 13 feet above the sewer, and consequently every care has to be taken to ensure satisfactory foundation and no settlement.

It is interesting to note that when tenders were called for the first, (Cadorna Avenue) trunk sewer, 90 inches and 96 inches in diameter, contractors were given alternatives of tendering on a 3-ring brick sewer, segmental block sewer, monolithic concrete with paving brick lining to the invert, and semi-elliptical reinforced concrete sections. This sewer was in tunnel at depths varying from 65 to 72 feet below the ground, and the lowest tenders from various firms on the concrete, brick, and segmental block were remarkably close to one another. As before-mentioned, the council wished to employ local materials, and inasmuch as there are several brick companies operating in the Township, the contract was awarded as a brick sewer. In this particular contract, the engineers sought tenders on a unit cost basis, but as the local contractors disliked this system, having been accustomed to bidding on a lump sum basis, and the township council were desirous of knowing the total expenditure to which they were committed when opening the tender and when awarding a contract, all further tenders were received as a lump sum for the construction of a definite specified piece of work. On a number of the other trunk sewers, contractors were permitted to bid on alternative sections, and in one or two instances, were given the choice of tendering on the work as an open cut or tunnel job. In the latter cases, the depth to invert, kind of ground, season of the year, and local conditions all had a bearing.

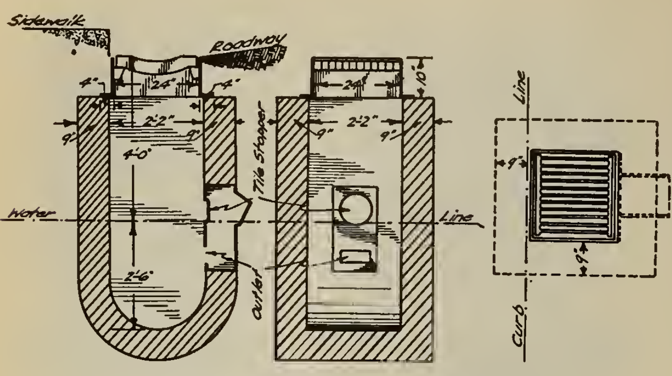

Figure No. 9.—Standard Catchbasin.

A schedule of prices to be paid for extras and additional work accompanied all specifications for sewer construction, but somewhat of an innovation was made in this respect, that the township, not the contractor, specified the rates and prices. These prices were most carefully considered for each contract and were accepted by all contractors without question. Deductions were based upon these prices less fifteen per cent.

Small sewers from 12 inches to about 27 inches in diameter have been built of vitrified clay pipe. Where such pipe is laid at depth greater than 12 to 14 feet, concrete cradles have been employed in order to ensure good bearing.

Sewers in tunnel, without exception, are built of brick and other sewers of large diameter have been built of brick, segmental blocks and monolithic concrete. The brick and segmental block sewers have been rendered with a one-half inch coat of cement mortar. The space between the sewer and the sides of the trench has been filled with concrete up to a height equal to two-thirds of the outside diameter of the sewer. Where necessary on account of unsatisfactory foundation, the bases of the sewers have been squared by means of a concrete filling. The monolithic concrete sewers have been constructed by the township works department and by the use of sheet metal forms, very satisfactory and smooth stream lines and crown have been obtained.

Brick sewers have been usually built 2 rings up to 48 inches in diameter, and 3 rings from 54 inches to 96 inches in diameter. The smallest diameter sewer that any contractor has elected to construct as a tunnel is 45 inches. In both the 45 inches and 48 inches diameter tunnels, the contractors made good progress, averaging 14 to 16 feet in each heading per 24 hours.

Figure No. 10.—Meeting of Two Headings on 6-foot Sewer in Greenwood Avenue Tunnel.

In the design of manholes interesting conditions had to be met. For instance, the invert of the Donlands Avenue sewer, which is an egg-shaped sewer 3 feet 2 inches by 4 feet 9 inches, is about 43 feet above the invert of the 8 feet diameter Cadorna Avenue trunk sewer in tunnel. This created a big drop which is taken care of by two vertical vitrified clay pipes encased in concrete. Figure No. 5 illustrates how this manhole was designed.

At another point in the Cadorna Avenue trunk sewer, two sewers, each 72 inches in diameter, converged into the main trunk. Both sewers were in tunnel, and built of brick. The contractor built the bell mouth 60 odd feet below ground, under an air pressure of about 20 pounds, and constructed the shaft of this manhole from the sewer upwards to about 20 feet from the ground surface, and simultaneously worked downwards from the ground to meet this shaft.

On the main trunk in Danforth Park area the manholes do not have such great drops and there has been incorporated in the design a chamber into which the water falls forming a water cushion and breaking the impact.

To facilitate construction, standard types of manholes, manhole covers, and catch basins were adopted. The catch basins were constructed of concrete, and the manholes of concrete or brick, as decided for the particular contract. Brick manholes were rendered on the outside. (See figures Nos. 7, 8 and 9).

All records of progress of construction are regularly reported by resident engineers and inspectors to the township office and there posted into various books. The inspector on each contract sends in a daily report of progress made, materials and labour employed, etc.

When contracts for the two largest trunk sewers were let to the contractors it was stipulated in the specifications that they should employ at least twenty-five per cent of township residents. This was done in order to try and relieve the unemployment situation in the township. but it soon developed that it did not in any way cope with the situation. It was therefore decided to create a works department which would be under the control of the engineering department. This department has grown, and to-day there are six gangs constructing sewers, and one constructing sidewalks, employing in the neighbourhood of two hundred men. As is usually the custom, these gangs are controlled by a foreman who is directly responsible to the township engineer, who has charge of all the work carried on by this department.

The foreman has control of his own organization and is required to make a daily report on a sheet provided him stating the number of feet of work completed, material received and any additional information which will be of use in connection with compiling the cost of construction. He is also required to make a daily time report to the township office stating the number of hours worked by each man in his organization and placing the different letters of the alphabet after each man's name according to the schedule given hereafter, so that the cost clerk in compiling his unit cost records of each job can arrive at the actual cost of each portion of this work. The schedule showing the division of labour and how they must be reported is as follows:—

From this information the unit cost of these jobs, day by day, are compiled as shown on the specimen distribution sheet. (see table B)

For the purposes of payment of men the foreman is required to forward a weekly time sheet giving the number of hours worked by each man per week.

Previous to starting a sewer, a schedule is given to the foreman setting out the amount of work that is expected to be completed by him each day according to the amount of payroll of his gang. Weekly reports are given to the engineer showing the progress made, and these are compared with the schedule drawn up before commencing the work. This information is passed on to the foreman. An accurate check is kept upon the work at all times, and the foreman knows from week to week what is required of him to keep within the contract price, if there is a tendency to fall behind in his work. All employees, as stated, are township residents and are paid a minimum wage of fifty-five cents per hour for forty-four hours a week with time and a half for any overtime.

In order to compete with outside contractors, who bid on this work, it was found necessary to invest in mechanical equipment. This has been found to be beneficial in all respects. As an example, the entire cost of one piece of machinery was paid for by the saving in labour, etc., on one contract alone.

Up to the present time the sewer branch of the works department has constructed over three hundred thousand dollars worth of work at a considerable saving to the municipality, at the same time providing the residents with employment.

During the winter months of 1924 and 1925, in order to relieve the extreme unemployment situation, two additional foremen were placed on contracts, with two gangs each per week, each gang working three days per week. In this way as many as two hundred men at a time were employed.

At the termination of each job the staff prepare the cost sheet, according to the following form.

Credit is due to the resident and assistant engineers for the efficient manner which they carried out their duties. Grant R. Jack, A.M.E.I.C., is township engineer, and R. O. Wynne-Roberts, M.E.I.C., is consulting engineer to the Township Council of East York.

The Water Supply of the Border Cities

William Gore, M.E.I.C.,
Consulting Engineer, Toronto, Ont.
and
J. Clark Keith, A.M.E I.C.,
Chief Engineer, Essex Border Utilities Commission, Windsor, Ont.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

In the south-western corner of Ontario there is an unusual situation,—eight incorporated municipalities lie side by side fronting along the Detroit river for a distance of about twelve miles and extending back about two miles. These municipalities, Tecumseh, Riverside, Ford, Walkerville, Windsor, Sandwich, Ojibway and Lasalle, are all on the same drainage basin, secure their water supplies from the same source, and have their own municipal governments but their problems are so inter-related that many of them cannot be solved independently.

The need for joint action and unity in handling some of these problems was recognized in 1916 which led to the creation of the Essex Border Utilities Commission. This body, composed of the mayors and elected representatives of all the Border Municipalities, more commonly known as the Border Cities, was empowered in 1916 by the Ontario Legislature to deal with the related problems of water supply and sewage disposal. Additional powers have since been secured from time to time until the health and general planning of the district come within the scope of its administrative powers. To the outsider it would seem that amalgamation would be the natural solution for the engineering and economic problems of the Border Municipalities. Different objections are offered by different municipalities to this idea but in the meantime there is a very evident desire to co-operate where possible in municipal undertakings.

The most important problem confronting the Commission after organization was the protection of the municipal water supplies. The upstream municipalities discharged their sewage above the waterworks intakes of those further downstream and owing to the rapid growth of the district this condition was yearly becoming more acute. Plans for further extension of sewers had been disapproved by the Provincial Board of Health owing to this situation and while it was recognized that sanitation must be provided, protection to the downstream municipalities was equally important. The problem was solved through the construction of five miles of intercepting sewers along the water front in which six municipalities participated and by which all sewage was discharged downstream with respect to the waterworks intakes of the Border Cities. Nine objectionable sewage outlets into the Detroit river were removed and when the International Joint Commission issues the mandate that the pollution of boundary waters must cease, the work on the Canadian side of the Detroit river is well under way.

There are two water supply organizations in the Border Cities, the municipally owned system of the city

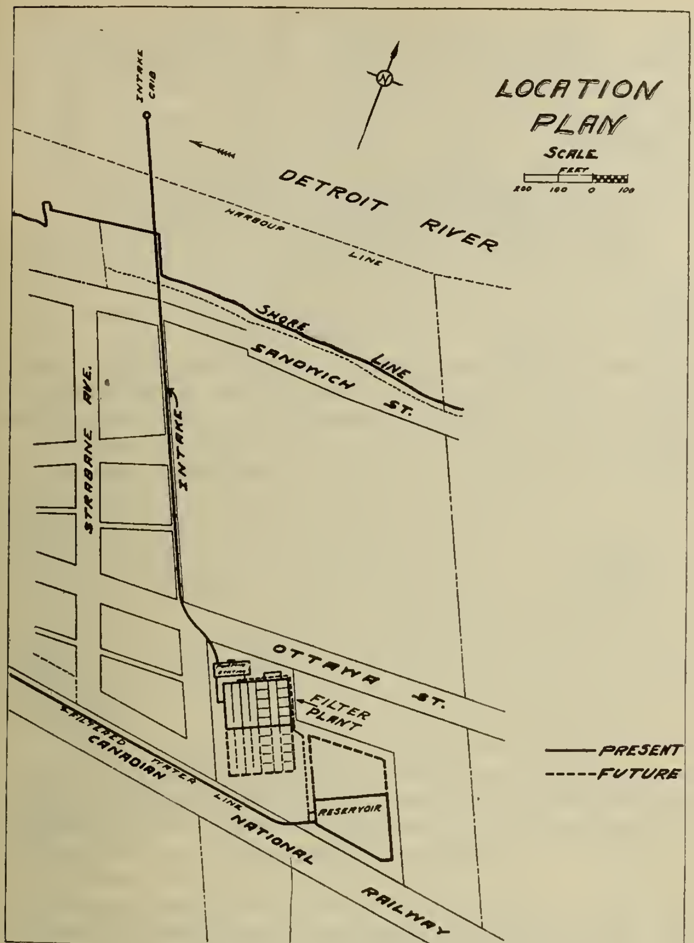

Figure No. 1.—Location Plan.

of Windsor and the privately owned works of the Walkerville Water Company. The area served by the former includes the city of Windsor and the towns of Sandwich, Ojibway, LaSalle and part of the township of Sandwich West, while the latter serves the towns of Walkerville and Ford City and a portion of the town of Riverside and the township of Sandwich East. These organizations have had a common problem in meeting the needs of the fastest growing communities in Canada. The population served has increased from 36,258 in 1915 to almost 90,000 in 1925, an increase of 148 per cent. or an annual increase of 15 per cent. Approximately one-quarter of the population is served by the Walkerville Water Company, the remainder by the municipal system of the city of Windsor. From present indications there does not appear to be reason why this population increase will not continue.

The history of water supply as a utility in the city of Windsor dates back just 52 years replacing the proverbial town pump at the river's edge. Fifteen years later the plant was destroyed but since that time has had a steady growth. The pumping units now installed have a capacity of 25 million gallons daily and plans are now maturing for a new 12 million gallon unit. The daily average output for 1924 was 10,160,000 gallons, equivalent to 170 gallons per capita.

The Walkerville Water Company is the outcome of action taken by Messrs. Hiram Walker and Sons to provide water for their employees. In order that this service might be extended the Walkerville Gas and Water Company was formed in 1892 for the purpose of supplying water to the citizens of Walkerville. The Walkerville Water Company has an installed pumping capacity of 19 million gallons per day. The average daily output for 1924 was just under 4 million gallons, a per capita use of 186 gallons. Industrial use accounted for 93 gallons per capita. From figures secured from various Ontario Cities last year, their maximum domestic rate of 10 cents per thousand gallons compares favorably with any system, either publicly or privately owned.

Like other communities situated upon the Great Lakes or some of their connecting rivers, the water supply of the Border Cities has intermittent turbidity due to wind action which is objectionable. The question of filtration has been under consideration by the Water Commissioners of the city of Windsor and by the Walkerville Water Company for almost ten years and both of these organizations have had independent reports submitted to them on this question by the late Winthrop Pratt of Cleveland. Detailed filter plans had been prepared for the Walkerville Water Company and also for the town of Ojibway, but final action had been deferred.

In 1917 a report was submitted by Mr. Morris Knowles of Pittsburg, then chief engineer of the Utilities Commission, on the joint question of sewage and water supply, in which he recommended the construction of an intake in the neighbourhood of Peche Island with one central filtration plant and pumping station to supply the entire district. The two present pumping stations were to be purchased by the Commission and were to be abandoned. This plan did not meet with general approval and no progress was made. In 1920 a board of three engineers was appointed, Mr. E. M. Proctor representing the city of Windsor, Mr. F. W. Thorold, the town of Walkerville, and Mr. Morris Knowles for the Essex Border Utilities Commission, to deal with the question of water supply for the entire district.

There appeared to be four possible solutions to the problem:-

(1) The construction of three filtration plants, one at Ojibway, one in Windsor and one in Walkerville.
(2) The construction in the city of Windsor of one plant to serve the entire district.
(3) The construction in Ford City of a new filtration plant and new high lift pumping station to distribute all water from this point.
(4) The construction in Ford City of a new intake and filtration plant which would furnish filtered water to the two existing pumping stations for distribution.

Project No. 4 received the unanimous recommendation of the Board. This involved the construction of an

Figure No. 2.— Filtered Water Line.

intake, a low lift pumping station, a 20 million gallons per day filter plant, a 2 million gallon pure water reservoir and a gravity main almost two miles in length to deliver the filtered water to the pump wells of the two present pumping stations.

Before this project could be proceeded with, it had to be submitted to the electors of the seven municipalities interested at that time. Since that time an eighth municipality, LaSalle, has been incorporated and is now participating in this joint project. The division of costs in any undertaking where a number of municipalities is involved is often a source of contention and may lead to the rejection of the proposed improvement. Under the Essex Border Utilities Act the vote of all municipalities must be favorable, failing which, the share of the rejecting municipality may be taken over by the other municipalities if they so desire. If more than two municipalities reject, it must be revoted on by all. The cost of this work was apportioned among the various municipalities on the basis of their estimated use in 1930. Provision is made in the Act under which the Utilities Commission functions by which this apportionment can be changed every two years. This project as submitted received the endorsement of the electors in all the municipalities in January, 1923. The citizens of Windsor were given the opportunity at the same time of voting for a separate plant to meet their own needs but the jointly owned plant received the favourable vote. Construction was started late the same year and it is expected that the plant will be in operation early this year.

As every water reacts differently to the process of filtration it was fortunate in this case that in 1917 the city of Detroit had carried out detailed examinations of the waters of the Detroit river drawn from their intake at the head of Belle Isle about 2 miles higher up the river than the proposed intake site of the Commission. These investigations were under the direction of the late Winthrop Pratt. Experimental filters with a capacity of 167,000 imperial gallons per day were constructed and

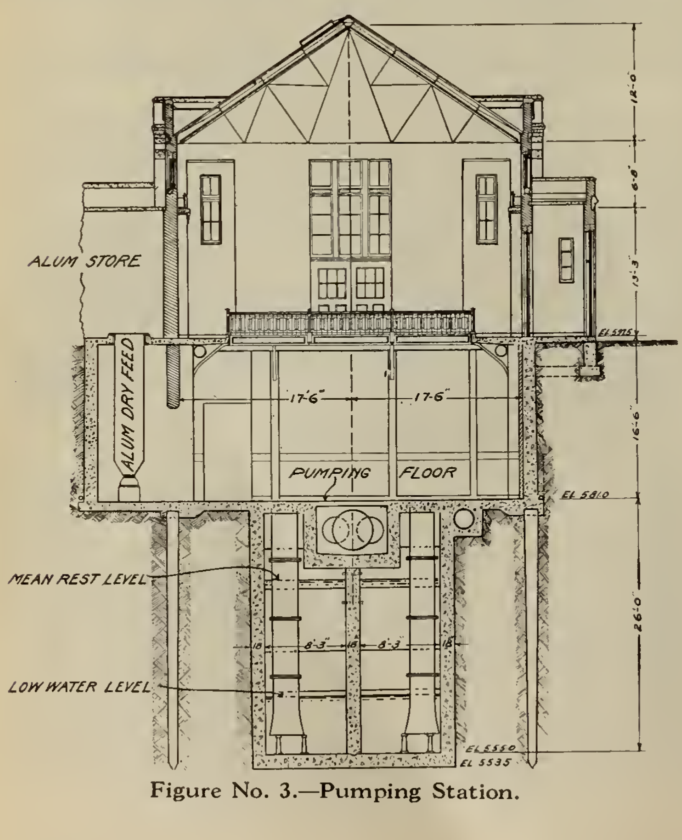

Figure No. 3.—Pumping Station.

kept in operation and under observation for an entire year. Samples of raw, settled and filtered water were collected four times a day and tested for turbidity, alkalinity and bacteria. The operating conditions were changed from time to time to determine the most favourable procedure in regard to time of mixing, period of sedimentation, rate of filtration, kind and amount of coagulant, rate of washing and effective size of sand.

The turbidities of the raw water averaged 30 parts per million with a maximum of 490 parts per million. These turbidities were reduced to almost zero when filtering at the average rate of 160 million gallons per acre per day using 0.80 grains of alum per gallon. In the raw water B. Coli was present in 25 per cent. of the 10 c.c. samples while in the filtered water this was reduced to 5 per cent. The period of coagulation or settlement was less than 2 hours. Mr. Winthrop Pratt's principal conclusions from the experiments were as follows:—

"1. The river water drawn through the present intake can be easily and satisfactorily purified by the process of rapid sand filtration. Its quality is well within the most severe standards fixed by sanitary authorities, for a filterable water.

2. It is feasible to use higher rates of filtration than has been the practice generally in the Middle West heretofore. This results in a decrease in the required area of filters and hence in a saving in the expense of constructing a filtration plant.

3. That instead of three or four hours sedimentation period, as has been the more general practice, less than a two hours' period will be ample, thereby making another large saving in construction cost.

4. That the use of a filter sand having an effective size of approximately 0.50 m.m. gives just as good results as the use of a finer sand and results in a large saving of wash water."

After reviewing the results of these experiments the design of the new plant was based on a rate of filtration of 127.5 million gallons per acre per day and a mixing and coagulation period of 2 hours. The filtration rate of the plant is 21 million gallons per day, that is 2.1 million gallons per day per filter. These rates allow 5 per cent. of filtered water for losses, back washing, and other purposes so as to provide a rated output of 20 million gallons per day. Parts of the plant difficult to construct at a later date or disproportionate in expense should provide for 42 million gallons per day. This applies to lands and easements, the intake, screens, the pumping station, switchboard, alum feed, the main conduits about the plant and the backwash system.

The Detroit river from which the water is derived is part of the Great Lakes system joining lake St. Clair to lake Erie. Its level at the side of the intake has varied during the last 15 years from elevation 569 to elevation 577, but surges in the pumping station are calculated to rise to elevation 579, and as a surge overflow could not well be constructed the possible surge level determined the elevation of the pumping station floor which was placed at elevation 581 and to provide for the surges it was necessary to have a suction well with a surface area as large as possible.

In addition to the filtration experiments referred to, various studies of the water in the Detroit river have been made. These show that there is serious contamination along the shore edges and a relative high degree of purity towards the centre of the stream. Lake St. Clair from which the water is derived being relatively shallow is easily disturbed by winds and the several rivers and water

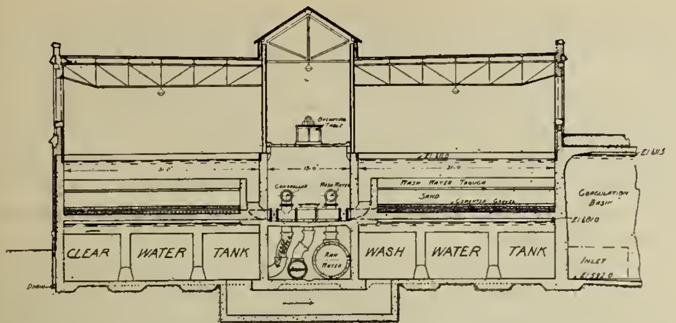

Figure No. 4.—Cross-Section of Filters.

courses which empty into it bring down large quantities of turbid waters particularly in the spring. The presence of Belle Isle protects the intake site from the very serious pollution on the Detroit side arising from its sewage which is discharged untreated into the river. While the river gets some direct contamination from the town of Riverside there is an intercepting sewer on the Canadian side taking domestic sewage from a point one mile upstream and discharging two miles lower downstream protecting the river from serious direct pollution in the vicinity of the intake but it has been observed that reversals of flow of the river have taken place for short periods due to head winds and in ice blockages and this is the most serious possibility.

The discharges from the very extensive shipping which pass close by the intake are a serious possible source of direct pollution. These possibilities of direct and indirect pollutions demand a filter plant maintained in the highest state of efficiency and everything possible has been done in the design and construction to this end.

The existing intakes of the city of Windsor and the Walkerville Water Company have met difficulties by choking due to frazil ice on the occasion of very cold strong winds blowing on open water and it is anticipated that the same difficulties might be experienced at the new intake and to this end the intake mouth which runs straight out from the pumping station with a small angle down stream into about 38 feet of water is terminated by a gradually expanding trumpet mouth 8 feet in diameter with rounded edges at its outer end so as to avoid high velocities of inlet current. But an intake in water running at 2 miles per hour inevitably produces eddies in the water and the formation and collection of frazil ice. Provision in the pumping station has been made to reverse the flow in the intake from the coagulating basins, which when full, are 38½ feet above the mean level of the river, the full pressure of which can be put upon the intake tunnel and pipe. No screens or covers of any sort are placed on the intake mouth because of possible ice difficulties, it being considered desirable to allow everything collectable to come through to the forebay of the screens in the pumping station where large objects would be easily lifted out, the smaller objects being removed by the screens.

The intake mouth is carried by a timber crib loaded with stone. Its placing introduced no serious difficulties. Alignment of it and the 48-inch intake pipes which were laid in a trench excavated in the bed of the river was secured with spherical joints. At the river edge, on Sandwich street, a shaft was sunk and the pipes were continued to it from the river in a short tunnel the entrance to which was protected by a coffer-dam. The remainder of the intake conduit was constructed in the form of an elliptical tunnel 48 by 60 inches driven in clay and lined with 9 inches of reinforced concrete. The total length of the intake conduit is 1,640 feet and it extends 480 feet out into the river.

The low lift pumping station and the filter plant forms a group of buildings of the same general character, and the site admits of the placing of a high lift pumping station which in the case of the second instalment of 20 million gallons per day will in all probability be used for a time at least as a booster station to drive the increased quantities of water through the 42-inch delivery main to the existing Walkerville and Windsor pumpings stations.

The necessity, for reasons of economy, that the first instalment of 20 million gallons per day be delivered by gravity to the existing pumping stations put conflicting conditions into the design. The filters had to be placed at a high level in order to provide the necessary gradient in the pipe line and provide for 10 feet loss of head in the filters and an equal amount in the pure water reservoir and the pumping station floor had to be down at such a level as to be able to draw water at the 42 million gallons per day rate with the river at the lowest level. Thus the water levels of the filters and coagulating basins stand 14 feet above the ground level and the pumping station floor level is 16 feet below ground level making both somewhat expensive to construct but the advantage of having all works together at a site not far from the river in excellent communication with both railway and road is apparent to any waterworks engineer.

The buildings are in one group, consisting of a low lift pumping station and screen house combined, a service building containing boiler house for heating, alum house and men's quarters, mixing and coagulating basins, office, laboratory, stores, garage and a filter house containing 10 rapid sand filters on top of an independent section of the pure water reservoir containing filtered water for backwashing. The pure water reservoir proper is independent and at a short distance away and is earth covered with grassed top and slopes but no embanking has been placed about the group of filters and coagulting basins. The top of the coagulating basins are covered with earth as a protection from frost but this is hidden by a parapdet wall faced with brick and stone. The roofing of the pure water reservoir is reinforced with steel on a three-way plan overlapping over the columns and the columns are staggered in successive rows. This arrangement works exceedingly simply.

The external covering of the buildings is of a specially selected colouring of composite red and brown or brindle rug brick with cut stone facings, plinths, cornices and copings. All parts of the concrete tank work which would otherwise have been exposed high above ground levels are faced with brick or stone leaving an air space averaging 1½ inches which protects the damp walls from frost penetration. Where the brickwork covers considerable plain areas these are relieved by panels of brick on edge with cut stone corners. The exposed tops of the filter walls are

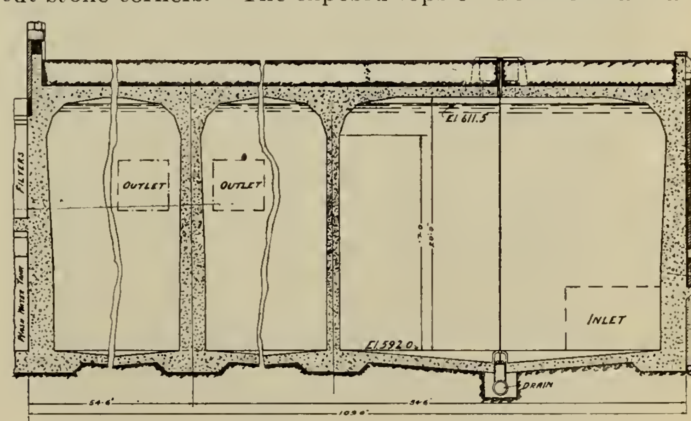

Figure No. 5.—Cross-Section of Coagulation Basin.

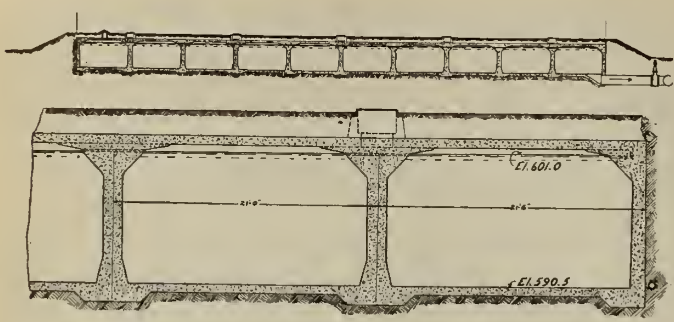

Figure No. 6.—Section of Reservoir.

faced with white glazed bricks and the inner walls of all principal buildings with brown glazed bricks up to a height of 4 feet, the remainder with buff colored brick. The principal floors, footways and stair treads are laid with terrazzo with a small portion of marble at the main entrance and stairways of the office building. The doors and window frames are either of metal or metal cover as kalemin. The roof of the pumping station is copper covered and the remainder of the buildings of composition over concrete except the portion over the filter operation gallery which is covered with wired glass. In the design and construction of these buildings every care has been exercised that the general appearance as well as the structural details and conveniences should be of the best class in waterworks engineering practice.

At certain seasons large quantities of weeds flow down the river and have caused considerable trouble at the existing intakes and to deal with this problem and also with floating ice two travelling screens of the "Link Belt" type have been provided in the pumping station. Each control an independent compartment of the suction well which can be isolated without stopping the supply being pumped from the other compartment. The pumps provided are driven by electric motors and consist of one 21-, one 14- and one 7-million gallons per day units, and a bed is provided for an additional pump of 21-million gallons per day capacity. This arrangement of three sizes of pumps gives considerable flexibility with a view to economical operation because of the methods of charging for electric power. The output of the pumps is controlled from an operating table either by hand or automatically by the level of the water in the coagulating basins.

For backwashing the filters two electric motor driven pumps of 5 million gallons per day each are provided either or both of which are started and stopped by push button remote control from each of the operating tables in the filter house. All gate valves in both the pumping station and filter house which have to be operated frequently are provided with hydraulic power using the pressure of the Walkerville Water Company service system with standby service in the pumping station. A small turbo generator operated by the water in the coagulating basins with independent wiring is provided for lighting in case of electric power failure. The subject of standby power in case of failure of the local Hydro-Electric System received much consideration and it was finally decided to omit this for the present because the provision of the 2-million gallon pure water reservoir would take care of most of the local failures and these could be reduced to a minimum by the provision of two lines, one a private line from the local substation in the town of Walkerville and the other from the nearby local distribution system on Ottawa street. In the event of prolonged failure of the main feeders of the Ontario Hydro Electric Power System, or of the substations, which have now become exceedingly rare, the existing intakes at the high level pumping stations could be brought into service again with the temporary disability of using unfiltered water. As chlorination is to be carried on at each high level pumping station this arrangement introduces no serious health hazard. The hydraulic supply for operating the gate valves is safe from interruption due to electric power failure except in a temporary way as the Walkerville Water Company has ample steam power standby.

The alum supply is of the dry feed type operated by electric motors and is applied after solution to the water as it enters the suction well from the intake tunnel. The dry alum is stored in the service building in the floor of which are openings to two hoppers which hold 6,000 pounds of powdered alum each for the two machines. It is intended that the filling of the hoppers be done by a day man and the capacity of the hoppers are such that they will contain sufficient alum to last from Saturday mid-day to Monday morning with a filtration rate of 42 million gallons per day. In the service building are provided two heating boilers one to use oil fuel, the other coal, and men's quarters with lavatory and shower baths are provided. In the pumping station a balcony at ground level 16½ feet above the pump floor is provided completely around the building. At one end this balcony is widened to carry the main switch board and at the other to provide for a machine shop.

The water from the low lift pumps passes through a 42-inch flow meter into duplicate mixing and coagulating basins built of reinforced concrete and brick faced on the outside. The mixing of the alum with the water is chiefly brought about by the action of the centrifugal pumps. The mixing basins are at the near ends of the coagulating basins and are deep channels with baffles at top and bottom leaving gradually widening spaces so that the alum treated water will be moving relatively slowly when it enters the coagulating basins. The coagulating basins are of the go and return type each passage being 25 feet 3 inches wide and 20 feet deep. Six sludge valves are provided in each basin to which the floors are sloped. The water enters the basins close to the bottom and leaves near the top through a valve chamber and concrete culvert leading to the filter house where it is distributed from a 5-foot concrete pipe placed together with a 30-inch main drain in a lower pipe gallery.

In the upper pipe gallery are placed the hydraulic gate valves for the rate controllers, the wash water pipes and hydraulic service pipes. An endeavour was made to have this pipe gallery more accessible and presentable than usual and to this end the operating gallery has been raised above the level of the filter walls so as to admit daylight and provide air circulation. Access is provided from a landing on the main entrance stairway.

The present filters are ten in number, each of 700 square feet in area, in two rows of five each with the operating platform and pipe galleries between them. While each filter can be operated independently each set of two filters opposite each other are operated together with one controller and one operating table with the necessary indicators, recorders, gauges, and meter but the backwashing is done to one filter independently while the other filter is in operation. The backwash water is metered by a flow meter. The operating tables face the entrance from the upper landing of the office building and are in the centre of the fairway of the operating platform leaving ample space on either side. This arrangement effects a considerable saving in expensive apparatus. It is possible to extend this idea to cover more filters but it introduces the difficulty to the operator of seeing the filters from the table and the necessity for backwashing all filters so grouped together at about the same period as a single controller to several filters overloads the filter with the least loss of head.

The underdrain system consists of 3-inch cast iron pipe laterals joining a manifold along the centre line of the filter. These pipe laterals are 7 inches apart and have brass nipples with 5/16-inch holes at 7-inch intervals placed on the undersides of the pipes. At the manifold where the depth of gravel covering is reduced, umbrella slot openings are provided. The whole is levelled up with two sizes of loose gravel and finally a 6-inch layer of cemented gravel which has passed through a 3-mesh per lineal inch sieve and caught on a 5-mesh. The proportion of cement by volume is one-twelfth. This forms a firm porous layer which with proper working can never be disturbed while backwashing. The porous cemented gravel is blinded with 2 inches of coarse sand or fine gravel on which the filter sand is placed. The total depth of gravel is 16 inches and the sand 28 inches. The sand has for the most part an effective size from 0.45 to 0.55 millimeters and a uniformity coefficient of 1.4 and comes from pits at Bay City, Michigan.

The pure water reservoir has been constructed in plan in the form of a rectangle with one corner cut off. The necessity for this arose from the form of the land acquired which owing to various limitations, historical, financial and political, has an exceedingly rugged boundary but when the plant is fully developed there will be very little of the area unoccupied.

The delivery main has been laid along the edge of the Canadian National Railway right-of-way which has a minimum width of 110 feet. The pipe is encased in concrete as it has to be capable of carrying over it the heaviest of locomotives. At the present an agreement with the railway limits the pressure in the main to 30 pounds per square inch, but it has been tested throughout to 110 pounds, so that if in the future this 30 pounds pressure allowance is augmented the physical conditions are satisfactory. The pipe for the most part is of rivetted steel plate 5/16 inch thick laid to a hydraulic gradient with a few short dips to avoid existing sewers and it is possible the pipe may run at some time only partly filled. Air valves of the double orifice type are provided where desirable. The connection to the Walkerville System introduced no difficulties as the pumps operate on a closed suction system and a large branch connection had already been provided to which the 24-inch branch is attached. The conditions at Windsor were not nearly so favourable as the pumps draw from a small open suction well, impossible to control by hand operation of the gates. In the event of a power failure when drawing water at the future maximum rate of 30 million gallons per day the Windsor pumping station would almost instantly be flooded or if automatic control closed the gates too quickly the main would be endangered. The situation was entirely unusual in waterworks practice for so large a quantity of water on so long a supply main. The situation was met by the provision of a regulating tank 25 feet square provided with the necessary valves for hand control, but also with duplicate automatic 30-inch float-operated safety valves specially designed for this work. These valves automatically maintain the water at a level not higher than some 8 inches below the floor of the pumping station and in the case of a power failure these valves close as the water rises in the tank but, when the pressure in the pipes increases due to momentum to the 30-pound limit, the floats immerse instead of closing the valves further. The excess water entering the tank then passes away by an overflow. Venturi meters measure the supply of water to the two high lift pumping stations.

The total cost of the work including everything is approximately one million dollars.

The extension of the main pipes from Windsor to Sandwich, Ojibway and LaSalle has been carried out for a further sum of $385,000. This work presented no unusual features.

The works described above were designed by the writers of this paper, William Gore, of Gore, Nasmith & Storrie, consulting engineers, Toronto, and by J. Clark Keith, chief engineer to the Essex Border Utilities Commission. A. W. Hammersley acted as resident engineer during the construction of the work.

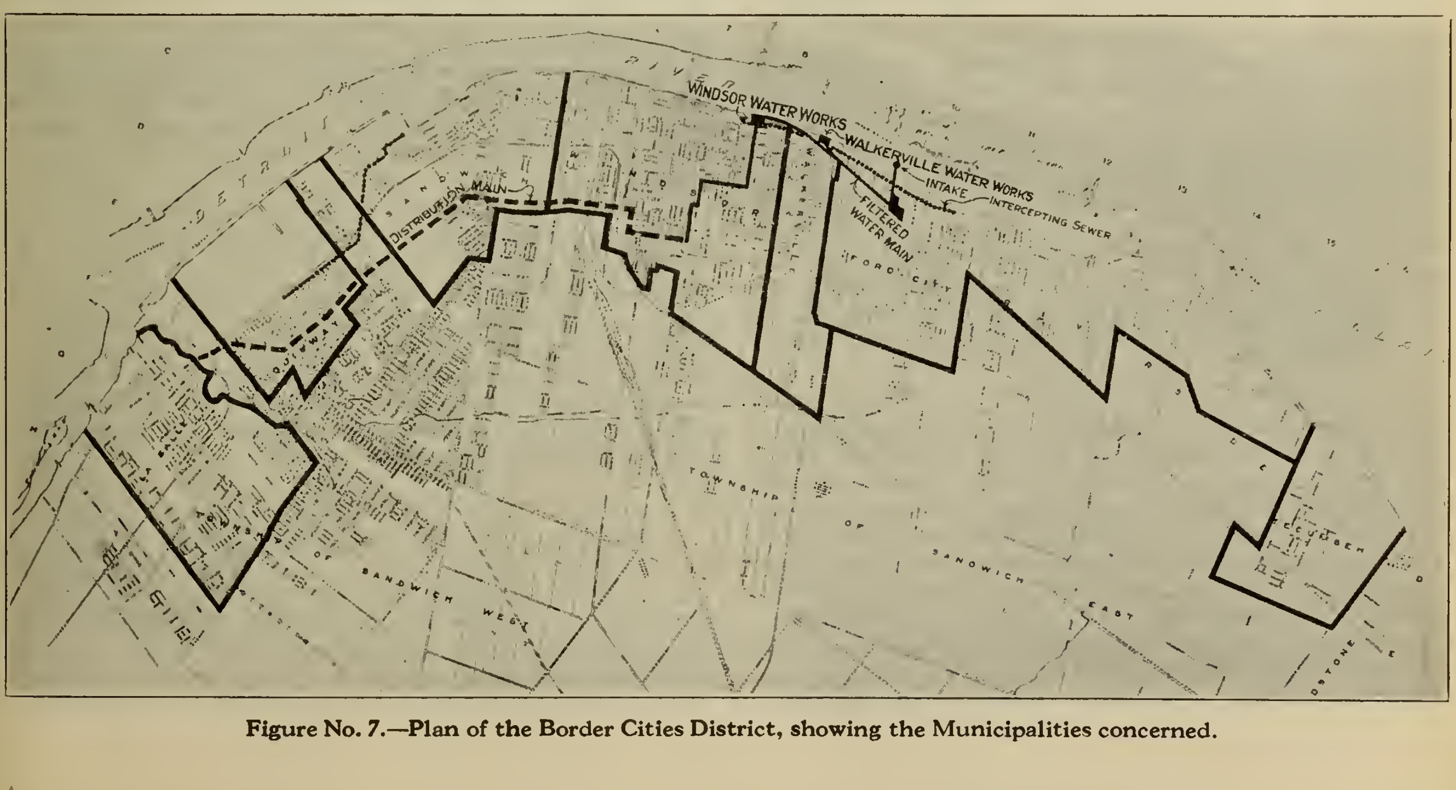

Figure No. 7.—Plan of the Border Cities District, showing the Municipalities concerned.

Influence of the Modern Highway

W. A. McLean, M.E.I.C.,
Consulting Engineer, Toronto, Ont.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 29th, 1926.

Different periods in the world's history have been distinguished by attainments and achievements of varying types; such periods as the golden age of art, the age of crusading, revival of learning, the age of discovery, or the golden age of the drama. The present period is notable with respect to development in means of travel, transportation and inter-communication. When the history of the present epoch is written, we may well expect it to be known as the age of transportation.

To this era belong the steam and electric railway, the motor vehicle, the aeroplane, and the allied means of communication by telegraph, cable, telephone, the modern postal service, wireless, and radio; all means for the transferrence of goods, people, thought, to an extent scarcely surpassed by the most fantastic imagination of fiction.

When our ancestors crossed the Atlantic a century ago, the journey occupied from six weeks to three months, and was an adventure indeed. To-day this trip may be made in luxury in less than one week. Crossing the continent from Montreal to Vancouver, 2,937 miles, was then almost an impossibility, but has recently been accomplished in 72 hours by diesel-electric car. A century ago, a letter from India by the most rapid means of communication, might reach Canada in a year. To-day a cable message is delivered within a day.

The civil engineer should be, to the municipal unit, and to the field of transportation, what the architect is to the house. He should build and remodel for present needs, and should foresee and provide for future requirements. The introduction of the motor car, and its growing use, are bringing about changes and creating opportunities so gradually that they pass almost unnoticed, yet are of very great moment in the municipal plan. Without enumerating all influences, one has only to refer to the character and rapid extension of highway improvement; to changed methods of paving and the more scientific use of paving materials; to the width and design of roads and streets; traffic regulation; the distribution of population; or the influence of motor traffic on other forms of transportation, particularly on steam and electric railways. It is therefore fitting that the economics of the highway as represented by the road and the vehicle using it, should be the subject of careful observation.

Growing Use of Motor Cars

There is already a younger generation who find it difficult to realize that the motor vehicle is a very recent addition to our means of travel. They reflect, no doubt, that it must have been a very crude world indeed, without the family motor car, — comparable to an earlier day of oxen and stage coach. Yet the motor car is so modern that, in many ways, its ultimate influence is still a matter of conjecture.

It was in the year 1898 that the first gasoline driven motor car was owned by a citizen of Toronto, and Hamilton had an automobile owner in the same year. In 1903, the use of motor cars was considered such a menace on the public highways that their registration was commenced, and in that year 220 were recorded; but probably 60 per cent of these were owned outside of Canada. Registrations grew to 4,230 in 1910, of which 1,977 were owned in Ontario. For the current year it is estimated that 293,000 passenger cars will be registered, and 33,000 commercial vehicles and trucks: in all 326,000 registrations for the year, not including several thousand motor cycles. This is an average of one vehicle for each nine of population; and compared with population, is on a par with the state of New York. Massachusetts has one car for each 8.28 of population, and Iowa one car for each 4.29. The proportion of cars to population is greater in agricultural than in manufacturing communities. In Ontario, somewhat midway between the agricultural character of Iowa, and the industrial character of the New England states, it is evident that the condition of maximum saturation has not yet been reached.

Increased Value of the Road

The vehicle and the road are but parts of one machine. The value of the common road is proportional to the capacity of the vehicle which uses it. Prior to the day of the motor vehicle, the value of the road, as a factor in transportation, was represented by the working ability of the horse-drawn vehicle.

For haulage, the horse-drawn vehicle is represented by an average day's work of twenty-four miles, twelve miles loaded, twelve miles light; a working capacity of 18 ton-miles daily. Motor trucks carrying five tons, with 3½-ton trailer, or 8½ tons in all, are making trips of one hundred miles in a day. If the return trip is made empty, the daily capacity is 425 ton-miles. That is, the haulage capacity of the modern road is nearly twenty-four times as great as in the day of horse-drawn traffic.

In the case of passenger traffic, forty miles was a long day's journey for an ordinary driving horse, and with two in the carriage, was equal to 80 passenger-miles. This is comparable to the motor car travelling 325 miles in a day, with six passengers, and equal to 1,950 passenger-miles. Again, for passenger traffic, the capacity of the common road is twenty-four times as great as in the day of horse-drawn traffic. This increase of efficiency throws light on the great strides now being made in the building of roads through the open country.

Road Expenditures

In keeping with the increased carrying capacity of the highway, expenditures in construction and maintenance have largely increased. In Ontario, expenditure on rural roads in 1900 was about $2,000,000. annually. In marked contrast to this was the outlay in excess of $175,000,000. during the period 1912-1925. During the same period, 1912-1925, the adjacent province of Quebec spent $68,000,000. on roads; and all provinces of the Dominion have augmented their road expenditures in proportion to their resources.

The advanced types of construction in use, and the general results of the large expenditures being made, are indicated by the following schedule drawn from official sources, and giving the mileage of various surfaces on rural roads in Ontario and Quebec at the end of 1924:

Type of surface	Ontario	Quebec
	miles	miles
Gravel	24,624.12	4,088.16
Broken stone	3,052.00	627.47
Macadam with oil or tar carpet coat	617.26	946.31
Tar or asphalt penetration	551.32	138.03
Asphaltic concrete	450.91	62.53
Sand clay	none	145.43
Other surfaces	2.00	none
Total miles surfaced	29,297.61	6,007.93

In addition to the foregoing surfaced roads, Ontario has 22,470 miles of graded earth road, and Quebec, 16,000 miles. While these are the two leading provinces of the Dominion, other provinces have been putting forth a similar effort to improve road conditions in accordance with their requirements.

New Demands on the Road Surface

Before the coming of the automobile, the water-bound Macadam and Telford surface was regarded as a high standard of construction, for roads of the open country. In some portions of the continent, gravel was available, and was regarded as a useful, if less durable, substitute. The most damaging form of traffic, was the rutting effect of narrow tires, and the pounding of steel shod horses' hoofs. The Macadam was invariably "water-bound"; that is, bonded by a mortar of dust and water. This mortar was being continuously restored and re-cemented, by the grinding effect of steel tires, combined with nature's rain-fall.

But with the self-propelled motor vehicle, new conditions arose, in which the wear of horse-drawn traffic has passed into insignificance. This new form of destruction, was the dust, removing effect of the motor vehicle, which lifted and scattered the bonding material of water-bound Macadam, developing the road into a pitted surface of shallow holes, finally leaving it a ravelled mass of loose stone. This difficulty was first met in Italy and then in England, by covering the Macadam with a carpet coat of tar, and this system of surface treatment was later followed in England by tar penetration, then by other forms of mixed bituminous construction.

The motor truck came into being with the perfecting of the gasoline engine, and has increased steadily in numbers. Many of these were of abnormal weight, and required of the roads not merely an armoured surface, but augmented depth and strength of foundation to carry the increased load. The weight of trucks is commonly restricted by law, a weight of 14 tons being ordinarily adopted in the United States. In Ontario the maximum weight of a loaded vehicle is restricted to 10 tons, no axle to be loaded in excess of 7 tons, and no wheel in excess of 600 pounds per inch of tire.

The decline of horse-drawn traffic, and growth of motor traffic are indicated by the following census statistics at several stations on the Ontario provincial highways.

Windsor-Quebec bdy. highway	Daily average Horse-drawn vehicles	Total daily average all vehicles

Width of Highways

Increased traffic has naturally turned attention to the width of highways. Of this, there are two phases: (1) The width of roadway graded and paved for vehicular traffic; and, (2) the total width of highway allowance reserved for all purposes.

The latter of the two, the highway allowance, has been generally surveyed in Ontario, with a width of 66 feet, but this has been commonly encroached upon by fences of adjoining property owners, so that the width has been frequently reduced to from 50 to 60 feet. The road reservation of 66 feet, (one chain), appears to have been arbitrarily selected because of convenience in chain measurement by the surveyor.

The width of 66 feet was found by experience to be well adapted to conditions of horse-drawn traffic, before the day of universal telephone and telegraph service and intensive motor traffic. In Michigan, to diminish the blocking of roads by snow-drift, the main highways are being widened to 150 feet in the northern part of the state, and to 100 feet in the south where land is more expensive. In Ontario, many main roads now have a width of 86 feet which is markedly beneficial to winter traffic, and is a minimum width which will provide space for adequate drainage, telegraph and telephone wiring systems, permanent tree growth, and foot-paths, in addition to reasonable increase of vehicular traffic. The need of foot-paths is everywhere becoming apparent on main highways, but unfortunately, as on parts of the Toronto-Hamilton highway, their construction has been delayed because of insufficient space within the road allowance of 66 feet.

Provincial highways of Ontario are generally graded to a width of 30 feet between open ditches, with the central 20 feet paved for traffic. Modern methods favour the adoption of a width of 10 feet for each lane of traffic. Where a double lane is not sufficient, experience indicates that a three-lane width tends to unsafe conditions and accidents: and that increase from a two-lane width should be to a four-lane width, from 36 to 40 feet wide.

Surface of the Motor Road

European practice, and particularly that of England, has developed the use of tar and tar mixtures spread over the surface of old Macadam. These old stone roads, well settled and compressed under traffic, made an admirable base for such protective treatment. The use of asphalt in Europe was largely confined to bituminous limestone and sandstone, one of the best known deposits being that of Val de Travers in Switzerland. This material was ground to powder, heated, spread and rolled in a manner and with results similar to the artificial mixtures of the American continent.

On this continent, tar was adopted at an early stage following over-seas practice. But in addition, asphaltic pitch and asphaltic oils were similarly used with a growing measure of success. The cement-concrete surface for main highways originated on this continent. Indeed the use of pitch asphalt, asphalt oil, cement concrete, and even the well-maintained gravel road, are among the contributions of the American continent to the modern motor road.

Sheet asphalt was first used on this continent about the year 1870; an artificial mixture of sand and Trinidad asphalt based on the use of bituminous rock asphalts of Europe. In American practice the sand and asphalt were heated separately, intermixed, then spread over a strong foundation, usually of concrete, to a depth of two or three inches.

In adapting asphalt to main country roads, much was learned from the early use of sheet asphalt. For instance, many early pavements developed a rippled surface, and it was found that the grading of the sand was as important as the quality of the asphalt. The asphalt pavement crept into a wavy, distorted surface, and this was overcome by using an open binder course, with a dense mixture for a wearing surface. Asphalt on little travelled streets cracked and disintegrated, and it was learned that asphalt needed a certain amount of traffic to keep it ironed out. A suitable mixture was found necessary to meet extremes of temperature; one which would not become excessively soft in hot weather, and which would not be brittle under low temperatures.

Nearly coincident with the coming of the motor vehicle, was the introduction of what is now generally known as "hot mix", and "stone-filled" asphalt. This is comparable to a sheet asphalt composed of sand and bitumen, to which a limited amount of crushed stone is added, of diameter up to 1-inch or 1½-inch material. The crushed stone is intended to provide a less slippery and more durable surface. With this type of surface is associated the theory of maximum density of aggregate: that is, a pavement composed of stony aggregate from fine dust to coarse stone, and so graded that all interstices are filled with stony material, but each particle thinly coated with bitumen to bond it to its neighbours. The object was to make a compact mixture, impervious to moisture, and strongly resistent to the weight of traffic. These features were originally incorporated in a patented specification, but the essential patents having expired, the principles are in general use in "hot-mix" pavements.

It is distinctive of the ordinary form of sheet asphalt, and of "hot-mix", (which is now commonly known as asphaltic concrete), that they are mixed hot and immediately taken to the road to be spread and rolled while still heated. There is another form of asphaltic surface which is mixed hot, but by special treatment may be allowed to cool, and applied to the road in a cold condition. In England, one form of such a material is well known under the proprietary name of "Tarmac", a mixture of tar and slag. On this continent, a proprietary pavement known as "Amiesite", is of a similar character. It obtains its mobile quality when cool by the use of fine crushed stone, (in place of sand), which has been coated with kerosene before the hot asphalt is intermixed with it. Used for a number of years in the United States, the methods of manufacture in Canada, are bringing it into prominence as a pavement having exceptional and interesting qualities.

It is notable that in the early use of bituminous penetration, based on the tar Macadam of England, there were many cases of failure on this continent. Many of these roads were built in America as one work, comprising a new earth grade, a comparatively thin, (four or six-inch), stone base, and a two or three-inch wearing surface of broken stone, with tar or asphalt poured into the interstices. The inevitable failure followed, and bituminous penetration came in for much condemnation. The new earth grades settled, the thin foundations followed, surface depressions developed which held water, the road became rough, and was ultimately broken up by heavy trucks and fast motors, a traffic for which the road was not designed. American road-builders were slow to learn the lesson that success in England was largely due to the fact that the tarred surface rested on an old, well-settled road-bed, and that similar conditions must be created here before the bituminous surface would support traffic. Roads of this type in Ontario, have been created very largely by a process of development, the foundation being subjected to traffic for two or three years with carpet treatment, before the penetration surface is laid.

The concrete pavement as applied to main country roads, is purely a new-world development. A few cement-concrete pavements had been laid on town and city streets, prior to 1908, notably in Windsor, Ontario. These were of a two-course type, very similar to the concrete sidewalks which had been in common use for a quarter century. But it was in Wayne county surrounding the city of Detroit that the modern cement concrete pavement came into being. The distinctive features of the Wayne county work, were:

(1) A one-course mixture, the full depth of the pavement;
(2) A mixture rich in cement using proportions of 1:1½:3; whereas in ordinary concrete a mixture of 1:3:5 had previously been employed.
(3) Carefully selected, clean aggregates.

Experience with cement-concrete used in this way, to meet the needs of motor traffic, was little short of revolutionary in highway methods. It set standards of quality and cost, which have largely governed the use of all materials.

Since the early use of the cement concrete pavement, there has been considerable refinement in methods, and superior results are now being obtained. A notable advance was made as a result of extensive tests in the state of Illinois, from which a more scientific section was evolved to meet the needs of heavy truck traffic.

Sanitary Conditions on the Street

The horse has been largely replaced on urban streets by motor vehicles, except in a limited degree for draft and delivery purposes. Statistics for Ontario show that the number of horses owned on the farms has increased from 617,309 in 1900, to 644,138 in 1925; but their use is largely confined to farm operations. The extent to which the horse has been withdrawn from use on the road is indicated by the disappearance of the blacksmith shop from rural corners and villages, and in place of the smithy is the garage. Farmers are largely using the motor in place of the driving horse, and local centres on Saturday night are lined with cars, in place of the horse and buggy of twenty years ago.

Improved sanitary conditions are an outstanding result of the withdrawal of the horse from urban streets. The menace of offensive street dust has been greatly lessened. It is no longer necessary to permit a thick layer of refuse to accumulate throughout the winter, to be removed in the spring. The garage has taken the place of stables with their adjacent piles of manure. Filth-carrying flies have had their breeding places lessened in stables and on the streets. Much less street refuse reaches the sewage disposal plant, but the problem of oil waste has taken its place.

Street cleaning has become a much simpler operation, and the amount of refuse to be removed has been substantially reduced. The number of men composing the old "white-wing brigade" has been greatly lessened. The following statistics from Toronto are representatives:

Year	No. of men employed	Refuse removed cubic yards	Miles of paved street
1914	440	139,000	323.02
1924	138	75,000	446.41

That is, in 1914 one man was required for each three-quarters of a mile of pavement for street cleaning operations. In 1924, the average is one man for 3¼ miles. In 1914 the refuse removed from streets was 430 cubic yards per mile annually; in 1924, the amount was less than 168 cubic yards per mile, or about 39 per cent of that removed in 1914.

Distribution of Population

The combined influence of the motor vehicle, and radial electric railway, of recent years has tended to the wider distribution of city population in suburban districts, and to the growth of satellite towns surrounding large cities. Men of wealth, by means of the motor car, have been enabled to adopt a rural method of living in well-appointed country homes. Their offices and places of business are often in congested "sky-scraper" areas, but the distance from office to home is traversed night and morning in a motor car.

A more striking manifestation of this influence, however, is to be seen in the number of small houses which gradually dot the country side around large centres of population, and which as they accumulate, are gradually grouped under the term of "shack-town". This is a form of modern pioneering which is deserving of all encouragement. Working men who take their families into the suburbs of a city under such conditions, are not devoid of ambition, nor are they willing to live permanently in a shack. Rather they are men of courage who are willing to accept the inconvenience of a pioneer shack for a time, in order that they may ultimately own a good home. They first pay a deposit on a plot of land and build a shack on it. By thrift they become able to pay for the land, and then by their own labour, are able to commence the building of the house that ultimately takes the place of the shack. Soon they are owners of a home and garden, in open air surroundings, a home that tends to the well-being of a sturdy family. The history of "shack-towns" as a rule is that they develop into districts of comfortable homes for labouring men.

The labouring man employed in the city can do this because of the facilities of a radial line within easy reach; or because he can buy a second-hand car for $100., to carry him to and from work. Shack-town, and its tendencies, are part of the problem of town planning.

Influence on the Steam and Radial Railway

Modern highway traffic has had a marked influence on other forms of transportation, particularly on the electric radial and inter-urban railway and on the steam railway. There are numerous examples in Canada of electric railways which have succumbed to the influence of the motor vehicle, and the end is not yet. The eastern states show many similar examples, where electric railways are rusting in idleness, not a wheel turning. Even steamship traffic on the Great Lakes has been yielding to the same pressure. Steam railways are finding a serious inroad upon their receipts through the loss of short-distance travel and transportation. The situation is unfortunate both for the public and for the companies affected.

The disarrangement arises out of the growing use of the privately owned motor car, the motor bus, and the motor-truck. The citizen of Toronto, for example, desiring to do business in Hamilton, can step into his car at his Toronto office or residence, and drive directly to the office of the man he desires to see in Hamilton. In Hamilton he can drive from place to place at his convenience. He is not tied to the railway time-table, and there is no tedious waiting for delayed trains. He goes and returns rapidly, comfortably, and for these reasons the short-distance railway journey is forsaken for the private motor car.

The motor truck is carrying much of the milk, fruit, farm produce, merchandise, brick, steel, for short hauls in competition with steam and electric railways, and lake transportation. Distances up to and exceeding 100 miles are covered in this way by the motor truck.

The reason is not that the motor truck, in actual mileage costs, is cheaper than the railway. On the contrary, the motor truck in straight running cost is not and never can be a competitor of the railway. But railway terminal costs are high, while the motor truck has practically no terminal charges. Delivery by truck is from door to door, costs of rehandling are eliminated, and delivery is made by the truck in one-third to one-half the time required by the railway.

The motor bus traverses the main highways, stops at gate-ways, the better class of busses are enjoyable to drive in, and to them electric railways are yielding much of their former revenue.

The president of the New York, New Haven and Hartford Railway has estimated on the basis of carefully ascertained statistics, that in the state of Connecticut in 1922 there was a potential loss to his railway of over $21,000,000. from the competition of the privately owned motor car, the motor truck and the motor bus. The case is no doubt extreme, but is indicative of the influence of motor transportation.

Railway companies have pointed to the low rate of taxation applied to motor trucks and motor busses, and the advantage they enjoy of the comparatively free use of the highway, while railways have their tracks to build and maintain.

On the other hand, the public reply that railways have been largely subsidized, — sufficiently in most cases to build their tracks. Also, that the citizen who pays taxes for the building of highways, is as much entitled to the benefit of cheap use of these highways by the truck he hires, or the bus he patronizes, as is the owner of a private car or truck.

The writer is of the opinion that the difficulty of the older transportation companies cannot be successfully met by any attempt to tax the truck or bus off the road. This principle, if generally applied, would mean the end of all progress. The situation is unfortunate, and until it is adjusted, inconveniences must necessarily arise.

The public are not always benefited by these changes. For example the well-heated electric car is more reliable, and is preferable for winter traffic. During January, February, and portions of December and March, at least three months of the year, steam railway and electric transportation are desirable, and in many cases a necessity. Yet the best service cannot be given by these, if service can be given at all, without a continuous patronage of the public throughout the year. Indeed many electric railways were formerly operated at a loss during the winter, for the sake of the profit of heavy summer traffic. The public need the winter railway service, but they cannot have it because of having withdrawn their summer patronage.

The solution may not be so much one of eliminating competition by arbitrarily adding to the cost of highway transportation, as one of increasing the service which steam railways can perform. Also there may be necessary, a clearer recognition of the respective fields in which the motor bus and the radial railway should be encouraged to function. It is long since steam railways have succeeded in materially reducing terminal costs, or lessening terminal delays, and in this an opportunity would seem to lie. The radial railway can best function in providing fast transit from satellite towns to a large urban centre, carrying passengers to the business hub at a speed and with convenience which private cars and motor busses cannot materially surpass. It is to be emphasized that the function of the radial railway is not that of a rural street railway. The "rural street railway" suggests frequent stops, and therefore slow service. The radial railway is essentially suited to fast inter-urban traffic, rapidity of service must be provided, and to this end frequent stops must be eliminated. Nor can inter-urban passengers be successfully dumped at, or taken from the terminus of a city street railway. To do so is to invite well-merited failure. If the electric radial railway is to co-operate with the facilities of the modern highway, rapid transit must by some means be continuous to and from the urban centre. Having determined economic limitations, suitable restrictions can be applied, to the advantage, not to the detriment, of the public. Co-operative rather than competitive measures are needed.

Future Development

"We judge of the future by the past." This brief outline of some phases of the highway situation has had its origin in a wish to suggest the possible lines of future development, rather than to assume the role of a prophet in regard to them. It is scarcely reasonable to assume that, in the brief period in which the gasoline engine has been in effective use on the highway, a maximum of efficiency has been reached on the part of the vehicle. As vehicle efficiency increases, as their number grows, the highway will be enhanced in economic value. Highway research is in progress, but is scarcely more than in its infancy. The field is new and the possibilities of the development of new ideas, and the more scientific application of old, are everywhere apparent. It is still a field in which much progress may be anticipated.

Some Phases of Industrial Relations

Homer E. Niesz,
Manager of Industrial Relations, Commonwealth Edison Company, Chicago.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 29th, 1926.

Industrial Relations in its simplest form is the relation between men and management,—the human relation in industry,—sometimes called "Human Engineering".

The usual conception of engineering in its broad sense is that of an exact science governed by definite laws and reasoning from cause to effect and from effect to cause. Human engineering may be considered a science, but it is far from exact. It deals with the minds and motives of men and the problems are more involved because of the many unknown quantities entering into the equation.

The solutions of these problems are as varied as the human element which is the principal factor to be considered first and always in every organization of men in industry.

A thorough, systematic, and continuous study of the wants and needs of men is a prerequisite of proper and intelligent administration of "Industrial Relations".

The medium through which this administration is carried on may vary as the type of management organization varies in different concerns but there should be, especially in every large company a definite unit of organization having charge of this important function. This unit is frequently called the Industrial Relations Department or Personnel Department.

The function of an Industrial Relations Department has been aptly expressed as "the direction and co-ordination of the human relation of any organization with a view to getting the maximum necessary production with a minimum of effort and friction, and with proper regard for the genuine well-being of the workers".

A department having such purposes and duties is essentially a "staff' unit of organization, although there are some elements of "line" duties which are, generally speaking, of a character pertaining to a "service" department. An Industrial Relations Department has therefore the functions of; advisory service to the management in the preparation and adoption of employee relations policies, responsibility for the administration of those policies, and a personnel service to the line organization to promote the ultimate successful operation of all the elements entering into these manifold and important relations.

Notwithstanding the extent to which the Industrial Relations Department may function in its administrative capacity, it must be constantly borne in mind that the final responsibility for any successful plan of employee relations rests fairly and definitely on the line organization. It is an integral part of operations and must be handled as such by those having responsibilities of management and supervision of men. It constitutes a major problem of administration and is of vastly greater importance than machinery or materials. It is essential that all executives, both major and minor, are well versed in the elements and principles of personnel policies, and it is no small part of the duties of those in charge of Industrial Relations Departments to thoroughly "sell" the entire supervisory force on the whole plan under their administration, not only as to fundamentals but as to details of operation. I wish to emphasize the necessity for proper attitude of mind and full understanding of the objectives of these policies on the part of those who are in charge of the working force. This particular phase of the subject is of special interest to engineers and engineering students for the reason that, if the estimate made by the dean of one of our engineering schools is reasonably accurate, 75 per cent. of the graduates of engineering schools subsequently occupy positions of an adminstrative character and are leaders or advisors of large groups of men. Engineers should therefore prepare themselves for these responsibilities by acquiring a knowledge of the fundamentals of industrial relations, preferably in my opinion, as a part of the curricula in engineering colleges.

The question of whether, and how much this subject should have a place in engineering courses has been much discussed both by industrialists and by deans and professors in our engineering colleges. Whatever policies may be followed in this connection in the various colleges, which will differ according to the weight given to this subject in its relation to other subjects, there is evident a growing tendency to give a place in engineering college curricula to the fundamentals of industrial relations as an important phase of management to which so many engineering students and engineers aspire and attain.

In order to present more clearly the various phases of industrial relations and the functions of the department responsible for the development and carrying out of personnel policies, I desire to outline to you the specific undertakings now in operation in the Commonwealth Edison Company, a public utility employing about 9,000 people supplying electricity in the city of Chicago. In citing our own experiences it is not intended to convey the impression that our plan is the best or that it should be followed by other companies. Each one should decide for itself what policies should be adopted to provide for its particular needs.

The Industrial Relations Department of the Commonwealth Edison Company was established January 7th, 1921, headed by the manager of industrial relations reporting to the president. To the manager was specifically assigned the administrative responsibility for developing and carrying out a comprehensive personnel and employment policy in the company service, and for the management of the units of the company organization performing functions of personnel adminstration. He is also responsible for co-ordinating the work of these units of organization and the personnel activities of company committees and employees' associations. The heads of departments were "directed to co-operate with the manager of industrial relations in such manner as to aid in the accomplishment of the purposes for which this department has been established in our organization".

The specific functions of the department may be divided into three parts: 1—Administrative functions, which include the operation of the Employment Division, Medical Division, Safety Division, Education and Training Division, and the Employees Service Division. 2—

Co-operative functions having to do with various employee activities, which include the Employees Representation Plan, the Edison Club, the Edison Symphony Orchestra, Edison Round Table, Lake Lawn Vacation Resort, Employees Suggestion System, Good-Will Service System, Commonwealth Edison Post, American Legion, two Companies in the Illinois National Guard, the lunch room, and recreation rooms for men and for women. 3—Thrift, insurance and service annuity plans, which include the Commonwealth Edison Mutual Benefit association and the company's plan of co-operation therewith, Group Insurance, Employees' Savings Fund, Building Loan and Savings Association, and the service annuity system.

Administrative Functions

Under the first division of administrative functions, while not attempting to enumerate the detailed duties and responsibilities of the divisions of the department, the scope of each of them may be summarized as follows:—

Employment Division:—Recruiting, interviewing, testing, selecting, and placing of new employees; arranging transfers and promotions, reviewing separations; classifications of employees, job specifications, wage studies, and employees' records.

Medical Division:—Conducts physical examination of all applicants for permanent employment and for membership in Mutual Benefit Association, also semi-annual physical inspection of all employees. Furnishes surgical and medical attention to employees injured while on duty, and emergency health service on request. Compounds medical and surgical supplies, conducts first aid classes for Safety Division, also maintains visiting nurse service.

Safety Division:—Conducts safety meetings, instruction in first aid, resuscitation and rescue methods and maintains safety bulletin service; receives and handles through committees safety suggestions made by employees; inspects tools, materials and equipment, methods, rules, specifications and properties; maintains records and statistics of accidents, time lost and analysis of accidents; inspects physical properties and fire apparatus and conducts fire drills.

Education and Training Division:—The principal educational work is conducted for the department by the Chicago Central Station Institute, and consists of courses for technical students and graduates of universities; special classes for instruction and training of employees in various departments; correspondence courses; special training of salesmen; and classes in National Electric Light Association courses. In addition there is, of course, much specific job training carried on in the departments, and we have recently started a course of training for public relations in the departments having employees who have frequent contact with customers and the general public. This training is being carried on by the case method in groups of twenty or twenty-five employees.

Employees Service Division:—The functions of this division are the administration of relief and aid work; disability and death benefits, (exclusive of those covered by workmen's compensation), under the company's plan of co-operation with the Mutual Benefit Association; the office of the Edison Club; the group life insurance; co-operative buying; employees publications; and miscellaneous service for employees.

The "Dean of Women is reponsible for promoting the well-being and representation of the women employees. She administers all employment activities for women employees and has charge of the company library and the lunch room.

Co-operative Functions

We believe in the policy of encouraging self-expression, self-development and ambition on the part of employees, and that participation in these various employee organizations will be of material benefit to them, not only in their daily work but in the fulfillment of their responsibilities as representatives of the company in their own communities and as citizens. It has been said that "the greatest source of undeveloped power in America is the soul of man". With this thought as the incentive, and because it is good business and not altruistic or partaking in any sense of paternalism, these employees' activities have been encouraged and developed:

Employees Representation Plan:—The motive actuating the establishment of the plan is definitely expressed in the following Premable to the Constitution: "We, the employees, the management, and the directors, of the Commonwealth Edison Company, realizing that in a large organization it becomes increasingly difficult to maintain the close personal contact between the employees and the management, which was possible in our organization when it was smaller, and desiring to continue and develop the mutual understanding and harmonious relations which have prevailed in the past, do hereby jointly adopt the Employees Representation Plan provided for in this Constitution".

The specific objects of this Employees Representation Plan are: (1) To establish a medium which will serve as the equivalent of the close personal contact between those of all ranks in a smaller organization, by affording opportunity for elected representatives of the employees and appointed representatives of those having responsibilities of management to meet frequently for the purpose of free and frank discussion of problems of mutual interest to the management and the employees. (2) To furnish by such medium a definite channel through which the employees individually or collectively, and either personally or through representatives, may take up with the management for discussion and recommendation, questions in reference to rates of pay, hours, conditions of work, or any other subject of interest to them as employees. The general objects are: (1) To promote mutual understanding, harmony and a spirit of co-operation among those of all ranks in our company organization. (2) To insure fairness and justice to the employees, the management, the stockholders and the public.

The Edison Club was organized to promote the friendly acquaintance of all Commonwealth Edison Company employees. The club fosters the "Edison Spirit" among its members through social and recreational good times and activities, to the end that their mutual relations shall be the happiest and most harmonious, and that active goodwill for and from the public shall continually increase. Big "good-time" party meetings are held during the year with an attendance of four to five thousand members and their friends. Other social gatherings are limited to members only. Twice during the year, at Christmas and at the Field Day merrymaking, the parties are open to all employees and members of their families. Any permanent employee of the company is eligible to membership in the club, and the dues are one dollar and a half per year. The company contributes very liberally to the support and maintenance of the various social, recreational and educational activities carried out by this employees' organization. The following are the principal recreational activities in which club members participate: Baseball league, bowling league for men and for women, billiard league, chess and checkers league, rifle league, basket ball league, tennis league and golf.

Seven handsome silver trophies have been donated by President Insull to be competed for each year by members or teams of the following leagues: bowling, base ball, golf, billiards, tennis, rifle shooting and revolver shooting. Medals are given to the winners of the individual cups and to the members of the winning teams each year, the names of the individuals or team winners being engraved on the trophies.

The Edison Symphony Orchestra, starting in 1910 as a group of fifteen amateur musicians in the company, has developed to an organization of one hundred, having complete properties and one of the largest musical libraries in Chicago. The orchestra gives a series of monthly popular public concert, each year in Orchestra Hall in the interest of civic music, and through this and other public appearances has become well known to music lovers and is considered to be the largest and finest orchestra supported by a corporation anywhere. The orchestra is under the supervision of the manager of industrial relations.

The Edison Round Table:—The Company issues and distributes to employees the Edison Round Table, which is the official organ of the Edison Club and contains accounts of all meetings and activities of the club and its various sub-organizations. It is also the company house organ and disseminates general knowledge about the business and policies of the company and news of the activities of individual employees and of organizations whether or not included in the Edison Club. Copies are sent to the departments and distributed to all employees interested.

Lake Lawn Vacation Resort:—About three years ago the Commonwealth Edison Company, together with the Peoples Gas Light and Coke Company, and the Public Service Company of Northern Illinois acquired property on the shores of lake Delavan, Wisconsin, where facilities are provided for employees to spend their vacations. These facilities include hotel service and cottages equipped for house-keeping purposes, where employees may secure accommodations according to their means and have the opportunity of enjoying a vacation under ideal conditions at a reasonable cost. The recreational facilities afforded include boating, bathing, fishing, tennis, base ball, golf and dancing.

Employees Suggestion System:—For the purpose of furnishing an incentive to employees to give closer attention to the various problems that arise in connection with their daily work or the general operation of the company, a revised "Suggestion System was adopted in February, 1925, which provides substantial awards in cash for valuable suggestions and in proportion to their value. During the ten months this system has been in operation 3,274 suggestions have been received and the total cash awards amounted to $3,267.50. The largest award for any one suggestion was $500.00 and the average $10.15.

Good-Will Service System:—This was established in June 1924 for the purpose of providing a systematic means for employees to report to the management any requests for information or any criticism of the company or its service received by the employee, while at his work or off duty. This information is transmitted to the proper department and is followed up to be sure it receives prompt attention. This system has proven to be a worth while addition to the mediums adopted for giving better service and improving public relations.

Commonwealth Edison Post, American Legion:—The company encourages and assists the Commonwealth Edison Post of the American Legion which has a membership of 1,100 and is the largest in the state.

Illinois National Guard:—The company has encouraged membership by its employees in the Illinois National Guard and sponsors one Company of Infantry and one Company of Engineers made up, officers and men, of Commonwealth Edison Company employees.

Lunch Room:—The company maintains a lunch room in its main office building and in each of the large generating stations where employees may obtain good food at reasonable cost.

Recreation rooms are provided in the Edison building for the men, where facilities for chess, checkers and other table games, including billiard and pool, are available during the noon and evening hours. A recreation room is also provided for women employees where various activities, which include millinery and dressmaking classes are carried on.

Thrift, Insurance and Service Annuity Plans:—The average wage earner has three principal causes of worry. (1) What will happen in case he is disabled through sickness or accident and is deprived of his usual compensation. (2) What will happen to his dependents in the event of his death. (3) What will happen when he becomes too old to continue work. These worries are ever present and increase as the individual's responsibilities are increased; therefore the desirability of insurance and thrift plans as a means of eliminating these worries becomes a question of paramount importance for the peace of mind and the efficiency of the workers.

The Commonwealth Edison Mutual Benefit Association, a voluntary organization of the employees, was formed as a co-operative society to provide at the least possible expense, income during periods when incapacitated for duty by illness or accident and, in the event of death, to provide benefits for their dependents. Any permanent employee who has been with the company six months or more is eligible for membership subject to his acceptance on physical examination.

Dues and benefits:—Members pay as dues a small percentage of their straight time semi-monthly pay, this rate increasing with member's age. After the first week of disability, benefit payments are made by the association during the continuance of the disability, (not exceeding two years) varying from 50 to 10 per cent. of the employee's rate of pay. Death benefit payments are made by the association equal to one-half of the member's annual pay. All funds and payments are guaranteed by the company.

Co-operation by the Company:—Under the company's plan of co-operation with the Commonwealth Edison Mutual Benefit Association all disability benefits allowed employees under the rules during the first week of disability are paid by the company. Disability benefits in addition to those paid by the association, in cases extending beyond one week, are also provided for members, in certain cases equalling one-half and in other cases the full amount paid by the association. The periods of continuation of such disability payments are based on length of service. Death benefits are paid by the company, to beneficiaries of members, based on length of service, ranging from 10 per cent. of the annual salary, (not in excess of $3,000), for one year's service to 100 per cent for fifteen years of service, and 1 per cent. additional for each year in excess of fifteen. The plan of co-operation also provides payment by the company of disability and death benefits for employees who are not members of the Mutual Benefit Association equal to one-half of those paid by the company to members.

Group Life Insurance:—In December 1922, acting on a recommendation of the General Joint Council under the Employees Representation Plan, the company presented to its employees life insurance policies under the group insurance plan in place of the Christmas remembrance previously given to employees in the form of a turkey. Under this group insurance plan every employee who has been with the company one year automatically receives an insurance certificate for $500 under the company's group policy on the first anniversary of his entering the company's service, and thereafter the amount of his insurance under the plan increases in accordance with the following table:

12 to 18 months	$ 500
18 to 24 months	750
2 to 3 years	1000
3 to 4 years	1200
4 to 5 years	1300
5 to 6 years	1400
Over years	1500

The company pays the entire cost of this insurance, which is in addition to and independent of all benefits under the Commonwealth Edison Mutual Benefit Association and the company's plan of cooperation therewith, and also of any compensation to which the employee may be entitled under the Workmen's Compensation Act. Every employee is eligible without physical examination and regardless of age, or kind of work in which engaged. Each individual policy is payable to the beneficiary named by the employee. Service annuitants also are included in this plan.

Shortly after this plan became effective a number of employees desired to purchase additional insurance under the group plan and in pursuance of this suggestion an arrangement was made with the insurance company to write a supplementary policy covering all employees who desired the additional group insurance for an amount equal to the amount presented by the company under its original policy at Christmas time.

The amount of life insurance in force, including that provided by the Mutual Benefit Association, and the company's plan of cooperation therewith, is approximately $12,000,000. The amount provided under the group insurance policy paid for by the company and the additional group insurance paid for by employees is approximately $15,000,000, or a total of $27,000,000 of life insurance which is a little over $3,000 per employee. The total amount of life insurance payments made during the year 1924, for 46 deaths, was $182,000 or approximately $4,000 per deceased employee. There was paid out in disability benefits under the Mutual Benefit Association, and the company's plan of cooperation therewith, $131,000, of which $49,000 was paid out by the Mutual Benefit Association for disability after the first week and $26,000 by the company. In addition to this $105,000 was paid out by the company for disability lasting less than one week.

Employees' Savings Fund:—For the purpose of encouraging thrift and of giving employees an opportunity of becoming stockholders in the company, the Board of Directors, on January 15th, 1909, adopted a plan for the creation of an Employees' Savings Fund. Under this plan any permanent employee of the company, who has been in its continuous service for a period of one year or longer may become a subscriber and shall pay into the fund, in semi-monthly installments, an amount equal to three or five per cent of his salary, as he may elect. The full subscription period is five years. At the end of this period the subscriber, (or his estate), will receive the total amount paid by him to the fund, with interest compounded semi-annually at the rate of 6 per cent per annum, either in cash or in stock of the company at $110 per share. In case of prior termination of payments, because the subscriber leaves the company's service or is discharged, the accumulated payments with interest as above stated will be paid in cash; but if the subscriber elects to discontinue his subscription agreement while still in the employ of the company the interest rate will be reduced from six to four per cent. This plan enables employees to obtain stock of the company at a price materially below the market value of the stock, and at the same time provides a plan for systematic definite savings. As a result of the operation of this plan and through other mediums about 6,000 or over two-thirds of the total number of employees are stockholders in the company.

Commonwealth Edison Building Loan and Savings Association:—This association was organized by the employees in February, 1923, under the Building and Loan Association laws of the state of Illinois. It provides a medium for systematic saving in any amount the employee desires according to the number of shares he may subscribe for. The money paid in by employees is loaned to those desiring to buy or build homes. About 1,800 employees are shareholders of whom 155 are borrowers. A total of $600,000 has been loaned to these employees for the purpose of financing their own homes.

Service Annuity System:—In order to make some special provision for faithful employees who have completed certain periods of service, the company adopted a Service Annuity System effective January 1st, 1912. Under this system employees who have reached the age of 60 years may be retired, and at the age of 65 are automatically retired, unless in special cases the committee having the operation of the plan in charge continues the employee in active service. The annuity is based on the number of years of continuous service times 1½ per cent. of the average annual pay of the employee during the highest five years. This annuity is paid by the company, the employees do not contribute to the plan.

Recognition for continuous service is given in the form of service badges with appropriate decoration for each five years of service or multiple thereof. At the end of 1925 there will be in the hands of active employees 3,295 service badges indicating five or more years of service. There were 5,822 employees in the service as of December, 1920, five years ago, and the percentage of the employees then in the service who are remaining after five years is 56.6. The company takes pride in the large number of its employees who have long records of faithful service and these employees likewise take a proper pride in their service records.

When the active period of service has expired, the employee is transferred to the Service Annuity Payroll. It is a mark of distinction and it is considered that the employees have earned by virtue of their long continued service, not as deferred payment for services rendered, a place of honour in the ranks of the service annuitants.

In conclusion:—Mutuality of interest on the part of the employee and of the company is an essential feature of the success of all the employee activities, and the company's part in connection therewith, including recreational, educational, social, thrift and insurance. All of them are voluntary so far as the employee's participation is concerned.

The success of any comprehensive plan of industrial relations depends upon the feeling which must come from within the employee creating the desire for better things and a better standard of living and a happier state of mind in his work. The attitude of management in the operation of such a plan is equally important and must include the elements of frankness, sincerity and the underlying principles of a square deal for all concerned.

The company firmly believes that its policy of a centralized Industrial Relations Department; of giving the employees a voice in their own affairs through the Employees Representation Plan; of fostering and promoting recreational, social, and educational activities; of encouraging thrift and stock ownership; of aiding in the provision for adequate protection in case of disability or death; and of providing a service annuity for old age; has materially increased efficiency, augmented loyalty, encouraged continuous service, improved public relations and has developed a happy and prosperous Edison family.

Reduction of Flexural Stresses in Fixed Concrete Arches

J. F. Brett, A.M.E.I.C.,
Designing Engineer, Montreal Water Board.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

The fixed masonry arch is a statically indeterminate structure affected by three external redundant conditions depending on the elastic properties of the material or materials of which the rib is made.

The essential difference between an arch and a beam is that in the case of the arch moment stresses due to the direct loading could be suppressed by selecting the curve of the arch axis so that the resultant thrust would pass through the center of gravity of the sections through the arch. Furthermore, because of the redundant conditions depending on the elasticity of the materials, the stresses due to the elastic deformations must also be suppressed in order to obtain a fixed arch free from bending moment stresses.

The first part of the problem of reducing the flexural stresses to a minimum which involves the designing of the arch axis so that it will coincide with the equilibrium polygon of the loads, is treated in this paper under the section on determination of the arch axis. The principle involved is accepted as the rational basis of design for arches to-day.

European arches have been designed in accordance with this principle since the beginning of the development of concrete arches in the latter part of the last century. Important modern American arches planned by specialists in the art are designed in the same manner, but it is to be regretted that the necessary data have not been made available to the engineering profession at large in this country. Most of the treatises on reinforced concrete construction contain a thorough discussion on the analysis of the stresses in arches by the elastic theory, together with worked out examples of calculations, but the matter of the design of the arch axis itself has in most cases received scant attention.

The second part of the problem of reducing the flexural stresses in arches relates to the elimination of those stresses due to the elastic deformation of the structure. This matter has received a great deal of attention in Europe and the underlying principle has been embodied in the design of arches during the last twenty-five years. The practice, however, has not yet been adopted in America, although its importance has been fully acknowledged by leading American engineers. In his treatise on "The Kinetic Theory of Engineering Structures", David A. Molitor refers to the elimination of flexural stresses due to elastic deformations as follows: "If an arch ring could be built in such a manner that its resultant polygon would pass through the center of the ring at the crown and springing points at the time of releasing the false work, a large proportion of the redundant stresses could be eliminated. In other words, the bending moment at the critical points would then be almost zero for symmetrical loading, reserving the strength for the unsymmetric live load and other contingencies affecting the shape of the arch ring".

Two different methods making it possible to obtain large reductions of flexural stresses are in use at the present time in Europe. The first method consists of providing temporary hinges at the skewbacks and at the crown during the period of construction until the arch is fully loaded and the rib shortening effect due to the shrinkage has taken place. Subsequent to the filling of the hinge gaps the arch becomes fixed. The usual type of temporary hinge consists merely of reinforcing bars, the device being known as semi-hinge construction.

In "Reinforced Concrete Construction", Vol. 3, George A. Hool makes the following statement: "The use of hinges and hinged construction of any type in connection with concrete bridge construction is still in its infancy in the United States, although it is one of the most important features or devices which has ever been introduced in concrete bridge construction".

Semi-Hinges

As examples of the best types of semi-hinges, those of Considère, Mesnager, and Freyssinet may be mentioned.

The Considère hinge has been successfully used throughout Europe for over twenty years by the Con-

Figure No. 1
Reinforced Concrete Bridge at St. Pierre du Vouvray crossing the Seine River, France. The Arch of the Bridge is 430 feet in length, and in the centre it reaches a height of 90 ft. above the water.

sidère Construction Company, whose activity as bridge builders is well known.

The Mesnager hinge, due to Augustin Mesnager, member of the French Institute, and Inspector-General of the French Department of Ponts et Chaussées, is fully described in this paper. The construction is very simple and the eccentricity of the resultant remarkably low. The Mesnager hinge has been successfully used in the following structures:

Arch covering over St. Martin canal, Paris, carrying a heavy earth fill across a clear span of 91 feet. The length of the arch covering is about 800 feet.

140-foot span arch over Canal St. Denis, Paris.

Sapiac bridge, Montauban, one arch of 175-foot span and one of 185-foot span.

Noce bridge, Truchino, Italy, one arch 100-foot span.

Airship hangar at Montebourg, France, span 82 feet.

Reinforced concrete hall in Lausanne, Switzerland, span 115 feet.

The Freyssinet hinge, details of which are also given in this paper, is a more recent feature of arch construction and is particularly adaptable to long spans, its limiting thrust carrying capacity being well over 200,000 pounds per lineal foot. The Freyssinet hinge was used by its originator at the Boutiron bridge, near Vichy, France. This bridge consists of two concrete arches of 223 feet and 238 feet respectively. The crown thickness of the center span is 21 inches and the thrust on the hinge is 218,000 pounds per foot.

Elastic Deformation Effects Reduced

The second method of reducing the flexural stresses has been developed by M. Freyssinet and has resulted in the creation of new standards of proportions for concrete arch bridges. Briefly stated the method consists of adjusting the position of the arch axis and compensating its length after erection by means of hydraulic jacks placed in a gap left in the rib at the crown. In other words, by applying a set of external forces of chosen intensity to the rib, the latter may be placed in any desired state of equilibrium. By introducing concrete slabs of proper thickness in the gap opened at the crown by the pressure of the jacks the arch is held in the desired position. A detailed outline of the method is given in this paper.

The method of rib compensation has been tried out for fifteen years and found entirely successful. Besides the large reduction in cross section of arch ribs obtained, the method developed by M. Freyssinet renders possible the construction of very much longer concrete arch spans than could be heretofore contemplated.

M. Freyssinet states that by the use of his method, and under the 1916 regulations of the French Department of Public Works, plain concrete arches of 1,115-foot span and reinforced concrete arches of 2,723-foot span can be constructed without special difficulties.

A list of the more important bridges designed by M. Freyssinet where his compensating method has been used follows:

St. Pierre du Vouvray bridge, over the Seine River, concrete arch of 430-foot span, the longest concrete arch in the world yet completed.

Plain concrete arch of 315-foot span over the river Lot at Villeneuve, France.

Three-hinged triple spans of 223 feet, 238 feet, and 223 feet over the river Allier near Veutre, France, and a like structure over the river Allier near Boutiron, France.

In the fall of 1924, construction work started on another concrete arch bridge designed by M. Freyssinet which will outdistance the St. Pierre du Vouvray bridge by some 200 feet. It is the Plougastel bridge, near Brest in Brittany, with three record breaking spans of over 600 feet. The tendered price for this arch was 7,340,000 frs. while the lowest bid for a steel bridge was 11,360,000 frs.

The designer of these bridges has also won the competition for the construction of the Viaduct du Bernard which involves a main arch of 560 feet, carrying a meter gauge railway track. It is stated by the designer that the ribs of the Bernard Viaduct would only be sufficient for a 330-foot span if the ordinary method of construction had been adopted.

Reference is often found in American engineering literature to the slender proportions of European arch bridges compared to those built in this country, although it is generally acknowledged that the European engineer is at least as conservative as his confrere on this side. The difference is certainly not due to the method of the analysis based on the elastic theory, which has been highly developed in this country. The writer believes that the difference is due to the fact that methods or devices whereby the flexural stresses in fixed arch rings may be reduced have not yet been investigated in this country.

Determination of the Arch Axis

The problem of making the arch axis coincide with the equilibrium curve of the loads upon the arch must be solved by successive approximations. The data usually given will fix the span and the rise within narrow limits and permit the complete design of the floor system. The size and the position of the arch ring, however, are depending on the yet unknown equilibrium curve and must be assumed.

The weight of either the earth filling, in closed spandrel, or of the supports, in open spandrel, and the weight of the ring will vary with each approximation.

The equilibrium curve is a function of the load and a first approximation of the curve may be made if the limits of the possible load variations over the span are established.

Consider the hypothetical case of a uniform load distribution. It is required to find the shape of the arch axis so that the pressure is uniform over all normal cross-sections. The span l and the rise f are given, also the uniform load w. What is the position of a point A through which the equilibrium curve will pass? The vertical reactions are equal to $\frac{wl}{2}$, and if the distance of A to the origin O of the curve, on the horizontal axis is X, the moment of the vertical reaction about X is $\frac{wlx}{2}$. If H is the horizontal thrust, Hy is the moment of the thrust about A. This moment acting counter-clockwise is negative, remains the moment of the load between O and A which is equal to $-\frac{wxx}{2}$ acting in the same direction as Hy.

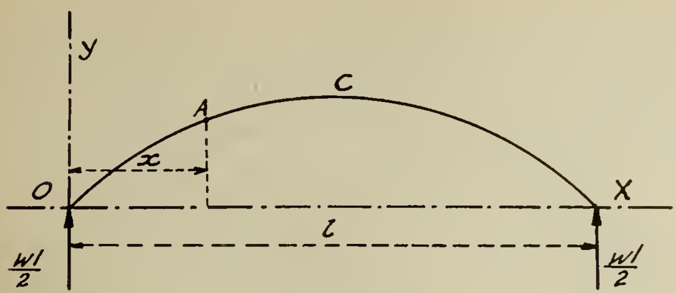

Figure No. 2

We have then: $\frac{wlx}{2} - Hy - \frac{wx^2}{2} = 0$ ....(1)

Solving for the crown thrust, $H = \frac{wl^2}{8f}$ ....(2)

Placing this value of H in (1), the ordinate at any point is

$$y = \frac{4fx}{l^2}(l-x) \qquad (3)$$

Equation (3) is the equation of the parabola.

If we transfer the origin to the crown the equation becomes

$$y = \frac{4fx^2}{l^2} \qquad (4)$$

If the load at the springing became infinite the equilibrium curve would be a circle. The radius R of a circle passing through the crown and the springing points of the same parabolic axis may be found from the property of the semi-circle. In figure No. 3 the semi-chord $\frac{l}{2}$ is a mean proportional between the two segments f and $(2r)-f$ of the diameter.

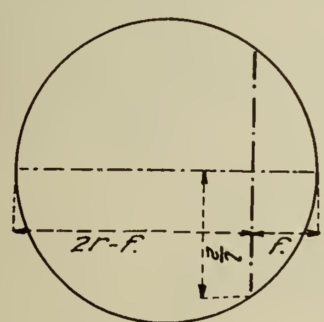

Figure No. 3

Whence, $\frac{l^2}{4} = f(2r-f)$

from which, $r = \frac{l^2}{8f} + \frac{f}{2}$ ....(5)

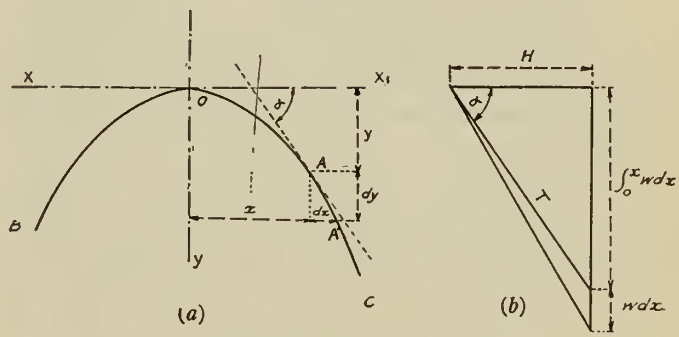
The equilibrium curve sought will lie between these two curves and a first approximation of the arch axis may be made between these limits. Assuming that a design based on the first approximation indicated above has been made and the loads taken off, then the analytical method of finding the equilibrium curve may be applied in order to obtain the true curve corresponding to the given load system. If the true curve does not coincide with the one selected in the first assumption, the design is revised, the axis of the ring is made to fit the equilibrium curve, the loads taken off the revised design and compared with those previously found. The equilibrium curve corresponding to the revised load system is determined, the loads compared, and the process repeated until sufficient accuracy between the load system and the resulting equilibrium curve is obtained.

Determining Equilibrium Curve Analytically

If we consider a linear arch loaded with a distributed load, the equilibrium curve may be found analytically as follows:

Let w equal the load per unit of horizontal distance, H, the crown thrust, T, thrust at any point A with coordinates (x, y) with respect to the horizontal and vertical axis through O.

The total load on the arch between the crown O and the point A is equal to $\int_0^x w\,dx$



Figures Nos. 4a and 4b

If α is the angle between the horizontal axis $o\,x$ and the tangent at A,

$$\tan\alpha = \frac{dy}{dx} = \int_0^x \frac{w\,dx}{H} \qquad (6)$$

If A' is a point on the curve whose co-ordinates are $(x+dx)$ $(y+dy)$ the increment in $\tan\alpha$ between A and A', is equal to:

$$d\frac{dy}{dx} = \frac{w\,dx}{H} \text{ or } \frac{d^2y}{dx^2} = \frac{w}{H} \qquad (7)$$

which is the equation of any linear arch whose axis coincides with the equilibrium curve of the load.

The results found above for the parabolic shape may be readily obtained by integrating (7).

Since $\frac{dy}{dx} = 0$ when $x = 0$, $\frac{dy}{dx} = \frac{wx}{H}$.

Integrating again, $y = \frac{wx^2}{2H}$, since $y = 0$ when $x = 0$......(8)

When $x = \frac{l}{2}$, $y = f$ and (8) gives $f = \frac{wl^2}{8H}$

Solving this last equation for the crown thrust, we get $H = \frac{wl^2}{8f}$ which is identical with that found in (2).

The thrust at any point is found from the triangle of forces, figure No. 4b,

$$T = \sqrt{H^2 + (wx)^2}.$$

When, as it is the case in practice, the load w is not uniform per unit of horizontal distance, but increases from the crown to the skewbacks, the equilibrium curve may always be obtained by this method providing w can be expressed as an integrable function of x.

Transformed Catenary Form

If it is assumed that the value of w between the crown and the skewback is proportional to the ordinate from the arch axis to a horizontal line XOX, at some distance d above the crown, the equilibrium curve of such a load system is the transformed catenary.

The distance d represents the intensity of the crown load and the distance Y, the increased intensity which occurs between the crown and the skewback. In order to obtain such a load distribution, the following assumptions must be made.

(1). In solid spandrel construction, the weight of the filling must be taken as acting vertically.
(2). In open spandrel construction the spandrel supports must be equally spaced and of like cross section.
(3). The increment in rib thickness along the ring must be proportional to the variation of y, although the thickness at the skewback may have any assumed value.
(4). The weight of the floor system must be constant per unit of length.

The equation of such a curve can be obtained from the general method expressed by equations (6) and (7) as follows:

The distance d is represented by OO', the load intensity at any point A is equal to $w\,y'$, w representing now the load per unit of area between the arch ring $B\,O\,A\,C$ and the horizontal line $X_{/} - X'_{/}$ at a distance d above the crown.

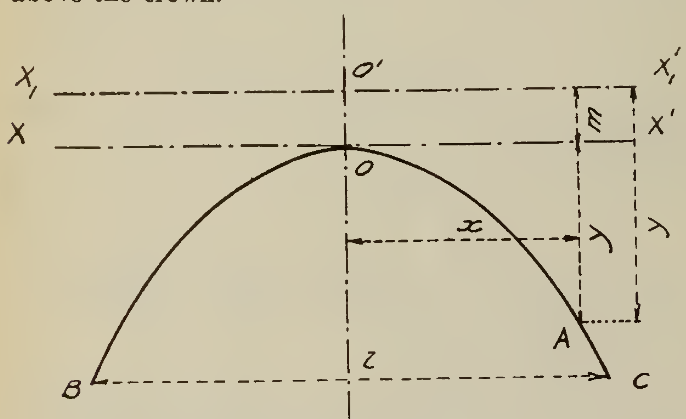


Figure No. 5

The equation of the curve becomes:

$$\frac{d^2y'}{dx^2} = \frac{wy'}{H} \quad \text{......(9)}$$

If we substitute y for y', equation (9) may be written:

$$\frac{dy}{dx}d\left(\frac{dy}{dx}\right) = \frac{w}{H}y\,dy \quad \text{......(9a)}$$

When $\frac{dy}{dx} = 0$, $y = d$, integrating (9a)

$$\frac{dy}{dx} = \sqrt{\frac{w}{H}(y^2 - d^2)} = \frac{1}{m}\sqrt{y^2 - d^2} \quad \text{......(10)}$$

$$\text{where } m^2 = \frac{H}{w} \quad \text{......(11)}$$

Equation (10) may be written: $\frac{dy}{\sqrt{y^2 - d^2}} = d\,\frac{1}{m}$

when $x = 0$, $y = d$, integrating again: $Log_e\left(\frac{y + \sqrt{y^2 - d^2}}{d}\right) = \frac{x}{m}$

which may be written in the exponential form:

$$y = \frac{d}{2}\left(e^{\frac{x}{m}} + e^{-\frac{x}{m}}\right) \quad \text{......(12)}$$

If the four assumptions made above are adhered to, then (12) represents the equation of the equilibrium curve. The loads per lineal foot at the crown and at the skewback are taken off from the drawings. The crown load P_c is then equal to wy_0 and the skewback load P_s equal to wy', in figure No. 6.

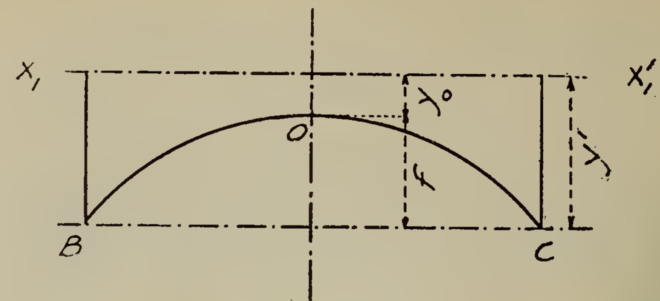

Figure No. 6

The expression $\left(\frac{e^{\frac{x}{m}} + e^{-\frac{x}{m}}}{2}\right)$ in (12) is a hyperbolic function, namely $cosh\,\frac{x}{m}$

We have then: $\frac{y_1}{y_0} = cosh\,\frac{x}{m}$ ......(13)

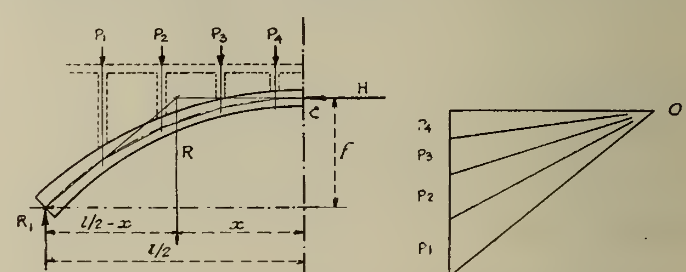
and when $x = \frac{l}{2}$, $\frac{P_s}{P_c} = \frac{wy^1}{wy} = cosh\,\frac{l}{2m}$ ......(14)

The value of $cosh\,\frac{l}{2m}$ is taken from tables of hyperbolic functions and the value of m obtained from (14).

The value of y_0 is obtained from the relation $\frac{y_1}{y_0} = \frac{f}{y_0} + 1$, $P_c = wy_0$ gives w and equation (11) can now be solved for the crown thrust H.

Graphic Determination of the Equilibrium Curve

Assuming that a design of the complete arch has been made where the axis of the ring is located between the limits of the parabolic and the circular curves already referred to, the equilibrium curve may be found by means of resultant polygons. For symmetrical loading, half the arch only need to be considered.



(a) (b)

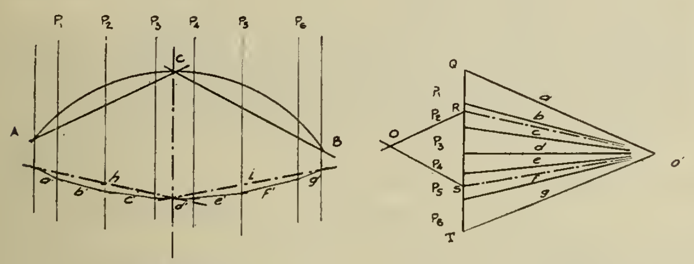
Figures Nos. 7a and 7b

The tabulated loads for each point are drawn to scale on a vertical load line and the pole distance H laid off horizontally from the crown point. The horizontal thrust H may be found graphically or by computation. For symmetrical arches and loading the value of H is readily calculated. In figure No. 7a, the lever arm x of R is obtained by taking moments of the loads P_1........P_4 about C and dividing the sum of the moments by $R = \Sigma_4^1 P$. Then, by taking moments about A, we have,

$$H = R \times \frac{\left(\frac{l}{2} - x\right)}{h}$$

The equilibrium polygon is now drawn through the points A and B, centres of the skewback and crown sections. The axis of the assumed ring is corrected to fit the equilibrium polygon and the loads recomputed, the process being repeated until the polygon corresponds with the loads. In order to obtain sufficient accuracy the arch should be drawn to a scale of ⅜ inch = 1 foot and the force polygon to a scale of 1 inch = 3,000 pounds.

The determination of the equilibrium polygon in the case of unsymmetrical arches can be made graphically. The complete arch and loading must now be considered, the loads being drawn to scale on a vertical load line as before.



(a) (b)

Figures Nos. 8a and 8b

Assuming any pole o' the preliminary force polygon $a \ldots\ldots g$, (figure No. 8b), and the corresponding equilibrium polygon a' g', (figure No. 8a) intersecting verticals through the center of the skewback sections are drawn.

The two closing lines h and i of the preliminary equilibrium polygon intercept the vertical through the center of the crown section and the adjacent rays of the equilibrium polygon. Parallels to the closing lines h and i drawn through the assumed pole O' intersect the load line in R and S. The two segments $Q\ R$ and $S\ T$ on the load line represent to scale the magnitude of the vertical components to the respective skewback reactions.

Lines $A\ C$ and $B\ C$ are now drawn through the centers of the skewbacks and crown sections, and parallels to these lines, through the ends of the segments $Q\ R$ and $S\ T$ will intersect at the true pole O. The true equilibrium polygon passing through points $A\ C\ B$ can be drawn from the true force polygon drawn from the pole O. The true equilibrium curve is a smooth curve tangent to the points of intersection of the equilibrium polygon.

Influence of Redundant Conditions upon Stresses in Arch Ribs

If a fixed arch rib whose axis has been made to follow the equilibrium curve of the loads is analyzed by the elastic theory, bending moment stresses will be found along the rib.

These moment stresses are due to the elastic deformations of the rib which are caused by:

(*a*)—Rib shortening due to compression of the material under the thrust.

(*b*)—Rib shortening due to the setting of the concrete.

(*c*)—Compression of the abutments.

(*d*)—Variation of temperature.

When the rib is hinged during the period of construction, that is until the structure is fully loaded and the concrete has set, then bending moment stresses due to A, B and C will be eliminated.

The rib hinged at the crown and at the skewback is free to rotate about these points under the influence of the stresses. When the false work is lowered, the crown joint will move downward through a small angle α which can be accurately computed. The resultant of the external forces passes through the hinges, and the rib, when properly designed, is subject to uniform compression only. The effect of the downward movement through the angle α need not be considered in practice.

After the filling in of the hinge openings, whereby the arch, temporarily hinged, becomes fixed, the bending moment stresses acting on the structure will be only those due to live load concentrations and the variations of temperature.

In concrete arches, the ratio of the dead load to live load is large, and the moment stresses due to the latter, are small. The combined moment stresses due to temperature and live load are not sufficiently large to cause the resultant to move outside of the middle third of the arch rib except in very short spans.

Symmetrical Parabolic Arch

In order to assign definite values to the stresses in fixed arch ribs built with and without temporary hinges, the symmetrical parabolic arch uniformly loaded will be analyzed.

Simplified formulae corresponding to those given by Professor J. Melan in his book "Theorie des Gewölbes und des Eisenbetongewôlbes im besonderen" are employed to determine the moment stresses due to the thrust in the rib built monolithic with the supports. The method is based upon the deflections of curved ribs.

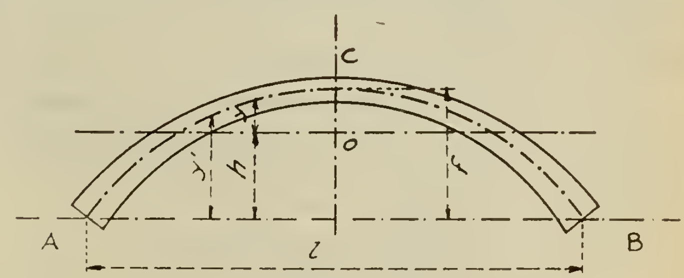


Figure No. 9

The supports being fixed, the rotation there is equal to zero and

$$\int_A^B \frac{M}{I} ds = \int_A^B \frac{M}{AI\cos\phi}\, dx = o \ldots\ldots\ldots\ldots\ldots\ldots (15)$$

The moment M equals He, where e is the eccentric distance between the rib and the equilibrium curve. We may write then:

$$\int_A^B \frac{e}{I\cos\phi}\, dx = o$$

For the purpose of this analysis, the value of $I\cos\phi$ is assumed to be I_0, a constant, I_0 being the value of the moment of inertia of the rib at the crown.

The formulas hereafter given are derived for a system of co-ordinate axes whose origin O is at the centre of gravity of the elastic weights $\frac{ds.}{I}$ The symbols are shown in figure No. 9. The distance h from the horizontal axis to the closing chord is equal to,

$$h = \frac{1}{l}\int_A^B y' dx = \frac{2}{3} f \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (16)$$

The equation for the crown thrust becomes,

$$H=\frac{\int_A^B \frac{M_1 y}{I} ds}{\int_A^B \frac{y^2}{I} ds+\frac{v}{r}\int_A^B \frac{dx}{A}} \quad \ldots\ldots (17)$$

where $\frac{v}{r}$ is the ratio of the co-ordinate of curvature centre to radius of curvature of the arch axis. The value of the integrals are as follows:

$$\int_A^B y^2 dx = \int_{-\frac{l}{2}}^{+\frac{l}{2}} f^2 \left(\frac{1}{3}-4\frac{x^2}{l^2}\right)^2 dx=\frac{4}{45}f^2 l.$$

$$\int_A^B \frac{}{} M_1 y\ dx=\frac{1}{8w}\int_{-\frac{l}{2}}^{+\frac{l}{2}} (l^2-4x^2) f\left(\frac{1}{3}-\frac{4x^2}{l^2}\right) dx=\frac{1}{90}wl^3 f.$$

M_1 being the moment in a simple beam uniformly loaded.

Solving for the crown thrust:

$$H=\frac{1}{8}\frac{wl^2}{f}\cdot\frac{1}{1+\frac{45}{4}\times\frac{I_0}{A_0 f^2}}=\frac{1}{8}\frac{wl^2}{f'} \quad \ldots\ldots (18)$$

wherein the value of the ratio $\frac{v}{r}$ is taken to *1*, and A_0 is the mean cross section and of the arch axis. The rise of the equilibrium curve is:

$$f'=f\left(1+\frac{45}{4}\cdot\frac{I_0}{A_0 f^2}\right) \quad \ldots\ldots (19)$$

The distance between the parabolic axis and the equilibrium curve is now:

$$\frac{1}{3}(f'-f)=\frac{15}{4}\frac{I_0}{A_0 f} \text{ at the crown} \quad \ldots\ldots (20)$$

$$\text{and } \frac{2}{3}(f'-f)=\frac{15}{2}\frac{I_0}{A_0 f} \text{ at the skewbacks} \quad \ldots\ldots (21)$$

If the depth of the rib at the crown is d, then the crown intercept above the parabolic axis is $5/16\ \frac{d^2}{f}$ and the skewback intercepts below the axis are $5/8\ \frac{d^2}{f}$

The crown moment is therefore equal to:

$$M_c=H\times\frac{5}{16}\frac{d^2}{f} \quad \ldots\ldots (22)$$

The stresses in the material are found by the formula:

$$f_a=\frac{H}{A}\pm\frac{My}{I} \quad \ldots\ldots (23)$$

where f_a = stress per unit of area, A, area of section, $\frac{I}{y}$ = section modulus.

Assuming $f=\frac{l}{10}$, = depth of section $=\frac{f}{10}$

we obtain for the maximum crown stress:

$$f_a=\frac{H}{A}(1+0.19) \quad \ldots\ldots (24)$$

The skewback intercept is twice that of the crown and the maximum stress there is:

$$f_a=\frac{H}{A}(1+0.38) \quad \ldots\ldots (25)$$

Equations (24) and (25) give only the stress due to the load and the elastic deformations resulting from it.

Temperature and Rib-Shortening Effects

The effect of temperature variation and the rib shortening due to the setting of the concrete must be added. We neglect the compression of the abutments.

Taking an average value for E of 2,500,000 pounds per square inch and assuming the average compressive stresses throughout the rib to be 350 pounds per square inch, the shortening due to the load and the elastic deformations resulting from it, per unit of length, is.... .00014

The effect of a fall of temperature of 40° Fahrenheit will cause a shortening per unit of length of.. .00028

The shortening due to the setting of the concrete at three month, according to Considère is per unit of length.......................... .00029

The total shortening per unit of length is....... .00071

The total shortening is 5.1 times greater than that due to the loading alone.

The values of the crown and skewback moment stresses, equations (24) and (25) are therefore multiplied

The total maximum crown stress intensity is,

$$f_a=\frac{H}{A}(1+.969) \quad \ldots\ldots (26)$$

and the total skewback stress is,

$$f_a=\frac{H}{A}(1+1.94) \quad \ldots\ldots (27)$$

At the crown, the maximum stress is about double that due to the centric thrust alone and the minimum stress is almost zero.

At the skewback, the resultant lies outside of the middle third and the compression stress is almost three times as large as the stress due to the centric thrust.

If the rib is made of 1:2:4 concrete having a safe working strength of 600 pounds per square inch, the crown section must be proportioned so that the average compression due to the thrust is limited to 300 pounds per square inch. The skewback thickness will be 1.5 times larger at least. In the case under consideration, temporary construction hinges will reduce the bending moment stresses by an amount equal to 60 per cent of the total moment stresses considered.

At the crown, the maximum compression stress becomes:

$$f_a=\frac{H}{A}(1+.388) \quad \ldots\ldots (28)$$

The crown section may be proportioned for an average unit stress of 435 pounds per square inch, as compared to 300 pounds per square inch when hinges are not used.

Determination of Angle of Rotation of Arch Ribs

The angular movement of arch ribs about hinges at the crown and at the skewback under the influence of shrinkage, rib shortening and variations of temperature, does not materially affect the rib stresses. The maximum value of the angle of rotation, should be ascertained, however, before designing the semi-hinges made of reinforcing bars.

The following method of calculating the angle of rotation is based on that given by M. Mesnager in his book Cours de Béton Armé.

In figure No. 10, the distance $B'.B.$ represents the total shortening of the half arch. Under the influence of the arch shortening, point B moves to B' and the half arch turns around point A until B' reaches B'' because of similar motion on the right side of the axis $O\ B$. The angle of rotation being very small, we admit

$$\alpha=\frac{B\ B''}{A\ B'} \text{ or } \frac{B'\ B''}{A\ B} \quad \ldots\ldots (29)$$

Also the arc $B'-B''$ is assumed equivalent to the distance $B'\ B''$. The two triangles $B\ B'\ B''$ and $A\ B\ O$ are similar.

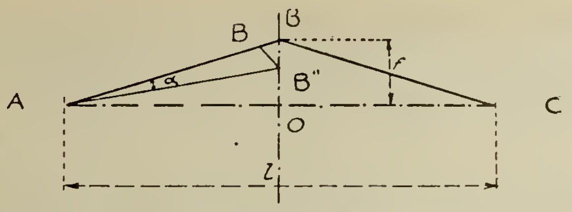

Figure No. 10

We have then:

$$B'B''=BB'\ \frac{l}{2f}\ \ldots\ldots(30)$$

Putting this value of $B'\,B''$ in (29) we have:

$$\alpha=\frac{B}{A}\frac{B'}{B}\frac{l}{2f}\ldots\ldots(31)$$

If we take the coefficient of shortening of 0.00071 obtained previously in the analysis of the parabolic arc, the shortening from A to B is $0.00071\times A\ B$.

Assuming $\frac{l}{f}=10$

The numerical value of α becomes:

$$\alpha=7.1\times 10^{3}\times\frac{1}{2}\ldots\ldots(32)$$

The value of the angle of rotation α at the skewback is the quotient of the shortening in the half arch and the length to rise ratio. At the crown, the angular deformation from the left and the right half arch are added and the value of the angle of rotation is twice that at the skewback.

Flexible Semi-Hinge

The semi-hinge is merely an open joint in the arch rib. A narrow opening is left in the concrete through which sufficient reinforcing steel is provided to carry the full thrust of the structure and to take care of the shearing stresses due to unequal loading. The hinge must be flexible enough to allow the rib to rotate when the false work is removed.

When the hinge openings are filled with concrete, rotation is no longer possible and the arch becomes fixed.

The semi-hinge is perhaps the most simple and the cheapest device yet found to reduce the bending stresses in arch ribs. It is extensively used in Europe and particularly in France where this device originated. There are at present in use several different methods of arranging the reinforcing bars across the gap of the hinge.

In the Considère hinge the main bars are placed near the edge of the section and across the hinge gap in a direction parallel to the arch axis. The Mesnager hinge consists of bent bars, (figure No. 11), placed across the central axis of the rib at the center of the gap.

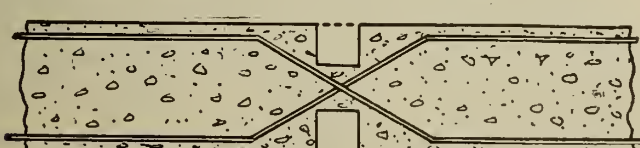

Figure No. 11

Results of tests upon this hinge were published by its inventor, Augustin Mesnager, Membre de l'Institut, Inspecteur-Général des Ponts et Chaussées, etc., in the Annales des Ponts et Chaussées, 1907, Vol. 2, page 180.

The tests pieces consisted of rectangular concrete sections 6 feet 2 inches long by 1 foot 4 inches deep, notched at the centre on both sides of the center axis, the thickness of the concrete there being 3.5 inches. The reinforcing consisted of 13/16-inch bars bent as shown on figure No. 11. The width of the gap in the middle of the piece was 3.5 inches, the ratio of the diameter of the reinforcing bars to width of gap being ¼. The elastic limit of the metal was 42,600 pounds per square inch.

In order to test the hinge under conditions similar to those that would obtain in an arch bridge, the hinge was bent through an angle of 2/100, that is three times more than the calculated value of angle α. Under a load of 300,000 pounds corresponding to 41,200 pounds per square inch, cracks began to appear along the reinforcing indicating slipping of the bars. The concrete was cracked on the tension side and chipping was noticeable on the compression side. The ultimate load put on the hinge was 323,000 pounds or 44,000 pounds per square inch. A second specimen similar to the one described above was next tested by alternately reversing the position of the wedges placed at the end of the piece to obtain the bending effect. After submitting the piece to a load of 144,000 pounds or 21,300 pounds per square inch, the wedges were reversed, the operation being repeated several times.

In order to ascertain the behaviour of the bars alone, the concrete in the gap was broken off, the piece being under load. An increase in flexibility was observed. The loading was increased gradually, the first crack along the reinforcing appearing at 235,000 pounds or 32,000 pounds per square inch. It is to be noted that the method of failure of the two specimens was alike and that by adding transverse reinforcing, which is recommended in practice, still higher strength may be obtained. In practice M. Mesnager limits the stress in the hinge bars to 11,400 pounds per square inch. The embedment required for bond stress is equal to 45 diameters. By hooking the ends of the extrados and intrados bars in the hinge gap, continuity of reinforcement is obtained through the rib and the gap section is made equally strong in tension and compression.

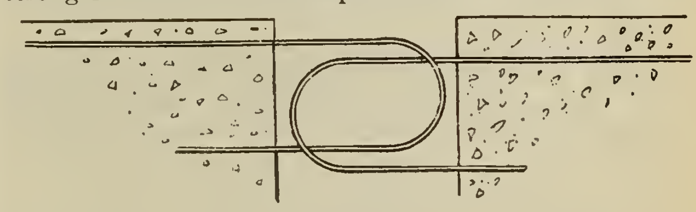

Figure No. 12

This device was first proposed and used by M. Freyssinet, the designer of the St. Pierre de Vouvray arch, the longest concrete arch yet constructed.

The eccentricity of the resultant for the ratio of diameter of reinforcing bars to width of gap equal to ¼ used in the tests is 1.51 inch. In practice, the width of the gap is made equal to five times the diameter of the bars and the resulting eccentricity under the working stresses used is 1.37 inch.

It is to be noted that the eccentricity of the resultant at the hinge decreases for a given size of bars as the width of the gap increases. If in the above test pieces, the width of the gap had been made equal to ten times the diameter of the bars, the eccentricity would have been reduced by 50 per cent.

The thrust intensity per unit of width that can be carried by semi-hinges made of reinforcing bars is proportional to the diameter of the bars used.

In the Canal St. Martin arch, M. Mesnager used forty 0.78-inch diameter bars per lineal meter to carry a thrust intensity of 220,000 lb. The larger size bars recommended for this type of hinge are 1¼ inch round with which a maximum thrust intensity of 100,000 pounds per lineal foot can be carried, allowing sufficient room in the hinge for tie bars and drainage openings.

The saving on the cost of construction made possible by the use of this hinge, determined by actual bid, M. Mesnager states is about 25 per cent.

Concrete Semi-Hinge Construction

When the thrust intensity per lineal foot exceeds 100,000 pounds the Freyssinet concrete hinge may be used.

The high compressive strength of hooped concrete is taken advantage in this form of hinge shown in figure No. 13. The concrete on each side of the hinge gap is heavily hooped in a transverse direction, the hoop bars being tied by stirrups. The cross bars are shear members. The bearing area of the concrete hinge core is one third that of the full rib section. M. Freyssinet uses a working compression stress of 2,500 pounds per square inch in the concrete core. The hooping is made of 5/16-inch bars.

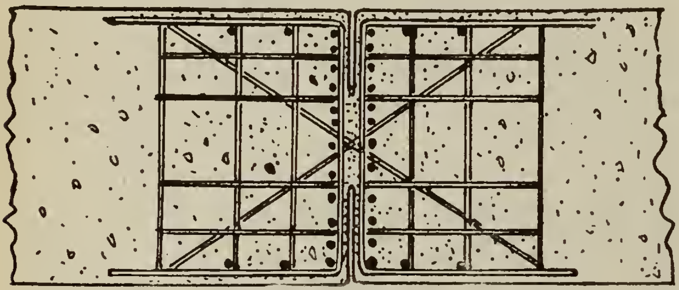

Figure No. 13

The hinge shown in figure No. 13 was used in the Boutiron arch bridge previously referred to. Semi-hinges of this type can be used for thrust intensity of over 200,000 pounds per lineal foot.

Shearing stresses at the hinge in both types of hinges described above must be considered. In the Mesnager hinge stirrups are usually employed, whereas in the concrete hinge diagonal bars across the gap are provided.

Reducing Flexural Stresses by Rib Compensation

As previously stated this important method is due to the French engineer M. Freyssinet who has published a complete account of it in Le Génie Civil.

The analysis of the elastic deformation of a parabolic rib given herein shows that the material of which the rib is made is subject to an elastic shortening when the false work which so far supported the rib is lowered and the rib placed under load.

M. Freyssinet defines the elastic conditions of the rib under load as follows:

(1). The angular change at the end of the rib axis is equal to the angular change of the corresponding support.

(2). The length of the axis is equal to that realized during the construction and modified by the elastic shortening, the linear defoimation of the supports, the shrinkage and the variations of temperature.

It is evident that the total work done in the rib under these assumptions, is much higher than it would be if the work of the elastic deformations could be suppressed. However, the conditions resulting from the elastic state of the rib created by lowering the falsework need not to be accepted as final if it is possible to control the elastic state of the rib and to select the one which will cause minimum stresses in the rib material.

Control of the Elastic State of the Rib

The arch rib is cut in two places and two groups of hydraulic jacks are placed in the joints thus formed. The pressure exerted by the jacks is independent of the rib deformation and the amount of opening of the two joints is a function of the applied pressure. Also, the pressure intensity exerted by one group of jacks is a function of that exerted by the other group and the position of the groups of jacks with reference to the rib axis may be varied at will.

In this way it is possible to vary three elements of the arch, namely, the length of the neutral axis and two angular deformations at two different points of the rib.

These three variable elements are then introduced as variable parameters in the three equations of the redundants. The unknowns in the system may be given any selected values corresponding to an arbitrarily chosen elastic state of structure.

The value obtained by solving the three parametric equations may be then realized by the application of the pressure from the jacks and the structure put in the chosen elastic state.

In the case of the symmetrical arch one of the redundants disappears by reason of the symmetry, and one joint placed at the crown is sufficient to obtain the desired result. In this case the two variable parameters of the elastic equations are simply the pressure and position of the jacks placed at the crown.

Practical Equalization of Stresses

By drawing the curve envelope of the total intradosal and extradosal stresses along the rib it will be found that in general at the crown the latter stresses are by far the highest and that the reverse is true at the skewback. This is due to the fact that the moments due to the elastic shortening compress the extrados at the crown and the intrados at the skewback. It is then possible to determine the magnitude of the moments to be introduced by the jacks in order to reduce the stresses along the rib to a minimum value, approximately equal for both the intrados and extrados.

Where the dead load moments are eliminated by proper design of the arch axis, and when it is not considered necessary to compensate the live load effects, the correction of the axis simply consists of lengthening the rib by an amount equal to the shortening caused by the elastic deformations.

As previously mentioned, the factors causing elastic deformations are rib shortening under load, shrinkage, variations of temperature and movement of the abutments. The structure is designed by the usual method of the elastic theory, the effects of live load concentrations being determined by influence lines and the effect of those elastic deformations which have been compensated are left out of the calculations.

The corrections may also be applied to the total stresses in the rib, which in this case includes bending moments due to loading. At the Villeneuve sur le Lot arch, M. Freyssinet states that important reductions of static moments were obtained in this way.

Application of Theory of Rib Compensation

In order to calculate the lengthening of the rib required to eliminate the effect of the elastic deformations, numerical values of the rib shortening caused by these deformations must be known.

Although the effect of the shrinkage of the concrete in setting has not received a great deal of consideration in this country, yet it is one of the most important factors causing elastic deformations.

We have seen that the shrinkage coefficient admitted by Considère at three months exceeds that of a fall of temperature of 40° F.

M. Freyssinet's observation on arches indicates yet higher values of shrinkage coefficient. The curve representing the shrinkage in a structure exposed to the air was found to swing on either side of a line of mean intensity with increasing amplitude until the maximum is reached after a long period of time. The maxima on the curve corresponds to the end of dry periods and the minima to wet periods. The amount of shrinkage varies with the nature and the proportion of cement, the characteristics of the sand and aggregates, the climatic conditions and the exposure of the structure. The observed shrinkage coefficients are as follows:

Bbl. of Cement per c.y. in place	Limits of Shrinkage
1.56	.0004 to .0006
1.78	.0005 to .0007
2.00	.0006 to .0008

If the total compensation was attempted before the effect of the shrinkage is fully felt on the structure dangerous stresses might result. Corrections from 3/4 to 4/5 of the full effect have been employed. The figures for the three mixes given above being respectively 0.0004, 0.0005, 0.0006. It is estimated that at the time the bridge is put in service the assumed values are within 0.0001 of the actual shrinkage.

In structures exposed to the air, the greater part of the shrinkage will occur during the first 60 days and the remainder only slowly through a long period of time during which the strength of the concrete will considerably increase. The rib shortening effect may be accurately determined if the value of the modulus of elasticity of the concrete is known. The modulus may be determined directly by means of test blocks.

The total shortening effect may also be obtained by observing the amount of opening in the joint at the crown under a known increment of jack pressure, before the arch begins to rise. In this case the result includes the elastic deformation of the abutments.

The amount of compensation to be applied to the ribs is determined, as already noted, from the analysis of the rib under the most severe conditions of loading, assuming that the rib shortening and other elastic deformations have reached their maximum values. The conditions of maximum loading do not usually occur at the time of striking the centres, and moreover, the rib shortening effect would not have reached its final stage at that time. It is therefore necessary to make a study of the elastic conditions of the unloaded rib after the compensation, taking into account the conditions most likely to prevail at the time. From this study, the amount of compensation that can be applied without creating dangerous stresses elsewhere in the rib can be ascertained.

It is to be noted that it is not necessary that the full compensation be carried out at the time of striking the centres if a smooth construction joint is provided at the crown. The gaps in which the jacks are placed can be left open under the roadway and the compensating operations continued whenever the rib shortening effect approach the final stage.

Such an operation was carried out at the Veutre bridge by M. Freyssinet. This bridge consists of three arches, the centre span being 240 feet in length with a rise of only 17 feet. The bridge was completed in January, 1911, and at that time the shrinkage amounted to only 0.0001. The amount of compensation then applied amounted to 0.0004. During the summer of 1911, the actual shrinkage was about equal to the compensation, but the shrinkage continued and in 1913 it had increased to 0.0008, with a resulting deflection of about 4 inches at the crown. The ribs were raised to the original position without any interruption of traffic and eleven 3 m/m steel plates added at the crown. Since that time the bridge has not required any further attention.

The fact that the centres are destroyed through flood or other cause do not prevent the jacking operations to be carried out.

The Veutre bridge was compensated after completion of the work, whereas at Villeneuve, owing to the war, the operation had to be carried out before the spandrels and the deck were built.

Details of Construction

The magnitude and the position of the external forces to be applied to the crown joint of the rib are determined from the study of the elastic state of the unloaded rib after compensation. High local compression stresses of a temporary nature are set up during the jacking operations which necessitates the use of richer mix and hooped or transverse reinforcing in the vicinity of the jacks.

The face of the open pocket in which the jacks and the metal wedges are placed is usually reinforced with a two-way reinforcing mat placed at right angles to the direction of pressure.

A mix having an ultimate strength of 5,700 pounds per square inch without reinforcing is used for a short distance back of the joint.

M. Freyssinet has used pressure as high as 4,270 pounds per square inch under the jacks and does not consider it the highest that can be used.

The average rib pressure is also increased under the wedges employed to block the opening of the crown joint, because the wedges do not occupy the whole rib section. It is possible however, to limit the increase of pressure there to much smaller values than under the jacks. By providing brackets on the side of the rib, or by increasing the section of tubular arches, increased compression stresses at the joint are entirely avoided. The former method is to be used at Bernard bridge and the latter was used at the St. Pierre de Vouvray bridge.

M. Freyssinet had made use of wedges of wood or iron and of hydraulic jacks to create the required pressure. The jacks however, were found to be the most practical methods. The jacks used were made of steel forgings 16 inches outside diameter by 6 inches in hight and having a maximum motion of 3⅛ inches. They are designed for a pressure of 500 metric tons. Each jack has two orifices which permit interconnection with the other jacks of the group in order to equalize the pressure. If the jacks are also directly connected to the pump, it is possible, by means of valves to vary the pressure in each jack and thereby shift the point of application of the external force. In this case, care must be taken against accidental pressure drop in one of the jacks whereby dangerous stresses might result. The best precautionary measure consists of using a number of steel wedges for the temporary blocking of the joint. The wedges can always be kept tight during the jacking process and prevent any movement of the rib should the pressure accidently drop. At the Villeneuve bridge where two groups of jacks were used for the operation a third group was kept in reserve. Careful record is kept of the behavior of the ribs during the jacking. The observations should cover the range of pressure in each group of jacks and the corresponding rib deformations, opening of joint, local deformation, movements of the abutments and variation of crown elevation.

Whenever the result of these observations shows that the desired elastic state of the rib has been reached, the joint is filled in. If it is possible to determine beforehand the exact amount of joint opening required, precast slabs of suitable thickness can be used to block the opening. The joint is opened a little over the required amount to permit the introduction of the slabs.

At the Veutre bridge, metal wedges were used to block the joint temporarily until the quick setting cement filling had hardened sufficiently to take the load.

Results Obtained by Method of Rib Compensation

The factor of safety of a simple structure statically determinate can usually be increased simply by increasing the cross-sectional area or the moment of inertia. The stresses due to the elastic deformations of a fixed arch cannot however be reduced in this way, because the moment stresses due to these deformations are proportional to the moment of inertia and increase with the depth of the section.

In the analysis for the determination of the maximum rib stress, M. Freyssinet includes all the elements affecting the equilibrium of the structure, that is:

(A). Compression due to the dead load.
(B). Effects of live load.
(C). Moment stresses from the dead load that can be limited by proper design of the axis to the elastic shortening of the rib under the thrust.
(D). Rib shortening due to shrinkage and possible movement of the abutments.
(E). Temperature variations between the mean temperature and the temperature at which the rib is closed.
(F). Variations of mean temperature.

Stresses due to A depends entirely on the curvature of the axis and the care taken to reduce the weight of the deck and the spandrel supports. B is a function of A, the stresses due to B are reduced if the ratio of the weight of the rib itself to the live load is increased. Stresses due to B remain constant when the span increases, the live load per lineal foot remaining constant. Live load stresses also decrease when the rise f increases, but in this case, stresses due to D and E also increase.

Stresses due to D increase with the span, the amoun. of cement in the mix and the ratio rise to span $\frac{f}{l}$. Both E and F are proportional to $\frac{f}{l}$.

The method of rib compensation makes it possible to eliminate stresses due to C, D and E. If B is kept constant when the span is increased, the reductions in C, D and E will only increase A, and the limiting possible span length depending on A is increased proportionally.

Table No. 1 gives the stresses at the crown and skewback and the characteristics of two of the longest bridges designed in accordance with the method of rib compensation. For the purpose of comparison the stresses that would occur if the ordinary method of construction had been employed are shown in the table. The stresses are grouped under items A to F, the wind stresses being considered separately.

Table No. 1

	Villeneuve Bridge				St. P. Vouvray Bridge			
	Crown		Skewback		Crown		Skewback	
	Top	Bottom	Top	Bottom	Top	Bottom	Top	Bottom
D.L. Compression.	547	547	401	401	445	445	313	313
DL Bending	-90	90	-20	20	—	—	—	—
Live Load.	190	78	159	192	200	200	232	216
Total.	647	715	540	613	645	646	545	529
Rib Shortening	85	-95	-81	74	61	-75	-73	61
Shrinkage	284	-320	-277	249	218	-256	-242	206
Temperature Variation.	171	64	55	148	94	51	48	123
Total.	540	331	-303	471	368	-280	-267	390
Correction Rib Shortening	-85	95	81	-74	-81	75	73	-61
Correction Shrinkage.	-227	256	222	-199	-170	206	193	-165
Correction, mean Temperature.	-57	64	55	-50	-43	51	48	-41
Total.	-369	415	358	-323	-274	331	314	-267
Max. fiber stress, ordinary method of decentering.	1187	364	237	1084	1013	351	279	918
Max fiber stress, Mr. Freyssinet method of decentering	818	779	595	761	768	668	593	651
Wind stress, 30.6 Lbs. per sq. ft.	not considered.				161	161	112	112
Span. ft.	321.				430.			
Rise, ft.	42.7				82.			
Rib section, width x depth, in ft.	9.94×4.75		9.94×7.87		8.2×8.2		8.2×16.4	
Weight at Crown, ribs only, Lbs per L.F.	14100				6700			
Total weight at Crown, Lbs per L.F.	23200				12800			
Live Load	One meter gauge track Uniform load 1080 Lbs L.F.				Uniform load 1250 Lbs L.F.			

The large reduction of total stress obtained by the method of rib compensation as shown in table No. 1 is the more remarkable because of the fact that the abutments were considered fixed.

A value of 2×10^{9} was used for the modulus of elasticity. The total shrinkage estimated at 5×10^{-4} and the correction made for for a shrinkage of 4×10^{-4}. Influence lives were used to determine the live load effect. It was assumed that the rib temperature at the time of the filling of the joint would be near the maximum, and that the temperature drop coefficient would be 3×10^{-4}. The mix in the two bridges was 350 kgs. per cu. m., or 1.56 bbl. per cubic yard of concrete in place.

Proportions of Long Span Arches

With the large increase of span of concrete arches rendered possible by the method of rib compensation, the resistance of these bridges to sideways buckling becomes an important factor. The slender proportions of the arch ribs of M. Freyssinet's bridges were adopted after careful consideration of the effect of deflections, lateral forces and wind stresses. The wind stresses can be easily computed and their intensity does not increase with the span because the section modulus about the horizontal axis increases at the same rate as the bending due to wind, when all the dimensions of an arch rib are multiplied by a given factor.

The transverse moment due to the thrust is the most important factor to be considered, and it must be shown that there is a definite limit to the deflections due to the transverse moment before the rib can be considered safe against sideways buckling.

If Z is the value of the deflection at any point and N the thrust along the neutral axis then $N Z$ is the bending moment. This moment $N Z$ produces a deflection Z' and a moment $N Z'$ which introduces again further deflections and moments.

If the series $(Z+Z'+Z'')$ has a limiting value, then the rib has a definite position of equilibrium. If the series do not converge there is danger of sideways buckling.

It is pointed out that the initial value of Z is never zero. Even if it was possible to construct a rigourously plane rib, warping would be caused by the wind stresses and the elastic deformations, particularly those due to difference of temperature on the two faces of the rib.

The value of $N Z$ due to these factors can be found by noting the action of the rib under the jack pressure. It is possible to correct the lateral displacement by shifting the position of the resultant of the jack pressure, the experiments made at Villeneuve showing that both lateral and vertical displacements can be controlled by the jacks.

Advantages of the Method.

The method of the rib compensation has been tried out with complete success over a period of fifteen years. It greatly simplifies the construction of concrete arches giving a far better control of the position of the ribs than the older methods using wedges or sand boxes. It is a logical step forward in the art of reducing the bending moment stresses set up during construction, which, with the older methods, necessitates costly increase of cross sectional area and a corresponding increase in the cost of the false work. Because of the fact that the moment stresses due to the elastic deformations increase with the moment of inertia of the section, it is evident that a given increase of cross sectional area does not increase the factor of safety of a fixed arch in the same way it does in a simple beam, the net result being a waste of material. Another advantage of the method is that it is possible to remedy possible movements of the abutments without impairing the strength of the structure in the least. The longest concrete arch bridge in the world was erected by this method and still longer compensated arches are under construction at the present time. The method offers truly remarkable possibilities to the builders of concrete bridges.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOL. IX FEBRUARY 1926 No. 2

The St. Maurice Valley Branch

The official inauguration of the St. Maurice Valley of *The Engineering Institute of Canada*, the twenty-fifth branch to be formed, took place at Three Rivers on the afternoon of Saturday, January 16th, 1926.

In the unavoidable absence of President Arthur Surveyer, Vice-President K. B. Thornton took charge of the proceedings, and was accompanied by Arthur Duperron, A.M.E.I.C., representing the Montreal Branch, and by the general secretary.

The establishment of the new branch was authorized by Council on January 27th, 1925, following an application made, in accordance with the by-laws, by ten corporate members of *The Institute* resident in the St. Maurice Valley. For various reasons the official inauguration of the branch did not take place for some time, but it is evident that the activity and enthusiasm of the members in Three Rivers, Shawinigan Falls and Grand'Mere has not been checked by the delay.

Through the kindness of Mr. Arthur Bettez, mayor of Three Rivers, the City Hall was available for the meeting, which was called to order by Mr. Thornton at 3.30 p.m.

His worship the Mayor delivered a graceful address of welcome in French and English, and said that on behalf of the city of Three Rivers he was delighted to welcome the members, and would afford any assistance in his power to further the activities of the branch.

The Mayor's remarks were suitably acknowledged by Mr. Thornton, who expressed the regrets of President Arthur Surveyer at his inability to be present, and the President's best wishes for the future progress of the branch.

The chairman then called upon the secretary to read the minute of Council authorizing the establishment of the branch, which runs as follows:

"An application for the establishment of a Branch of *The Institute* in the St. Maurice Valley District was presented as follows:

Three Rivers, January 26th, 1925.

To the Council,
The Engineering Institute of Canada,
Montreal, Que.

Gentlemen:—

We, the undersigned corporate members of *The Engineering Institute of Canada*, in conclusion of a meeting held in Trois Rivières on January 26th, 1925, wish to take advantage of the privileges granted by By-law Section 48 and form into a local Branch including members resident in the St. Maurice Valley district:

F. O. White, M.E.I.C.
C. R. Lindsey, A.M.E.I.C.
J. Henri Valiquette, A.M.E.I.C.
Bruno Grand Mont, A.M.E.I.C.
J. A. Bernier, A.M.E.I.C.
C. H. Jetté, A.M.E.I.C.
C. E. Gélinas, A.M.E.I.C.
Henri Dessaulles, A.M.E.I.C.
J. E. A. Warner, A.M.E.I.C.
Louis McCoy, A.M.E.I.C.

The application was approved, the Secretary being instructed to complete the necessary organization. The decision as to the name of the Branch being left with the Council, it was resolved that this Branch be known as the St. Maurice Valley Branch of *The Engineering Institute of Canada.*"

The secretary also read the sections of the *Institute's* by-laws dealing with branch affairs.

The chairman explained that in accordance with the by-laws an Executive Committee would have to be elected, which would include a chairman, vice-chairman, and secretary, and not less than three elected members, and he asked to the members present for nominations for these officers.

Ellwood Wilson, M.E.I.C., nominated C. E. Gélinas, A.M.E.I.C., city engineer, Three Rivers; S. W. Slater, A.M.E.I.C., chief engineer, St. Maurice Paper Company, Cap de la Madeleine; Henri Dessaulles, A.M.E.I.C., Shawinigan Falls; J. H. Valiquette, A.M.E.I.C., city manager, Shawinigan Falls; H. O. Keay, M.E.I.C., manager of research, Laurentide Company, Grand Mere, and Ellwood Wilson, M.E.I.C., chief forester, Laurentide Company, Grand Mere, as members of the Executive Committee.

No further nominations being made, it was moved by Mr. Ellwood Wilson, seconded by Mr. H. Kirsh, that the above named gentlemen be elected as members of the Executive Committee of the St. Maurice Valley Branch, and the resolution was passed unanimously.

The chairman suggested that the election of chairman and vice-chairman might perhaps be postponed, as some of the gentlemen elected on the Executive Committee were unavoidably absent from the meeting, but that in the interim Mr. Gélinas should be requested to act as secretary. This was unanimously approved, and Mr. Gélinas accepted the task.

The chairman then reminded the members present that *The Engineering Institute of Canada*, founded originally in 1887 as the Canadian Society of Civil Engineers, had changed its status and greatly widened its sphere of development in 1918 when its name was changed to *The Engineering Institute of Canada*.

He drew attention to the decentralized system of organization of *The Institute* and pointed out that this imposed upon the branches certain responsibilities which were recognized by Council, as was evidenced by the by-laws dealing with the organization of branches.

The branches thus had a considerable measure of autonomy, and one of the first tasks of the new Executive Committee would be to draw up suitable branch by-laws for the approval of Council. These should be in accordance with the by-laws of *The Institute* as regards matters of general policy, but could be framed so as to suit local interests and requirements in so far as purely branch matters were concerned.

He thought that the St. Maurice Valley was a very fitting place for the development of a branch of *The Institute*, as that Valley was now playing such an important part in the industrial development of the province of Quebec. This development had originally been made possible by investigations and explorations by engineers, and was now proceeding with the assistance of and under the direction of members of the profession.

He trusted that the formation of the branch would result in the development of a strong esprit de corps among the engineers engaged in similar lines of work in the district, and was sure that it would be of the greatest benefit to all members of the engineering profession.

He had great pleasure in presenting to the newly elected Executive Committee the Charter, authorized by Council, and bearing the seal of *The Institute*, constituting an expression of their authority to carry on the activities of a branch of *The Engineering Institute of Canada*.

The Charter was gratefully accepted by Mr. Gélinas on behalf of the St. Maurice Valley Branch.

Arthur Duperron, A.M.E.I.C., spoke as the delegate of the Montreal Branch, and presented to the meeting the following resolution which, on the motion of Mr. C. J. Desbaillets, seconded by Mr. George MacLeod, was unanimously passed at a meeting of the Montreal Branch on Thursday, January 14th, 1926:—

> "The Montreal Branch of *The Engineering Institute of Canada* desires to convey to the newly formed St. Maurice Valley Branch its hearty congratulations, and its best wishes for the prosperity and progress of the twenty-fifth Branch of *The Institute*."

Mr. Duperron then made a pleasing address in French, in the course of which he said that it was a pleasure to take part in the congratulations on the formation of the new branch, and pointed out that the government of the province of Quebec had always taken an enlightened attitude in its policy of developing the natural resources of the province. That government had, throughout, encouraged and supported *The Institute* in the development of the status of the engineering profession, and as a result we now had in the province a body of competent and experienced engineers whose professional abilities compared well with those of other countries.

He trusted that the continuation of this policy would develop the prosperity of the province and of the Dominion, and regretted greatly that Mr. Lefebvre of the Quebec Streams Commission, who was always greatly interested in the St. Maurice Valley, could not be present. On behalf of the Montreal Branch he wished all success and prosperity to the newly formed branch.

Mr. Thornton then called upon Mr. Gélinas to take the chair and hold the first meeting of the branch.

Mr. Gélinas expressed the gratitude of the members present for the action of Council and also for the congratulations and good wishes conveyed by Mr. Thornton and Mr. Duperron, and thought that he would be safe in assuring Council that the newly formed branch would be a most active and lively one. He read a telegram of regret just received from Dr. Surveyer, and stated that when making arrangements for the present meeting it was at first thought that about fifty members would be interested, but on inquiry it appeared that there were in the district a much larger number of engineers who were apparently eligible for membership in *The Institute*, and he believed that there would be little difficulty in obtaining a much larger membership.

Mr. Keay pointed out that one of the great advantages of the branch organization of *The Institute* was that this provided organized local bodies of engineers who were available to deal with problems of local interest, and who were at the same time able to take part in the engineering activities of the country as a whole by contributing both to the proceedings of the branches and also to those of the general meetings of *The Institute*. He felt sure that the common interests of engineers in the Valley would be well served by the new branch, and they would, at the same time, feel that they were an active part of a national Dominion-wide organization.

Mr. Thornton remarked that arrangements were being made for promoting the interchange of papers between different branches, and suggested that the new Executive Committee should communicate in this regard with headquarters and with the Montreal and Quebec branches.

Mr. Sabbaton of the Laurentide Company suggested that it was important to lose no time in approaching the considerable number of engineers resident in the St. Maurice Valley who are not now members of *The Institute*, and thought that the formation of a membership committee should be one of the first acts of the new executive. He asked that the secretary would see that the Executive Committee was furnished with the necessary application forms and literature for this purpose.

Mr. Lauriault, of the Three Rivers Technical School, inquired as to the relationship between *The Engineering Institute* and its branches, and the Corporation of Professional Engineers of the Province of Quebec.

Mr. Thornton, as vice-president of that Corporation, stated that the relation was a very cordial one, and that the functions of the two bodies were essentially different, the Corporation of Professional Engineers being charged with the protection of the legal interests of engineers in the province of Quebec, whereas *The Engineering Institute*, as a Dominion-wide body, was occupied with the professional and technical welfare of engineers for the whole Dominion. He was glad to note that the relations between *The Institute* and the professional associations in the other provinces of the Dominion were just as satisfactory as those with the Quebec Association. He pointed out further that in all of the professional associations a very large proportion of the members were loyal and active members of *The Engineering Institute.*

There being no further business, the meeting adjourned at five o'clock p.m., and through the kindness of the Mayor and Mr. Gélinas the members present had the privilege of visiting the new pumping station and filtration plant of the city of Three Rivers, now just approaching completion.

Among those present were the following members and guests:—

L. C. Anderson
Chas. L. Arcand, A.M.E.I.C.
John A. Barckley
Carl G. Bjerkelund
J. E. Bonoventure
T. G. W. Boxall
Ernest Butler
W. J. Carson
D. S. Christie
E. A. Cowan, S.E.I.C.
A. I. Cunningham, A.M.E.I.C.
J. L. Davison, S.E.I.C.
E. A. Delisle
A. Duperron, A.M.E.I.C.
J. E. Fleury
R. P. Freeman, A.M.E.I.C.
C. E. Gélinas, A.M.E.I.C.
W. E. Hall
F. Hart
H. O. Keay, M.E.I.C.
H. Kirsh
W. E. Lauriault
G. W. Lusby, S.E.I.C.
D. C. Macpherson, S.E.I.C.
J. A. Michaud, A.M.E.I.C.
Roméo Morrissette
Frank Panneton
A. D. Ross
Frederic A. Sabbaton
J. Irving Smith
L. Sterns, Jr.E.I.C.
L. S. Tuck, A.M.E.I.C.
R. A. Vincent
Ellwood Wilson, M.E.I.C.

The Association of Consulting Engineers of Canada

A new organization of engineers, with the above title, was incorporated by Federal Charter in June of this year, with the following as its first members:—

H. G. Acres, M.E.I.C.	Toronto
de Gaspé Beaubien, M.E.I.C.	Montreal
J. L. Busfield, M.E.I.C.	"
F. B. Brown, M.E.I.C.	"
Henry Holgate, M.E.I.C.	"
L. A. Herdt, M.E.I.C.	"
R. S. Kelsch, M.E.I.C.	"
R. S. Lea, M.E.I.C.	"
W. S. Lea, M.E.I.C.	"
T. R. Loudon, M.E.I.C.	Toronto
F. C. Laberge, M.E.I.C.	Montreal
G. K. McDougall, M.E.I.C.	"
C. N. Monsarrat, M.E.I.C.	"
R. A. Ross, M.E.I.C.	"
J. M. Robertson, M.E.I.C.	"
Arthur Surveyer, M.E.I.C.	"
W. G. Swan, M.E.I.C.	Vancouver
Lesslie R. Thomson, M.E.I.C.	Montreal

The objects of the Association are by Charter,—

"To promote ethical standards and practical efficiency in all branches of consulting engineering as a profession, and to increase the usefulness of consulting engineering to the public at large."

Consulting engineers have felt frequently the lack of a distinctive organization which could speak with authority for their own especial group, and this need has led to the establishment of the association.

The association does not propose to encroach on the field of *The Engineering Institute of Canada* by preparing or discussing professional papers, by holding technical meetings, or by embarking upon any other similar activities. The acquisition and spreading of technical and professional knowledge by means of papers, meetings, transactions, etc., is beyond the scope of this new body.

The constitution provides that consulting engineers of acknowledged standing are eligible for membership in the association, which is limited to engineers of at least 35 years of age qualified in any recognized branch of the engineering profession, who are members of *The Engineering Institute of Canada* and of the Professional Engineering Corporation of the province in which they reside, and who are chiefly engaged in consulting engineering work. Engineers employed upon or connected with contracting, sales, or promotion, (except in a strictly advisory or supervisory capacity and whose compensation is for professional service and not contingent on profits) are not eligible for membership.

Special Privileges as to Publications of Other Engineering Societies

The attention of members of *The Engineering Institute of Canada* is directed to the exchange arrangements made with the American Institute of Electrical Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Civil Engineers, and the American Society of Mechanical Engineers, whereby our members are able to subscribe for their journals or transactions, and can purchase their other publications, at the same rates as those paid by their own members.

While this scheme has been in effect since 1921, it does not appear to have been fully utilized by our members, many of whom, it is felt will be glad to add to their libraries one or more of such important technical periodicals.

Subscriptions may be sent, either directly to New York, or through Headquarters. The following list of rates gives in the first column the amounts payable by members of *The Engineering Institute* for the various publications.

	Rate to Members	Rate to Non-Members
American Institute of Electrical Engineers		
Journal, single copies	$0.50	$ 1.00
" per year	5.50	10.50

**If subscription is received before January 1st, otherwise $10.00.*

†If received before February 1st, otherwise price $16.00.

National Research Council

The work of a body like the National Research Council of Canada does not lend itself readily to modern methods of publicity, and it is doubtful whether the results the Council has already achieved are adequately understood by the general public.

A large proportion of the modest grant given by the Dominion Government is expended in providing for studentships at various universities, in this way encouraging post-graduate work, and training a body of scientific workers available for the conduct of investigations.

The Council also devotes its funds to assisting researches which may involve scientific questions connected with any branch of industry. An outstanding example of this has been the very successful work in connection with the determination of the cause of black discoloration in canned lobster, which had been the cause of great loss to the industry, and for which a satisfactory and simple remedy was found by an investigation organized and supported by the Council.

The Council is now proposing to develop this policy further, and is organizing local or provincial sub-committees for the purpose of ascertaining what problems involving physical or engineering questions now present themselves to various industries and await solution. Many such problems, of course exist, but have not yet been attacked, owing to the lack of funds, opportunity, necessary accommodation and equipment, or the want of a competent investigator.

The National Research Council is at present assisting many investigations, and is ready to consider sympathetically all applications for research assistance. This assistance may be of the following kinds:—(1) Furnishing expert opinions. (2) Arranging for the investigation of problems in some appropriate institution. (3) Arranging to provide or train an expert for special work. (4) Cooperating in certain cases of importance in the provision of financial aid for research.

Members of *The Institute* throughout Canada will be interested in this development, and it is hoped will be able to assist the work of the local committees by suggesting problems awaiting solution.

The list of local Committees, with their chairmen, to whom communications regarding this matter should be addressed is as follows:

Division	Chairman	Address
British Columbia	J. S. Plaskett, B.A., D.Sc., F.R.S.C.	Director, Astrophysical Observatory, Victoria, B. C.
Alberta and Saskatchewan	R. W. Boyle, M.A., Ph.D., F.R.S.C., M.E.I.C.	Dean, Faculty of Applied Science, Univ. of Alberta, Edmonton, Alta.
Manitoba	Frank Allen, M.A., Ph.D., F.R.S.C.	Prof. of Physics, Univ. of Manitoba, Winnipeg, Man.
Ontario	J. C. McLennan, O.B.E., Ph.D., LL.D., F.R.S.	Prof. of Physics, Univ. of Toronto, Toronto, Ont.
Quebec	A. N. Shaw, B.A., D.Sc., F.R.S.C.	Assoc. Prof. of Physics McGill Univ., Montreal.
Maritime Provinces	H. L. Bronson, B.A., Ph.D., F.R.S.C.	Prof. of Physics Dalhousie University, Halifax, N. S.

The President-Elect

In accordance with time-honoured custom, the name of one member has been submitted by the Nominating Committee for election as President of *The Engineering Institute of Canada* for 1926, that of George Alexander Walkem, M.E.I.C.

Major Walkem was born July 8th, 1872, at Kingston, Ontario, and was educated at the Kingston Public Schools, and at McGill University, taking his degree in 1896 in Mechanical Engineering. He has had varied and extensive engineering experience, serving his apprenticeship in the Kingston Locomotive Works and Kingston Foundry, working on the water intake pipe into Lake Ontario for the City of Toronto, and later, in the West on survey and track superintendence in steam and electric railways.

From 1901 to 1905 Mr. Walkem was Works Manager for the Vancouver Engineering Works Ltd., and in 1906 organized the Vancouver Machinery Depot Ltd., of which firm he is now Managing Director. He has been greatly interested in the development of the University of British Columbia and in 1922 gave his services to that University as lecturer in Industrial Management in the Department of Mechanical Engineering.

In addition to these interests he is President of the Gulf of Georgia Towing Co., Limited, and of the British Columbia Dock Company Limited, and takes a prominent part in the commercial and industrial life of Vancouver.

MAJOR GEO. A. WALKEM, M.L.A., M.E.I.C.
President-Elect of The Institute for 1926.

He rendered distinguished service during the Great War, leaving the Royal Engineers (Railway Troops) on demobilization with the rank of Major. His duties in Egypt and Palestine with the Railway Operation Division, R.E., included the charge of the Kantara Military Railway, and work in connection with its extension across the Sinai Desert, if not to Dan at least to Beersheba, with other branches to Jerusalem and Haifa. This involved a great deal of construction as well as maintenance work, and Major Walkem was mentioned in despatches by General Allenby.

The President-elect joined *The Institute* in 1906 as Associate Member and was elected Member in 1920. He served as a Councillor during 1921 and 1922, and was a Vice-President during 1923 and 1924, so that he brings to the President's chair ample experience of *Institute* affairs. His interest in professional matters is evidenced by his active connection with the Association of Professional Engineers of British Columbia, of which body he has for some time been a Councillor, and by a happy coincidence is this year the President. He has been a vigorous supporter of all movements in British Columbia for the advancement of the engineering profession, and was one of the original promoters of the Act incorporating the Association of Professional Engineers of British Columbia.

As one of the increasing number of engineers who take an active part in civic and public life, Mr. Walkem has been Reeve of Point Grey, which constituency he now represents in the Provincial Legislative Assembly. He finds time also for the support of social welfare work and is a Director of the Vancouver General Hospital and of the Children's Aid Society of Vancouver.

EMPLOYMENT BUREAU

Situations Vacant

Research Assistant Wanted

A research assistant on certain structural investigations in both steel and reinforced concrete is required. A graduate of an engineering college is preferred, but in any event he must be especially proficient in higher mathematics and in the making of precise measurements. Minimum salary, $150 per month. Give full details of qualifications and experience. Apply Professor C. R. Young, Electrical Building, University of Toronto, Toronto, Canada.

Construction Superintendents

Large paper company constructing in an outlying district a townsite, fifty thousand horse power hydro-electric plant and pulp mill requires a general construction superintendent; a dam construction superintendent; a mill construction superintendent; a carpenter foreman; a master mechanic; and a master electrician for pulpmill. Excellent opportunities for right parties. Applications must contain full record of previous employment and state salary expected and names of previous employers. Apply Box No. 150-V.

Situations Wanted

Electrical Engineer

Technical graduate, University of Toronto, 25 years of age, good personality, two years Westinghouse electrical engineering training, one year installation and maintenance, familiar with inspection and maintenance of electrical equipment, desires situation with public utility or industrial organization. At present employed. Apply box No. 202-W.

Sales Engineer

Advertiser desires to communicate with firms requiring the services of a technical representative or sales manager. Thoroughly experienced in sales work including organization, sales promotion advertising, correspondence, etc. B.Sc., age 30, married, speaking both languages. Apply Box 203-W.

BOOK REVIEWS

Economics of Highway Engineering

by H. T. Tudsbery. E. & F. N. Spon, London, 1925. Cloth 5½ x 8¾ in. 48 pp. 4/6 net.

This brief work is intended to interest highway engineers more effectively in the economic and financial side of their work, as distinguished from the purely technical aspect. Its four chapters deal respectively with Traffic increase and cost, Track, Vehicles, and Fundamental Principles, more particularly from the British point of view, and contain pertinent information regarding highway problems in Great Britain.

The Erection of Engineering Structures and Plant

by Harry Atkin. Chapman and Hall, London, 1925. Cloth 5½ x 8¾ in. 198 pp., illus. 9/6 net.

Forming one of a series of "Directly-Useful" books designed to offer hints and assistance regarding shop or constructional methods and processes which will be of service to technically trained men confronted with jobs outside of their office experience.

Much of the contents is of course familiar to a practical erector, but will be a welcome supplement to the native ingenuity and common sense of the engineer who has little experience in work of this kind.

How to Build up Furnace Efficiency

by Jos. W. Hays—17th edition. Published by the author, Michigan City, Indiana, 1924. Cloth 5½ x 7½ in. 534 pp., illus. $3.00.

In writing "How to Built up Furnace Efficiency" the author has adopted what he calls a narrative style of writing, and his method of presenting the subject is certainly unique; if presenting a thesis in an unexpected way is likely to stimulate interest in it, Mr. Hayes has succeeded admirably. One is not accustomed to look for jokes in a treatise on boiler plant operation, but in this book there are more jokes and amusing cartoons than will be found in *Puck*, *Judge* and the *College Widow* combined.

But there is more than entertainment in the book and we find on investigation that the whole question of combustion and its bearing on how to build up furnace efficiency is ably treated. There is just one difficulty about handling a subject of this kind in this way: the reader is in danger of losing the thread of the argument while looking for the next joke.

Chapter I treats of the available supply of coal in the world and contains the "Alphabet of Steam Engineering" which would not pass as high class poetry, but it contains some real facts.

The next chapter, known as Reel I, points out why fuel is wasted in the boiler room.

Reel II shows how fuel is wasted and two graphical charts make this quite clear.

Chapter III treats of finding fuel wastes, and the next chapter shows how to stop them.

The whole subject of the losses due to excess air is considered and the advantages of flue gas analyses pointed out. The method of analyzing gas by the Orsat apparatus and the operation of CO_2 recorders is taken up in detail.

There is a chapter on Marine boiler plants and another on the burning of oil and waste fuels. The author claims that firemen will read this book and understand it, and if so, a copy of the book should be placed in every boiler plant.

L. M. Arkley.

Wasserkraft — Jahrbuch

Richard Pflaum, Munich, 1924. Cloth 6 x 9¼ in. 612 pages. Illus., and tables. 24 mk.

The first issue of this year book gives a general survey of the present European situation as regards the utilization of water power, brief articles dealing with the position in all the principal European countries, including Russia and particularly Scandinavia and Switzerland.

These chapters are followed by a series of technical papers on the development of water powers, treating such subjects as preliminary calculations and estimates, stream measurement, difficulties from silt and detritus, the relations between water power requirements and those of navigation, the use of wood stave pipe, spillways, and other similar topics. The third part of the volume deals with present practice regarding cavitation difficulties, draft-tubes, runners, governors and methods of increasing the efficiency of existing turbines. A series of useful tables is given in an appendix.

While it treats the subject almost entirely from the European point of view, this volume will be found of considerable interest to hydraulic engineers on this side of the Atlantic.

THE

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 176 Mansfield Street, Montreal, by The Engineering Institute of Canada. Incorporated in 1887 as The Canadian Society of Civil Engineers.

ENTERED AT THE POST OFFICE, MONTREAL, AS SECOND CLASS MATTER

THE INSTITUTE as a body is not responsible either for the statements made or for the opinions expressed, in the following pages.

VOLUME IX | MONTREAL, MARCH 1926 | NUMBER 3

Report of Council for the Year 1925

During the past year the policy of Council has been one of steady development in so far as the financial resources of *The Institute* have permitted.

In view of the amount of arrears of fees outstanding it has been found necessary to make a special effort to regularize the situation in this respect, and Council, while giving careful consideration to the conditions of individual cases, has taken action which is resulting in a marked reduction of the amounts owing.

In the month of May, Mr. Fraser Keith retired from the secretaryship, carrying with him the regrets of the membership at the loss of his services, and their best wishes for his success and prosperity. He was succeeded by Mr. R. J. Durley, formerly secretary of the Canadian Engineering Standards Association.

During the year charters have been formally presented to the Hamilton, Kingston, London and Vancouver branches.

Council has authorized the formation of the St. Maurice Valley Branch, with headquarters at Three Rivers, Que., and its inauguration will shortly take place, bringing the number of branches up to twenty-five.

The Council desires to point out the very important part played by *The Journal* in the organization and work of *The Institute*, and the desirability of increasing and extending its usefulness to the membership, which can only be done by the provision of additional funds.

It is also thought desirable that the issue of *Transactions* should be resumed as soon as circumstances permit, as such a publication would preserve in a convenient and accessible form the more important papers presented to *The Institute*, together with an adequate record of the discussions upon them; material which, in *The Journal*, is necessarily scattered and in a form less suitable for permanent preservation.

A strong recommendation regarding this matter is contained in the report of the Finance Committee, and deserves careful consideration.

The Journal publishes in the branch news fairly complete abstracts of the papers presented at branch meetings, and finds space for printing some of these in full, together with the papers presented at the General Professional Meeting and at the Western and Eastern Professional Meetings. The diversity of subjects thus dealt with is shown by the fact that during the past three years — 1923, 1924 and 1925 — *The Journal* has published in full thirty-four papers dealing with civil engineering, surveying and construction subjects; fifty-two papers dealing with mechanical and electrical matters; four mining and metallurgical papers, and eleven treating of miscellaneous topics, including engineering education.

The work on the library catalogue has been continued during the year, and shelving is being installed which will render the books and periodicals recently catalogued accessible for consultation and use.

The Council has pleasure in drawing attention to the satisfactory progress of the work of the Committee on the Deterioration of Concrete in Alkali Soils, this being clearly shown by the paper on the subject to be presented at the General Professional Meeting in Toronto.

It is expected that the Committee on War Memorials will complete its work during the coming year, as the membership will be asked to contribute the comparatively small amount necessary to complete the amount required for the Bronze Tablet and Honour Roll.

MEETINGS

The thirty-ninth annual general meeting of *The Institute* was held at the Windsor Hotel, Montreal, on Tuesday, January 27th, 1925, and after the approval of the minutes of the previous annual meeting, and the appointment of scrutineers to report the results of the officers' ballot and auditors for the ensuing year, the report of Council for the year 1924 was considered and adopted.

The reports of the various committees and branches were presented and adopted, and following the morning session many of the members attended the luncheon of the Rotary Club of Montreal, at which J. D. Craig, M.E.I.C., Director General of Surveys, gave an interesting address on conditions in the Arctic.

During the afternoon session an invitation from the Toronto Branch to hold the 1926 annual meeting in Toronto was presented by Mr. Morrow Oxley, chairman of the Toronto Branch, and was accepted and approved.

The report of the scrutineers appointed to examine the ballot for the election of officers was presented, and the elections were confirmed, after which the President, Dr. Arthur Surveyer, took the chair and delivered a brief address.

On the evening of the 27th, a smoker was held at the Windsor Hotel, at which a varied programme was presented.

The first session of the general professional meeting was held on Wednesday, January 28th, and the entire day was devoted to the presentation of papers and discussions on the subject of engineering education.

The second professional session was held on the 29th, and was devoted to a discussion of the difficulties of construction under winter conditions.

Other functions in connection with the annual general professional meeting included a luncheon on January 28th, given to visiting members by the Montreal Branch, a dance and supper on the evening of January 28th, and visits to works of interest in Montreal and the vicinity.

Western Professional Meeting

The western professional meeting took place at Banff, Alta., July 11th to 16th, and was held in a camp pitched by kind permission of the Parks Branch, Department of the Interior, at the junction of the Bow and Spray rivers. Arrangements for the equipment, organization and operation of the camp were admirably carried out by members of the Calgary Branch, and about one hundred members and guests were in attendance.

The following papers were presented and discussed, and the meeting afforded a welcome opportunity for a gathering of the western members.

"Park Highways", by J. M. Wardle, A.M.E.I.C.

"Reconstruction of Lake Louise Hotel during winter 1924-25", by H. S. Bare, A.M.E.I.C.

"Vancouver Harbour Development", by Major Geo. A. Walkem, M.E.I.C.

"Alberta Natural Resources", by Edgar Stansfield, M.E.I.C.

"Aerial Photography", by F. H. Peters, M.E.I.C.

"Alberta Petroleum Geology", by Dr. O. B. Hopkins.

Maritime Professional Meeting

An equally successful maritime professional meeting was held in Halifax, October 8th and 9th, with a total registration of one hundred and forty-seven, very satisfactory arrangements being made by the executive of the Halifax Branch, who provided a programme of visits and excursions in addition to the professional work.

At this meeting the following papers were presented and discussed, the proceedings terminating with a very enjoyable and well attended dinner:—

"Short Electric Transmission Lines", by Gordon Kribs, M.E.I.C.

"Building and Care of Roads", discussion led by R. W. McColough, A.M.E.I.C.

"Marketing of Cape Breton Coal". by H. A. Hatfield.

Branch Meetings

The activities of the twenty-four branches have been well maintained during the year, particulars being submitted in the accompanying reports.

Roll of The Institute

During the year nineteen twenty-five, two hundred and twenty-nine persons have been elected to various grades of *The Institute*. These are classified as follows: eighteen Members, sixty-four Associate Members, thirty Juniors, one hundred and twenty-five Students and eight Affiliates. The elections during 1924 totalled 271.

Transfers from one grade to another in *The Institute* were as follows:—Associate Member to Member, thirty-five; Junior to Associate Member, twenty-seven; Student to Associate Member, twenty-six; Student to Junior, forty-seven; a total of 135 as compared with 78 in 1924.

A summary of these elections and transfers is given below. The names of those elected or transferred are published each month in *The Journal* immediately following the election, and are added to the official membership roll as acceptances are received.

Elections

Removals from the Roll

There have been removed from the membership roll during the year nineteen twenty-five, by resignation and for non-payment of dues, twelve Members, fifty-four Associate Members, twenty-two Juniors, one hundred and twenty Students, and six Affiliates, a total of 214.

Deceased Members

During the year nineteen twenty-five the deaths of twenty-eight of *The Institute's* members have been reported:

Honorary Member

Ruttan, Brig.-Gen. H. N., C.M.G.

Members

Bruce, Robert F. H.
Butler, W. R.
Cushing, Richmond Hersey
Edington, John
Foss, Charles O.
Hardman, John Ernest
Henry, A. R.
Marrs, Charles Hawkins
McArthur, J. J.
Molesworth, Arthur N.
Richardson, W. F.
Stewart, William J.
Thompson, Hedley V.
Tracy, Col. Thomas H.
Wise, Frederick A.

Associate Members

Calder, L. R.
Cameron, Charles F.
Daniel, Major Wm. Tulloch
Hagarty, R. E. W.
Lamb, Harry M.
Smith, Richard Henry
Starr, H. Graham

Juniors

Brinkman, F. L.
Taker, Frank O.

Students

Gagnon, A.
Padden, John E.

Affiliate

McLean, Donald M.

Total Membership

The membership of *The Institute* at present totals five thousand, one hundred and nineteen, while there are eighty-two applications which have been favourably received, the addition of the names of these applicants to the roll being delayed pending the receipt of their formal acceptance of election. The corresponding numbers for 1924 were, 5125, and 101, respectively. The corporate members total 3,651, as compared with 3,593 on Dec. 31, 1924.

The membership according to grade is shown in the following table:—

	Dec. 31, 1925	Dec. 31, 1924
Honorary Members	9	10
Members	1,162	1,139
Associate Members	2,486	2,451
Juniors	433	421
Students	984	1,061
Affiliates	45	43
	5,119	5,125
Elections — acceptance pending	82	101
	5,201	5,226

While the corporate membership shows an increase, and the total membership only a slight decrease, during the year 1925, Council desires to point out that the policy of removing from the list all members in serious arrears, which is now being put in effect, will result in some diminution of the apparent strength though not of the real strength, of *The Institute*.

Respectfully submitted on behalf of the Council,

Arthur Surveyer, m.e.i.c., *Chairman.*
R. J. Durley, m.e.i.c., *Secretary.*

Library and House Committee

The President and Council,—

During the past year the work of recataloguing the library has been continued, and the resulting card catalogue is now available for use, although, while the catalogue is practically complete as regards printed books, some work still remains to be done upon it in connection with periodicals and reports.

Through the kindness of the Director of the Engineering Societies Library, New York, we have again been it able to obtain the services of a qualified technical cataloguer. The work of cataloguing will be followed by the systematic arrangement of the books and sets of periodicals, for which purpose an expenditure not exceeding seven hundred dollars has been authorized for steel library shelving required to accommodate the large number of publications awaiting shelf room.

The thanks of *The Institute* are due to a number of individuals and organizations for the presentation of books and reports acknowledged herewith.

The expenditure on the library during the year amounted to one thousand four hundred and seventy-five dollars and thirteen cents, the bulk of which represents the cost of cataloguing work.

The expenditure on repairs and maintenance of the headquarters building during the year amounted to eleven hundred and thirty-five dollars and seventy-five cents, and included the cost of interior and exterior painting and the necessary repairs to roofing, etc.

During the year the gallery of portraits of *The Institute* has been enriched by the kind presentation by Mrs. P. A. Peterson of a portrait of her husband, the late Peter Alexander Peterson, Past-President. This painting by Robert Harris, r.c.a., has been suitably hung, and Mrs. Peterson's generosity fittingly acknowledged.

The Library and House Committee would welcome any suggestions which would increase the usefulness of the books and periodicals at headquarters to the general membership of *The Institute*, and believes that this object can best be effected by making the membership at large better acquainted with the conditions under which they can obtain books on loan, and information and data on various topics on applications to headquarters.

New books added to the library and contributions received during the past year, have been listed each month in *The Engineering Journal* and may be found on pages 134, 171, 190, 232, 258, 320, 363, 466 and 505. These are gratefully acknowledged, together with the following special donations:—

Presented by James White, M.E.I.C.
Twenty-seven publications of the Commission of Conservation.

Presented by A. Mossman from the library of his late son, Harold Alexander Mossman.
Twenty text-books listed in the April *1925 Journal*, page 190.

Presented by W. Bell-Dawson, M.E.I.C.
Collection of data concerning land surveyors' by-laws, etc. 1876 to 1890.
The Channel Tunnel. 1882.
Notice sur le modèle des Barrages de la Meuse. 1876.
The Forth Bridge. 1890.
Les chemins de fer en Amérique par E. Lavoinne et E. Pontzen. 1880.

Presented by J. W. Heckman, A.M.E,I.C.
A number of negatives and prints of old groups of members of The Institute.

A detailed list of the publications which are regularly placed in the reading room will be found on page fifty-three of the February nineteen twenty-four *Journal.*

Respectfully submitted,

O. O. Lefebvre, m.e.i.c., *Chairman.*

Finance Committee

The President and Council,

Your Committee begs to present the Financial Report for the year ending December 31st, 1925.

The financial operations for this period as compared with 1924 show a decrease in revenue of some eleven thousand dollars. This is due largely to the absence of special revenue from the July World Power Conference number of *The Journal*, an item in last year's revenue amounting to nearly eight thousand dollars. The decrease has been met by a reduction in expenditure, and the final result is a surplus of $1,964.77. This result is better than was contemplated by the Budget prepared at the beginning of the year, but it must be acknowledged that the surplus is in a great measure due to the fact that some legitimate expenditures have been postponed to this year's budget.

Your Committee has been instructed by Council that members in arrears must pay the amounts owing or have their names removed from the list of members. As a consequence your Committee is recommending the removal of a number of names from the Roll of *The Institute*. In this connection, thanks are due to officers of the various branches who are assisting in clearing the arrears.

The year's work shows that it requires extreme economy to keep the current expenditure within the present revenue, and while it is possible to continue to do this, the Committee is of opinion that ends are being made to meet only at a sacrifice. There is much that the E. I. C. as a representative body of Canadian Engineers ought to be able to record and place to the credit of their own country. But they cannot do this without some official record and publication of their Transactions. There is an increasing demand for the revival of such a publication for it is felt that while *The Journal* fulfils the demand for the circulation of current news, keeps the Branches informed of each others activities, and can be used to advantage for giving advance copies of Papers to be discussed, it does not appear to be satisfactory as a permanent record in public and private libraries where the papers of our most eminent engineers should be.

The cost of publishing one volume of Transactions is about $6,000.00, which is more than the present revenue of *The Institute* can afford. On the other hand, this and other expenses for the publishing of papers and discussions of which Canada may be proud seem to be most necessary if Canadian Engineers are going to take their legitimate place in their profession. It is, or ought to be, through the records of the National Institution that the achievements of Canadian Engineers should be known. The Finance Committee therefore feels bound to recommend to the incoming Council that some means be found to meet the expense of publishing Transactions either by a voluntary assessment or other suitable way.

It should also be pointed out that the fees of the E. I. C. are very much less in proportion than those of any other National Engineering Society, and the fact that the membership is so widely scattered geographically makes the problems of its financial policy more difficult. Nevertheless, it is felt that when the members solve important engineering problems, and when they accomplish engineering feats, these should be adequately recorded by *The Engineering Institute of Canada* and not by the Institutions of other countries.

F. P. Shearwood, M.E.I.C., *Chairman.*

Legislation and By-laws Committee

The President and Council,

During the year consideration has been given to the question of harmonizing Branch By-laws, and as a result of correspondence, and inquiry by the Secretary during his visits to various Branches, your Committee's conclusion has been confirmed that Branch By-laws cannot be absolutely standardized, and that freedom of action to the Branches is desirable so far as this is compatible with the By-laws of *The Institute.*

Your Committee therefore recommends that no action be now taken with a view to obtaining uniformity of By-laws among the various Branches, but that Branch Executives be requested to observe such uniformity so far as this is possible, having regard to local conditions and the main By-laws of *The Institute.*

Various suggestions have been referred to your Committee during the current year, as a result of which a number of amendments to the By-laws have been proposed, and are now before the membership for consideration. These proposals are printed at length in the January *Journal*, pp. 24-25, and relate to the following subjects:

Examinations. Your committee recommends the adoption of the amendments suggested by the Board of Examiners and Education, and considers these desirable as they provide a more logical series of examinations than those at present in force.

Signing of Cheques. An amendment to Section 16 is recommended in order to provide for the case where the Secretary, through illness or inability to act, is unable to draw cheques.

Treasurership. An amendment to Section 17 is proposed in order to give the Treasurer the right to attend Council meetings.

Election to Membership. The proposed amendment to Section 30 is recommended, because difficulty has arisen in the case of a number of persons elected to membership, who have failed to accept and make payment of their entrance fees within a reasonable time. It therefore seems advisable to amend Section 30 so as to provide that the entrance fee shall in all cases accompany the application for admission. This arrangement can most readily be made by a change in the form for application for admission. At the present time this form, known as Form A, states, "I will accept membership in the class to which I may be elected and will conform to the By-law requirements in connection therewith".

It is recommended that this undertaking be replaced by the following, which is a combination of the present Forms A and D, with some additions:—

"I, the undersigned, hereby agree to accept membership in the class to which I may be elected and will conform to the requirements of the Charter and By-laws, and I hereby promise to promote the objects of *The Institute* so far as shall be in my power, and to attend the meetings thereof as often as I conveniently can. In accordance with the Schedule of Fees accompanying this form, I enclose herewith the sum of dollars covering the entrance fee for the grade of , for which, in my opinion, I am eligible, and it is understood that should I be admitted to a higher class I will, on notification of admission, pay the additional sum covering the entrance fee for that grade.

If elected to membership, I hereby agree to subscribe two dollars annually for *The Journal* of *The Institute.*

It is understood that whenever I shall signify in writing to the Secretary for the time being, that I am desirous of withdrawing from *The Institute,* I shall, (after the payment of any arrears which may be due by me at that period, be free to resign my membership."

Expulsion and Discipline. The recommendations of the Committee on Professional Conduct with reference to Section 32 have been considered. In the present By-laws the rules governing the Code of Ethics as printed on pages 22 and 23 of the Year Book apparently have no connection with the rules which are given in Section 32 of the By-laws and which govern the action of Council when a complaint is received as to the conduct of any member.

It is therefore recommended that Section 32 be entirely rewritten and that the matter now printed in pages 22 and 23 of the Year Book and following immediately after the Code of Ethics be deleted. The version of Section 32 now proposed is in accordance with the opinion of the legal adviser to whom it was referred by Council.

Annual Fees. While recommending the payment of entrance fees with applications for admission, your Committee is of the opinion that the desire of the Finance Committee to secure prompt payment of annual fees, as indicated in their reports to Council, will be best attained by increasing the annual fees of all grades by the sum of one dollar, but allowing a reduction of one dollar if such annual fees are paid on or before March 31st.

Changes are accordingly recommended in sections 33, 34 and 37.

Arrears of Fees. In regard to arrears of fees, your Committee recommends that Section 38 be amended to accord with the provisions of Section 20 of the By-laws of 1916, since there have been continually a number of members in arrears for more than one year, and it has not been found feasible to apply Section 38 literally.

It is therefore recommended that the first paragraph of Section 38 be amended.

Branch By-laws. Your Committee recommends slight verbal changes in Sections 52 and 53.

Rebates to Branches. Your Committee has not thought it advisable to recommend any change in Section 57 regarding rebates.

Grades of Membership. Your Committee has had before it letters from the Chairman of the Saskatchewan Branch, dated March 30th, 1925, and from the Secretary of the Cape Breton Branch dated May 14th, 1925, regarding changes in the classification of Associate Member and Junior, but is of the opinion that no action should be taken at this time, as the classification question was settled so recently in accordance with the Report of the Committee on Policy.

Geo. R. MacLeod, M.E.I.C., *Chairman.*

The Engineering Sections Committee

The President and Council,—

A canvass of the various branches was made to find out if there was any desire on their part for the formation of sections. The committee indicated its willingness to co-operate in any way.

The answers indicated that the time was not opportune for pressing this matter, so nothing further has been done.

Respectfully submitted,

Chas. M. McKergow, M.E.I.C., *Chairman.*

Papers Committee

The President and Council,—

There are grave difficulties in the proper functioning of this committee. The widely scattered branches and the large number of members make its operation almost impossible.

Your committee therefore suggested to Council that the various members, who, with the exception of the chairman, are the secretaries of the various branches, send into the head office copies of the best papers delivered at their branch and that these be given publicity in *The Journal*. Further that these papers should be available for other branches if they desire to use them.

Respectfully submitted,

Chas. M. McKergow, M.E.I.C., *Chairman*.

Nominating Committee—1926

The following nominations to the Nominating Committee for the year 1926 have been made by the various Branches, have been noted by Council, and are herewith presented to be announced at the Annual Meeting in accordance with the By-laws.

Halifax Branch	F. A. Bowman, M.E.I.C.
Cape Breton Branch	W. E. Clarke, M.E.I.C.
St. John Branch	F. P. Vaughan, M.E.I.C.
Moncton Branch	F. B. Fripp, A.M.E.I.C.
Saguenay Branch	A. A. MacDiarmid, A.M.E.I.C.
Quebec Branch	Hector Cimon, A.M.E.I.C.
Montreal Branch	E. A. Ryan, A.M.E.I.C.
Ottawa Branch	C. P. Edwards, A.M.E.I.C.
Peterborough Branch	B. L. Barns, A.M.E.I.C.
Kingston Branch	R. J. McClelland, A.M.E.I.C.
Toronto Branch	J. G. R. Wainwright, A.M.E.I.C.
Hamilton Branch	H. A. Lumsden, M.E.I.C.
London Branch	E. A. Gray, A.M.E.I.C.
Niagara Peninsula Branch	L. L. Gisborne, A.M.E.I.C.
Border Cities Branch	W. J. Fletcher, A.M.E.I.C.
Sault Ste Marie Branch	J. W. LeB. Ross, M.E.I.C.
Lakehead Branch	F. C. Graham, A.M.E.I.C.
Saskatchewan Branch	R. N. Blackburn, M.E.I.C.
Lethbridge Branch	H. W. Meech, A.M.E.I.C.
Edmonton Branch	R. W. Ross, A.M.E.I.C.
Calgary Branch	J. H. Ross, A.M.E.I.C.
Vancouver Branch	A. K. Robertson, M.E.I.C.
Victoria Branch	E. P. Girdwood, M.E.I.C.
Winnipeg Branch	J. N. Finlayson, M.E.I.C.

Code of Ethics Committee

The President and Council,—

Your Code of Ethics Committee has the honour to report that in their opinion no further changes should be made in the present code until a further opportunity has been given to see how it works out in practice.

The matter of the administration of the code has been referred to the Committee on By-Laws, and we understand that they have recommended certain changes in the By-laws which would eliminate the paragraphs appended to the code relating to its administration.

We also understand that some cases coming within the scope of the code are now under consideration by Council, and we consider that it would be well to await the results of these and some further developments before any changes in the code are considered.

Respectfully submitted,

Frederick B. Brown, M.E.I.C.
F. P. Shearwood, M.E.I.C.
Committee.

Gzowski Medal Committee

The President and Council,

Your Committee on the Gzowski Medal has examined the papers published in *The Engineering Journal* from June, 1924, to May, 1925, inclusive, with a view to making an award of the Gzowski Medal for that period.

Some of the papers prepared for the World Power Conference, and published in the July 1924 number of *The Journal* are excellent and one of these might possibly have been selected, but by the rules governing the award they are barred from consideration.

There are a number of other papers which were considered by the Committee, and, as a result of careful deliberation, the consensus of opinion is that the paper entitled "Concrete in Sea Water", by A. G. Tapley, A.M.E.I.C., published in *The Journal* of November, 1924, is the one most worthy of the award. It presents the results of an original investigation and is of general importance.

A number of other papers were rated highly, and some of these are worthy of being considered as a contribution to the literature of engineering. Amongst others, and without making comparisons, and without ranking the papers in order of merit, the contributions of Messrs. Henry, Wynne-Roberts, Oxley, Fortin, Blair, Theuerkauf, Bronson and Smith, might be mentioned.

Some members of the Committee feel that until *The Institute* is able to resume the issue of Transactions the papers presented are not likely to be generally of Gzowski Medal calibre. It is felt that authors will not take the great amount of trouble and pains required to prepare a monumental paper if it is not going to be published in full and in permanent form. Under present conditions it is difficult to publish an exhaustive paper satisfactorily in *The Journal*, and your Committee feels that *The Institute* should endeavour to find ways and means to re-establish the publication of Transactions for this and for other reasons.

Respectfully submitted,

Frederick B. Brown, M.E.I.C., *Chairman*.

Students' Prize Committee

The President and Council,

Your Committee on Students' Prizes has examined the thirteen essays submitted to it, and takes pleasure in reporting as follows:

The thirteen papers fall into four groups under the headings of Electrical, Mechanical, General and Chemical, there being no papers submitted in the Mining section. The only paper in the Mechanical division is not considered good enough for an award. Your Committee therefore recommends that two awards be made in the General section, two in the Electrical division and one in the Chemical. At least seven papers in these three divisions are worthy of a prize, but as only five awards are permissible under the regulations, the following are your Committee's recommendations:

Electrical. "Automatic Control of Railway Substations" by E. Gray-Donald, S.E.I.C. "Electric Steam Generators and Their Possibilities" by J. Archambault, S.E.I.C.

General. "Hazards and Safeguards of Highways" by J. S. Webster. "Humble Window Glass" by S. S. Colle, S.E.I.C.

Chemical. "An Outline of Flour Manufacturing and Laboratory Tests of Mill Products" by M. Katz, S.E.I.C.

While these awards represent the consensus of opinion of the five members of the Committee, there are two other papers which are of considerable merit, and which are also of prize calibre, namely, "Elements of Automatic Telephony", by A. Lister, S.E.I.C., in the Electrical section, and "Location and Construction of Overhead Transmission Lines", by G. Rinfret, S.E.I.C., in the General section, and your Committee regrets that there are not sufficient prizes to include these two also.

The seven papers mentioned above are of a better grade than the average of those usually submitted.

The President and Members of Council, E. I. C.,

Your Committee wishes to draw the attention of Council to the fact that no papers for the Students' Prizes have been submitted from any point except Montreal. It is to be hoped that Students and Juniors in Toronto, Kingston and in other parts of Canada will in future be encouraged to submit papers for these awards. Perhaps some publicity might be given to this suggestion, as the preparation of these papers is important in the training of the young engineer. It may be that Student and Junior Members of *The Institute* do not realize that if in good standing at the end of the year ending June 1st, they are eligible for the competition.

It is pleasing to the Committee to note that Mr. E. Gray Donald has been successful for two years in succession in winning a prize in the Electrical section.

Respectfully submitted,

FREDERICK B. BROWN, M.E.I.C., *Chairman.*

Leonard Medal Committee

The President and Council,—

The Leonard Medal Committee has considered the various papers eligible for the medal and has decided by majority vote to recommend that the award be made this year to Mr. C. V. Corless for his paper "The Mineral Wealth of the Pre-Cambrian".

In making this recommendation the committee would like to record the fact that there were this year a very large number of papers presented which might be considered eligible for the medal and that the general quality of the papers reached a very high standard.

Respectfully submitted,

CHARLES CAMSELL, M.E.I.C., *Chairman.*

Plummer Medal Committee

The President and Council,—

The committee recommends that the Plummer Medal be awarded to Mr. C. B. Bronson for his paper on "Steel Rails", which was printed in *The Journal* of *The Institute,* December, 1924.

The committee also recommends:—

1. That, as chemical as well as metallurgical papers have to be read in awarding the medal, there should in future be a chemist on the Plummer Medal Committee.

2. That, if the consent of the donor can be obtained, the Plummer Medal shall be awarded, in future, for papers that have been presented either to *The Engineering Institute of Canada* or to The Canadian Institute of Mining and Metallurgy, as in the case of the Leonard Medal.

On behalf of the committee,

ALFRED STANSFIELD, M.E.I.C., *Chairman.*

Board of Examiners and Education Committee

The President and Council,—

During the year your board has given careful consideration to the examination schedules and has recommended to your consideration a change in the by-laws, which, if adopted, will make it necessary for candidates for the grade of Junior, who are not otherwise qualified, to take an examination in the fundamentals of engineering science along the lines of that now prescribed under Schedule B. It is felt that this examination can be more conveniently and appropriately taken by younger men than by those who have been in practice a sufficient length of time to qualify them, as regards experience, for the grade of Associate Member. The work of revising and extending these schedules so as to adapt them better to present conditions is well advanced.

Examinations were held as usual in May and November. The number of candidates was smaller than for some years, but they were evidently better prepared. The following table gives the results:—

Schedule	Number of candidates	Passed	Failed
B	2	2	0
C (railway engineering)	1	1	0
Total	3	3	0

Respectfully submitted,

H. M. MACKAY, M.E.I.C., *Chairman.*

Canadian National Committee of the International Electrotechnical Commission

The President and Council,—

The committee has held one special and three regular meetings during the year.

At the special meeting, held in March, the Constitution agreed upon in collaboration with *The Engineering Institute of Canada* was formally adopted, and arrangements were made for the Secretary to attend the Advisory Committee meetings at the Hague as Canadian delegate. The report of these meetings has already been published in *The Journal.*

The committee has been considerably enlarged during the year, comprising now thirteen members; and owing to the increase in the scope of its work, sub-committees are being appointed in order to take care of the different branches. As a result of the Hague Conference there has been greatly increased activity, particularly in the work of the committees on symbols, rating, prime-movers and transformer oils.

The committee has been in frequent communication with the central office on a variety of questions, and a number of decisions of the Commission are likely to be published during the coming year.

The work of the Commission steadily increases in scope so that several of the sub-committees now have more work in hand than the entire committee had a few years ago. The committee now has regular quarterly meetings, and may soon find even that number insufficient, whereas formerly more than a year would elapse between meetings.

Respectfully submitted.

HOWARD T. BARNES, M.E.I.C., *President.*

H. A. DUPRE, M.E.I.C., *Secretary.*

Report of the E.I.C. Members of the Main Committee of the Canadian Engineering Standards Association

The President and Council,

The Institute's nominees on the Main Committee of the C.E.S.A., are now as follows:—

Prof. C. J. McKenzie M.E.I.C., (retires March 1926).
F. B. Brown, M.E.I.C., (" March 1927).
Sir Alex. Bertram, M.E.I.C., (" March 1928).

During the year 1925 the Sectional Committees of the Association have been reduced in number from 13 to 7, and are as follows:—

Sectional Committee on Civil Engineering and Construction.
Sectional Committee on Mechanical Work.
Sectional Committee on Electrical Work.
Sectional Committee on Automotive Work.
Sectional Committee on Railway Work.
Sectional Committee on Ferrous Metals.
Sectional Committee on Mining Work.

The total number of working Committees and Panels is now 53, and the membership of the Association totals 425.

In May last the resignation of the Secretary, R. J. Durley M.E.I.C., took effect, on his becoming Secretary of *The Engineering Institute*, and Professor W. F. McKnight, A.M.E.I.C., of the Nova Scotia Technical College, Halifax, has been Acting Secretary since that time. It is expected that the appointment of a permanent Secretary will be made shortly.

The finances of the Association have been seriously affected by the withdrawal in March of the grant of $10,000 annually, which had been received from the Dominion Government, and it is fortunate that the National Research Council have been enabled to provide for the office accommodation and secretarial service of the Association. In order to facilitate this arrangement, the Main Committee of the C. E. S. A. has been constituted an Advisory Committee of the Research Council; the Association thus retaining its corporate existence, and functioning as before, but carrying on its work with the support and countenance of the Research Council, the necessary additional funds being secured from commercial and technical firms and other organizations interested in the work of Engineering Standardization.

Owing to the various changes mentioned above, the programme of work for 1925 has naturally been somewhat curtailed, and only two publications have been issued during the year. It is expected, however, that as soon as the new arrangements become effective, normal development will be resumed.

Publications issued in 1925:

No. C17-1925 Standard Requirements for Alternating Current Watthour Meters, constitutes the first report of the C. E. S. A. Committee on Watthour Meters. It applies primarily to alternating current watthour meters which have no special measuring attachments such as "maximum demand," etc.

The Requirements cover all the features of alternating current watthour meters on which it was found that an agreement could be reached by the Committee. The report also covers certain features of meter transformers on which agreement was found possible.

As the membership of the Committee includes representatives of all the manufacturers and most of the large power distributing organizations, it is hoped that the Requirements will be adopted by all concerned.

No. B18-1925. Standard Specification for Stove Bolts was issued in October, and constitutes the work of the Committee on Stove Bolts, the membership of which included representatives from manufacturers, tap and die makers, and the larger users. It is expected that the adoption of the standards as outlined therein will eliminate the difficulties and confusion which have heretofore existed.

A complete list of the Reports published by the Association to date, is as follows:—

C. E. S. A. Publications.

No. A 1-1922	Standard Specification for Steel Railway Bridges.
A1a-1922	Material Specifications, Steel Railway Bridges. (*Separate reprint.*)
C 2-1920	Standard Requirements for Distribution Type Transformers.
C 3-1924	Standard Specification for Galvanized Telegraph and Telephone Wire.
B 4-1921	Standard Specification for Wire Rope for Mining, Dredging and Steam Shovel Purposes.
A 5-1922	Standard Specification for Portland Cement.
A 6-1922	Standard Specification for Steel Highway Bridges.
D 7-1922	Standard Specification for Flexible Steel Wire Rope and Strand for Aircraft Purposes.
G 8-1923	Standard General Specification for Commercial Bar Steels.
A 9-1923	Standard Specifications for Reinforcing Materials for Concrete.
C10-1923	Standard Specification for Tungsten Incandescent Lamps.
D11-1924	Interim Report on the Manufacture, Testing and use of Gasoline for Automotive Purposes (with notes on Lubricating Oil).
B12-1924	Standard General Specification for Galvanized Steel Wire Strand.
E13-1924	Standard Specification for Railway Wire-Fencing and Gates.
C14-1924	Standard Specification for Reinforced Concrete Poles.
C15-1924	Standard Specification for Eastern Cedar Poles.
A16-1924	Standard Specifications for Steel Structures for Buildings.
C17-1925	Standard Requirements for A. C. Watthour Meters.
B18-1925	Standard Specification for Stove Bolts.

Mechanical Work

Machine Screw Threads. A committee has been organized for the purpose of preparing a report on the standardization of Machine Screw Threads in Canada.

Sheet Metal Gauges. A request having been received to undertake the standardization of sheet metal gauges, and the project having been approved by the Executive Committee, manufacturers of black and galvanized sheets in Canada were circularized, asking for their views on the matter, and their replies are now being awaited.

Cast Iron Pipe. The committee at work on this project has not yet reported.

Corrugated Iron Pipe. This subject, suggested by the Chief Engineer of a Provincial Highway Department, will be considered as soon as the Panel on Road Structures have completed their report.

Electrical Wire Gauges. A request has been received for the establishment of a standard Canadian wire gauge for electrical conductors, and information has been gathered as to work accomplished in other countries in this respect.

Electrical Work

Western Cedar Poles for Transmission Lines. A draft of the proposed specification has been prepared and circulated to members of the Committee for criticism.

Rating and Testing of Electrical Machinery. The two panels of this committee, on Large Power Rotating Machinery, and Rotating Machinery under ordinary conditions, have made progress, and it is expected that their reports will be submitted shortly.

Canadian Electrical Code. The preliminary draft of Part I of the proposed Canadian Electrical Code has been circulated to members of the several Provincial Committees: their comments have been tabulated and, together with copies of the draft of Part I of the Code, have been distributed to members of the C. E. S. A. Committee and chairmen of the Provincial Committees for consideration.

Power Transformers. Under the chairmanship of A. A. Dion, M.E.I.C., a committee on this project has been formed, combining the former Committee on Station Type Transformers and Panel C on the Rating and Testing of Transformers. Two meetings have been held and the work is progressing satisfactorily.

Automotive Work

Traffic Signals for Highways. Reports have been received from the three panels of this committee, and comments thereon have been circulated for consideration.

The question of the use of red light as a rear danger signal on vehicles was brought up by the Hamilton Chamber of Commerce and discussed by the Committee. In view of the recommendations contained in the American Engineering Standards Committee Final Draft Code of Colors and Forms for Traffic Signals for Highways and Vehicles, it was not considered that anything would be gained by giving the question further consideration at present.

Ferrous Metallurgy

Heavy Steel Castings. The preparation of a draft specification is in the hands of the Chairman of this Committee.

Structural Silicon Steel. A specification has been drafted, and the matter is receiving the attention of the Committee on Steel Highway Bridges.

Co-operation

The Association has appointed representatives to act on committees of the American Engineering Standards Committee dealing with the following subjects:

Numbering of Steel.

Galvanizing and Sherardizing of Iron and Steel.

The Association has also co-operated with the A. E. S. C. in the following matters:

Manhole Frames and Covers

Rating of Rivers.

Tubular Steel Poles for Electric Line Construction.

There has been the usual exchange of information with the other foreign standardizing bodies, and co-operation with the British Standards Association in the preparation of electrical standards.

Respectfully submitted,

Work in Progress

Civil Engineering and Construction

Moveable Bridges. The first draft of this specification is in the hands of members of the Committee on Steel Railway Bridges and the Committee on Steel Highway Bridges, and their criticisms and comments are under consideration.

Concrete and Reinforced Concrete. The various panels of this committee have not yet completed their reports on the sub-divisions of the work undertaken by them.

Reinforcing Materials for Concrete. Standardization of sizes of round and square reinforcing bars, as recommended by the U. S. Department of Commerce and the American Railway Engineering Association, has been considered by the Panel in charge of this matter, and the list of sizes will, it is expected, shortly be added to and form part of C. E. S. A. Specification No. A9-1923, as a favorable vote has been received from the Panel and from the Committee on Concrete and Reinforced Concrete.

Road Materials and Construction. Progress has been made by the panels of this Committee, dealing with the following subjects:—

Bituminous Roads. A draft specification has been prepared and is under consideration by members of the Panel.

Block Pavements. The Panel has completed its report, which covers brick paving, asphalt block pavement, granite block pavement, and creosoted wood block paving, and the specification is now in the hands of the Committee on Road Materials and Construction.

Broken Stone Roads. Comments are being received from members of the Panel on a specification for Water-bound Macadam Highway Pavement, including specification for Broken Stone and Tests for Broken Stone.

Concrete Roads. A draft specification will shortly be submitted to members of the Panel.

Earth Roads. A draft specification is being prepared by the Chairman of the Panel.

Foundations and Sub-Grade Preparation. This Panel has not yet reported.

Gravel, Sand and Sand-Clay Roads. Preparation of a draft specification is under way.

Road Structures. Draft specifications have been sent to all members of the Panel, and comments are now being received.

Classification of Items of Highway Expenditure. The Report is practically completed; a few minor amendments are under discussion.

Definitions of Road or Highway Terms. Comments on this Report are under consideration.

Respectfully submitted,

Alex. Bertram, M.E.I.C.

Committee on the Deterioration of Concrete in Alkali Soils

The President and Council,—

Your committee begs to report that during the past year the following papers bearing on the work of our committee have been prepared and published:

No. 1—"Disintegration of Portland Cement in Sulphate Waters", by T. Thorvaldson, R. H. Harris, D. Wolochow — Journal Ind. and Eng. Chem. *17* — 467 (1925).

No. 2—"Action of Sodium and Magnesium Sulphates on the Constituents of Portland Cement", by G. Shelton — Journal Ind. and Eng. Chem. *17* — 589 (1925).

No. 3—"Action of Sodium and Magnesium Sulphates on Calcium Aluminates", by G. Shelton — Journal Ind. and Eng. Chem. *17* — 1267 (1925).

No. 4—"Review of Paper No. 1 from an Engineering Standpoint", by C. J. Mackenzie—*Engineering Journal* November, 1925.

No. 5—"Differentiation of the Action of Acids, Alkali Waters and Frost on Normal Portland Cement Concrete", by C. J. Mackenzie and T. Thorvaldson — Presented at the Annual Meeting of *The Engineering Institute of Canada*—Toronto, Ont. — Jan. 1926.

The first three of the above papers are of a strictly scientific nature, while the last two are written from an engineering viewpoint for the purpose of indicating some of the practical bearings of the work to date.

It may be of interest to note that requests have been received from the United States, England and Germany for copies of the scientific papers and that over one hundred reprints of each of these papers have already been distributed to interested parties.

In the future we shall follow generally the procedure of the past year with regard to publications, i.e. (1) Publish purely scientific papers in a scientific journal, whenever a definite phase of the problem has been completed; (2) prepare and publish articles and reviews written from the engineering viewpoint to indicate the practical importance of the scientific findings.

FINANCIAL

The following summary of expenditures and receipts as to December 1st, 1925, is submitted: A detailed and itemized statement of expenditures from December 1st, 1924, to December 1st, 1925, is being sent to the financial supporters of the research.

TOTAL EXPENDITURES TO DECEMBER 1ST, 1925.

GENERAL	Committee meetings, travelling expenses	$ 1,836.56	
	Misc. telegrams, office expenses	353.85	
			$ 2,190.41
PHYSICAL TESTS	Travelling allowances and expenses	$ 1,123.66	
	Material and special equipment	1,728.58	
	Freight and cartage	353.09	
			$ 3,205.33
CHEMICAL RESEARCH	Travelling expenses	$ 340.81	
	Salaries	28,967.74	
	Materials	5,457.00	
			$34,765.55
			$40,161.29

TOTAL RECEIPTS TO DECEMBER 1ST, 1925

	1921	*1922*	*1923*	*1924*	*1925*	*Total*
Research Council	5,000	5,000	5,000			$15,000.00
Canada Cement Co.	3,000	3,000	3,000		2,997	11,997.00
Saskatchewan	3,000	3,000	3,000			9,000.00
Alberta	1,000	1,000				2,000.00
C. P. R.	1,000	1,000	1,000			3,000.00
City of Winnipeg	200	200	300			700.00
Interest on bank acc.			139.41	422.14	190.65	752.20
Total receipts						$42,449.20
Total expenditures						$40,161.29
Balance in bank, Nov. 30, 1925						$ 2,287.91

NOTE: — The National Research Council has donated another $5,000., but as this money was received in December, 1925, it does not show in the above statement.

The Greater Winnipeg Water District has written off accounts against this research amounting to $342.78 for work done in connection with our field tests and while this can not appear in our accounts, we wish to formally acknowledge this contribution.

EXPENDITURES IN YEAR DECEMBER 1ST, 1924 TO DECEMBER 1ST, 1925

PHYSICAL TESTS	$ 32.47
CHEMICAL RESEARCH — Salaries	6,990.27
Materials, etc.	396.29
Total	$7,419.03

From the above statement it will be seen that we have received during the past year another grant from the Canada Cement Company of $3,000. and another grant of $5,000. from the National Research Council (which does not show in the statement as to November 30th, 1925). And that accordingly we have on hand at present (January 1st, 1926) about $7,000. As our salary expenditures will be considerably less during the next year, we will probably be able to carry on another year and a half with the moneys now available.

Respectfully submitted,

C. J. MACKENZIE, M.E.I.C., *Chairman.*

Honour Roll and War Trophies Committee

The President and Council,

As a result of the appeal sent out last year for funds for the erection at headquarters of a Memorial to the members of *The Engineering Institute of Canada* who gave their lives in the Great War, and for a Record, in bronze, of those members who served, your committee has now in hand the sum of $3,125.49 out of the $4,000. necessary for the completion of the work.

As $875. still remains to be collected, your committee recommends that the contract should not be let until this amount has been received, and a further appeal is being sent out in order to give members another opportunity of subscribing.

Your committee is confident that as a result the balance required will be forthcoming from the members, and that the work can accordingly be commenced at an early date.

Respectfully submitted,

CHARLES J. ARMSTRONG, M.E.I.C., *Chairman.*

Committee on Biographies

The President and Council,

A considerable number of biographies of deceased members of *The Engineering Institute of Canada* and the Canadian Society of Civil Engineers, in addition to those already completed, have been allocated to writers and are now under preparation. These have been undertaken by men whom the committee considered most competent to undertake their preparation and it is believed the completed work will be entirely creditable.

Owing partly to illness, the chairman, during recent months, has not been able to follow up the work as he desired, and in consequence is not able to report the progress anticipated a year ago.

Respectfully submitted,

PETER GILLESPIE, M.E.I.C., *Chairman.*

Committee on International Co-operation

The President and Council,—

Apart from correspondence and unofficial conversations with officers of other national societies, for the purpose of keeping in touch with them, there have been no activities of the International Co-operation Committee during 1925.

Delegates from many countries are expected to meet in New York in April, 1926, for the scheduled meeting of the International Electrotechnical Commission and preliminary arrangements are now being developed with the view of having Canada join with the United States in welcoming the visitors to North America.

A short trip to Canada may be made by the visitors and, in that event, officials and members of *The Engineering Institute of Canada* will be expected to welcome them heartily. Announcements will be made in due time through *The Engineering Journal.*

The officials of the American National Committee of the International Electrotechnical Commission have been most gracious in inviting Canada to act with the United States as joint-host to the delegates from other countries.

Respectfully submitted,

JOHN MURPHY, M.E.I.C., *Chairman.*

Fuel Committee

The President and Council,—

In January, 1925, the Annual Meeting appointed a Fuel Committee of *The Institute;* and the writer has the honour to submit a report.

During the year the secretary of the committee sent out memos to all members asking them to advise him of any changes in fuel matters that occurred. There are only two changes to which attention need be called:—

1. The imposition of a duty of 50 cents per ton on bituminous slack coal.
2. The steady increase in the use of British anthracite in the eastern portion of the acute fuel area.

The effect of these changes is being discussed, together with other national fuel matters, in a paper to be presented at the Annual Meeting, 1926, by the secretary of the committee, Lesslie R. Thomson, M.E.I.C. The Fuel Committee feels that this paper will act in some measure as a detailed report of the activities of the committee during the year.

In closing, your committee wishes to record again its sense of the great value of the work being done by the Dominion Fuel Board.

On behalf of the committee,

F. A. Combe, M.E.I.C., *Chairman.*

Committee on Engineering Education

The President and Council,

Following the resolution of the 1925 Annual Meeting the following Committee has been appointed and has commenced work with the view of co-operating with the Society for the Promotion of Engineering Education.

Chairman—F. B. Brown, M.E.I.C.
J. D. Craig, M.E.I.C.
T. H. Hogg, M.E.I.C.
C. C. Kirby, M.E.I.C.
H. J. Lamb, M.E.I.C.
S. G. Porter, M.E.I.C.

Frederick B. Brown, M.E.I.C., *Chairman.*

Branch Reports

Border Cities Branch

The President and Council,

The Executive of the Border Cities Branch beg to submit the following annual report for the year ending December 31st, 1925.

This past year has been one of the most successful in the history of the branch. The attendance at the meetings has varied from the minimum of 23 to the maximum of 40, the average being 29. Although the total membership of the branch is 137, of these, only 114 are resident members and many of these 114 are students who are away the university but are classed as resident members due to their homes being in the Border Cities, so in view of these facts the attendance was very good.

Meetings

The meetings held during the year and the speakers or the entertainment are as follows:—

Jan. 9.—Social evening spent in smoking and playing cards.

Feb. 13.—Wm. Gore, M.E.I.C., spoke on "**A Mechanical Explanation of Einstein's Theory of Relativity**".

Mar. 13.—Prof. Peter Gillespie, M.E.I.C., spoke on "**Engineering Achievements in Canada**".

Apr. 17.—Lt.-Col. H. J. Lamb, M.E.I.C., spoke on "**Engineering Works on the Great Lakes**".

May 8.—Social evening.

Aug. 15.—Extra meeting at which the Border Cities Branch entertained members of the London Branch.

Oct. 9.—Prof. C. R. Young, M.E.I.C., spoke on "**Triumphs in Bridge Building**".

Nov. 13.—Chas. McTague, barrister, spoke on "**Some Phases in Company Law**".

Dec. 11.—Annual meeting and election of officers.

During the year the Executive have met on 9 different occasions, transacting all necessary business so that it was not necessary to bring any before the regular dinner meetings.

The Membership Committee were quite active during the year. They have circularized all members of the branch with a view to ascertaining the names of any engineers in the district who would be eligible for membership in *The Institute* but who are not already members. Much valuable information was thus obtained and praise is due the Chairman A. E. West, A.M.E.I.C.

The Papers and Entertainment Committee, as usual, functioned in a most excellent manner. This was evidenced by the excellent papers presented, the entertainment provided for the different meetings and the splendid attendance at the meetings. Up to the May meeting the committee was composed of A. J. Bowman, A.M.E.I.C., and L. M. Allan, A.M.E.I.C. The members for the period beginning Oct. 1925, and ending May 1926, are W. B. Pennock, Jr.E.I.C., and E. G. Ryley, A.M.E.I.C.

A statement of the membership of the branch for the years 1924 and 1925 is as follows:—

	Branch Resident Members		*Branch Non-Resident Members*	
	1924	*1925*	*1924*	*1925*
Members	19	20	2	3
Associate Members	38	47	11	10
Juniors	14	15	7	5
Students	25	31	5	5
Branch Affiliates	1	1	—	—
Total	97	114	25	23

Financial Statement

Receipts

To balance in bank	$235.83	
Rebates from headquarters	175.80	
Branch News	22.25	
Received from dinners at meetings	214.75	
Advertising	9.00	
Miscellaneous	2.00	
Interest at bank	3.01	
Total		$662.64

Disbursements

Printing of Notices	$ 33.38	
Services, entertainments, cigars at meetings	167.18	
Revenue and postage stamps	2.00	
To hotel for dinners at meetings	288.75	
Expenses representative Magrath dinner	32.00	
Gift to officer of *Institute*	25.00	
Express	2.90	
Lantern	45.00	
Stationery	2.40	
Cash in bank	64.03	
Total		$662.64

Respectfully submitted,

J. Clark Keith, A.M.E.I.C., *Chairman.*
F. Jas. Bridges, A.M.E.I.C., *Secretary-Treasurer.*

Calgary Branch

The President and Council,—

On behalf of the Executive Committee we beg to submit the following report of the activities of the Calgary Branch for the year ending December 31st, 1925.

The slate of officers elected on March 8th, 1924, held office untill March 14th, 1925. The following is a list of officers elected on March 14th, 1925, for the branch year 1925-1926:

Chairman	A. L. Ford, M.E.I.C.
Vice-Chairman	W. S. Fetherstonhaugh, M.E.I.C.
Secretary-Treasurer	G. P. F. Boese, A.M.E.I.C.
Committee	R. S. Stockton, M.E.I.C.
	T. Lees, A.M.E.I.C.
	R. M. Dingwall, A.M.E.I.C.
Ex-officio, emeriti	A. S. Dawson, M.E.I.C.
	B. L. Thorne, M.E.I.C.
	R. S. Trowsdale, A.M.E.I.C.
Auditors	H. R. Carscallen, A.M.E.I.C.
	H. J. McLean, A.M.E.I.C.
Branch Editor	W. St. J. Miller, A.M.E.I.C.

Membership

The membership of the branch is as follows:

	Branch Resident	*Branch Non-Resident*	*Total as at Dec. 31, 1925*	*Total as at Dec. 31, 1924*
Members	21	4	25	23
Associate Members	54	20	74	71
Juniors	2	1	3	3
Students	2	2	4	1
Affiliates	1	..	1	1
Branch Affiliates	15	..	15	16
Totals	95	27	122	115

Membership as a whole shows a satisfactory increase.

Meetings

Fifteen executive meetings were held during the year and the business of the branch was kept up to date.

Arrangements for the Western Professional Meeting of *The Engineering Institute of Canada* were carried out by the Calgary Branch. This meeting was held at Banff from July 11th to 16th inclusive, and although the attendance was not as large as anticipated, the meeting was considered a great success and the Calgary Branch had no financial loss.

General meetings, dinners, luncheons, and special affairs were as follows:

Jan. 7.—Annual dinner with entertainment provided by the Brooks Troupe of Entertainers, consisting of members and others of the C.P.R. Irrigation Staff headed by Major F. G. Cross, A.M.E.I.C.

Jan. 28.—**"Main Highway Organizations"**, by C. A. Davidson, commissioner, Alberta provincial highway.

Feb. 9.—**"Ceramics"**, by Prof. W. G. Worcester, M.E.I.C., professor of Ceramics, University of Saskatchewan.

Feb. 23.—**"Hydro-electric Development"**, by A. N. Sanborne, manager, East Kootenay Power Company, Fernie, B.C.

Mar. 6.—**"Steam Power Plant Engineering — Modern Practice"**, by A. J. T. Taylor, M.E.I.C., president, Vickers Combustion Engineering Corporation. This address was divided into two parts: **"Pulverized Fuel"** and **"The Accumulator"**.

Mar. 14.—Annual meeting.

Mar. 30.—**"Hydraulic Mining"**, by W. D. Armstrong, A.M.E.I.C.; **"Aero Engines, General Design and Performance"**, by W. St. J. Miller, A.M.E.I.C. These papers in their order were awarded first and second prizes in the competition for the two best papers open to the branch.

May 18.—General meeting, with regard to holding the Western Professional Meeting at Banff. Discussion on Mr. Henry's paper **"The Motor Vehicle as a Transportation Facility"**.

July 9.—Luncheon in honour of R. J. Durley, M.E.I.C., general secretary.

Aug. 5.—Dinner in honour of R. J. Durley, M.E.I.C., general secretary. Address by Mr. Durley.

Sept. 4.—**"Conditions, Experiences, and Impressions of Great Nations, resulting from two complete Trips around the World"**, by Hiram N. Savage, consulting engineer, Berkeley, Cal.

Oct. 15.—General open meeting and ladies night. Address by Dan McCowan, Naturalist **"From Indian Trails to World Highways"**. This lecture was illustrated by lantern slides, and particularly described Sir James Hector's journey through the Rockies in 1857. Supper was provided.

Nov. 6.—**"Alberta Tar Sands"**, by Dr. S. C. Ells, M.E.I.C.

Nov. 26.—**"Operation and Maintenance of the Lethbridge Northern Irrigation Project"**, by P. M. Sauder, M.E.I.C.

Dec. 8.—Joint meeting of members of the Calgary Branch and the Association of Professional Engineers of Alberta at dinner. Addresses by Dr. R. W. Boyle, M.E.I.C., president of the Association, and Dr. F. A. Wyatt, professor of soils, University of Alberta, on **"Soil Surveys and what they have shown about Alberta Soils"**.

The average attendance at the above meetings was 50.

Cape Breton Branch

The President and Council,

The Executive Committee of the Cape Breton Branch submits the following report of the branch activities during the year ending December 8th, 1925:

The annual meeting for 1924 was held on December 9th, in the branch rooms. At this meeting the following officers were elected:

Chairman	S. C. Mifflen, A.M.E.I.C.
Committee men	W. C. Risley, M.E.I.C.
	W. E. Clarke, M.E.I.C.

On January 13th, George Morrison, A.M.E.I.C., resigned from the Executive as he intended to be away from Cape Breton for some time. At an Executive meeting held on February 12th, W. S. Wilson, A.M.E.I.C., was appointed to take Mr. Morrison's place on the committee and W. C. Risley, M.E.I.C., was appointed vice-chairman.

The number of resident members at the time of the last annual meeting was thirty-eight, with four pending. There are now only thirty-four and three pending.

The holding of a Maritime Professional Meeting in Sydney during the summer of 1926 is now being considered and your advice will later be sought in this connection.

Financial Statement

The financial statement is as follows:

Receipts

On Hand, December 8th, 1924	$192.70	
Rebates from Headquarters for dues and branch news used in *The Journal*	100.64	
Local dues	185.00	
Dinner tickets	60.00	
Total		$538.34

Expenditures

Rent for one year	$180.00	
Printing, stationery and advertising	8.55	
Postage, telegrams, telephone calls, etc.	10.21	
Dinner at Glace Bay, August 29th	77.48	
Donation towards Halifax Professional Meeting	25.25	
Presentations and entertaining	16.45	
Balance on hand	220.40	
Total		$538.34

Meetings

The following meetings were held during the year:—

1924

Dec. 9.—Sydney. Annual Meeting. Paper on **"Radio Reception with the Super Heterodyne"**, by E. L. Ganter, A.M.E.I.C., Cape Breton representative of the Canadian General Electric Company, Limited.

1925

Jan. 13.—Sydney. **"The Use of Electricity in Coal Mining"**, by C. H. Wright, M.E.I.C., Maritime manager for Canadian General Electric Company, Limited. This paper was also read at Glace Bay on the following night by E. L. Ganter, A.M.E.I.C.

Feb. 17.—Sydney. **"The Relation of the Engineer to Railway Operations"**, by D. W. McDonald, superintendent, Sydney and Louisbourg Railway.

Mar. 10.—Sydney. **"Steam Boilers and Furnaces"**, by H. A. Hatfield, Maritime representative of Babcock-Wilcox & Goldie-McCulloch, Limited.

Apr. 14.—Sydney. Discussion on Mr. Henry's paper on **"Motor Transportation"**, led by W. S. Wilson, A.M.E.I.C.

Aug. 29.—Glace Bay. **"No. 1-B Colliery"**, by A. L. Hay, M.E.I.C., This paper was followed by a visit to the colliery and a dinner at the Official Club.

Oct. 2.—Sydney. Smoker for Mr. Durley.

Nov. 3.—Sydney. **"The Marketing of Cape Breton Coal"**, by H. A. Hatfield. This paper was read previously by Mr. Hatfield at the Maritime Professional Meeting at Halifax.

Respectfully submitted,

Sydney C. Mifflen, A.M.E.I.C., *Chairman.*
Donald W. J. Brown, Jr.E.I.C., *Secretary.*

Edmonton Branch

The President and Council,—

We beg to submit, below, our annual report, covering the activities of the Edmonton Branch for the year 1925:—

Lectures have been given or papers read at general meetings as follows:—

Jan. 15.—R. W. Boyle, M.E.I.C., dean of the Faculty of Applied Science, the University of Alberta, spoke on **"A recent Electrical Application"**.

Feb. 26.—C. A. Davidson, R.P.E., commissioner of highways for the province of Alberta addressed the branch and outlined the work being carried out for the improvement of the highways of Alberta.

Mar. 13.—B. A. MacGibbon, professor of political economy at the University of Alberta, explained the methods of **"Marketing Canada's Wheat"**.

Nov. 2.—S. C. Ells, M.E.I.C., field engineer, Mines Branch, Ottawa, gave a résumé of this work in connection with the **"Bituminous Sands of Northern Alberta"**.

The Executive Committee has also met at regular intervals.

The visit to the branch by the general secretary was appreciated by those members in Edmonton at the time.

Membership

The branch membership, in comparison with the same date in 1924 is given:—

	1924 Branch	1924 District	1925 Branch	1925 District
Members	14	2	15	2
Associate Members	47	8	46	8
Juniors	5	1	5	1
Students	7	2	10	0
Affiliates	1	.	2	.
Total	74	13	78	11

Some applications for admission are pending at the present time.

		$188.64

Respectfully submitted,

A. G. S. Stewart, A.M.E.I.C., *Chairman.*
W. R. Mount, A.M.E.I.C., *Secretary-Treasurer.*

Halifax Branch

The President and Council,—

The Executive Committee of the Halifax Branch for the year 1925 respectfully submits this report of the activities of the branch

The Halifax Branch is very appreciative of your kindness in permitting the Maritime General Professional Meeting 1925 to be held in Halifax. The comments which we have heard concerning the meeting itself are such as to make us believe that it was successful in promoting the exchange of engineering knowledge and in promoting still further the *esprit de corps* of our *Institute* in the Maritime Provinces. This meeting was much less of a financial burden to the branch than was expected, as is apparent in the report of the branch treasurer, and no member of the branch subscribed more than $2.00 towards it.

The Halifax Branch wishes you individually and collectively a happy and prosperous New Year.

Meetings

During the year 1925 this branch has held six meetings as follows:—

Jan. 22.—Regular monthly meeting held in the Green Lantern. K. H. Smith, M.E.I.C., chief engineer of the Nova Scotia Power Commission, gave a most interesting and instructive illustrated description of his trip through the Scandinavian countries with delegates to the World Power Conference, London, England. Attendance 38.

Feb. 19.—Regular monthly meeting held in the Green Lantern. Prof. H. W. McKiel, M.E.I.C., professor of engineering at Mount Allison University, Sackville, N.B., gave his address on **"The Mineral Resources of Canada"** which promoted considerable discussion and brought many compliments to the speaker. Present 30.

Mar. 19.—Regular monthly meeting held in the Green Lantern. A. F. Dyer, A.M.E.I.C., read an illustrated paper on **"The Lake Kenogami Storage Dams"**. In a vote of thanks which was passed to Mr. Dyer his paper was called "A clear, lucid, and distinct description of an important and extensive work". Present 35.

Apr. 23.—Regular monthly meeting held in the Green Lantern. This was Water Power night and was arranged by E. M. Archibald, A.M.E.I.C. Short papers ten to fifteen minutes each were given by the following:

K. G. Chisholm, A.M.E.I.C., **"Stream Measurement"**.
H. W. Mahon, A.M.E.I.C., **"Storage and Pondage"**.
K. E. Whitman, A.M.E.I.C., **"Turbines"**.
J. F. Lumsden, A.M.E.I.C., **"Selection of Electrical Equipment"**.
E. M. Archibald, A.M.E.I.C., **"Pipe Lines"**.

With the exception of Mr. Archibald all the engineers on this programme are members of the staff of the Nova Scotia Power Commission. Mr. Archibald is an engineering-contractor. The papers were illustrated with slides and curves. Present 52.

Nov. 19.—Regular monthly meeting held in the Green Lantern. Business meeting for the appointment of 1926 nominating committee and other routine business.

Dec. 17.—Annual meeting and dinner in the St. Julien Room of the Halifax Hotel. Speaker of the evening, Col. E. C. Phinney. Subject, **"Canada's National Problems"**. Attendance 62.

Kingston Branch

The President and Council,

On behalf of the Executive Committee of the Kingston Branch, we beg to submit the following report of the activities of our branch, from January 1st, 1925 to December 31st, 1925.

Numerous meetings were held during the first three months of the year, but during October, November and December it was so difficult to choose dates with no conflicts that our meetings during this latter period were considerably fewer than usual. The fact that a very large percentage of the membership of the branch is drawn from the staff and students of Queen's University, makes it very difficult during the busy college term to ward these conflicts and also makes it inadvisable to attempt any meetings during the summer months. The attendance was fairly satisfactory, though somewhat less than the previous year, due to the fact that the Student membership had considerably dropped off with the graduation from the university of a large number of Students of years that were unusually large.

Nine meetings were held during the year, the list of which is as follows:—

Jan. 15—**"The Operation of a Modern Telephone Exchange".** The Kingston staff of the Bell Telephone Co. of Canada.

Mar. 3—**"Electricity in the Paper Industry,"** by Prof. J. W. Bain, A.M.E.I.C., of Queen's University, Kingston.

Mar. 5—**"Pulp and Paper,"** by T. Linsey Crossley, A.M.E.I.C.

Mar. 10—**"Power Plant Design and Operation,"** by Prof. L. M. Arkley, M.E.I.C., of Queen's University, Kingston, assisted by final year students in mechanical engineering at Queen's.

Mar. 17—**"Telephone Engineering,"** by W. K. Detlor, of the staff of the Bell Telephone Co. of Canada.

Mar. 27—**"The Welland Ship Canal,"** by E. G. Cameron, A.M.E.I.C., principal assistant engineer on the Welland canal.

Oct. 28—**"Sculpture and Architecture, Ancient and Modern,"** by J. W. McCallum of the McCallum Granite Co., Kingston.

Nov. 17—Annual business meeting, election of officers and executive for ensuing year.

Nov. 23—Annual dinner, special speakers, R. J. Durley, M.E.I.C., and Gen. Sir Alex. Bertram, M.E.I.C., on **The Institute.**

Membership

The approximate membership of the branch is as follows:—

Honorary Members	1
Members	11
Associate Members	20
Juniors	4
Students	14
Affiliates	1
Total	51

Executive Committee

The Executives holding office during the parts of the two years covered by this report are as follows:—

1924-1925		1925-1926
Major L. F. Grant, A.M.E.I.C.	Chairman	R. J. McClelland, A.M.E.I.C.
R. J. McClelland, A.M.E.I.C.	Vice-Chair	Prof. L. T. Rutledge, M.E.I.C.
G. J. Smith, A.M.E.I.C.	Sec.-Treas.	G. J. Smith, A.M.E.I.C.
G. C. Wright, M.E.I.C.	Executive	Col. D. S. Ellis, A.M.E.I.C.
J. M. Campbell, M.E.I.C.		Prof. D.M. Jemmett, A.M.E.I.C.
Col. W. P. Wilgar, M.E.I.C.		J. M. Campbell, M.E.I.C.
		Major L. F. Grant, A.M.E.I.C.
		Col. W. P. Wilgar, M.E.I.C.

Financial Statement

The following is the financial statement for the year 1925:

Receipts

	Total		$193.97

All of which is respectfully submitted,

R. J. McClelland, A.M.E.I.C., *Chairman.*
G. J. Smith, A.M.E.I.C., *Secretary-Treasurer.*

Lakehead Branch

The President and Council,

On behalf of the Executive Committee, I beg to submit the following annual report of the Lakehead Branch.

Membership

On January 1st, 1925, there were 40 corporate members and 14 non-corporate members, and on December 31st, 1925, there are 40 corporate members and 18 non-corporate members, showing an increase during the year of 4 non-corporate members.

Meetings

Meetings of the Lakehead Branch were held as follows:—

Jan. 28.—A dinner was held at the Shuniah Club, Port Arthur, at which J. Antonisen, M.E.I.C., addressed the members.

Mar. 11.—A meeting was held in the City Hall, Fort William, at which G. H. Burbidge, M.E.I.C., addressed the members on **"Plane Table Work in British Columbia, 1909"**.

Mar. 25.—A dinner was held at the Prince Arthur Hotel, Port Arthur, at which Francis Kiefer addressed the members on **"Forestry"**. This was the largest meeting yet held by the branch, fifty members and guests being present.

June 19.—A dinner was held at the Shuniah Club, Port Arthur, at which Lt.-Col. H. J. Lamb, M.E.I.C., of Toronto, addressed the members on **"The Association of Professional Engineers of the Province of Ontario"**, and H. M. Lewis, A.M.E.I.C., addressed the members on **"Aerial Photography"**.

Aug. 12.—A luncheon was tendered R. J. Durley, M.E.I.C., on the occasion of his first visit to the branch as general secretary of the Institute. Mr. Durley addressed the members on subjects of interest to the branch and the Institute as a whole.

Dec. 10.—A dinner was held in the Shuniah Club, Port Arthur, at which H. G. Acres, M.E.I.C., of Niagara Falls, addressed the members on **"Reminiscences of the World Power Conference at London"**, and H. G. O'Leary, A.M.E.I.C., addressed the members on the **"Diversion of the Northern Watershed"**.

No regular meetings were held during the summer months.

Officers

The result of the ballot for officers of the Branch for the ensuing year resulted as follows:—

Chairman	H. M. Lewis, A.M.E.I.C.
Vice-Chairman	D. C. Chisholm, M.E.I.C.
Secretary-Treasurer	Geo. P. Brophy, A.M.E.I.C.
Executive Committee	F. C. Graham, A.M.E.I.C.
	E. W. Robison, A.M.E.I.C.
	C. B. Symes, A.M.E.I.C.
	M. W. Turner, A.M.E.I.C.

The following members were nominated to represent the Lakehead Branch on the Council of *The Institute:*—

G. H. Burbidge, M.E.I.C., Port Arthur.
D. G. Calvert, A.M.E.I.C., Fort William.

Lethbridge Branch

The President and Council,—

On behalf of the Executive Committee of the Lethbridge Branch we beg to submit the following report for the year ending December 31st, 1925.

At the annual meeting held on March 7th, 1925, the following officers were elected:—

Chairman	Robert Livingstone, M.E.I.C.
Secretary-Treasurer	N. H. Bradley, A.M.E.I.C.
Executive	G. S. Brown, A.M.E.I.C.
	G. N. Houston, M.E.I.C.
	M. Freeman, A.M.E.I.C.
Ex-officio	John Dow, M.E.I.C.
	S. G. Porter, M.E.I.C.
	H. W. Meech, M.E.I.C.

S. G. Porter, M.E.I.C., removed to Calgary in April, 1925, no appointment made in his place.

MEETINGS

The executive held seven meetings during the year with an average attendance of six. Eleven regular general meetings were held during the year and one special meeting on August 3rd, at which R. J. Durley, M.E.I.C., general secretary was present.

Jan. 10.—"**Central Heating**", by W. B. Trotter, A.M.E.I.C.

Jan. 24.—"**The Mining Industry in Canada**", paper prepared by J. B. deHart, A.M.E.I.C., and read by Mr. Quigley, mine manager, Coalhurst.

Feb. 7.—"**Main Highways of Alberta**", by H. P. Keith, A.M.E.I.C., chief construction engineer, province of Alberta, Edmonton.

Feb. 21.—"**Manufacture of Portland Cement**", by W. G. Armstrong, A.M.E.I.C., Exshaw, Alberta.

Mar. 7.—Annual branch meeting. "**Use of Aeroplanes in Forest Patrol**", by Major A. L. Cuffe, squadron leader, High River, Alberta.

Aug. 3.—Special general meeting. "**Institute Affairs**", by R. J. Durley, general secretary, Montreal, Quebec.

Oct. 9.—"**Rambles in the Rockies with a Camera**", by Dan McCowan, naturalist, Banff, Alberta.

Oct. 24.—"**Present Status of Oil and Gas Development in Alberta**", by S. J. Davies, A.M.E.I.C., petroleum engineer, Department of Interior, Calgary, Alberta.

Nov. 7.—"**Hydro-Electric Power for Alberta**", by R. A. Brown, superintendent, Electric Light and Power Department, Calgary.

Nov. 21.—"**The Manufacture of Beet Sugar**", by C. R. Wing, superintendent, Canadian Sugar Refineries Ltd., Raymond, Alberta.

Dec. 5.—"**Banff National Park**", by C. G. Childe, A.M.E.I.C., resident engineer, Banff, Alberta.

Dec. 19.—"**Operation and Maintenance of the Lethbridge Northern Irrigation District**", by P. M. Sauder, M.E.I.C., project manager, L.N.I.D., Lethbridge.

ROBT. LIVINGSTONE, M.E.I.C., *Chairman.*

N. H. BRADLEY, A.M.E.I.C., *Secretary-Treasurer.*

London Branch

The President and Council,—

On behalf of the Executive Committee of the London Branch, we beg to submit the following report for the year ending December 31st, 1925.

Seven regular, one special, seven executive meetings and two motor trips were held during the year.

MEMBERSHIP

	1924	*1925*

Respectfully submitted,

W. C. MILLER, A.M.E.I.C., *Chairman.*

E. A. GRAY, A.M.E.I.C., *Secretary-Treasurer.*

Moncton Branch

The President and Council,

On behalf of the Executive Committee, we beg to submit the sixth annual report of Moncton Branch.

The Executive Committee held seven meetings during the year and transacted a considerable amount of business. There were seven meetings of the branch held, three of which were supper-meetings, and two were open to the public. At one of the supper-meetings Moncton Branch had as their guest the newly appointed general secretary of *The Institute*, R. J. Durley, M.E.I.C., who received a hearty welcome from all members present, and his address on *Institute* affairs was most interesting and instructive.

Membership

Our membership at present consists of 85, made up as follows:—

		Resident	*Total*
Members	—	10	
Associate Members	—	25	
Juniors	—	3	
Students	—	25	
Affiliates	—	1	
			64
		Non-Resident	
Members	—	2	
Associate Members	—	10	
Juniors	—	4	
Students	—	5	
			21
Total			85

During the year the branch suffered the loss of one of its most prominent members in the death of Mr. John Edington, formerly city engineer of the city of Moncton. The late Mr. Edington was a Charter Member of Moncton Branch and had been a member of the Executive Committee.

Officers

The annual meeting of the Branch was held on May 28th, and the following officers were elected for 1925-26.

Chairman..........C. S. G. Rogers, A.M.E.I.C.
Vice-Chairman......A. S. Gunn, A.M.E.I.C.
Secretary-Treasurer..M. J. Murphy, A.M.E.I.C.
Executive Committee A. F. Stewart, M.E.I.C.
J. D. McBeath, M.E.I.C.
J. R. Freeman, A.M.E.I.C.

The following members of the Executive hold office for another year.

F. B. Fripp, A.M.E.I.C.
G. C. Torrens, A.M.E.I.C.
G. E. Smith, A.M.E.I.C.
F. O. Condon, M.E.I.C., *ex-officio.*

Financial Statement

The financial statement for the year ending December 31st, 1925, is as follows:—

Revenue		
Balance in bank, January 1st, 1925	$146.67	
Rebates on dues and Branch News	129.36	
Tickets sold for supper-meetings	43.00	
Bank interest	3.36	
	$322.39	
Rebates due from headquarters	13.65	
Total		$336.04
Expenditures		
Postage	$ 6.50	
Expenses of meetings	105.94	
Printing	31.54	
Telegrams and telephones	8.80	
Miscellaneous	66.30	
	$219.08	
Balance in bank	103.31	
	$322.39	
Rebates due from headquarters	13.65	
Total		$336.04

Balance in bank	$103.31

Respectfully submitted,

C. S. G. Rogers, A.M.E.I.C., *Chairman.*
M. J. Murphy, A.M.E.I.C., *Secretary-Treasurer.*

Montreal Branch

The President and Council,—

We have the honour to make our report to you covering the activities of the Montreal Branch of *The Engineering Institute of Canada* for the year 1925.

The Executive Committee

The personnel of the Executive Committee is given in the following table:

Name	*Office, etc.*
J. L. Busfield, M.E.I.C.	Chairman, 1925.
C. J. Desbaillets, M.E.I.C.	Vice-Chairman, 1925.
W. C. Adams, M.E.I.C.	Elected, 1924-1925.
C. V. Christie, M.E.I.C.	Elected, 1924-1925.
P. S. Gregory, M.E.I.C.	Elected, 1924-1925.
F. C. Laberge, M.E.I.C.	Elected, 1925-1926.
P. L. Pratley, M.E.I.C.	Elected, 1925-1926.
Jas. Robertson, A.M.E.I.C.	Elected, 1925-1926.
C. K. McLeod, A.M.E.I.C.	Secretary, 1925.
E. A. Ryan, A.M.E.I.C.	*Ex-officio*, Past Secretary.
A. Surveyer, M.E.I.C.	*Ex-officio*, President, E.I.C.
J. M. R. Fairbairn, M.E.I.C.	*Ex-officio*, Past President, E.I.C.
R. A. Ross, M.E.I.C.	*Ex-officio*, Past President, E.I.C.
J. B. Challies, M.E.I.C.	*Ex-officio*, Vice-President, E.I.C.
F. P. Shearwood, M.E.I.C.	*Ex-officio*, Vice-President, E.I.C.
K. B. Thornton, M.E.I.C.	*Ex-officio*, Vice-President, E.I.C.
O. O. Lefebvre, M.E.I.C.	*Ex-officio*, Past Chairman and Councillor.
F. B. Brown, M.E.I.C.	*Ex-officio*, Councillor, E.I.C.
J. T. Farmer, M.E.I.C.	*Ex-officio*, Councillor, E.I.C.
J. H. Hunter, M.E.I.C.	*Ex-officio*, Councillor, E.I.C.
Geo. R. MacLeod, M.E.I.C.	*Ex-officio*, Councillor, E.I.C.
C. M. McKergow, M.E.I.C.	*Ex-officio*, Councillor, E.I.C.

There were 17 meetings of the Executive Committee during the year, all of which were well attended, the average attendance being 9 members.

Papers and Meetings Committee

Following out the policy which has been adopted in recent years of appointing a member of the Executive Committee as chairman of the Papers and Meetings Committee, in order to provide proper co-relation in the work of the two bodies, J. L. Busfield, M.E.I.C., chairman of the branch, was appointed chairman of the Papers and Meetings Committee, and W. Walker, A.M.E.I.C., was appointed vice-chairman, and C. K. McLeod, A.M.E.I.C., secretary of the branch, *ex-officio.*

The branch by-laws provide that this committee consist of a chairman and vice-chairman, and also of the chairman and vice-chairmen of the various sections of the branch, who were appointed as follows:—

Civil Section	A. Duperron, A.M.E.I.C.	Chairman
	C. L. Cate, A.M.E.I.C.	Vice-Chairman
Electrical Section	R. H. Mather, A.M.E.I.C.	Chairman
	G. A. Wallace, A.M.E.I.C.	Vice-Chairman
Mechanical Section	J. A. McCrory, A.M.E.I.C.	Chairman
	J. W. McCammon, A.M.E.I.C.	Vice-Chairman
Industrial Section	K. G. Cameron, A.M.E.I.C.	Chairman
	R. E. MacAfee, A.M.E.I.C.	Vice-Chairman
Municipal Section	G. R. MacLeod, M.E.I.C.	Chairman
	J. A. Lalonde, A.M.E.I.C.	Vice-Chairman
Railway Section	A. R. Ketterson, A.M.E.I.C.	Chairman
	V. I. Smart, M.E.I.C.	Vice-Chairman
Student Section	F. E. Winter, S.E.I.C.	Chairman
	G. Gingras, S.E.I.C.	Vice-Chairman

While this committee commenced its work early in 1925, its function was the preparation of the programme for the 1925-1926 season, which is reported on elsewhere.

Membership Committee

Considerable attention has been paid during the year to the question of increasing our membership. Early in the year, a special committee consisting of J. H. Hunter, M.E.I.C., chairman, and J. L. Busfield, M.E.I.C., C. J. Desbaillets, M.E.I.C., T. J. Lafrenière, M.E.I.C., and K. B. Thornton, M.E.I.C., was appointed for the express purpose of obtaining new members and also following up the question of existing members transferring to a higher grade.

Reception Committee

A Reception Committee, under the chairmanship of H. Massue, A.M.E.I.C., together with F. B. Heward, A.M.E.I.C., H. G. Thompson, Jr.E.I.C., L. G. Boisseau, A.M.E.I.C., E. Prévost, Jr.E.I.C., W. H. Abbott, A.M.E.I.C., S. A. Neilson, A.M.E.I.C., E. Roy, Jr.E.I.C., and L. O'Sullivan, A.M.E.I.C., was appointed early in the season.

Publicity Committee

A committee consisting of S. A. Neilson, A.M.E.I.C., chairman, and E. Prévost, Jr.E.I.C., was appointed for the purpose of arranging publicity matters for the branch in the public press.

The Secretary-Treasurer

Early in the year the resignation was regretfully accepted from E. A. Ryan, A.M.E.I.C., who has been secretary-treasurer of the branch since 1922. This action was taken on Mr. Ryan's part on account of the pressure of his own affairs and of the demands made on his time by the affairs of the branch. After due consideration, C. K. McLeod, A.M.E.I.C., was appointed to the office in February 1925, since which date he has continuously fulfilled his duties to the complete satisfaction of the Executive Committee and the branch has undoubtedly benefitted by his whole-hearted service.

Membership

The membership of the branch is given in the following table. It will be noted that there is practically no change in the numerical position of the branch except for a falling off in the number of Branch Affiliates, which is largely due to the dropping from the roll of a number of Affiliates who had failed to pay their dues.

Statement of Membership, 1924-1925

		Dec. 31st, 1924	*Dec. 31st, 1925*
Honorary Members	Resident	1	1
Members	Resident	205	212
	Non-Resident	16	15
Associate Members	Resident	410	406
	Non-Resident	46	48
Juniors	Resident	70	65
	Non-Resident	13	12
Students	Resident	285	280
	Non-Resident	30	35
Affiliates	*Institute*	10	11
	Branch	28	20
Total		1114	1105

Sincere regret was felt by the branch at the loss by the death of Professor H. A. Lamb who had been of valuable assistance to the branch in connection with the various committees for a number of years. A. R. Henry was another well-known member of the engineering fraternity of Montreal who passed away during the year.

Papers and Meetings

The meetings of the first half of the season were arranged by the Papers and Meetings Committee under the chairmanship of W. C. Adams, M.E.I.C., who made their report at the last annual meeting. The meetings of the latter half, i.e., since October, have been arranged by the Papers and Meetings Committee, under the chairmanship of J. L. Busfield, M.E.I.C. The complete list of meetings as held throughout the year is given in table below.

The general attendance at the meetings has shown a slight decrease and leaves very much to be desired. The members of *The Institute* must bear in mind that if the policy of inviting men of standing to give addresses before a branch is to be maintained, that the meetings of the branch must be well supported. It is only natural that if we have a reputation of poorly attended meetings it is going to be impossible to obtain the best authors or speakers. From another point of view it is only reasonable that the members of the branch should be asked to give their hearty support not only to the committee which devotes a great deal of time to the preparation of a programme for the edification of the members, but also to those members who go to the trouble of time and expense in the preparation of papers. Apart from the benefit to the member of such technical or other information, as may be disseminated, the benefit of social intercourse between the members must not be overlooked.

A large number of members of *The Institute* are absolutely throwing away the opportunity of benefit to themselves through non-attendance at the meetings. The excuse which is so frequently made, that the member is not interested in the particular subject is a very poor one and indicates a mental attitude which, from the point of view of the profession at large, is regrettable, to say the least. Even in the case of the member who is not directly connected with the subject under discussion, there are five excellent reasons why he should attend the meetings:

1. For the value to himself of broadening his own general knowledge of some branch of engineering other than his own.
2. For the value to himself of the social intercourse with his fellow-members.
3. For the value to himself of the possibility of outstanding speakers being invited to meetings, provided a good attendance is regularly assured.
4. For the value to himself of building up the prestige of the branch and the general interest of the members therein.
5. For the courteous expression of appreciation of the work of his fellow-members.

It is appreciated that the foregoing remarks will in all probability only come to the attention of those members to whom they do not apply, but they are inserted in this report, in the hope that those members to whose attention they do come, will use their best efforts towards passing on the word to their fellow-members at every possible opportunity.

Meetings — 1925

Jan. 8.—**"The Kenogami Dam,"** by O. O. Lefebvre, M.E.I.C. Attendance 128.

Jan. 15.—**"Some of the Economic Phases entering into Adjustment of Motor Vehicles to Railway Requirements,,'** by R. A. C. Henry, M.E.I.C. Attendance 61.

Jan. 22.—**"Automatic Electric Stations,"** by D. V. Canning, Jr.E.I.C. Attendance 90.

Feb. 5.—**"Recent Developments in the Design of Long Span Bridges,"** by Dr. G. F. Porter, M.E.I.C. Attendance 147.

Feb. 12.—**"Some English Paper Mills,"** by J. N. Stevenson. Attendance 51.

Feb. 19.—**"Maintenance of Way of the Lehigh Valley Railroad,"** by C. R. Moore. Attendance 125.

Feb. 26.—**"Export of Power."** Discussion. Attendance 195.

Mar. 5.—**"Invisible Radiations,"** by Dr. L. E. Pariseau. Attendance 135.

Mar. 12.—**"Improvements in Design and Appearance of Highway Bridges,"** by C. J. Desbaillets, M.E.I.C. Attendance 140.

Mar. 19.—**"Steam Storage and Steam Accumulators,"** by G. E. Lofgren. Attendance 80.

Mar. 26.—**"Reconditioning Frogs and Rails by Oxy-Acetylene under Traffic,"** by Major G. P. MacLaren, M.E.I.C. Attendance 56.

Apr. 2.—**"Municipal Underground Conduit System, of Montreal,"** by G. E. Templeman, A.M.E.I.C. Attendance 106

Apr. 9.—**"Vancouver Harbour,"** by A. D. Swan, M.E.I.C. Attendance 71.

Apr. 16.—**"Consideration of Rainfall and Run-off in connection with Sewer Design,"** by J. G. Caron, A.M.E.I.C. Attendance 108.

Apr. 23.—**"Transformers,"** by C. E. Sisson, M.E.I.C. Attendance 109.

Apr. 30.—**"Preservation of Forest Products,"** by Dr. Hermann von Schrenk. Attendance 88.

June 6.—Visit to Shawinigan Falls. Attendance 46.

Oct. 1.—**"Evolution,"** by Dr. L. E. Pariseau. Attendance 160.

Oct. 8.—**"Hydraulic Regulating Gates,"** by F. Newell, M.E.I.C. Attendance 143.

Oct. 15.—No meeting, (A.S.C.E. ball).

Oct. 22.—**"High Voltage Phenomena,"** by F. W. Peck, Jr. Attendance 135.

Oct. 28.—**"Steel Construction,"** by Lee H. Miller. Attendance 110.

Nov. 5.—**"Rate Making—Public Carriers,"** by Dr. S. J. McLean. Attendance 102.

Nov. 12.—**"Rock Ballasting on Eastern Lines, C.P.R.,"** by A. C. MacKenzie, M.E.I.C. Attendance 80.

Nov. 19.—**"Stress Analyses by Means of the Photo-Elastic Method,"** by Dr. P. A. Heymans. Attendance 133.

Nov. 26.—**"Aviation and Modern Engineering Practice,"** by Wing-Commander E. W. Steedman, O.B.E. Attendance 120.

Dec. 3.—**"Automatic Control for Railway Sub-Stations,"** by E. Gray-Donald, S.E.I.C.; and **"Scientific Principles Applied to Dwelling House Construction"**, by H. A. Gauvin, S.E.I.C. Attendance 52.

Dec. 10.—**"Transmission Line Towers,"** by C. M. Goodrich, M.E.I.C. Attendance 85.

Dec. 17.—Annual meeting.
Average attendance: 109.

General

In addition to the routine affairs described in the foregoing part of this report, the branch has been active in other ways with the object of enhancing its usefulness to the members and to the public.

Resolution to Provincial Government

Following an address by R. A. C. Henry, M.E.I.C., director of the Bureau of Economics of the Canadian National Railways, given before the branch on January 15th, 1925, dealing with the use of public highways by trucking and bus companies, the Executive Committee held a number of meetings for the express purpose of discussing this subject.

A resolution was sent to the provincial government, the Canadian Good Roads Association, Royal Automobile Club of Canada, Chambre de Commerce and the Board of Trade. The branch was gratified at receiving the commendation of Council and advice that the subject had been referred for discussion to the other branches of *The Institute*.

During the convention of the Canadian Good Roads Association in Quebec, on September 23rd, the chairman of the branch attended the convention and outlined the action of the Montreal Branch of *The Engineering Institute of Canada*. While no definite action appears to have been taken nevertheless we have been given to understand that the government is giving serious consideration to the proposal.

Export of Power

During the early part of the year, a subject in which there was great public interest was that of the export of power. It was felt that the atmosphere of uncertainty might be somewhat cleared if a discussion was held under the auspices of the Montreal Branch. With that idea in mind, a number of speakers took part in the meeting which was arranged for February 26th. The addresses and discussions were fully reported in *The Engineering Journal* for April 1925, so no further reference is necessary in this report.

Visit to Shawinigan Falls

An event of unusual interest took place on June 6th, 1925, when the members of the Montreal Branch visited Shawinigan Falls. Through the courtesy of the Shawinigan Water and Power Company, a very enjoyable and instructive time was had by 46 members of the branch. A full account of the visit appeared in *The Engineering Journal* for July, 1925.

Branch Sections

One of the subjects which was left over from last year for action by the 1925 executive was that of the organization of the sections of the branch. It will be remembered that suggestions had been made that each section should have its own organization and also that members of other societies, resident in Montreal, should become complimentary affiliates of the section in which they were directly interested. Considerable study was given to this matter and we also had a number of communications with headquarters regarding the second suggestion, the last advice being to the effect that the matter had been referred to the Committee on International Co-operation.

With regard to the first suggestion, it was felt that the proposed action was somewhat premature but an innovation was introduced this year by the chairman of each section of the branch calling a meeting of engineers, both members of *The Institute* and otherwise, representative of his section. While there were no new or drastic recommendations made at any of these meetings, they nevertheless fulfilled an important function and gave an opportunity for views to be expressed by all parties. We would recommend that an effort be made to have these meetings held every year and would lay stress on the advisability of inviting engineers who are not members of *The Institute* take to part in the discussions.

Students Section

What may possibly be looked upon as an outstanding action during the year was the formation of a Students Section of the branch. It was felt by the Executive Committee that there had not been sufficient means in the past for co-operation between the branch and its Student members.

After considerable discussion of the subject, the formation of a Students Section of the branch was decided upon. This section is on the same footing as the other sections with a chairman and vice-chairman who, *ex-officio*, become members of the Papers and Meetings Committee.

The chairman of the Students Section, F. E. Winter, S.E.I.C., and the vice-chairman, G. Gingras, S.E.I.C., have not only co-operated regarding the obtaining of papers but have also been of value to the organization in many ways. It is hoped that now that the Students Section has been inaugurated care will be taken to built it up as an integral part of the branch.

At the meeting of the branch, held on December 3rd, under the auspices of the Students Section, it may well be noted that the quality of the papers, the delivery of the speakers, the conduct of the meeting by the Student chairman, were all of very high order, and compared favourably with the very best meetings arranged by any section of the branch.

While dealing with the subject of Students, it is a matter for gratification that three of the four prizes awarded to Students in 1924 were won by members of the Montreal Branch.

A. S. C. E. Fall Convention

During the week of October 12th, Montreal was honoured by the presence of the members of the American Society of Civil Engineers holding their Fall Convention. It was felt that the occasion was of such importance as to warrant the Montreal Branch doing something in the way of entertainment to the visiting engineers, and, after due discussion and co-operation with headquarters, it was decided that the branch should act as hosts at a smoking concert which was held on October 14th. This function was successfully carried out and was thoroughly enjoyed by the visitors. President Ridgway, Past-President Grunsky and Secretary Seabury of the American Society of Civil Engineers were singled out as recipients of gifts in the shape of walking canes.

The American Society of Civil Engineers were glad to accept the offer of the secretary of the Montreal Branch, C. K. McLeod, to take charge of the registration of the meeting.

Annual and Professional Meeting

An important event in the work of the branch during the year was the holding of the Annual and Professional Meeting on January 27th, 28th and 29th. The request of the Montreal Branch to conduct a Professional Meeting in conjunction with the Annual Meeting of *The Institute* was duly granted and towards the end of 1924, a special committee was appointed to co-operate with a committee of Council for the arrangement of all the functions. The details of the meeting have already been fully reported in *The Engineering Journal* for February, 1925.

Entertainment of Visitors

On the occasion of outstanding speakers visiting Montreal for the express purpose of addressing the branch, it has been the policy of the Executive to entertain them at a small dinner prior to the meeting. Among others who have been invited were Dr. Hermann von Schrenk of St. Louis, Mo.; Dr. S. J. McLean of Ottawa; Dr. Paul Heymans of Cambridge, Mass.

On May 21st, 1925, Mr. F. Gill, past-president of the Institution of Electrical Engineers of Great Britain, accepted an invitation to a luncheon. This meeting was fully reported in *The Engineering Journal* of June, 1925.

The whole respectfully submitted, on behalf of the Montreal Branch,

J. L. BUSFIELD, M.E.I.C., *Chairman.*

C. K. MCLEOD, A.M.E.I.C., *Secretary-Treasurer.*

NOTE:—The original of the above report contained additional details regarding the various activities of the branch mentioned.

Niagara Peninsula Branch

The President and Council,

On behalf of the Executive Committee we beg to submit the annual report of the Niagara Peninsula Branch.

The Executive met as the necessity arose. These meetings were well attended.

There were nine general meetings of the branch, at which the attendance averaged 44. In addition, the annual dance was a very successful function.

The annual picnic, held at Niagara-on-the-Lake, was not as well patronized as usual. Threatening rain kept many away. The following functions have been reported at length in *The Journal.*

Jan. 9—Business meeting at Thorold. **"The Yukon, '97 and To-day,"** by W. R. Bramley. Attendance 50.

Mar. 19—General meeting at St. Catharines. **"The New Filtration Plant,"** by Alex. Milne, A.M.E.I.C., superintendent St. Catharines Water Works, — attendance 25.

Mar. 24—Dinner meeting at Niagara Falls. **"Contracts,"** by Lt.-Col. W. R. Robertson, — attendance 25.

April 25—Trip to Hamilton. Visit to Hamilton By-Products Coke Co., followed by dinner-meeting, — attendance 75.

May 19—Annual meeting at Welland. **"The Life and Works of Sir Sanford Fleming"**. Prof. Peter Gillespie, M.E.I.C., — attendance 50.

June 27—Picnic at Niagara-on-the-Lake, — attendance 42.

July 8—Trip to Buffalo. Visit to Pierce Arrow plant, — attendance 75.

Aug. 15—Visit of Hamilton Branch. Trip over Welland ship canal, — attendance 38.

Oct. 29—Trip over Flight locks Thorold. Dinner-meeting at Welland. **"Harbor Development,"** by J. A. Grant, A.M.E.I.C., — attendance 40.

Nov. 26—Dinner-meeting at St. Catharines. **"Achievements in Bridge Building,"** by Prof. C. R. Young, M.E.I.C., — attendance 40.

MEMBERSHIP

The membership shows a slight loss from last year.

Ottawa Branch

The President and Council,

On behalf of the Managing Committee of the Ottawa Branch, we beg to submit the following report for the calendar year 1925.

The branch has completed another very successful year in every respect.

During the year the Managing Committee held ten meetings. In addition the branch held eight evening meetings and eight luncheons. The annual smoker took the form of a joint smoker with the Professional Institute of the Civil Service of Canada and the evening meeting on December 8th, was a joint meeting with the Ottawa Valley Graduates Society of McGill University.

One of our members, C. A. Magrath, M.E.I.C., was appointed chairman of the Ontario Hydro-Electric Power Commission to succeed the late Sir Adam Beck. While the selection reflected great honour on not only Mr. Magrath in particular, but upon the engineering profession in general, it also indicated a development of uncommon sense in political minds and a better appreciation of engineering training for executive work in public utilities. The publicity gained through our meetings is now beginning to make itself felt so that, in the formation of committees on questions of municipal or provincial affairs, a place is now generally reserved for a representative from the engineers. It is certainly gratifying to know that we are getting away rapidly from that position known as the lone voice in the wilderness.

The Ottawa Centenary to be celebrated in 1926 has an engineer on the general committee and an engineering committee to advise on construction details.

It is with profound regret that we report the loss through death of four of our members, namely, two Members, J. J. McArthur and W. J. Stewart and two Associate Members, L. F. Brinkman and J. A. Symes.

The annual ball was held at the Chateau Laurier on January 22nd and well upheld the reputation established in previous years. It is one of the few affairs that bring us together socially whereby we may become known to one another.

During the year the Managing Committee lost one of its valuable members, R. J. Durley, M.E.I.C., who was appointed general secretary of *The Institute.*

The balance sheet shows that we had a successful financial year. Although considerable expense was incurred our assets have been decreased by only $7.38, leaving a working capital of $1,603.45.

Regardless of deaths and removals from the city, our membership shows a net increase of 20 for the past year.

PROCEEDINGS AND PUBLICITY

During the year eight luncheons and eight evening meetings of the branch were held, as follows:—

Jan. 8—**"A Visit to Wembley,"** by Fraser S. Keith, M.E.I.C.; general secretary, "Engineering Institute of Canada," Montreal; luncheon meeting at the Chateau Laurier.

Jan. 8—Annual meeting — Daffodil Tea Rooms.

Feb. 10—**"The Expedition of 1924 to the Arctic Islands of Canada,"** by F. D. Henderson, D.L.S., senior officer in charge of the expedition, Ottawa; evening meeting at the Victoria Memorial Museum.

Feb. 19—**"Wagner Motor Film,"** by John Murphy, M.E.I.C., Ottawa; evening meeting at the Victoria Memorial Museum.

Mar. 3—**"Technical Education,"** by Prof. L. W. Gill, M.E.I.C., principal of the Hamilton Technical Institute, Hamilton; luncheon meeting at the Chateau Laurier.

Mar. 19—**"The Motion Picture Industry of Today,"** by B. E. Norrish, A.M.E.I.C., manager, Associated Screen News of Canada, Ltd., Montreal; luncheon meeting at the Chateau Laurier.

Mar. 26—**"The Practical Man versus the Theorist,"** by H. M. Tory, D.SC., LL.D., chairman of the Honorary Advisory Council for Scientific and Industrial Research of Canada, and president of the University of Alberta, Edmonton; luncheon meeting at the Chateau Laurier.

April 24—Joint smoker with the Professional Institute of the Civil Service of Canada at the Chaudiere Golf Club.

April 30—**"Structural Steel,"** by Lee H. Miller, chief engineer of the American Institute of Steel Construction, New York; evening meeting at the University Club.

May 16—**"Field Control of Concrete,"** by Colonel H. C. Boyden, chief engineer, Portland Cement Association, Chicago; evening meeting at the University Club.

Oct. 6—"**The Work of the Royal Canadian Air Force in Canada,**" by Captain J. Stanley Scott, M.C., A.F.C., A.D.C., director of the Royal Canadian Air Force, Ottawa; luncheon meeting at the Chateau Laurier.

Nov. 13—Complimentary luncheon at the Chateau Laurier in honour of C. A. Magrath, M.E.I.C., chairman, Ontario Hydro-Electric Power Commission.

Nov. 19—"**Highway Bridges,**" by C. J. Desbaillets, M.E.I.C., chief engineer, Montreal Water Board, Montreal; evening lecture at the University Club.

Nov. 26—"**The Newly Developed Oil-Electric Car,**" by C. E. Brooks, chief of motive power, Canadian National Rys., Montreal, and A. E. L. Chorlton, representing Wm. Beardmore's Works, London, England; luncheon meeting at the Chateau Laurier.

Dec. 8—"**The Ascent of Mount Logan,**" by H. F. Lambart, D.L.S., co-leader of the Mount Logan expedition, Ottawa; joint evening meeting with the Ottawa Valley Graduates Society of McGill University at the Victoria Memorial Museum.

Dec. 15—"**Some Economic Phases entering into the Adjustment of Vehicular Traffic to Steam Railways,**" by R. A. C. Henry, M.E.I.C., director of the Bureau of Economics, Canadian National Rys., Montreal; luncheon meeting at the Chateau Laurier.

The attendance at the luncheon meetings has averaged about 110, the largest attendance being at the complimentary luncheon to Mr. Magrath when 180 were present. During the year the Committee carried out the established policy of inviting prominent speakers to address the luncheon meetings. While the addresses, as a rule, had a general engineering trend, they were not in many cases strictly technical but it is the opinion that this policy works out to the best interests of all concerned.

The evening lectures were also well attended as many as 400 having been present at some of them. At the annual meeting on January 8th, the Charter was presented to the local branch by General Secretary, Fraser S. Keith.

Membership

During the year the total membership increased from 452 to 472, and the corporate membership from 344 to 357.

The following table shows in detail the comparative figures of the branch membership for the years 1923, 1924 and 1925:—

	1923	*1924*	*1925*
Honorary Members	2	1	1
Members	113	112	113
Associate Members	207	232	244
Affiliates of *Institute*	6	6	8
Juniors	30	35	35
Students	18	31	34
Branch Affiliates	32	35	37
Total	408	452	471

Rooms and Library

The branch library is situated on the third floor of the Stephen building where it is open for consultation by members under the same conditions that have previously prevailed.

Accessions to the library consisted of government reports, the Proceedings of the American Society of Civil Engineers, presented by F. H. Peters, M.E.I.C., and the Proceedings of the Institution of Civil Engineers, provided by the librarian.

Advertising in The Journal

Commissions for advertising secured in *The Journal* during 1925 amount to $107.19, which is equivalent to the rebates received from 53 Associate Members.

Finances

The financial position of the branch continues to be very satisfactory as may be seen from the attached statements of assets and liabilities and of receipts and expenditures. Although these statements show a somewhat smaller bank balance our assets show a decrease of only $7.38.

The branch closed the year with a balance of $560.36 in the bank, $4.50 cash on hand and $700.00 in Victory Bonds. In addition to this balance the branch has assets of $55.40 in rebates due from headquarters $107.19 due for advertising in *The Journal* and $176.00 in furniture, equipment, etc., making a total of $1,603.45.

The income for the last two years was, for 1924 — $1,209.93 and for 1925 — $712.59; the expenditure for 1924 — $1,548.90 and for 1925 — $833.66. The annual income of the branch from Victory Bonds is $36.25.

Officers for 1925

The annual meeting of the Branch will be held in Ottawa on January 14th, when the officers and members of the Managing Committee will be elected for the year 1926.

Respectfully submitted,

A. F. Macallum, M.E.I.C., *Chairman.*

F. C. C. Lynch, A.M.E.I.C., *Secretary-Treasurer.*

Peterborough Branch

The President and Council,—

The year 1925 is the sixth in the history of this branch. The annual meeting was held on May 14th, which resulted in the election of the following executive.

Past-chairman	E. R. Shirley, M.E.I.C.
Chairman	A. L. Killaly, A.M.E.I.C.
Vice-chairman	B. L. Barns, A.M.E.I.C.
Treasurer	A. B. Gates, A.M.E.I.C.
Secretary	P. Manning, A.M.E.I.C.
Executive	W. M. Cruthers, A.M.E.I.C.
	R. C. Flitton, A.M.E.I.C.
	J. H. MacIntosh, A.M.E.I.C.
	D. L. MacLaren, A.M.E.I.C.
	A. H. Munro, A.M.E.I.C.
	W. E. Ross, A.M.E.I.C.

During the summer, however, D. L. MacLaren, A.M.E.I.C., was transferred to Toronto, and is now in the Toronto Branch. The executive unanimously agreed that this vacancy be filled by B. Ottewell, A.M.E.I.C.

The executive, feeling that the interests of this outspread branch will be better served, have during the year, elected representatives in each of the outlying centres, as follows:—

Lindsay — E. L. Miles, M.E.I.C.
Port Hope — A. A. Outram, Jr.E.I.C.
Belleville — O. R. Thomson, M.E.I.C.
Campbellford — A. E. Caddy, M.E.I.C.

Mr. Caddy having been transferred to Peterborough, his position as representative in Campbellford has been filled by A. L. Malcolm, M.E.I.C.

It is realized that these representatives cannot possibly attend the executive meetings, so that to keep them in touch with executive activities, copies of the minutes of each meeting will be mailed to them as in the the case of other members of the executive.

Meetings

Twelve regular meetings were held throughout the year. The papers varied as usual in the subjects taken, and the average attendance turned out to be the same as last year, the good figure of 48. The very pleasing feature has developed throughout the meetings in the eagerness for discussion; it displays the interest the members are taking in the papers presented.

The social activities covered our annual outing held during the summer and the annual banquet held in November. Both these events were very well supported and thoroughly enjoyed. The venue of the former being Campbellford and district, where the automatic generating stations in actual service were visited. The latter event, though, not having any special attraction as in previous years was quite a success.

The complete list of meetings being as follows:—

Jan. 8.—**"Radio for Emergency Communication"**, F. K. Dalton, assistant laboratory engineer, Hydro-Electric Power Commission, Toronto.

Jan. 22.—**"Impressions and Views of Wembley"**, Frederick B. Brown, M.E.I.C., and Fraser S. Keith, M.E.I.C.

Feb. 12.—**"Factory Management"**, W. R. McGie, A.M.E.I.C., chief engineer of Ford Motor Company of Canada, Ford, Ont.

Feb. 26.—**"Modern High Voltage Insulation"**, W. R. Goddard, president, Canadian Porcelain Company, Hamilton.

Mar. 12.—**"Modern Paper Making"**, A. D. Ross, Canadian General Electric Company, Toronto.

Mar. 25.—**"Electrical Wiring Devices, Past and Present"**, C. S Mallett, manager of Ward St. Works of Canadian General Electric Company, Toronto.

Apr. 23.—**"Radio — Frequency Amplification"**, W. B. Cartmel, M.E.I.C.

May 14.—**"Field Control of Concrete"**, Col. H. C. Boyden, Portland Cement Association.

Sept. 22.—**"Some Economic Results of Use of Electric Power"**, C. M. Ripley, publicity Department of General Electric Company, Schenectady, N.Y.

Oct. 8.—Central Ontario System of Hydro-Electric Power Commission.

Oct. 22.—**"Rail Steel for Concrete Reinforcement"**, J. B. Carswell, A.M.E.I.C., president, Carswell Construction Company, Toronto.

Nov. 23.—Annual banquet.

Dec. 10.—**"Reclamation of Lands in Western Canada"**, E. L. Miles, M.E.I.C., Lindsay, Ontario.

Membership

The total membership remains at the same total as in the previous year, the grades of members and associate members increasing by a total of three, but the three remaining grades each decreasing by one offset it.

Quebec Branch

The President and Council,—

The Executive of the Quebec Branch begs to present the following annual report on the work of said branch during the year 1925:—

Membership

	Resident	*Non-Resident*	*Total*
Honorary Members	1	..	1
Members	17	1	18
Associate Members	61	15	76
Juniors	9	3	12
Students	17	5	22
Affiliates	1	..	1
Total membership			130

Annual Meeting

The annual meeting of the Quebec Branch was held on June 29th, 1925, under the presidency of A. R. Décary, M.E.I.C. The following officers were elected for the year 1925-1926:

Honorary President (for life)	A. R. Décary, M.E.I.C.
President	A. B. Normandin, A.M.E.I.C.
Vice-President	S. L. deCarteret, A.M.E.I.C.
Secretary-Treasurer	Louis Beaudry, S.E.I.C.
Executive Committee	T. E. Rousseau, A.M.E.I.C.
	Hector Cimon, A.M.E.I.C.
	L. C. Dupuis, A.M.E.I.C.
	Alex. Larivière, A.M.E.I.C.

Meetings

The executive of the Quebec Branch has held its meetings regularly during the year 1925.

The monthly luncheons and evening meetings of the branch were held regularly at the Chateau Frontenac and at the City Hall from the month of December, 1924, to the month of July, 1925.

It has been our pleasure to have frequent opportunities of welcoming outside members of our *Institute*, and also prominent men in public life at our different luncheons and evening meetings. At all our meetings, practically the full membership of the branch attended, and very good publicity of the activities of the branch was given through the press.

All questions submitted by the Council of *The Institute* have been studied, discussed and transacted.

Our branch has followed with interest *The Institute* deliberations and has devoted its full energy to all matters aiming to the protection and promotion of the interest of *The Institute* and its members.

Our special committee has followed closely, studied seriously and made as complete report as possible on all applications for membership which have been referred to this branch, and the necessary recommendations have been made to the Council of *The Institute* who has kindly taken them into consideration.

ADDRESSES

The following addresses were made at our different luncheons and evening meetings:—

"Exploitation of Forests." by G. C. Piché, A.M.E.I.C., chief of the Provincial Forestry Service of Quebec.

"The Difference Between a Land Surveyor and a Civil Engineer," by David W. Mill, Q.L.S., A.M.E.I.C., F.S.I., director of surveys of the province of Quebec.

"The Engineer and the Industry," by J. H. Fortier, president of the Manufacturers Association of Canada, general-manager of the P. T. Légaré Co.

"Some Duties Common both at this Time to the Engineer and to the Lawyer," by Louis S. St-Laurent, K.C.

"Aerial Photography applied to Engineering," by Ellwood Wilson, M.E.I.C., manager of the Forestry Division, Laurentide Co. Ltd.

"Mining Deposits of the North-West of Quebec," by A. O. Dufresne, M.Sc., mining engineer.

"Earthquake," by Rev. Alex. Vachon, honorary member of the Quebec Branch of the E.I.C., professor at Laval University.

"Field Control of Concrete," by Col. H. C. Boyden, Chicago.

Au Président et au Conseil,—

Le Conseil de la Section de Québec a l'honneur de vous soumettre son rapport annuel pour l'année 1925 comme suit:—

RÔLE DES MEMBRES

	Résidents	*Non résidents*	*Total*
Membres honoraires	1	..	1
Membres	17	1	18
Membres associés	61	15	76
Membres juniors	9	3	12
Membres étudiants	17	5	22
Membres affiliés	1	..	1
Total des membres			130

ASSEMBLÉE ANNUELLE

L'assemblée annuelle de la Section de Québec a été tenue le 29 juin 1925, sous la présidence de A. R. Décary, M.E.I.C. Les officiers dont les noms suivent ont été élus pour l'année 1925-1926:

Président Honoraire (à vie)	A. R. Décary, M.E.I.C.
Président	A. B. Normandin, A.M.E.I.C.
Vice-Président	S. L. deCarteret, A.M.E.I.C.
Secrétaire-Trésorier	Louis Beaudry, S.E.I.C.
Conseillers	T. E. Rousseau, A.M.E.I.C.
	Hector Cimon, A.M.E.I.C.
	L. C. Dupuis, A.M.E.I.C.
	Alex. Larivière, A.M.E.I.C.

ASSEMBLÉES

Le Conseil de la Section de Québec a tenu ses assemblées régulièrement durant l'année 1925.

Les déjeuners et assemblées du soir de chaque mois ont été tenus régulièrement au Château Frontenac et à l'Hôtel de Ville de Québec, à partir du mois de décembre 1924 jusqu'au mois de juillet 1925.

A nos différents déjeuners et assemblées du soir, nous avons eu fréquemment l'occasion de compter parmi nous des membres de l'*Institut*, étrangers à notre branche, ainsi que des personnages de marque dans la vie publique. Toutes nos réunions ont assemblé la presque totalité des membres de notre branche, et la presse a toujours eu l'amabilité de donner de très bons comptes rendus de nos travaux.

Toutes les questions soumises par le Conseil Général à la Section de Québec ont été étudiées, discutées et transigées.

Notre section a suivi avec intérêt les travaux de l'*Institut*, et a prêté son plein concours à toutes les questions ayant pour but de protéger et de promouvoir les intérêts de l'*Institut* et de ses membres.

Notre Comité Spécial s'est occupé de surveiller, de faire une étude sérieuse et de faire un rapport aussi complet que possible sur toutes les demandes d'admission qui ont été référées à notre branche, et les recommendations nécessaires ont été faites au Conseil Général de l'*Institut* qui a bien voulu en tenir compte.

CAUSERIES

Les causeries suivantes ont été faites à nos différentes assemblées du soir et des déjeuners:

"Exploitation des Forêts," par M. G. C. Piché, A.M.E.I.C., chef du Service Forestier de la province de Québec.

"L'Arpenteur et l'Ingénieur," par M. David W. Mill, A.M.E.I.C., surintendant des Arpenteurs de la province de Québec.

"L'Ingénieur et l'Industrie," par M. J. H. Fortier, président de l'Association des Manufacturiers du Canada, gérant général de la Cie "P. T. Légaré Co.".

"Quelques devoirs communs actuellement à l'Ingénieur et à l'Avocat," par M. Louis S. St-Laurent, C.R.

"La Photographie Aérienne appliquée au Génie," par M. Ellwood Wilson, M.E.I.C., gérant du département des Forêts de la Laurentide Company Limited.

"Les Gites Miniers du Nord-Ouest de Québec," par M. A. O. Dufresne, M.Sc., ingénieur des mines.

"Les Tremblements de terre," par M. l'abbé Alex. Vachon, membre honoraire de la Section de Québec, professeur à l'Université Laval.

"Le contrôle du béton sur le chantier," par le Colonel H. C. Boyden, de la Portland Cement Association.

Saint John Branch

The President and Council,—

On behalf of the executive the eighth annual report of the Saint John Branch for the year 1925 is herewith submitted.

Twelve meetings of the executive and nine meetings of the branch have been held during the year. Nine papers on varied engineering subjects have been presented before the branch.

The members of the branch have taken an active interest in the affairs of *The Institute.* Eleven members attended the Annual and General Professional Meeting at Montreal in January last, and fifteen members visited Halifax in October for the Maritime General Professional Meeting.

Engineers have participated in the public life of the province. During the year a member of this branch held cabinet rank in the government, four members of the engineering profession were candidates for election, a member of this branch is at present a member of the provincial legislature.

The aid of the engineer has been sought in civic affairs. Members of this branch served acceptably as members of a committee during the construction of a war memorial, erected this year, in Saint John. The committee revising the by-laws of the city of Saint John includes members of this branch on its personnel.

This branch has been addressed by members of other branches during the year and has welcomed as guests transient members of sister branches. The public is invited to attend all branch meetings and those of a popular nature have been advertised in the press.

The interests of the members not residing in Saint John have been attended to as far as possible by holding a meeting at Fredericton jointly with the Engineering Society of the University of New Brunswick. By this means the work of *The Institute* is brought to the attention of the engineering students.

The members of this branch learned with regret of the resignation of Fraser S. Keith, M.E.I.C., as general secretary, during the year, and by a resolution forwarded to Mr. Keith expressed its appreciation of his work for *The Institute.* The members have been pleased to welcome R. J. Durley, M.E.I.C., as successor to Mr. Keith.

MEMBERSHIP

A statement of membership as on December 3rd, 1925, follows:—

	Branch Residents	*Branch Non-Residents*	*Total*
Members	17	11	28

Saguenay Branch

The President and Council,—

On behalf of the Executive Committee we take pleasure in submitting the following report of the activities of the Saguenay Branch for the year 1925.

EXCURSIONS

Following the policy adopted at the annual meeting in 1924, no winter meetings were held owing to the difficulty of transportation during these months, but during the summer three very interesting excursions were held, namely:—

July 20th, — The complete power developments of the Chicoutimi river were visited. These comprise three electric generating stations and two pulp mills. The annual meeting was also held during this outing at Chute Garneau power house, where the members had been guests at luncheon of la Compagnie Électrique de Chicoutimi, Limitée.

August 21st. — The second excursion was held to the new town and mill at Riverbend, Que., both the property of Price Brothers. The afternoon was devoted to a visit to Isle Maligne where the immense progress made since last year was very much in evidence.

September 19th. — The final excursion of the year was held, the trip being on the north shore of the Saguenay and comprising a visit to the power developments and logging flumes of Price Brothers in that region.

OFFICERS

The general elections gave the following results:—

Chairman	C. N. Shanly, M.E.I.C.
Vice-Chairman	Georges LaMothe, A.M.E.I.C.
Secretary-Treasurer	Burroughs Pelletier, A.M.E.I.C.
Executive Committee	Edouard Lavoie, M.E.I.C. (1 year).
	J. E. A. McConville, A.M.E.I.C. (1 year).
	J. L. Delisle, A.M.E.I.C. (2 years).
	A. A. MacDiarmid, A.M.E.I.C. (2 years).
	W. G. Mitchell, M.E.I.C. (*ex-officio*).

(Georges LaMothe, A.M.E.I.C., is also, *ex-officio*, a member of the Executive.)

MEMBERSHIP

The membership of the branch is as follows:—

BURROUGHS PELLETIER, A.M.E.I.C., *Secretary-Treasurer.*

Sault Ste. Marie Branch

The President and Council,—

The attendance at the meetings for the year averaged fifteen, and the meetings were all preceded by a dinner at the Y.W.C.A. rooms.

The low attendance may be partly explained by the continued commercial depression in the Sault.

On account of the extended area covered by our district, it was impossible to have any of our Branch District Members present although they were individually notified of all meetings.

The papers and publicity committee and the entertainment committee provided good material in the way of papers and inspection trips, all of which were of great interest to the members.

The entertainment of R. J. Durley, M.E.I.C., the general secretary of *The Engineering Institute of Canada*, at a luncheon on August 14th, was exceptionally well attended and all present enjoyed and derived much benefit from the "round table talk" after the luncheon.

MEETINGS

The regular meetings were held on the last Friday of each month except June, July, August and November, and the papers given and the inspection trips made were as follows:—

Jan. 30.—**"The Modern Blast Furnace"**, by F. Smallwood, M.E.I.C., chief engineer of the Algoma Steel Corporation.

Feb. 27.—**"Safety First as Practised at the Coke Ovens of The Algoma Steel Corporation"**, by Mr. E. A. Davis, assistant superintendent of the Coke Plant, Algoma Steel Corporation.

Mar. 27.—"**Paper**", by H. A. Morey, A.M.E.I.C., resident engineer, Lake Superior Paper Company.

Apr. 24.—"**Economic Aspects of the Dye Industry**", by G. Durgin, superintendent of operation, Research Department, of the Spanish River Pulp and Paper Mills Limited.

May 29.—"**The Equipment of the Modern Blast Furnace**", by F. Smallwood, M.E.I.C., chief engineer of the Algoma Steel Corporation.

June 17.—A special meeting was held to meet Lt.-Col. Lamb, M.E.I.C., representing the Association of Professional Engineers of Ontario.

Aug. 14.—A special luncheon-meeting was held to welcome R. J. Durley, M.E.I.C., the general secretary of The Engineering Institute of Canada. In the evening in co-operation with the local Board of Trade, the members of the Michigan Mining Institute were entertained at a dinner at the Pavilion.

Sept. 25.—An inspection trip was made through the local plant of the Bell Telephone Company.

Oct. 30.—An inspection trip was made through the power plant of the Great Lakes Power Company.

Dec. 18.—Annual meeting — reports of committees and address of retiring Chairman Wm. Seymour, M.E.I.C. Election of officers. Address by L. R. Brown, A.M.E.I.C., city engineer, on "**Municipal Affairs**". Subjects of general interest.

MEMBERSHIP

The present membership of the branch is:—

	Branch Residents	Branch District	Total
Members	10	12	22
Associate Members	14	37	51
Juniors	7	4	11
Students	6	19	25
Affiliates	1	—	1
Branch Affiliates	11	—	11
Total			121

This is a decrease of nine members as shown by the 1924 report. This is caused by the continued depression throughout the North Country. There are three applications for admission pending.

Respectfully submitted,

A. H. RUSSELL, A.M.E.I.C., *Secretary-Treasurer.*

Saskatchewan Branch

The President and Council,—

On behalf of the branch executive we beg to submit the following report concerning the activities of the Saskatchewan Branch during 1925. This report is supplemental to the report which will be issued in March, covering the branch year.

Early in the year an attempt was made to secure engineering legislation similar to that obtained in other provinces. A bill was introduced but was defeated in committee. However it has been a matter of satisfaction to the branch that the Provincial Public Health Act has been amended so that a civil engineer is included in the Council of Public Health.

Other matters occupying the attention of the branch have been attendance at meetings and the requirements for admission to corporate membership in *The Institute.* With regard to the latter the branch has gone on record as desiring a tightening up and stricter adherence to the rules concerning admission. Motives prompting this action are a desire to enhance the standing given by membership in *The Institute* and to remove the chance of discrimination when considering applications.

The branch was glad to welcome our new general secretary, R. J. Durley, M.E.I.C., at a special meeting this summer, and it is hoped there may be frequent opportunities for improving acquaintanceship.

During the fall a Saskatchewan Section of the American Institute of Electrical Engineers has been formed with headquarters in Regina. Cordial relations have been established between the new organization and the local branch of *The Institute.*

The executive wishes to record its thanks and appreciation for the efforts of the committees which have arranged and put into effect the various functions and activities.

MEETINGS

During the year there have been held seven executive meetings, six regular meetings, one special meeting and one social evening.

Meetings and papers were as follows:—

Jan. 8.—Business meeting, consideration of qualifications for admission to Institute and classification of membership. Branch goes on record as desiring a tightening up and stricter adherence to regulations.

Feb. 12.—"**Military Engineering**", Capt. G. R. Chetwynd, M.C., D.C.M., A.M.E.I.C.

Mar. 13.—Eighth annual meeting, reports of committees, election of officers, address by retiring chairman, Prof. C. J. Mackenzie, M.E.I.C., dinner and social evening.

Apr. 17.—"**Transmission of Speech over Long Distances**", S. R. Muirhead, Jr.E.I.C.
Discussion of matters relating to improvement of attendance at meetings, reading and discussion of paper submitted from headquarters by R. A. C. Henry, M.E.I.C., "**The Motor Vehicle as a Transportation Facility**".

Aug. 10.—Special meeting for R. J. Durley, M.E.I.C., general secretary. "**Institute Affairs**".

Oct. 14.—"**Duties of a Municipal Engineer**", R. W. Allen, A.M.E.I.C.
"**Features of Supply in Light and Power Business**", E. W. Bull.
"**Retail Business of a Waterworks Department**", J. W. D. Farrell, A.M.E.I.C.

Nov. 12.—"**Outline of the Work of Some Branches of the Department of the Interior, Ottawa**", Lt.-Col. A. C. Garner, D.S.O., M.E.I.C.
"**History of Town Planning**", Stewart Young, A.M.E.I.C.
"**Parks and Boulevards**", J. M. Craig, Parks Supt., Regina.
"**Some Court Decisions bearing on Surveying**", R. W. E. Loucks, A.M.E.I.C.

Dec. 15.—Social evening in collaboration with the A.I.E.E. Cards and dancing.

Toronto Branch

The President and Council,

The Executive Committee of the Toronto Branch respectfully submits the following report for the calendar year 1925.

During this period, the present executive was elected in March at the branch annual meeting.

EXECUTIVE COMMITTEE

January to March, 1925.		*March to December, 1925.*
J. M. Oxley, M.E.I.C.	Chair.	T. R. Loudon, M.E.I.C.
N. D. Wilson, M.E.I.C.	V.-Ch.	J. G. R. Wainwright, A.M.E.I.C.
J. H. Curzon, A.M.E.I.C.	Sec.-T.	C. B. Ferris, A.M.E.I.C.
R. W. Angus, M.E.I.C.	Exec.	R. W. Angus, M.E.I.C.
H. K. Wicksteed, M.E.I.C.		E. T. J. Brandon, A.M.E.I.C.
E. T. J. Brandon, A.M.E.I.C.		R. B. Young, M.E.I.C.
J. G. R. Wainwright, A.M.E.I.C.		J. A. Knight, A.M.E.I.C.
T. R. Loudon, M.E.I.C.		A. C. Oxley, A.M.E.I.C.
Peter Gillespie, M.E.I.C.		L. W. Wynne-Roberts, A.M.E.I.C.
G. T. Clark, A.M.E.I.C.	*Ex-O.*	H. K. Wicksteed, M.E.I.C.
C. R. Young, M.E.I.C.		G. T. Clark, A.M.E.I.C.
E. G. Hewson, M.E.I.C.		E. G. Hewson, M.E.I.C.
J. A. Knight, A.M.E.I.C.		J. M. Oxley, M.E.I.C.
R. O. Wynne-Roberts, M.E.I.C.		J. H. Curzon, A.M.E.I.C.

COMMITTEES

The standing committees and chairmen are:—

Programme..................T. R. Loudon, M.E.I.C.
Finance.....................J. G. R. Wainwright, A.M.E.I.C.
Publicity....................S. G. Talman, A.M.E.I.C.
" ....J. W. Falkner, A.M.E.I.C.
Library......................A. C. Oxley, A.M.E.I.C.
Attendance.................L. W. Wynne-Roberts, A.M.E.I.C.
Student Relations.............W. L. Thompson, S.E.I.C.

The Toronto Branch representative on the Nominating Committee of *The Institute* is J. G. R. Wainwright, A.M.E.I.C., who has been re-elected by the executive for this office during 1926.

ANNUAL MEETING COMMITTEE

In anticipation of the Annual Meeting of *The Institute* in Toronto on January 27th, 28th, and 29th, 1926, an Annual Meeting Committee was appointed which consists of the executive and the following members who have been making preparations under the direction of Professor C. R. Young, M.E.I.C., who was unanimously selected chairman of this committee.

Chairman....................C. R. Young, M.E.I.C.
Vice-Chairman and Papers.....W. P. Dobson, M.E.I.C.
Secretary......................L. W. Wynne-Roberts, A.M.E.I.C.
Finance.......................W. E. Douglas, A.M.E.I.C.
Dinner........................Col. H. J. Lamb, M.E.I.C.
Entertainment................B. N. Simpson, jr.E.I.C.
Service........................H. W. Tate, A.M.E.I.C.
Accommodation...............J. B. Carswell, A.M.E.I.C.
Publicity......................C. A. Meadows, A.M.E.I.C.
Reception.....................R. O. Wynne-Roberts, M.E.I.C.
Convener of Ladies Committee. Mrs. C. H. Mitchell.

MEETINGS

The executive held fourteen meetings for the transaction of branch affairs. There were nineteen general meetings. Of these, three were luncheon-meetings which are now held down town at 12.30 noon on the first Thursday of each month and are well attended.

The October, November and December luncheon meetings were addressed respectively by C. A. Magrath, M.E.I.C., N. D. Wilson, M.E.I.C., on "Mexico City" and Sir Robert Falconer on "Geneva".

For the general meetings, held on Thursday evening of each week, the endeavor has been to have subjects which conform to the aims and technical requirements of *The Institute*, interspersed with those of popular interest. The average attendance is under one hundred. An indication of the present trend was the attendance of over two hundred to the open meeting on "Matter, Energy and Radiation".

The advisability of social meetings was indicated at the smoker in Hart House on December 17th. J. A. Knight, A.M.E.I.C., led the discussion which followed the report of R. B. Young, M.E.I.C., A. C. Oxley and J. A. Knight, A.M.E.I.C., as a committee on the subject of "Membership Standards" which had been brought forward by the Saskatchewan Branch. The branch were greatly pleased to have Mr. Durley, the general secretary, present and thoroughly appreciated his visit.

The programme for the year was the following:—

Jan. 22.—"**Canadian Woods and Their Uses**", W. Kynock, superintendent, Forest Products Laboratories.
Jan. 29.—"**Developments in Structural Steel Design**", L. H. Miller.
Feb. 5.—"**The Coal Problem**", Dr. E. S. Moore.
Feb. 12.—"**The Rubber Industry**", D. E. Beynon.
Feb. 19.—"**The Design and Construction of the new Niagara Arch**", H. Ibsen.
Feb. 26.—Joint meeting with A.S.M.E.
Mar. 5.—"**Recent Developments of the Hydro-Electric Power Commission of Ontario**", T. H. Hogg, M.E.I.C.
Mar. 12.—"**The Relation of Mining to our Industrial Life**", G. C. Bateman.
Mar. 19.—Branch annual meeting and elections.
Oct. 15.—Luncheon in honour of C. A. Magrath, M.E.I.C.
Oct. 22.—"**Speculations on the Mechanisms Along the Lines of Relativity**", W. Gore, M.E.I.C.
Oct. 29.—"**The Winds of the Globe**", Sir F. Stupart.
Nov. 5.—Luncheon — "**Mexico City**", N. D. Wilson, M.E.I.C.
Nov. 12.—"**Nipigon Region Development**", O. Holden, A.M.E.I.C.
Nov. 19.—"**Mining Developments of Ontario**", The Hon. C. McRae.
Nov. 26.—"**Modern Views on Matter, Energy and Radiation**", Dr. J. G. McLennan.
Dec. 3.—Luncheon — "**Geneva**", Sir Fobert Falconer.
Dec. 10.—"**Brazil**", F. J. Mulqueen.
Dec. 17.—Smoker — Hart House — Report by Committee on "Membership Standards" and discussion led by J. A. Knight, A.M.E.I.C.

MEMBERSHIP

The membership of the branch has continued with the usual fluctuations due to transfers, etc.

The total at Dec. 31st, 1925, was:—

	Branch Residents	*Branch Non-residents*	*Total*
Members	146	5	151
Associate Members	265	14	279
Juniors	50	1	51
Students	104	9	113
Affiliates	5	—	5
Total	570	29	599

FINANCIAL STATEMENT

Respectfully submitted,

T. R. LOUDON, M.E.I.C., *Chairman.*
C. B. FERRIS, A.M.E.I.C., *Secretary-Treasurer.*

Vancouver Branch

The President and Council,—

I have the honour to report on the affairs of the Vancouver Branch, for the year 1925, as follows:—

GENERAL MEETINGS

During this year the policy in regard to general meetings of the branch has been to invite by personal notices, the members of sister organizations, such as the Association of Professional Engineers of B.C., the Vancouver Section, American Institute of Electrical Engineers and the Vancouver Section, Canadian Institute of Mining and Metallurgy. The attendance at our meetings, including visitors, has averaged about 65, as compared with 95 during 1924.

In addition to five general meetings, the branch participated in a convention with the B.C. Division, Canadian Institute of Mining and Metallurgy during February, and a joint meeting with the Vancouver Branch, Town Planning Institute of Canada in November.

The result of this broadened policy has been to stimulate to a marked degree the cordial relations existing between ourselves and sister organizations and to generally increase the usefulness and influence of *The Engineering Institute of Canada* in British Columbia.

The seven meetings occurred as follows:

Feb. 18, 19 and 20.—Convention: B. C. Division, C.I.M.M.
The whole of the second day was devoted to a joint survey and discussion of the **"Pacific Great Eastern Railway Problem"**. The Vancouver Branch contributed two papers: **"The P.G.E. Railway Problem"**, by W. G. Swan, M.E.I.C., chairman, Vancouver Branch; and **"Hydro-Electric Power Possibilities Along the Route of the P.G.E. Railway"**, by Ernest A. Cleveland, M.E.I.C., comptroller of water rights, province of British Columbia.
At the luncheon on Feb. 20th, an address was given on: **"The History of Highway Construction in British Columbia"**, by Patrick Philip, M.E.I.C., chief engineer, Dept. Public Works, province of British Columbia; and at the dinner on the same day an address was given on: **"Professional Engineering Relations"**, by E. A. Wheatley, A.M.E.I.C., registrar, Association of Professional Engrs. of British Columbia.

Mar. 26.—Lantern lecture: **"Highway Bridges in British Columbia"** by A. L. Carruthers, M.E.I.C., bridge engineer, Dept. of Public Works, province of British Columbia. At this meeting the Branch Charter was presented by Major Geo. A. Walkem, M.E.I.C., on behalf of the Council and received by H. J. Cambie, M.E.I.C., on behalf of the branch.

Apr. 2.—Lecture: **"A Standard Specification for Structural Steel"** by Lee H. Miller, New York, U.S.A.

May 21.—Lantern lecture: **"Dominion Dry Dock, Esquimalt, B.C."** by J. P. Forde, M.E.I.C., district engineer, Dept. of Public Works, Victoria, B.C.

Oct. 23.—Lantern lecture: **"The Mount Logan Expedition"** by Lieut.-Col. W. W. Foster, D.S.O., past-president, Alpine Club of Canada and member of expedition.

Nov. 18.—Lantern lecture: **"Town Planning in Practice"**, by W. Brand Young, A.M.E.I.C., assistant city engineer, Vancouver, B.C.
This was a joint meeting with the Vancouver Branch, Town Planning Institute of Canada.

Dec. 17.—Annual general meeting: Annual business and election. Lecture: **"A Talk on the Meteorological Service and Weather Forecasting"** by E. B. Sherman, weather observer, Vancouver, B.C.

Executive Committee

The executive committee held five meetings during 1925, the average attendance being seven. All branch business was transacted by the executive, with the single exception of the annual general meeting.

General Review of 1925 Business

Institute Nominating Committee

On December 16th, A. K. Robertson, M.E.I.C., was appointed to represent the Vancouver Branch on *The Institute* Nominating Committee during 1926.

Branch Elections

Sixty-two marked ballots were returned out of a total of 157 mailed to the membership of the branch for the 1926 election. Last year 52 were returned out of 154.

Library

L. F. Merrylees, A.M.E.I.C., was appointed to act with E. A. Wheatley, A.M.E.I.C., registrar, Professional Engrs. of British Columbia, in negotiations with the University Club of Vancouver relating to the removal of the Joint Library from 931 Birks building to the visitors' room in the new quarters of the Club. Arrangements have been completed, whereby the Club will house the library in the visitors room at a rental of $100. per annum, and will grant free access to the library to all members of the two engineering organizations.

The former room at 931 Birks building was vacated on November 30, 1925, and the library stored until the new library quarters in the University Club are ready for occupation, which is expected in the near future.

Negotiations with headquarters are being conducted by the executive with a view to a loan of $300. to finance new book cases and the binding of certain periodicals. It is confidently expected that a real library will eventually be available for the use of our members in place of the collection of dusty books heretofore.

Branch Office

The branch will retain its headquarters at 930 Birks building at a greatly reduced rental. This question is practically settled but official confirmation has not been given to the details of the arrangement as yet. It is expected that the net result of the changes made in the present joint quarters will be an annual saving to the branch, in rent, of about $115.

Presentation of Branch Charter

This ceremony occurred at the general meeting of March 26th, held in the auditorium of the Vancouver Board of Trade. The presentation address was made by Major Geo. A. Walkem, M.E.I.C., M.L.A., and H. J. Cambie, M.E.I.C., senior life member of *The Institute*, a charter member of the Vancouver Branch, received the charter on behalf of the branch.

Professional Engineering Relations

As a result of the special attention given to this matter by the executive, a distinct step forward has been made, in improved relations with sister engineering organizations. A free discussion of the question was held at a luncheon in February, attended by representatives of the various bodies interested, at which W. G. Swan, M.E.I.C., chairman, Vancouver Branch, presided.

The ultimate objective is the formation of a voluntary body whose membership will consist of all members of professional associations throughout the Dominion. W. G. Swan has been active in promoting this idea but the time is not ripe for its consummation.

During the July visit of R. J. Durley, M.E.I.C., general secretary of *The Institute*, he was the guest at an informal dinner given by the executive, following which the feasibility of such a scheme was discussed with him at considerable length.

Further important developments are looked for during the coming year.

Joint Committee on P. G. E. Matters

W. G. Swan, M.E.I.C., and Wm. Anderson, M.E.I.C., were appointed as representatives of the branch on a joint committee organized by the B. C. Division C.I.M.M., to examine and report on the Pacific Great Eastern Railway Problem. This committee undertook an exhaustive study of the problem and submitted a report to the provincial government in October. W. G. Swan, M.E.I.C., acted as chairman of the committee.

Western Professional Meeting at Banff

Geo. A. Walkem, M.E.I.C., M.L.A., was a delegate from the Vancouver Branch at this meeting, at which he read a paper on "The Vancouver Harbour", prepared by W. G. Swan, M.E.I.C., consulting engineer for the Vancouver Harbour Commissioners.

Students' Prizes

The Walter Moberly Memorial Prize

The initial award of this prize was made to Bruce M. Callander, 1925 graduate of the University of British Columbia in the Faculty of Applied Science, for a summer essay on "The Construction of the Connaught Tunnel". The prize consisted of $25.00 in books.

The A. D. Swan Special Book Prize

This prize was divided equally between two winners in Class 1926, Faculty of Applied Science, University of British Columbia, namely, Harry V. Warren, for a summer essay on "A Reconnaissance in the Whitesail District", and Alexander M. Richmond, for a summer essay on "The History and Development of Copper Mountain, B.C." Each winner received books to the value of $12.50.

We have pleasure in noting the recent announcement that Harry V. Warren has been awarded a Rhodes Scholarship.

H. H. Broughton Prize

This prize, $50.00 cash, was awarded to A. M. Anderson, S.E.I.C., as winner in an essay competition on "Handling of Bulk Cargo". The second prize, $25.00 offered by Mark R. Colby, was not awarded.

We regret to record the death of H. M. Burwell, M.E.I.C., on July 30th, 1925, and that of Thos. H. Tracy, M.E.I.C., on October 30th, 1925.

FINANCIAL STATEMENT

Receipts

Balance on hand at Dec. 18th, 1924	$175.51		
A. D. Swan Prize, donation	25.00		
		$200.51	
Rebates on fees, Nov., 1924, to July, 1925		247.05	
Branch news to Dec., 1925		28.30	
H. H. Broughton, donation for Students' Prize		50.00	
Refund of expenses on Cambie, White and Kennedy Group, photograph enlargement		45.45	
			$571.31

Expenditures

Rent — 930 Birks building to Nov. 30, 1925		$220.00	
Rent — Board of Trade auditorium		25.00	
Printing and typing		44.00	
Postage and revenue tax		10.82	
Telegrams		5.84	
Stationery		1.20	
Addressograph		2.36	
Bank exchange		1.20	
Honorarium to secretary		50.00	
Library		3.15	
Entertaining, etc.		8.85	
A. D. Swan prize	$ 25.00		
H. H. Broughton prize	50.00		
		75.00	
Balance paid on Cambie, White, Kennedy Group photograph		32.20	
Line cuts for book plates—Swan and Moberly prizes		7.09	
Engrossing 12 book plates—Swan and Moberly prizes		3.00	
Wreath for late T. H. Tracy, M.E.I.C.		6.00	
Contribution to expenses of Joint Committee on P.G.E.		15.00	
Balance on hand Dec. 17, 1925		60.60	
			$571.31

There are no outstanding accounts to be paid, excepting rent of office space at 930 Birks building for the month of December. The amount will not be fixed until the tentative agreement with the Association of Professional Engineers has been approved. In any case the amount owing will not exceed $10.00.

The balance, $60.60, on hand at the date of this report, shows a shrinkage of $114.91 since the beginning of the year: but it should be noted that the rebates on fees cover a period of only nine months as compared with fourteen months shown in last year's report.

The average monthly rebates on fees for nine months of this year were about $27.50. Assuming this average for a period of twelve months, our receipts from this source would increase our balance to about $145.00, as compared with an adjusted balance of about $130.00 in last year's report.

If the large amount of arrears of fees could be collected our position would be still better.

The ordinary expenses of operating the branch during 1925 were approximately $375.00 as compared with $370.00 for the two previous years.

Our financial position will be greatly strengthened in future through the large reduction in rent which will result from the removal of the library to the University Club. The estimated annual saving in this respect will be $115.00.

One cheque for $25.00 was drawn on the Moberly Memorial Fund this year to cover the prize awarded to Bruce M. Callander. The balance in the fund at the date of this report is $39.04.

Respectfully submitted,

W. G. SWAN, M.E.I.C., *Chairman.*
P. H. BUCHAN, A.M.E.I.C., *Secretary-Treasurer.*

Victoria Branch

The President and Council,—

On behalf of the Executive Committee of the Victoria Branch, we beg to submit the following report of branch activities for the year ending November 30th, 1925.

The membership was increased by the addition of nine names:— Messrs. Barltrop, Bourne, Finlay, Hodgson, Livingstone, Porritt, White, Whitman, Wood; but the following left the jurisdiction of the branch during the same period, namely: — Messrs. Cummings, Faulkner, Graham, Grant, Kingham, McRae and Orton, so we can only claim an increase of two.

The standing of the branch membership is as follows:—

	Resident	*Non-Resident*	*Total*
Members	31	4	35
Associate Members	40	5	45
Juniors	1	1	2
Students	4	1	5
Affiliates	2	..	2
Total	78	11	89

The branch officers for the year were as follows:—

Chairman	G. B. Mitchell, M.E.I.C.
Vice-Chairman	J. N. Anderson, A.M.E.I.C.
Secretary-Treasurer	E. P. Girdwood, M.E.I.C.
Executive	E. E. Brydone-Jack, M.E.I.C.
	P. Philip, M.E.I.C.
	F. C. Green, M.E.I.C.
	M. P. Blair, M.E.I.C.
	R. A. Bainbridge, M.E.I.C.

Conveners of committees:—

Papers	F. L. Macpherson, M.E.I.C.
Social	F. G. Aldous, A.M.E.I.C.
Library	E. P. Girdwood, M.E.I.C.
Town Planning	E. A. Cleveland, M.E.I.C.
Publicity	C. A. Faulkner, A.M.E.I.C.

MEETINGS

A very successful series of meetings were held during the year.

Jan. 15.—E. A. Cleveland, M.E.I.C., gave an outline of the work of the World Power Conference of 1924, and a description of the power plants visited during the subsequent Scandinavian tour, with many references to matters of general interest.

Jan. 28.—A talk was given on **"Radio Communication"** by H. C. Vickers, M.E., M.Sc., Ph.D., a recognized authority on this subject.

Feb. 11.—After a paper by A. L. Carruthers, M.E.I.C., bridge engineer of the Provincial Department of Public Works, a number of members joined in the discussion, with particular reference to foundation work.

Feb. 14.—The members and their friends paid a visit to the works of the British America Paint Co., an industry known to all visitors to Victoria.

Feb. 19.—Two members of the Provincial Forestry Branch, Messrs. E. C. Manning and Geo. Wilkinson, spoke on the **"Depletion of our Timber Resources"** and **"Forest Protection"**, the mechanical superintendent of the same branch, J. H. Blake, A.M.E.I.C., following with a paper on **"Some Economics of Steam Plants"**.

Mar. 11.—Major G. G. Aitken, chief geographer of the province, gave an illustrated address on **"Comparative Geography"**, drawing many very interesting comparisons between the climate, natural resources, and productive capabilities of British Columbia and those of other places and countries on the continents of Europe and America.

Mar. 14.—The branch paid a visit to the plant of the Sidney Roofing and Paper Co.

Mar. 25.—A brief outline of **"Some of the Problems that are met with in Town Planning"** was given by E. G. Marriott, A.M.E.I.C., and was followed by one of the most vigourous discussions the branch has had, everyone present taking part under the capable management of the chairman.

Mar. 26.—The new gasometer of the Victoria Gas Co. was inspected. This is of the latest type with spiral guides, and was of particular interest to the structural members of the branch.

Apr. 8.—At the invitation of F. Napier Denison, director of the Meteorological Observatory, Gonzales Hill, another outing was enjoyed by members and friends; Mr. Denison being a specialist on seismic observations.

Apr. 18.—J. P. Forde, M.E.I.C., district engineer for the Dominion Public Works, gave an address on the **"Construction of the New Dominion Drydock at Lang's Cove, Esquimalt"**. This paper, which was of outstanding interest, has been published in The Journal for the benefit of the members of The Institute at large.

May 8.—A visit of a lighter nature was taken advantage of by a good number, when they learned something of the commercial production of a variety of biscuits and candy at the factory of Ormonds Limited.

July 24.—As many as possible of the members in town at such a time of year enjoyed the opportunity of making the acquaintance of R. J. Durley, M.E.I.C., our now well-known general secretary.

Nov. 11.—A joint lunch was held with the members of the Provincial Association of Professional Engineers, at which E. A. Wheatley, M.E.I.C., the registrar, spoke on the "**Business Organization of Engineering Societies and Branches**", showing very effectively the opportunities for progress.

Nov. 14.—The last and best attended of the branch meetings was held, the speaker being Col. W. W. Foster, A.D.C., D.S.O., and his subject "**The Mount Logan Expedition**". After giving an outline of the difficulties that had to be faced, and the methods by which they were overcome, Col. Foster showed a set of magnificent views. The public had been cordially invited to this meeting, and some three hundred people were present.

The financial statement of the branch is attached and shows a small increase in the balance on hand.

FINANCIAL STATEMENT

Balance sheet — Dec. 1, 1924 to Dec. 1, 1925

M. P. BLAIR, M.E.I.C., *auditor.*
E. G. MARRIOTT, A.M.E.I.C., *auditor.*

In conclusion the executive wish to record their appreciation of the assistance given by many members of the branch, through whose co-operation 1925 may be classed as a very satisfactory year in the history of the branch.

Respectfully submitted,

J. N. ANDERSON, A.M.E.I.C., *Chairman.*
E. G. MARRIOTT, A.M.E.I.C., *Secretary-Treasurer.*

Winnipeg Branch

The President and Council,—

On behalf of the Winnipeg Branch, the following report is submitted:—

MEMBERSHIP

The membership of the branch as at December 31st, 1925, is as follows:—

	Resident	*Non-Resident*	*Total*
Members	44	4	48
Associate Members	137	17	154
Juniors	18	4	22
Students	47	4	51
Affiliates	5	..	5
	151	29	280

MEETINGS

Fifteen regular meetings were held during the year 1925. There was an average attendance at the meetings of 42. Two special meetings might well be mentioned, namely that addressed by Mr. Lee H. Miller at which there was an attendance of 101; and that held during the convention in Winnipeg, during August, 1925, held with the Minnesota Federation of Architectural and Engineering Societies, at which there was an attendance of 223.

The following is a detailed list of the regular meetings:—

Jan. 8.—"**Prospecting**," Prof. DeLury. Attendance 51.

Jan. 23.—"**Manufacture and Use of Industrial Alcohol**," C. D. Lill. Attendance 42.

Feb. 5.—"**Railway Water Supply**," C. H. Fox, M.E.I.C. Attendance 29.

Feb. 19.—"**Heat Treatment and Metallography of Steel**," J. Gilchrist and C. H. Turtle. Attendance 30.

Mar. 4.—"**Steam Storage**," A. J. T. Taylor, M.E.I.C. Attendance 65.

Mar. 18.—"**A Koppers Gas Plant**," Hugh McNair. Attendance 39.

Apr. 2.—"**Central Steam Heating Project of City of Winnipeg**," N. W. Calvert. Attendance 80.

Apr. 16.—"**Use of Compressed Air in Engineering**," A. A. Paoli, A.M.E.I.C. Attendance 42.

May 7.—Annual Meeting of Winnipeg Branch. Attendance 18.

Oct. 1.—"**Reinforcement of Weir at Pointe du Bois**," W. G. Chace, M.E.I.C. Attendance 45.

Oct. 15.—"**Some Problems in Railway Transportation**," H. J. Symington. Attendance 43.

Nov. 5.—"**Long Distance and High Voltage Transmission**," E. P. Fetherstonhaugh, M.E.I.C. Attendance 53.

Nov. 19.—"**Island Falls Development**," Martin O'Day, S.E.I.C.; and "**Spokie Valley Extension of the North Shore Line**," C. V. Antenbring, S.E.I.C. Attendance 33.

Dec. 3.—"**Primary Triangulation**," A. Bain; and "**Precise Levelling**," H. E. Treble, S.E.I.C. Attendance 26.

Dec. 17.—"**Patents and Inventions**," G. S. Roxburgh, A.M.E.I.C. Attendance 25.

GENERAL

The visit of R. J. Durley, M.E.I.C., general secretary, was an outstanding event of the year. He was present as a guest at a meeting of the branch executive on July 7th, and, on his trip returning from visiting the branches further west, he entertained some members of the branch to luncheon. Matters of interest to *The Institute* were discussed and considered on both occasions.

A. L. Ford, M.E.I.C., chairman of the Calgary Branch, attended a meeting of Winnipeg Branch executive as a guest, on September 10th.

The convention held in Winnipeg during August, with the Minnesota Federation of Architectural and Engineering Societies was pleasant and profitable. It lasted officially for two days. During that time an afternoon was devoted to the exchange of technical papers at a formal meeting. The entertainment of the visitors included a visit to the City of Winnipeg Hydro Electric System's plant at Pointe du Bois, as the guests of the city. Some 260 people enjoyed this trip.

It is to be noted that the papers of the regular meetings of November 19th, and December 3rd, were prize winning theses by students in the electrical and civil engineering sections of the University of Manitoba.

At the meeting of October 15th, on the motion of H. A. Bowman, A.M.E.I.C., and C. A. Millican, A.M.E.I.C., both charter members, Winnipeg Branch, there was recorded a vote of condolence to the members of the family of the late Brig.-General H. N. Ruttan, M.E.I.C., who died during the week of October 10th.

FINANCIAL STATEMENT

Following is the financial statement of the branch as from the date of the annual meeting of the branch on May 7th, 1925, to December 31st, 1925.

Receipts and Expenditures			
Cash in bank May 7, adjusted		$ 998.11	
Receipts: Local dues	$280.00		
Interest	18.73		
Rebates	227.00		
Branch news	21.33		
		547.06	
			$1,545.17
Expenditures		$ 684.98	
Bank balance December 31, 1925		874.69	
Cash balance December 31, 1925		1.63	
		1,571.30	
Over deposit, (deduct)		26.13	
			$1,545.17
Assets			
Cash balance		$ 815.19	
Rebates, branch news and advertising		119.41	
Interest		13.75	
Local dues in arrears less 50 per cent written off		807.00	
Office furniture and library, less 5 per cent depreciation		292.09	
War bonds		500.00	
			$2,582.44
Liabilities			
Accounts payable		$ 21.04	21.04
Surplus			$2,561.40

Respectfully submitted,

C. H. ATTWOOD, M.E.I.C., *Chairman.*
JAMES QUAIL, A.M.E.I.C., *Secretary.*

Discussion on the Trend of Steam Power Plant Development

Discussion of paper presented by A. G. Christie, Professor of Mechanical Engineering, The Johns Hopkins University, School of Engineering, Baltimore, Maryland, before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

Brig.-Gen. C. H. Mitchell, D.S.O., M.E.I.C.

General Mitchell remarked that there were two features which Professor Christie brought out in his paper to which he wished specially to draw attention. The first of these was the statement that low cost stand-by steam stations will soon fill an economic need in Canada.

The employment of steam power supplementary to hydro-generated power, migth seem superfluous in this country so full of water powers, but the employment of such supplementary steam plants had been or was being dictated, either by geographic conditions, of which New York state powers were an example, or by a scarcity of hydro sources with a shortage of supply visibly in sight, of which Ontario at present was an example. In the case of Ontario, it was obvious, notwithstanding the many hydro sources tributary to its industrial region, that some temporary measure, at least, must be taken, by which peaks could be taken care of until the development of St. Lawrence powers, necessarily requiring a long period of time, could be effected, or unless more power could quickly be made available by additional water at Niagara Falls or otherwise, Such a plant or plants would come under the head of low load-factor plants referred to by Professor Christie.

The other feature to which he wished to draw attention was the relation of fixed charges to the other costs of steam power developments.

Fixed charges had remained high, especially during the post war years. This doubtless meant high initial and other capital costs of construction as reflected in interest charges, which also had been high since the war.

Another interesting factor in costs of operation of the modern steam plant was to be observed in the uniformity of the annual costs of operation and maintenance throughout the whole ten years.

All these features were very clearly exhibited by the author in the curve of figure No. 1.

Important economical deductions could be made from these facts and curves, and the speaker desired particularly to impress upon the members of *The Institute* the desirability, as expressed by the author, of "the reduction of initial investment in the plant so that the trend of the curves for fixed charges and for total cost may be downward".

The responsibility would fall on designing and constructing engineers to secure economically — not cheaply, — built plants in the first instance, not unduly over powered, and free from unnecessary adjuncts and experimental features. This economic practice should apply most particularly in low load-factor plants, secondary plants or plants used in conjunction with water powers, particularly in this part of Canada, a caution which was specially voiced by the author in the fourth paragraph of his valuable paper.

Mr. E. W. Bull

Mr. Bull remarked that in discussion of this paper, he wished to concur in the desirability of working the steam through the greatest possible temperature range, the conservation of heat units by the use of closed circuit air coolers for the electric generator, using condensate as a cooling medium, preheated air to furnaces, and the reduction of banking losses by the use of powdered coal furnaces.

He particularly referred to the question of load-factor and use-factor of equipment. The daily load-factor on plant falling below unity, was usually accounted for by a general slump in demand after midnight, and extending to six or seven a.m., and was often a relief to the operating force, as it allowed of shutting down parts of plant equipment for minor repairs, that might extend the periods between general overhauls considerably, and might allow of this overhaul taking place in a period favourably influenced by amount of load or demand on plant. This feature influenced the amount of reserve equipment necessary and thereby reduced the fixed charges.

In connection with the author's reference to base load plants and to their doubtful life as base load plants, Mr. Bull said that this condition could be parallelled by a condition of a base load machine in a plant, which naturally with its complement of boilers formed a unit; due to the economy feature, the unit was kept in service at all times, and was only helped out or relieved from service by other machines and boilers not capable of the same economy.

This base load feature brought up the consideration of what use-factor could be expected of the base load equipment. This could be best decided by operating records as to the availability of equipment, and the speaker submitted the following on a steam turbine, and boilers equipped with underfeed stokers.

A highspeed turbine was installed and commenced operation on November 10th, 1920. It was the most efficient machine in the plant and was capable of carrying most of the load. It was kept continuously at work whenever possible until November 10th, 1925, an elapsed time of 43,934 hours, of which the turbine operated 42,227 hours or 96 per cent of the time; at which time a more efficient turbine was installed and took up the base load work.

A group of boilers was also installed and commenced operation January 1st, 1922, and were capable of supplying this turbine. One boiler, No. 6, was fitted with a larger superheater, furnished higher temperature steam, and consequently was operated at all times possible. All boilers were fed by condensate and distilled makeup.

On December 31st, 1925, after an elapsed time of 35,064 hours, No. 6 boiler had operated 27,487 hours or 81.24 per cent of the time, the rating varying from 100 per cent to 300 per cent with an average of 170 per cent.

An analysis of the causes of this equipment being out of service would no doubt assist in the design of power plants. The turbine with its auxiliaries was laid idle once each year for a thorough examination and overhaul which was carried forward with all dispatch and 916 hours of the total of 1,707 hours of off-service was required for this work. This period was not likely to be lowered and could be considered as a necessary outage for this very necessary work in the operation of turbines.

The balance, of 891 hours, of outage was caused by the auxiliaries of turbine requiring attention and was largely due to many stops to clear weeds, grass and trash from the condenser tube plates. This was not due to fault in the condenser, but was caused by the fact that screens, no matter how well made and fitted, will allow of small quantities of weeds and blades of grass to pass through screen wire endwise and later block some of the tubes at tube plate of condenser. The remedy for this feature in the design of plant was to have the condenser arranged in two independent sections to allow of one section being cleaned while the other is in operation, or to have circulating water piping and valves arranged so that a back flow through tubes can be brought about for a short period and wash any accumulated weeds and trash away to discharge lines.

In the latest installation both of these features had been incorporated in one condenser, with the additional features of being able to change from a two- to a four-pass condenser, during cold circulating water and light load periods, to conserve auxiliary power, as the circulating water pumps were driven by constant speed motors. It was expected that this arrangement of condenser would reduce the period of outage of a turbine by nearly 50 per cent.

No. 6 boiler likewise had an annual period of inspection and overhaul, and 1,584 hours of the total outage of 7,577 hours was consumed in this necessary procedure. This left a balance of 5,993 hours that the boiler was out of service due to a variety of causes, the furnace and stoker predominating in the causes for withdrawal from service.

The boiler proper had surprisingly few occasions for withdrawal from service and from a study of all conditions it appeared that any design that will eliminate the carrying of many tons of fuel bed in furnace at one time and the elimination of metal supports for this fuel bed, cannot be a development in the wrong direction.

In considering the use of powdered fuel system of burning, the fact that the mechanical parts are outside of furnace and any minor repairs can be made without waiting for boiler furnace to cool, had not been given the prominence that it deserves.

Professor L. McK. Arkley, M.E.I.C.

Professor Arkley remarked that in the first paragraph of Professor Christie's paper, the statement regarding the present efficiency of the modern steam central station was rather conservative and the prediction that further reduction in heat consumption per kilowatt hour was likely to be delayed on account of increasing fixed charges, etc., was to say the least, rather pessimistic.

In a paper by Sir Chas. Parsons, the father of the reaction steam turbine as it is known to-day, read before the World Power Conference in 1924, he made the statement that his company was at that time building a 50,000 kw., turbo-generator for the Commonwealth Edison Company of Chicago, to be placed in their Crawford Avenue station and to operate at 550 pounds pressure and a temperature of 750° F. at the throttle, for which a heat consumption from steam to electricity, of 10,265 B.t.u. was anticipated. This would represent an overall heat consumption of about 12,300 B.t.u. per kilowatt hour. In this paper, the author estimates that with a pressure of 1,500 pounds per square inch, and a temperature of 750° at the throttle, an overall heat consumption of about 11,000 B.t.u., would result. The 1,200 pounds boiler and throttle temperature of 750° F. were already with us. It therefore seemed probable that a substantial reduction from the 15,000 B.t.u., heat consumption quoted might be looked for in the near future.

With the author's statement a little farther on, that it is quite probable that low cost stand-by steam plants, hooked up with hydro-electric systems, will soon fill an economic need in Canada, the speaker heartily agreed, and said he was glad that an authority of Professor Christie's standing had made this statement, for it was surprising how many engineers believe that in harnessing a water power you get something for nothing and that all steam generated power must be very costly.

The author just mentioned that local conditions may favour the addition of a central heating load to a stand-by steam station. In this, the speaker believed, may be found the real solution of our economical steam power plant. After all the refinements which the author described in his paper had been made; after the questions of high pressures and high superheats had been exhausted, and all this at a very high cost, it was found that there was an overall thermal efficiency of from 25 to 30 per cent. The chief reason for this was that the exhaust steam is condensed from the turbines and in this way its latent heat is lost.

A simple computation would show that if all the exhaust steam from a power plant can be used for heating purposes, for which live steam would have to be supplied if we did not have the exhaust, the steam plant would operate at over 60 per cent. efficiency. The central heating plants in connection with the universities and hospitals were doing this now.

Mr. J. O. Twinberrow, A.M.E.I.C.

Mr. Twinberrow remarked that he regretted that so much of Prof. Christie's paper dealt with considerations peculiar to problems incident to large central station designs. He thought that it was questionable whether conditions in Canada, generally speaking, are suitable as yet for installations of large plants, and one might estimate that 98 per cent of the plants to be installed in this country during the next few years would be of the smaller industrial plant class.

The connecting together of a number of small plants had not been given the attention it should on this continent. In this respect attention should be drawn to the results achieved in England by the Newcastle-on-Tyne Electric Supply Company, Limited, and its associated companies, who in 1924 had some 600,000 h.p., connected to their system over an area of some 1,400 square miles. In addition to the three large power stations — Carville, Dunstan, and North Tees, there were twenty-five small stations utilizing waste heat from gas and coke ovens and other processes which were connected to the common system of cables. Of these twenty-five small stations fourteen were operated entirely by the company. These small plants produced 14 per cent. of the total kilowatts sold.

In dealing with the history of the rise in steam pressures and temperatures, credit should be given for what has been done in Europe. For instance: in 1913 a pressure of 275 pounds and 700° total temperature was being used in a central power plant in England., while in 1917 the North Tees plant was designed to work at a pressure of 475 pounds and gave an output of one kilowatt for 16,271 B.t.u.

Professor R. W. Angus, M.E.I.C.

Professor Angus said that in the curves shown on figure No. 1, in Professor Christie's paper, some information was given as to the magnitude of the different factors entering into the cost of power production, and that it was interesting to note that the operating and maintenance costs had remained constant during the last thirteen years at about one-half mill. each per kilowatt hour, even though the wages paid to the employees had very materially increased.

The curve of fuel cost per kilowatt hour showed that from 1913 there was a rise from two mills. per kilowatt hour to five mills. in 1922, and since that year a very marked decrease had taken place, giving a final value of about 2.3 mills. in 1925. While the downward slope was no doubt due to a certain extent to the decreased cost of fuel per ton, it also indicated a marked gain in efficiency of the steam plants, and as the curve had a distinct downward trend at the present time, it would suggest that further improvements are probable.

It was worthy of note that the modern cycle tends to approach the theoretical conditions described by Carnot one hundred years ago, when he stated that maximum efficiency would be obtained by a reversible cycle of operations. In the modern plant the process of bleeding the turbine at various stages for feed water heating was one which caused the actual cycle to approach the theoretical cycle. If the number of stages of reheating by the bleeding process were sufficiently increased the cycle became fully reversible, and therefore one of maximum efficiency.

In this connection the author gave the illustration (figure No. 8) of the Gould St. station of the Consolidated Gas, Electric Light and Power Company of Baltimore, in which he showed that 21 per cent. of the steam was withdrawn from the turbine for feed heating purposes, the turbine being supplied with steam at a pressure of 405 pounds absolute, and the feed heating steam being drawn off at absolute pressures of approximately 183 pounds, 94 pounds, 28 pounds and 9 pounds, respectively. There was considerable expense involved, as a closed heater must be used for each stage from which steam is drawn.

In his paper, Prof. Christie referred to the steam pressures and temperatures being raised, and the speaker urged that there is a great field of advancement in this direction, the tendency at the present time being to increase the pressures rather than the temperatures, one reason being that the properties of metals at high temperatures are not sufficiently well established.

The author had calculated some efficiencies, using the Rankine cycle, to compare the results obtained by using high pressure saturated steam to produce a given temperature, rather than using lower pressure superheated steam to produce the same result, in all cases the back pressure being taken at one inch of mercury. The results showed that saturated steam produces a higher efficiency in the Rankine cycle than superheated steam at the same temperature; thus, if the supply steam temperature were to be 500° F., and this were produced at 200 lbs. pressure, the cycle showed 32.6 per cent, while if the same temperature was produced by raising the pressure to 679 lbs., at which the steam was saturated, the efficiency rises to 37.4 per cent.

In any event, he said, a certain amount of superheating was essential to the life of the turbine, as it prevented condensation in the earlier stages, and for that reason it was true that, as the author stated, there was considerable gain from the higher superheats, and probably both pressures and degrees of superheat would continue to be raised in the future.

The speaker was of the opinion that there was a great future for the use of several working fluids in power plants, and had followed with very much interest the work of Mr. Emmet on the mercury vapour turbine. Should it be found practicable to use some such fluids as mercury for the upper temperature range, steam for the intermediate temperature range, and such a fluid as ammonia for the low temperature range, it would be possible to utilize a much greater range of temperatures than was now possible, and still keep the pressures within ordinary working limits, and one naturally looked forward to advancement along this line.

The author's statement about the operation of boilers at capacities of 300 per cent of their nominal output, the speaker thought, called for a criticism of the present method of rating boilers, as it seemed absurd to classify a boiler so that its continuous output would be 300 per cent of its rating. Engineers should establish some new rating for boilers which would make the continuous maximum output more nearly agree with the rated capacity.

The author laid considerable stress on the use of powdered coal, and this, the speaker said, had also been a distinct advance in recent years, enabling exceedingly high efficiencies to be obtained during regular operation, and very much reducing the standby losses when the plant was shut down. It was, therefore, a method which offered very great promise where high efficiency was desired, and also where the steam plant was used as a standby on any system, because powdered fuel, being practically as flexible in its use as oil, enabled the full power to be thrown on the plant within 15 or 20 minutes from stationary condition.

The author had spoken of the large size of turbines now being installed and this would seem to account, at least partly, for the horizontal operating cost curves in figure No. 1. The cooling water required for condensing the steam for such units, amounting to about two gallons per kilowatt per minute, offered a very serious problem, and practically compelled the placing of any large station close to the water front, which indeed would be a desirable location on account of the convenience for taking in coal. A 50,000-k.w. turbine would require about 100,000 gallons of cooling water per minute, which is 144 million gallons per day, or about 50 per cent. more than the amount used by the city of Toronto.

The speaker wished to emphasize the importance of securing the coldest cooling water for the condenser, as had already been mentioned by the author, for which purpose not only must the intake be placed as far below the surface as possible, but its design must be thought out with the greatest care, otherwise it would draw in surface water, even though it might be 15 feet or 20 feet down. The design of this intake tunnel also affected the power required to operate the circulating pumps, the entry losses to such an intake tunnel being a fairly large proportion of the total head; too little attention had been paid to this important feature of power station design.

Mr. R. E. MacAfee, A.M.E.I.C.

Mr. MacAfee remarked that the author had suggested that stand-by plants could be used for central heating plants during the winter months. This would probably work out very well in a peak load plant where the boiler capacity at maximum rating is based on the expected requirements. But where a steam plant was installed as a stand-by to an hydro-electric development it would not seem good practice to use the plant as a central heating plant during the winter, as it was very possible that the stand-by service would be needed much more during the winter months than during the summer. This would, of course, depend on local climatic conditions. Records over a period of years would be a guide as to whether it would be possible to use a stand-by plant as a central station heating plant with safety. If the plant were built with the idea of being a stand-by, nothing should be permitted to creep into the development to interfere with the plant's actual stand-by capacity.

Boilers for use in purely stand-by plants could be arranged to operate at very high ratings to keep down the capital cost. It was interesting to note that in some cases boilers are being installed to operate at ratings of 500 per cent and over. In deciding on the ratings at which boilers are to be operated for stand-by purposes, the speaker said, it was necessary to take into consideration the character of service to be rendered, for instance, whether the interruption of the hydro plant was likely to be due to breaks in transmission lines or trouble at wheels due to ice conditions, which would require a comparatively short period to put the plant back in operation, or whether the interruption would be due to low water, which might last for considerable periods of time In the former case all the boilers could be operated at maximum rating, while in the latter it would evidently be better to be more conservative in the matter of ratings.

With reference to the method of driving the auxiliary equipment on which the operation of the plant depends, Mr. MacAfee said that it would seem wise to decide this on continuity of operation rather than maximum efficiency. In any power station ample reserve should be arranged for such items as boiler feed pumps, forced and induced draft fans, stoker drive, condenser auxiliaries and exciters. The necessary reserve might be supplied by electric drive fed from sources other than that supplying the main drive, or where this was not available steam driven units as stand-bys should be provided.

Pulverized fuel was undoubtedly coming rapidly to the front as a method of burning coal and should be given consideration in any new power plant designs. Pulverized fuel could be arranged on the central system where a certain amount of coal in the pulverized state was carried in storage, or with the unit system where the coal was pulverized and fed directly to the burner.

The question of whether one system or another should be used was an exceedingly interesting one, and Mr. MacAfee thought that the author could probably give a general idea as to what size of boiler and what size of plant could best be handled with one or the other system. He agreed that unit mills were not too reliable, and raised the question as to what has been found to be the trouble in these mills and what is the general trend of development to overcome this trouble.

Mr. J. G. Worker

Mr. Worker remarked that the Richmond station of the Philadelphia Electric Company, with an ultimate capacity of 600,000 kilowatts, had recently gone into operation, and was generating electric energy at less than the figures mentioned by Professor Christie. This plant was interesting on account of the use of highly preheated air with underfeed stokers. At this company's Chester station, very close to 90 per cent. boiler efficiency was being obtained by the use of air preheated to 500 degrees.

The Philo station of the Ohio Power Company had been in operation since the fall of 1924, and over long periods of time had shown an expenditure of about 14,000 B.t.u. per kilowatt-hour of net station send-out. This station was designed for a steam pressure of 550 pounds per square inch gauge and a temperature of 725° F. and reheating steam which later was sent back to the turbine. Chain grate stokers were used with preheated air, burning a low grade coal of about 10,000 B.t.u. per pound.

The author had make the following statement: "Powdered coal requires more auxiliary power than stokers. On the other hand, it gives a higher efficiency over a wider range of boiler rating and is more independent of the grade of coal than the best stokers." This statement, the speaker said, was of interest, because there was agreement among engineers with respect to the first part of the statement, but some recent developments in stoker fired plants might be taken to indicate opposite conclusions relative to efficiency and burning of a variety of coals.

The author's statement that powdered coal more nearly approached test efficiency in daily operation and had lower stand-by losses and lower maintenance cost than stokers was the issue on which the two factions split; namely, those who favoured pulverized coal firing and those who favoured stoker firing. Perhaps the truth of the matter was that there was as yet insufficient information to justify any definite statement in this connection.

Professor E. A. Allcutt, M.E.I.C.

Professor Allcut remarked that the author's paper was an interesting résumé of the development of the steam power plant generally, the influence of the various components on its efficiency and economy, and the probable directions in which future improvements may be expected. The present tendency towards the use of higher pressures and temperatures had been outlined, and up to the present, as the author had pointed out, the maximum steam temperature available was about 750° F. All materials weakened at high temperatures, — this might be allowed for, — but the experiments of Dickenson* and others also showed that steels which purport to stand a given load at a certain temperature under ordinary test conditions, would fail at lower loads if time be allowed. A steel which broke at 19,000 pounds per square inch, at 1,500° F. in 6 seconds, failed under the same load in 28 hours, with a temperature of 1,150° F., and at lower temperatures in longer periods. Thus, with the tendency of cast iron to grow and of steels to flow at high temperatures, the limiting temperature of steam production was comparatively low, particularly when high pressures were used to obtain the maximum thermal efficiency.

Mellanby and Kerr** put the economic limit of temperature at about 900° F., and of pressures at about 1,250 pounds per square inch.

*Proc. Iron and Steel Institute — Sept. 6th, 1922.

**North East Inst. Coast of Engineers and Shipbuilders, Feb. 27th, 1925.

This temperature, however, was far less than the combustion temperature, and even though the boiler gives an efficiency of 90 per cent. the result was to transform the heat to a form of lower thermodynamic value. In fact a large quantity of heat was transferred to the condenser cooling water, where, owing to its low temperature, it could not be utilized effectively.

The question therefore arose as to whether the problem of heat conservation was being tackled along the right lines. The internal combustion engine could and did handle heat at the temperature of combustion, and enormous strides had been made recently in its practical application for the production of large powers. Only a few weeks ago the liner "Asturias" was launched, containing two 10,000-h.p. internal combustion engines, having eight cylinders each. This power was small as compared with the steam turbines described in the paper, but when it was considered that this century had seen the power per cylinder of the internal combustion engine raised from 300 to 1,250 h.p., it was at least conceivable that this type would develop further and would (as it did now) produce fuel economies unapproached by any steam plant. Further, the exhaust loss of the internal combustion engine was at a considerably higher temperature than that of the steam plant, and therefore offered greater potentialities for development. In fact, the internal combustion engine left off where the steam plant commenced.

Mr. J. W. Sanger, A.M.E.I.C.

Mr. J. W. Sanger remarked that in his opinion for many years to come, in the field of steam power production, Canada would not be at all interested in thermal efficiency except in a few isolated cases. The intensive hydro-electric development which now existed and the far greater expansion which had yet to come, would restrict the steam power plant to the minor function of carrying peak loads, and this condition would exist until the total power demands of the country far exceed the available water power resources.

The design of steam plants for extremely low annual load-factors was the problem to be faced. There did not seem to be any cure for this poor load-factor condition, except that used in Winnipeg, where a steam standby plant, a central steam heating system, and a battery of large electric boilers had been combined with a hydro-electric system, in an effort to get relief from the expense of carrying a steam standby plant for the hydro-electric system. In such a combination, if the central steam heating system could be made to carry itself, there should be attractive profits from the sale of off-peak hydro-electric power to the electric boilers, and from the saving of operating labour in the boiler house of a joint central heating and standby plant.

A steam standby plant of any appreciable size was too great a burden for a hydro-electric system to carry, as the annual cost would be at least $16.00 per kilowatt of installed capacity. Moreover, the interconnection of a number of hydro plants and their transmission lines would make the likelihood of a lengthy interruption to service extremely remote.

He considered that the most important opportunity for the use of steam power plants in Canada would be the period between the loading up of one large hydro plant and the development of another. To cite an example, we might consider the development of a power site on the Nelson river for the Winnipeg market. The initial expenditure on a 150,000-h.p. site and 350 miles of transmission line would be not less than $15,000,000, representing annual cost of approximately $1,500,000. If the first block of power supplied were 20,000 h.p. it would cost delivered $75.00 per horse-power-year, or about three times the annual cost of a 20,000-h.p. steam station located in Winnipeg and operating over the peak loads of the system. Hence, provided that the annual increase of load of a system is small compared with the initial annual cost of a new hydro-electric development, the intermediate steam plant would function economically.

Annual load factors as low as five per cent must therefore be considered, which immediately eliminated from the problem of design the cost of coal, thermal efficiency, cost of water and those maintenance costs which depend on the output of the plant. Capital expenditure would then become the sole item of importance, and surveying the trend of steam power plant development one would be inclined to suggest that boilers of medium pressure and extremely high rating, unit pulverizer fuel systems, high speed turbo-generators, small condensers and a minimum quantity of auxiliary apparatus would be the ultimate selection to give the best financial results.

Mr. Christie's Reply

The author, in reply, observed that a study of the load-duration curve of almost any power system would disclose the fact that the upper 25 per cent of the maximum demand existed for only about 800 hours per year, while the upper 10 per cent might last even less than 200 hours per year. Only the cheapest possible station could carry economically a load that lasts for only 200 hours per year. Hydro plants paid best on base loads, and it would be apparent that a steam station should carry this portion of a system's load if it could be built at a lower cost than an equivalent hydro station, as fixed charges were the most important element in the cost of such power.

Many people believed that large sums of money would be spent on coal for such a steam station. This was not the case. If a gross rate of 2 lbs. of coal per kilowatt hour were assumed for a 50,000 K.W. plant to carry the upper 10 per cent of a system's peak, then at $5. per ton, the coal cost would be about $1.75 per kilowatt year. This would probably be about one-eighth of the yearly fixed charges on such a plant. It was therefore evident that economic pressure would force the construction of a low cost steam plant to get the cheapest service.

Mr. Bull had contributed valuable data on the performance of his own plant. The Regina station had long been regarded as one of the best operated steam stations in America and these figures confirmed this reputation.

Professor Arkley had presented some figures indicating very low B.t.u. per Kw.H. on some of the newer stations in the United States. Plants that would operate on 12,000 B.t.u. per Kw.H. could not be built cheaply. The real criterion was the total cost of power, which considers the fixed charges on first cost plus operating costs including fuel. Executive officials did not ask how efficient a plant one could design, but how cheaply could one produce the power. These officials now scrutinized first cost very closely, and limited investments might make the highest efficiency unobtainable. A high efficiency plant could readily be designed if fuel costs warrant it. Low coal consumption could never be justified in a peak load plant, on account of high first cost.

He considered that the addition of a heating system to a steam station was an economic problem, and in many cases this combination would yield large financial savings.

Mr. Spotton had felt that the large plant had received overemphasis. The paper had dealt principally with the large plant, as past records show that the small plant follows the practice of the large plant.

The connection of small plants to a power system had been suggested. This scheme had many advantages and deserved careful study on the part of the power supply organizations.

While the mercury vapour system had been demonstrated in an experimental way, no cost figures were yet available to indicate that it could produce power more cheaply than by our present steam systems.

Regarding Professor Angus' discussion of the steam cycles, it should be noted that if total steam temperatures could be raised to 1,000° F., the plant efficiency at all pressures would be increased several per cent. This was the next direction to look for improvements in plant economy, as the advantages and utility of higher pressures are now recognized.

In connection with Mr. MacAfee's discussion it might be well to point out that ratings are a factor of furnace design rather than of boilers.

Attention had been called to underfeed stokers, on the ground that these might provide a more economical station than pulverized fuel. This was a timely discussion, for it indicated that engineers may not agree on the present trend of development.

Discussion on the Principles of Combustion and Heat Transfer as Applied to Steam Generation

Discussion of paper presented by John Blizard, Research Engineer, Power Specialty Company, New York, before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 29th, 1926.

Mr. V. Z. Caracristi

Mr. Caracristi remarked that it was difficult to determine what constitutes a combustion space which is "too small". In stationary practice as at present commercialized, approximately one and one-half pounds of coal were burned per hour for each cubic foot of combustion space, and by "combustion space" was meant all the space available for combustion below the heat-absorbing elements, without regard to the manner in which localized combustion takes place.

There were installations in service, burning pulverized coal, in which the amount of coal burned ran as high as eighteen pounds to the cubic foot of combustion space, using the same definition for "combustion space", with a fuel loss well within the commercial limitations of results obtained under similar operating conditions where less coal was burned per cubic foot of combustion space. He considered that the amount of coal burned per cubic foot was dependent on design, and that the limitations the author had imposed as to capacity were within reasonable commercial limits, non-existent.

It was difficult, also, to conceive the authority for the implied additional cost of installing and operating equipment for burning pulverized coal, as compared with an installation for burning solid coal on grates or stokers. The cost of an installation was not measured by the number of boilers or units installed, or the heat-absorbing surface available, but only by the ability of the installation to deliver steam, under the required pressure and superheat conditions. He believed that when measured on this basis, the difference, if any, would be in favour of powdered coal.

The limit of heat-transfer rate stated by the author was approximately correct, but this rate of heat transfer could not be obtained if the heat-absorbing surface of the tubes were shielded in any way from the direct action of the radiant heat. Were this not true, there would be no material available suitable for heat insulation purposes.

In his discussion of the relative values of economizers and air heaters, the author had not brought out the value of the admission of heated air to the combustion chamber.

Mr. J. G. Worker

Mr. Worker remarked that in order to attain high efficiency in the combustion of pulverized coal provision must be made for the maintenance of the highest possible temperature in all parts of the combustion space, and the possibility of loss of unburnt coal carried through the furnace must be carefully watched.

Professor John Stephens, M.E.I.C.

Prof. Stephens remarked that with regard to burning coal on grates, it was a matter of general experience, with eastern Canadian coals of about 30 per cent volatile content, that there is some minimum draft difference between the furnace and ashpit, necessary for efficiency, with any practical thickness of fire.

In the tests on a domestic boiler referred to by the author, 50 per cent was given as a low efficiency with bituminous coal. He had found it difficult in such boilers, using coal from either the Sydney or Minto fields, to attain an efficiency of 50 per cent, 40 per cent being a more usual value. He would ask what were the volatile content of the coal, the draft conditions, and the depth of the layers of coal put on at each firing, in the tests where an efficiency of 50 per cent had been attained or exceeded. In his experience, efficiency increased with the frequency of firing in proportionately thin layers, if the volatile content of the fuel was high.

He desired to point out, as arising out of the ideas suggested by the paper, that a fuel of increasing industrial importance in some parts of Canada, namely wood, required no air to be admitted above the grate.

Mr. A. R. Mumford

Mr. Mumford remarked that a study of combustion by means of gas samples withdrawn from the furnace through water-cooled samplers had recently been completed in one of the stations of the New York Steam Corporation and was progressing in another.

It had been found that some means of mixing the several streams of gases rising from the fuel bed of a chain grate stoker was necessary in order to reduce the

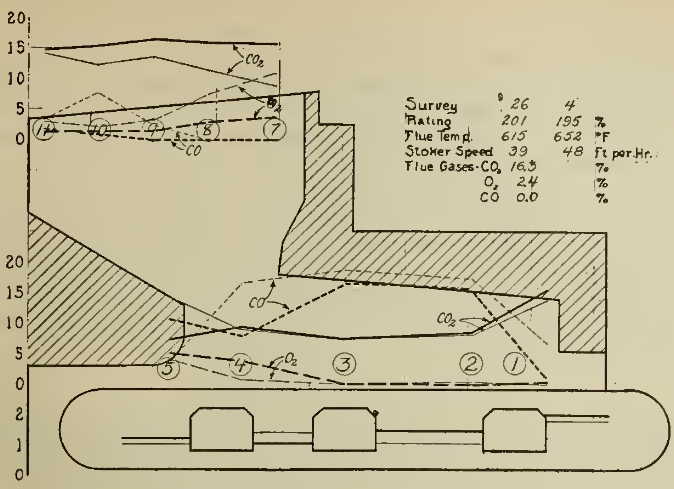

Figure No. 1.—Actual Effect of a Rear Arch.

losses due to incomplete combustion. In this particular case an arch extending forward above the stoker from the bridgewall had been found to be the solution. Figure No. 1 gave a comparison of the combustion conditions before and after the installation of the arch at the rear of the furnace. The heavy lines showed the gas composition after the arch was installed, and the light lines that before the arch was installed. Over the fuel bed the gas composition was different in the two cases, although this was obviously not due wholly to the rear arch. The air pressure in the last air chamber was maintained considerably higher with the rear arch in service, and the refuse passing over the end of the stoker appeared well burnt out.

In the first pass the gas composition showed that the CO_2 was higher at all points and that the CO was lower. The arithmetical averages of the gas composition showed that without the rear arch about one-fifth of the CO formed in the furnace entered the boiler, and that with the rear arch in service only one twentieth of the CO formed entered the boiler.

Here evidently the enforced mixing of the streams of gases from the sections of the stoker had resulted in an improved gas composition. The shape and size of such an arch must be adapted to the furnace available, and it is not always necessary to make the mixing action so vigourous as in this case.

In the second plant in which a study of furnace conditions was now progressing a different shape of furnace had been found, as shown in figure No. 2. The height to which the gases may rise in this furnace was much greater than in the other and the effect of this longer path was evident in the absence of combustible gases entering the boiler. The conditions immediately above the fire were identical with those found in Plant No. 1, as would be expected. The stratification of the gas streams was also identical in character, (namely, the air from the rear of the stoker rose vertically and entered the boiler in the region of point II while the rich gases from the front of the stoker passed vertically up to point 7 after emerging from under the combustion arch). Evidently diffusion was rapid enough to permit the combustion of the unburned gases in this length of travel, and the function of an arch would only be the elimination of the severe stratification that existed.

He considered it evident from these two series of experiments that gaseous combustion could be completed in a small furnace, if the several gas streams were forced to mix, and that although there might not be combustible

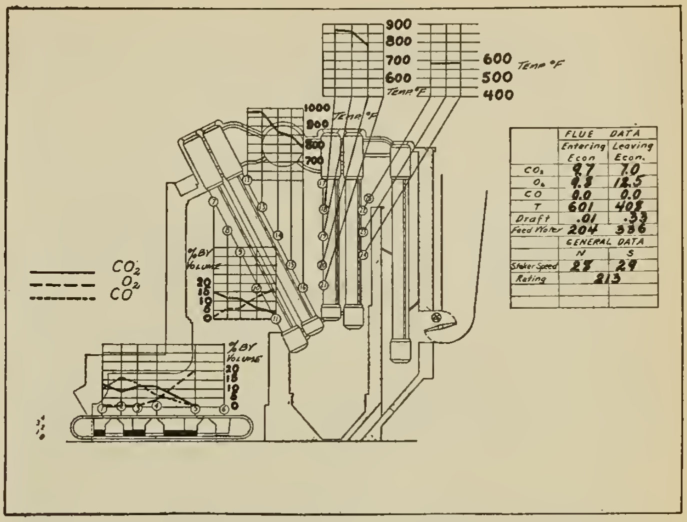

Figure No. 2.—Survey of Furnace Boiler No. 3 Station J, N.Y. Steam Corporation.

gases entering the boiler from a large furnace, stratification existed which might be eliminated to advantage by the introduction of enforced mixing combined with changed operating methods.

Unfortunately all of the fuel fed to the stokers did not remain on the grates. Varying quantities of solid particles were lifted from the fuel bed and carried through the boilers by the gas stream. Unlike pulverized fuel these were comparatively large and required considerably more time to burn than did the gases. The installation

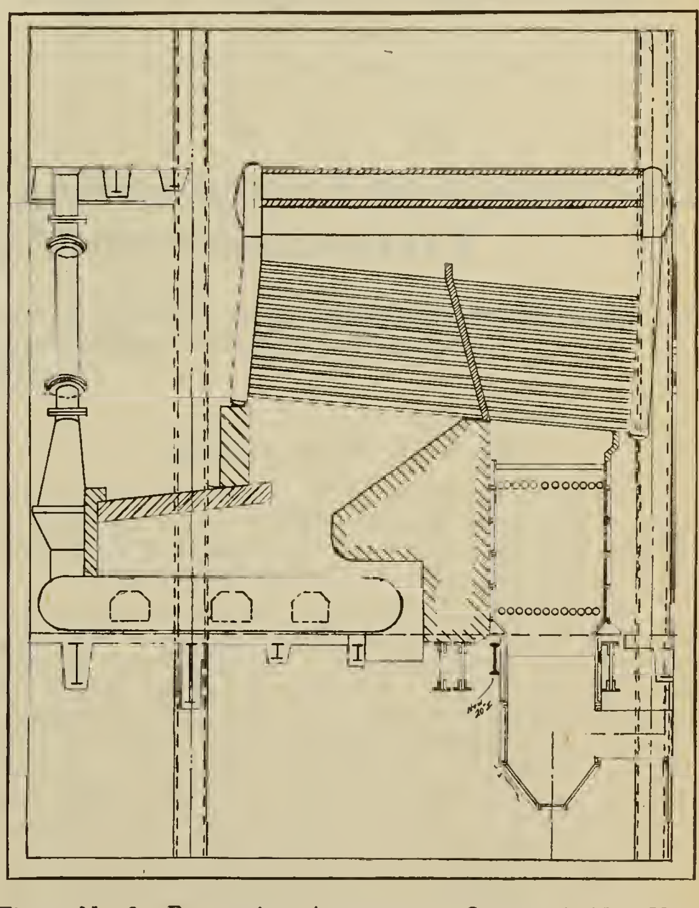

Figure No. 3.—Economizer Arrangement Station A, New York Steam Corporation.

of enforced mixing had no noticeable effect on these particles, and here the only solution seemed to be increased volume, or increased length of travel, which might result from increased volume, under high temperature conditions.

In reference to the second section of the paper he wished to point out that any increase in the rate of gas flow caused by increasing the number of baffles would result in increased cost of baffle maintenance, which was very likely to materially affect the estimated saving. As a rule baffles were continually in need of some repair, and any leak that developed would immediately reduce the estimated improvement. He believed, therefore, that any design eliminating baffles would result in a closer approach to test efficiencies under operating conditions. His attitude toward baffles was one of the factors which had led to the change of design in plant No. 1, where the boiler had been rebaffled so that the original three passes were replaced by two, and one baffle eliminated. An economizer had been installed under the second pass, as shown in figure No. 3. The results of this change were best expressed in terms of gas temperatures at several rates of steam flow, as follows:—

Relation of Steam Flow to Temperature of Exit Gases in 3-Pass Boiler and 2-Pass Boiler with Economizer.

Steam flow M Lb. per hr.	Temperature of gases. Deg. Fahr.		
	Leaving 3rd pass (3-pass boiler)	Leaving 2nd pass (2-pass boiler)	Leaving economizer (2-pass boiler)
50	580	570	219
75	662	642	254
100	765	705	286
115	?	727	293

The change from 3-pass to 2-pass had accompanied by baffle replacement and he believed that this change accounted for the existing gas temperature reduction where an increase was expected.

The reduction in gas temperature by the economizer was, in this case, the same as would have resulted if the economizer had been installed on the original 3-pass boiler. The savings arising from the 2-pass arrangement occurred through the reduction of draft loss, baffle maintenance, and space occupied. The compactness of the new arrangement was clearly shown in the sketch, and was of great importance because of structural features and land values.

Mr. H. A. Tuttle

Mr. Tuttle remarked that in the case of domestic boilers it seemed doubtful whether the actual efficiencies obtained in practice exceeded 40 per cent. He believed that an improvement in this respect would effect a substantial saving on our total annual fuel bill, and would reduce the necessity for the purchase of imported coal. He considered that domestic furnaces should be designed so as to run more efficiently with less attention, and that provision should be made for their operation with high volatile bituminous coal by arranging for the admission of preheated air over the fire.

Mr. Blizard's Reply

The author, in reply, pointed out that the use of powdered fuel would not replace mechanical stokers, as each filled a separate need. Stokers needed more attention, but ash loss was more readily detected.

He drew attention to the valuable information contained in Mr. Mumford's contribution to the discussion, and would remind Mr. Tuttle that the efficiencies quoted in the paper were obtained in laboratory tests, and should be compared only with results obtained in similar tests.

Discussion on European Engineering Practice in Production, Transmission and Use of Electrical Energy

Discussion of paper presented by A. E. Davison, Transmission Engineer, Hydro-Electric Power Commission of Ontario, before the Annual General Professional Meeting, Toronto, Ont., January 28th, 1926.

Mr. K. H. Smith, M.E.I.C.

Mr. K. H. Smith had read the advance proof of the paper with special interest because of the fact that in 1924 he had covered some of the same territory as that which formed the basis for the author's paper.

With reference to Northern France, the author had remarked that "the towns of the war zone are being restored very slowly indeed". His impression in 1924 was quite the reverse. He had spent three days in the Canadian section of the war zone, and had been impressed with the great progress which had been made in the rebuilding of villages, particularly during the time elapsed since the war. It was true that little or nothing had been done to many non essential or public buildings such as the Cloth Hall in Ypres and the Cathedral in Albert. He agreed with the author that there had been a large amount of temporary overhead construction of a very flimsy character. The same applied to Norway and Sweden where there appeared to be much distribution construction intended as permanent but actually very flimsy according to our standards.

The author had referred to rural distribution and rates in Sweden. The *Electrical World* of July 25th, 1925, contained an interesting and informative article on this subject as to previous costs and new rates. Cost at the so-called tertiary sub-stations at 3,000 volts was shown to be about 3.6 cents per k.w. hr. while the charges to the consumer were 6.7 to 8.75 cents per k.w. hr. in densely populated areas and 12.1 to 13.5 cents in moderately populated districts. New rates consisted of a demand charge based on the area of land served and an energy rate of 1.8 cent per unit. He had been informed that 40 per cent of all the agricultural sections of Sweden were now provided with electrical service. This might, of course, not be inconsistent with the author's statement that 70 per cent of the possible rural customers had been served with distribution lines.

Reference had been made to the need of standardization of frequencies in Europe. Such was undoubtedly the case, particularly in England. This immediately raised the question, why the large Queenston development at Niagara perpetuated a 25 cycle system in the face of the almost universal use of 60 cycles in this country. Possibly the author could without impropriety give us some useful information in this connection.

In two different parts of the paper, the author had referred to reactances, relays and protective devices of one kind or another, with the comment that the tendency is to minimize their use, and he was in agreement with the author's view. In Sweden particularly, he had been constantly impressed with the lack of elaborate protective devices.

He expressed surprise at the statement that aluminum paint was used on galvanized material after it had been in contact with salt-laden atmosphere for five or six years. Having recently carefully examined galvanized structures near Halifax which had been exposed to salt atmosphere for over five years, he had found not the slightest evidence of deterioration. Moreover, similar structures in railway yards at Halifax and subject to smoke as well as salt-laden atmosphere for a somewhat less period, also showed no deterioration. He desired to point out, however, that in this country an excellent job of galvanizing on transmission line material is usually obtained.

The references to the economics of the distribution of electricity raised a question of the greatest importance. He believed that a proper rate structure was one of the most important factors in stimulating electricity consumption as well as in adequately meeting the various requirements of all classes of customers under modern conditions with satisfaction to everyone concerned.

He had seen the Lila Edet development in its thin state of construction in 1924 and the Kaplan water-wheel unit for this development in the shop at Kristinehamn. This was undoubtedly one of the most interesting hydro-electric developments now existing or under construction anywhere. It would have one Kaplan runner with moveable buckets, and two Lawaczech runners, their capacity being somewhat larger than the author had stated, viz.: 11,200 h.p. instead of 10,000 h.p. with a head of 21.25 feet and a speed of 62.5 r.p.m., giving units of tremendous proportions.

On the whole, he would have liked to see the author, with his particular qualifications along this line, discuss the subject at somewhat more length, and, if possible, draw conclusion as to the approved practice in Europe for various types of construction and the conditions governing the selection of these. There were for example, the important questions of overhead and underground distribution, secondary distribution voltage, transmission line supports, insulators, and spacing.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOL. IX MARCH 1926 NO. 3

Retiring President's Address

Delivered by Dr. Arthur Surveyer, M.E.I.C., before the Fortieth Annual General Meeting of The Engineering Institute of Canada, Toronto, Ont., January 27th, 1926.

Members of The Engineering Institute of Canada,
Gentlemen:—

This is the time of the year when bank presidents review the economic conditions which have obtained in Canada during the past year, attempt to predict what we may expect and generally conclude by expressing an optimistic opinion on the future of Canada. I may possibly be pardoned, therefore, if I attempt, in a more modest way, to predict what is in store for the engineers in Canada.

You have all heard of the construction boom which has taken place in the United States during the last few years. In 1919 the construction programme, measured by the value of the contracts let, called for an expenditure of about $3,142,000,000. Last year this figure reached a total of $6,500,000,000. or an expenditure for construction purposes only at the rate of over $54.00 per capita. In the meantime the volume of construction in Canada had risen from about $190,000,000. in 1919, to about $280,000,000. last year, or at the rate of about $33.00 per capita.

In going over the figures published by the Dominion Bureau of Statistics, I was surprised to note that the yearly post-war volume of construction, including residential, business, industrial and engineering, had never reached, even in 1922, the figures of the three pre-war years of 1911, 1912, and 1913, and this, notwithstanding an increase of about 60 per cent in the cost of construction, and notwithstanding the fact that we have had, during the last few years, a number of very large industrial developments which have contributed very materially to the raising of our total figure.

The average yearly volume of construction during the three pre-war years just noted was about $400,000,000. compared with an average yearly expenditure of about $290,000,000. during the last three years. If we reduce this last figure to the pre-war cost of construction we are forced to the conclusion that the volume of construction in the last three years has been less than half of the pre-war figures.

Judging by the fact that our railroad expansion is about completed, that our population has practically stopped increasing, and that necessity will compel us to curtail our public works, it would seem that it will be some years before our construction activities will again reach our actual pre-war figures.

Luckily, the education received by engineers does not, in any way, limit their usefulness to the design or construction of engineering works. Engineers have recently discovered that they are also competent to operate mines and manufactures, to manage cities and public utilities, and, in other words, to fill numerous positions which have hitherto been filled by business men.

Two years ago the National Industrial Conference Board of the United States reported the astonishing finding that there were 750,000 major technical and supervisory positions in the manufacturing and mechanical industries of the United States, and that in 1930 American industry might need 400,000 more, and this without taking into account the necessary replacements.

These figures, of course, cannot be applied bodily to Canadian conditions, but there is no doubt that even in this country there is a rapidly growing need for administrative and technical ability in practically all lines of human activity, especially in the manufacturing industries and in the field of public utilities. It has been observed that the engineering courses have, in the past, succeeded in developing, in a certain measure, these two talents in the best graduates. The training of the engineer, besides, gives him the ability to analyze causes and effects, as well as the faculty of working out in his own mind original solutions of the business or technical problems which he has to solve. Engineers could also be employed more frequently, not only by investment bankers, but even by the banks themselves on question of industrial loans.

In France, where the field of the banks is broader than in Canada, each important bank has its own technical staff, and for an engineer to be in charge of such a department is considered as the crowning of his career.

I remember seeing, some years ago, a report analyzing the occupations of the engineering graduates of Rensselaer, Pennsylvania, Harvard, Lehigh and Stevens Institute. This report showed that 15 years after leaving college, from 35 to 60 per cent of the engineers had risen from purely engineering positions to executive work, and that 25 years after graduation, these percentages had increased to 45 and 72 per cent. It is needless to tell you that the larger salaries are certainly drawn by the engineers who have become administrators, and we are being forced to the somewhat paradoxical conclusion that the crowning of an engineer's career is out of the pure engineering into the executive field.

And why should it not be so? These functions are all implied in our name "engineer", which according to some British authorities does not come from the word "engine", but rather from the Latin verb "ingenere" and from the corresponding French verb "s'ingénier". The import of this word has nothing whatever to do with engines or machines, but is purely psychological and is defined by Littré as follows:

"S'ingénier: Chercher dans son génie, dans son esprit, quelque moyen pour réussir"; or in other words, an engineer is one who sets his mental power in action in order to discover or devise some means of succeeding in a difficult task he may have to perform.

The engineer who wishes, however, to graduate from the designing and supervising field into an executive position must be well informed on all financial matters, and he must remember at all times that all engineering problems are dominated by the financial aspect of the question, and that to forget this truth is to condemn himself to remain for ever what an ex-president of this *Institute*, Mr. R. A. Ross, once called a "glorified slide rule", and with no great chance for advancement. This fact is beginning to be realized by the men in charge of engineering education, and that is why you will note in the various curricula a larger portion of the time being devoted to the teaching of financial subjects, such as economics, accounting, business administration, etc.

Ten or twelve of the leading American engineering schools have gone so far as to create courses in business administration and engineering, which are known as courses in administrative engineering. It is now a recognized truth that all engineering activities are dominated by economical and financial requirements. It is therefore advisable for all engineers who, during their stay at college, did not have the benefit of modern engineering teaching, to devote as much time as possible to the study of financial questions. There is such a thing as obsolescence of knowledge, and the engineer who does not improve continually is very rapidly left behind by his colleagues.

In closing this address, gentlemen, I wish to express my sincere thanks to F. P. Shearwood, M.E.I.C., our Minister of Finance, to Sir Alexander Bertram, M.E.I.C., our honorary treasurer, Fraser S. Keith, M.E.I.C., our ex-secretary, and to R. J. Durley, M.E.I.C., our present secretary, and to all the members of Council, for the quiet and effective way in which they have carried out the work of *The Institute* during my tenure of office as president of *The Engineering Institute of Canada.*

The Fortieth Annual General and General Professional Meeting

Convened at Headquarters, Montreal, January 26th, and adjourned to Toronto, January 27th, 28th and 29th, 1926.

The fortieth annual general meeting of *The Institute* was held at headquarters, on Tuesday, January twenty-sixth, nineteen twenty-six. President Arthur Surveyer, D.Eng., M.E.I.C., took the chair at ten twenty a.m.

Reading of Minutes

The minutes of the thirty-ninth annual general meeting were submitted, and on the motion of J. T. Farmer, M.E.I.C., seconded by O. O. Lefebvre, M.E.I.C., were taken as read, and confirmed.

Appointment of Scrutineers

On the motion of E. A. Ryan, A.M.E.I.C., seconded by J. M. Robertson, M.E.I.C., Messrs. H. Massue, A.M.E.I.C., and J. L. T. Martin, A.M.E.I.C., were appointed scrutineers to report the result of the ballot.

Appointment of Auditors

On the motion of Fraser S. Keith, M.E.I.C., seconded by W. Hamilton Munro, M.E.I.C., Messrs. Riddell, Stead, Graham and Hutchison were appointed auditors for the ensuing year.

Proposal Regarding Date and Time of Annual Meeting

J. L. Busfield, M.E.I.C., drew attention to the inconvenience due to holding the first session of the annual general meeting in the morning, and he suggested that since in accordance with the by-laws this meeting has to be held in Montreal, for the transaction of formal business, and can take place in any date in January selected by Council, it would be advisable to make this date coincide with that of one of the January meetings of the Montreal Branch, and hold an evening meeting, just before or after the Montreal Branch meeting, so that there would be no difficulty in obtaining a quorum.

The president concurred, and thought also that in future it would be well to arrange for the adjourned annual general meeting to be held on some date in February, as the customary time at the end of January had been found to conflict with the annual meetings of a number of other organizations in which our members desire to take part. He thought this matter should be considered when selecting the time for the annual meeting in 1927.

The opinion of the members present appeared to be that the suggested changes in the hour of the first session and in the date of the adjourned meeting, were very desirable, and that the question should be favourably considered by Council.

There being no other formal business, it was resolved, on the motion of G. K. McDougall, M.E.I.C., seconded by F. A. Combe, M.E.I.C., that the meeting should adjourn, to reconvene on Wednesday, January twenty-seventh, at ten a.m., at the King Edward Hotel, Toronto.

The meeting adjourned at ten forty a.m.

Toronto Sessions

The meeting was called to order by President Arthur Surveyer, M.E.I.C., at 10.10 a.m., January 27th, 1926, in the Banquet Hall of the King Edward hotel, Toronto.

Reports of Council and Committees

The report of Council for 1925 was presented and, on the motion of C. H. Rust, M.E.I.C., seconded by F. P. Shearwood, M.E.I.C., the report was approved.

The report of the Library and House Committee was read by O. O. Lefebvre, M.E.I.C., and on the motion of O. O. Lefebvre, M.E.I.C., seconded by W. H. Baltzell, M.E.I.C., the report was approved.

The report of the Finance Committee was read and explained by F. P. Shearwood, M.E.I.C., and, after the auditors' certificate had been read by the president, the report was approved on the motion of F. P. Shearwood, M.E.I.C., seconded by H. A. Lumsden, M.E.I.C.

Amendments to By-laws

During discussion on the report of the Legislation and By-laws Committee, Mr. Doane presented a letter from the Halifax Branch in which attention was drawn to the fact that under section 52 of the by-laws, the secretary-treasurer of the branch is elected, whereas the branch is of opinion that he should be appointed in all cases by the executive committee, and this was, in fact, now required by the Halifax Branch by-laws.

Mr. Busfield agreed that in this respect some of the existing branch by-laws do conflict with the by-laws of *The Institute*, and the procedure of the Ottawa Branch was explained by J. L. Rannie, M.E.I.C., the branch secretary in that case being elected in accordance with *The Institute's* by-law, but only one name being placed upon the ballot paper, this arrangement being, therefore, practically equivalent to nomination by the executive committee of the branch.

A resolution from the Niagara Peninsula Branch was presented recording the objection of that branch to the proposed amended version of section 32 of the by-laws, because it does not specifically require Council to make known the identity of the complainant to the respondent, does not specifically require the complainant to attend an enquiry, and does not state that twenty members may force Council to hold an enquiry.

After further discussion it was resolved on the motion of Duncan MacPherson, M.E.I.C., seconded by C. H. Rust, M.E.I.C., that the report of the Legislation and By-laws Committee be approved, and that the consideration of the question raised regarding the amendment to section 32 of the by-laws be left in the hands of Council, and that in accordance with section 76 of the by-laws, Council send out with the letter ballot for the proposed amendments, a statement of the reasons pro and con.

On the motion of J. L. Busfield, M.E.I.C., seconded by C. K. MacLeod, A.M.E.I.C., it was resolved that Council be requested to appoint a special committee to co-ordinate the existing branch by-laws with those of *The Institute.*

On the motion of R. W. Downie, A.M.E.I.C., seconded by J. L. Busfield, M.E.I.C., the reports of the Engineering Sections Committee, Papers Committee, Nominating Committee, and Committee on Code of Ethics, were approved.

The president read the reports of the Gzowski Medal Committee, Students' Prizes Committee, Leonard Medal Committee, and Plummer Medal Committee. Attention was drawn to the small number of papers for Students' prizes submitted from points other than Montreal, and Major Walkem suggested that more publicity should be given to these prizes, and that a statement of the conditions governing the Students' Prizes should be forwarded in good time to the Deans of the engineering schools of the various universities. This was approved, and on the motion of Major Geo. A. Walkem, M.E.I.C., seconded by G. G. Murdoch, M.E.I.C., the above named four reports were approved.

P. Burke-Gaffney, A.M.E.I.C., said that he had been delegated by the Winnipeg Branch to urge upon the meeting the desirability of publishing transactions in addition to *The Journal.* He enquired whether a circular letter could be sent out to all members to ascertain how many of them would be willing to pay an additional subscription of from $1.00 to $3.00 to cover the expense of publishing transactions.

After discussion it was moved by Prof. C. R. Young, M.E.I.C., seconded by P. Burke-Gaffney, A.M.E.I.C., and unanimously resolved that Council be urged to take such measures as will enable the publication of transactions to be resumed.

The reports of the Canadian Engineering Standards Committee, the Committee on Deterioration of Concrete in Alkali Soils, the Committee on Biographies, and the Committee on International Co-operation were read and approved.

In connection with the report of the Honour Roll and War Trophies Committee, the President drew attention to the appeal which is being sent out to the membership for the necessary contributions to complete the work. The report of this committee was approved.

The reports of the four following committees were approved, on the motion of J. A. Bernier, A.M.E.I.C., seconded by W. H. Baltzell, M.E.I.C.:—

Fuel Committee;

Committee on Engineering Education;

Canadian National Committee of the International Electrotechnical Committee;

Board of Examiners and Education Committee.

Branch Reports

The reports of the following branches were unanimously approved, the movers and seconders of the resolutions being as follows:

Branch	*Moved by*	*Seconded by*
Border Cities	J. Clark Keith, A.M.E.I.C.	W. H. Baltzell, M.E.I.C.
Calgary	B. L. Thorne, M.E.I.C.	P. Turner Bone, M.E.I.C.
Cape Breton	H. W. L. Doane, M.E.I.C.	O. O. Lefebvre, M.E.I.C.
Edmonton	J. M. Oxley, M.E.I.C.	B. L. Thorne, M.E.I.C.
Halifax	H. W. L. Doane, M.E.I.C.	O. O. Lefebvre, M.E.I.C.
Hamilton	C. Harvey, A.M.E.I.C.	H. A. Lumsden, M.E.I.C.
Kingston	R. J. McClelland, A.M.E.I.C.	L. M. Arkley, M.E.I.C.
Lakehead	H. J. Lamb, M.E.I.C.	O. O. Lefebvre, M.E.I.C.
Lethbridge	B. L. Thorne, M.E.I.C.	P. Turner Bone, M.E.I.C.
London	H D. Lumsden, M.E.I.C.	J. Clark Keith, A.M.E.I.C.
Moncton	John Stephens, M.E.I.C.	J. A. Bernier, A.M.E.I.C.
Montreal	J. L. Busfield, M.E.I.C.	C. K. McLeod, A.M.E.I.C.
Niagara Peninsula	R. W. Downie, A.M.E.I.C.	W. J. Johnston, A.M.E.I.C.
Ottawa	J. L. Rannie, M.E.I.C.	J. A. Knight, A.M.E.I.C.
Peterborough	A. L. Killaly, A.M.E.I.C.	Geo. Coutts, A.M.E.I.C.
Quebec	O. O. Lefebvre, M.E.I.C.	C. R. Young, M.E.I.C.
St. John	G. G. Murdock, M.E.I.C.	John Stephens, M.E.I.C.
Saguenay	O. O. Lefebvre, M.E.I.C.	C. R. Young, M.E.I.C.
Sault Ste. Marie	A. E. Pickering, M.E.I.C.	F. P. Shearwood, M.E.I.C.
Saskatchewan	L. W. Gill, M.E.I.C.	L. W. Wynne-Roberts, A.M.E.I.C.
Toronto	T. R. Loudon, M.E.I.C.	C. R. Young, M.E.I.C.
Vancouver	Geo. A. Walkem, M.E.I.C.	C. H. Rust, M.E.I.C.
Victoria	Geo. A. Walkem, M.E.I.C.	C. H. Rust, M.E.I.C.
Winnipeg	J. W. Sanger, A.M.E.I.C.	P. Burke-Gaffney, A.M.E.I.C.

J. W. Sanger, A.M.E.I.C., stated that he was requested by the Winnipeg Branch to urge upon the meeting the desirability of arranging each year for one meeting of Council to which Councillors from all branches would have their expenses paid. The president said that this proposal had been debated by Council on many occasions, and had been approved, as it was considered a most important and desirable event. The cost, however, estimated at some $2,000., could not at present be met out of funds at the Council's disposal.

F. P. Shearwood, M.E.I.C., as Chairman of the Finance Committee, concurred with the president, and was of the opinion that this and other important objects referred to in the Finance Committee's report could only be attained if the membership is willing to agree to an increase in the annual fee.

After further discussion, on the motion of J. W. Sanger, A.M.E.I.C., seconded by P. Burke-Gaffney, A.M.E.I.C., it was unanimously resolved that Council be asked to consider the possibility of arranging for one meeting a year, preferably in Montreal, to which the expenses of all councillors will be paid.

The meeting adjourned at 11.45 a.m., to reconvene at 2.30 p.m.

On reassembling, the retiring president, Dr. Arthur Surveyer, M.E.I.C., delivered his valedictory address. This appears in full in this issue of *The Journal.*

On the conclusion of his address the president announced that he had pleasure in taking advantage of this opportunity to present to the officers of the Toronto Branch the Charter authorizing the formation of that branch.

On the Charter would be found the names of a number of the oldest members of *The Institute*, of whom he believed only one, C. H. Rust, M.E.I.C., was present at the meeting. He asked Prof. T. R. Loudon, M.E.I.C., chairman of the Toronto Branch, to take charge of the Charter, which was the visible expression of the authority granted by *The Institute* for the establishment and operation of the branch. The Charter was accepted and fittingly acknowledged by Prof. Loudon on behalf of the Toronto Branch.

Scrutineers Report

The president read the report of the scrutineers announcing the election of officers as follows:—

President	George A. Walkem, M.E.I.C.
Vice-Presidents:	
Zone B	Peter Gillespie, M.E.I.C.
Zone C	W. G. Mitchell, M.E.I.C.
Zone D	Geo. D. Macdougall, M.E.I.C.
Councillors:	
Victoria Branch District	F. C. Green, M.E.I.C.
Vancouver Branch District	James Muirhead, M.E.I.C.
Lethbridge Branch District	John Dow, M.E.I.C.
Calgary Branch District	R. S. Trowsdale, A.M.E.I.C.
Edmonton Branch District	A. W. Haddow, A.M.E.I.C.
Saskatchewan Branch District	H. R. Mackenzie, A.M.E.I.C.
Winnipeg Branch District	D. L. McLean, A.M.E.I.C.
Lakehead Branch District	G. H. Burbidge, M.E.I.C.
Sault Ste. Marie Branch District	C. H. E. Rounthwaite, A.M.E.I.C.
Border Cities Branch District	J. E. Porter, A.M.E.I.C.
London Branch District	E. V. Buchanan, M.E.I.C.
Niagara Peninsula Branch District	T. S. Scott, M.E.I.C.
Hamilton Branch District	W. F. McLaren, M.E.I.C.
Toronto Branch District	J. M. Oxley, M.E.I.C.
Peterborough Branch District	R. L. Dobbin, M.E.I.C.
Ottawa Branch District	O. S. Finnie, M.E.I.C.
	J. L. Rannie, M.E.I.C.
Kingston Branch District	L. M. Arkley, M.E.I.C.
Montreal Branch District	J. L. Busfield, M.E.I.C.
	C. M. McKergow, M.E.I.C.
Quebec Branch District	A. B. Normandin, M.E.I.C.
Saguenay Branch District	E. Lavoie, M.E.I.C. } Tie
	G. F. Layne, A.M.E.I.C. }
Moncton Branch District	F. O. Condon, M.E.I.C.
St. John Branch District	A. G. Tapley, A.M.E.I.C.
Halifax Branch District	C. H. Wright, M.E.I.C.
Cape Breton Branch District	W. C. Risley, M.E.I.C.

President Surveyer drew attention to the fact that in the election of a councillor for the Saguenay Branch, a tie had occurred between Messrs. E. Lavoie, M.E.I.C., and G. F. Layne, A.M.E.I.C. On motion of Brig.-Gen. C. H. Mitchell, M.E.I.C., seconded by Duncan MacPherson, M.E.I.C., it was resolved that E. Lavoie, M.E.I.C., be elected as councillor from the Saguenay Branch.

On the motion of Major Geo. A. Walkem, M.E.I.C., seconded by C. K. McLeod, A.M.E.I.C., it was resolved to convey to the scrutineers a vote of thanks for the efficient manner in which they carried out their duties on the previous day in Montreal.

The president next requested C. H. Rust, M.E.I.C., to conduct the incoming president to the chair, and briefly welcomed his successor in the presidency of *The Engineering Institute of Canada.*

The newly-elected president, Major Geo. A. Walkem, M.E.I.C., of Vancouver, accordingly took the chair, and expressed the pleasure which he experienced in being so heartily welcomed, and particularly in being conducted to the chair by such an old friend as Mr. Rust, a Charter Member of *The Institute.*

President Walkem was of the opinion that the important problems before *The Institute* at the present time are:—First, how to take care of the students and young graduates entering the profession, particularly with reference to retaining their services in Canada, and, secondly, to find the best methods of co-operation between *The Institute* and the seven provincial associations of professional engineers. He expected that light would be thrown on this question at the forthcoming conference to be held next week in Montreal. He was particularly glad to note an increasing tendency on the part of the members of *The Institute* to take part in public life and interest themselves in civic activities. He desired to congratulate the Toronto Branch on the admirable arrangements made for the conduct of the present meeting, and thought that the members present might fittingly pass a vote of thanks embodying such congratulations.

On the motion of T. S. Scott, M.E.I.C., seconded by J. L. Busfield, M.E.I.C., it was unanimously resolved that the secretary convey to the officers and members of the Toronto Branch the thanks and congratulations of *The Institute* on the occasion of the Fortieth Annual General Meeting, expressing gratitude for the trouble they have taken, and appreciation of the success which has attended their efforts. The resolution was suitably acknowledged by Prof. T. R. Loudon, M.E.I.C., on behalf of Prof. C. R. Young, M.E.I.C., the chairman of the Meetings Committee of the Toronto Branch, and his committee.

There being no other business, the meeting adjourned at 4 p.m.

OBITUARIES

Phelps Johnson, M.E.I.C.

With the death of Phelps Johnson, LL.D., M.E.I.C., which occurred at the Royal Victoria Hospital, Montreal, on February 20th, 1926, *The Institute* has lost one of its outstanding members and one who, through his engineering achievements, became internationally known and honoured and has been recognized as one of the outstanding engineers of this continent.

The late Mr. Johnson was born at Warwick, Orange County, N.Y., on October 23rd, 1849. He was educated in the public schools of Springfield, Mass., and Goldthwaite's Private School, Longmeadow, Mass. He began his engineering career in Springfield where from March 1867 until December 1878 he was engaged as draughtsman and engineer with R. F. Hawkins Iron Works. In 1879 and during the succeeding three years he was assistant engineer with the Wrought Iron Bridge Company at Canton, Ohio.

In February of 1882 he came to Canada and joined the Toronto Bridge Company at Toronto, Ont. In May 1883 he was appointed manager and engineer in charge of the Toronto works of the Dominion Bridge Company Limited, succeeding in June 1888 to the post of chief engineer of the company at Montreal. From 1892 to 1904 he was general manager of that company and from 1904-19 general manager and chief engineer; from 1910-13 he was managing director and from 1913-19 he was president. During the years 1911-20, and during the construction of the Quebec bridge, he was president and general manager of the St. Lawrence Bridge Company Limited. Two years previously he was called in as one of the four experts to advise the Quebec Bridge Commission as to the character of piers, construction, etc., in connection with the structure. The history of this construction is well known to all engineers and it remains one of the outstanding engineering accomplishments of the world. Mr. Johnson had nothing to do with the first undertaking which ended so disastrously, but was connected with the existing structure, which was crowned with such signal success.

PHELPS JOHNSON, M.E.I.C.

Mr. Johnson was elected Member of *The Engineering Institute of Canada*, then the Canadian Society of Civil Engineers, on April 20th, 1893. He was a member of Council during the years 1904-6 inclusive, and the following year, 1907, was elected vice-president. He was again elected a member of Council during the years 1910-12 inclusive, and in 1913 he became president. In 1921 the honorary degree of LL.D. was conferred upon Mr. Johnson by McGill University.

Herbert M. Burwell, M.E.I.C.

It is with sincere regret that we record the death of Herbert M. Burwell, M.E.I.C., which occurred at Vancouver, B.C., on July 25th, 1925. The late Mr. Burwell was born at Port Talbot, Ont., on October 23rd, 1863. He received his early engineering education from private tutors and practised in British Columbia continuously since 1887. From March 1902-1906 he was engineer in charge of construction of the Vancouver Power Company's Hydro-Electric Power development at Lake Buntzen, B.C. In April 1906 he was consulting engineer and in charge of construction of Vancouver water works system. He was also consulting engineer for the city of New Westminster, B.C. water works, and has continued in consulting practice in Vancouver up till the time of his death.

Among his earlier works are the following: design and construction of the Lake Buntzen concrete dam and the Coquitlam Lake rock-filled timber crib dam; construction of the Lake Buntzen pipe line and power house; construction of the westerly half of Coquitlam tunnel, a total length of two and a half miles; extension of Capilano water works system, Vancouver, B.C.; and design and construction of Seymour Creek water works system.

The late Mr. Burwell was elected a Member of *The Engineering Institute of Canada*, then the Canadian Society of Civil Engineers, on January 8th, 1910, and was a councillor of *The Institute* during the years 1920-22 inclusive.

Joseph Arthur Henri Marchand, A.M.E.I.C.

Regret is expressed at the news of the death of Joseph Arthur Henri Marchand, A.M.E.I.C., which occurred after a long illness on December 12th, 1925.

The late Mr. Marchand was for many years connected with the Department of Public Works of Canada and at the time of his death was assistant engineer at the Montreal office of the department. He was a graduate of the Ecole Polytechnique, having received his degree of B.A.Sc. in May 1910. Before joining the staff of the Department of Public Works in March 1913, he had been engaged for two years in making preliminary surveys and construction of the Roberval-Saguenay Railway and Ha-ha Bay Railway in the Saguenay district. Prior to that he had been engaged on lake and railway surveys on the upper St. Maurice Valley.

PERSONALS

A. G. Graham, A.M.E.I.C., who was previously located at Gold Coast Colony, B.W.A., is now assistant engineer in the municipal engineer's office at Point Gray, B.C.

C. R. Bown, Jr.E.I.C., who has been located at Fall River with Messrs. Stone and Webster, Inc., has been transferred to Beaumont, Texas, on the construction of the power station in that city.

J. G. Campbell, A.M.E.I.C., has severed his connections with the Hamilton Bridge Company Limited, and has accepted a position in the draughting department of the Canadian Bridge Company, Limited, at Walkerville, Ont.

G. W. Coward, A.M.E.I.C., has been appointed assistant to the chief engineer of the joint North-East Argentine and Entre Rios Railway Companies at Concordia, Entre Rios, Argentina.

E. E. Lord, A.M.E.I.C., who has been in Vancouver, B.C., on leave for some six or seven months, has returned to Newchwang, N. China, where he is assistant engineer on the Lower Liao River Conservancy.

T. B. Fraser, S.E.I.C., has been appointed to the staff of the Forestry Engineering Branch of the Wayagamack Pulp and Paper Company, Limited, at Three Rivers, Que. Mr. Fraser has for the past two years been with Messrs. Sutcliffe Company Limited, at New Liskeard.

E. K. Macnutt, S.E.I.C., who graduated from McGill University in 1924 and subsequently with the E. B. Eddy Company Limited, Hull, Que., has accepted a position with the Port Alfred Pulp and Paper Corporation, Port Alfred, Que.

John Paris, A.M.E.I.C., who graduated from the University of Toronto, 1924, is resident engineer with the Northern Development Branch of the Department of Lands and Forests on the North Bay-Cobalt road, in charge of residency No. 2, twenty-five miles north of North Bay.

R. S. Baker, A.M.E.I.C., is located at Smooth Rock Falls, Ont., with the Mattagami Pulp and Paper Company, Limited, on the construction of a hundred-ton bleaching plant for the company. During 1924 and 1925 Mr. Baker was with the Riordon Pulp Corporation at Temiskaming, Que.

Arthur Donaldson, Jr.E.I.C., who graduated from the University of Alberta in 1922, is at present with the Burns McDonnell Engineering Co., consulting engineers, Los Angeles, California, as supervising engineer on construction and design in connection with waterworks and sewerage systems.

E. L. Zealand, Jr.E.I.C., has been appointed to the engineering staff of the Aluminum Company of Canada, Limited, Arvida, Que. Mr. Zealand is a graduate of the University of Toronto of the class of 1922, and has been junior engineer on dam and power house construction with the Quebec Development Company at St. Joseph d'Alma, Que., since 1923.

A. W. Swan, A.M.E.I.C., former assistant editor of *The Engineering Journal*, who resigned to return to England in the early part of 1922, and who is at present advertising manager for Evershed & Vignoles, Ltd., Chiswick, London, has been awarded the £50 prize offered by the *Electrical Review* (London) for the best series of six half-page advertisements in that journal for the latter half of 1925.

R. H. N. Lockyer, A.M.E.I.C., formerly assistant superintendent, West Kootenay Power and Light Company's generating stations at Bonnington Falls, B.C., is now in the employ of the Southern California Edison Company on their Big Creek system operating four hydro-electric plants with a combined capacity of 250,000 h.p. and transmitting their power at 220,000 volts.

George P. MacLaren, A.M.E.I.C., formerly engineer maintenance-of-way of the Central Region of the Canadian National Railways, Toronto, has been appointed general tie and timber agent of Canadian National Railways with headquarters at Montreal, succeeding W. H. Grant, who has been granted leave of absence pending retirement after many years of service with the company. Mr. MacLaren served overseas as captain and major with the 10th Canadian Railway Troops.

Roy A. Crysler, A.M.E.I.C., is designing engineer with Messrs. Chapman and Oxley, engineers and architects, Toronto. Mr. Crysler is a graduate of the University of Toronto of the year 1920, and following graduation he was engineer and surveyor with the Town Planning Commission of Niagara Falls, Ont. Later in the same year he joined the staff of the Hydro-Electric Power Commission of Ontario and was located at Niagara Falls. In April 1922 he was appointed engineer with the reinforced concrete branch of the City Architect's Department, Toronto, Ont.

P. E. Cooper, Jr.E.I.C., who for the past three years has been with the Singer Manufacturing Company, has accepted a position with the Canadian International Paper Company, and is engaged on the new construction work now in progress at East Templeton, Que. Mr. Cooper was topographical engineer in charge of surveys on the Singer Manufacturing Company's limits north of Ottawa and later as location engineer in connection with the location of thirty miles of standard gauge railroad in the vicinity of Thurso, Que., and still later as office engineer for the company in connection with the railway and Thurso works construction. He graduated from McGill University in the class of 1923 and had considerable general engineering experience prior to graduation.

F. S. Lazier, M.E.I.C., Enters Private Practice

F. S. Lazier, M.E.I.C., of Thorold, Ont., has resigned as division engineer of the Welland ship canal, and is entering private practice with headquarters at Toronto. Mr. Lazier is a graduate of Queen's University of the

F. S. LAZIER, M.E.I.C.

year 1907. Following graduation Mr. Lazier was engaged on the surveying and construction of the Trent canal, first as instrumentman and later as assistant engineer until April 1908. During the summer of 1908 he was engaged on survey and construction work for National Transcontinental Railway and in November of that year again joined the staff on the construction of the Trent canal as assistant engineer. Two years later he was division engineer of Rice Lake division of the Trent canal and in July 1913 was appointed division engineer on the surveys, design and construction of the Severn division, on which he was engaged until July 1918, when he was appointed engineer-in-charge on power survey of the St. Lawrence river for the Hydro-Electric Power Commission of Ontario. In March 1919 Mr. Lazier was appointed resident engineer on the construction and survey of sections 3 and 4 of the Welland ship canal.

A. G. Tapley, a.m.e.i.c., awarded Gzowski Medal

A. G. Tapley, a.m.e.i.c., who was recently awarded the Gzowski Medal for his paper entitled "Concrete in Sea Water", published in the November 1924 issue of *The Journal*, and who was also recently elected Councillor representing the Saint John Branch, is a native of Saint John, N.B., where he was born in 1880. He received his early education at Fredericton High School and Fredericton Business College, followed by a course with the International Correspondence Schools. His early engineering work was with the Intercolonial Railway with which he became connected in 1898, and between that date and August 1905 he occupied the positions of draughtsman, transitman and engineer in charge of construction. During the following two years he was with the National Transcontinental Railway as leveller, draughtsman, instrumentman and resident engineer. During 1908 he again became connected with the Intercolonial Railway. From 1909 until the present time he has been with the Department of Public Works of Canada as assistant engineer, located in Saint John, N.B.

A. G. TAPLEY, A.M.E.I.C.

He was a member of the executive of the Saint John Branch in 1921 and chairman in 1922, continuing as a member of the executive in the following year.

Max. V. Sauer, m.e.i.c., receives Appointment

Max V. Sauer, m.e.i.c., formerly hydraulic engineer for Canadian Vickers Limited, Montreal, is vice-president of the William Hamilton, Limited, Peterborough, Ont. Previous to joining the staff of the Canadian Vickers Limited, Mr. Sauer was with the engineering department of the Hydro-Electric Power Commission of Ontario. He is a graduate of the School of Practical Science, University of Toronto, of the class of 1901 and took a post-graduate course in 1902, receiving a fellowship in 1903. After his university course he was with the Ontario Power Company at Niagara Falls, first as draughtsman and the following year as assistant to the mechanical engineer. He was appointed chief designer of the Niagara Falls Power Company, Niagara Falls, N.Y., in 1905, and the following year was construction engineer to the Iroquois Construction Company, Buffalo, N.Y. In 1907 he again became associated with the Ontario Power Company as chief designer, then as mechanical assistant to the engineer-in-charge, and subsequently in 1912 as mechanical engineer in full charge of design, field, and inspection department.

MAX V. SAUER, M.E.I.C.

James Blain Woodyatt, a.m.e.i.c., becomes President of Southern Canada Power Company

James Blain Woodyatt, a.m.e.i.c., has been appointed president of the Southern Canada Power Company, Montreal. Mr. Woodyatt was born at Brantford, Ont., on July 2nd, 1886, and after graduating from McGill University in 1904, he was engaged in his first engineering work as chainman with the Niagara and Welland Power Company. The following year he was topographer with the Toronto and Hamilton Railway. Between the years 1906-8 he was with the Canadian Westinghouse Company Limited at Hamilton, Ont., as engineering apprentice and in 1909 he assisted in carrying out investigations on the flow of ice in the St. Lawrence river and in the gulf on behalf of the government. During 1909-10 he was on the sales staff of Allis-Chalmers-Bullock Limited, in Montreal, after which he was appointed superintendent of power with the Sherbrooke Railway and Power Company, Sherbrooke, Que. In this capacity he was with the company until 1913 when he became general superintendent of the Southern Canada Power Company. In 1916 he was appointed general manager of this company and in 1920 vice-president and with his appointment as president of the company at the present time, he retains the position of general manager.

Mr. Woodyatt is connected in an executive capacity with a large number of power companies including the following: Ottawa-Montreal Power Company, Ottawa-Hull Power Company, Ottawa-Hull River Power Company, Northern Canada Power Company, East Kootenay Power Company, Power Corporation of Canada, Dominion Power and Transmission Company, Winnipeg Electric Company, Manitoba Power Company. He is also vice-president of the Canadian Electrical Association.

J. B. WOODYATT, A.M.E.I.C.

Charles Warnock, A.M.E.I.C., Heads New Inspection Company

Chas. Warnock, A.M.E.I.C., formerly president of the Robert W. Hunt and Company Limited, is president of the newly incorporated firm of Chas. Warnock and Company, Limited, Montreal, specializing in the inspection of railway materials, structures, and pulp and paper mill equipment.

Mr. Warnock was born at Fort William, Ont., when it was then called Prince Albert's Landing, on November 9th, 1875. He was educated at Lake Forest University, Forest, Ill., and subsequently was employed with the Illinois Steel Company and other metallurgical firms for a period of eight years. In 1902 he joined the staff of the Robert W. Hunt and Company in the United States and in the following year was sent to Montreal as the company's Canadian representative, opening an office for the company in Montreal and becoming manager of the same. Subsequently, he became vice-president and general manager of the Robert W. Hunt and Company, Limited, following the death of Thomas Irving, and in 1923 after the death of Captain Hunt, Mr. Warnock was elected president of the company. Associated with Mr. Warnock in the new company will be Mr. H. W. Greene, until recently secretary of the Robert W. Hunt and Company Limited, and now vice-president and treasurer of the newly organized company. The foreign interests of the new company will be represented by R. H. Laverie and Sons Inc., of New York City.

President of Ontario's Association of Professional Engineers

Lt.-Col. H. J. Lamb, M.E.I.C., was recently elected president of the Association of Professional Engineers of Ontario. Col. Lamb graduated from the Royal Military College, Kingston, Ont., in 1893, and was subsequently engaged on geological surveys and railway surveys as assistant engineer. His early engineering work included the construction of the street railway of the city of

LT.-COL. H. J. LAMB, M.E.I.C.

Quebec and the erection of steel bridges and masonry substructures for Canadian Pacific Railway. In 1897 he was appointed section engineer on construction of the Crow's Nest Pass Railway for the C.P.R., and was made assistant engineer, maintenance-of-way, on the western division of the C.P.R. the following year. He joined the staff of the Department of Public Works of Canada in 1901 as assistant engineer on construction and maintenance of harbours and rivers. He was promoted to district engineer in charge of harbours and rivers in west of Canada in 1905. From 1909-12 he was engineer in charge representing the Dominion Government on the construction of the Detroit River Tunnel.

His service during the Great War dates from the first days of hostilities and he served throughout as general staff officer at headquarters, 1st and 3rd divisions and also as assistant director on the Air Ministry in London. Col. Lamb was twice mentioned in despatches and was awarded the D.S.O. for conspicuous gallantry during operations in the field. On returning to Canada in 1919 Col. Lamb was appointed supervising district engineer for the Department of Public Works for the Province of Ontario.

G. G. Mills, A.M.E.I.C., Receives Appointment

G. G. Mills, A.M.E.I.C., has been appointed Toronto manager of the Babcock-Wilcox and Goldie-McCulloch Company, Limited, succeeding the late Wm. McKay, who died at his home in Toronto on January 30th, 1926. Mr. Mills was born in Winnipeg, Man., in 1887, and received his primary education at the public and high schools of Toronto and graduated from the School of Practical Science, University of Toronto, with the degree of B.A.Sc. in 1907. From that date until the outbreak of the World War he was engaged in engineering in Canada, the United States and Mexico. He served overseas with the Canadian Artillery and at the conclusion of hostilities was in charge of the vocational department of the province of Quebec. Mr. Mills was appointed manager of the Underfeed Stoker Company of Canada in June 1920, a position he held until the amalgamation of that concern with the Riley Engineering Company on January 1st, 1925, when he became manager and vice-president of the

G. G. MILLS, A.M.E.I.C.

new company, the Riley Engineering and Supply Company. He joined the Babcock-Wilcox and Goldie-McCulloch Company in September 1925. Associated with Mr. Mills in the Toronto office is W. A. Osbourne, who, prior to joining the staff of the Babcock-Wilcox and Goldie-McCulloch Company Limited, at Galt, Ont., was with the Hydro-Electric Power Commission of Ontario on the Chippawa development.

Studies of Bond Between Concrete and Steel

"Studies of Bond between Concrete and Steel" by Professor Duff A. Abrams, M.E.I.C., has just been published as Bulletin 17 of the Structural Materials Research Laboratory, Lewis Institute, Chicago. The report is reprinted from the 1925 Proceedings of the American Society for Testing Materials.

Bond tests were made by applying a pull on one end of 1-in. plain round steel bars embedded axially in 8- by 8-in. concrete cylinders; parallel compression tests were made on 6- by 12-in. concrete cylinders. The concrete covered a wide range in quantity of mixing water, cement and size and grading of aggregate. Tests were made at ages of 7 days to 1 year; 735 pull-out bond tests and 735 parallel compression tests were made.

Conference of Delegates from Provincial Associations of Professional Engineers

A conference of delegates from the seven provincial bodies of professional engineers of Alberta, British Columbia, Manitoba, New Brunswick, Nova Scotia, Ontario and Quebec, was held at the rooms of *The Engineering Institute of Canada*, 176 Mansfield Street, Montreal, on February 2nd, 3rd and 4th, 1926.

The delegates were as follows:—

Messrs. B. L. Thorne, Calgary, and R. J. Gibb, Edmonton, Alberta.
Major Geo. A. Walkem and Mr. E. A. Wheatley, Vancouver, B.C.
Messrs. J. W. Sanger and P. Burke-Gaffney, Winnipeg, Man.
Messrs. D. W. Robb, Amherst, and H. W. L. Doane, Halifax, N.S.
Mr. Alex Gray, St. John, and Prof. E. O. Turner, Fredericton, N.B.
Col. H. J. Lamb, Prof. H. E. T. Haultain and Mr. F. R. Ewart, Toronto, Ont.
Messrs. A. R. Décary, Quebec, and Frederick B. Brown, Montreal, Que.

The conference assembled at ten o'clock on Tuesday morning, February 2nd, and were welcomed by Dr. R. A. Ross, one of the past presidents of *The Institute.*

After a few felicitous words, in which he welcomed the members, Dr. Ross retired; the business of the meeting then commenced; Mr. A. R. Décary was elected chairman for the day, and Mr. E. A. Wheatley secretary for the conference.

Meetings were held morning, afternoon and evening during the three days, and many important points were discussed. On Tuesday, February 2nd, Mr. A. R. Décary was chairman, while on Wednesday and Thursday Professor H. E. T. Haultain and Mr. Frederick B. Brown, respectively, occupied the chair.

The discussion and exchange of ideas proved very valuable to the delegates under the following heads:—

1. Benefits to the Public and to the Engineer arising from Regulation of the Profession.
2. Definitions of Engineer and Engineering.
3. Standards Required for Admission to Practise.
4. Methods of Admission to the Profession.
5. Methods of Internal and External Administration of Engineering Acts.
6. Standards of Remuneration for Professional Engineers.
7. Code of Ethics.
8. Reciprocal Courtesies between Professional Engineering Bodies.
9. Temporary Licenses between Provinces.
10. Transfer of Membership between Provinces.
11. Temporary licenses for Foreign Engineers.
12. Membership of Foreign Engineers.
13. The Story of the Provincial Bodies, — History, present status and outlook.
14. Methods of Co-operation between Professional Engineering Bodies.
15. Features of Activities which help the prestige and influence of the Profession.
16. Moulding Public Opinion.
17. The Education of the Engineer and the Public in regard to the importance of Engineering and The Engineering Acts.
18. The need for Engineers in Public Life.
19. The Co-ordination of Provincial Activities through a central Clearing House.
20. Registered Pupils and Engineers-in-Training.
21. The Desirability of the Use of a Seal for Engineering Documents.
22. The Desirability of the Classification of Engineers into Main Divisions or Branches of Engineering.
23. The Systematic Watching of Federal and Provincial Acts where the interests of the Engineering Profession are concerned.
24. General Welfare.
25. Co-operation with *The Engineering Institute of Canada.*

The delegates made a number of recommendations to be submitted to the Council of each provincial body. It was unanimously felt that the conference had proved valuable, not only for the discussion it produced, but also since it gave much needed personal contact, and the delegates left Montreal with a sense of good fellowship and co-operation which was expressed in the following resolution:—

"Resolved that the Delegates of the Associations, or Corporation, of Professional Engineers of Alberta, British Columbia, Manitoba, New Brunswick, Nova Scotia, Ontario and Quebec desire to express to *The Engineering Institute of Canada* their most grateful thanks and hearty appreciation for its courtesy and thoughtfulness in convening this meeting of Delegates, held on February 2nd, 3rd and 4th, 1926, at the headquarters of *The Institute*, 176 Mansfield Street, Montreal, Quebec, and at which a great many valuable and interesting discussions took place, and further, that the Delegates express to *The Institute* their feeling that the seven provincial bodies of professional engineers here represented desire to co-operate with *The Institute* in everything which will advance the interests of the profession and that the delegates will take back to their respective bodies the sense of good fellowship and close association developed and strengthened by this conference.

"It Was Further Resolved that special appreciation should be expressed for the hospitality of *The Institute* at hotel, club and headquarters in so kindly providing such excellent accommodation in every respect."

ELECTIONS AND TRANSFERS

At the meeting of Council held on January 27th, 1926, the following elections and transfers were effected:

Members

ALLCUTT, Edgar Alfred, B.Sc., M.Sc., (Birmingham Univ.), associate professor of mechanical engineering, University of Toronto, Toronto, Ont.

TEAZE, Moses Hay, B.Sc. (Worcester Polytech. Inst.), project engr., with H. S. Ferguson, M.E.I.C., consltg. engr., New York, N.Y.

Associate Members

ASHWORTH, John Kershaw, designing and sales engr. for Canada, Jones & Glassco Regd. (for the Coventry Chain Co. Ltd., Coventry, England), St. Nicholas Building, Montreal, Que.

CARR, David Leonard, cable sales specialist, Northern Electric Co. Ltd., Montreal, Que.

DUBE, Wilbrod, B.A.Sc., C.E., (Ecole Polytech.), in office of Tanguay & Chenevert, Archts., Quebec, Que.

QUIGLEY, Daniel Hugh, manager, North American Collieries, Coalhurst, Alta.

SPENCE, John James, Diploma, (Univ. of Tor.), demonstrator, Faculty of Applied Science, University of Toronto, Toronto, Ont.

Juniors

ARTHUR, Harold Franklyn, B.Sc. (N.S. Tech. Coll.), asst. to chief elect'l. engr., British Empire Steel Corpn., Glace Bay, N.S.

JOHNSTON, Harry Lloyd, Jr., B.C.L.S., 851 University Street, Montreal, Que.

NENNIGER, Emile, design and preparation of plans, office of Dr. Arthur Surveyer, M.E.I.C., Montreal, Que.

ROSE, Alexander Andrew, B.A.Sc. (Univ. of Tor.), instructor, mechanical drawing and mathematics, Sault Ste. Marie Technical School, Sault Ste. Marie, Ont.

Affiliates

HATFIELD, Hubert A., maritime representative, Babcock-Wilcox & Goldie-McCulloch, Ltd., New Glasgow, N.S.

McDONALD, Alexander, chief inspr., steam locomotives, with supervision over design and specifications, Dominion Steel Corpn., Sydney, N.S.

McMANUS, Michael Howard, contractor, Halifax, N.S.

WATT, John Gordon, engrg. dept., Northern Foundry & Machine Co., Sault Ste. Marie, Ont.

Transferred from the class of Associate Member to that of Member

MORRISON, George, dist. mgr., maritime provinces, English Electric Co. of Canada, Ltd., Sydney, N.S.

ROUSSEAU, Théodore E., B.A.Sc., C.E. (Laval Univ.), chief engr. and gen. mgr., T. E. Rousseau Ltd., engrs. and contractors, Quebec, Que.

STEPHENS, George Leslie, Engr. Lieut.-Commdr., R.C.N., engr. officer, Esquimalt Naval Base and consltg. engr., H.M.C. Dockyard, Esquimalt, B.C.

WYNN, Guy Montague, 2nd vice-president and director, T. Pringle & Sons, Ltd., Industrial Engineers, Montreal, Que.

Transferred from the class of Junior to that of Associate Member

ARDAGH, Sydney Vernon, asst. engr., S.P.R.R. Co. of Mexico, Empalme, Sonora, Mexico.

ROBINSON, William Cecil Elwood, transitman, operating dept., C.P.R., Toronto Terminals, Toronto, Ont.

ROY, Eugène, B.Sc., C.E., (Ecole Polytech.), asst. city engr., City of Outremont, Que.

TEMPEST, Frank, Imperial Oil Refineries, Calgary, Alta.

Transferred from the class of Student to that of Associate Member

ASKIN, Robert James, B.Sc. (Queen's Univ.), engr. in charge of mill efficiency, etc., Fort William Paper Co., Fort William, Ont.

BALL, Francis Caldwell, B.A.Sc. (Univ. of Tor.), dftsman., City of London, Ont.

BEAUDRY, Louis, B.A.Sc., C.E. (Ecole Polytech.), Dept. of Public Works, Quebec, Que.

CHISHOLM, Alexander Harold, B.Sc. (McGill Univ.), chief dftsman., Laurentide Company, Grand Mere, Que.

JONES, Vernon C., B.Sc. (Queen's Univ.), supervising engr., Bell Telephone Co. of Canada, Montreal, Que.

LAJOIE, Joseph Louis Charles, B.A.Sc. (Univ. of Montreal), chief chemist, Imperial Oil Refineries, Montreal East, Que.

VILLENEUVE, Joseph Arthur, B.A.Sc., C.E. (Laval Univ.), 565 Berri Street, Montreal, Que.

Transferred from the class of Student to that of Junior

DIONNE, Joseph Alexandre, B.Sc. (McGill Univ.), engr. of constrn. methods, Bell Telephone Co. of Canada, Montreal, Que.

DUBUC, Antonio E., Electrical Commission of the City of Montreal, Montreal, Que.

GILLEY, James Royden, B.A.Sc. (Univ. of Tor.), comptroller, Hart House, University of Toronto, Toronto, Ont.

LANGLOIS, William Lawrence, B.A.Sc. (Univ. of Tor.), estimating, dfting, etc., with H. G. Acres, M.E.I.C., Niagara Falls, Ont.

OAKS, Harold Anthony, B.A.Sc. (Univ. of Tor.), pilot, Provincial Air Service, i/c Orient Bay Station, Sault Ste. Marie, Ont.

SCHURMAN, Hulbert Hartt, B.Sc. (N.S. Tech. Coll.), meter engr., St. Francis Water Power Co., Thetford Mines, Que.

SIMMERS, Joseph Adolph, B.A.Sc. (Univ. of Tor.), asst. to res. engr., Spanish River Pulp & Paper Mills, Ltd., Sturgeon Falls, Ont.

At the meeting of Council held on February 25th, 1926, the following Students were admitted:

BEAM, Donald Carleton, East House, University of Toronto, Toronto, Ont.

BÉLANGER, Réal, C.E. (Univ. of Montreal), 5283 Park Avenue, Montreal, Que.

BURDETT, George Henry, 29 Botrel Avenue, Montreal, Que.

CHOROLSKY, Eugene, North House, University of Toronto, Toronto, Ont.

COMPLIN, Edward Reginald, 101 Willcocks Street, Toronto, Ont.

CREED, Kenneth B., 645 Union St., Fredericton, N.B.

HOWARD, James Phineas, 37 Clergy St. West, Kingston, Ont.

JENNINGS, George Lorne, 49 St. Clair Avenue, West, Toronto, Ont.

KRIBS, W. Herbert, East House, University of Toronto, Toronto, Ont.

McCLURE, Lindley Wilberforce, 4321 Bordeaux St., Montreal, Que.

MULLIGAN, Henry Iveson, 50 Victoria Street, Montreal, Que.

PETZOLD, Henry Paul, 100 Somerville Avenue, Westmount, Que.

RUSSELL, George Alan, 8 Willcocks Street, Toronto, Ont.

SILVER, Ralph Charles, 743 University Street, Montreal, Que.

SUDDEN, Edwin Alexander, 320 Huron Street, Toronto, Ont.

SWITZER, Henry Rea, 62 Melbourne Avenue, Toronto, Ont.

TAYLOR, Frank Denzil, 348 Sherbrooke Street, West, Montreal, Que.

WHITSON, Duncan David, 617 Huron Street, Toronto, Ont.

WYSE, Lyell Smith, 387 Mance Street, Montreal, Que.

YUILE, William Sclater, 70 Ontario Avenue, Montreal, Que.

CORRESPONDENCE

A Correction

The following communication has been received from the President of *The Institute:—*

The Editor,
The Engineering Journal.

Dear Sir;—

My attention has been called to the article regarding myself published on pages 121-122 of the February number of *The Journal.*

Lieut.-Col. W. G. Tyrrell, D.S.O., R.E., was officer-in-charge of the Kantara Military Railway, and I had the honour of serving under him as engineer in charge of maintenance.

Faithfully yours.

(*Signed*) GEO. A. WALKEM.

NOTE: — Lieut.-Col. Tyrrell, a member of *The Institute,* is a Canadian and a distinguished graduate of the Royal Military College.

Recent Ruling Regarding Income Tax Exemptions

The Secretary has received the following letter from the Inspector of Taxation of the district of Montreal which is published herewith for the information of our members:—

6th January, 1926.

Dear Sir:—

The Commissioner of Taxation has brought to my attention the fact that your members had been advised that depreciation on engineers' instruments and library is a proper deduction in arriving at taxable income.

This information was based on my letter of the 26th of March, 1924. I may say that this letter should have been more explicit, and I understand that Mr. Leroux telephoned your office in the former part of June, 1924, for a copy of your Charter, and the question had been verbally explained.

In order that uniformity be obtained, I submit, for the guidance of your members, the following information for Income Tax purposes.

Association Fees

(a) Only the fee paid to the Corporation of Professional Engineers of the Province of Quebec may be allowed as a deduction in this Province.

(b) A fee paid to *The Engineering Institute of Canada* being a voluntary contribution, is not a permissible deduction.

Depreciation on Instruments

(a) Depreciation on instruments is only allowed where the tax-payer exercises his profession on his own account.

(b) When engaged on salary and is under an agreement to furnish his own instruments, full details must be furnished the Department, in each case, before consideration may be given to the claim.

Depreciation on Library

(a) Depreciation is allowed only when the engineer exercises his profession on his own account.

(b) When employed on salary no depreciation will be allowed.

Will you please acknowledge the receipt of this letter.

Yours very truly,

(*Signed*) P. F. MCCAFFREY,
Inspector of Taxation.

Trade Publications

Link-Belt Limited, Toronto, Ont., have issued a new booklet on their "All-Purpose Crawler Crane", the number of this publication being 895. The book contains 48 pages, generously illustrated to show the use of the drag-line, dipper and trench shovel, skimmer scoop, hook blocks and pile drivers. Data on lifting capacities, approximate operating speeds, line pull, tractive effort, etc., are given. The tables in which this data is arranged have been supplemented by line drawings which show dimensions for operating limits. Finally in a brief and interesting way, information is given on some of the usual, as well as the more ingenious uses to which the various types of cranes can be put.

The Riley Engineering & Supply Company, Limited, Toronto, Ont., have issued a bulletin fully describing the Riley Atritor Unit Pulverizer. The booklet contains some twelve pages describing the system fully and illustrating the various parts of the equipment.

Lectures on Ice Engineering

Dr. Howard T. Barnes, M.E.I.C., will give four lectures on ice engineering at the Macdonald Physics Building, McGill University, on March 11th, 18th, and 25th, from 5 to 6 p.m. Members of *The Engineering Institute of Canada* may attend these lectures on the same basis as the graduates and under-graduates of McGill, i.e., without charge.

Trade Publication

The De Laval Steam Turbine Company, Trenton, N.J., have issued a sixteen-page bulletin entitled "Superior Speed Reducers for Every Service", describing a line of speed reducers for use with standard or high speed motors driving slow or moderate speed machinery, including worm reduction gears of the horizontal and vertical shaft and double reduction types, also helical gears for low ratios, and double helical gears for high power service. The illustrations include many coloured views, which clearly set forth the details of construction, materials used, the pressure oiling system for heavy duty service, etc.

Association of Professional Engineers of Nova Scotia

ANNUAL MEETING

The annual meeting of the Association of Professional Engineers of Nova Scotia was held at the Green Lantern restaurant, Halifax, on January 21st, 1926. The meeting was attended by fifty-seven members and after the reading and adoption of the minutes of the last meeting, and the reports of the secretary, registrar, and council, the scrutineers reported the results of the election of officers as follows:—

President.........D. W. Robb, M.E.I.C., Amherst.
Vice-President....Hon. J. F. Cahan, A.M.E.I.C., Halifax.
Councillors.......O. S. Cox, A.M.E.I.C., Halifax, G. S. Stairs, A.M.E.I.C., Windsor, H. S. Johnston, M.E.I.C., Halifax, H. W. L. Doane, M.E.I.C., Halifax, J. F. Lumsden, A.M.E.I.C., Halifax, J. E. Belliveau, A.M.E.I.C., Halifax, Wm. H. Noonan, A.M.E.I.C., Halifax, R. M. McKinnon, A.M.E.I.C., Halifax.

Appointed by Governor-in-Council:—
F. R. Faulkner, M.E.I.C., Halifax, F. H. Sexton, Halifax, G. D. Macdougall, M.E.I.C., New Glasgow, T. J. Brown, M.E.I.C., Halifax, L. H. Wheaton, A.M.E.I.C., Halifax, J. L. Allan, M.E.I.C., Dartmouth, W. P. Morrison, M.E.I.C., Dartmouth.

The scrutineers also reported that the amendment to the by-laws had carried. Other business of the meeting included the appointment of the president-elect D. W. Robb, M.E.I.C., and councillor H. W. L. Doane, M.E.I.C., to represent the Association of Professional Engineers of Nova Scotia at the meeting of delegates of the Professional Engineering Associations in Montreal.

In a brief address the newly elected president Mr. Robb thanked the members for the honour conferred upon him by electing him president of the Association. Among other things he referred to the recently issued list of members and by-laws of the Association which have been made available in printed form.

In connection with the conference of delegates of the Professional Associations in Montreal Mr. Robb referred to the report of the Association's Council for discussion at this conference, quoting from this report the sentence "The respect of the public will come when engineers really learn to respect and be loyal to one another"; in other words to co-operate and to fill to the best of their ability the important place that engineers occupy in this progressive and scientific age. He then reviewed the many fields in which engineers are now engaged, speaking more particularly of the various branches of engineering with which members of the Association in Nova Scotia were connected. He urged engineers to take a more personal interest in the matter of the government, advancing the claim that the methods of conducting government business would be greatly improved by the election of engineers as members of parliament.

F. R. Faulkner, M.E.I.C., as representative of the Association at the Annual Meeting of the Association of Professional Engineers of Ontario presented a report of his trip to the meeting.

International Electrotechnical Commission Meetings in New York

The International Electrotechnical Commission desires to call attention to the following important matters which will come before the I.E.C. Advisory Committee at the meetings to be held in New York from April 13th, to 22nd, 1926.

1. Preparation of Part 2 of International Specification for Electrical Machines. (Large Machines.)
2. General discussion on Rating of Electrical Machinery, including presentation of papers by experts on the subject from various countries.
3. Preparation of a Specification for Traction Meters.
4. Revision of the I.E.C. Publication 29 — Hydraulics, including proposals for an International Specification for Hydraulic Turbines.
5. Preparation of an International Specification for Steam Turbines for driving Electrical Plant.
6. Completion of the list of International Graphical Symbols.
7. Preparation of an International basis for the testing of insulating oils.
8. Approval of the International Standards for Lamp Caps and Holders
9. Confirmation of the list of International Standard High Pressures.
10. Preparation of International Standards for High Pressure Tests.
11. Preparation of an International Code of Rules and Regulations for Overhead Lines.
12. Preparation of an International Code of Terminal Markings.
13. Preparation of an International Electrical Vocabulary.
14. Some additional minor matters.

It will be seen that the questions under discussion at this meeting are of vital industrial interest to this country.

Delegates will be present from all the principal countries, and information in regard to the meeting can be obtained from the secretary of the Canadian National Committee of the I.E.C., Electrical Standards Laboratory, Department of Trade and Commerce, Ottawa.

Galvanizing

By Heinz Bablik. Translated by C. T. C. Salter.
E. & F. N. Spon, London, 1926. Cloth, 6 x 9 in., 166 pp., illus., 12/6 net.

This book, as the name implies, is a treatise on galvanizing. It covers the field very thoroughly, describing in detail the different processes with their chemical reactions and giving diagramatic cross-sections of their structures.

The author first devotes some space to "Rust and its Prevention", and then goes on to describe the preparation of surfaces of articles to be galvanized, viz., the pickling bath and the flux; in this description, chemical formulae are given and consideration to acid strength, temperatures, and time of pickling.

The galvanizing process is described in a very comprehensive manner, descriptions and illustrations of equipment are amply employed. Hot galvanizing, electro-galvanizing, Sherardizing and the Schoop process are all fully explained and a chapter is devoted to testing and judging galvanized coatings.

Raw materials used in the galvanizing process, and waste products of the process are the subjects of another chapter.

While it is evident that European practice has furnished the date and methods to the author, the book is one which should be of very great interest to those who produce galvanized articles of any description. It is written in terms which require only ordinary technical knowledge and on this account is the more useful to the man who can use it to best advantage.

H. HORSFALL, M.E.I.C.

EMPLOYMENT BUREAU AND MEMBERS' EXCHANGE

Situations Wanted

ELECTRICAL ENGINEER

Technical graduate, University of Toronto, 25 years of age, good personality, two years Westinghouse electrical engineering training, one year installation and maintenance, familiar with inspection and maintenance of electrical equipment, desires situation with public utility or industrial organization. At present employed. Apply box No. 202-W.

ENGINEERING STUDENT

Engineering student desires position either with mining company or with survey party. Available May 25th. Apply box No. 203-W

CONSTRUCTION ENGINEER

University graduate with fifteen years experience in construction and office work, desires permanent position. Experience covers water power developments, pulp and paper mills, and other industrial plants. Available on short notice. Apply box No. 204-W.

SALES ENGINEER

Advertiser desires to communicate with firm requiring the services of a technical representative or sales manager. Thoroughly experienced in sales work including organization, sales promotion, advertising, correspondence, etc. B.Sc. (Civil). Age 30, married, speaking both languages. Apply Box 205-W.

CIVIL ENGINEER

Technical graduate, University of Manitoba, 25 years of age, good personality, one year surveying experience, two years municipal engineering training, including design and construction of concrete pavements and sewers, reinforced concrete floor design, etc., desires position with municipal engineering firm in Ontario or Quebec. At present employed. Apply Box No. 206-W.

Situations Vacant

PULP AND PAPER MILL DESIGNERS AND DRAUGHTSMEN

A large pulp and paper company, north east of Montreal, requires competent draughtsmen, thoroughly experienced in paper mill work. These positions are on permanent staff and afford excellent opportunity for advancement, with liberal salaries based on experience and qualifications. Give full particulars of experience, etc., with application. Apply to Box No. 151-V.

Members' Exchange

For sale one Buff and Buff 15½-inch engineer's dumpy level in good condition, reasonably priced. Apply box No. 12-E.

Abstracts of Papers read before the Branches

Mining Operations in Northwestern Quebec

Prof. S. N. Graham, Mining Department, Queen's University, Kingston, Ont.

Kingston Branch, January 21st, 1926.

The mining activity or boom in northwestern Quebec is a direct result or extension of the mining industry in Ontario. This Ontario industry is, comparatively speaking, quite new, and if the growth in Quebec is as rapid it will lead to a wonderful development in the northern part of that province. To estimate what may happen in Quebec, we may look to the Sudbury district and study the growth of the nickel industry since the discovery of the deposits in 1883. Twenty years later Cobalt was discovered and the mining industry there now sustains a large population. About six years later, Porcupine was discovered and gold mining in Ontario was put on a firm foundation. Its growth has been so rapid that the production in 1925 will be about thirty millions.

With such an industry in Ontario, it was but natural that prospectors should work eastward into Quebec. That this movement did not take place earlier was probably due to the fact that the prospectors did not look with favour on the Quebec mining laws. Revisions of the law removed some of the objections, and prospecting in Quebec became the fashion, particularly after Ed. Horne's discovery was optioned by the Thompson-Chadburn Syndicate. This discovery was in Rouyn township and though the prospecting has extended east and west, the district takes its name from this township. The area considered, in which many promising prospects have been discovered, extends from the Ontario boundary eastward to the Bell river, a distance of one hundred miles. The width of the zone now most actively prospected is twenty to twenty-five miles, while most of the properties now working are in or near Rouyn township. The possibilities of the larger area are very great.

The district as a whole is accessible in the summer by water routes on the many lakes and rivers. The trip is about one hundred miles from the present terminus of the Canadian Pacific Railway on the east side of lake Temiskaming, and can be made in a day by steam and power boats.

At present various railroad schemes are being considered with a view of reaching the district in the most economical way.

There is a large power development on the Quinze river, and it is reported that this winter construction work will be started on a power line to Rouyn. The district will therefore soon be supplied with two necessities, power and transportation. If it can supply ore, the principle requisite, and this now seems certain, then the stage is well set for successful mining operations.

The heart of the activity is around Osisko, or as it is also called Tremoy lake. It was near the shore of this lake that Ed. Horne made the first discovery of heavy sulphides in 1919. In the fall of 1922 the Thompson-Chadburn Syndicate took an option on this property, paying for it a 10 per cent interest and $320,000., cash payments extending until 1928. The Horne claims form the part of the Noranda Company holdings and with the continually rising prices quoted for Noranda stock, it is difficult to place a value on the holdings of the Lake Tremoy Syndicate, which grub-staked Horne. As the expenses of this syndicate are said to have been altogether about $5,000., its profits are enormous. In fact the story of this syndicate might be called one of the romances of mining and its success is sufficient to encourage other similar grub-staking syndicates.

The history of the Thompson-Chadburn Syndicate is also extremely interesting. The early work on the Horne did not show the gold values hoped for, and at that time while there were slight indications of copper, people were thinking mostly of gold. The Thompson-Chadburn Syndicate then optioned the Powell claims and opened up a vein which gave promise of being a gold producer. They also did a lot of work on a body of auriferous pyrite on the Chadburn claim. Getting only moderate success on these properties, they turned again to the Horne and were successful in discovering some enormous bodies of high grade copper ore.

This turned the thoughts of the prospectors from gold deposits, which up to the present have not proved up very well, to copper. The Amulet property was the next to be discovered and on this some rich copper and copper-zinc ore was discovered. This showing so enthused the prospectors that most of them started looking for copper. The next discovery was the Waite which is reported to have a large body of 17 per cent copper ore. Many other discoveries have been reported this winter, and undoubtedly the camp has a very bright future.

Much of the ore reported is very high grade and this is very apt to cause such a boom as will bring out the usual number of "wild-cats". Some of the ore is said to carry considerable zinc. This may cause metallurgical trouble, or expense, and good engineering is essential in order that even a good property may be successful.

Improvements in the General Plan of the City of Montreal

Geo. R. MacLeod, M.E.I.C., Department of Public Works, City Hall, Montreal, Que.

Montreal Branch, February 18th, 1926.

For the purposes of the construction and maintenance of streets, sidewalks, sewers, pavements and the numerous utilities owned by the city and by public utility companies, it is necessary to have definite and accurate plans and profiles of every street in a city.

These plans are also very necessary for the fixing of the boundary lines between streets and private properties, and the more valuable the property, the greater need there is for precision in establishing these boundaries.

Not only it is necessary to have the plan of each individual street made with clearness and accuracy, but it is necessary to make a general plan that will show without doubt the exact position of each street in relation to all other streets, in such a manner that the whole framework can be plotted together and fitted in the same manner as the frame of any other structure, each member (that is, each street) being given its true length and width so that it may fit in precisely where it belongs.

This feature of a city plan is especially necessary when planning any major projects, or making serious town planning studies.

The whole system of surveys and plans which have been made during the past six or seven years, by the technical service of the city, and especially during the past four years, have been conducted in a manner which keeps these main features in view, namely, accuracy and clearness in each individual plan, and accuracy in the inter-relations of all streets to each other.

With these objects in view, a main triangulation survey was first made, utilizing as far as possible a net-work of survey points established by the Geodetic Survey of Canada, the city engineer co-operating with the Dominion engineers, in such a manner that 45 main survey points were established in Montreal and its suburbs; these points being such a character that the Geodetic Survey could give the exact co-ordinates, otherwise the true position on the earth's surface. These points are so selected that any local surveys in the immediate vicinity of any of them can be connected to the main survey monument.

During the past season, 139 intermediate survey monuments were installed by the engineers of the technical service, and the exact co-ordinates of each of these are being established in reference to the original main triangulation of 45 points.

When completed there will be about 800 of the survey monuments, which consist of permanent concrete piers sunk in the ground below the frost line, each pier being protected by an iron and bronze cover, under which is the copper bolt with suitable point marked thereon for survey purposes.

Not only are these points being used as reference points for all street lines, but the exact elevation of each copper bolt head will be established by precise level survey, and these will hereafter constitute the permanent bench-marks for all our profiles and construction of all kinds carried on in our streets or squares, as well as for giving official levels to all proprietors erecting private buildings.

All of the individual surveys and levellings taken even three or four years before the new monuments were installed can, of course, be referenced to the fixed monuments at any time and this will be done as economical occasion arises.

Care is being taken that when a survey is being made in any portion of a street, it shall be made in such a way that it need never be duplicated. The plan and profile thus established must hereafter serve for the construction of street works, for assessment purposes, for change in homologated lines, for the location of all kinds of utilities such as poles, conduits, pipes, tracks, etc., etc.

Great efforts have been made during the past three or four years to establish homologated lines where none formerly existed, or where old ones had to be changed.

Instead of starting at one end of the city and making a clean sweep to the other extreme of the community, it has been found expedient to make the surveys for these plans where building development seems to be imminent, this applies more particularly to the newer wards, such as Notre-Dame de Grâces, St-Paul, Mercier, Rosemont, Villeray, Ahuntsic, Côte des Neiges, etc., the idea being to control the placing of street lines in advance of new subdivision plans if at all possible.

Other examples are the surveys for widening and straightening older streets, where the traffic density makes it urgent.

The total of new homologated line surveys executed during the past four years, totals about 80 miles of streets, and to tie in the surveys to reference points and lines it was necessary to cover about 30 square miles of city territory, — which, of course, will not have to be traversed again.

These activities will very soon cover the whole of the city, so that private subdivisions can be controlled.

During the past four years over 850 subdivisions were submitted for approval, and many of these were not approved until after they were altered to meet the city engineer's requirements, such as conforming to the existing or projected homologated lines and also the principles governing street grades, drainages, etc.

Special studies have been made of the main drainage districts where trunk sewers do not exist, or where they are incomplete. In the greater part of the city we have for this purpose made up-to-date contour plans, which we consider indispensable in the lay-out of streets, drainage system, water distribution, etc., etc.

Besides the contour plans, we are rapidly plotting the official profiles of every street, accompanied by an individual plan showing all existing works, and the private lots fronting thereon.

These are at a scale of 40 feet to the inch horizontal, and 4 feet to the inch vertical.

As part of the work asked for by the Provisional Town Planning Board of Montreal, a very interesting traffic survey has been made at 195 important intersections in the area bounded by the river St. Lawrence, Atwater Avenue, Pine Avenue and Delorimier Avenue.

About one-third of these traffic counts were made by employees under the direction of the chief engineer of the tramways commission.

These traffic counts were made in January 1925, and August 1925, to obtain both winter and summer conditions.

The data is carefully plotted to show the density of every variety of traffic at any given point, and also a plan ensemble is now being plotted from these individual charts which form a very valuable asset in town planning studies, as well as in traffic regulation activities, from time to time.

Operation of Lethbridge Northern Irrigation District

P. M. Sauder, M.E.I.C., Project Manager,
Lethbridge Northern Irrigation District, Lethbridge, Alta.
Lethbridge Branch, December 19th, 1925.

Mr. Sauder gave a most interesting description of the operation of this irrigation system, which embraces no less than 600 miles of canal of various sizes carrying water from one to seven feet deep, and supplies 100,000 acres of agricultural land just north of Lethbridge.

The system represents a construction cost of $5,500,000 and some idea of the work involved may be gleaned when it is stated that 3,500,000 board feet of lumber was used for bridges and small structures; 20,000 lineal feet of round piling. There were 25 tons of nails and another 25 tons of miscellaneous bolts, washers, etc., used, not to mention the cement and concrete entering into the structures.

There are 110 miles of telephone wires connecting all parts of the system with headquarters.

The system takes its water from the Old Man river at a point nine miles west of Macleod. A dam 524 feet long and 6½ feet high on the south side of the river diverts a stream 7 feet deep into a main canal 33 feet wide at the bottom and 63 feet wide on top.

Four miles from the intake the canal crosses the river through a sheet iron flume, 3,322 feet long and 14 feet wide. Another flume eleven miles from the intake crosses Willow creek and in the course of its progress to Keho reservoir, the main canal finds its way through two great siphon pipes 10½ feet in diameter, one of which is 3,000 feet long and the other 950 feet long.

The main canal empties into Keho lake south east of Barons which has a capacity of 40,000 acre feet of water and serves as a storage reservoir for the east end of the district.

Following the main canal from the intake through Keho to Turin, a canoe trip of 80 miles could be negociated.

"The real test of operating and irrigation district," said Mr. Sauder, "is in the staff's relation to the farmer. We must keep continually in mind that an irrigation system is primarily intended to deliver water for the growing of crops. Especially is this so, with a new system like the Lethbridge Northern where all farmers are just learning irrigation methods. We have chosen our staff carefully with this end in view. Our men must be not only engineers but they must be able to advise on agricultural matters when such advice is asked for. Friction will occur and complaints will be received, but these difficulties can be adjusted by a sympathetic understanding on the part of the staff."

"The growing of crops," he emphasized, "is the sole reason for an irrigation system. Everything must be subordinated to this end and the farmers' viewpoint must be fully respected."

Economy of management was a factor of great importance and Mr. Sauder explained that this year 43,000 acres had been served with water with a staff of five water masters, 18 ditch riders, and 26 teamsters and labourers, the latter being employed only during the irrigation season.

Each year a budget is prepared to cover water service, and capital charges. The water service for 1925 was budgeted at $125,000. and the capital charges at $400,000. or a total of $525,000. On a basis of 100,000 irrigable acres, the assessed rates for 1925 was struck at $5.25 per acre.

Mr. Sauder referred to the assistance being given district farmers by the government under the Colonization Act by which part of the farmers' assessment is carried by the government during a period of years.

"While the Lethbridge Northern," he said, "is unable to get along without government assistance, that does not imply that it is a liability. Lands intelligently farmed and irrigated show a good return over the irrigation rates, and it is only a matter of time before the whole district will be paying its way and shouldering the full rate without assistance.

The success of irrigation depends upon the farmer. He must have the proper farm ditches, both as to size and location. He must know how and when to apply the water and be able to get the necessary assistance to do the work. And, last but not least, he must get service from the operating department. I wish therefore to strongly emphasize the importance of giving real service.

To be a real benefit, however, irrigation must be sold to the farmer. He must thoroughly understand the use of irrigation and must see that it produces a good profit. Irrigation makes much more labour and expense and calls for a much higher degree of intelligence. The provincial and federal governments have given some assistance in locating the head ditches, but the farmers have then been left to work out the rest of their systems themselves. They are seriously handicapped for want of experience and reliable information and the job is slow and discouraging. It is true, that the farmer who masters the job himself is much more likely to be successful than the one who is hand fed, but the test is very severe and it is not surprising that many accomplish very little and become discouraged. Provision should be made for technical assistance and advice in preparing the land, locating the ditches, choosing the crops to grow, deciding best methods of irrigating, and determining the proper time to irrigate. Demonstration plots have been grown in the district but the assistance of demonstration agents who can show the farmers how to produce the good results on his own land are required. The governments should therefore be strongly urged to assist the farmer in getting started in the use of irrigation.

Jenkins Engineering Scholarships Awarded

Scholarships in engineering to be competed for annually were established last year at both University of Toronto and McGill University by Messrs. Jenkins Bros., Limited, of Montreal. The winner of this scholarship at the University of Toronto is Mr. Carol A. Pollock, Kitchener, Ont. The McGill award goes to Guy Rinfret, S.E.I.C., Shawinigan Falls, Que.

Design of Concrete Mixtures

The Structural Materials Research Laboratory of the Lewis Institute, Chicago, have issued a revised edition of Bulletin 1, Design of Concrete Mixtures by Duff A. Abrams, M.E.I.C.

BRANCH NEWS

Calgary Branch

G. P. F. Boese, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch-News Editor.

ANNUAL DINNER

Once more the annual dinner of the branch has come and gone. This year's performance proved to be no exception to the rule in functioning as a successful gathering of the clans. In fact it might almost be said that it eclipsed previous endeavours of its kind in so successfully attaining the main object of such gatherings, namely a happy reunion and fraternizing that are the essence of social affairs of this nature.

After Chairman, A. L. Ford, M.E.I.C., had taken his seat everyone commenced to wear the smile that refuses to budge, together with a dinky little paper cap. Things passed rapidly from the sublime to almost the ridiculous at times. A clever menu outlined in technical style the calorie contents of the foods served, together with the various liquids consumed. In reference to the points plotted on the curve apparently beer contains a maximum calorific value as its tendency was to wander off the chart altogether. The turkey course took a good second place. Such ordinary things as soup and rolls showed up badly, while the values increased somewhat erratically from sherry to nuts.

The calories having been demolished, or rather absorbed into the humane frame, S. G. Porter, M.E.I.C., rose to propose the toast to *The Institute*, outlining its aims and objects in a few clear cut remarks lasting one second short of his allotted time. J. H. Ross, A.M.E.I.C., seconded with a few well selected words, but exceeded his time by one second!

The entertainment side of the programme was excellently arranged, traverse stations indicating the items with a T. P. for intermission. Under the chairmanship of R. S. Stockton, M.E.I.C., and leadership of G. H. Patrick, A.M.E.I.C., things got away to a splendid start and continued to the end in excellent style. Ably assisted by C. A. Lydiatt, B. Plesner, W. G. Guthrie, and C. Elliott, A.M.E.I.C., at the piano, G. H. Patrick, A.M.E.I.C., arranged a programme that was just right, not too long nor too short, and of a quality that one could sit back and take it all in, — together with a little refreshment occasionally, — with great pleasure. W. G. Guthrie's scotch turns produced a sensation of extreme hilarity almost to the choking point, while B. Plesner played his violin with a most sympathetic touch. Altogether the programme was a rare good one, not soon to be forgotten, and was arranged by branch members living at Strathmore, to whom a great credit is due for the results.

Some rare stunts were "pulled off" by our stunt committee of one, namely, W. B. Trotter, A.M.E.I.C., who, dressed in dilapidated silk hat, evening suit, black wig, and pre-war moustaches, made some valuable presentations, typical of which was one to R. S. Stockton, M.E.I.C., of the Order of the Garter (literally). The various presentations, ranging from first prize champion bull to third prize baby beef in the form of rosettes, were made with much gusto with the aid of an umbrella mixed with a grotesque choice of vociferous expletives, that only one of such extremely high calorific value as Mr. Trotter possesses could conjure up.

T. Lees, A.M.E.I.C., ably proposed a hearty vote of thanks to the Strathmore contingent and other entertainers for giving the branch such a very enjoyable evening's entertainment.

Edmonton Branch

W. R. Mount, A.M.E.I.C., Secretary-Treasurer.

At a general meeting held in the MacDonald hotel on January 20th, W. Dixon Craig addressed the branch, his subject being "Law and the Engineer".

The fact that Mr. Craig was some years ago a member of the engineering profession, may be one reason for his undoubted ability to interest and inform a gathering of engineers to-day. All present were of the opinion that Mr. Craig's paper should be printed in full in *The Journal* for the benefit of others besides local members. It is hoped that at a later date this will be found possible.

Halifax Branch

K. L. Dawson, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Halifax Branch of *The Engineering Institute of Canada* was held in the St. Julien room of the Halifax hotel on Thursday evening, December 17th, 1925. About sixty members and guests sat down to dinner, during which there was music from the orchestra under the leadership of J. G. Mills and several numbers from *The Institute* song sheet were sung by the diners. Following the toast to the King, the chairman read a letter from Hon. E. N. Rhodes, premier of Nova Scotia, dated at Montreal, regretting his inability to attend because of illness and the instructions from his doctor to refrain from all public functions for a considerable time. It was moved by C. H. Wright, M.E.I.C., seconded by H. B. Pickings, A.M.E.I.C., and carried, that a night letter be sent from the meeting containing our regrets at his inability to be present and wishing him a prompt and complete recovery. The chairman then read a letter from Sir. Andrew Rae Duncan, the chairman of the Royal Commission investigating the coal situation in Nova Scotia, expressing his regrets that circumstances would not permit him to attend.

The chairman then introduced the following guests:—Hon. J. A. Walker, minister of natural resources in the Nova Scotia cabinet. Dr. F. H. Sexton, president of the Nova Scotia Technical College, Mr. A. S. Gunn, A.M.E.I.C vice-chairman of the Moncton Branch, Col. E. C. Phinney, B.A., L.L.B.

The Hon. Mr. Walker spoke briefly expressing his appreciation of the honour of being invited. He mentioned that it was his privilege to be associated frequently with engineers. He thought his first knowledge of engineers came when as a school boy he read Kipling's "Letters of a Family" in which Kipling wrote that among the marvels he found in Canada were the engineers whom he saw in the Rocky Mountains teaching young avallanches to jump over railway tracks. In the engineering profession he had noted a great diversity of activities, the engineers being found even in political circles when it was necessary to find someone to "engineer a campaign". He felt that he could depend on the co-operation of engineers wherever the welfare of the province is concerned.

Dr. F. H. Sexton, comparing *law* and *engineering* as professions, said that law was perhaps more honoufed but not more honourable. The engineering profession is just coming to maturity and the engineer is asking to be accorded things he most rightly deserved. It was the aim of the Nova Scotia Technical College to give the students a broader training which would acquaint them with the wealth and culture of literature so that they will feel more keenly their duty as public citizens. He was glad to see the large representation of engineers which was a proof of the hope that the professional esprit de corps is materializing,

R. S. Gunn brought fraternal greetings from the Moncton Branch.

At this point in the meeting the secretary lead in several songs, after which the speaker of the evening, Col. Phinney delivered his address on "Canada's National Problems".

CANADA'S NATIONAL PROBLEMS.

After a few intimate remarks in which he expressed his appreciation of being asked to address the Halifax Branch of *The Engineering Institute of Canada*, Col. Phinney explained how the use of the Panama canal is changing the trend of the grain business of western Canada.

Leading to the discussion of economic conditions Col. Phinney reviewed the events leading to Confederation, referring particularly to the Conference in Charlottetown in 1864, when the union of the Maritime provinces was being discussed, and the subsequent appeal for the larger union by representatives from Upper Canada and the promise of a railway connecting the Maritime provinces with Quebec and Ontario. He contended that the real essence of the British North America Act lies in the promises made to Nova Scotia at that time.

He referred to the period between Confederation and the Great War as one of prosperity, with rapid development and increasing population, and the period of readjustment following the war, which period he suggested is probably now at an end.

The Conference of the Canadian Boards of Trade held at Winnipeg a few weeks ago, he thought, was an outward sign of a new era, and he remarked on the fact that at this conference there was evidence that every province of the Dominion seemed now to be thinking *Nationally*, considering their problems to be national ones, and national problems to be theirs, relegating to second place their province and domestic problems.

Col. Phinney defined the national problems under three heads:— First, national debt; second, railway; and third, fiscal. Under each of these headings he reviewed the existing conditions, and claimed that the one main solution for all these problems seemed to be the adoption of a proper up-to-date immigration and settlement scheme and that this was advocated by both President Beatty of the Canadian Pacific Railway, and President Thornton of the Canadian National Railways. The type of people to come in under this immigration and settlement scheme said Col. Phinney were:—First English or British decent; second those who have left and won't come back unless there is a better scheme to take care of them than when they left; third, people from eentres of Europe other then "red", that is people of the Nordic races. Under no circumstances should the bars be thrown down for indiscriminate immigration. The steady plodding immigrant who will be satisfied with a fair return is the only type which Nova Scotia can absorb, for her type of soil must be cultivated by this type of person. The other provinces are willing that the Canadian immigration system will recognize our needs and provide for them. It is estimated that such a scheme will make it necessary for the government to spend 250 million dollars over a period of five years, and that it will result in the settling of about 800 thousand people in Canada who will in time, repay the money which has been advanced to them, by paying off a portion of it each year. It is estimated that the government would not loose more than 20 per cent of the money expended in this way.

Referring to the industrial situation Col. Phinney thought that a solution seemed to lie in the education of people towards traffic and trade in Canada. He deplored the quantity of foreign products being purchased where equally good were manufactured in Canada. He thought that there was a field here for government support, because it was a matter of education.

With particular reference to Halifax he urged that co-operation in any good effort on the part of the citizens was essential and showed how the city of St. John had raised $40,000 by private subscription, by which trade commissioners had been sent through Western Canada to urge the routing of freight through St. John ports during the winter months with the result that to the present St. John has already handled much more grain than she did all last winter, and that there is enough freight in sight to keep the port of St. John busy all winter. Similar co-operation will accomplish equivalent results in Halifax

At the close of his address Colonel Phinney was tendered a vote of thanks by chairman McKnight which was moved by C. E. W. Dodwell, Hon. M.E.I.C. and seconded by Vice-President F. A. Bowman, M.E.I.C.

Election of Officers

The scrutineers report presented by F. R. Faulkner, M.E.I.C., chairman, showed that the following branch officers were elected:—Chairman, H. W. L. Doane, M.E.I.C. Members of the Executive Committee residing in Halifax, Prof. D. W. Munn, M.E.I.C., W. A. Winfield, M.E.I.C., H. F. Bennett, A.M.E.I.C., for 1926-27; J. S. Misener, M.E.I.C., for 1926. To represent the members residing more than over twenty-five miles from Halifax, H. C. Burehell, M.E.I.C., Windsor, N.S., C. W. Archibald, A.M.E.I.C. J. S. Misener, M.E.I.C., was elected to fill out the unexpired term of E. M. Archibald, A.M.E.I.C., who has removed to Saint John, N.B.

Chairman W. F. McKnight, A.M.E.I.C., spoke briefly in comment and acknowledgement of the support which had been given him by the branch. He took advantage of the happy precedent afforded by the ehairman of the previous year and did not attempt to deliver a separate address. He suggested that at future meetings we take more advantage of our own local talent, and as an instance referred to the meeting on Water Power Development at which a series of short papers were read. He suggested that our being able to accomplish a Maritime Professional Meeting during the year at an expense of $2.00 per head was the achievement of the year. He appointed F. R. Faulkner, M.E.I.C., and D. W. Munn, A.M.E.I.C., as auditors for the 1925 accounts. He then gave up the chair to the chairman-elect, H. W. L. Doane, M.E.I.C.

The officers of the Halifax Branch for the year 1926 are:—

Chairman	H. W. L. Doane, M.E.I.C.
Vice-Chairman	(To be selected by the executive committee from its own members.)
Seeretary-Treasurer	K. L. Dawson, A.M.E.I.C.
Executive Committee	(In addition to the above):—
(*Retiring 1926*)	W. F. McKnight, A.M.E.I.C., (*ex-officio*).
	H. S. Johnston, M.E.I.C.
	W. P. Copp, A.M.E.I.C.
	J. S. Misener, M.E.I.C.
	R. R. Murray, A.M.E.I.C.
	J. G. W. Campbell, M.E.I.C.
(*Retiring 1927*)	H. F. Bennett, A.M.E.I.C.
	D. W. Munn, M. E. I. C.
	W. A. Winfield, M. E. I. C.
	C. W. Archibald, A.M.E.I.C.
	H. C. Burchell, M.E.I.C.

Kingston Branch

Gordon J. Smith, A.M.E.I.C., Secretary-Treasurer.

Annual Dinner

The annual dinner of the Kingston Branch was held in the Queen's Cafe, Kingston, on the evening of November 23rd.

The meeting was a memorable one in the annals of the branch, as it was the oceasion of the presentation of the Charter to the branch. This pleasant duty was to have been performed by Dr. A. Surveyer, M.E.I.C., the president of *The Institute*, but at the last moment Dr. Surveyer found it impossible to be present and General Sir Alexander Bertram, M.E.I.C., eame in his stead. R. J. Durley, M.E.I.C., the secretary of *The Institute* was also a very welcome guest.

The dinner was in itself very successful, and during it several enjoyable numbers were rendered by Mr. George Kateledsky, a Russian pianist, who is attending Queen's University. There was no formal toast list and after drinking to the King, General Bertram presented the Charter to the branch. The General spoke of the pleasure it gave him to be connected with *The Institute* of which he is treasurer at headquarters, and of the complete harmony that existed in the adminstration of this large organization. Finally he stated that he considered it an honour indeed to present a Charter on which were inscribed the names of the Charter members of the Kingston Branch, who had occupied such prominent and enviable positions in the engineering activities of the Dominion.

The date of the formation of the original Kingston organization was February 17th, 1911, and the Charter members were:

L. W. Gill, M.E.I.C.	W. R. Butler, M.E.I.C.
G. H. Herriott, M.E.I.C.	A. K. Kirkpatrick, M.E.I.C.
W. L. Malcolm, M.E.I.C.	H. B. R. Craig, M.E.I.C.
A. Macphail, M.E.I.C.	G. G. Hare, M.E.I.C.
J. C. Gwillim, M.E.I.C.	E. R. Beckwith, A.M.E.I.C.
J. A. Cochrane	J. G. Lindsay, A.M.E.I.C.
F. F. Miller, M.E.I.C.	

The Charter was received on behalf of the branch by the chairman, R. J. McClelland, A.M.E.I.C., with a few well chosen words of thanks as well as of welcome to the visiting guests.

R. J. Durley, M.E.I.C., spoke next and he covered in a very informal and enjoyable manner, the many activities at headquarters, giving an account of many interesting episodes of his visits to the various branches throughout the Dominion. He asked for any suggestions from the members present, as to changes or improvements that could be made in the general administration.

The meeting was then thrown open for discussion in which many useful points were brought up.

January Meeting

A regular meeting of the Kingston Branch of *The Institute* was held in Carruthers Hall, Queen's University on the evening of January 21st, to hear an address by Prof. S. N. Graham of Queen's Mining Department on "Mining Operations in Northern Quebec" and also a description by the same speaker on "The Objects and Aims of the Professional Engineers' Association of Ontario."

Professor Graham has been in very close touch with the Quebec area since its discovery, being amongst the first professional men to visit the district and his description an abstract of which appears on another page of this issues of this new field was most interesting. In his talk on the Professional Association Prof. Graham said in part:

The Association of Professional Engineers of Ontario

For many years engineers have felt that their status and legal standing in modern society are not what they should be or what the value of their work in the advance of civilization demands. This has led to several efforts at incorporation along similar lines to the medical profession. The old Canadian Society of Civil Engineers which has developed into *The Engineering Institute of Canada*, fathered a bill presented to the Ontario Legislature in 1899. This was not given unanimous support by the engineers of the province as many feared that it gave too much importance to the civil engineering branch. As a result much opposition developed and the bill was not passed. Some of this opposition came from Kingston but the fact that such no longer exists and that exactly the reverse is the present stand is well shown by the resolution passed by the Science Faculty of Queen's University strongly endorsing the Bill when it was presented in 1922.

The present Bill is the result of many long conferences of engineers belonging to all branches of the profession. It is very broad and moderate. It protests the graduate engineer and at the same time gives opportunity for the so-called practical man to prove that he is properly qualified. It will not and it is not intended to keep out the consulting expert from other provinces or countries. Neither does it form an impregnable wall to exclude qualified engineers from other districts. Its basis is qualification just as in the case of the medical and legal professions.

The regulation of engineers practising in Ontario when based on qualifications protects the public from risking their money, health and lives in processes and structures controlled and erected by men who are not properly fitted to do so. It protects the engineer who has spent time and money on an education to fit him to handle these matters. It also protects the pratical man who, by his own efforts in study and experience has become qualified and needs such recognition and endorsement to place him on a more even footing with the college graduate. Against the advantages of such protection is placed the fear of intolerant and autocratic control by a ring or clique. A study of the bill readily shows that there are many safeguards against this.

Since legislation regulating the praetice of engineering has been passed in five provinces of Canada, it would be of great advantage to the profession to have similar legislation in Ontario. In addition to the advantage of free interchange from one province to another a few others might be mentioned,—more general intercourse between all engineers and not only those practising in one branch; legislation would tend to raise the status of the engineer in the community; more general recognition of the importance of the work done by the engineer; freedom from unfair competition with unqualified men; more uniform and satisfactory recompense for the important work of the engineer.

If society is to sanction such a type of bill, which may be called "class legislation", there must be good and sufficient reasons. The precedents established by the medical and legal professions may not be considered sufficient reasons, though it is difficult to see why reasons which apply to other professions should not apply to engineering. Society owes most of the comforts and conveniences of our present civilization to the scientific engineer and, if the march of civilization is to continue, society must take care that it has the engineer to guide it. Since governments support or help support colleges and schools for engineering training, it may reasonably be inferred that they recognize a necessity for such and therefore should have an interest in properly maintaining the status of the engineers they have helped to train. The public also needs some guidance to enable it to judge the qualifications of the men it employs. This need will become constantly greater as our civilization becomes more complex year by year.

Such objections as have been raised against this as class legislation or rather against legislation for this particular class have been extremely well answered in the small booklet prepared for the Association by Frank R. Ewart, M.E.I.C. It has also been said that engineers do not demand the legislation. There is no better answer to this than the large and growing membership of the Association of Professional Engineers of Ontario. The fact that such a large percentage of engineers voluntarily join this society, whose object is obtaining such legislation, is an irrefutable answer.

Lethbridge Branch

N. H. Bradley, A.M.E.I.C., Secretary-Treasurer.

The Lethbridge Branch has always been noted for its singing. There may be other Branches that can sing too. We don't know, but we have a sneaking feeling that for volume and ability to take the high notes, Lethbridge leads. Recently we have added "Oh Katarina" to our repertoire and we recommend it highly to all other branches.

Whether it is because of our singing or the addresses along professional lines, we are receiving splendid support from all branch members. It is seldom that we have less than forty men at our dinners twice a month. Most of these are, of course, Branch Affiliates, but it is the effort of this branch to make our meetings so interesting that they will attract men of other business, and thus indirectly inspire the public with the work of the engineer.

Hydro-Electric Development

On Saturday, November 7th, 1925, we had a splendid discussion on "Hydro-Electric Development" led by R. A. Brown, M.E.I.C., superintendent of the city of Calgary Street Railway and Electric Light Department.

Beet Sugar Industry

On Saturday the 21st, the members and their ladies motored to Raymond and inspected the plant of the Beet Sugar Company. In the evening we were addressed by Superintendent C. R. Wing of the plant and learned the technical process of turning a beet into sugar. Mr. Taylor, field superintendent, followed with details of the agricultural side of beet production. His job this year covered seven thousand acres of growing beets and when it is remembered that beets are still in the pioneer stage here, it may be imagined that his task of instructing farmers is no small one.

Construction of this factory commenced in the early spring and it is something of a tribute to the engineers that it was in operation on October 19th.

One and a half million dollars was the cost of erection and the plant has a capacity of a thousand tons of beets daily. The farmer is guaranteed a base price of $6.00 a ton and with a run this year of 50,000 tons, it represents the circulation of $300,000 among our farmers.

Banff National Parks

On Saturday, December 5th, C. G. Childe, A.M.E.I.C., resident engineer, Banff National Park, showed moving pictures and slides of Banff National Park. His description gave the largely attended meeting an opportunity to get better acquainted with one of Canada's National Play Grounds. Community singing and solos by Messrs. Stott and Rannard after the usual dinner helped to create that feeling of fellowship so essential to meetings.

Operation of Lethbridge Northern Irrigation District

Lethbridge Branch at its dinner meeting on December 19th had for its guests Senator W. A. Buchanan; E. H. Hann, chairman of the Trustee Board of the Lethbridge Northern Irrigation District; and A. B. Hogg, solicitor, the occasion being an address by P. M. Sauder, M.E.I.C., on the Operation of the Lethbridge Northern Irrigation District. It proved a most interesting and profitable evening and the invited guests entered largely into the general discussion which followed the address.

The musical end of the programme was well looked after as usual and violin solo by Mr. Geo. Brown, and vocal solo by Mr. Smith added much to the general enjoyment.

London Branch

E. A. Gray, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the London Branch was held at the Blue Dragon Tea Room, Wednesday, January 20th at 6.15 p.m.

Following the dinner and the presentation of the secretary's and auditor's reports, the election of officers for the ensuing year was proceeded with, the following being elected:—

Chairman	W. P. Near, M.E.I.C.
Vice-Chairman	J. R. Rostron, A.M.E.I.C.
Secretary-Treasurer	E. A. Gray, A.M.E.I.C.
Executive	E. V. Buchanan, M.E.I.C.
	F. A. Bell, A.M.E.I.C.
	W. M. Veitch, A.M.E.I.C.
	H. A. Brazier, M.E.I.C.
	R. Angus, M.E.I.C.

The retiring chairman, W. C. Miller, A.M.E.I.C., and the chairman-elect, W. P. Near, M.E.I.C., addressed the meeting.

The address of the evening was delivered by Dr. H. R. Kingston of the University of Western Ontario, his subject "Warders of the Skies" proving most interesting to those present.

Several solos were rendered during the evening by Messrs. Wood and Ballantyne and contributed very much to the success of the evening.

The following members were present:—W. P. Near, M.E.I.C., F. M. Brickenden, A.M.E.I.C., Col. I. Leonard, M.E.I.C., F. A. Bell, A.M.E.I.C., J. R. Rostron, A.M.E.I.C., R. Angus, M.E.I.C., W. C. Miller, A.M.E.I.C., C. Talbot, A.M.E.I.C., H. A. Brazier, M.E.I.C., W. M. Veitch, A.M.E.I.C., E. A. Gray, A.M.E.I.C., W. M. Smith, S.E.I.C., G. H. Chalmers, A.M.E.I.C., H. A. McKay, Jr.E.I.C., R. H. B. Cook, S.E.I.C., F. C. Ball, S.E.I.C., G. E. Martin, A.M.E.I.C., and H. B. R. Craig, M.E.I.C.

Moncton Branch

M. J. Murphy, A.M.E.I.C., Secretary-Treasurer.
V. C. Blackett, A.M.E.I.C., Branch News Editor.

On January 25th, a number of members of the branch journeyed to Sackville, where a special meeting was held for the benefit of the engineering students of Mount Allison University.

Railroad Location

An exceedingly practical paper on "Railroad Location" was read by A. S. Gunn, A.M.E.I.C., assistant engineer of the Canadian National Railways. Mr. Gunn's remarks, replete with dry wit and humourous personal anecdotes made an ordinarily uninteresting subject not only instructive but extremely entertaining as well.

At the outset, the speaker declared that he did not intend to deal with the theory of railroad location but rather to give a friendly and practical talk that might be of service to any who, through ill-luck or ill-advice might find themselves on a railway survey party.

The successive steps in the building of a railway are: reconnaissance, preliminary survey, location survey and construction.

A reconnaissance party is small, sometimes consisting of but one man who, in a general way, with the aid of an aneroid barometer and hand compass, determines the grade and alignment of several possible routes. These routes having been reduced to two or three, preliminary surveys are run and then the final choice made. The average survey party consists of about fifteen men. The engineer-in-charge who directs operations should be able to do the work of any of the men under him and do it just as well. Two simple rules he would do well to adopt: (1) "Never ask a man to do anything you are unwilling to do yourself". (2) "Take darn good care that what you do ask is done". The transitman should be able in an emergency to take the place of the engineer. He should be able to set up quickly and should form the habit of reading the instrument correctly at the first attempt, without having to take a second, third or fourth reading to check the accuracy of his work. Being in direct touch with the axmen, he should carry a first-aid kit on his person. The qualifications of the leveller, as regards the handling of his instrument, are practically the same as required of the transitmen. The topographer is generally overworked and not sufficiently appreciated. On the accuracy of his work the success of the projected location depends. He should have a good eye for country, particularly contours, that is, he should be able to visualize the shore lines which would be formed by successive rises of water, such as must have occurred in that great freshet that brought disaster to all but father Noah.

The speaker discussed at some length the degrees of accuracy required in various kinds of survey work. He also dealt with the methods employed in running curves. In conclusion, Mr. Gunn touched briefly upon tachometer and aerial surveys.

A vote of thanks, moved by Prof. F. L. West, A.M.E.I.C., and seconded by Carl Anderson, S.E.I.C., was tendered Mr. Gunn for his excellent address.

Tunnelling Experience During the War

Captain R. B. Murray, of Amherst, gave a very interesting illustrated address before the branch, at the regular monthly supper meeting at the Barker House on February 15th, his subject being "Tunnelling Experience during the War".

C. S. G. Rogers, A.M.E.I.C., chairman of the branch, presided. During the evening a vocal solo was rendered by Mr. Geo. C. Davidson, while Dr. F. E. Burden favoured the gathering with a clarinet selection, both numbers being enthusiastically received.

Capt. Murray was an officer in No. 1 Tunnelling Company, attached to General Plummer's Army, and took part in tunnelling work at Hooge, Spoil Bank and Messines Ridge, the latter being, undoubtedly, the scene of the most important tunnelling in the history of warfare. In 1917 he was badly wounded in the Ypres-Menin Road district.

Until the late war, Capt. Murray said, very little attention had been given to military mining, except by the Germans. It had been rendered unnecessary for the reason that no fortification could withstand the shock of modern artillery fire. Some mining was done during the Russo-Japanese war, but none before that since Balaclava.

The advent of trench warfare, however, resulted in mining becoming a highly specialized branch of the service. From the beginning of the war, Germany had a well-trained, thoroughly-equipped mining organization. The Allies, on the other hand, were entirely unprepared, and had to hastily build up a force recruited as far as possible from men skilled in industrial mining.

The duties of a mining or tunnelling corps are two-fold—defensive and offensive. The purpose of defensive mining is to discover and defeat the plans of enemy miners. Two tunnels or galleries are driven out from the front line trench, a cross gallery connecting these two is driven parallel to the front line; from this gallery a number of blind tunnels are pushed forward toward the enemy line, and in these are posted listeners who endeavour to detect sounds of enemy tunnelling. By the aid of the geophone, mining operations can be heard through the earth for a distance of one hundred feet. Should the enemy be discovered at work, a hole is bored towards his galleries with an earth auger, and a charge pushed through and exploded.

In offensive mining, tunnels are driven forward under strong points in the enemy lines, and mines laid and exploded. The reserve trenches are chosen as starting points for these tunnels since they offer better protection from enemy raids. Furthermore, disposal of spoil without knowledge of the operations coming to the enemy, is made easier.

The standard tunnel or gallery is very small, being only two feet wide and four feet high. Comparatively little can be done in the way of ventilation, which, naturally is very poor. Towards the end of the war experiments were made with tunnelling machines, but hostilities ceased before these could be perfected.

At the conclusion of the address, a vote of thanks proposed by A. S. Gunn, A.M.E.I.C., was tendered Capt. Murray by the chairman.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-treasurer.
Stanley A. Neilson, A.M.E.I.C., Branch News Editor.

Features of the Design and Construction of the Isle Maligne Station

On January 7th, the Montreal Branch were fortunate in having as their speaker W. S. Lee, M.E.I.C., who told of a number of the many interesting features in the design and construction of this huge hydro-electric development.

Some of the difficulties which they experienced were extreme cold, a huge volume of water that did not take kindly to being diverted out of its ordinary channel and just to add to their troubles a bad fire in their material handling plant.

Mr. Lee pointed out that it had been a saving in the end to spend large sums of money on construction equipment which had expedited the work. He also made the statement that there had been more time spent on the engineering of the construction plant than on the station itself.

The approximate cost of the development, $30,000,000, is a good example of the size of the figures which Mr. Lee used all evening.

After giving his paper Mr. Lee extended a very hearty invitation to the members of the Montreal Branch to visit him and his associates at the plant next summer. This invitation was warmly applauded and, by the murmuring which followed, it would appear that the members were already arranging parties to go. They probably had in mind the very pleasant visit to the plants at Shawinigan Falls last summer.

Dr. R. A. Ross, M.E.I.C., presided in the absence of Julian C. Smith, M.E.I.C., who was confined to his home, and a vote of thanks was extended to the speaker at the close of his address by Dr. Arthur Surveyer M.E.I.C., on behalf of the branch.

Effect of Personnel on Industry

R. A. C. Henry, M.E.I.C., director of the Bureau of Economics of the Canadian National Railways read a paper on the above subject before the Montreal Branch on January 14th.

The question was put before the meeting, a number of phases of it were discussed but no attempt was made to put forth a solution.

Mr. Henry told in some detail of the workings of the various Boards in the C.N.R. which handle the greivances and keep harmonious relations between the officials and the employees.

In the discussion which followed the speakers each brought out some point which had particular appeal to them.

Dr. R. A. Ross, M.E.I.C., moved the vote of thanks.

Pulp and Paper

The development in the paper making industry and the processes involved from the time the tree is cut until it is sold in the form of newspaper was the theme of the lecture given to the Montreal Branch on January 21st., by H. S. Taylor, M.E.I.C.

Mr. Taylor pointed out that the two essentials to a modern paper mill were wood and water, the wood to supply the material and the water to supply the power and also to be used in the process of reducing the log of wood to the roll of paper. The speaker confined himself to the manufacture of newsprint, it being typical of all paper making. He gave the details of the preparation of the groundwood and the sulphite pulps and of their proper mixing before being introduced into the paper making machine itself.

Mr. Taylor gave some interesting figures of the quantities of paper that are being manufactured each year in Canada. He also gave some data as to the power required, and the materials necessary to keep a modern 400 ton mill running.

With a number of slides the main point that had been brought out in the paper were illustrated, in particular the sequence of operations through the various departments from the time the log comes out of the water until it is shipped as paper on cars or on boats.

J. W. McCammon, A.M.E.I.C., conducted the discussion from the chair.

Protective Features and Emergency Equipment of the Montreal Aqueduct

In opening his lecture on the "Protective Features and Emergency Equipment of the Montreal Aqueduct" before the branch, on January 28th, C. J. Desbaillets M.E.I.C., emphasized the 100 per cent reserve capacity available.

Speaking on what a water works meant to the community, he said that in a city of over one million population, the water works system should be looked upon as the only efficient means of protection against conflagration. The life and health of the citizens, also depended largely on the permanence and quality of the water supply. Therefore it was absolutely essential that the water supply should be free from all interruptions and pollutions.

Mr. Desbaillets then gave a brief account of the workings of the more important sections of emergency apparatus in the Montreal aqueduct.

In the new pumping station, practically the whole equipment was installed on the double system principles. After dealing with many points such as distribution systems, chlorination equipment, the lecturer dealt at some length on the new pipe tunnel under the Lachine canal. Mr. Desbaillets' lecture was illustrated with lantern slides and plans. The chairman was Geo. R. MacLeod, M.E.I.C.

In the discussion which followed the lecture, the question was asked as to what measures had been taken to prevent the pollution of the water, to which Mr. Desbaillets replied that fences had been erected and a motor cycle police squad placed at the boards disposal, whose duty it is to patrol the length of the canal continuously. There will be no more picnics permitted along the banks of the canal.

A number of other points were raised and questions answered, after which J. A. Burnett, M.E.I.C., proposed a vote of thanks to the speaker which was tendered to him by the chairman.

Presentation of Branch Charter

Presentation to the Montreal Branch of its charter from the parent organization was made on February 4th, by Major Geo. A. Walkem, M.L.A., M.E.I.C., of Vancouver, and president-elect of *The Engineering Institute of Canada.* C. J. Desbaillets, M.E.I.C., the chairman of the branch accepted the charter on behalf of his fellow members.

Before proceding to the formal presentation, Major Walkem delivered a short address directed particularly to the students present, upon the lives and contributions of the great men of science.

Electrolysis

Following the presentation of the branch charter on February 4th, P. LeBel, S.E.I.C., delivered his paper on the subject of "Electrolysis". He dealt more particularly with the application of the electrolitic method to the refining of copper. His paper was illustrated with numerous slides and was followed by a very excellent moving picture entitled, "Copper from the mine to the consumer," which showed in some detail the processes which Mr. LeBel had described in his paper.

Pulverized Coal

H. G. Barnhurst, advisory engineer to the Fuller-Lehigh Company, delivered an address on the above subject to the Montreal Branch on February 11th.

Starting with the assumption that coal was the basic fuel for power and other purposes, Mr. Barnhurst gave technical reasons why coal should be pulverized. He then told of the three operations needed, crushing, drying, and pulverizing. The ease with which coal in the pulverized form could be handled was then pointed out, the speaker telling of instances where it was pumped like water for distances of over a mile.

Some quite sharp discussion followed, local protaganists of the stoker method of firing making their side of the story known in no uncertain terms. Others who were not quite so partizan agreed that pulverized fuel was making headway and always had to be taken into consideration when figuring any new installation.

Mr. Barnhurst replied that he had not tried to create the impression that pulverized coal was putting all the others out of the game but that there were many cases where its use had produced considerable savings, there were also cases where it could not compete economically.

The vote of thanks was proposed by John T. Farmer, M.E.I.C., and J. A. McCrory, A.M.E.I.C., occupied the chair.

Dr. Barnes Lectures on Ice Engineering

An invitation has been extended to the members of the Montreal Branch to attend a series of lectures to be given on the subject of "Ice Engineering," by Dr. Howard T. Barnes, M.E.I.C., on March 4th, 11th, 18th, and 25th in the Macdonald Physics Building, McGill University. This series should prove interesting, especially to those who run into ice difficulties in hydro-electric work.

Improvements in the General Plan of the City of Montreal

On February 18th, George R. MacLeod, M.E.I.C., gave a talk to the Montreal Branch on the "Improvements in the General Plan of the City of Montreal". An abstract of this paper is published on page 176.

The discussion which followed was entered into by:—Mayor McLagan of Westmount who said a few words about the Metropolitan Commission, by Mr. Percy Nobbs who explained the position of the City Improvement League and by James Ewing, M.E.I.C., and numerous others.

W. M. Gardner, A.M.E.I.C., of the Montreal Tramways Company in proposing a vote of thanks spoke on the very satisfactory dealing which he had had with the city engineering department as regards lines and levels. J. L. Busfield, M.E.I.C., occupied the chair.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

A general meeting of the branch was held on January 20th at St. Catharines for the purpose of discussing the annual dance. It was decided to hold the dance at St. Catharines as soon as possible after Easter.

Amendments to Institute By-Laws

The attention of the meeting was directed to a proposed amendment to by-law 32, which is to be discussed at the Annual General Meeting of *The Institute* in Toronto and later voted upon by letter ballot. This proposed amendment makes certain drastic changes in the policy of *The Institute* as regards "expulsion and discipline". "The present by-law reads in part as follows":—"In case the Council on receiving a complaint in writing, shall be of the opinion that the conduct of any corporate or non-corporate member should become the subject of inquiry ...., or in case twenty or more corporate members shall think fit to draw up and sign a request for such an inquiry...... ; the Council shall first notify by registered mail, the member against whom the complaint is laid, setting forth the charges and by whom made, ... Should any complainant member, after receiving due notice, fail to appear at the inquiry without having previously given reason, ... satisfactory to council, the council shall demand of such delinquent member, ..., that he furnish the defendant member through Council, a written apology satisfactory to Council, or send in his resignation from *The Institute*.

Under the proposed amendment the above provisions are altered or deleted. Council will be vested with very great powers and no twenty or more members will be able to force an inquiry. The name or names of complainant members need not be divulged to the accused and no apology or resignation is called for in the event of charges being dropped.

The meeting considered that any such changes to the present by-law are inadvisable and passed a unanimous resolution to that effect and also moved that the matter be brought to the attention of all other branches.

Henry Goldmark, M.E.I.C., the eminent authority on locks and lock gates, was a visitor to the Welland ship canal last week. It is understood that Mr. Goldmark has just been retained by the state of Maine to report upon an immense tidal power project near Passemequoddy bay. Alex. J. Grant, M.E.I.C., engineer-in-charge of the Welland ship canal and F. E. Sterns, A.M.E.I.C., chief designing engineer, are making a tour of inspection comprising the works at Muscle Shoals, New Orleans ship canal and the Panama Canal. Mr. Sterns was responsible for the design of much of the machinery and steel work on the two latter projects and will be much interested in seeing the result of his work after the practical test of years of operation.

Visit to Hydro-Electric Power House at Queenston

On February 3rd, this branch enjoyed a visit to the Hydro-Electric power house at Queenston, followed by a dinner-meeting at The Inn, Niagara Falls, and a most interesting illustrated address by D. A. Andrus, M.E.I.C., managing engineer in Canada for Sir Wm. Arrol and Company, Limited.

The staff at the power house, headed by H. L. Bucke, M.E.I.C., and L. L. Gisborne, A.M.E.I.C., took charge of their visitors at 3 o'clock in the afternoon and for more than two hours guided tham through a maze of machinery and tunnels and answered innumerable questions.

Seventy-five members signed the register and it reflects great credit on our hosts that to date none of the party has been reported as missing. It is whispered, however, that Mr. Bucke lost his voice.

At the dinner and subsequent meeting, more than a hundred members were present, a record for the season and a tribute to the popularity of this series of engineering reminiscences in foreign lands.

T. S. Scott, M.E.I.C., was recently elected to the Council of *The Engineering Institute* in the place of F. S. Lazier, M.E.I.C., who has deserted. Mr Scott thanked the members of the branch for the honour and then moved a vote of thanks to Mr. Andrus. This was seconded by Alex. Milne, A.M.E.I.C., and heartily applauded. Mr. Milne then extended a general invitation to the branch to attend the dinner, smoker and proceedings of the Canadian Section of the American Waterworks Association to be held at the Welland Inn, St. Catharines on March 4th, 1926.

In explanation of Mr. Lazier's desertion, aforementioned, it may be said that he has joined the ranks of the contracting fraternity and is reported to have stated with great feeling "since then I have been hounded by fate and crucified by brother engineers". Verily! contracting is a sad business.

Visiting members to the meetings were F. W. Cowie, M.E.I.C., late Harbour Engineer at Montreal and now acting in a consulting capacity, and W. J. Johnston, A.M.E.I.C., assistant engineer in the Department of Public Works and secretary-treasurer of the St. John Branch, F. Y. Harcourt, M.E.I.C., district engineer at Port Arthur for the Department of Public Works and Mr. Don Carlos of the Hydro-Electric Power Commission.

Inspection Trip over Welland Ship Canal

Shigeru Sameshima, engineer, Home Department of the Imperial Japanese Government made an inspection trip over the Welland Ship Canal on February 9th. The Japanese Government are replacing the sea wall at Yokohama, damaged by the earthquake, with concrete cribs, similar to those in use on the Canal and they also contemplate a thirty-five mile barge canal between Yokohama and Tokyo.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

A special standing engineering committee to advise the Dominion government on engineering projects with regard to national defence was recommended by Major-General J. H. MacBrien, chief of staff, Department of National Defence, in his address before members of the Ottawa Branch at a luncheon at the Chateau Laurier on January 14th.

General MacBrien emphasized the importance of engineering in national defence, and he urged that military engineers be given practical experience through other federal departments, and that civil engineers be given a thorough military experience which would further the engineering strength of the national defence programme.

The military engineer, past, present and future, was dealt with in a most interesting manner by the speaker. The education, qualifications, experience and value of military engineers in war were particularly dwelt upon by General MacBrien. He said that the future would undoubtedly bring about an evolution in engineering methods, although he warned that old methods should not be discarded for new inventions until they were proved reliable. General MacBrien advocated the closest possible relations between military and civil engineers, stating they were invaluable to the national defence programme.

ANNUAL MEETING

J. D. Craig, M.E.I.C., director general of surveys, Department of Interior, who has a long and distinguished term of public service to his credit, was elected chairman of the Ottawa Branch at its annual meeting held in the Daffodil Tea Rooms on the evening of January 14th. F. C. C. Lynch, A.M.E.I.C., was re-elected secretary-treasurer. New members elected to the Managing Committee were A. E. Dubuc, M.E.I.C., and W. A. Rush, A.M.E.I.C., for two years and Allan K. Hay, A.M.E.I.C., for one year. Members of the 1925 committee who continue in office for another year are: J. A. Ewart, A.M E.I.C., and S. J. Fisher, M.E.I.C.

The report of the retiring chairman, A. F. MacCallum, M.E.I.C., indicated in no uncertain manner, the success that has crowned the efforts of the branch in its various fields. Reference was made to the loss sustained through the deaths of L. F. Brinkman, A.M.E.I.C., J. J. McArthur, M.E.I.C., J. A. Symes, A.M.E.I.C., and W. J. Stewart, M.E.I.C. The reports of F. C. C. Lynch, A.M.E.I.C., secretary-treasurer of the branch, J. D. Craig, M.E.I.C., chairman of the Proceeding Committee, A. G. L. McNaughton, A.M.E.I.C., chairman of the Membership Committee, M. F. Cochrane, A.M.E.I.C., branch librarian, and S. J. Fisher, M.E.I.C., chairman of the Committee on Advertising all indicated that splendid progress has been made during the year.

J. L. Rannie, M.E.I.C., introduced a motion to be placed before the Council in Montreal to the effect that steps should be taken to appoint a representative from *The Institute* on the Advisory Committee which Major-General J. H. MacBrien, chief of staff, Department of National, Defence, is anxious to have formed with a view to utilizing the experience of engineers in the solution of problems that effect the well-being of Canada and the Empire, both from a military and civil view-point, in reality a co-ordination of the brains of civil military engineers and other technical experts.

During the evening the meeting was entertained with songs by Messrs. Jack Grace and Jack Powell.

Sault Ste. Marie Branch

A. H. Russell, Jr.E.I.C., Secretary-Treasurer.

The annual meeting of the Sault Ste. Marie Branch was held on December 18th, 1925 in the Y.W.C.A., following a dinner. The chairman Wm. Seymour M.E.I.C., called the meeting to order and called on L. R. Brown, A.M.E.I.C., city engineer, who gave a talk on "Municipal Subjects of Interest." Mr. Brown first took up the question of the renewal of the Street Railway franchise this coming summer. He outlined the early history of the International Transit Company, explaining the relationship between the existing agreement and franchise which expires on July 1st, 1926. Mr. Pickering, manager of the Transit Company, was present and was able to help out with valuable information. Mr. Brown pointed out that unless the franchise was renewed, the city would be forced to take over the street railway at a price set by arbitration. He stressed the possibility of extensions to present lines which would not be a paying proposition and also the uncertainty of the street railway, due to the motor bus.

Then the question of the diversion of the creeks in the Bay View and Steel Plant subdivision was outlined and as Mr. Brown clearly showed that an expense of $8,000 now would ultimately mean an expenditure of approximately $80,000 for a sewer system and on account of the low value of the houses and lots in this section, it would be impossible for the property owners to carry the additional taxes that would result from such an improvement.

The third subject touched on by the speaker was "Street Lighting". This question arose by the Retail Merchants Association having asked for a better system of street lighting. Mr. Brown outlined the report of the Water and Light Commission to the City Council. He explained the underground and overhead systems as used in different cities, giving a comparison of the costs. Photographs taken by him showing the types of standards and reflectors as used in other cities were exhibited. The costs and the types of standard and reflectors that would suit the conditions in the Soo were explained.

A lively discussion followed Mr. Brown's interesting talk and the interest taken was apparent by the following resolution of J. R. Ross, Jr.E.I.C. and C. H. Speer, M.E.I.C.

> "That it is the opinion of this meeting that in view of the great cost to the city, (approx. $300,000.00) in taking over the street railway we would recommend that the by-law to renew the franchise should carry".
>
> "That as the by-law for the diversion of the creeks in Bay View and Steel Plant subdivisions would later involve an ultimate expenditure of $60,000. to $80,000. for a sewer system, that this by-law should not carry."

A hearty vote of thanks was tendered to Mr. Brown for his splendid talk.

The minutes of the previous meeting were read and reports from the various committees were read and adopted. The secretary's report showed the branch in a good way financially, but the membership had a slight decrease in the district members from last year. The chairman appointed Messrs. Rounthwaite and Jenkinson as auditors.

ELECTION OF OFFICERS

The Nominating Committee then reported the result of the election of officers as follows:—

Chairman........................C. H. Speer, M.E.I.C.
Vice-Chairman....................G. H. Kohl, A.M.E.I.C.
Secretary-Treasurer..............A. H. Russell, A.M.E.I.C.
Executive Committee (2 years)......W. S. Wilson, A.M.E.I.C.
C. R. Murdock, A.M.E.I.C.

The Committee also reported that the adoption of the revised By-Law carried unanimously.

The chairman gave an account of the year's work and thanked the committees for their co-operation during the past year. He stressed the point of attendance and hoped that 1926 would see a larger attendance and also that he would like to see a closer connection with the district members.

C. H. Speer, M.E.I.C., the chairman-elect took the chair and thanked the members for the honour bestowed upon him, and said he hoped to live up to the records of his predecessors. He apparently has given a good deal of thought to the future activities of the branch as the programme that he outlined will make a busy and interesting year for the branch.

The regular meeting of the Sault Ste. Marie Branch was held on January 29th, at 7.30 p.m., at the Y.W.C.A., following a dinner of members and guests.

C. H. Speer, M.E.I.C., chairman, called the meeting to order and introduced the speaker, Mr. James Govan, R.A.I.C., a consulting architect of Toronto, who addressed the meeting on "Canadian Engineering and Architectural Problems".

CANADIAN ENGINEERING AND ARCHITECTURAL PROBLEMS

With the aid of his numerous lantern slides, Mr. Govan clearly demonstrated the advisability of a better design for buildings throughout the country. The design and construction of the average building nowadays fails, he said, to take advantage of the snow which is a natural insulator, and the sun's rays which carry natural heat from the sun. By the proper location of windows and situation with reference to the north, he added, a house that has its walls and roof insulated with any of the numerous insulating materials on the market will be the warmest in the winter and the coolest in the summer.

As the loss in Canada each year is about $60,000,000. due to faulty design and construction, he said that this loss was due to the amount of heat that escaped through the walls and roof of the building. The prevention of heat losses helps in the prevention of fire losses as the insulation used in the walls and roof in any building decreases the fire hazard.

He pointed out that the conductivity of the standard frame construction is 0.267 by test, but with the use of insulating in the walls the conductivity is reduced to 0.05 or one fifth.

Among the charts shown by Mr. Gowan was one giving the relative heat consumptions of twenty-seven houses as follows:

> Five cement, common block and reinforced concrete houses 181.5 to 221. Eight brick houses 13½ inch walls 156 to 188.5. Fourteen wooden (frame) houses 96.5 to 129. The standard adopted for comparison purposes was 100, and the house used was a standard frame construction. The frame house that registered 96.5 had the space between studding filled with shavings.

A recent test carried out by Mr. Govan on four different types of roofs showed that the roof costing the most, due to being insulated with four inches of Insulex would be the most economical, as the consumption of coal per year would be greatly reduced and also the number of feet of radiation necessary to be installed would be greatly reduced.

The concrete roof is the poorest roof that can be put on a building unless it is thoroughly well treated with one of the many insulating materials. He showed a test made on concrete walls and the wall that had not been treated with Insulex lost 395 times as much heat as the one that had been treated with it.

He showed by the use of insulating materials forming the curtain walls between pilasters or columns supporting the steel in fire proof building that the dead loads existing in the average building of that type could be greatly reduced and that in no way was the strength of the building decreased.

The speaker clearly showed that with very little additional cost at the time of construction, the average house of to-day would be much more comfortable to live in, it would have an even temperature, higher humidity and be free from all drafts, and that this additional construction cost would be wiped out the first year on the saving on fuel and heating plant. The question of fuel economy is a vital one to Canadians, he said, at the present time.

The two hours that Mr. Govan used in making his address were considered well spent by all present, and the interest that was aroused was shown by the numerous questions asked and the lengthy discussion on building that followed the address.

On motion of C. H. E. Rounthwaite, A.M.E.I.C., and L. R. Brown, A.M.E.I.C., a hearty vote of thanks was tendered Mr. Govan for his most interesting and instructive talk, and the appreciation of the branch was extended to Mr. J. Biscomb for being instrumental in getting Mr. Govan to come to Sault Ste. Marie.

Saint John Branch

J. W. Johnston, A.M.E.I.C., Secretary-Treasurer.

Following its policy of making available to the general public any lectures of a popular nature the Saint John Branch met at a joint dinner and meeting with the Men's and Women's Canadian Clubs on the evening of January 6th, at the Admiral Beatty hotel. An assembly of over 200 persons enjoyed a fine supper and were later addressed by George P. Mackenzie, A.M.E.I.C., officer-in-charge, Canadian Arctic Expedition, 1925, speaking on the cruise of C. G. S. "Arctic" in northern waters during 1925. The favourable comment from those present at the action of the Saint John Branch in having others to share in the meeting showed that all present were pleased with the innovation.

The address by Mr. Mackenzie dealt with a subject of which the average Canadian knows very little and consequently in which he takes little interest. The fact that Canada's northland is rich in fur products, has mineral possibilities, and is a worth-while part of Canada was forcefully brought home to the audience. It was a good story well told to a gathering including most appropriately the members of the two Canadian Clubs.

In detail the voyage of the steamer "Arctic" from her departure from Quebec on July 1st, 1925, until her return there 102 days later was described. Four reels of moving pictures were shown and included a map showing the progressive stages of the journey.

After leaving Quebec on July 1st. the steamer "Arctic", under Capt. J. E. Bernier as chief navigating officer, sailed along the coast of Labrador. On July 18th, the steamer became wedged in the ice while attempting to reach Cumberland gulf to land supplies at Pangnirtung but after a 20-day struggle had to abandon the effort for the time being. The ship proceeded to Disco island, Greenland, and up the eastern side of the strait to Godhavn, Greenland which was reached on August 10th, Under the Danish government there is a local parliament for Greenland which was then in session. Some of the members of the expedition were entertained on shore by Governor Rosendahl and this courtesy was returned on board ship to the members of the local parliament by the members of the expedition. A noteworthy feature of their stay there was the resolution of good-will to the expedition passed by the members of parliament.

On August 11th, the ship left Godhavn and after many experiences with the ice arrived on August 21st, at Fram harbour, 78 degrees 46 minutes north latitude, this being the most northerly point reached on the voyage. After a stay of several days the ship started on the return voyage calling en route at Craig harbour, on Ellesmere island; Dundas harbour, on Devon island; Pond's inlet on Baffin island; and finally a successful landing was made at Pangnirtung where it was previously unable to land. The ship arrived at Quebec on October 10th.

The trip was made for the purpose of landing of supplies at the posts of the Royal Canadian Mounted Police, for the delivery and collection of mail, and to keep in touch in general with Canada's northern territory. Included in the party on the outward voyage was Dr. L. P. Livingston, as surgeon; L. J. Weeks of the Geological Survey, Department of Mines geologist; Captain Harwood Steele, secretary; Messrs. R. M. Foster and R. S. Finnie, wireless operators; G. H. Valiquette, cinematographer; Inspector Wilcox and several constables of the Royal Canadian Mounted Police.

W. R. Pearce, M.E.I.C., presided over the meeting. Others at the head table included Mr. and Mrs George P. Mackenzie; Lt-Col. E. C. Weyman, O.B.E., president Men's Canadian Club; Mrs. A. H. Fitz-randolph, president Women's Canadian Club; Mrs. H. A. Powell; Hon. R. J. Ritchie; Geoffrey Stead, M.E.I.C. A vote of thanks was extended the speaker on motion of Lt.-Col. Weyman and Mrs. Fitz-randolph.

Dinner and Meeting

Members of the Saint John Branch held a dinner on the evening of January 21st, 1926, at the Admiral Beatty hotel. In addition to branch members there were also in attendance members of the Association of Professional Engineers of the Province of New Brunswick, the annual meeting of the Professional Association being held in the afternoon. Forty-five persons were present and enjoyed a splendid meal- A. R. Crookshank M.E.I.C., presided and guests of honour were Lt.. Commander C. P. Edwards, A.M.E.I.C., Ottawa, and F. O. Condon, M.E.I.C., Moncton, retiring president of the Association of Professional Engineers of New Brunswick. No formal toast list was carried out but the following members spoke briefly, Lt.-Commander C. P. Edwards, A.M.E.I.C. and Messrs. F. O. Condon, M.E.I.C., A. Gray, M.E.I.C., and Geoffrey Stead, M.E.I.C.

Radio Direction Finding

Following the dinner an illustrated lecture on "Radio Direction Finding" was delivered by Lt.- Commander C. P. Edwards, A.M.E.I.C. The subject of this lecture was of especial interest to this locality with a radio direction finding station located in the vicinity of the port of Saint John as one of the safe-guards to navigation.

The story of radio and wireless was traced through the several discoveries since 1878 of J. Clerk Maxwell, Sir Oliver Lodge, Marconi, and others, and mention made of the research work and inventions of one being of assistance to later workers. Previous to radio direction finding being adopted the navigator had to depend on observations on sun and stars for ship's position and where practicable soundings were also of assistance. At present ships within range of radio direction finding stations may be safely guided through fog or darkness around obstructions or shoals. Radio direction finding is also of use in air navigation and by its means many airplanes have been piloted to safety.

The technical features underlying transmitting and receiving wireless stations were explained by a number of slides. The subject was further illustrated by several reels of motion pictures. A vote of thanks was extended on behalf of the branch by Geoffrey Stead M.E.I.C., and F. P. Vaughan, M.E.I.C.

On the following night Lt-Commander Edwards repeated his address at the University of New Brunswick at Fredericton before the engineering students and members of *The Institute* resident in Fredericton. This lecture was also very much enjoyed and the kindness of Lt.-Commander Edwards in repeating his address was very much appreciated.

Saskatchewan Branch

J. W. D. Farrell, A.M.E.I.C., Secretary-Treasurer.

The November meeting of the Saskatchewan Branch was held at the Parliament Buildings restaurant on November 12th, R. N. Blackburn, M.E.I.C., presiding. Following the dinner the meeting was commenced in one of the committee rooms. The programme being the second of a series put on by different occupational groups, was devoted to "Town Planning and Surveying", and was arranged by Messrs. Loucks and Young. By way of atmospheric prologue some excellent lantern slides were exhibited. These had been kindly loaned by the Department of Education and showed the results and benefits of tree planting on the prairies.

Lt.-Col. A. C. Garner, D.S.O., M.E.I.C., called the attention of the branch to the death of the late Gen. Ruttan who had been an outstanding man amongst western engineers. A resolution of deep sympathy and regret at the passing of Gen. Ruttan was moved by Col. Garner and seconded by Stewart Young, A.M.E.I.C., the resolution to be conveyed to the immediate family of the deceased, to Institute headquarters and to the Winnipeg Branch.

Work of some Branches of the Department of the Interior

The chairman then called on Col. Garner for his address on "An Outline of the Work of some Branches of the Department of the Interior" The speaker prefaced his remarks by recalling a very pleasant visit recently made to Ottawa where he was greatly impressed by its natural beauties and spoke of that city as the Edinburgh of Canada. The speaker then outlined the different branches of the department's work, covering Dominion lands, natural resources, water power and reclamation, forestry, parks, observatories, international and provincial boundries and the different classes of surveys such as topographic, geodetic, aerial, etc. While not encroaching on local or provincial adminstration, much of the department's work is international and has earned for Canada a recognized place at international conferences, as for example the Power Conference at Wembley in 1924. By such means Canada is becoming well and favorably known to other nations.

In forestry, the department, from investigations, estimates that originally Canada possessed 1,300,000 square miles of standing timber, of which it is estimated 60 per cent has been destroyed by fire, 13 per cent has been cut, 27 per cent left. The department recognizes the need for conservation, afforestation and fire prevention.

In the Arctic Archipelago, surveying and other work is going on in connection with establishing Sovereignty. Geodetic and boundry surveys and precise levelling are being carried on at different points from coast to coast. Wireless signals broadcasting Standard time have been particularly helpful in geodetic work. Brief descriptions were also given of the two Dominion observatories at Ottawa and Victoria, of the work of the Department of Natural Resources and of the testing laboratory. Topographical surveys include the examination and classification of thirty million acres of land in western Canada during the past six years. Section sheet maps of the Dominion are under preparation, of which thirty-three have been completed and published in the last six years.

In connection with map making and exploration of new areas, Col. Garner exhibited some very fine specimens of aeroplane photography and maps compiled therefrom and outlined the co-operation between the Royal Canadian Air Force and the Department of the Interior that existed for the carrying on of this phase of the work.

In concluding, Col. Garner paid tribute to the work of the Dominion Land Surveyors and the work which they had done in opening up new territories.

HISTORY OF TOWN PLANNING

The chairman then called on Stewart Young, A.M.E.I.C., for his paper on "History of Town Planning". First example of a comprehensive plan is that of Kahun in Egypt built about 3000 B.C. Selinus in Sicily, established in 628 B.C., was also laid out on geometric lines. The Romans in building some of their newer cities followed definite plans with regard to the layout of the cities.

In the middle ages the growth of towns was slow and the arrangement of streets and buildings for the most part haphazard. Towards the end of the mediaeval period prosperity promoted the beautifying of public squares and public buildings.

In the sixteenth century Italian towns commenced straightening and widening their streets and improving public places. The movement spread to France and soon became general throughout Europe.

Town plans may be classified as, radial, rectangular, or a combination of these two.

In the nineteenth century industrial expansion and lack of a directing authority in building and planning of cities lead to traffic congestion and slum conditions. To rectify these evils the zoning system was evolved in Germany and spread to other countries. In England, Port Sunlight and Bournville were built in an effort to achieve model towns. Some time later Letchworth was built following on the ideas advanced by Howard in his book "Garden Cities of Tomorrow".

In the United States progress had been fairly rapid since 1916 and today at least 50 per cent of the urban population in some three hundred and fifty urban cities is under zoning regulations.

In Canada legislative provision has been made in the statutes of most of the Provinces but on the whole little has been done in the way of comprehensive town planning.

PARKS AND BOULEVARDS

The chairman then called on J. M. Craig, Superintendent of City Parks for his address on "Parks and Boulevards". Mr. Craig dealt chiefly with the parks system in Regina saying that it comprised some 257 acres and included about 200 park and play ground areas. A census taken in 1923 showed that there were approximately 43,000 trees in the city counting publicly and privately owned trees but not counting trees in the Parliament Buildings grounds. At present the city has some 65,000 to 75,000 trees in the nursery, of which 5,000 are ready for planting out. Mr Craig advocated the planting of the elm tree on account of its beauty, long life and being fairly free from blights. The Russian poplar has the advantage of quick growth but has a life of only twenty-five to thirty years. The city has about thirty-four miles of improved boulevards in grass and trees and five miles of new boulevards under construction. The cost for maintenance is about 3½ cents per foot annually. In conclusion Mr. Craig outlined plans for the future expansion of Wascana park, including a drive-way along the lake shore easterly to the power house, in co-operation with the provincial government.

SOME COURT DECISIONS BEARING ON SURVEYING

R. W. E. Loucks, A.M.E.I.C., was then called on for his paper on "Some Court Decisions Bearing on Surveying". As the hour was late Mr. Loucks spoke briefly on the following subjects: Conflicting evidence with regard to boundry mound. In this case the decision was given in favor of the evidence supported by the earliest survey. The matter of adverse possession was touched on briefly showing the peculiar situation of ownership without title. A case concerning validity of railway location plans was also described.

JOINT MEETING WITH A. I. E. E.

On December 15th the Saskatchewan Branch E.I.C. joined with the Saskatchewan Section A.I.E.E. in holding a social evening in the City Hall auditorium. The first part of the evening was devoted to a whist drive. Following this, supper was served and the remainder of evening spent in dancing.

Toronto Branch

C. B. Ferris, A.M.E.I.C., Secretary-Treasurer.
J. W. Falkner, A.M.E.I.C., Branch News Editor.

The monthly luncheon of the Toronto Branch was held on January 7th, at the King Edward Hotel, when R. A. C. Henry, M.E.I.C., director of the Bureau of Economics, Canadian National Railways, addressed the branch.

THE MOTOR VEHICLE VS. OTHER FORMS OF TRANSPORTATION

Mr. Henry predicted that to that extent to which the motor vehicle can, all factors considered, perform more economic and convenient service than other existing means of transportation it must ultimately supplant them. He thought it distinctly in the public interest that co-operative effort should strive for the assignment of each of the various available transportation facilities to its most economic field, and that their services should be so co-ordinated as to produce "the most convenient, adequate, regular, expeditious and economic transportation system possible."

"I am not an advocate of undue regulation of any transportation service," said the speaker, "nor do I believe that any special protection should be given to any form of transportation not economically sound. It is a fact, however, that in the period of development of steam and electric railways to date there has been developed a code of regulations applicable to these forms of transportation which materially affect the cost of the transportation provided by these facilities, and it is, I think, but reasonable to suggest that the motor vehicle when engaged in common carrier service should be similarly regulated.

"As regards taxation," he continued, "it would be unwise to unduly tax common carrier motor vehicles. It seems to me but fair that the motor vehicle as a freight or passenger facility,(apart from reasonable private use), should bear the cost of the additional capital and additional maintenance which such traffic involves and pay in addition the same amount relatively that other forms of transportation pay in taxes."

He foresaw a distinct field for the motor-vehicle in handling urban passenger traffic in co-operation with the electric street railway. For suburban passenger traffic it would appear, beyond a certain density of highway traffic, to require a private roadway. For local and interurban passenger hauls, the motor vehicle might in some instances replace steam and electric railway services. Its successful use on long-distance passenger hauls would, however, have to wait on the solution of a number of important problems.

THE WORK OF THE ONTARIO EXPERIMENTAL STATION IN PROMOTING THE ART OF SEWAGE DISPOSAL

On January 21st a paper was read before the Toronto Branch by F. A. Dallyn, M.E.I.C., director, Sanitary Engineering Division, Ontario Department of Health, and A. V. DeLaporte, A.M.E.I.C., chemist in charge of Experimental Station, on "The Relation of the Experimental Station to the Advances in Sewage Disposal in the Last Decade".

After dealing with the history of experimental station work on this continent and in the old country, and explaining the difference between a laboratory experiment, — which was usually on a small or restricted scale, giving little information regarding plant operation or design, — and work in an experimental station, the paper then outlined the reasons that in 1909 had impelled the Ontario Government to place such a station at the disposal of the Provincial Board of Health, showing that since that date there had been developed a mass of data having special regard to Ontario's local climatic conditions, storm water and trade waste problems, discharges into small water courses, and similar problems, that was leading to the installation of better plants for sewage treatment.

Intensive study had been given to the biological processes for the digestion of organic matter in sewage, aerobic vs. anaerobic digestion, experimental work in connection with activated sludge, the effect of agitation, spiral flow tanks, separate digestion, iron content, fertilizing value, stability of effluents, etc. Such study showed the simplicity of control of the activated sludge process.

The paper was very fully illustrated with tables and experimental data, and samples of sewage, sludge, effluents, etc., from different plants were handed around for inspection; following which an experiment was made showing that the oxygen dissolved from the air used for agitation could only account for a fraction of the reduction in the oxygen demand of the sewage so treated.

Professor T. R. Loudon, M.E.I.C., extended the thanks of the branch to the authors for their excellent paper and for the trouble to which they had gone in setting up their apparatus.

LUNCHEON TO GEORGE HOGARTH, M.E.I.C.

A well attended luncheon meeting was held on February 4th, at the King Edward hotel in honour of George Hogarth, M.E.I.C., formerly chief engineer of the Ontario Department of Highways, who was recently appointed deputy minister of public works; Mr. George Henry, minister of public works also being a guest of the meeting.

The chairman, Professor T. R. Loudon, M.E.I.C., offered the congratulations of the meeting to Mr. Hogarth, and expressed his pleasure that Mr. Henry had also found it convenient to be present, following which Mr. Henry addressed the meeting, outlining the functions and the probable future developments of his department, and introducing the new deputy minister.

Mr. Hogarth then addressed the meeting, dealing with the history of the highway system of the province, the different types of highways, and recent improvements in methods of construction and maintenance.

Engineering Specifications

A very timely address was given on February 11th, by S. E. Craig, assistant laboratory engineer, Hydro-Electric Power Commission of Ontario, on "Engineering Specifications".

Mr. Craig dealt with his subject in a very full, practical and interesting manner, paying special attention to the different viewpoints and functions of the engineer, resident engineer, contractor, sub-contractor, inspector, foreman, etc., and dealing with those features that would have to be observed in the writing of a specification to ensure a concise and practical document, readily understood by and equitable to all parties, and resulting in material and workmanship of the desired standards at the lowest cost to the client.

A spirited discussion took place at the conclusion of Mr. Craig's paper.

Annual Meeting Committee's Work Appreciated

The members present passed the following resolution:—"That the hearty thanks and appreciation of the branch be tendered to the Chairman and members of the Annual Meeting Committee for the able and highly satisfactory manner in which they applied their efforts, organized and conducted the Annual General and Professional Meeting for 1926".

Victoria Branch

E. G. Marriott, A.M.E.I.C., Secretary-Treasurer.

The Annual meeting of the Victoria Branch was held in the club-room of the branch on Wednesday evening, December 9th, 1925, the room being comfortably filled.

Election of Officers

The chair was taken by G. B. Mitchell, M.E.I.C., chairman of the branch, after dealing with routine matters, Messrs. Carruthers and Hodgson were appointed to act as scrutineers and ballotting took place for officers for 1926, with the following results:—

Chairman.....................J. N. Anderson, A.M.E.I.C.
Vice-Chairman................M. P. Blair, M.E.I.C.
Secretary-Treasurer............E. G. Marriott, A.M.E.I.C.
Executive......................E. P. Girdwood, M.E.I.C.
" ....R. F. Davy. A.M.E.I.C.

The following are also on the Executive, having been elected in 1925 for two years.

E. E. Brydone-Jack, M.E.I.C.
P. Philip, M.E.I.C.
G. B. Mitchell, M.E.I.C., past-chairman, *ex-officio*.

A hearty vote of thanks was passed to the retiring officers for their services, and an honorarium unanimously voted to the retiring Secretary-treasurer for his untiring work of the past five years as treasurer, and then as secretary-treasurer.

The new chairman then took the chair, and after asking the membership of the branch to support the efforts of those who freely gave their time and interest to serve their fellow-engineers, called upon Mr. Mitchell to give his talk on his experiences in Central and South America.

This proved to be a very out-of-the-ordinary address, dealing mostly with the natural history, botany, climate, local customs and other interesting phases of an engineer's life in Nicaragua, Peru and Chile. The paper of course lacks the running comment and humour that made it so enjoyable to those present. It was unanimously voted to be one of the most interesting talks the members had heard, and was followed by reminiscences from other members who had seen life in various parts of the world.

Appointment of Committees

At an executive meeting held on December 15th, the following committees were appointed by the chairman:—

Papers:—Convener, F. L. Macpherson, M.E.I.C., W. S. Drewry A.M.E.I.C., A. F. Mitchell, A.M.E.I.C., A. L. Carruthers, M.E.I.C., K. Chadwick, A.M.E.I.C.

Duties:—To secure speakers, settle place of meeting make all arrangements for use of room, working of lantern, etc. Arrange for outings, visits, speakers for lunches.

Town Planning;—Convener, M. P. Blair, M.E.I.C., R. Fowler, M.E.I.C., F. M. Preston, A.M.E.I.C., F. C. Green, A.M.E.I.C., R. F. Davy, A.M.E.I.C., H. F. Bourne, A.M.E.I.C.

Duties:—To keep in touch with the progress of town planning, report if branch can assist locally, arrange with Papers Committee for speakers if desirable, etc.

Social:—Convener, W. M. Everall, A.M.E.I.C., E. P. Girwood, M.E.I.C., F. G. Aldous, A.M.E.I.C., A. J. Gray, A.M.E.I.C., G. B. Forde, S.E.I.C.

Duties:—To arrange lunches at request of executive, see to details, also arrange details and superintend outings, visits, etc.

Library:—Convener, F. W. Knewstubb, A.M.E.I.C., H. Peters, A.M.E.I.C., H. Icke, A.M.E.I.C., W. M. Stokes, A.M.E.I.C., E. G. Marriott, A.M.E.I.C.

Duties:—To see to upkeep of club-room, and make recommendations as to purchase and disposal of magazines, etc.

Publicity:—Convener:—G. B. Mitchell, M.E.I.C., A. W. R. Wilby, A.M.E.I.C., S. Hodgson, A.M.E.I.C., W. S. Lawrence, Jr. E.I.C., J. H. Blake, A.M.E.I.C.

Duties:—To submit items of public interest concerning engineering and engineers to the press, and secure items of branch news for *The Journal.*

Applications, Attendance, and Legislation committees are composed of the whole Executive.

Winnipeg Branch

James Quail, A.M.E.I.C., Secretary-Treasurer

A regular meeting of the Winnipeg Branch, was held on Thursday December 17th, in the evening.

G. S. Roxburgh, A.M.E.I.C., manager of the Winnipeg office of Fetherstonhaugh and Company, patent barristers, was the speaker of the evening. His subject was 'Patents and Inventions' and was illustrated by lantern slides.

Mr. Roxburgh sketched the history of the development of British Patent Law, that of the United States, and that of Canada. Principles involved in patenting and patents, and what, as the result of the application of the principles, might or might not be patented were discussed. Applications for patents, and the filing of them were explained. Details were given as to the number of patents applied for in different sections and over particular periods, and comparisons were drawn. Attention was directed to the class of patents being applied for, and generally, by whom. Protection of employees in the case of patentable articles worked out in the time of an employer, was noted.

E. P. Fetherstonhaugh, M.E.I.C., moved the vote of thanks.

Preliminary Notice

of Applications for Admission and for Transfer

February 19th, 1926

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in March, 1926.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council, shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering with special reference to the branch of engineering in which he has been engaged. This examination may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the first year in such a course, shall be required to pass an examination in the following subjects: geography, history, (that of Canada in particular), arithmetic, geometry, euclid (books I, IV and VI), trigonometry, algebra up to and including quadratic equations.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed successfully an examination equivalent to the final examination of a high school or the matriculation of an arts or science course. He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which cash he shall pass an examination equal to that prescribed for admission to the grade of Junior in the foregoing section and he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineer in the advancement of professional knowledge.

> The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BOIVIN—THOMAS JOSEPH, of 189 Holland Ave., Quebec, Que. Born at Quebec, P.Q., Aug. 19th, 1894. Educ., private tuition; I.C.S. structr'l and civil engr'g. diploma; at present continuing course in structr'l. engr'g., Univ. of Wisconsin; 1910-13, constrn. work with M. P. & J. T. Davis, contracting engrs.; 1914-19, checking and designing, and at present chief dftsman., under F. T. Cole, M.E.I.C., Eastern Canada Steel & Iron Works, Ltd., Quebec, P.Q.

References: F. T. Cole, I. Vallee, J. E. Roy, E. Lavigne, A. Fraser.

BOLTON—LAUNCELOT LAWRENCE, of Ottawa, Ont. Born at Portland, Ont., Sept. 14th, 1881; Educ., M. A. 1903, and B.Sc., 1906, Queen's Univ.; 1907-14, geologist and utility engr., Mines Dept., Lake Superior Corpn., Sault Ste. Marie, student asst. under Dr. R. W. Brock, M.E.I.C., studying economic geology of Rosslind Mining Camp, asst. engr., calculation of ore reserves in iron mines in Ontario, Minnesota and Michigan; 1915-26, with Dept. of Mines, Ottawa, as follows:—asst. mining engr., Divn. of Mineral Resources and Statistics—1916, private secretary, Office of Deputy Minister, 1919, Secy., Dept. of Mines, and at present, Asst. Deputy Minister.

References: C. H. Speer, J. D. Jones, R. S. McCormick, C. H. E. Rounthwaite, G. C. Mackenzie, C. Camsell, B. F. Haanel, L. H. Cole.

BOULIAN—JOB IVAN, of Montreal, Que. Born at Mattawa, Ont., Aug. 9th, 1888; Educ., Case School of Applied Sci., Cleveland, Ohio, 1915-17, and partial course electricity, McGill Univ., 1919-20; 1910-12, rodman and instr'man., Algoma Central & Hudson Bay Rly.; 1912-14, chief of party, traverse and hydrographic survey, Algoma Steel Corpn., power dept., J. S. H. Wurtele, M.E.I.C., chief engr.; 1917-19, overseas; 1919 to date, dftsman., designer, field engr., supt. of transmission line and substation constrn., and at present, asst. constrn. engr., Southern Canada Power Co., Ltd., Montreal, Que.

References: J. B. Woodyatt, J. S. H. Wurtele, J. H. Trimingham, F. F. Griffin, T. C. Connell.

BRETCHEN—MAX, of 834,—7th Street South, Lethbridge, Alta. Born at Winterthur, Switzerland, May 22nd, 1895; Educ., Land Surveyer, Diploma from Swiss Confederation, 1918. At present taking I.C.S. rly. engrg.; In Switzerland, surveying and mapping in mountainous districts, topographical work in connection with constrn. of waterworks, pipe lines, reservoirs, constrn. of roads and drainage etc.; 1920-23, dftsman., field and office, C.N.R.; 1923 to date, with C.P.R. as follows: 1923, instr'man. on mtce., 1923-24, dftsman. and instr'man. on location, 1924 to date, instr'man. on constrn.

Members of Council for 1926

PRESIDENT

*GEO. A. WALKEM, Vancouver, B.C.

VICE-PRESIDENTS

*A. S. DAWSON, Calgary, Alta.
†PETER GILLESPIE, Toronto, Ont.
*K. B. THORNTON, Montreal, Que.
†W. G. MITCHELL, Kenogami, Que.
†GEO. D. MACDOUGALL, New Glasgow, N.S.

PAST-PRESIDENTS

J. M. R. FAIRBAIRN, Montreal, Que.
J. G. SULLIVAN, Winnipeg, Man.
ARTHUR SURVEYER, Montreal, Que.

COUNCILLORS

*L. M. ARKLEY, Kingston, Ont.
*E. V. BUCHANAN, London, Ont.
*G. H. BURBIDGE, Port Arthur, Ont.
‡J. L. BUSFIELD, Montreal, Que.
*E. V. CATON, Winnipeg, Man.
*F. O. CONDON, Moncton, N.B.
*R. L. DOBBIN, Peterborough, Ont.
*JOHN DOW, Lethbridge, Alta.
†J. T. FARMER, Montreal, Que.
*O. S. FINNIE, Ottawa, Ont.
*F. C. GREEN, Victoria, B.C.

*A. W. HADDOW, Edmonton, Alta.
*E. G. HEWSON, Toronto, Ont.
*J. H. HUNTER, Montreal, Que.
*E. LAVOIE, Chicoutimi, Que.
*O. O. LEFEBVRE, Montreal, Que.
*H. R. MacKENZIE, Regina, Sask.
†GEO. R. MacLEOD, Montreal, Que.
‡C. M. McKERGOW, Montreal, Que.
*W. F. McLAREN, Hamilton, Ont.
†D. L. McLEAN, Winnipeg, Man.
*JAS. MUIRHEAD, Vancouver, B.C.

*A. B. NORMANDIN, Quebec, Que.
‡J. M. OXLEY, Toronto, Ont.

*For 1926 †For 1926-27 ‡For 1926-27-28

TREASURER

MAJOR-GEN. SIR ALEX. BERTRAM, Montreal

SECRETARY

R. J. DURLEY, Montreal

OFFICERS OF BRANCHES

HALIFAX
Chairman, H. W. L. DOANE
W. A. WINFIELD
Sec.-Treas., K. L. DAWSON, 115 Morris Street, Halifax, N.S.
Executive, W. F. McKNIGHT
H. S. JOHNSTON
W. P. COPP
J. S. MISENER
R. R. MURRAY
J. G. W. CAMPBELL
H. F. BENNETT
D. W. MUNN
C. W. ARCHIBALD
H. C. BURCHELL
(Ex-Officio) C. H. WRIGHT W. F. McKNIGHT

CAPE BRETON
Chairman, W. C. RISLEY
Vice-Chair., W. S. WILSON
Sec.-Treas., D. W. J. BROWN, Bank of Commerce Bldg., Sydney, N.S.
Executive, J. J. McDOUGALL W. E. CLARKE
J. R. MORRISON
(Ex-Officio) S. C. MIFFLEN

ST. JOHN
Chairman, W. R. PEARCE
Vice-Chair., A. R. CROOKSHANK
Sec.-Treas., W. J. JOHNSTON, Box 1417, St. John, N.B.
Executive, G. STEAD S. R. WESTON
E. A. THOMAS G. G. HARE
G. G. MURDOCH
(Ex-Officio) A. G. TAPLEY

MONCTON
Chairman, C. S. G. ROGERS
Vice-Chair., A. S. GUNN
Sec.-Treas., M. J. MURPHY, Eng. Dept., C.N.R., Moncton, N.B.
Executive, A. F. STEWART J. R. FREEMAN
J. D. McBEATH F. B. FRIPP
G. C. TORRENS G. E. SMITH
(Ex-Officio) F. O. CONDON

SAGUENAY
Chairman, C. N. SHANLY
Vice-Chair., G. E. LAMOTHE
Sec.-Treas., BURROUGHS PELLETIER, Box 181, Chicoutimi, Que.
Executive, E. LAVOIE
J. E. A. McCONVILLE
J. L. DELISLE
A. A. MacDIARMID

QUEBEC
Hon.-Chair., A. R. DECARY
Chairman, A. B. NORMANDIN
Vice-Chair., S. L. deCARTERET
Sec.-Treas., LOUIS BEAUDRY, P.O. Box 115, Quebec, Que.
Executive, T. E. ROUSSEAU H. CIMON
L. C. DUPUIS A. LARIVIERE

MONTREAL
Chairman, C. J. DESBAILLETS
Vice-Chair., C. V. CHRISTIE
Sec.-Treas., C. K. McLEOD, 318 Lagauchetiere St. W., Montreal, Que.
Executive, A. DUPERRON
A. R. KETTERSON
J. A. McCRORY
P. L. PRATLEY
JAS. ROBERTSON

Some Recent Stress Analyses by Means of the Photoelastic Method

An Historical Survey of its Development with Some Recent Investigations carried on by this Method

Paul Heymans,
Assistant Professor, Massachusetts Institute of Technology, Cambridge, Mass.

As is well known, the mathematical theory of elasticity is the fundamental tool for the determination of the state of stress at all points of a structure. However, its scope is limited, on account of the unsolvable equations to which it leads, even for some of the very simplest cases encountered in practice. Simplifying assumptions are then made and approximate solutions are obtained. Such empirical calculations are acceptable when they have been sufficiently checked by experience, if in other words the factor of safety has been for each particular case adequately adjusted. For new types of construction, for the explanation of unexpected failures, whenever it is of importance to distribute the material in the most economical manner, approximate calculations are often inadequate. The photoelastic method is a method which uses the effects of mechanical stress on polarized light and thereby permits, for the majority of the cases of plane stress, the direct measuring of the state of stress at any point of a stressed model made of transparent material such as celluloid. The measurements are readily translated into the stresses which will exist in the full size structure made of structural material. A brief description of the method will be given first, followed by an account of some of the recent stress analyses made by means of this method.

Historical Survey of Development of the Method

Temporary double refraction observed in transparent amorphous material, when put under thermal and mechanical stress, was first studied by the English physicist, Sir David Brewster. He published[1] several papers reporting his various investigations beginning in 1814 until 1830. Later, A. Fresnel[2], F. E. Neumann[3], Clerk Maxwell[4], and G. Wortheim[5], made further contributions to the study of temporary double refraction.

Although Maxwell had already pointed out the possibility of employing temporary double refraction for the study of problems in elasticity, C. Wilson[6] was first to attempt solving problems of the distribution of mechanical stress in an elastic body by analysis of the double refraction. More recently F. Pockels[7] and especially L. N. G. Filon[8] determined in a more complete manner the laws relating the double refraction to the state of stress, thereby paving the way to Mesnager's work.

A. Mesnager[9], in his remarkable study of the stresses in the La Balme bridge, developed the method which up to the present day forms the corner stone of the photoelastic method of stress analysis. Mesnager's work should receive credit for the later development of this method.

E. G. Coker[10] applying Mesnager's methods, developed the technique of the photoelastic method by studying a series of problems of stress distribution for which there existed an analytical solution, such as the stresses around a circular hole in a plate. He thereby showed that agreement exists between the results of photoelastic analysis and those obtained by analytical methods, where such analysis was possible without

introducing simplifying assumptions or approximations. The limitations of agreement between the result of a stress analysis by means of the photoelastic method and the stress distribution in an actual structure have been studied theoretically by L. N. G. Filon[11]. In the photoelastic apparatus which were developed by E. G. Coker, the optical part is due to Silvanus Thomson, and the principle of the measurements by means of a lateral extensometer is due to Mesnager.

A photoelastic laboratory for the investigation of engineering stress problems was first started by the Research Laboratory of the General Electric Company, in Schenectady, N. Y., and later developed by co-operation between the General Electric Company and the Massachusetts Institute of Technology. In this laboratory, under the direction of A. L. Kimball and the author, with the collaboration of T. H. Frost and other associates[12], a series of problems have been investigated which were submitted by various departments of the General Electric Company, and other industries. The apparatus of E. G. Coker were redesigned in order to adapt them to investigations for the more complicated stress distributions. L. N. G. Filon's method was put into use, by means of which the state of stress for all two dimensional elastic stress problems can be determined from the isoclinic and the isochromatic lines only, thereby eliminating the difficult measurements of transverse change in thickness by means of a lateral extensometer.

Definition of the State of Stress

Let us consider at any point A inside of a loaded elastic body a small plane surface. A resultant force F will act on this surface of area a and the resultant stress across this plane will be $\frac{F}{a}$. In general it will not be normal to the surface A. However, there exist at each point in the case of the plane stress two orientations for those surfaces where the resultant stress is normal to the surface. Those two surfaces are normal to each other and are called the planes of principal stress at point A. The resultant stresses on the planes of principal stress are the two principal stresses at A. Lines tangent to the directions of the principal stresses at all points are the lines of principal stress. The maximum principal stress at any point is the maximum normal stress at that point.

The component of F in the plane a is the shearing stress. It is zero in the planes of principal stress, and is a maximum in the planes bisecting the planes of principal stress. The magnitude of the maximum shearing stress is equal to one-half the difference of the two principal stresses.

The normal component S_n of the stress on any plane whose direction cosines are l and m with respect to the planes of principal stress, is given by:

$$S_n = l^2 p + m^2 q$$

where p and q are the values of the two principal stresses.

Knowing the principal stresses, the deformations in any direction are obtained by means of the stress-strain relations.

It is therefore seen that the directions and the magnitudes of the principal stresses at any point A define completely the elastic state at that point.

We shall now describe shortly how the directions and magnitudes of the principal stresses are obtained by means of the photoelastic method in the case of two dimensional stress.

Resumé of the Photoelastic Method

The directions of the principal stresses are obtained by examining the transparent model by means of plane polarized light. Indeed if plane polarized light is first passed through a stressed transparent model, normally to the plane of the two principal stresses, and afterwards through a second Nicol prism, whose principal section is perpendicular to the principal section of the polarizing prism, the field remains dark only at those points where the principal stresses are parallel and perpendicular to the principal sections of the crossed Nicols.

By rotating the Nicol prisms, the directions of the principal stresses at all points of the model are obtained and the lines of principal stresses can be readily drawn.

The differences of the two principal stresses are obtained by examining the transparent model by means of circularly polarized light. Indeed mechanical stresses cause the model to become double refracting and the isochromatic bands which are obtained when polychromatic light is used, are the loci of the points of equal relative retardation of the ordinary and extraordinary rays in the double refracting model. They are the loci of equal values of the differences of the principal stresses. By a compensation method, based upon the interposition in a suitable direction of a comparison member of constant cross-section, put under uniform tension in an appropriate frame, the value of the differences of the principal stresses is obtained at any desirable point of the model.

Figure No. 3.—The Loading Frame Designed by Heyman & Frost for the Comparison Member in Heyman's Photo-elastic Apparatus.

The separate values of the two principal stresses at any point are then derived from the following relations:

$$\frac{\delta p}{\delta s_1} + \frac{p-q}{\rho_2} = 0$$

$$\frac{\delta q}{\delta s_2} + \frac{p-q}{\rho_1} = 0$$

where s_1 and s_2 are arcs taken along the lines of principal stress corresponding to the stresses p and q respectively, and f_1 and f_2 are the radii of curvature of the two lines of principal stress. These equations can be readily obtained by expressing the equilibrium of a curved elementary rectangle bounded by four near lines of principal stress.

By integration along the lines of principal stress, we obtain:

$$p = p_0 - \int_0^A \frac{p-q}{\rho_2}\, ds_1$$

$$q = q_0 - \int_0^B \frac{p-q}{\rho_1}\, ds_2$$

Figure No. 4.—Pinions Ruptured by Radial Pressure Applied at the Bore.

where ρ_1 and ρ_2 are known from observation under plane polarized light, $(p\text{–}q)$ from measurement under circularly polarized light.

The separate values of the two principal stresses can thereby be obtained at any desirable point of the model.

Relation between the Stress Distribution in a Transparent Model and the Actual Structure

The linear reduction of dimensions and load is a matter of common practice and will not be discussed here. The more special question which arises is whether it is legitimate to compare the stress distribution which has been determined on a celluloid model with that existing in a homogeneous engineering material.

It will be remembered that the theory of elasticity is based upon three postulates, namely:

1. The material is isotropic, i.e. it has the same elastic properties in all directions.
2. The deformations per unit length are sufficiently small so that the square of any of them can be neglected when compared to the first power value.
3. The material obeys Hooke's law of linear proportionality between stress and strain.

The stress distribution in all materials which fulfil the above three conditions obeys the general equations of elasticity. Now, it can be shown by means of those equations that the stress distribution is independent of the elastic constants of the material, i.e. independent of the nature of the material, in the general case of plane or two dimensional stress. Hence the stress distribution determined in a celluloid model, — celluloid satisfying the three conditions given above, — is the same, — all other things being equal, — as the stress distribution existing in any structural material which is isotropic,

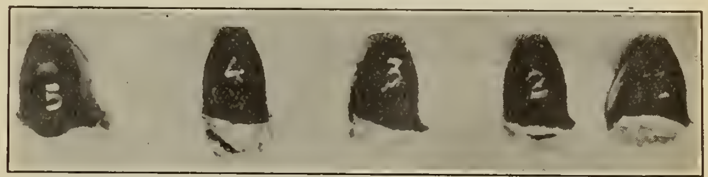

Figure No. 5.—Fractured Teeth of a Series of Pinions Tested by Repeated Compact.

Tooth No. 1 shows a fracture without radial pressure.
Tooth No. 2 shows a slightly convex fracture of a pinion having a radial pressure resulting from forcing a plug into the bore with a load of 5,000 pounds.
Tooth No. 3 shows a gear tooth having double the radial presure of Tooth No. 2.
Tooth No. 4 shows a tooth broken from a pinion having a radial pressure five times that of Tooth No. 2.
Tooth No. 5 is a tooth broken from a gear having eight times the radial pressure of Tooth No. 2.

Figure No. 6.—Example of a Service Fracture Resulting from very high Radial Stresses.

presents small deformations per unit length and obeys Hooke's law. Only the reduction of dimensions and of the external load have to be taken into consideration.

Some Recent Investigations by Means of the Photoelastic Method

A study of the stresses in gear pinions was first started under static loading. The stress distribution after the pinion has been shrunk on to the shaft was first examined. For the calculation of those stresses, the pinion is usually considered as a ring whose outside diameter is the average between the root and the outside diameter of the pinion. The radial and tangential stresses rr and $\theta\theta$ at a point r from the center, are calculated by means of the relations

$$\left.\begin{aligned} rr &= p\frac{r^2_1(r^2-r^2_2)}{r^2(r^2_1-r^2_2)} \\ \theta\theta &= p\frac{r^2_1(r^2-r^2_2)}{r_2(r^2_1-r^2_2)} \end{aligned}\right\} \qquad (1)$$

Where r_1 and r_2 are the inside and outside diameters of the ring and p the uniform radial pressure applied at the inside boundary, the stresses resulting from the relations (1) for a pinion will be smaller than those for a ring whose outside diameter would be equal to the root diameter of the teeth of the pinion, and greater than those for a ring whose outside diameter would be equal to the outside diameter of the pinion, for same values of p. The photoelastic analysis showed that the maximum stress in the pinion was greater than either of the above stresses. This is due to the irregularities of outside contour formed by the teeth, which cause a non-uniform stress distribution and result in regions of higher stress.

Mechanical rupture tests by means of radial pressure subsequently carried out on steel rings and pinions, are recapitulated in the table below and are confirmatory of the photoelastic results.

	Inside diameter (inches)	Outside diameter (inches)	Root diameter (inches)	Rupture load* (lbs.)
Ring...........	1.854	3.5	...	85,000
Ring...........	1.854	2.5	...	51,000
Pinion.........	1.854	3.5	2.5	47,000

*Axial load applied to the conical plug forced into the conical bore of the rings and pinions.

The photoelastic analysis also showed that the maximum stress existed at the periphery of the bore beneath the teeth. Consequently, it was expected, contrary to ordinary expectation, that rupture would start at the inside periphery under the teeth and would not occur through the thinner layer of material between the teeth. Figure No. 4 shows pinions, ruptured afterwards in mechanical tests.

The stress distribution under the simultaneous application of radial shrinking pressure and static torque applied at the teeth was also studied. It was found that the stress distribution across the root sections of the teeth cannot be approximated by the cantilever formula but presents variations which depend on the shape of the teeth and the relative value of the torque and the shrinking pressure.

When the shrinking pressure is small, the section of maximum stresses runs linearly across the root section of the tooth and failure would be expected to present approximately a flat section. As the ratio of the shrinking pressure to the torque increases the section of maximum stresses takes the form of a V, whose apex is directed towards the bore and whose aperture decreases as the above ratio increases. If the torque is very small compared to the radial pressure, the section of maximum stresses runs radially as illustrated by the ruptures shown in figure No. 4. Mechanical rupture tests were made and figures Nos. 5 and 6 show a series of ruptured teeth for increasing ratios of the shrinking pressure to the torque.

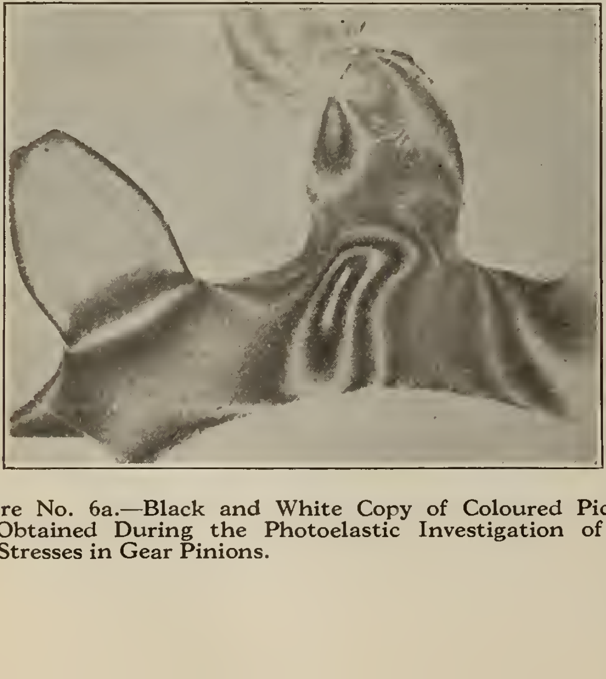

Figure No. 6a.—Black and White Copy of Coloured Picture Obtained During the Photoelastic Investigation of the Stresses in Gear Pinions.

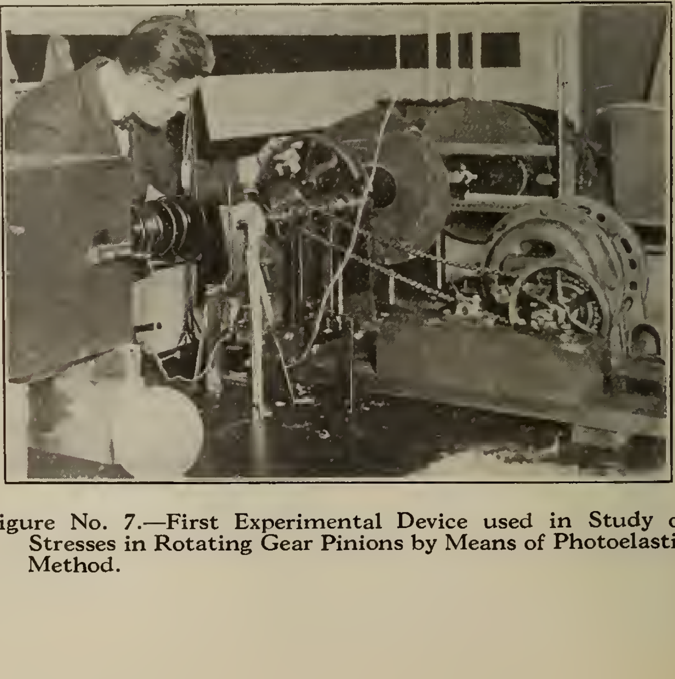

Figure No. 7.—First Experimental Device used in Study of Stresses in Rotating Gear Pinions by Means of Photoelastic Method.

Figure No. 8.—Later Experimental Device used in Study of Stresses in Rotating Gear Pinions by Means of Photoelastic Method.

The question having also arisen if dynamic stresses of a vibratory nature might not be more important in rapidly rotating pinions than the stresses solely due to shrinking pressure and constant torque, the photoelastic study was extended to rotating pinions. By means of a repeated electric spark, which is made to synchronize with the passing of the pinion at every revolution through the same position, a stationary image in the photoelastic apparatus of the moving pinions is obtained. Moreover, for speeds exceeding 700 revolutions per minute, the image perceived by the eye becomes continuous.

Figure No. 7 shows the first driving device used for applying a known torque to the pinions, which could be rotated at speeds up to 1200 r.p.m. It was found that the maximum stress increased with the speed but the interpretation of the results was not possible due to the mechanical complication of the driving and driven devices. A new set-up was built consisting of two identical halves which each comprise one electric motor (driving end) or generator (driven end), one steel shaft, one celluloid pinion. These apparatus are shown in figure No. 8. The stresses for speeds up to 2200 r.p.m. are being investigated at present.

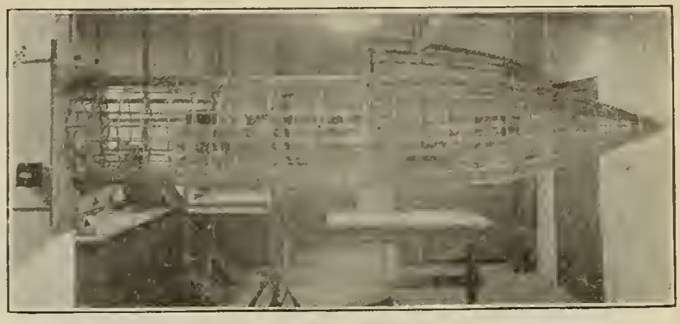

Figure No. 9.—Celluloid Model of the Frame Structure of the U. S. S. Shenandoah.

As recent investigation by means of the photoelastic method, a study of the stresses in the frame structure of the rigid airship U. S. S. Shenandoah should be mentioned. The complication of the frame structure of the ship is such that unusual difficulties accompany the calculations of the stresses in the different members. Approximately a 1/30 full size celluloid model of the structure was built as closely similar on the point of view of stress distribution to the full size structure. Figure No. 9 is a photograph of the model on which extensive measurements of the stresses were made.

Except for Mesnager's investigation of the stresses in the La Balme bridge, at which time he developed the photoelastic method, it seems surprising that occasion does not seem to have arisen as yet to apply the photoelastic method to any important problem of bridge construction. A great number of stress problems of different nature have been and are under investigation at present for industry. The results of the majority are not our property and information cannot be divulged.

Let it, however, be said that seldom has so powerful a tool for the determination of the stresses actually existing in engineering structures become available, and that a more extensive use of it to problems of structural design could hardly be too strongly recommended for the purpose both of safety and economy.

Discussion on Generation of Explosive Gases in Electric Water Heaters and Boilers

Discussion of paper presented by J. W. Shipley, Assistant Professor of Chemistry, University of Manitoba, Winnipeg, Man., and A. Blackie, National Testing Laboratories, Winnipeg, Man., before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

Messrs. F. T. Kaelin, M.E.I.C., and H. W. Matheson

Messrs. Kaelin and Matheson remarked that this paper dealt with experiments connected with the investigation of the explosion of an electric water heater used to heat a house in Winnipeg. One of them had had the opportunity of being present at the examination of the exploded water heater, and had found no direct proof that the accident was due to an explosion of gases, as it might have been due to the faulty installation of the piping leading to the expansion tank. The piping to the expansion tank in this case was much too small to take care of any extraordinary shutting off of heating requirements. The explosion, therefore, might have been caused by a sudden increase in pressure which would rupture the flat steel top of the heater and the explosion would then be due to the sudden evaporation of the heated water under pressure. Furthermore, the heater in question had only been running for a period of five days, and with normal production of hydrogen from such a heater there would be insufficient hydrogen and oxygen formed in the system during this time to give an explosive mixture.

They admitted, however, apart from these considerations, that an electric water heater operated under the conditions outlined in this paper would be unsafe, unless precautions were taken to vent the non-condensable gases. This might be done readily and by the installation of a valve at the top of the boiler and at a suitable distance from the heat, such that when the valve became cold it automatically opened, and again closed when heated by the escape of steam. The design and use of such electric water heaters was a field, however, in which they had no experience.

With reference to the formation of hydrogen and oxygen in electric steam generators, the authors in their paper had merely stated the facts that hydrogen and oxygen were formed, and that they were explosive under certain conditions. In the account of their experiments the authors gave no information regarding the current density used on their electrodes, which was one of the most important features in the control of the formation of non-condensable gases.

Determinations of hydrogen and oxygen in the original installations at Shawinigan had shown the hydrogen to run as high as 15 to 30 parts per million of steam. It had since been found, however, that this could be greatly reduced by modifying the electrode design and by controlling the current density used, which preferably should not rise above ¾ ampere per square inch. It had been found important to design the high tension electrode in such a way as to give as even a distribution as possible of the current over the whole area. A large percentage of the steam was formed on the high tension electrode surface, due to the large voltage drop at this point, with the consequent formation of a steam envelope over the surface of this electrode, particularly when this consisted of a cylindrical tube. This tended to cause a high current density at the base of the electrode, which gave rise to arcing. A new design of electrode consisted of a series of conical frustra placed in such a way that the steam passed up through the centre of the inner high tension electrode and away from the path of the current. This gave a more uniform distribution of the current over the whole electrode. With this design of boiler at the Belgo Paper Company's plant, a series of five tests had been made, with an operating load of 25,000 k.w. and current density of from .5 to .75 amperes per square inch, and the average hydrogen given off as shown by the five tests made had been 0.7 parts per million, which was practically as low as given in a coal-fired boiler. The boiler had been operated on 60-cycle power. It might be stated, however, that it was found difficult to maintain this low percentage of hydrogen in the steam, having in mind the various conditions under which the boilers operated in various parts of the country.

In general it might be stated from the results of a series of experiments carried out in a glass boiler, that the hydrogen and oxygen formation was due to arcing in the water, and by "arcing" was meant not a power arc, but an arc extending from the high tension electrode to the water particles. This experimental boiler had been arranged so that the voltage could be readily controlled and the arcing was visible, and in all cases this showed that when no arcing occurred the hydrogen averaged from one to four parts per million of steam, but as soon as arcing started the hydrogen jumped very quickly from the above mentioned amount to an amount of the order of 100 parts per million, but this latter amount depended upon the intensity of the arcing. The important points, therefore, to be concerned with in the use of electric steam generators were the proper control of the current density, to avoid arcing by the proper immersion of the electrode, and the correct withdrawal of the impure water from the base of the boiler.

With reference to the origin of the hydrogen and oxygen, it should be mentioned that the hydrogen is only formed in quantity when arcing takes place, and it would seem that the gases are formed by the thermal decomposition of water vapour at the temperature of the arc, the gases being suddenly cooled by the surrounding water which prevents their recombination. On the other hand, there was a possibility that arcing would cause rectification and consequent electrolysis, but so far they had been unable to get any evidence in support of the latter contention. In the steam from an ordinary coal-fired boiler the amount of hydrogen varied from .3 to 1.5 parts per million of steam, and they would expect this amount to be formed in the electric boiler from the same cause, namely; the reaction of steam on iron.

Their experiments confirmed certain of those cited by the authors in that the oxygen occurred in the non-condensable gases in a lesser proportion than would be expected from its formation from water. Their experiments, however, proved that in the normal operation of a boiler without arcing this oxygen largely disappeared, not because it attacked the iron of the electrodes, but because it oxidized the organic impurities in the water. To confirm this, they had analyzed the sludge accumulating in the base of the boiler and had found only a very small percentage of iron present. The oxygen disappearing might, of course, vary with the organic content of the water used. If, however, the boiler was operated under such a condition that arcing occurred, then the electrodes would be attacked, due to the formation of colloidal iron. Any serious loss of electrode weight would, therefore, indicate arcing in the boiler.

With reference to the danger of explosion in buildings or establishments heated by steam from electric boilers, in their experience they had seen little or no danger in this connection, and would mention that no further explosions had come to their knowledge. The electric boiler business had grown to large proportions, so that at the present time in Canada and the United States boilers of a total capacity of 400,000 k.w. were installed. In manufacturing establishments where steam is utilized, the small amounts of hydrogen in the gases did not, of course, cause any danger unless they were allowed to accumulate in some portion of the system where they might be ignited. In ordinary manufacturing establishments this was impossible, since the hydrogen was swept on through the heaters with the condensate and the non-condensable gases were vented in the hot-well. In the case of public buildings the same held true. The hotel at Shawinigan Falls had now been heated with an electric steam generator for three years, the gases in the radiators had been analyzed several times and practically no hydrogen had been found present in any case.

Mr. E. V. Caton, M.E.I.C.

Mr. Caton remarked that the authors were to be congratulated upon researches into a new field. The question of electrolysis by A. C. currents was one which had not been very widely investigated and also was one that had not appealed to the industrial world. With the use of electric boilers and other types of submerged electrode heaters it had, however, become one which was worthy of careful study, and the researches of the writers had indicated that considerable work yet remains to be done.

No definite conclusion could be arrived at, either as to the conditions which tend to produce gases by electrolysis or the means for preventing these. That the paper itself conclusively proved that explosive gases are generated in boilers operating with submerged electrodes could not be denied, but that these gases are a source of danger must not be taken too seriously.

The quantity of gases actually evolved as a proportion of the steam generated was extremely small, and, provided proper precautions were taken to prevent the trapping of these gases and the ignition by spark or arc, the danger was practically negligible and was no more than is usual in the operation of any high pressure power boiler.

The boiler which exploded was of such a design as to trap all the gases generated, which accumulated in the electrode chamber. There was a strong possibility of an arc being drawn between the electrodes and the water surface at light loads, and from experience now available he did not believe that a design of this nature would ever be made again. Whether the explosion had been due to gases was, of course, impossible to state definitely. An inspection of the boiler after the explosion and an examination of the damage done indicated that the explosion was of a very severe nature, and assuming that the initial explosion had been due to gases, the subsequent occurrence would, of course, be the same as if the boiler had exploded by steam. A steady rise in steam pressure would, in all probability, have shown itself by the bursting or breaking of some of the auxiliary apparatus rather than the boiler. However, this matter had been very fully threshed out at the time and no definite conclusion could be arrived at.

Mr. J. W. Sanger, A.M.E.I.C.

Mr. Sanger remarked that his close connection with the authors' investigations on the generation of explosive gases in electric boilers prompted him to stress the object of the research. Although the explosion of an electric boiler, from some cause which could not be established, was the reason for giving the subject serious consideration, the scope of the enquiry was confined to qualitative and quantitative studies of the oxygen-hydrogen gases generated and the possibility of their accumulation in the boiler, or at some remote point in a heating system attached thereto.

He believed that certain definite conclusions must be accepted, the most important of which were as follows:—

(1) Hydrogen and oxygen are generated in all alternating current electric boilers and are combined and proportioned in such a manner that they can be ignited—provided that the type of boiler and the operating conditions are of a certain character.

(2) Oxygen-hydrogen gas mixture in large quantities has been found in commercial steam heating installations. Samples of this gas have been withdrawn and exploded.

(3) The dilution of the explosive gas mixture with steam or carbon dioxide does not seem to prevent its ignition.

(4) In an electric steam boiler, if there is no place where the gases can separate themselves from the steam and collect in large quantities, there is no danger.

(5) There is no conclusive proof to show that the explosive gases are generated by electrolysis.

(6) There is no danger if the mixture of explosive gases and steam always exists in the proportion in which they are generated.

He was of the opinion that future research should be conducted with the main object of finding out how the gases are generated, as this would lead most quickly to the development of preventative measures. Some observations showed that high current-density at the electrode had a marked effect on the rate at which the gases are generated. Other observations showed that the relation between the quantity of gas and the current-density is by no means constant. In fact there were good grounds for believing that the explosive gases are generated from steam and not from water, which would upset the electrolysis theory altogether.

Electrode current-density was not as easy to control as might be imagined. While the average current-density on an electrode surface could easily be fixed, there were sure to be a number of "hot spots" at the point of contact between the surface of the water and the electrode. Experience had shown that these "hot spots" may increase local potential stresses in such a manner that they ultimately develop into short circuits.

In concluding he would recommend that investigators resist the natural desire to conduct their researches with high current-density electrodes. Current-densities of less than one ampere per square inch would give more consistent results, and would eliminate a number of peculiar conditions which accompany high current-densities.

Mr. W. P. Dobson, M.E.I.C.

Mr. Dobson remarked that in the type of heater considered in this paper, the water is used as the conducting medium. The case of the heater should, therefore, be grounded in order to eliminate the possibility of shock. This was especially important where the heater may be used for domestic water heating, as serious injury might result from a shock of as low a voltage as 110. If higher voltages were used, this precaution became even more necessary.

Mr. H. L. Sanborn

Mr. Sanborn remarked that doubtless the primary cause of the Winnipeg explosion, wherein an electric boiler used for heating purposes wrecked a house, could be directly traced to the use of a closed system, allowing explosive gases to collect over a period of time and ultimately being subjected to an arc or spark resulting in the explosion. This danger of a closed system was now generally recognized.

He did not consider that the data in this well written paper were applicable to the present comparatively minor use of electric water heaters, but rather to the larger use of surplus hydro-electric energy in the form of large blocks of power in electric steam generators.

This paper of Messrs. Shipley and Blackie, dealing with the subject only in general terms, while proving pretty conclusively that explosive gases in fairly large quantities are formed by the generation of steam from electricity, did not make any specific recommendation as to how this condition ought to be remedied; or whether or not it may be safely controlled.

The paper was well timed, however, coming, as it did, shortly after the pioneer application of 13,000 volts to electric steam generation by the Abitibi Power and Paper Company, whose first unit of a 20,000 kw. Kaelin single-phase three tank electric steam generator had been placed in operation December 2, 1925, to be followed by a second duplicate unit, and a third three-phase 13,000 volt 20,000 kw. single tank Canadian General Electric unit, a total of 60,000 kw. Prior to this 6,600 volts had been the usual voltage in commercial use, and for the past four years had been successfully employed by the Laurentide, Shawinigan, and Price Bros. companies, without hydrogen explosions.

With regard to the data presented, there was no doubt about the correctness of the theory of electrolysis by single-phase alternating current, especially at 25 cycles.

It was interesting to note that hydrogen was no newcomer in coal-fired steam mains but could, and did, form by the action of steam on iron. It followed that in meter piping, hot wells, paper machine dryers and other places wherein hydrogen might be trapped, this situation had actually been prevailing since the advent of the use of steam, but that vents and natural neutralizers had prevented the fact from being generally recognized.

Moreover, since combustion was impossible except with sufficient oxygen present to support it, a logical conclusion would be to evacuate the oxygen from any and all sources, and if this were done, explosion or combustion of the other gases formed would be quite impossible.

It had also been proposed to deactivate and deaerate the feed water before its entry into the boiler, thus removing to a large extent both the air in the water and the oxygen previously absorbed by the water.

If, as is usually the case, the feed water contained free CO_2 and bicarbonates, the CO_2 was usually somewhat increased by this pretreatment, and being an inert gas, the dilution of the gaseous mixture evolved would be somewhat greater, so that the limits of inflammability of the mixture would be narrowed considerably. This was shown in the paper, where in one test carbon dioxide made non-explosive a gas mixture containing 34.5 per cent of hydrogen.

The next point was that if hydrogen were present in combination with sufficient oxygen to cause combustion, and if the ignition temperature of hydrogen were from 1076 to 1094 degrees Fahr. it would be reasonable to assume that ignition could only be caused by the presence of an arc; apparently no amount of increase in compression of the hydrogen would cause it to reach a sufficiently high temperature to ignite spontaneously, because the hydrogen being in the presence of steam would be in or nearly in thermal equilibrium with the steam.

It was considered safe to assume, from the observations so far made on the first electric steam-generator at Iroquois Falls, that when delivering steam at the approximate rate of 62,000 lbs. per hour, the liberation of hydrogen with the steam as produced was so rapid that any explosion in the three single-phase 20,000 kw. tanks was impossible.

Tests were being carried on at various points in the distribution system, but these had not yet advanced to such a point as to be checked and used at this time.

Would it be possible, after removing most of the oxygen in the feed water, to instal some form of absorption apparatus on the main header of the boiler for the purpose of removing oxygen mixed with the steam? For example charcoal would absorb approximately 9.25 times its weight of oxygen, and the oxygen was capable of being removed by means of a vacuum pump; it had also been suggested that an alkaline solution of pyrogallol would absorb oxygen, but this was doubtless not an economic possibility.

It appeared that lime, $Ca(OH)_2$, could be added to our feed water, somewhat preventing corrosion of the electrodes, also decreasing scale, and greatly decreasing the amount of hydrogen liberated.

The current density should be properly maintained.

What would be the rate of evolution at variable voltages?

The paper stated that the accumulation of gases in radiators or other cooling parts of a system provided with steam from an electric boiler, must be considered extremely hazardous — should this statement not be confined to small heaters for domestic heating purposes and was it applicable to power plant steam from large electric steam generators?

Would the authors state, from their experiments, what they would consider the relative hazard as between the three shell single electrode type of generator and the single shell three electrode type, operating on a three phase system 12,000 volts, using ground plate, the capacity of the generators compared being at least 10,000 kw.?

The paper indicated that the addition of salts to the electrolyte increased the amount of oxygen and hydrogen gases given off at the electrodes; it could, therefore, be deduced that the greater the proportion of condensate used in an electric boiler, the less of those explosive gases would be given off at the electrodes; was it not therefore advisable to run such boilers with as much condensate as possible, and thus produce a minimum quantity of hydrogen, rather than to use raw water and get a large volume of hydrogen while depending on the gases dissolved in the raw water to reduce the violence of the explosion?

Did the authors not consider that their experiments were carried out in too small a scale to render their conclusions applicable to electric steam generators of large capacity, and that with a more systematic investigation as to the proper working conditions, an electric boiler could be built, such as were now in service or were now being installed, which would be just as safe as a fuel fired boiler? Did the authors believe that the generation of steam using water as a resister would always be accompanied with the danger of an explosion? While appreciating the full worth of the facts as outlined in the paper as a general summary of dangers to look for and prepare against, he felt that the problems involved in the design and operation of electric steam generators could be solved with resultant safety and efficiency.

Mr. C. E. Sisson, M.E.I.C.

Mr. Sisson remarked that the paper when read without reference to other data gave a somewhat alarming impression, quite out of proportion to any possible danger that might exist, at least in the case of electric steam boilers, a large number of which had been in operation for some time without giving any trouble. Of course, the accident which took place in Winnipeg could not be ignored, but it had not been definitely determined, so far as he was aware, that the explosion was caused by ignition of gases generated within the heater.

The experiments of the authors showed that the amount of hydrogen generated in an electric steam boiler was dependent upon the material used in the electrodes and the amount of current passed or the current density of the electrodes. It had also been found with electrodes of certain composition that the liberation of gases was very much decreased after the boiler had been in operation a considerable time.

With the proper design of boiler it had been found that for every cubic foot of water evaporated there is formed 0.002 cubic foot of hydrogen measured at atmospheric pressure. One cubic foot of water, however, gave 1687 cubic feet of steam measured at normal pressure, so that the ratio of the volume of hydrogen and the volume of steam would be one to 840,000. As the addition of only twenty parts of air to one part of hydrogen was sufficient to prevent an explosion of the latter, it would be seen that 840,000 parts of steam diluted the hydrogen so far that the possibility of explosion was too remote to be considered.

He believed that the hydrogen mixtures which collected in radiators, traps, etc., on condensation were not explosive mixtures of the first magnitude as the authors had stated. Owing to the fact that air and carbon dioxide are liberated along with and in relatively larger quantities than the hydrogen, these mixtures must not be considered as composed of pure hydrogen and pure oxygen but should be classed with hydrogen-air mixtures. The most explosive mixture of hydrogen and air was composed of one part hydrogen to 2.4 parts air and the maximum theoretical explosion pressure of this mixture is 102 lbs. per square inch gauge (Kratz and Rosecrans — University of Illinois Bulletin No. 133, page 52).

Practically no pressures greater than 95 lbs. per square inch gauge had been recorded. Increasing the hydrogen or increasing the air lowered the explosion pressure. The 9 per cent hydrogen mixture, which, as the authors point out, may collect on condensation of steam, would fall far short of an explosion pressure of 100 lbs. per square inch, and certainly therefore should not be put in the class with high explosives. However, one had a somewhat uncomfortable feeling on realizing that it was possible to have a more or less explosive mixture in radiators, etc., and due caution should be taken for venting these in the same way as is desirable and necessary in the case of their being supplied from a coal-fired boiler.

Discussion on the Fuel Problem in Canada

Discussion of paper presented by Lesslie R. Thomson, M.E.I.C., Consulting Engineer, Montreal, before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 29th, 1926.

Mr. G. R. Pratt, A.M.E.I.C.

Mr. Pratt remarked that from the point of view of history and statistics Canada's coal problem was excellently put by the author, but that from the point of view of an engineer his paper seemed lacking in constructive effort.

The following main facts had been brought out:—

1. Canada has 16 per cent of the world's coal, which is sufficient, if used, to place Canada in a position independent of any other nation as regards fuel.

2. Canada has a coal industry in the East with ample coal reserves to supply a large part of Canada's fuel requirements, but it is in an insolvent condition because it cannot sell its coal at the going price in the market (not because there are no markets).

3. Canada has a coal industry in the West with unlimited coal reserves which could supply the whole of Canada's fuel. The factor which prevents this is not the price of coal at the pit, but the cost of transporting it to the place where there is a market.

4. Canada has an industrialized area in Central Canada with no coal within its borders, which at the present time is purchasing its fuel from its manufacturing competitor.

5. Due to the present over production of coal by this competitor, and due to inequality of laws which permit of dumping the surplus coal, Central Canada is obtaining coal at very low cost.

6. That apparently the life of this industrialized area depends upon a continuance of the supply of coal from its competitor.

Why were the coal reserves referred to in item (1) always considered as a valuable resource if they were to be outlawed on account of their location? If these coals were not to be used, they merely locked up capital which might be used to better purpose elsewhere.

Referring to items (2) and (3) he was of the opinion that under the present rates for transportation the markets for Canadian coal could not be extended to any great extent, and that no rate which will include all the so-called costs of operation would permit of moving Canadian coal over long distances.

The railroads insist that it is their right to establish rates which will cover the cost of operation and show a profit, regardless of the effect of such a rate on the activities of others. Canada should insist that the railroads make full use of their equipment. Instead of holding idle equipment in waiting for high priced freight, any non-competitive freight would be profitable. The movement of coal could be made from east and west into the central area, pay the cost of movement as compared with keeping the equipment idle, and permit of the coal meeting foreign competition.

As regards the supply of Central Canada, a study of public statements made across the line warranted the belief that the American supply would not always be given so freely as at present.

Industry in Central Canada would at some time have to face a condition of embargo on United States coal, or a gradual movement of Canadian industry to coal districts in Canada.

The author had stated that the members of the E.I.C. Fuel Committee were unanimous in their findings. If the minutes of the various meetings were gone over it would be found that the Western members objected very strongly to the local viewpoint of the investigation and insisted that the investigation of fuel conditions should be on a national basis.

With regard to the work of the Dominion Fuel Board, the scope of this board should be extended to the solving of the fuel problem upon a national basis and should include the marketing problems of both East and West.

Too much attention had been given to the need of converting the raw coal into coke, for this idea was not economically sound unless the coke were to be considered as a by-product to some other commodity obtained from the raw coal.

He questioned the desirability of establishing coking plants solely for the purpose of making domestic coke with Nova Scotia coal, unless there were a profitable market for the by-products.

Mr. James McEvoy, M.E.I.C.

Mr. McEvoy remarked that the author had approached the fuel question with direct honesty of purpose, free from any local self-interest, and had not allowed national sentiment in the matter of the origin of our fuel supply to obscure his vision of what was really best for our national welfare.

The author had used the expression "metallurgical coke", probably in contra-distinction to gas-house coke. However, the coke considered by many persons as the best kind for domestic fuel was neither gas house coke, nor was it suitable for metallurgy. It was a coke similar to metallurgical coke but allowed to retain a small amount of volatile matter, say up to as high as 5 or 6 per cent. This coke could be produced by moderately low temperature coking, but that method was slow and the throughput correspondingly low. In high temperature fast coking the difficulty was to get a uniform grade and avoid loss by crumbling of portions of the charge which had not firmly cohered.

It would be useful if we had a name for such fuel to distinguish it from straight metallurgical coke.

Leaving coke fuel out of the question for the moment, the author brought out very clearly the difficulty of supplying Central Canada with all Canadian coal, on account of the long hauls. Whether a tariff on coal with a subsidy for long hauls would be a benefit to Canada in the long run or not was very debatable. It would undoubtedly give more employment and increase the prosperity in our coal mining communities, and it would give more tonnage for our railways. It would also, to the extent to which it became effective, retain in Canada a percentage of the money which was now sent out to purchase foreign coals.

On the other hand, however, it would inevitably increase the cost of living and of manufacturing, and as a consequence tend to reduce our export trade. The burden of tariff and subsidy would not be carried evenly by all the people of Canada, but a disproportionately large part of the burden would have to be carried by the individuals in the central part.

He believed that too much stress was laid upon the advantage of retaining in Canada the money which was now paid out for foreign fuel. The whole amount so spent was only about one per cent of the total amount of our exports. The disturbance of trade by increased cost of living and manufacturing might easily cause a reduction in exports of several times that percentage and leave the country as a whole much worse off than before such uneconomic experiment was attempted.

Perhaps we might venture to lay down as an axiom that only suitable coals of high calorific value should be transported for long distances. In cases where the transportation charge was the greater part of the price of delivery, there was no need of argument to prove the soundness of this axiom.

The author had given food for serious thought in pointing out the falling off in efficiency in the mines of Eastern Canada, similar to the decrease in the British mines, and in contrast the rise in efficiency in the Pennsylvania mines.

Mr. Frederick Burnett

Mr. Burnett remarked that the development of a "Made in Canada" substitute for Pennsylvania anthracite as a domestic fuel was of extreme importance, and that coke from bituminous coals imported from the United States, appeared at this time to be the only product worthy of serious consideration.

Even under the present exceptionally favourable circumstances for importation of coal from Alberta and Nova Scotia, these could not meet other available fuels of similar grade in price or efficiency in utilization. What could they hope to accomplish under normal conditions?

Importation of good grades of Welsh anthracite should be encouraged, as these coals had no equal as domestic fuel and were well worth the extra cost over American anthracite.

He pointed out that the Canadian public is now becoming educated to the high value of coke as a domestic fuel, when properly prepared and sized. Any Ontario company or utility which could produce coke for sale at a price per ton slightly lower than anthracite would be assured of a good market.

A partial solution of our domestic fuel problem in Central Canada would be attained if the existing gas utilities of the province of Ontario made all coal gas in place of manufacturing a very large volume of carburetted water gas, requiring large quantities of anthracite or coke and imported gas oil.

Why were these coal gas plants not installed? Because electricity for cooking and water heating had been sold at such low rates throughout Ontario that expansion of the gas utilities had been retarded, and they quite naturally feared to venture upon large capital expenditures when electric enthusiasts were everywhere predicting the eventual displacement of gas altogether by electricity.

The Dominion Fuel Board had seen fit to report that by-product coke ovens were the Alpha and Omega methods of producing domestic coke, but the fact remained that such installations could not be made profitable at any point in central Canada unless the chief by-product, gas, could be disposed of at remunerative rates, which was not possible, except at one or two points, by reason of the fact that other types of high temperature coal carbonization plant are available which show better financial returns than by-product coke ovens, in connection with gas supply.

It seemed to him unfortunate that the Dominion Fuel Board should not have investigated and included in their reports a study of the other types of high temperature carbonizing plant. Where comparisons were made between coke from coke ovens and from "gas retorts", the coke from the old fashioned horizontal retorts was the product used for comparison. That was somewhat unfair, as the later type gas ovens and vertical retort systems produced a most excellent domestic coke, without the imperfections in structure and variable physical properties which were inherent in coke made in the old style retorts.

To attain more freedom from dependence upon Pennsylvania anthracite the logical sequence of action appeared to be:

1. Import good grades of Welsh anthracite.
2. Promote the installation of coal gas plant to replace the carburetted water gas process now so largely in use at Ontario gas works, thereby increasing the available supply of domestic fuel.
3. Build coking plants wherever they can be shown to be commercial possibilities, and self-sustaining without government bonusing.

Professor R. W. Angus, M.E.I.C.

Professor Angus referred to the author's statement that "except in time of war, that coal will reach the consumer which, in the long run, is the most economical", and believed that the consumer would select the article which he thought best suited to his purpose, and which could be purchased for the least possible price. It should be remembered that the location of the coal beds was determined long before the international boundaries were established, and that there would always be a marked tendency for people to select coal from the nearest available source of supply, unless some economic reason prevented its use.

He thought that most householders were willing to pay an extra price for fuel that they could use without undue trouble, and from which they knew the type of results to expect. On the other hand the number of persons using coke and other substitutes for anthracite was increasing.

In the table on page 66 the author had made a very interesting comparison of the cost of coal in Toronto which came from various sources, showing that the cheapest bituminous coal used in the Toronto district was secured from the United States, the price of Alberta coal being high, even when the extremely small freight rate of $6.00 per ton was charged. There seemed to be little doubt that Alberta coal would have to bear, in the end, the exact cost of transportation, which would bring it up to a still higher price.

In the interests of economy he did not believe that our national railway should haul coal at less than cost, because that would put a burden on the people of Canada as a whole, for the benefit of a few who would get the benefit of the reduced rate.

He felt that under the present circumstances Alberta coal could not be economically used in Ontario.

Mr. A. W. McMaster, A.M.E.I.C.

Mr. McMaster remarked that the author had suggested Montreal as the limit of the Eastern section, but that the problem was really one of transportation and the transfer of coal from ocean-carrying vessel to lake carrying vessel. If the grain carriers could be induced to take coal on the return trip, he saw no reason why the differential of 50 cents per ton against American coal could not be overcome.

He also wished to give full credit to the Dominion Fuel Board for their investigations and study of this problem.

Referring to the author's curves showing that Nova Scotia mining costs had gone up where, on the other hand, West Virginia and Alberta coal costs had gone down, he desired to point out that 70 per cent of the present Cape Breton output came from submarine areas. Shafts could not be put any further out than on the edge of the ocean, and some of the workings were now 1½ miles from the shore. Under present operating conditions Cape Breton mines were producing about 22,000 tons per day, and without much capital expenditure the output of Nova Scotia coal could be increased to approximately 10,000,000 tons per year. He believed, however, that the peak cost had been reached and that costs were coming down. On the other hand, West Virginia fields were non-union, most of the mines were shallow, dry and non-gaseous, a condition which also applied to most of the Alberta coal fields. In both cases the problem of winning coal was easier than the problems facing the Eastern Canadian operator. This to some extent explained the difference in the curves referred to.

The author had mentioned the domestic fuel situation and referred to by-product coke as a substitute for anthracite and the building of coke plants in Toronto, Montreal and Ottawa, where the gas products could be taken care of with existing equipment. He had no doubt that coke as a domestic fuel was superior to the anthracite we were getting from the country to the south of us.

In regard to using bituminous coal for domestic purposes, he wished to point out that most of the people of the civilized world to-day were using it for heating, and the eastern provinces of our country had always used bituminous coal for heating their homes.

He looked forward to developments such that coke made from Canadian coal would replace anthracite, which is really a luxury fuel, for this purpose.

Mr. C. P. Hotchkiss, A.M.E.I.C.

Mr. Hotchkiss remarked that on account of his connection with the Dominion Fuel Board, and because of the fact that this question is being discussed by Parliament almost every day, he should not be expected to express any personal opinions.

He believed that what had been said regarding the attitude and work of the Board would perhaps indicate the difficulties of the Board's position in trying to keep in mind the welfare of the whole country, rather than being swayed by sectional interests. The national aspect of the problem must always be considered.

He would remind both the East and the West that the Board's primary object is to extend their markets and build up the coal industry of this country insofar as this seems possible in the best interests of the nation as a whole.

As regards the present situation, he was of the opinion that the strike in the anthracite fields of the United States had been one of the best things that could possibly have happened for Canada. Four or five years ago Central Canada normally consumed about 5,000,000 tons of American anthracite, and was wholly dependent on this fuel for domestic purposes. In 1924 we only consumed about 3,500,000 tons, and this year, 1925, we only brought in a little over 3,000,000 tons. He believed that we were saving a huge amount of money in being forced to turn to other fuels, and that the other fuels were just as good.

He thought that Mr. Pratt had cleared up another point, and that the general public were under a misapprehension as to just what our fuel problem was. We continually heard of the $100,000,000 or the $200,000,000 that were going out of this country for fuel. Mr. Pratt, he believed, had made the definite statement that we cannot hope to bring Alberta industrial coal into Ontario. We could get imported industrial coal in here at between $5. and $6. a ton. Complete fuel independence would mean replacing this coal by either Alberta, British, or Nova Scotia coal. A great many people thought when they urged a $7. freight rate for Alberta coal, that if such a rate were obtained, this coal would replace all the foreign coal that is now used in Ontario.

Mr. Jesse Gouge

Mr. Gouge remarked that he belonged to the Coal Operators Convention of Alberta, a body which is desirous of furthering the sale of Alberta domestic coal in the province of Ontario. He had been impressed with the fact that speakers in the discussion had so far sounded nothing but a note of despair on the subject of substituting Canadian domestic coal for the fuel ordinarily used in Ontario.

From his knowledge of the fuel situation as a coal operator of many years' experience, and from his association's experience in shipping fifty thousand tons of Alberta domestic coal into the province of Ontario, he ventured to prophesy that within five years there would be no anthracite problem in Ontario because Alberta domestic coal would be used there. He believed that Alberta domestic coal had every feature of desirability possessed by anthracite. It had cleanliness and absolute freedom from soot and dirt. The only objection raised against it was that it had not as many heat units.

The western domestic coal could be taken because of its quicker lighting, quicker heating, and ability to reduce the fire by an application of drafts, and it could be adapted to the necessities to such an extent as to save the extra amount of heat units wasted with anthracite coal because the fire could not be controlled.

He felt sure that with a seven dollar freight rate, Alberta coal would replace anthracite coal in Ontario. He did not discuss the problem from the industrial point of view because he did not think that there was a well posted coal operator in western Canada who believed that the time would ever come, short of an absolute embargo, when he could put his coal into Ontario on an economical basis and compete with American coal for industrial purposes.

In Alberta they desired the railways to take their coal at a rate which would pay the railways, and he was of the opinion that with a seven dollar freight rate the domestic coal of western Canada could come to Ontario and be satisfactory to the purchasers and to the coal dealers.

His mission was to see whether at this time, when there is a fuel shortage in Ontario, and when anthracite coal cannot be procured, the supply of Alberta coal cannot be enlarged and the rate of seven dollars per ton continued well on into the spring.

Mr. Thomson's Reply

THE AUTHOR, in reply, observed that he differed from Mr. Pratt, who had stated that American coal was dumped into Canadian markets. He ventured to disagree with this as a broad statement. That there had been some dumping was true, but that all American shipments to Canada are dumped was, in his opinion, not correct.

Nor did he believe that Mr. Pratt was correct in his statement that the Canadian railroads could handle a large share of the needs of Ontario if Alberta were to supply them. The railway members of *The Institute's* Fuel Committee had stated that 500,000 tons per annum would be about the amount which could be handled by the railways at present, unless large capital expenditures were made for new equipment.

It was not unreasonable to see an embargo upon the export of American anthracite coal, but to prophesy an embargo on the export of American bituminous coal was hardly justified in view of the immense quantities of the bituminous reserves.

The author wished to emphasize again that in the event of a considerable movement of coal from Alberta on a commercial or semi-commercial basis, the competing American coal in Ontario would not be anthracite, but would be some of the high quality low volatile bituminous coals. Hence he believed that the oft repeated comparisons of prices with American anthracite were misleading.

Mr. Gouge's remarks were emphatic but perhaps not so convincing to the author as to some others. Mr. Gouge prophesied a glittering future within five years in the acute fuel area, but the author doubted whether in the absence of new tariffs or bounties, the realization of the dream would be as rosy as Mr. Gouge believed.

The kernel of the whole question was as follows: The author believed that under the present condition of prices, tariffs, etc., Alberta coals could not compete at Toronto. If for national reasons it were desirable to become self-supporting in coal, then this could be done only by means of tariffs or bounties. This obviously would be a matter for governmental decision, but before such a decision could be given from a national point of view, it would be necessary to know the facts, to reach an intelligent understanding of them, and then lay down a competent national policy.

Discussion on Fuel Preparation and Treatment

Discussion of paper presented by J. L. Landt, Consulting Engineer, Buffalo, N.Y., before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 29th, 1926.

Mr. R. E. Gilmore

MR. GILMORE remarked that the terms "carbonization" and "coking", which were used by the author interchangeably, did not necessarily mean the same thing. Carbonization applied to the heat treatment of solid fuels in general, while the term coking applied more particularly to those coals, belonging mostly to the bituminous class, which on being heated without access of air, cake, melt or coalesce into a coke structure. The manufacture of metallurgical coke on the one hand and city gas on the other hand, had in the past been carried out by high temperature processes, and the fuel used had been restricted to high grade bituminous coals. In low temperature carbonization processes, as pointed out by the author, the prospect was that the poorer grades of bituminous coals and the lower grade non-coking coals may be used. The author mentioned three methods of utilizing the solid residue product of low temperature carbonization, viz.; as low temperature coke, a briquetted product, or as powdered fuel. In this connection it might be pointed out that for the non-coking coals, the carbonized residue or char would have to stand the extra expense of being briquetted to find use as a domestic or household fuel, as it could not very well be used for this purpose in the powdered state.

Good coking bituminous coals occurred in the Maritime Provinces and in British Columbia, while 70 per cent of the coal in Alberta, where was to be found the bulk of the country's coal, belonged to the non-coking sub-bituminous and lignite grades known as "domestic" coals. These non-coking Alberta coals were used extensively for household purposes and, inasmuch as they burned with a white or blue smoke, did not require carbonization treatment to render them smokeless as did the ordinary soft coals. With these coals carbonization followed by briquetting, where a pitch binder is added, failed in most cases to produce a household fuel superior to the lump coal or even the screened run of mine. Unless, therefore, the yield of gas and oil by-products were large, the inducements for carbonizing would not be promising.

In England low temperature carbonization supplemented the high temperature processes as an important factor in ridding the industrial centres of the smoke nuisance. There, where low temperature coke containing 7 to 10 per cent volatile matter is welcomed as an easily ignited open grate fuel, and is considered superior to the high temperature products with 1 to 3 per cent volatile matter, coke was being used as a substitute for smoky soft coals. Low temperature coke, however, was more friable, that is, more liable to crumble when handling, than the better grades of high temperature coke, and in Canada, at least for central Canada where coke is a substitute for anthracite, this difference should be kept in mind; the requirements here being for a properly sized, clean, dense and non-friable coke such as produced in by-product ovens.

He believed that the temperature range given by the author for the low temperature processes, namely 450° to 550° C. was low. While 550° C. was given by the eminent authority, Franz Fischer, as the maximum temperature of reaction to produce genuine primary tar, the carbonization temperature might, apparently, be as high as 700° to 750° C., that is 1350° F., without producing naphthalene, a characteristic constituent of high temperature tar. Low temperature tar contained the olefins, naphthenes and paraffin, as in crude petroleum, and also phenols, whereas in the high temperature product the typical coal tar aromatic hydrocarbons, namely benzol, naphthalene and anthracene, were evidently products of secondary decomposition above 750° C. of the primary tar constituents. Attention was constantly being drawn to the phenol content of low temperature tar, as giving such tar an enhanced value for creosoting purposes. When the cost of extraction and refining of these phenols to meet fairly stringent specifications was taken into account, the net value was not so promising. In England the low temperature tar oils are desired to mix with crude petroleum for use as fuel oil, and in Canada for some time to come there are many reasons for not counting on low temperature tar at higher than fuel oil value.

The author had mentioned that with non-fusible coals it is apparently possible to drive off the gases and oil vapours at a much faster rate than with fusible coking coals. This might be of interest when treating the poor coking bituminous coals and also the fines or slack of non-coking coals for use as powdered fuel as he suggested, but it had already been shown that where the moisture content is not excessive, the higher grades of these non-coking coals can be used directly as powdered fuel, which powdered fuel would have to be used locally for steam raising purposes. The briquetting of these fines without preliminary carbonization for shipment to outside points to be used either for steam raising or household use was a problem seemingly worth investigation.

As to the yield of methanol, the figure of 350 gallons per ton of coke was used. The authority for this yield was not given, and it would seem that the authors quoting Fischer's work are responsible rather than Fischer himself. Exact information as to the details of processes and the commercial quantities of coke and water gas used and also the commercial conversion efficiencies and yields of refined methanol, was not readily available. Assuming 13,000,000 B.t.u. as the heat in the water gas per ton of coke gasified, as used on page 96 by Mr. Landt in "Coke as a Household Fuel in Central Canada", and also assuming an 18 per cent loss in heat in the reaction $2H_2 + CO = CH_3OH$, as given by Fischer in his article "Liquid Fuels from Water Gas",* (page 574, June 1923), it was interesting to note the maximum yield of methanol possible, as follows:

Heat in water gas per one ton of coke gasified...	13,000,000 B.t.u.
Heat in methanol, allowing 18 per cent loss......	10,660,000 "
Calorific value per gallon methyl alcohol (8×9600)	76,800 "
Yield of pure alcohol (methanol) per ton of coke $\frac{10,660,000}{76,800}$ =............................	139 Imp. gals.

On these assumptions, the highest possible yield from a ton of (high temperature) coke would not exceed 140 (Imp.) gallons, equal to less than 100 gallons per ton of coal carbonized. No allowance for the coal or coke used in producing the steam to make the water gas had been made here, nor was the expense of carrying out a catalytic reaction under comparatively high temperatures and pressures taken into account.

Mr. Lesslie R. Thomson, M.E.I.C.

Mr. Thomson remarked that the author had stated in passing that German methods for the treatment of German coals were not necessarily a success on this continent, and he believed that that statement was eminently true. He would not subscribe to the idea that no German method is applicable to our coals, but knew, from many years investigation, that our sub-bituminous and lignite coals are of a different structure, and German methods can not be transposed wholesale for the successful treatment of them.

He agreed with Mr. Gilmore that 550° C. was not a fair figure to allow for low temperature carbonization, for a number of very clear low temperature results were obtained at from 600° to 650° C.

He desired to ask Mr. Landt if he had heard correctly when he stated that the very low volatile char would be suitable for pulverized fuel, especially in the cement industry.

He did not think, also, that Mr. Landt had given sufficient prominence to some very recent work that had been done on this continent. Might he recall the tremendous amount of money that had been invested in low temperature carbonization processes, and some of the troubles that that industry went through. He was permitted, by one of his correspondents in New York, to state publicly that they had been successful in the development of their retorts, one of which had operated almost continuously for 19 months with the original parts, shaft, etc., still in good condition, and at reasonable expense for power, repairs and fuel. Over half a million gallons of tar had been produced and sold. Coke produced prior to October 1925 had been sold as such; after that date it had been converted into briquettes and found a ready market. A simple, inexpensive system had been perfected for carbonizing briquettes, and completely eliminated the smoke forming properties of the pitch binder.

He thought that presaged a very important development in North America of low temperature work.

Professor A. G. Christie

Professor Christie remarked that Mr. Thomson had questioned whether low volatile coal could be burned in powdered form. He would mention that the Holtwood Steam Station of the Pennsylvania Water and Power Company is located at their hydro-electric plant on the Susquehanna river, which flows through the hard coal region of Pennsylvania and washes down large amounts of fine anthracite from the culm piles and from the washeries, so that quantities of this coal have accumulated in the back water above the dam at Holtwood. The steam station was designed to burn this recovered coal along with bituminous, and its powdered coal furnaces had successfully operated with as much as 100 per cent of such anthracite coal.

Mr. Landt's Reply

The Author, in reply to Mr. Thomson's question as to the applicability of the low temperature char after carbonization to pulverized fuel on account of its low volatile content and, therefore, short flame, remarked that he did not know exactly how far he was permitted to go in saying what the success of that application had been. There were one or two coals on this continent that he knew were really non-coking. When he said non-coking coals he meant coals from which a fuel is made which is unsuitable for use without further processing. The scheme to-day of a very successful installation was to grind the fuel to the fineness required before carbonization, and this was being done on quite a large basis, and on a practical scale. It was planned to leave between 8 and 10 per cent of the volatile matter in the coal.

*Industrial and Engineering Chemistry

Discussion on the Influence of the Modern Highway

Discussion of paper presented by W. A. McLean, M.E.I.C., Consulting Engineer, Toronto, Ont., before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 29th, 1926.

Mr. Geo. Hogarth, M.E.I.C.

Mr. Hogarth remarked that while Ontario had today a network of highways second to none, the motoring public and trucking interests were not confined to their own highways but passed freely over the splendid roads of adjoining provinces and states. The day of the mud road and difficult travel was drawing to a close and with it went the isolation so much felt in some sections. The resident of rural Ontario today thought nothing of driving 20 or 25 miles to the nearest town or city in order to enjoy an evening's entertainment and the main streets of our towns and cities were crowded with the cars of people from the surrounding country. Good roads everywhere encouraged our Canadian automotive industries, which had an investment of almost $61,000,000 and about 110,000 people directly or indirectly employed. The pay-lists of motor vehicle manufacturing concerns amounted to almost $15,000,000 per annum.

The large expenditures on road improvement had caused those responsible for the work to give the closest study to every phase of highway activity. The fact that certain methods and types of road construction were satisfactory yesterday was not accepted at all today. The contractor in buying new equipment did not buy the same model as the machinery he purchased only a few years ago. Rapid changes were continually occurring in methods and equipment. Buses almost over night had developed from a combination of the old bus body set on a discarded truck into a palatial, electric lighted, heated, cushion seated affair as comfortable as a Pullman car. The time honoured method of dragging a gravel road, by pulling over it a timber frame hitched to a team of horses, had been replaced by a motorized grader that could do almost three times the work of a team at a fraction of the cost.

Intensive study of the motor vehicle was now proceeding in an effort to improve it so as to reduce the damage done to the roads, and great advances in that direction were expected.

One feature of the modern highway called for the deepest concern, namely the terrible daily toll of fatal accidents. The careless, thoughtless and reckless driver was abroad on the highways and his shortcomings would seem seldom fatal to himself. Vigilance was demanded of every driver of a moving vehicle, and excessive speed and lack of caution should not be tolerated He urged all to work towards safer practices that will reduce this record of carelessness.

On good roads the motor truck could undertake the distribution of package freight to distances of over a hundred miles in a day. This convenient motor truck service had been attacked by the railway companies as unfair competition, which was causing branch line railways to be abandoned and was seriously curtailing the earnings on some main lines. In a recent investigation of the causes of abandonment of railway lines, it had been shown that less than 5 per cent of the abandoned mileage could be attributed to motor vehicle competition. The main reasons given for the abandonment of many miles of railway were the exhaustion of the natural resources that originally caused the railway to be built, competition from other railways, and miscellaneous causes.

It would seem however that the competition of the motor vehicle had proved such an incentive to the railroads, that to meet it they had developed the oil electric car, and while this type of vehicle was still in its infancy it had possibilities that may revolutionize motive power on railways.

Professor R. deL. French, M.E.I.C.

Professor French remarked that in his paper, the author had discussed the influence of the "machine" — motor vehicle and improved highway — as a factor in modern life, and was to be congratulated on the success of his efforts to make interesting what might very well be a dry subject. He believed that the author had omitted to mention one of the most important functions of the "machine" in any country, and one which was of particular importance in Canada at this juncture. He referred to the sociological effect of cheap motor vehicles and good roads upon the rural population.

It seemed to be thoroughly admitted that this Dominion needed an increase in population of a relatively high type, and this increase would have to come largely from immigration from the older and more highly developed countries of Europe. It was also generally admitted that immigrants should be of the agricultural class as far as practicable. We did not need industrial labour, nor had we any great demand for additional merchants and professional men, but we did need, and must have, if we are to progress, those who would settle in areas at present sparsely populated, till the soil, and be prosperous and happy doing it.

The farmer's lot fifty years ago was not a particularly happy one, but he accepted it with fewer murmurings than one would hear to-day, for two reasons,—there was no great industrial demand for workers in the cities to draw him to them, and the attractions of city life were not so alluring then as now. It was a matter of record that the drift to the cities had become of increasing economic importance, and that it caused much heart-searching and worry to-day. Rural life had certain advantages and attractions. The way to a prosperous and contented rural population lay in extending to it every possible advantage as regards education, amusement and opportunity for social intercourse, as well as assuring it reasonable income for its labour.

In the author's "machine" we had the best possible agency for doing just these things. Automobiles and good roads had made practicable the consolidated school, surely a great educational improvement. They had added immensely to the farmer's material well-being by making it possible for him to market his products so that his share of the price they bring would be larger than hitherto, and by extending his buying area. They had, in effect, brought him miles nearer his neighbours, and had made it easy for him to enjoy some city pleasures, without sacrificing his rural independence. They had lightened his labours, and thus given him more time to himself for recreation or what you will. Next to the general introduction of labour-saving machinery on the farm, motor vehicles and good roads had probably been the most potent influence in ameliorating the farmer's lot.

If Canada advertised its attractions in this respect, it would go far toward dispelling the natural reluctance of possible immigrants to abandoning familiar living conditions — unattractive from our viewpoint perhaps — for those which they feared would isolate them from human intercourse in a strange country. Give these prospective settlers to understand that farm life in Canada did not necessarily mean being thrown upon their own resources for relaxation and social intercourse now, and that conditions in this respect were improving every year, thanks to motor vehicles and good roads, and one of the greatest deterrents to immigration would be removed.

The sociological effect of cheap and easy transportation upon the rural population might be impossible of evaluation in dollars and cents, but it had a very real value nevertheless, and one which should not be neglected nor underestimated in any discussion of our highway problems as a whole.

Turning to the author's remarks on bus traffic, he desired to point out that recent investigations * in eight of the United States indicated that the competition between bus lines and the railways was not as keen as might be expected. In these eight states there were 626 routes comprising 16,574 miles over which buses operated, and which might be divided as follows:—

	Routes	Miles
Directly competitive........	37%	41%
Indirectly competitive.......	25	28
Non-competitive............	38	31

Directly competitive routes paralleled the railways; indirectly competitive routes connected points between which there is railway service, but more directly, as their name implies; and non-competitive routes connected points having no railway service. As an extreme example of an indirectly-competitive route, he would take that from Bantam to Torrington, Conn., in the territory of the New York, New Haven & Hartford R.R., to which the author had referred. The bus trip was 10 miles long and the fare $0.60. By railway, the distance between these two towns was 73 miles, and the fare was $2.63, with two train changes. Indirectly competitive and non-competitive routes in these eight states accounted for about two-thirds of both routes and mileage.

Proper governmental regulation of bus traffic should do much to eliminate harmful competition between buses and railways, but in the end that form of transportation would survive which best met public demands. It was the age-old struggle between the old and the new, and duplicated very nearly the competition which had resulted in the disappearance of coaches and the great reduction of canal traffic in England when the railways were young. The public demanded service and was willing to pay for it. Some form of close co-operation between the railways and the buses seemed inevitable, if both were to reach their highest pitch of efficiency.

Mr. R. A. C. Henry, M.E.I.C.

Mr. Henry remarked that the development of the motor vehicle during the last few years had attracted the very serious attention of the public, students of economics and those interested in the problem of transportation in general.

The subject was one of great interest to society at large and particularly to members of the engineering profession, and as the author had so aptly put it, the engineers "should be to the municipal unit and to the field of transportation, what the architect is to the house".

If we reviewed the historical development of the past for the purpose of studying the influence of trade upon history, we should find that the older civilizations were built up to a great extent upon transportation. Probably the most striking feature in the whole Roman economic system was the network of roads radiating throughout the Roman Empire, which had so greatly facilitated her commerce and perhaps rendered the existence of that Empire possible. It had been said, and perhaps rightly so, that "from the Golden Milestone in the Forum at Rome, roads spread in all directions and were conspicuous and abiding evidence of Rome's greatness".

He agreed with the author that the value of the common road, or for that matter of any other facility, was in proportion to the use which might be made of it. There was no doubt that the motor vehicle had rendered available a potential carrying capacity many times that of the horse drawn vehicle, and to the extent to which this increased capacity could be economically utilized, to that extent was the community at large benefitted.

The influence of the motor vehicle and the improved highway upon the distribution of population had been great and there had been a marked tendency towards a wider distribution of city population in the urban districts. It was interesting in this connection to note a very natural, but at the same time, stimulating effect of the motor vehicle upon the building industry, because of the fact that the rapid development of the motor vehicle as a transportation facility, had suddenly extended the residential limits around large centres, with the result that a large area between the industrial sections of these centres and the outlying residential areas had developed into what had been termed the twilight zone, to such an extent that in a great many cases, both land values and building values in these areas had declined temporarily.

The author had referred briefly to the influence of the modern highway and with it, the motor vehicle, upon the steam and electric railways, which had resulted in a decline in the use, and the abandonment in some cases, of electric lines, and a marked decrease in certain classes of traffic upon steam lines. This was a question which was now receiving the very serious attention of all concerned, because it was obviously in the public interest that our various transportation facilities should be so co-ordinated as to permit of the establishment of a general system which would fully meet our public requirements.

Professor A. T. Laing

Professor Laing remarked that one of the most important features in the paper which had been emphasized, to some extent by previous speakers, was the economic question. He was not sure that we were altogether seized of the attitude of the country as a whole to the problems that had arisen. We were in the peculiar position of having granted to certain transportation companies, the railways' franchises, on the understanding that ruinous competition would be eliminated. Subsequent developments however had brought in this incongruous situation, viz:—while we had granted these protec-

* "The Motor Bus as a Common Carrier", H. R. Trumbower, U. S. Bur. Pub. Rds., "Public Roads", Dec., 1925, VI-p. 213.

tive franchises we had, on the other hand, subsidized a competitive industry, by placing at the disposal of modern transportation companies high grade highways at practically no cost to the operators except that of maintenance. This applied both to bus transportation as well as to that of the truck.

This had developed at an enormous rate, and he would ask: What degree of fairness was there in this recent development in which we had practically subsidized a competitive industry against the companies to whom we granted franchises. This situation was not only felt in this country but was affecting conditions in England; some of the tramway companies there had been obliged to abandon routes which they had been operating, and the reasons given were, "unregulated competition of motor omnibus companies under conditions quite unfair to the tramways."

He found a very similar situation in Canada. In 1924, out of 64 operating radial railway companies, forty were in financial difficulties of a very serious character, and were considering the question of abandonment. A survey made of some 37 railway companies operating in Canada and the United States in 1924 had revealed these conditions; five seeking abandonment, five total abandonment, six partial abandonment; seven with serious deficits and none of them meeting operating expenses; all due to the unregulated competition of the motor vehicle. This seemed to him a very serious question, and it concerned the whole country. What we were concerned about, especially in industrial centres, was that there should be good transportation facilities and that these should be conducted on sound economic bases.

The eight States to which Professor French had referred had 705 bus routes operating over a mileage of 18,200 miles, or 68 per cent of the State highway systems. Within these States there were only 23,000 miles of steam and electric railway in operation. Thus it could be seen how seriously the question was being pressed home in these States. In a great number of instances they had been compelled to abandon trackage.

It was not altogether a question of cheapness of handling our transportation problems. It was largely a question of convenience. Take for example L.C.L. freight between Toronto and Hamilton. He understood that, by the ordinary routine the materials had to go through, after the order was placed, it took six days to make delivery in Hamilton, whereas the goods might be placed on a truck and delivered in six hours, a much more satisfactory service. Time was often the factor which determined the method to be employed. In the eight states referred to above passenger traffic on the bus lines was continually increasing even though fares were considerably in advance of those offered by this railways. The fact that the bus provided a very much more elastic service than the steam and electric roads commended it to the travelling public, and passengers were willing to pay the difference. Fares within these eight States ranged anywhere from 2.7 to 18 cents a mile, while the railroads offered a rate from 2 to 3 cents per mile.

The feature that demanded special attention was that of devising some method by which transportation problems could be handled, not by ruinous competition but by the correlation of all the various interests. The steam road and the electric road could do the long-distance business much more economically than could the motor bus or truck. That was clearly established. We had an analogy in the wholesale and retail business. The steam and electric roads could do the wholesale transportation, but the motor bus and truck must in future be relied upon to do the retail business in these lines. The railways had their handicaps in their terminal facilities which were difficult to overcome. At these points the bus and truck could much more expeditiously handle the problems. These features clearly pointed to the necessity of so co-relating these systems that our transportation problems might be handled with dispatch and at the same time on an economic basis. Essentially the two systems were supplementary. Actually we had not yet made them so.

Major Geo. A. Walkem, M.E.I.C.

Major Walkem remarked that in discussing the competition between motor buses and railways it was often forgotten that this is confined to comparatively short hauls, and it seemed likely that the success of motor buses on such routes is largely due to the fact that they only hauled approximately six hundred pounds of equipment and vehicle for each passenger, whereas a steam railway has to haul nine or ten tons.

The Diesel-engine driven car, which was being developed and applied by the Canadian National Railways would seem to be a very promising solution of the difficulty, but even with this development the railways could not give such convenient service as that of a bus, from which the passenger is delivered practically at his door.

In British Columbia concrete roads were largely favoured on account of their durability and non-skidding qualities. Next in order came the road with a concrete base and black top, next, — asphaltic concrete, and last — the water bound macadam road with oil treatment. The latter type of road was not now being constructed in British Columbia, because motor traffic ruined them in from three to five years. They could be treated with hot asphalt to save the tops, but this had not been found very satisfactory.

He wished to compliment the author upon his timely and excellent paper.

Discussion on Differentiation of the Action of Acids, Alkali Waters and Frost on Normal Portland Cement Concrete

Discussion of paper presented by Messrs. C. J. Mackenzie, M.E.I.C., Dean of Engineering, University of Saskatchewan, Saskatoon, Sask., and Dr. T. T. Thorvaldson, Professor of Chemistry, University of Saskatchewan, Saskatoon, Sask., before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

Mr. W. G. Chace, M.E.I.C.

Mr. Chace remarked that when a few Winnipeg engineers, who had identified the source of the decay of concrete noted throughout the prairie provinces during the middle of the last decade, were bold enough to announce their opinions, they had been scornfully met by architects, contractors and by a few of the engineering profession with the statement that good concrete would not decay and that all concrete which had deteriorated was originally poor in quality and had either been frozen or washed out, or even lacking in cement. Such opinions had now been proven unsound and without warrant of fact, although certain "hardshells" still refused to believe the evidence accumulated.

He pointed out that students of the phenomenon which appeared at various points in the clay deposits of Western Canada soon identified the source of trouble as the sulphate salts in the soil and in the soil waters, occurring as Epsom and Glauber salts. It had been observed that the injury occurred to good concrete rich in cement and to poorer concrete lean in cement; that the injury to dense or impervious concrete was progressive from the surface of the structure; that the destruction of porous concrete whether rich or lean in cement took place throughout the body of the mass as well as upon the surface. It was observed also that soil waters carrying less than 1/10 of one per cent of the SO_3 molecule seemed immune unless also subject to frost action or to the concentration due to alternate wetting and drying. Other conclusions since verified by the committee were also arrived at with respect to the "free lime" or to the "released lime" following the setting of the concrete.

The authors had shown concisely and definitely how injuries of the three sorts might be differentiated. Happily injury due to concentrated acid discharges as into sewers from industrial plants were local and could easily be stopped and the cause corrected. Injuries due to frost could seldom occur if the concrete were made impervious, which could be done by experienced and skilled engineers and constructors. Injuries due to soil conditions of sulphate concentration must be fought by efficient drainage, and by the use of porous backfilling against the exterior surface planes, and underdrained in such manner as to prevent the soil solutions from coming into contact with the structure. These methods must be applied to footings as well as to walls and conduits.

As indicated by the authors the injury to concrete structures would be accelerated by alternate wetting and drying thereof by even weak solutions of sulphate salts. He had observed such instances where the interior surface of a basement wall was being injured by reason of the concentration of these waters due to the evaporation from within the basement. Such injury was not confined to concrete alone but could appear on limestone walls and on brick and tile.

He confessed to some disappointment in that the Committee of *The Institute* had not yet reached that point in their studies which would enable them to indicate to us how we should be able to construct safely caissons and other elements difficult to drain. They had not indicated whether it would be necessary to devise a new specification for cement for this purpose, the market for which would be partly throughout the Northern and Western States of the Union and in Western Canada as also in certain isolated spots elsewhere in America, to say nothing of the structures to be built in sea water. Judging from the very complete summary prepared by Messrs. Attwood and Johnson published during 1925 in the Transactions of the American Society of Civil Engineers, it seemed possible that the answer lay in the adaptation of European practice, utilizing trass or pozzuolanic materials in the cement or in the concrete. This idea had been utilized by the engineers of the Los Angeles aqueduct but not for the purpose in our view. It seemed to have met with considerable success in Europe for sea-walls. It was desirable that this idea should be sifted thoroughly and tested. For certain portions of the aqueduct of the Greater Winnipeg Water District, which portions were incapable of drainage because of their low elevation, concrete had been built of Portland cement and of an aggregate entirely silicious and in proportions such that the resultant body was impervious. It was hoped by this means to assure a long life to this portion of the structure. It would be interesting to inspect the condition from time to time to discover the efficacy of this precaution. For the pipe lines an underdrainage of gravel backfill had been provided; since completion of the structure certain of the horseshoe section which lies in sulphate bearing soil had been underdrained and so backfilled. For a very large building now in process of construction in Winnipeg the architects had taken the precaution of thorough underdrainage and had combined it with a complete backfill of gravel surrounding the basement walls.

He considered that the subject was of intense interest to investors, whether public bodies or private owners, as also to the architects and engineers in Western Canada, and hoped that practical answers to the problems he had mentioned would be developed by the Committee, whose efforts so far seemed to have been concentrated on the investigation of causes and characteristics of the phenomena observed, and on preliminary studies necessary for an understanding upon which practical results might be based.

Mr. E. Viens, M.E.I.C.

Mr. Viens wished to express his appreciation of the very fine piece of original work carried out by Professors Mackenzie and Thorvaldson. To his mind this was a great step in the advancement of our knowledge of the causes and the possible solutions of the factors of concrete disintegration. Heretofore, we had had no basis of comparison and it was fortunate that examples of the different causes of disintegration had fallen into the hands of men who were so well prepared, through their investigations of the effects of alkali waters on concrete, to grasp the full significance of the results of their chemical analyses. He believed that we now had a true basis on which to draw conclusions from the study of other failures from these causes.

He desired to speak more particularly on the Eastern phases of the problem. He had made a trip through the Eastern provinces during the month of October last, and had visited some forty odd concrete works, a large number of which were along the Atlantic sea-board, but would confine his remarks to observations on three of the larger ones. First, a breakwater on the South shore of Nova Scotia which was built in 1912-13, was a demonstration of the fact that concrete can be made to withstand the double action of sea-water and frost for a reasonable time, for it was still in good condition with the exception of some spalling at the joints. This structure was apparently as good, and even better, than many a concrete structure of equal age in fresh water. He understood that the proportions used were fairly rich in cement and that the work was performed with considerable care.

Another concrete work which had been constructed about the same time as the above, on the North shore of Nova Scotia, was badly disintegrated, especially immediately above the water line, in places to a depth of 45 inches. The failure of this work was, at least, attributable to the following factors: — porous concrete containing fine and dirty sand; inferior crushed sandstone, fifty per cent of which composed the coarse aggregate; an excess of water; and lack of control of proportions. From the reasoning given in the paper under discussion it was evident that this porous concrete had absorbed much sea-water which had ascended above the water level by capillarity and thus caused failure both by concentration of the salts and by freezing.

A third example of the deterioration of concrete was that of structures in St. John Harbour, N.B., where at least one pier had disintegrated to such an extent that repairs were impossible. The concrete in this pier was poor, due to the use of too lean a mixture and excess of water, and was at present in a soft and mushy condition. The causes for the failure in this case were, he believed, the same as in the previous case mentioned and pointed towards the need of better concrete to withstand these actions.

At the present time the concrete investigator was struck by the fact that notwithstanding the present day knowledge of the need for high class aggregates there are yet so much of the poor grades in use. It would be well to remember that even though nature may have deposited large quantities of sand and gravel, that she did not make these, as a rule, any more fit for concrete purposes without treatment than she has done for any other raw material used in industry.

If concrete, one of the most useful and flexible engineering building materials, were ever to be truly considered as permanent structurally, more consideration would have to be given to the quality of the aggregate. The trouble with many natural deposits of sand and gravel was that they are composed of a variety of rocks, some durable and others not so durable. Consequently, every deposit, before being used, should be thoroughly examined and tested, having in mind the conditions to which the proposed concrete was to be subjected. When field stone or boulders were used for crushed aggregate, the same precaution should be exercised as in the choosing of gravel, for there again one was liable to get stone from a great variety of formations having a different state of preservation and therefore some having a much lower resistance than others to weathering. The same applied to crushed stone from quarries.

Heretofore our difficulty in the art of making good, permanent concrete under our Eastern conditions had been the lack of knowledge of the quality of the aggregate, and lack of proper control of the proportions of the components: the water-cement ratio, the fine and coarse aggregate ratio; the effect of the time of mixing and the proper methods of placing had in many cases also been overlooked.

He had mentioned two cases where concrete had failed in sea-water and one where it was apparently standing fairly well. To what extent the cement was responsible for these failures was not known, and we had no means of knowing, for the problem was complicated with too many other factors. We did know, however, that the cement that would produce the most impervious concrete would be the least affected. We knew also that one brand of cement will produce much higher strength than another at 28 days or even at longer periods, but we did not know whether the stronger brand of the two would be less affected than the other by sea-water or frost action. It was even possible that the same brand might vary in these respects from time to time owing to slight variation in its chemical composition, in the degree of fineness of the raw materials before being burned, in the temperature at which it was burned, and in the fineness of the finished cement. Comparative tests along these lines were lacking, and more complete records of the chemical analysis and the physical properties of the cement should be kept when used in large works in sea-water.

One aspect of concrete in sea-water, as well as in fresh water, which had been fairly well established was that for a given cement and aggregate, the more impermeable the concrete is made the longer it will last. Porous concrete contained in itself the elements of failure, because the salts dissolved in sea-water attacked hydraulic cements with energy if the water were able to permeate or wash through the mass continuously, for it was a well known fact that the aluminate and ferrate of calcium are not only decomposed and rapidly softened by sea-water, but they also give rise to the formation of double compounds which in their turn destroy the cohesion of the mass by producing cracks, fissures and bulges.

He would therefore say in conclusion, that while the means of carrying out a post mortem examination of disintegrated concrete that has been developed by Professors Mackenzie and Thorvaldson was of great interest and value, yet the fact should be clearly appreciated that we could at present rely on but one method of combatting disintegration, whether it be from the attack of sulphate waters, acid or frost, and that method lay in the direction of the development of impermeable concrete.

To make impermeable concrete under practical working conditions we must exercise caution in the selection of materials and in our use of them.

Primarily we should look to the quality of the cement, and we would do well in this connection to ask the manufacturers to seek diligently all means in their power to produce as uniform a product as possible and that would also make a more impermeable concrete. Modern cement was a product of wonderful utility but improvement in that direction might not be impossible.

In our selection of aggregates we must then ensure that they are composed of structurally sound, dense and durable rock, well graded to minimize the tendency to segregation in handling.

Sufficient cement must be used to fill the total voids of the aggregate and to give a workable consistency without the use of too high a water-cement ratio.

The concrete must be mixed for an adequate period (1½-2 minutes) and must be properly rodded after placing to bring any entrapped air and excess water to the top, where the latter may be removed.

Finally the concrete must be given ample time to cure under moist conditions and without danger of freezing, for otherwise it would have neither the strength nor the endurance that it is capable of developing.

Mr. R. B. Young, M.E.I.C.

Mr. Young remarked that the authors had offered us another method by which we can examine the causes of defective concrete. Any engineer who had had anything to do with concrete structures which have become in bad condition would welcome any means whereby he could settle some points, positively, that are in dispute.

He thought that chemical tests of concrete must be used with a good deal of caution, for the reason that an interpretation of a chemical analysis might prove to be misleading unless it presented a very positive means of identification with respect to the trouble which was being investigated.

He believed the method outlined by the authors answered the requirements of the proper chemical method to be adopted. There were quite positive defects which caused disintegration. Alkali attack was ordinarily considered to be a peculiarly Western problem, but the same causes were met with in the East. One of such causes had come to his attention several years ago, in the case of a tunnel where the work was subject to a drip from the roof, and the concrete had disintegrated in a manner which is typical of alkali action, to a depth of from four inches to six inches. On examination it was found that the water carried about 300 parts to the million of calcium sulphate solution, and an almost unlimited supply came in contact with the concrete. The concrete had disintegrated where this solution ran down over the surface. A chemical analysis showed that this alkali action, mentioned as taking place in the West, had taken place here. The SO_3 test of the concrete was as high as six or seven per cent, which was a figure impossible to account for by any other theory.

Frost action would only take place in concrete in which there was moisture present. If the concrete were dry the frost would have no other effect on it than surface changes of volume. The moisture in the concrete must have some space which it occupies, and that meant that the concrete, in order to contain moisture, must have pore space in order to hold the moisture. All concrete had a certain amount of pore space, but lean concrete and wet-mix concrete was far more susceptible to frost action than where the quantity of cement was higher. We could obviate the defect in lean concrete to a certain extent by supplying filling material, but it would be dangerous practice to carry that remedy too far.

Probably the most serious trouble was due to excess of water. He had examined a great many concrete structures and believed that 90 per cent of the porosity trouble was due to excess of water.

If there were water in excess of that actually required to hydrate the cement, that water occupied space in the concrete, and when the water finally dissipated it left that space open to permit other water to penetrate at a later time.

Wet concrete was extremely liable to segregation, which was the arch enemy of concrete. Even where the concrete had been faced with plaster or mortar, and the plaster or mortar had separated from the mass of concrete, such places were liable to start disintegration; in fact he believed that where segregation had occurred on the surface of the work signs of disintegration would be evident in a few years.

Discussion on the Water Supply of the Border Cities

Discussion of paper presented by William Gore, M.E.I.C., Consulting Engineer, Toronto, Ont., and J. Clark Keith, A.M.E.I.C., Chief Engineer, Essex Border Utilities Commission, Windsor, Ont., before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

Mr. R. O. Wynne-Roberts, M.E.I.C.

Mr. Wynne-Roberts remarked that he had been much impressed by the spirit of co-operation among the municipalities concerned in the water supply system of the Border Cities, for no less than eight municipalities in the locality had joined hands to carry out the undertaking. This was an example worthy of emulation.

There had been a remarkable increase in the population and activities of the border cities, and while the consumption of water was exceedingly high, namely 170 gallons per head in Windsor, and 186 in Walkerville, he understood that half of the Walkerville consumption was used industrially.

The low rate at which Walkerville supplies water (10 cents per thousand gallons) was unusual, and it would be useful to know how this low rate was maintained.

The capacity of the filters was higher than normally adopted, although not as high as that proposed by the late Winthrop Pratt.

With regard to the screens, he had himself used similar screens in 1918, and he considered them superior to the old fashioned fixed screens which had to be hoisted up to be cleaned.

Would the authors explain how the output of the pumps is automatically controlled by the level of the water in the coagulation basin, and how the generator is operated by the flow into this basin?

He would ask the authors to state what quantity of alum is proposed to be used, and what is the estimated cost to operate the filter per thousand gallons delivered.

Mr. A. U. Sanderson, A.M.E.I.C.

Mr. Sanderson remarked that great thought and care had evidently been taken both with design and construction to produce a plant of the best class in water works engineering practice.

In this connection he would draw attention to the provision to reverse the flow in the intake to discharge frazil ice, the travelling screens in separate compartments, the capacities of the three main supply pumps in order to economize in electric power, the terrazzo and marble floors and stair treads, the brick and stone facings to cover exposed concrete walls, the copper covered roof, the duplicate lighting set, the duplicate hydraulic pipe line to operate all valves, the accessible pipe gallery, the skylight over the filter operators' gallery, the control of the backwash pumps from the operating gallery by push button, the cast iron pipe laterals in the underdrain system, and the cast iron overflow troughs in the filters.

Two novel features at this plant were the operators' tables in the filter house and the cemented gravel in the underdrain system. The former provided an economical arrangement that should be quite satisfactory, and the latter had been used in Toronto with excellent results.

In the formation of floc, prior to sedimentation, agitation was an important matter, and this would be produced at the Border Cities by the action of the centrifugal pump and mixing chambers. To illustrate what took place in lake Ontario water, which is somewhat similar in character, two grains of alum were added to a sample and left quiescent and floc was visible after 30 minutes, but was very fine. Another sample of the same water was subjected to 5 minutes agitation, which caused a precipitating floc after 15 minutes. At the end of 30 minutes, the water, which had been subjected to the agitation, produced a heavier floc than that which occurred in the other sample after four hours sedimentation.

In lake Ontario water, containing Humber Valley flood water, colloidal colouring matter and turbidity were present up to 110 p.p.m. This water with two grains of alum took over one hour to show visible floc, and three hours before any sign of precipitation occurred. After three hours the turbidity was reduced to approximately 50. The effect of agitation had been demonstrated very clearly at Cleveland. It was interesting to point out that, in passing through the Toronto mechanical plant, there is considerable agitation in the water. The turbidities mentioned above were completely removed in a 30-minute period when using only 1 grain per gallon.

The absence of standby power at the purification works of the Border Cities might cause considerable inconvenience in the future. When interruptions in electric power occurred, it was generally due to meteorological conditions, and the raw water supply at the different cities might be badly polluted and high in turbidity or colour at this particular time. There might be difficulties in starting up from the old sources of supply, due to the gates becoming fixed, or it might be impossible to overload the chlorine machines sufficiently to provide the large quantities of chlorine that are necessary at such times. In his experience, any deviation from normal operation by a failure from one source, might cause other links in the system to give way at the same time.

In plants where it is possible to use small quantities of alum for a long period, considerable economy might be effected by pre-chlorination with alum treatment. This was a phase of purification in which medical officers of health and engineers should co-operate with the same end in view, viz:—the most economical treatment consistent with a sterile effluent.

Pre-chlorination was being used in many plants besides Toronto, such as Louisville, Ky., Baltimore County Water Co., at Avalon, Newport News, Davenport, Virginia Beach, part of the supply of the river Thames in London, England, and many others. Robert Spurr Weston of Boston, had recommended its adoption in many waters in conjunction with alum for some time, and N. J. Howard and he himself had advocated its use at Toronto. Besides the economies effected, a purer water was often obtained.

Mr. R. L. Dobbin, M.E.I.C.

Mr. Dobbin observed that the authors had given in concise form a very comprehensive description of the filter plant now under construction at Ford City and also of the water supply situation in the Border Cities.

The plant followed standard practice in general, but there were several novel features. He noted the provision of only one operating table and rate-of-flow controller for each pair of filters. There was no doubt considerable saving, but an accident to table or controller would tie up two filters instead of one, in which case 20 per cent of the capacity of the plant would be out of business.

The storage capacity appeared small, being two million gallons. This was only 10 per cent of the capacity of the plant. In Peterborough the same size of reservoir was employed for a six million-gallon plant or 33-1/3 per cent.

At the average daily rate of use in the district in 1924, viz: 14 million gallons, this storage would last only three hours. The peak rate would be nearly twice the average, so that the storage could only be counted on for at the most, one and one-half hours, which was a very short time to repair breakdowns.

The underdrain system was similar to the Peterborough plant, in that three-inch cast iron pipe laterals were used. At Peterborough however 7/32-inch holes with 3-inch spacing were drilled in the laterals, as against 5/16-inch holes with 7-inch spacing in the plant under discussion. It would be interesting to see which scheme gave the least pumping head for the wash water pump to work against.

Examination of the strainer system at Peterborough showed no measurable change in the size of the holes after four years operation.

He remarked that the total gravel layer at Windsor was 16 inches in depth, which included six inches of cemented gravel. This was a departure from standard practice and it would be interesting to have the cost compared to loose gravel.

The depth of sand used was 28 inches, which made a total depth of bed of 34 inches as against 42 inches at Peterborough, a much shallower bed than had been used hitherto.

The authors had not given the rate of wash, but figuring from the capacity of the wash-water pumps it appeared to be about 19 inches vertical rise per minute. At Peterborough 22 inches and 24 inches had been used without any perceptible disturbance of the gravel layers.

The sand at Windsor was coarser than that used at Peterborough, which would be expected, as the plant had been designed for a rate of 127.5 million Imperial gallons per day as against 103.5.

The period of sedimentation was 2 hours, as compared with 2.5 hours; this seemed well advised and in accordance with recent practice as most filter plants had been designed with too long a period of sedimentation.

He had mentioned these points, not in a spirit of criticism, but in order to point out the differences between two plants constructed five years apart.

Mr. Gore's Reply

Mr. Gore in reply observed that Mr. Wynne-Roberts had referred to the considerable consumption of water in the Border Cities. That was a matter quite outside the function of the Essex Border Utilities Commission which supplied water to the two distributing authorities, but was not responsible in any way for the manner in which that water was used.

The Walkerville Water Company has a complete metering system throughout its district, but the Windsor district is only partially metered. A policy of complete metering to reduce the consumption was started but has now been halted because of the considerable expense involved due to the fact that few of the houses were provided with cellars in which to place the meters; boxes had to be provided. Also, a number of the services were in a very unsatisfactory condition and had to be replaced when installing the meter. It was this incidental work that brought up the cost. In this case the reduction in the use of water would in part be due to the improvement in the service pipes.

The travelling screens were a very desirable feature in modern waterworks practice, for the removal of ice and weeds coming through the intake.

These screens were similar to those in use at Toronto Island and Belleville. As the screen panels travelled the jets impinged upon them on the reverse side, fish or fragments of ice and weeds were washed away into a catch pit containing a basket which can be lifted out by the travelling crane and removed from the building. Screens were not placed on the intake mouth because of its inaccessibility. It was thought better to let anything caught in the intake current pass quite through to a place where it could be more easily dealt with.

Regarding the rate of filtration at the Essex Border Cities plant as compared with that at Detroit, he would say that at Detroit the maximum rate is 140 Imperial gallons per acre per day, the corresponding figure at Windsor being 127.5. If the hydro power failed there was no power to drive the pumps or auxiliary machinery. It was not thought advisable to saddle the Essex Border Utilities Commission with the increased cost of standby power, particularly as the Ontario Hydro-Electric Power Commission had proposed a steam generating plant in the vicinity. If considerable disturbances did take place through lack of power an auxiliary generator would be introduced.

Generally speaking, however, power failures were of short duration, and in any case the supply, if recourse had to be had to the river, would be no worse than it had been for many years. The record of failures during the past two years did not show any greater period than half an hour. That half hour might occur during the night, and therefore a small turbine generator had been provided taking water from the coagulating basins and supplying current to an independent series of lights which are distributed about the whole works. On starting this generator, the plant was lighted sufficiently for the operations of switching and the closing of gates to be carried on.

They did not use electricity for auxiliary power to close or open the gate valves, etc., which was done hydraulically by the Walkerville Water Supply Company's service pressure. That company's system had full steam standby.

The cemented gravel, as anticipated by Mr. Dobbin, did reduce the depth of the filter and consequently the amount of concrete that entered into the construction of the work. The author's experience with the filter-bed washing back was that if a square tank were subjected to high rate back wash then loose gravel tended to creep up into the corners and the bed ultimately fractured. They felt that cemented gravel was an entire success, as it gave a firm and stable bottom on which one could absolutely rely. Examinations had been made in Toronto, and no clogging had been found. They calculated the rate of wash-back required as 16 inches vertical rise per minute, but this could be increased to 24 inches if necessary.

He believed that the amount of alum per gallon required would not be greatly different from that at Detroit, which in the past had averaged about one grain per gallon.

As regards agitation, to which Mr. Sanderson had referred, he agreed that rapid mixing of alum with the water was the first essential, also that a short period of more or less gentle agitation was a condition which produced the best results with most waters.

He had always felt that the water storage should be located where it could be supplied direct to the citizens in case of failure of any part of the works. No doubt Windsor would be better off with large elevated tanks.

Discussion on Reduction of Flexural Stresses in Fixed Concrete Arches

Discussion of paper presented by J. F. Brett, A.M.E.I.C., Designing Engineer, Montreal Water Board, before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January, 28th 1926.

Mr. W. Chase Thomson, M.E.I.C.

Mr. Thomson congratulated the author on his paper, which should do much to promote better designing of concrete arches in this country. It was considered by many people that any engineer could design a concrete arch, and there were numerous cases where the design of an important structure of this type had been entrusted to a man of insufficient knowledge and experience, with most unsatisfactory results, particularly from artistic and economical standpoints. But such structures usually stood up and showed no signs of failure, no matter how badly proportioned, which sometimes led one to doubt the magnitude of the flexural stresses from rib-shortening and variations of temperature, as computed by the usual methods. Some years ago, he had been required to investigate and to report upon the design of a certain bridge which had recently been constructed. This bridge included flat arches having a span of about 114 feet with a rise of about 9 feet. The thickness of the ribs at the crown was 2.5 feet and at the skewbacks, 5 feet. The temperature and rib-shortening stresses, particularly at the skewbacks, were found to be enormous; but he had repeatedly searched for cracks at these points, without finding any.

The author's analytical method for determining the equilibrium curve for an arch appeared to him rather formidable. It was his own practice to assume for the first approximation a circular curve, and to make the necessary corrections by the graphical method described in the paper. Moreover, many years ago he had adopted the practice of designing the arch-axis so as to produce a positive moment at the skewbacks, from dead-load alone, approximately equal to the negative moment at these points due to rib-shortening from the full dead-load, together with live-load over one-half of the span. The literature in English on this subject might not be voluminous, but it was sufficient. The subject was treated quite fully in several text-books by United States engineers.

Although the practice of reducing the flexural stresses due to rib-shortening might not be general on the American Continent, there was at least one example in Canada where temporary hinges had been employed, viz., in the main span of the Ashburnham bridge at Peterborough, designed by Mr. Frank Barber, M.E.I.C., of Toronto. In most United States and Canadian bridges of importance, compensation for the shrinkage of concrete had been partially made by the voussoir method of construction; and the arch centres were usually cambered so that, when removed, the elevation of the crown would coincide as nearly as practicable with its geometrical position. In arches of moderate span, the volume of concrete in the ribs was usually small compared to that in the abutment or piers; and it was doubtful whether the saving in concrete would be sufficient to compensate for the additional labour incident to temporary hinges, especially in cases where reinforcement might be required to resist the flexural stresses due to live-load and variations in temperature. In long spans, temporary hinges would be very desirable, not only in reducing the quantity of concrete in the ribs but in the additional security due to the elimination of such stresses, which can only be roughly approximated at best.

He considered that the part of the paper dealing with rib compensation was particularly interesting and could be studied with much profit by any engineer who may be contemplating the design of a long-span arch.

Mr. E. H. Darling, M.E.I.C.

Mr. Darling remarked that the author had given a very lucid description of the problems of arch design and construction, and the paper contained much of interest and value to anyone designing concrete structures.

He believed, however, that there were few Canadian or American engineers having to do with arch construction, who would not be conversant with the methods of design and construction described in the paper. There was at least one instance in Canada where temporary hinges had been used: the bridge at Peterborough, Ont. He could not recall an instance on this continent of the use of jacks for adjusting the stresses at the crown of a concrete arch, though this had been standard practice in the erection of steel arches since the building of the G. T. R. arch at Niagara Falls, twenty-nine years ago.

In a brief description of the St. Pierre du Vouvray bridge in the Engineering News-Record of March 20th, 1924, the use of jacks at the crown to take the weight of the arch off the centering was described, and deserved as careful consideration as the design of the arched rib itself. This probably indicated the American attitude regarding the relative cost of steel and concrete designs for this bridge, although he believed that the great difference in cost was due not only to the arch rib but also to the hangers supporting the floor system and other details whose design would not appeal to engineers in this country.

While recognizing the splendid work done by French and European engineers in concrete arch construction, he would point out that economic conditions here were quite different for we had keener competition from structural steel, we wanted rapid completion, we had a severe winter season and a different scale of labour costs. We preferred to put additional concrete into the work, rather than an equivalent value into the special equipment required to save that concrete; this policy resulted in an apparent relative waste in the finished structure. He doubted whether the question discussed in the paper ever was the deciding factor against a concrete design.

He was strongly in sympathy with the author's attitude towards design, and had met many engineers, especially those associated with contracting, who, on account of the spirit of impatience mentioned, deprecate mathematical analysis that goes beyond their idea of the practical. The paper indeed pointed out a case where extra concrete placed in the arch ring "to be on the safe side" actually reduced the factor of safety.

In an article published in the Canadian Engineer, September 7th, 1916, Mr. C. B. McCullough, the assistant highway engineer, Iowa Highway Commission, had compared two reinforced concrete arches submitted to the commission for approval. They were of the same general dimensions and were found to be correctly designed for dead and live load stresses, temperature, and rib shortening, and yet one had 21 per cent more concrete than the other. He pointed out, as did the author, that these last two stresses are the limiting factor in design and that "in many cases an increase in material in the arch ring actually operates to raise the unit fiber stress —".

According to the elastic theory, these stresses in an arch rib varied directly as the moment of inertia of the rib section or, what is the same thing, the cube of the depth, while the resistance moment of the rib varied as the square of the depth. So the effects of these stresses varied directly as the depth. For a steel arch where unit stresses might be twenty or thirty times those for concrete, the depth of the rib was so much smaller that the stresses due to temporary and rib shortening might reasonably be called secondary.

He would point out to those not familiar with the mathematics of arch design that the method of the paper might be looked on as an adaptation of the theory of the three-hinged arch to a fixed concrete arch.

All structural steel designers in the habit of designing structures having a live-load comparable in magnitude with the dead load, knew that the two-hinged arch was, in theory, more economical than the three-hinged arch, the continuous member giving lower bending moments for unsymmetric positions of the live-load. By the same line of reasoning the fixed arch was more economical than the two-hinged. The point brought out in the paper, which should be of general interest, was, that for concrete arches, on account of the relative insignificance of the live-load on the one hand and the greater depth of the rib on the other, the so called secondary stresses became the limiting stresses in design. To reduce these to a minimum one must go back to the three-hinged type for the greatest economy.

If permitted to broaden this discussion he would like to state that in his opinion many examples which had come to his notice of defective concrete water tanks, silos, grain bins, reservoirs and similar structures, were due to this neglect of elastic and shrinking stresses.

Mr. William Gore, M.E.I.C.

Mr. Gore remarked that his own experience with fixed concrete arches related to the long and heavy horizontal arches of masonry dams, and that experience had drawn his attention to the movements that take place in concrete due to changes in moisture contents.

Generally in estimating the movements in concrete arches the designer took account of the effect of initial contraction of the concrete in setting, the expansion and contraction due to changes in temperature, and stresses, but little or no consideration was given to the effect of changes in moisture contents.

He had witnessed experiments on a prism of concrete over 100 feet long and of 1 foot square cross-section. It was laid on rollers in the open, provided with gauge points, and a careful record was kept of its changes in length and of the meteorological conditions. As a result it was found that the temperature effects were almost entirely masked by the effects of moisture, which caused the prism to expand, and it contracted again when the moisture had evaporated, showing that this effect was of considerable importance in exposed structures.

Professor C. R. Young, M.E.I.C.

Professor Young remarked that while the design of reinforced concrete arches had progressed considerably along traditional lines in recent years, it was probable that in the 400-ft. Cappelen Memorial Arch at Minneapolis, engineers had about reached the economic limits of structures so designed. Such an achievement was not very remarkable in view of the fact that the great plain masonry arch at Plauen, Saxony, has a span of 295 feet.

Since the use of permanent and temporary hinges in concrete arch construction had been a matter of course for a considerable number of years, the most important part of Mr. Brett's paper dealt with the comparatively recent device of rib compensation.

Whatever merits arches with permanent hinges might have, it must be admitted that they are relatively flexible, heavy in fact and in appearance, uneconomical and troublesome to construct. The use of temporary hinges, so common in Europe, if not in America, could not give anything like the advantages of the device of rib compensation. As M. Freyssinet had pointed out in his notable paper in Le Génie Civil, construction with temporary hinges cannot make provision for more than a fraction of the secondary stresses, and that fraction a very indefinite one. Of course one might deliberately set the arch forms high in order to make provision for the crown settlement resulting from rib shortening, shrinkage, time yield, abutment shifting, and non-conformity of the temperature of placing with the mean temperature, but a great many things had to be guessed at if this were done. The estimate so made might be, in certain items, as for example, yield of abutments, very wide of the mark. By adopting M. Freyssinet's method of rib compensation, it was possible to put the rib in any desired final position and so make it conform as accurately as may be with the dead load line of pressures. Then, by leaving the crown gap open for a year or more, as was done in the Vouvray Bridge, the various deformations could be followed up with accuracy as they occur. Consequently the greater part of the secondary stresses could with definiteness, be eliminated by rib compensation.

He considered it rather remarkable that neither in the author's paper nor in that of M. Freyssinet, was any reference made to the matter of progressive or time yield of concrete under stress. The author had estimated the rib shortening effect for an average pressure stress of 350 lb. per sq. in. as 0.00014 per unit of length. Observations made by Franklin R. McMillan, A. C. Janni, and others, had indicated a yield of from 0.0002 to 0.0004 per unit of length in a period of about two years, Such a yield would produce a shortening of a rib 100 ft. in length of from ¼ to ½ inch, obviously a very important item. Otherwise put, it had been found that altogether exclusive of shrinkage effects, concrete yields in 50 days under a fixed load, about 2.4 times as much as it yields on the initial imposition of this load, and in 950 days 4.4 times as much.

In view of the well established phenomenon of time yield, he believed that the author would have done well to include such an effect in the development of his equations (26) and (27).

In making available in compact form in English, the results of the newer work of the great exponents of reinforced concrete in France, Mr. Brett deserved the thanks of the profession.

Mr. Brett's Reply

The Author in reply, remarked that he had now learned that the designer of the 235 foot arch at Peterborough, Ont., Mr. Frank Barber, M.E.I.C., had made use of a type of semi-hinge there. In this case, the Peterborough arch would be the first structure of this kind on the North American continent.

Since his paper had been published, Mr. Henry Quimby had drawn his attention to the Walnut Lane bridge, Philadelphia, where some form of flexible connection had been used at the skewbacks and at the crown.

He would point out, however, that in order to reduce deformation stresses to a minimum, the semi-hinge must be designed to take up the whole dead-load thrust of the bridge complete. Further, it must remain open until the shrinkage effect had disappeared.

The volumetric change coefficients noted in his paper were those used upon the continent of Europe. Recent investigations in this country had confirmed these data.

In connection with the fitting of the load curve to the arch axis he had stated in the paper that several important structures in this country have been so designed. A great many structures, however were not, and he thought this was due to the fact that in the study of arch design, the elastic theory has been emphasized almost to the exclusion of any other consideration. In other words, a lot of time was spent checking stresses, but the underlying principles of the reduction of such stresses were given scant attention.

The parabolic theory and its numerous variations were being used a great deal in Europe to design concrete arch bridges up to 150 feet span. For longer spans, the integration of the load curve was usually carried out by means of series, and there usually resulted an equation of the fourth degree which is known as the fourth degree parabola.

Discussion on Some Phases of Industrial Relations

Discussion of paper presented by Homer E. Niesz, Manager of Industrial Relations, Commonwealth Edison Company, Chicago, Ill., before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 29th, 1926.

Mr. Wills MacLachlan, M.E.I.C.

Mr. MacLachlan remarked that he was not willing to accept the definition of engineering as pertaining only to the material end of the welfare of humanity.

He thought it would be well for the engineer to pay more attention to the human element in connection with his operations than he had done in the past.

In connection with any work in industrial relations, such as the author had outlined, dealing with 9,000 employees, it was not satisfactory to work the scheme out on a sentimental or on a welfare basis. The facts of the question must be faced just as in going into any other engineering problem. The scheme decided upon should be carried out after complete investigation, in an able way that would work for the good of the whole organization instead of trying to make a sentimental decision here, there or elsewhere. In dealing with the problem of pensioning the old employee, it was not a satisfactory method to wait until that old employee had reached the age of 65 and then try to work out some scheme where by he would be looked after. Such a scheme should be put into effect in the very early stages of the development of any organization, and should be applied to all members of the group.

The president of *The Institute* had pointed out that one of the important problems before engineers was the early training of graduate engineers so that they can be effective at a later time for an organization, or for the profession in general. In Toronto they had instituted a course for engineer graduates, running over two years, including work on construction, in operation, and in the engineering department, so that by coming in contact with the construction and operation work of a big utility they felt they were learning how to become engineers.

Another important question that would demand more attention in the future was the development of organizations to prevent accidents to employees, particularly on construction. He knew of some construction jobs in which the cost of accident had run to 10 per cent of the pay-roll, an item well worth while getting after. There were other cases where the accident cost had been as low as 2 per cent, showing what could be done by effective organization.

He desired to emphasize the fact that the problems of industrial relations, whether relating to the organization of any kind of service, the working out of a pension plan, or the organization of a force for the prevention of accidents, were essentially engineering problems.

Mr. L. St. J. Haskell

Mr. Haskell remarked that personnel problems were largely the same for all industries, and the way in which they are being handled by a progressive organization had been very ably described by the author.

It was however necessary to adapt the details of administration to the industry concerned. For instance, an organization such as the one outlined in this paper would not ordinarily apply to a small industry or one in which the force was considerably scattered. In the Bell Telephone Company of Canada there were 14,000 employees distributed throughout Ontario and Quebec, and it was obviously impossible for an administrative organization such as that described to function in matters of employment under these conditions. However, it was possible to set up a slightly different organization which would give similar results.

He desired to emphasize the importance of having the engineer study the fundamentals of industrial relations. For the last three or four years his company had been engaging graduates from the engineering schools and training many of them for supervisory positions, where one of the biggest problems is the handling of the working force. He considered it most desirable that some study of industrial relations should be incorporated in the training of engineers, either during their course, or as soon after graduation as possible.

His company had an Employees' Representation Plan similar to that given in the paper and found it extremely valuable. Representatives of the employees met periodically with representatives of the management, and in this way grievances and suggestions found a convenient avenue of expression. These meetings, however, were not limited to the discussion of wages and working conditions; methods of operation and changes in equipment were discussed, and many valuable suggestions were obtained. In addition, these meetings enabled the management to keep the working force informed as to company policy, and to obtain their co-operation in initiating changes. This last was particularly important because changes which are not understood by employees are frequently regarded with suspicion and may cause serious dissatisfaction.

One of the difficulties in employee representation was to avoid management domination. Consider the case of a meeting between, say, a number of telephone operators and the management, in which a certain point has been raised by an operator. It would be very easy for the superintendent to give a definite ruling without adequate explanation. This, too often, had the effect of closing the discussion, as very few operators would care to press the point further. They would leave the meeting still convinced that they were right, and the conference would have failed in its primary function, to overcome misunderstanding by free and frank discussion. As an illustration of a more satisfactory attitude towards these meetings, the experience of a district traffic superintendent might be worth relating.

All operators are scheduled to work for so many hours a day; to work a certain "trick" is the term used. Now in order to handle the load at all times during the day, certain operators are required to work tricks which are considered to be undesirable. In this particular case a new schedule issued by the traffic department was criticized by operator representatives, who thought that certain undesirable tricks could be eliminated. The district traffic superintendent replied that he would be only too pleased to have the schedule improved and suggested that the girls work out one which would be more satisfactory. He supplied them with all the necessary information regarding load conditions and said, "Now go ahead, work out your schedule and bring it to me. If it is all right I will put it into effect". The operators prepared the schedule and put it forward for approval. The district traffic superintendent pointed out to them where their proposals failed to meet conditions, and referred the schedule back to them for correction. After two or three attempts the girls began to realize the difficulties involved in preparing such a schedule and also saw the necessity for undesirable tricks. Their confidence in the management was thus strengthened and they expressed entire satisfaction with the existing schedule. Employee representation plans carried out in this way would be of value to almost any kind of industry.

Mr. H. G. Millson

Mr. Millson remarked that after watching the remarkable results of the study of industrial relations, as applied in Canada and in the United States, he had gone over to European countries during the last two or three years to see how those plans applied to European people and to get firsthand experience. He had been glad to find that the industries abroad who had taken up that work sincerely and who had followed it in a democratic way had been the only industries to weather the storms during the last five or six years there. They had neither lost financially nor had their men become less efficient by the terrible doctrines being preached to them. Take, for instance, Port Sunlight, Lever Bros., Cadbury's, Guinness' of Dublin, close to his own home, those industries stood storm-proof today. And the sole reason had been, that they had created a confidence in their employees and the employees in turn had placed the destiny of their welfare in their hands.

He believed that the man who can handle labour is as great as the man who can handle anything material or who can handle capital. A man might be a remarkable engineer with the greatest detail knowledge of his job, but he would be a greater engineer if he developed along the lines of Industrial Relations. If an engineer were in command of a great many men, then he should have a deep-seated interest in them, so that from them he could get the highest efficiency, teaching them the lesson that it is not the hours you put in that count, but what you put in the hours; getting in turn from them a confidence and close relationship, such that there would be on their part a readiness to learn. His job would then be co-ordinated very closely with industrial relations.

Mr. Niesz's reply

The Author in reply observed that his Company as a public utility, believed very strongly in the desirability of stock ownership, not only on the part of their employees, but also on the part of the general public, with the object of increasing the number of persons owning the stock. Their stock ownership was distributed over about 45,000 different owners. He believed in the acquiring of stock by employees, on a savings fund method, primarily as a means of encouraging thrift. They were able to give their employees the opportunity to acquire stock in the company at a low price, because there is a statute in the state of Illinois which permits a corporation to set aside a certain amount of its stock for sale to its employees at whatever price is determined by the board of directors of the company, and that stock could be sold to the employees at a very favourable price. Their representation plan was a joint one, participated in equally by employee representatives elected by themselves, and by management representatives appointed by the management. They did not believe in the domination of management in these councils, and there could be no domination of management under their plan of employee representation. Such employee representation, supplementing the organization channels of communication, enabled the employees to voice their desires, whether on a question of wages, hours, working conditions, or any other phase of employees' needs.

He desired to emphasize the point that it is necessary for every supervisory man who has to do with the handling of men to understand industrial relations, and to apply their principles to the organization over which he has jurisdiction.

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOL. IX APRIL 1926 No. 4

Students' Prizes

Association with his National engineering society should be the ambition of every young man interested in the engineering profession, and this fact is so generally recognized that the constitutions and regulations of all important technical societies rightly lay stress on the advantages of such membership to the young graduate or engineering pupil.

At the present time the Council of *The Institute* has three committees whose activities are concerned with the prospects, training, and development of the students of *The Institute*, and the time seems opportune to bring to the attention of the membership at large, and particularly the students, the facilities and opportunities that are now offered to them.

Five Students' Prizes were established in 1902, and for many years have been awarded for papers submitted by students on a great diversity of subjects. Among the recipients of the prizes will be found the names of many members who have distinguished themselves and are now occupying prominent positions in the engineering world and in the affairs of *The Institute*.

A Student sometimes hesitates to undertake the preparation of a paper as he feels that his lack of experience may prevent his accomplishing anything really worth while, but he should remember that the collection of the necessary data for his paper will lead him to consult text books, original papers, and other sources of information, and cannot fail, in this way, to benefit, not only his fellow students, but also himself. It is generally recognized that the most effective way to learn about a subject is to make adequate preparation for teaching it.

During the past years, Council has noted with regret that the papers sent in in competition for the Students' Prizes come almost entirely from the territories of one or two of our branches, and the opportunity is now taken to place the conditions regulating the award of students' prizes more prominently before the members of *The Institute*, with the hope that during the current year a more representative body of papers will be submitted. An abstract of the conditions governing the award of the students' prizes follows:—

1. An award shall be made in each of the five sections —general, mechanical, electrical, mining and chemical— if in the opinion of the examiners a paper of sufficient merit has been presented therein.
2. Prizes of twenty-five dollars each are awarded yearly for the best papers presented by Students of *The Institute*, in each of the five sections.
3. Prizes shall be awarded only to those who are in good standing as Students or Juniors of *The Institute* at the close of the year ending June first.
4. The award of prizes shall be for the year ending June first.
5. The papers eligible for competition must be the bona fide production of those contributing them and must not have been previously made public or contributed to any other society in whole or in part.
6. In the event of no award being made in one or more of the sections, it shall be permissible for the examiners to recommend the award of two prizes in one or more sections.
7. The examiners shall be the members of the Gzowski Medal Committee.

In addition to embracing the opportunity thus offered to the student for practice in the art of presenting technical matters in writing, advantage should be taken of the meetings for students organized from time to time by various branches, at which they are offered special opportunities for practice in the art of oral discussion, one of the most valuable accomplishments a young engineer can possess.

International Electrotechnical Commission Delegates Visit Canada

In connection with the forthcoming visit of delegates of the International Electrotechnical Commission to the United States and Canada, it may be interesting to recall that this important body was founded as a result of the International Electrical Congress held in St. Louis, U.S.A., in 1904, under the auspices of the American Institute of Electrical Engineers.

National committees have now been formed in all the principal industrial countries of the world, and these committees are charged with the duty of furthering international co-operation in connection with electrical industries with a view to obtaining uniformity in such matters as practice, nomenclature, and the rating of electrical machinery and equipment.

The activities of the International Electrotechnical Commission were of course greatly limited by the War, but the work has now been resumed with greater activity, relations have been established with the various national bodies dealing with engineering standardization questions in general.

The National Committees of the International Electrotechnical Commission are in most cases nominated bodies, the members being appointed by the several national engineering societies, and this arrangement obtains in Canada, where the Canadian National Committee of the International Electrotechnical Commission includes a number of members appointed by *The Engineering Institute of Canada* together with other members co-opted by the committee itself.

It is expected that over one hundred European delegates from more than twenty different countries will shortly pass through Canada, staying three days with us on their journey from Chicago to Boston via Niagara Falls, April 29th and 30th; Toronto, evening of April 30th; Ottawa, morning of May 1st; and Montreal, evening of May 1st, and all day on May 2nd. All members of *The Engineering Institute of Canada* will unite in welcoming this important delegation and will hope that their too brief stay with us will be an experience from which they will carry away the pleasantest recollections.

The Engineering Institute of Canada branches in the Niagara Peninsula, Toronto, Ottawa, and Montreal are taking an active part in welcoming the distinguished visitors.

OBITUARIES

Martin Murphy, D.Sc., M.E.I.C.

In the death of Dr. Martin Murphy, M.E.I.C., which occurred at St. Catharines, Ont., on January 9th, 1926, the engineering profession in Canada has lost one of its outstanding figures, and *The Institute* one of its past-presidents and one of its oldest and best known members. At the time of his death Dr. Murphy was in his ninety-fourth year, and while for some time past his health had been failing rapidly, he ever displayed a keen and active interest in the affairs of the profession which he loved. An instance of this may be cited when about three years ago Dr. Murphy undertook to write his reminiscences of engineering with particular reference to railway construction in Canada but due to his failing health was unable to continue the work.

The late Dr. Murphy was born in Cooleycarny, Wexford, Ireland, on November 11th, 1832, and was educated at Ballindagin National School and by private tutor in Ireland. Subsequently, he occupied many positions before emigrating to Canada to accept the appointment as city engineer of Halifax in 1868. After serving for two years in this capacity, he became engaged in railway survey work in Nova Scotia and after a further two years on this work he was employed as contractor on the construction of bridges on the Intercolonial Railway. In the year 1875 he was appointed provincial chief engineer for the Government of Nova Scotia, which position he occupied for about thirty years, and in addition to his duties as chief engineer for the province, he was active in the laying out of the gold mining districts in Nova Scotia. During this period he was honoured with the degree of Doctor of Science, by King's College, Windsor, N.S., in 1890. Subsequent to his retirement from this position, in 1905, he was engaged in constructional work in connection with the National Transcontinental Railway in the capacity of chief inspecting engineer of the western division. It was on his appointment to this work that he moved to Ottawa where he resided until only a few months ago when he took up residence at St. Catharines, Ont.

During his earlier years in Canada, Dr. Murphy was noted for his work on highway bridges and has been credited with being the first Canadian engineer to introduce the use of the concrete culvert. As an engineer, he was beloved by all members of the profession and he was especially considerate to the younger members assisting them at all times through his sympathy and understanding.

The late Dr. Murphy, while not a Charter Member of *The Institute*, was admitted to full membership on February 3rd, 1887, some months prior to the incorporation of the Canadian Society of Civil Engineers. During the years 1888-89-97, he was a member of Council of the Society. In 1895 he was elected vice-president and in 1905 president. He was also president of the Nova Scotia Institute of Science during 1882-83. In 1893 he was awarded a gold medal for his paper illustrating bridge work in Nova Scotia which was read before the Engineering Congress at the World's Fair, Chicago, Ill., that year.

MARTIN MURPHY, D.Sc., M.E.I.C.

Kenneth Stockton Pickard, M.E.I.C.

It is with sincere regret that we note the death of one of the most prominent of the younger engineers of the Maritime Provinces, Kenneth Stockton Pickard, M.E.I.C., who passed away at his home in Sackville, N.B. on March 6th, 1926, as the result of a stroke of apoplexy. The late Mr. Pickard was born in Sackville on May 9th, 1889, and received his early education in the public and high schools of that town. Upon matriculating he entered the faculty of applied science of Mount Allison University at Sackville, and received his engineering certificate in 1911. Continuing his course he graduated from McGill University in 1913 with the degree of B.Sc., in mechanical engineering. That year he was also licensed as stationary engineer in the province of New Brunswick. In the fall of 1913 he was appointed chief engineer of the Sackville Freestone Company, then engaged in building the breakwater for the Prince Edward Island Car Ferry Terminals at Cape Tormentine, N.B. This position he held until 1916 when he joined the staff of the Imperial Ministry of Munitions as superintendent of stores and shipping for the engineering department Division of Gauges and Standards. In 1917 he enlisted in the engineers and was gazetted lieutenant. Upon his discharge in 1920, he entered provincial land survey work, under Mr. C. E. Lund, deputy land surveyor. In 1921 Mr. Pickard was himself appointed deputy land surveyor, and shortly after was licensed as a provincial land surveyor, in Nova Scotia. Since that time he had been engaged in private practice and had completed several large projects in each province.

Mr. Pickard was a member of the New Brunswick Association of Professional Engineers and had served three years as councillor of that body, being also a member of it's examining board. He was admitted to The Engineering Institute of Canada as Associate Member on April 18th, 1916, and was transferred to full membership on June 17th, 1924.

Mr. Pickard's interests were not confined entirely to the enginerring field, for at the time of his death he was in his seventh year as a member of the School Board of the town of Sackville, and for some years had been secretary-treasurer of the Eastern Electric and Development Co., of Sackville.

His loss will be keenly felt, not only by his own community, but by the entire engineering profession of the Maritime Provinces, as his sincere interest in all projects promoting the common good, and his untiring energy in furthering such projects, as well as his genial and kindly disposition, made him a favourite with all who came in contact with him, and caused him to be held in the highest respect by all who knew him.

KENNETH STOCKTON PICKARD, M.E.I.C.

Robert Hobson, M.E.I.C.

Robert Hobson, M.E.I.C., president of The Steel Company of Canada, died at his home in Hamilton, Ont., on February 25th, 1926, after an illness of only one day.

Mr. Hobson was widely known throughout Canada being an outstanding figure in Canadian industry and the news of his death came as a great shock to his many friends in the engineering profession and in public life. Born at Kitchener, Ont., on August 13th, 1861, the late Mr. Hobson received his early education at the public schools of Guelph and Hamilton. At an early age he joined his father on engineering work and for seventeen years was engaged with his father on engineering work in connection with the Great Western Railway and Grand Trunk Railway, of which the senior Mr. Hobson was at that time chief engineer.

About the year 1896, he became secretary-treasurer of a company engaged in the manufacture of pig iron in Hamilton and was continuously connected with this industry up till the time of his death. In addition to being president of the Steel Company of Canada, the late Mr. Hobson had many financial affiliations; he was president of the Landed Banking and Loan Company of Hamilton; director of the Bank of Hamilton, and subsequently of the Canadian Bank of Commerce; a director of Tucketts Tobacco Company, the Dominion Power and Transmission Company, and the Canadian Locomotive Company of Kingston. He was at one time president of the Canadian Manufacturers' Association, and was a Fellow of the Royal Colonial Institute, London, England. He was also a member of a large number of clubs in Canada.

The late Mr. Hobson was elected Member of *The Engineering Institute of Canada* on March 25th, 1919.

Walter Chamblet Adams, M.E.I.C.

The sudden death of Walter C. Adams, M.E.I.C., which occurred at Porterville, California, on February 28th, 1926, in his fifty-fourth year, as the result of a paralytic stroke, has deprived the engineering profession of Canada of a man who was pre-eminent in his special field, which, for the past ten years or more, has been particularly the study of bituminous materials and bituminous mixtures in their relation to pavement construction in Canada and elsewhere.

A few weeks before the end came, Mr. Adams accompanied by Mrs. Adams had gone to California for a rest, and there was no indication when he left Montreal that he was suffering from anything but a fatigue such as a few months vacation would remedy.

The late Mr. Adams was born in Montreal, on August 21st, 1872, and was educated at McGill University, where he received the degree of B.A.Sc., in chemistry in 1892, and in mining in 1894.

The earlier years of his professional career were spent as a mining engineer, in a consulting capacity and in charge of development work on properties in British Columbia and in Mexico; in which latter country he spent most of his time between 1905 and 1912, when he returned to Montreal following a severe attack of malarial fever.

At this period, his health was such that he was compelled to forego the active practice of his profession for a year or so; and, in fact, the effects of the fever were such that he no longer felt equal to the rugged life required of a mining engineer in the field.

In 1914, Mr. Adams became interested in the technique of asphalt paving, and first undertook some work for the towns of Maisonneuve and Verdun. In 1916, the city of Montreal engaged the firm with which he was associated, the Milton Hersey Company, Limited, to act with the city engineer, Paul E. Mercier, M.E.I.C., in connection with its asphalt street paving, and it was at this time that he became associated with Charles A. Mullen, M.E.I.C., in direction of the paving department of that firm. This arrangement continued until the time of his death, Mr. Adams and Mr. Mullen becoming close business associates and warm personal friends.

Mr. Adams still practised his profession as a consulting mining engineer, in conjunction with Captain James G. Ross, consulting mining engineer with the firm, occasionally going out to examine a property or co-operating in the preparation of a difficult report. During the last few years of his life, he became a close student of hydraulic cement concrete work, and was in charge of inspection of concrete on the substructure of the Montreal-South Shore bridge at the time of his death.

The late Mr. Adams was elected Member of *The Engineering Institute of Canada* on March 22nd, 1921.

Outside of his professional studies, the subject which seemed to interest Mr. Adams most was the rapid development of the political and economic movements of his day, which he examined, not as a partisan, but as a scholar. His oldest friend and associate in Montreal was Doctor Milton L. Hersey, the head of the firm with which his last years were spent; and his nearest relative in Montreal was Mr. Robert Job, vice-president of the same company.

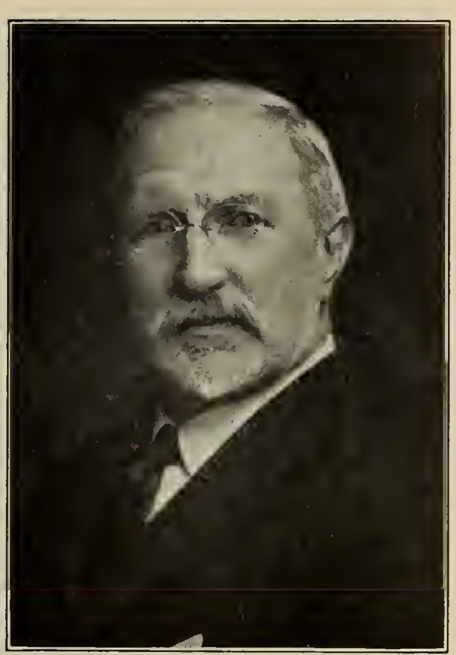
James McGown, M.E.I.C.

Regret is expressed at the death of James McGown, M.E.I.C., which occurred at his late residence, Joan Crescent, Victoria, B.C., after an illness of about two months.

The late Mr. McGown was superintendent engineer of the British Columbia Coast Steamship Service. He was born at Glasgow, Scotland on June 13th, 1863, and made an early choice of his profession or life work. He served his apprenticeship as a machinist with the Jimmie Jacks Engineering Works, Liverpool, gaining a knowledge and training that is proverbial in connection with Old Country engineering works. Having completed his apprenticeship in 1884, he joined the Cunard Line as engineer, going to sea in the Atlantic trade on different vessels, among others the Umbria, Etruria and the Oregon.

Mr. McGown joined the Canadian Pacific when that company built the first Empresses for transpacific trade and came to the British Columbia coast on the Empress of Japan, in a short time attaining the position of chief engineer of that vessel, when the company, when recognizing his thorough knowledge of marine engineering and executive ability, appointed him early in 1902 superintendent engineer jointly of the Canadian Pacific Ocean Services, Limited, and the British Columbia Coast Steamship Service, with headquarters at Vancouver. During the following years the transpacific services, as well as those of the British Columbia Coast Service lines, were gradually expanding, and in 1923 the company decided to appoint Mr. McGown as superintendent engineer for the Princess lines exclusively, with headquarters at Victoria.

Mr. McGown was held in the highest regard by all of the company's officials and by the entire staff and others serving with him. He was a recognized authority on marine engineering questions. His death will be keenly felt by a large number of friends up and down the coast and on the company's transpacific service.



JAMES McGOWN, M.E.I.C.

At the meeting of the Victoria Branch of *The Institute*, on February 17th, 1926, the following resolution was passed;

"That the Victoria Branch of *The Engineering Institute of Canada* learn with sincere regret of the passing of one of its esteemed members, Mr. J. McGown, M.E.I.C., who held such an honoured position professionally amongst his engeering confreres and associates, and that this branch place itself on record as to the loss thereby sustained by the local branch in particular, and by the engineering profession in general, and that a copy of this resolution be forwarded together with a message of condolence in their bereavement to his wife and family."

The late Mr. McGown was elected Member of *The Engineering Institute of Canada* on September 30th, 1920.

Will Reid Wellington Parsons, M.E.I.C.

It is with regret that we record the death of Will Reid Wellington Parsons, M.E.I.C., which occurred at Toronto, Ont., on January 5th, 1926.

The late Mr. Parsons was born at Orangeville, Ont., on December 24th, 1877, and received his engineering education at the School of Practical Science, University of Toronto. In February of the year 1901 he joined the staff of the Parsons Iron Works at Toronto as draughtsman and in April of the same year was appointed assistant engineer in the city engineer's office at Toronto, where he was engaged until March 1906, at which time he became city engineer of Stratford, Ont. The following year he joined his brother, J. L. R. Parsons, and subsequently moved to Regina, Sask., where he resided until 1918 when he returned to Toronto. During his stay in Regina he was engaged on construction work and many of the more important buildings throughout the province of Saskatchewan were products of the Parsons Construction Company, of which he was secretary-treasurer. Just prior to his death he joined the staff of the Massey-Harris Company, Limited.

The late Mr. Parsons was admitted to *The Institute* as Associate Member on February 7th, 1907, and was transferred to Member on August 1st, 1916.

PERSONALS

Major G. R. Evans, A.M.E.I.C., is with Messrs. Morrow and Beatty, Limited, and is located at Kapuskasing, Ont.

S. F. Ricketts, A.M.E.I.C., formerly of Winnipeg, Man., is now with Messrs. Sidney Darnbrough Limited, electrical engineers, Vancouver, B.C.

R. S. Logan, Jr., S.E.I.C., is with Messrs. Fraser, Brace Company on the construction of the International Paper Company's mill at East Templeton, Que.

O. B. Bourne, A.M.E.I.C., is with the sewer section of the Department of Works of the city of Toronto. Mr. Bourne graduated from the University of Toronto in 1907.

Mark C. Trueman, S.E.I.C., formerly of Winnipeg, Man., is located in Rio de Janeiro with the Rio de Janeiro Light and Power Company.

R. L. Dunsmore, A.M.F.I.C., formerly assistant superintendent of the Calgary refinery of the Imperial Oil Refineries Limited, is now located in South America with the International Petroleum Company, Talara, Peru.

A. H. Milne, A.M.E.I.C., has been appointed superintendent of buildings with the Protestant Board of School Commissioners of Montreal. Mr. Milne is a graduate of McGill University of the year 1917.

C. D. Sampson, Jr.E.I.C., is with the International Coal Mining Company, Limited, Westville, N.S., in charge of the surveying and draughting work for this company.

C. P. Reaper, S.E.I.C., of Montreal, is located at Port Alfred, Que., with the Foundation Company of Canada, Limited, in connection with the construction work for the Port Alfred Pulp and Paper Company.

Arthur Fraser, A.M.E.I.C., who was formerly on the staff of the Topographical Survey, Calgary, Alta., is now with the Geodetic Survey of Canada, Department of the Interior at Ottawa.

Geo. Hemmerick, A.M.E.I.C., formerly of the Ontario Department of Highways, is now representing the Dow Chemical Company in connection with their calcium chloride product for roads in the province of Ontario and has his headquarters at Toronto, Ont.

A. E. Eastman, A.M.E.I.C., is with the Central Main Power Company of Augusta, Me., and is located at Lewiston, Me. This company is installing an hydroelectric plant on the Androscoggin river at Gulf island, about five miles from Lewiston.

L. Murray Duclos, Jr.E.I.C., has been transferred from the position of transitman at Ottawa to assistant engineer with the Canadian Pacific Railway at North Bay, Ont. During 1920-21, Mr. Duclos was senior instrumentman in the office of the assistant engineer, Montreal Division of the Canadian National Railways.

H. B. Hanna, S.E.I.C., who graduated from Queen's University in civil engineering in 1924, is with the W. I. Bishop Limited of Montreal at Shawinigan Falls, Que., on the extension of the plant formerly owned by the Belgo Company but now owned by the St. Maurice Valley Corporation.

Harold E. Barnett, Jr.E.I.C., has severed his connection with the New Brunswick Electric Power Commission and has joined the staff of H. G. Acres, M.E.I.C., consulting engineer, Niagara Falls, Ont. Mr. Barnett received his degree of B.Sc. from the University of New Brunswick in 1918, and subsequently was engaged on survey work in connection with the Canadian National Railways.

Arthur Donaldson, Jr.E.I.C., is with Messrs. Burns, McDonnell Engineering Company, consulting engineers of Los Angeles, California, and is engaged as supervising engineer on the construction and design of water works and sewage projects. Mr. Donaldson is a graduate of the University of Alberta from which he received the degree of B.Sc. in civil engineering in 1922. Subsequently, he was on the staff of the Edmonton, Alberta, office of the Carter Halls Aldinger Company, Limited, of Winnipeg.

E. A. Cleveland, M.E.I.C., comptroller of water rights for the province of British Columbia has recently resigned, and has accepted the position of sole commissioner to the Greater Vancouver Water Board and chairman of the Vancouver and Districts Joint Sewerage and Drainage Board. Mr. Cleveland is a native of New Brunswick, having been born at Alma, N.B., in 1874. His engineering education was received at the University of Washington, where he was a special student during 1907. He was first engaged on railway location work in New Brunswick but since 1890 has been located in British Columbia where he has had extensive experience in engineering works.

Major J. C. MacDonald, M.C., M.E.I.C., has been appointed comptroller of water rights for the province of British Columbia succeeding E. A. Cleveland, M.E.I.C. Major MacDonald was born in Nova Scotia in1880, and graduated from Dalhousie University with the degree of Bachelor of Arts in 1904 and Bachelor of Science in 1906. After four years engineering work in eastern Canada he moved to British Columbia, where as a member of the firm of Cleveland and Cameron of Vancouver, he was engaged on various works principally in connection with the design and installation of municipal water systems, including the system at Richmond and that at Burnaby. Major MacDonald served with distinction overseas with the Canadian Engineers, having risen from lieutenant to major during service. Since 1919, he has been in charge of the reorganization and reconstruction of irrigation systems in the interior of the province of British Columbia for the provincial Department of Lands.

EMPLOYMENT BUREAU

Situations Vacant

An unmarried engineering graduate of one or two years' standing is wanted on the administrative staff of a large institution. He must be of especially good address, have an aptitude for business and be willing to start at the bottom. Apply Box No. 152-V.

CHEMICAL ENGINEER

Chemical Engineer. For particulars communicate with N. J. Gareau, Room 503, Jackson Building, Ottawa, Ont.

Situations Wanted

CIVIL ENGINEER

Shortly disengaged, age 39, married, experience on design and construction of highway and railway bridges, steam and electric railways, including street railway work, roads, sewers, main drainage, harbour work and city surveys. Apply Box No. 207-W.

COMMERCIAL ENGINEER

Young graduate wishes opening in commercial organizing and financial work for a company. Both business and technical experience. Will locate anywhere in Canada, and available early in May. Apply box No. 208-W.

ELECTIONS AND TRANSFERS

At the meeting of Council held on March 23rd, 1926, the following elections and transfers were effected:

Members

COULTIS, Samuel George, Ph.C. (Univ. of Mich.) supt. design'g and erect'g. absorption, compression and desulphurizing plant and operation with Royalite Oil Co., Black Diamond, Alta.

EDDY, Harrison Prescott, B.S. in Chem. (Worcester Polytechnique Inst.) partner Metcalfe & Eddy, Boston, Mass.

KIRCHNER, Paul, B.A., B.Sc., C.E., (Univ. of Ill.) res. mgr Union Switch & Signal Co. and engrg. advisor to pres. Massey Concrete Products Corp.

Associate Members

BENNETT, Stewart Gordon, B.A.Sc. (Univ. of Toronto), lecturer and secretary, Univ. of Toronto, Toronto, Ont.

BERRY, Edward Wilson, surveys engr. grade 3, Geodetic Survey of Canada, Ottawa, Ont.

BURKET, Leslie Howard, i/c city designing office, superintending design of all building structures, Dominion Bridge Co. Ltd., Montreal, Que.

CAREY, Edward George, elect'l. supt., town dept., Newfoundland Power & Paper Co. Ltd., Cornerbrook, Nfld.

COOTE, James Alexander, B.Sc. (McGill Univ.) Asst. professor McGill University, Montreal Que.

CRAIG, Stephen E., B.A.Sc. (Univ. of Toronto), asst. laboratory engr., i/c of inspectn. of all materials of constrn. except concrete, H.E.P.C of Ontario, Toronto, Ont.

HAWTHORNE, George, asst. engr. H.E.P.C. of Ontario, Cambellford, Ont.

HIBBERSON, Robert William, pres., Ryan McIntosh, Hibberson, Blair Timber Co. Ltd., Victoria, B.C.

JAMES, David Harries, dftsman, i/c boiler and plate work, Canadian Vickers Ltd., Montreal, Que.

KALBHENN, Josef, M.E. (Aachen Univ.) asst. ventilation engr. Dominion Coal Co. Ltd., Glace Bay, N.S.

MacCRIMMON, Duncan Daniel, Quebec Development Co., Isle Maligne, Que.

THOMAS, Arthur Stanley, B.Sc. (Queens Univ.), asst. engr., under O. S. Finnie D.L.S., director of N.W.T. & Yukon Branch., Ottawa, Ont.

WAKE, Harold Robert, B.Sc. in C.E. (Univ. of Nebraska), acting in executive capacity with Aluminum Co. of Can. Ltd., Arvida, Que.

Juniors

GUTHRIE, Kenneth MacGregor, flying officer, pilot and administrative officer, Royal Canadian Air Force, Ottawa, Ont.

KIRSCH, Harry, B.Sc. (McGill Univ.) dftsman, St. Maurice Paper Co., Cap Madeleine, Que.

McILQUHAM, Walter Scott, B.Sc. (Queens Univ.), Dominion Engineering Co. Ltd., Montreal, Que.

WOLSEY, Maunsell, B.A.Sc. (Univ. of Toronto), in engrg. cost office of Goodyear Tire & Rubber Co., New Toronto, Ont.

WOOLLCOMBE, Edward Mickle, B.Sc. (McGill Univ.) woods engrg. dept., Riordon Pulp Corpn. Ltd., Montreal, Que.

Transferred from Class of Associate Member to that of Member

BOOTH, Mark Westaway, steam engr., British Empire Steel Corp., Sydney, N.S.

COCHRANE, Morton Farrer, hydro-electric engr., Dominion Water Power & Reclamation Service, Dept. of the Interior, Ottawa, Ont.

JAMES, Edward Henry, partner with A. D. Swan, M.E.I.C., constlg. engr. Montreal, Que.

LEFEBVRE, Joseph Alexis, head of district, Roads Dept. Province of Quebec.

LUMSDEN, James Freeman, B.Sc., E.E., (N. S. Tech. Coll.); electrical engr., i/c elec'l. dept., N.S. Power Commn., Halifax, N.S.

MILLS, Thomas Stanley, B.A., B.Sc. (C.E.) (Queens Univ.), asst. chief engr., Dominion Parks Branch, Dept. of the Interior, Ottawa, Ont.

STERNS, Frank Ernest, M.Sc., (McGill Univ.) designing engr., design structures and equipment, Welland Ship Canal, St. Catharines, Ont.

Transferred from Class of Junior to that of Associate Member

DUCLOS, Lewis Murray, transitman, C.P.R., Ottawa, Ont.

GRADY, John Earle, asst. supt., By-Product Coke Plant of Steel Co. of Canada, at Hamilton Works, Hamilton, Ont.

PRIEUR, Henri, asst. engr., sewers branch, City of Montreal, Montreal, Que.

SHEPHERD, Hugh Wallis Robertson, res. engr., highway dept., Prov. of Alberta, Edmonton, Alta.

TURNBULL, Aubrey Arnold, B.Sc. (N.S. Tech. Coll.), plant engr., The New Brunswick Telephone Co., St. John, N.B.

WALTON, Frederick Stanley, instrman. on Smithers Divn. of C.N.R., Prince Rupert, B.C.

Transferred from Class of Student to that of Associate Member

AHERN, Arthur Weston, B.Sc. (McGill Univ.), vice-pres., James Ruddick Constrn. Co., Quebec, Que.

BENNETT, George Clifford, B.A.Sc. (Univ. of Toronto), vice-pres. and mgr., Burk Investments Ltd., Gen. Contractors, Real Estate & Insurance, Toronto, Ont.

CARTWRIGHT, George Herbert, B.Sc. (McGill Univ.), asst. engr., mtce. of way, Quebec Railway Light & Power Co., Quebec. Que.

DORIAN, Robert, divn, engr., i/c St. Hyacinthe Bagot Drummond and Yamaska counties, for Quebec Road Dept., St. Hyacinthe, Que.

LeBARON, Karl Shurtleff, B.Sc. (McGill Univ.), chief engr., Dryden Paper Co., Dryden, Ont.

McLELLAND, William James, B.A.Sc. (Univ. of Toronto), W. J. Westaway Co. Ltd., Hamilton, Ont.

MITCHELL, Gordon, B.A.Sc. (Univ. of Toronto), supt., i/c constrn., Virgin Falls Dam, Thunder Bay System, for H.E.P.C. of Ontario.

MOTT, Harold Edgar, B.Sc., E.E. (McGill Univ.), i/c test depts., drafting office, and factory designs, Can. Marconi Co., Montreal, Que.

PARKER, John Bruce, B.Sc. (McGill Univ.), asst. to head of engrg. dept., Sastatchewan Govt. Telephones, Regina, Sask.

WAIT, Eric Holloway, B.Sc., Met. (McGill Univ.), engr., divn. of Mineral Resources, Mines Branch, Dept. of Mines, Ottawa, Ont.

Transferred from Class of Student to that of Junior

BURTON, Harry Robert, B.A.Sc. (Univ. of Toronto), retort foreman, i/c treating at Edmonton Plant, Canada Creosoting Co. Ltd., Edmonton, Alta.

EADIE, Thomas W., B.Sc. (McGill Univ.), engrg., practices section, outside plant divn., supervisory work, Bell Telephone Co. of Canada, Montreal, Que.

ELLIOT, Gerald Burton, B.Sc. (McGill Univ.), sales engr., mech. refrigeration engrg., Montreal Office, Refrigerating Engineers Ltd., Montreal, Que.

HICKS, Alva, B.Sc. (Queens Univ.), tech. engrg., tech. dept., Northern Electric Co., Montreal, Que.

HOLMAN, John Longmaid, B.Sc. in E. E. (Univ. of N.B.), traffic engrg., traffic dept., New Brunswick Telephone Co. Ltd., St. John, N.B.

HOLT, Ernest William, B.Sc. (McGill Univ.), Canadian Mead Morrison Co. Ltd., Welland, Ont.

MILLER, Wilfred Laverne, B.A.Sc. (Univ. of Toronto), transformer designing engr., Can. Westinghouse Co. Ltd., Hamilton, Ont.

MOORE, Reginald Arthur, B.Sc. (McGill Univ.), demonstrator, dept. electrical engrg., McGill University, Montreal, Que.

NUTTER, Jack C., B.Sc., (McGill Univ.), electrical engr. and asst. to chief engr., Groveton Paper Co. Inc., Groveton, N.H.

PATTERSON, Thomas Bilton, res. engr. on prelim. survey and constrn. with dept. of Highways, Saskatchewan.

SCHERMERHORN, Henry Lewis, instrman, with Ontario Dept. of Highways, Napanee, Ont.

SCOTT, William Orville Craig, B.A.Sc., M.A.Sc., (Univ. of B.C.) smoke inspr., City of Vancouver, Vancouver, B.C.

SOMMERVILLE, Archibald Laurence Harold, B.A.Sc., (Univ. of B.C.), dftsman, reinforced concrete, Sydney E. Junkins Co. Ltd., Vancouver, B.C.

YOUNG, Dudley Stewart, B.Sc., C.E., (Univ. of Man.), field engr., Winnipeg Hydro-Electric System, at Point du Bois, sluiceway constrn.

The following students were admitted:

ADAMSON, Francis Stanley, 122 Arlington St., Winnipeg, Man.

ALLAN, John Charles, 300 Pearl Ave., Peterborough, Ont.

BRYANT, James Sanborn, 1991a De La Roche St., Montreal, Que.

CARTER, Francis Tracey, 882 George St., Fredericton, N.B.

GOUGH, Robin William, 63 Shore St., Fredericton, N.B.

GREGORY, Hurd Anthony Forbes, 149 Drummond Street, Montreal, Que.

MacPHAIL, Gordon Miller, 239 Smythe St., Fredericton, N.B.

SALTER, Frederick Cumberland Jr., 51 Vendome Ave., Montreal, Que.

SEELY, Harold Chipman, 651 Union St., Fredericton, N.B.

STOREY, Thomas Edwards, 255 Glenwood Crescent, Winnipeg, Man.

BRANCH NEWS

Border Cities Branch

W. H. Baltzell, M.E.I.C., Secretary-Treasurer.

The Border Cities Branch, *Engineering Institute of Canada,* held its regular monthly meeting on February 12th, 1926, in the Prince Edward hotel, Windsor, Ont. Twenty-eight members and friends sat down to dinner.

During the course of the meeting the chairman announced that a free post graduate course in concrete was about to be conducted in Detroit under the auspices of the Detroit Engineering Society. The following asked to be enrolled for this course: J. E. Porter, A.M.E.I.C., J. Clark Keith, A.M.E.I.C., E. S. Carlyle, Harvey Thorne, M.E.I.C., Thos. H. Jenkins, Jr. E.I.C., Harold J. A. Chambers, S.E.I.C., and Sidney Hogg, and the secretary was instructed to advise the Detroit Engineering Society asking that their names be placed on the roll for the entire course. J. Clark Keith, A.M.E.I.C., past-chairman, was the speaker of the evening. Having been solicited by the membership committee to do so Mr. Keith gave the branch the benefit of his paper on "The Border Cities Water Supply" presented in Toronto at the annual general meeting of *The Institute.* He illustrated his talk with stereoptican views, in a most entertaining and instructive way. The paper has been printed in full in the February issue of *The Journal of The Institute.*

The paper was enthusiastically received by those present, as was evidenced by the subsequent interrogations and discussion, and a hearty and sincere vote of thanks was given to Mr. Keith by those assembled.

As this closed the business of the evening, a short social period was indulged in and the meeting adjourned at 9.45 p.m.

Executive Meeting

A meeting of the Executive of the Border Cities Branch was held on Thursday, February 10th, 1926, in the office of J. Clark Keith, A.M.E.I.C., afforded the members an opportunity of meeting Major George Alexander Walkem, M.E.I.C., president of *The Institute,* but prior to convening a message was received, from Major Walkem indefinitely postponing his visit.

The following were appointed members of the standing committee of the branch for 1926.

Membership Committee:— A. E. West, A.M.E.I.C., (chairman), C. G. R. Armstrong, A.M.E.I.C., J. E. Porter, A.M.E.I.C.

Papers and Entertainment:—R. J. Desmarais, Jr.E.I.C., (chairman), W. B. Pennock, Jr.E.I.C., E. G. Riley.

It was decided to add to the duties of the Papers and Entertainment Committee by asking them to make such arrangements, with the Border Cities Star, as may be necessary to insure the meetings of this branch being given publicity.

It was suggested that a registration book, for use of those attending branch meetings, be provided in lieu of roll call but after discussing the matter it was agreed that the secretary should place slips or cards before each attendant upon which he could register.

The matter of papers for future meetings was discussed. It was suggested that we have one meeting at which papers of five or ten minutes length be read by several members, the chairman to nominate at a previous meeting, from amongst those present, the ones to present these. It was thought this would be particularly helpful to the younger members who might be hesitant about presenting more extended papers.

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch-News Editor.

Visit of President Geo. A. Walkem, M.E.I.C.

On March 1st, a welcome was tendered to President Geo. A. Walkem, M.E.I.C., which took the form of a luncheon. The chair was taken by R. S. Trowsdale, M.E.I.C., in the unavoidable absence of chairman A. L. Ford, M.E.I.C.

Major Walkem gave a talk on *Institute* affairs which was of very great interest, and was most enthusiastically received. We in the west are forced to miss a good deal of knowledge concerning the bigger business activities of *The Institute* as transacted by our chief executive council, and the speaker gave us an insight into these matters, linking us up, as it were, with such affairs. The west is honoured this year in having one of its members elected to the highest position attainable, that of president of *The Institute.*

Our guest referred to the possibility of the publication of the transactions of *The Institute* being resumed, which proved a matter of much interest to those present. Considerable care, however, had to be exercised, he said, in the expenditure of monies especially when the budget prepared for the year exceeded the anticipated income. He was emphatic on the principle of keeping up a high standard of admission for new members, pointing out how essential it was that this should be at least equal to that obtaining for admission to professional institutes in the provinces.

His reference to his visits to eastern Canadian branches was most interesting. He strongly recommended a closer touch being kept with student activities, and related how in British Columbia every student in communication with *The Institute* branch had been successfully placed in a position. He emphasized the probability of such students or young engineers being lost to Canada in many cases, if such action is not taken, and this was a responsibility that any branch might well foster.

He announced that Rudyard Kipling was very interested in the E.I.C. and had specially written a ritual for engineers, and also that there was a possibility of his coming out in July of this year to open that portion of new road forming the closing link of the main highway through British Columbia.

Major Walkem's conclusion was followed by a very hearty round of applause.

A. S. Dawson, M.E.I.C., expressed a high appreciation of Major Walkem's presence, his words, his message of goodwill from the east, and the information given, and congratulated him on the high honour bestowed on him by his election to the presidency. He stated that only on two previous occasions had western members been elected, namely J. G. Sullivan, M.E.I.C., and Colonel J. S. Dennis, M.E.I.C.

The Sugar Beet Industry

An instructive and exceptionally interesting lecture was given on March 2nd, by C. R. Wing, the superintendent of the Canadian Sugar Refineries at Raymond, Alberta. Mr. Wing addressed a big gathering of members and visitors and outlined the process of growing sugar beets, marketing, and handling them in the factory.

He explained that sugar cane and maple sugar were chemically identical, and that there was no difference whatsoever between the chemical analysis of cane sugar and beet sugar. Dealing with the history of the industry he went back to the days of Queen Elizabeth, who was the first to introduce sugar into the household, probably because it was a very expensive luxury, about $275 a hundred pounds. The first commercial extraction of sugar from the sugar beet was in 1797 when a Frenchman named Karl Achard was successful with its production. The industry did not become profitable until the Napoleonic wars. In 1830 sugar beet was first grown in the United States, near Philadelphia. There are now one hundred sugar beet factories in the States from which twenty-two million 100-pound bags of sugar were produced last year, forming only 20 per cent of the sugar consumption. The per capita sugar consumption in the States for 1925 was 107.5 pounds, an increase of 13.5 per cent over the year 1924. Relative to the growing of sugar beets, he stated that they must be properly cultivated, also that the southern Alberta climate was practically ideal for their growth and full maturity. He claimed that the growing of beets will solve to a large extent the problems of the irrigation farmers. A minimum price is guaranteed by the operating company. Besides the value of the crop in sugar product there are the by-products of pulp, beet tops, and molasses, all returning large values and of great assistance to the dairy industry.

The speaker pointed out that in the case of wheat the value of the soil fertility is also being exported, whereas with sugar it is only the air and water that acutally leaves the field in addition to the sugar, for sugar is a hydro-compound holding not a single particle of mineral matter from the soil. The tops and by-products are returned to the soil by feeding to sheep, hogs, and cattle. In the extensive cultivation necessary, weeds are destroyed, and by crop rotation the value of the land increased.

His reference to the factory was no less interesting, and with a complete set of bottles containing samples he was able to illustrate clearly the process of manufacture from the ribbon like "cossettes" or slices of beets to the finished table product. A million and a half dollars have been expended on the plant and he went into the multifarious treatments and extraction processes in considerable detail, at the same time pointing out that not a particle of the produce is manhandled and that the final product is 99.9 per cent pure sugar as determined by the provincial analyst.

His detailed explanation of the various mechanical features of the factory proved conclusively that his company are down to the minute in respect to modern equipment. It was interesting to note that sugar cannot be manufactured chemically or in any other way, but humanity is solely dependent on nature to produce this all-essential commodity in the raw state.

W. H. Snelson, A.M.E.I.C., gave a very opportune short talk on the retentiveness of soil for moisture and applied water, pointing out with the assistance of diagrams, the crop growth of beets with varying applications of water both natural and artificial. It was readily observed that there was a "just right" condition that should and could be maintained by the farmer, given the opportunity and ability to study in a more or less scientific manner the problem of the application of water to the land.

S. G. Porter, M.E.I.C., was eloquent in his remarks on the stabilizing effect that such an industry was bound to have on the province, dependent as we are to so large an extent on the products of the soil. He considered this new industry would be of lasting benefit and should open up a new era of prosperity to farming communities.

UNDERGROUND MAPPING OF OIL, GAS AND WATER HORIZONS

On February 18th, S. J. Davies, A.M.E.I.C., delivered an address to the branch on "Underground mapping of oil, gas, and water horizons encountered in drilling operations". This address created particular interest at this time especially, as considerable activity is evident in the Turner Valley oil field adjacent to the Calgary area. Mr. Davies spoke to a crowded house, in fact it was with difficulty that late visitors were able to find standing room. Engineers, operators, promoters, drillers, and brokers were in evidence on all sides, and all listened with keen attention. Many questions were asked and were very ably answered by the speaker.

At the conclusion of the lecture the geological samples displayed were closely examined by many of those present. Mr. Davies is to be congratulated on his presentation of a paper that showed careful study and accurate knowledge of the subject selected, and which was much appreciated by all who were fortunate enough to be able to attend.

LIGHT RAILWAYS IN FRANCE DURING THE WAR

On January 25th, F. K. Beach, A.M.E.I.C., gave the branch a talk on light railways in France during the great war. Mr. Beach, at very short notice, kindly filled the gap caused by the unavoidable absence of one of the scheduled speakers.

It proved an excellent discourse on methods adopted to overcome difficulties in track-laying at the scene of warfare and was followed closely by all present. The speaker displayed the somewhat rare gift of making things quite clear in a few well chosen words, and with the aid of several charts illustrated his points in a very interesting manner. Considerable discussion followed on the question of steel versus wooden ties and on the stability of light railway wagons on narrow gauges, etc.

Edmonton Branch

W. R. Mount, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the branch was held in the Macdonald hotel on February 23rd. The chairman, A. G. Stewart, A.M.E.I.C., briefly introduced Mr. Bache Wiig who had come to address the branch concerning the possibilities of making paper from Alberta straws.

The paper was listened to with the greatest interest by a large meeting and much discussion was entered into. The samples of papers and boards which were shown were of large variety and interest. It is hoped that at a later date Mr. Bache Wiig's paper will be printed in full, as it was felt by all present that it would be of far wider interest than to this branch alone.

A very hearty vote of thanks was accorded Mr. Bache Wiig.

Lethbridge Branch

N. H. Bradley, A.M.E.I.C., Secretary-Treasurer.

The Lethbridge Branch met on February 21st, for its usual bi-monthly dinner. The guest of the evening was Prof. Edgar Stansfield, M.E.I.C., honorary secretary of the Research Council of Alberta.

Mr. Stansfield gave a most interesting and instructive address on the work being done by the Research Council and showed the results obtained by the experiments of Professor Clark of the Alberta University in developing a process for extracting the bitumen from the McMurray tar sands. Professor Stansfield stated that the process was now available for commercial purposes, but he pointed out that so far the experiments in the use of bitumen were all to the end of developing an all-weather service for dirt roads. The bitumen was mixed into the clay and produced a waterproof layer that so far has made the roads treated adaptable to traffic throughout the year.

Professor Stansfield also entered into the work being done with coals and elaborated somewhat on the briquette. He referred to the fact that briquettes were now being manufactured on a commercial scale at Canmore and that the Research Board was finding there a proving ground for their laboratory experiments.

Professor Stansfield showed a number of slides and charts of coal areas and systems of analyses for coal. The meeting was enlivened as usual by community singing and by solos from Messrs. Parsons and Meldrum. The Rainbow Orchestra, which is always a feature of the Lethbridge Branch, was again in evidence and played throughout the dinner.

There were about forty members and affiliates present and these entered earnestly into the general discussion following Professor Stansfield's able address.

London Branch

E. A. Gray, A.M.E.I.C., Secretary-Treasurer.

The regular February meeting of the London Branch was held in the Board Room of the Public Utilities Commission on Thursday, February 18th, at 8.15 p.m.

The branch was most fortunate in having as the speaker of the evening President Geo. A. Walkem, M.L.A., M.E.I.C. President Walkem discussed several phases of engineering as obtaining in British Columbia, especially pointing out the work which is being accomplished there in the way of providing employment for students graduating from the university, and assisting them in every way possible in their chosen profession.

Moncton Branch

M. J. Murphy, A.M.E.I.C., Secretary-Treasurer.
V. C. Blackett, A.M.E.I.C., Branch News Editor.

MANUFACTURE OF PORTLAND CEMENT

The "Manufacture of Portland Cement" was the subject of a very interesting illustrated address delivered by H. S. Van Scoyoc, M.E.I.C., in the City Hall, Moncton, N.B., on March 4th. Mr. Van Scoyoc is consulting engineer for the Canada Cement Company and is widely known for his work in connection with concrete highways. Because of the importance of the subject the meeting was open to the public, and in addition to a large attendance of branch members, a number of persons, prominent in building work, were present.

C. S. G. Rogers, A.M.E.I.C., chairman of the branch presided.

Mr. Van Scoyoc stated that although the patents on Portland cement were taken out over a century ago, it is only within recent years that concrete, of which Portland cement is the principal ingredient, has come into general use. In 1880, the annual output of cement, on this continent was only 40,000 barrels; at the present time the output is 150,000,000 barrels per annum.

Hydraulic cements were not unknown to the Ancients. They were, however, mostly used in mixing mortar. It is interesting to note that the cement made by the Romans from volcanic dust was almost exactly the same as the slag cement manufactured at Sydney, C.B.

Briefly, the manufacture of Portland cement consists in passing a mixture of pulverized limestone and clay, to which a small quantity of gypsum is added, through a rotary kiln. This kiln is about 9 feet in diameter and 150 feet long and is set on a slight slope. The ingredients are fed in at the upper end of the kiln, either in the dry state, (dry method), or else mixed with water to form "slurry", (wet method). The slope and rotary action of the kiln causes the mixture to move slowly from the upper to lower end, during which time it is subjected to a temperature of upwards of 3,000° F. After passing through the kiln, the cement is again pulverized, and then stored for shipment. To maintain the intense heat in the kilns, large quantities of coal are required. The manufacture of one cubic foot of cement calls for an equal volume of coal. In the central province plants alone about one million tons of coal is required annually. Mr. Van Scoyoc, on being questioned, was unable to state what percentage of coal used, was mined in Canada.

The address was followed by a very interesting discussion. Mr Rogers described methods of calculating stresses in rotary kilns, and Prof. H. W. McKiel, M.E.I.C., told of his experiences while chemist of a cement plant.

A vote of thanks moved by Prof. McKiel, and seconded by A. S. Gunn, A.M.E.I.C., was tendered Mr. Van Scoyoc for his excellent address.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
Stanley A. Neilson, A.M.E.I.C., Branch News Editor.

Tribute Paid the late Phelps Johnson, M.E.I.C.

Prior to the regular meeting on February 25th., an expression of the feeling of loss that the profession had sustained through the death of Mr. Phelps Johnson was given by Mr. Duggan. He spoke very feelingly of their close associations on various engineering enterprises and suggested that the branch executive be instructed to word a suitable resolution of regret to be inscribed in the records of the branch. The resolution follows:—

"At the suggestion of Mr. Duggan, the Montreal Branch of the Engineering Institute of Canada wish to go on record as expressing their deep regret on the death of Mr. Phelps Johnson, past-president and past-vice-president of the Institute, and for six years a member of Council.

His admirable personality and his unassuming character gained for him a host of friends; his eminence as an engineer was acknowledged by the profession on both sides of the Atlantic; and his death leaves a vacant place which will be difficult to fill.

The branch desires to place on record its sense of loss and its appreciation of the importance of the services rendered by Mr. Johnson to The Institure, to the engineering profession and to the public welfare."

The development of the outside plant of the Bell Telephone Company

W. H. Winter, assistant to the general manager of the Bell Telephone Company of Canada, and himself one of the telephone pioneers, having seen over forty years of service in the telephone company, was the speaker for the evening on February 25th., before the Montreal Branch.

Mr. Winter's address contained much information tending to disabuse the mind of the average telephone user that the telephone instrument is all that is necessary for the carrying on of conversation over the wire. He outlined the main features of the outside plant which he defined as "all the structures, apparatus and appurtenances required to connect the central offices to the subscribers' stations and to connect the various central offices with each other."

His treatment of the subject was for the most part historical, beginning with the first telephone system, if it may be so called, which Professor Alexander Graham Bell erected on a fence in Brantford, Ontario, in 1876. Limited development took place until 1880, when the Bell Company was organized and absorbed a number of small exchanges in Quebec and Ontario.

At the start the outside plant work followed the methods that had been laid down by the telegraph companies, but as the service expanded and the number of lines increased the poles and numbers of cross-arms became so numerous that the development of a suitable cable was made necessary, and a system of underground conduits was considered. The first underground cable was laid in Toronto in 1889, Mr. Winter gave some very interesting figures as to the miles of cables in Toronto and Montreal, as to the numbers of poles, etc., in use, and then dealt with the company's work of planning for the future, through commercial surveys, fundamental plans and construction programmes, on which plant development is based.

Dealing with the matter of expenditures, the speaker stated that in 1925 over five million dollars had been spent in outside plant and that for the period 1926-1930, thee stimated expense was placed at nearly twenty-eight millions, with an average per year for Montreal and Toronto of about one million each.

In conclusion, he said that the tradition of the company has been to use the best of equipment, to be ever seeking something better, to improve the service and to find new means of meeting the steadily-increasing requirements, which policy has brought about a development, beginning with a few small isolated telephone exchanges, with 2,100 stations, in 1880, to an up-to-date telephone system, second to none, of 592,000 exchange stations and long distance facilities to interconnect with 17,000,000 telephones throughout Canada and the United States, an achievement of which any builder may justly be proud.

J. A. McCrory, A.M.E.I.C., occupied the chair and tendered to the speaker the vote of thanks that was proposed by C. K. McLeod, A.M.E.I.C.

The Chicago Drainage Canal

So completely was this subject covered, and exhaustive elucidation given to every aspect of the question by J. L. Busfield, M.E.I.C., at the Montreal Branch meeting on March 4th., that not one query was put by any member of the large audience or exception taken to any of his observations. when the meeting was thrown open for discussion.

In the expressed opinion of J. W. Hayward, A.M.E.I.C., who was called on by the chairman, C. J. Desbaillets, M.E.I.C., to propose a vote of thanks to the speaker, no other paper to which he had ever listened at the Institute had proved of such interest or been so completely comprehensive in character, treating in detail every phase of a very broad subject in the short space of two hours.

Vancouver Narrow's Bridge

An engrossing description of the recent construction of the Vancouver Narrow's Bridge was given to the members of the Montreal branch by E. H. James, A.M.E.I.C., on March 11th.

In his address Mr. James, who was resident engineer during the building operations, told of the method of construction and the many difficulties that had to be overcome before the link between Vancouver and North Vancouver was completed. The paper was illustrated by a large number of lantern slides showing the bridge at all stages, as well as many details of the fabrication of the concrete piers on which the superstructure was placed.

The project was mooted before the war, said the speaker, but was not taken up again in real earnest until the beginning of this decade. The bridge consisted of a trestle span, fixed span, bascule span, tower span, and two other spans terminating in a trestle span on the north shore. It was designed to carry a single railroad track and two highways 10 feet wide on either side, and one sidewalk, and its need was proved in the month after the opening on November 7, 1925, when 5,000 automobiles and 125,000 people crossed the bridge.

The work of trestle driving began in January, 1924, and the construction of the concrete cylinders for the piers soon followed.

The designers were faced with a difficulty in that no solid rock foundation could be found for the main caisson of the bridge although a depth of nearly 100 feet under water was reached at high tide, and it, was this fact that occasioned the most difficult problem that arose during building operations.

After the caisson for pier No. 2 had been constructed and floated out to position in mid-stream, not without difficulty as a seven-mile an hour current necessitated the work being done during the slack water, they found that after the caisson had been sunk to a depth of 90 feet at high water it rested on a ledge rock, apparently on the edge of a vertical cliff. Dynamite did not reveal any great amount of rock bottom at a lower depth and only damaged to some extent the walls of the working chamber.

Consequently the engineers were forced to add to the base the caisson where it did not rest upon solid rock and as the work had to be done at a considerable depth below water the task was none too easy.

The men working on the pier had to work in short shifts of 50 minutes and so great was the pressure at that depth that many of them suffered from the "bends."

Following an agitation on the part of shipping companies and lumber companies who claimed that the bridge as designed would greatly interfere with their operations, the suprestructure of the bridge was set at a height of five feet more above the water than was called for in the original design, and part of the trestle span was replaced by two steel spans.

During the summer of last year the steel spans were built and placed in position, the last 150-foot span being finished in August.

The bascule, which is raised by two 100-horse-power electric motors may be fully opened in 75 seconds, it having a counterweight concrete block weighing 1,000 tons.

A short discussion followed the paper and a hearty vote of thanks was tendered the speaker.

History of the Locomotive, its development and Future possibilities

The history of the locomotive, its development and future possibilities was the subject of the lecture delivered by W. A. Newman before the Montreal Branch on March 18th, 1926.

From very early times it was customary to convey coal first by panniers on horses, then by horse-drawn carts and by barges to a considerable distance from the mines themselves. The carts were first used on dirt roads, then flagstones were laid as cartways, next the carts became four wheel wagons and early in the 17th century the collieries commenced to haul their waggons on wooden rails which very greatly increased the hauling capacity of horses. These roads of rails or railroads, as they were soon called, first consisted of long wooden rails with a flange built on the inside but which were later abandoned in favour of a plain rail with a flange on the wheel. Cast iron rails were used as early as 1738 and the flanged wheel made its appearance about the year 1789.

The speaker gave a description of the progress of the steam locomotive. The Cornwall man, Richard Trevithic constructed what was really the first successful steam locomotive, some years elapsed before any further developments occurred with locomotives during which period the combined use of horses and fixed winding engines was considerably extended. In 1811 Blenkinsop constructed for the Middleton colliery a locomotive which cost £380. The engine performed satisfactorily and a few others were built of the same type which worked for a considerable number of years. In 1814 George Stephenson, who with his son, was destined to become the most outstanding figure in the development of the locomotive, produced one for the Killingworth colliery.

All the railways in operation at this time, the speaker said, were intended for the haulage of coal and merchandise and passengers were not even considered. One writer of eminence at that time went so far as to declare that he would as soon think of being fired off on a ricochet rocket as to travel on a railway at twice the speed of the old stage coaches.

Shortly after the opening of the Liverpool and Manchester railway a passenger train was run as an experiment and greatly to every one's surprise more passengers presented themselves than could be carried. From this time passenger traffic grew to such an extent that it became a big proportion of the business and in fact called for the entire remodelling of the railways. The locomotive at this time was, of course, intended as a substitute for the horse. With continued improvements, it soon demonstrated that its capacities were away beyond those of horse haulage and heavier and more powerful locomotives succeeded each one after the other. The speed of the trains also increased which improvements called for still heavier rails which in turn became obsolete with further increases in locomotives weights and speeds and this succession of heavier locomotives and rails has not only continued up to the present but will undoubtedly continue into the future.

As for the American continent the locomotive only really started in 1828 with the importation of two English locomotives. The first locomotives to be built in America was not constructed until after 1830. The speaker also dealt with the electric locomotive and the internal combustion locomotive. The lecture was illustrated with lantern slides depicting the different types.

The chairman was A. R. Ketterson, A.M.E.I.C.

Visit of Sir Sefton Brancker

On the occasion of the visit of Sir Sefton Brancker, director of civil aviation of Great Britain, to Montreal on March 19th, 1926, the executive of the Montreal Branch and the resident members of Council entertained him to an informal luncheon at the University Club.

Following the luncheon, Sir Sefton told those present of the progress that is being made in Britain in the field of civil aviation. He complimented Canada on the aerial survey work that was being done here, saying that in this particular line Canada leads the world.

C. J. Desbaillets, M.E.I.C., acted as chairman, and J. M. R. Fairbairn, M.E.I.C., thanked the speaker for his interesting talk.

Papers and Meetings Committee

The following have been appointed to the above committee:— R. E. MacAfee, A.M.E.I.C., chairman, A. Duperron, A.M.E.I.C., vice-chairman.

Civil Section;—A. Plamondon, A.M.E.I.C., chairman.

Electrical Section:—G. A. Wallace, A.M.E.I.C., chairman.

Mechanical Section:—J. W. McCammon, A.M.E.I.C., chairman, F. S. B. Heward, A.M.E.I.C., vice-chairman.

Municipal Section:—J. G. Caron, A.M.E.I.C., chairman, J. F. Brett, A.M.E.I.C., vice-chairman.

Railway Section:—D. Hillman, M.E.I.C., chairman, J. A. Ellis, A.M.E.I.C., vice-chairman.

Student Section:—G. Gingras, S.E.I.C., chairman, H. L. Johnston, S.E.I.C., vice-chairman.

International Electrotechnical Commission

On April 30th and May 1st., Montreal will be visited by members of the above mentioned body. Prior to this date a meeting is to be held in the United States, the members then coming through Canada visiting Niagara, Toronto, Ottawa and Montreal. It has been proposed that the Montreal Branch entertain them and the details of this are to be announced later.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The motion pictures taken during the 1925 Canadian Arctic expedition were screened for the first time before a large audience in the Victoria Memorial Museum hall last night. The screening and lecture by George P. Mackenzie, officer in charge of the 1925 expedition, was under the auspices of the Ottawa Branch, and was open to the public.

There were a great many good reasons to justify the expenditure of time and money on such expeditions, Mr. Mackenzie stated. Canada's root of title to the Canadian Arctic Archipelago is an Imperial order-in-council passed in 1880, a good holding title but to be made indefeasible must be followed by occupation and government.

It would be a dangerous thing for Canada to say that her northern possessions were not worth while. Mr. Mackenzie recalled that at one time Alaska had been considered useless and that Canada had lost untold wealth by failing to take it over.

The motion pictures formed a most complete story of the whole trip of 102 days. Pictures were taken at the farthest north post of the R.C.M.P. and at all points visited. From a scenic standpoint the pictures of icebergs in the polar seas were exceptionally fine. J. D. Craig, M.E.I.C., director general of surveys, Department of Interior, and chairman of the Ottawa Branch, was in the chair.

Some Great Men of Science and Their Books

An eloquent and erudite address was delivered before the Ottawa Branch when Dr. Leo E. Pariseau, of the Hotel Dieu, Montreal, who has achieved distinction both as scientist and bibliophile, lectured on "Some Great Men of Science and Their Books."

Dr. Pariseau in an interesting manner traced the trend of scientific thought and progress from the time of the Greeks down to comparatively recent times and he pointed out what the world owed to the countries bordering on the eastern section of the Mediterranean for here not only occurred the founding of Christianity, but from this comparatively small area also came the foundations of modern arts and sciences from the Greeks, Egyptians, Phœnicians and Romans.

The lecturer referred to the notable achievements of the Greeks in the study of astronomy, metaphysics, biology, anatomy and kindred sciences and stated that in this respect they excelled the Romans, who though capable soldiers and administrators, were more given to moralising and copying the Greeks than to looking into the basic cause of things. The library at Alexandra founded by Ptolemy contained 700,000 books and the speaker referred to the loss sustained to learning when this collection was destroyed by the Arabs in the 7th century.

Dr. Pariseau said that the Middle Ages could be called the Dark Ages so far as advance in science was concerned, with some notable exceptions, and in illustration of this he stated that many of the learned Greeks and Roman savants held that the world was spherical, for which belief Columbus and Gallileo were persecuted so many years later.

References were made to the great scientists of the 15th and following centuries and particularly to their contributions made to anatomical and physiological science in the invention of the microscope and the discovery of the circulation of the blood. A valuable collection of scientific books dating from the 16th century were placed on view and created particular interest.

J. D. Craig, M.E.I.C., chairman of the branch, who occupied the chair, expressed the thanks of the meeting to Dr. Pariseau for his valuable address and this was ably seconded by Noulan Cauchon, A.M.E.I.C.

Major Walkem's Visit

The part played by engineers in the making of Canadian history, and particularly the history of British Columbia, was outlined by Major George A. Walkem, M.L.A., M.E.I.C., of Vancouver, B.C., in an address at the luncheon of the Ottawa Branch, at the Chateau Laurier. J. D. Craig, M.E.I.C., chairman of the branch was in the chair.

Major Walkem first paid high tribute to the Ottawa Branch, and then gave a very interesting and graphic summary of the history of Victoria, B.C., pointing out that the first white man to explore the coast was Captain Vancouver. He also made reference to the epic-making journey of Sir Alexander Mackenzie, the first white man to reach tidal waters at the Bellacoola river.

Major Walkem also spoke of the railway engineering feats of British Columbia, and of water power developments.

At the conclusion of the address Mr. Craig thanked the speaker on behalf of the Ottawa Branch, and invited the new president to address the Ottawa engineers on subsequent visits to the capital. The president exemplified in his person the type of engineer which was his ideal—a man versed in commerce and public affairs, the chairman said.

Peterborough Branch

P. Manning, A.M.E.I.C., Secretary-Treasurer.
W. E. Ross, A.M.E.I.C., Branch News Editor.

Trees

On the evening of January 14th, a very interesting meeting was held at which Mr. H. J. Moore, of the provincial department of agriculture presented a most interesting and enlightening talk on "Trees."

A. L. Killaly, A.M.E.I.C., chairman of the branch, introduced the speaker and made brief reference to the long experience that Mr. Moore had had in this particular work, which experience includes ten years at Queen Victoria Park, Niagara Falls; the planting of the trees along the highway between Niagara Falls and Fort Erie and other service with the provincial department of highways.

Mr. Moore in his address covered the various uses of trees, for parks, shade purposes and the preservation of wild flowers and wild birds, and he also discussed reforestation and the effect of this on the economic life of the country. Reference was also made to the effect of trees on waterflow, and the influence on climate and rainfalls. He made a particular appeal for action to offset the great loss occasioned, due to the improper pruning of trees by inexperienced people, and stated, that, in his opinion, in all towns or cities a by-law should be introduced for the protection of trees, giving the parks commissioner the sole authority to prune, remove or otherwise attend to all trees.

The address was illustrated with excellent lantern slides, some of which depicted some very interesting examples of tree surgery.

Power Factor Correction

On February 4th, B. L. Barns, M.E.I.C., gave an interesting and instructive paper on "Power Factor Correction" before a goodly attendance of members and friends.

Mr. Barns, for the benefit of those of the audience not familiar with electrical matters first briefly explained power factor, the causes of low power factor and the general effects, both from the consumers' and the supply company's point of view.

The speaker then elaborated his remarks regarding the objectionable features and disadvantages of low power factor, explaining in detail the effect as regards size of transmission lines, capacity of machines, cables, transformers and switching apparatus and the detrimental effect on voltage regulation.

Passing to the question of power factor correction, Mr. Barns stressed the point that there is no general solution of the problem of power factor correction and each case must be treated according to its merits. He stated, however, that it is generally accepted that the greatest benefit is to be derived by correcting the power factor on the premises of power users where it is possible to obtain the same results with less investment and maintenance cost and contingent losses by the use of synchronous motors operating at leading power factor, and at the same time bring about a corresponding improvement in the power factor conditions of the secondary distribution system. The use of synchronous condensers, static condensers and induction motors for power factor correction was then discussed and the advantages and disadvantages of each pointed out, after which Mr. Barns cited several concrete examples, quoting actual figures.

R. L. Dobbin, M.E.I.C., was in the chair at this meeting and on motion of Mr. Wells Fraser, president of the Chamber of Commerce, tendered to Mr. Barns a hearty vote of thanks.

Aviation and Modern Engineering Practice

A regular meeting was held on the evening of February 11th, at which Commander E. W. Stedman O.B.E., M.E.I.C., gave a paper on "Aviation and Modern Engineering Practice."

This lecture has already been given by Commander Stedman before the Montreal Branch, and was described in these columns in the January issue, therefore, we do not propose to describe it in detail.

The description to above had prepared us for a pleasant evening, and it is no exaggeration to state that the lecture, and the lecturer, fully lived up to the advance notices, with the result that a thoroughly enjoyable evening was afforded the goodly number of members and friends present at this meeting.

The lantern slides used by Commander Stedman as illustrations for this lecture include some of the most remarkable and beautiful photographs ever shown before this branch.

At the conclusion of the paper a fair amount of discussion followed and several questions were asked of the speaker, after which R. C. Flitton, A.M.E.I.C., proposed a vote of thanks, which was approved by all present and tendered to Commander Stedman by the chairman, A. L. Killaly, A.M.E.I.C.

The branch had the pleasure of the company of G. E. Bell, M.E.I.C., of Ottawa at this meeting.

Saint John Branch

J. W. Johnston, A.M.E.I.C., Secretary-Treasurer.

Interconnection of High and Low Pressure Turbines

On February 19th, 1926, the members of the Saint John Branch were addressed by J. D. Garey, A.M.E.I.C., chief engineer, New Brunswick Power Company, Saint John, on "The Interconnection of High and Low Pressure Turbines." The meeting was held in the New Brunswick Telephone Company's building with W. R. Pearce, M.E.I.C., presiding.

In introducing his subject the speaker briefly traced the growth of the steam turbine in America during the past thirty years. The several types of turbine were clearly shown by slides, and other features of the address were also explained by slides.

The speaker described an actual problem met with in the operation of the power house of the New Brunswick Power Company at Saint John, where electricity is generated for domestic and public utility uses. In 1918 there developed such an overload on the company's system that it became imperative that something be done to obtain more power, and this at a time when new equipment was expensive, hard to obtain, and time of delivery uncertain. This was overcome by operating a high pressure condensing turbine as an extraction unit to supply steam to a low pressure turbine operated as a bleeder unit. By this means equipment on hand was utilized whereas otherwise expensive machinery would have had to be installed.

The power house of the Saint John Drydock and Shipbuilding Company was also described. The excess power generated here is used as required during peak loads on the system of the New Brunswick Power Company under an arrangement between the two companies. The first-named is supplied with oil-burning equipment, and at the second coal is used as fuel.

A discussion by those present disclosed many interesting points. A hearty vote of thanks on behalf of those present was moved by S. R. Weston, M.E.I.C., and G. G. Murdoch, M.E.I.C. After the meeting the members visited the power house of the New Brunswick Power Company and saw in operation the machines described in Mr. Garey's paper.

The Manufacture of Cement

A meeting of the Saint John Branch was held on March 5th, 1926, in the New Brunswick Telephone Company's building with W. R. Pearce M.E.I.C., as chairman. H. S. Van Scoyoc, M.E.I.C., of Canada Cement Company, Montreal, addressed the branch on "The Manufacture of Cement". The various processes of manufacture from the quarrying of the limestone to the storing and shipping of the finished product were shown by a moving picture film, and were also described by the speaker. More than eighty operations are required during the manufacture of cement, and the description of the care taken in making samples through out the process to ensure a proper finished product was very interesting.

The speaker also described the advances made in the use of cement whereby better concrete was now being obtained by controlling the proportions of the aggregate and using proper quantities of water. The use of a small proportion of calcium chloride and heating the aggregate were described as means employed for hastening the setting of the concrete.

The discussion at the close of the address proved a very interesting part of the meeting. Many questions were asked Mr. Van Scoyoc and great interest was shown. A vote of thanks was moved by Geoffrey Stead, M.E.I.C., and G. G. Murdoch, M.E.I.C.

Sault Ste. Marie Branch

A. H. Russell, Jr.E.I.C., Secretary-Treasurer.

A special meeting of the Sault Ste. Marie Branch was held on Monday February 22nd, at Y.W.C.A. rooms. The guest of honour at the dinner was Major Geo. A. Walkem, M.E.I.C., president of *The Institute.*

C. H. Speer, M.E.I.C., chairman, called the meeting to order and introduced Major Walkem by outlining his civic, political, military and engineering activities. He gave a brief history of the local branch, showing the growth and the prospects ahead of it.

Major Walkem expressed his pleasure in being able to meet the members of the Sault Branch again as he still carried pleasant memories of his last visit to the Sault, in 1924, when he had presented the charter to the branch. He briefly outlined the activities at headquarters and stressed the point of getting the young engineers into *The Institute* and the encouragement of giving prizes for the Student members while attending university. The average engineer, he said, is too modest and should serve the public more, as taking part in public life, (politics), broadens and strengthens the engineer. In the Vancouver Board of Trade, the engineering section is one of the most important and every city having a Board of Trade should have an engineering section.

Then, by special request of the chairman, Major Walkem gave a most vivid description of his work with the Royal Engineers in the Suez canal area and Palestine on railroad construction and maintenance. He had charge of the construction of 500 miles of road, the excavation of which was all done by native labour without the use of mechanical devices such as steam shovels, etc. In the whole distance of 500 miles one standard frog, a No. 7, was used throughout. The flies, heat and sandstorms caused the most trouble to the men and the white men worked in the morning and evenings only, as they couldn't stand the heat in mid-day. He said that the 75-pound rails used were carried on the backs of twelve natives and laid in place. These rails weighed about 900 pounds each. Modern shops and roundhouses were built and equipped with the latest machinery. A chlorination plant was installed and water trains were run to carry water to the front line trenches. He said that the pipe line used to carry the water pumped from Suez to Palestine was constructed from lap welded pipe and as this pipe line was being constantly bombed, considerable work was required at night repairing it. The track suffered from bombing also and the maintenance crew were kept constantly at work repairing and as the track went within three miles of the front line trenches, it was extremely dangerous work. The rolling stock consisted mostly of old engines dug out of scrap at Cairo and repaired. The fire boxes of these engines were made of copper and their efficiency was very low as most of the $75.00 per ton coal went out through the smoke stack.

The new road connected with the old Jaffa railway built in 1892, and Major Walkem said that they standardized the old road from where they cut into it to Jerusalem. His description of this old railroad was most interesting. All culverts were built of stonework and no steel was used and around all cliffs and bluffs, no cuts were made but embankments of stonework were built to support the tracks. In describing general conditions in Palestine, he said that the conditions were very much the same as in Bible days. The beasts of burden were, camels, donkeys and women, and that the men supervised. The farming is done in January, as from May to November the rains are very heavy.

A lively discussion followed and Major Walkem had to answer numerous questions as several members desired more detailed information as to his methods used in overcoming some of the many difficulties with which he had to meet.

A most hearty vote of thanks was moved by C. H. E. Rounthwaite, A.M.E.I.C., and J. H. Jenkinson, A.M.E.I.C., to Major Walkem for his interesting talk and they extended to him a cordial invitation to visit the Sault Branch whenever it was possible for him to do so.

A regular meeting of the Sault Ste. Marie Branch was held at the Y. W. C. A., on March 5th, 1926.

THE MANUFACTURE OF ARTIFICIAL SILK

C. H. Speer, M.E.I.C., chairman, called the meeting to order and the business was first disposed of. Then Mr. Speer introduced the speaker A. D. Hone, principal of the Technical School, who gave a splendid paper on "The Manufacture of Artificial Silk," an abstract of which appears on another page of this Journal.

This subject is of both local and general interest—local because the chief raw material is wood pulp, which is manufactured in the local plant of the Spanish River Pulp and Paper Company, and general because it has to do with clothing, one of the fundamental necessities of life.

Toronto Branch

C. B. Ferris, A.M.E.I.C., Secretary-Treasurer.
J. W. Falkner, A.M.E.I.C., Branch News Editor.

THE ECONOMIC AND ENGINEERING SITUATION IN CANADA

Brig. Gen. C. H. Mitchell, C.B., C.M.G., C.E., M.E.I.C., addressed the Toronto Branch on Thursday evening, February 18th, on the above subject, and the relation of the engineering profession as a definite factor in the economic and industrial fabric of the country was ably indicated.

A brief resumé of the above paper will be given in the next issue.

After discussion, which was led by J. A. Knight, A.M.E.I.C., the chairman, Professor T. R. Loudon, M.E.I.C., extended a hearty vote of thanks to the speaker for his interesting and instructive paper.

CONSERVATION OF RAINFALL IN SOUTHERN INDIA

It was a great pleasure to be addressed on February 25th by one of our own branch members whose professional life has been largely spent in a climate and under labour conditions very different to those prevailing in Canada today.

The speaker, G. W. Winckler, M.E.I.C., unfolded the story of a paternal British government, that, faced with the administration of the Native State of Mysore, Southern India, during the minority of the child Maharaja, and the necessity, in the interest of the native cultivators, of rehabilitating the badly run down water storage and irrigation systems, placed him about 1872 in charge of a large rainfall conservation district, thousands of miles from the world's markets, and from such everyday commodities as iron bolts and nails, and where he was directly dependent on native labour and workmanship, and local materials.

Fortunately, there are found throughout the Deccan nodules of pure limestone from which the natives make most excellent lime, and they are also adept in brick making. These, together with earth, rock, teak, and bamboo were structural materials ready to hand. Mr Winckler described in detail the excellent work done to conserve rainfall, the method of constructing dams, etc., illustrating his address with diagrams. Excellent lime concrete had been made, using 4 or 5 parts of stone to one part of lime mortar.

An interesting discussion followed after which R.O. Wynne-Roberts, M.E.I.C., moved a vote of thanks to the speaker. The discussion disclosed the interesting fact that two or three of our branch members present had spent time in Southern India, and were very familiar with the conditions depicted by Mr. Winckler.

CIVIC FINANCE

At the monthly luncheon meeting held at the King Edward hotel on March 4th, we welcomed as our guest and speaker Geo. H. Ross, finance commissioner for the city of Toronto.

We suppose there are some to whom the term "Civic Finance" means little more than frequently recurring tax demand notes. Mr. Ross, in a witty and — as also befits a finance commissioner — a partly statistical speech, showed that engineers, at any rate should have more interest than that, because *they* are the men who keep the finance commissionners busy. "*Debt charges* are the sons of *capital expenditure;* the *engineer* is the father of capital works" and however much capital works may be apprecia ed by the public, their progeny, (our *GRANDCHILDREN*, if Mr. Ross be correct!), certainly are not.

Mr. Ross explained in a very lucid manner the high mysteries of civic finance, the functions of the various departments that collect monies from the public, and the percentage requirements of our annual civic budget. With regard to debt flotation, Mr. Ross sounded a note of warning. It was, however, cheering to know that debt charges, which have steadily risen from $1,600,000. in 1912 to $6,400,000. per annum in 1925, will for the first time in 1926 show a diminution.

Mr. Ross urged the members present to assume responsibility in the affairs of the city. They were shareholders in a billion dollar corporation, and those who were directing the affairs of the city would welcome expressions of public opinion to aid them in their work. "Every man owed more than his taxes".

Victoria Branch

E. G. Marriott, A.M.E.I.C., Secretary-Treasurer.

CANADA'S NEW PACIFIC PORT

On January 20th, J. P. Forde, M.E.I.C., gave an exceedingly interesting talk on "Canada's New Pacific Port."

After outlining the historical events that deprived Canada of the coast line north of the Portland canal on the Pacific, a map was shown on which were marked the approximate positions of the ice front at different periods in Glacier bay, Icy Straits.

At the time of a visit by Capt. George Vancouver in 1794, the glacier line was only 3 miles from the mouth of the bay; between 1794 and 1912 the line retreated some 62 miles, or an average of half a mile a year; while in the last thirteen years it has receded a further 4000 feet.

At the present time, after entering Glacier bay, a distance of 44 miles is covered to a point where three inlets meet; the most westerly of these, Reid inlet, stretches for 12 miles, and then divides into two, the more westerly Tarr inlet having a length of 13 miles, with the Grand Pacific glacier at its head.

The line of vegetation was of considerable interest, as at Icy Straits the growth was similar to that on the near Alaskan coast, whereas in Glacier bay it was smaller.

Willoughby island was reported to be bare in 1869, but now had a covering of willows, and a number of spruce up to twenty feet in height. Hugh Miller islets also had some willow, and about a dozen spruce from six to eight feet high.

Composite island was bare, except for sea-grass and moss and, a few alpine flowers, while Reid inlet above its mouth was devoid of vegetation.

The change in rate of the recession of the glaciers seemed to take place after deep water was passed, and now about half of the toe of the Grand Pacific glacier is exposed at low water.

Glacier bay, as its name suggests, is touched by many glaciers, and the noise made by the tons of ice falling from the faces was almost continuous.

The speaker outlined their efforts to mark the international boundary line at its intersection with the shore of Tarr inlet, owing to the prevalent fog an approximate position was first located by comparison with the contour map of that area, and when, a little later, a fortunate opportunity enabled them to get a transit line on stations 160 and 161 they were agreeably suprised at the closeness of their first mark.

It was found that there is now some 4,000 feet of water in Canadian territory, and though the roughness of the mountain ranges, and the numerous glaciers, prevent access by land, it may prove to be of use as a harbour for industrial purposes.

A number of slides illustrating the trip up the coast, with reference to many points of interest were shown, also unique photos of the icebergs and glaciers in Tarr inlet and vicinity.

A curio of note was on exhibit, on the shores opposite Willoughby island, buried forests have become gradually uncovered, as the ice cap receded, and Mr. Forde was fortunate in obtaining a section of the trunk of a Sitka spruce released from the glacial morain, which showed a growth of some 124 years, and was estimated to be about 300,000 years old.

EARTHQUAKES

On February 10th, F. Napier Denison, director of the Dominion Meteorological Observatory on Gonzales Hill, Victoria, gave an illustrated lecture on "Earthquakes".

After dealing with the latest views as to the structure of the earth and its crust, and illustrating the scientific theory of earthquakes by sections showing the comparative height of mountains and sea depths at the critical world seismic zones, Mr. Denison sketched the improvements in seismographs, and showed a number of records made at Victoria at the time of well-known quakes, and also outlined the methods by which the location of such disturbances was fixed.

Mixed feelings of regret and pleasure mingled at a luncheon held on February 22nd, at which E. A. Cleveland, M.E.I.C., was the guest, and at which some thirty engineers met to offer their congratulations to Mr. Cleveland on his appointment as commissioner of the Greater Vancouver Water District and chairman of the Vancouver and Districts Joint Sewerage and Drainage Board.

Mr. Cleveland, who has filled the position of comptroller of water rights for the last seven years, gave a concise outline of the progress of legislation in regard to water in the province of British Columbia from the days of Sir James Douglas, emphasizing the gradual growth of a policy that insists on beneficial use being made of water and also of the granting to the crown of the rights to all unrecorded water, thus abrogating the old doctrine of riparian rights; the respective duties of the comptroller of water rights, and the board of investigation under the present Water Act were also mentioned.

After thanking the speaker for his interesting outline of the water laws of th eprovince, the chairman, J. M. Anderson, A.M.E.I.C., tendered to Mr. Cleveland the congratulations of the engineers, and their regret at his departure from Victoria. P. Philip, M.E.I.C., deputy minister of public works; E. Davis, M.E.I.C., chief engineer, Water Rights Branch; J. Umbach, surveyor-general; F. L. MacPherson, M.E.I.C., of the provincial civil service, voiced their regret at losing such an outstanding member of the engineering profession, while feeling that Vancouver was to be congratulated on its choice. Satisfaction was also expressed that the position had been filled from among the engineers of the province.

Col. A. W. R. Wilby, A.M.E.I.C., Bateman Hutchinson and G. B. Mitchell, M.E.I.C., past chairman of the branch, also spoke, after which opportunity was given for a personal word with Mr. Cleveland by many of his friends.

Mineral Industry in British Columbia

On February 17th, members of the branch and their friends enjoyed a talk by J. P. Galloway, Provincial Minerologist, who gave some interesting statistics regarding the mineral industry in British Columbia. The mineral production last year in British Columbia, said Mr. Galloway, represented $61,500,000, of which metals represented $47,000,000, coal and coke $11,500,000 and the remaining $3,000,000 included non-metallics and building material. Of the lode production 72% was treated in the Province, 15% was shipped in a crude condition, while the remaining 13% was partially treated in British Columbia. He also mentioned that 15,000 men were employed in mining in British Columbia, which represented a payroll of $25,000,000.

Mr. Galloway then referred to the difficulty in determining the profits made from mines. He quoted figures as to the investments in the industry and stated that the capita value of mining production in British Columbia was $93.00, whereas in the whole of Canada it was only $24.00. He referred to the future prosperity of the mining industry in the province and pointed out that improper transportation was greatly aiding production. In the coal industry better conditions might be expected in view of the increased cost of crude oil, Mr. Galloway then referred to the existing conditions dealing with the subject under the heading of the various districts created by the Provincial Government. In each of the six districts he showed that there was increased activity.

On the conclusion of the address a hearty vote of thanks was given the speaker for his excellent address upon one of the great industries of the province, which had proved most interesting to all present.

J. N. Anderson, A.M.E.I.C., chairman of the branch, added his thanks to that expressed in the motion, describing the address as one of the most enlightening that had been given before the body.

Preliminary Notice

of Applications for Admission and for Transfer

March, 19th, 1926

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in April, 1926.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council, shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering with special reference to the branch of engineering in which he has been engaged. This examination may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the first year in such a course, shall be required to pass an examination in the following subjects: geography, history, (that of Canada in particular), arithmetic, geometry, euclid (books I, IV and VI), trigonometry, algebra up to and including quadratic equations.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed successfully an examination equivalent to the final examination of a high school or the matriculation of an arts or science course. He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which cash he shall pass an examination equal to that prescribed for admission to the grade of Junior in the foregoing section and he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineer in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BRANDON—HARRY ELMER, of 24 Abbott Ave., Toronto, Ont. Born at Cannington, Ont., Feb. 7th, 1884. Educ., B.A.Sc., Univ. of Toronto, 1907; 1908-11 detailing and designing structural steel, Manitoba Bridge & Iron Works, and Vulcan Steel Works; 1911-15 Vulcan Iron Works, chief engr. i/c design and fabrication; 1915-19 overseas military service; 1919 to present, station structural and mechanical engr. with Hydro-Electric Power Commn. of Ont.

References: E. T. J. Brandon T. H. Hogg, J. J. Traill, W. P. Dobson, R. B. Young.

COX—LEONARD MARTIN, of 57 Post St., San Francisco, Cal. Born at New Liberty, Ky., Mar. 21st, 1870. Educ., Renselaer Polytechnic Inst.; 1892-99, Union Iron Wks. N.Y. Louisville & Jeffersonville bridge and ry. wk.; 1899-23, in U.S. Navy; 1899-1901, Lieut. asst. to Pub. Wks. Officer, Navy Yards New York, immediate charge reconstrn. drydock No. 2; 1901-03 Pub. Wks. Officer, Isl. of Guam, constrn. of roads, design of watrworks and survey; 1903-06 i/c design and constrn. floating dock; 1906, chief engr. Louisville Henderson & St. Louis Ry.; 1907, recommissioned Lieut. U.S. Navy 1907-08, asst. to Pub. Wks. Officer, i/c constrn. drydock No. 3 Navy Yard Norfolk, Va; 1909 Commander; 1909-11 asst. ch. of Bureau Yards & Docks, Washington, 1911-14 Pub. Wks. Officer Navy Yard Norfolk, Va. i/c pub. wks. design constrn. and operation; 1912-13, member Taft Alaska Railroad Comm; 1915-17 Pub. Wks. Officer, Navy Yard, New York; 1917-18, Pub. Wks. Officer San Diego, Cal., initiating work on Naval Air Sta. and Marine expeditionary Depot; 1918-19, Asst. Mgr. div. ship yard plants, Emergency Fleet Corp. Philadelphia; 1919-23, Pub. Wks. Officer Navy Yard Mare Isl. Cal., i/c pub. wks. and constrn.; 1921, Captain; 1924 to date, consltg. in San Fransisco; economic study of ship canal, design for reconstrn. of Tampico harbour, other harbour and minor bridge projects.

FOR TRANSFER FROM CLASS OF ASSOCIATE MEMBER TO MEMBER

DEVEY—JOHN HARDY, of Richmond Va. Born at Staindrop Eng., Feb. 12th, 1883. Educ., 1903-05 Durham Col. of Science; 1900-02 pupil with Sir Wm. Arrol & Co. Glasgow, Scotland; 1902-05 articled pupil C. F. Bengough M.I.C.E. chief engr. North Eastern Ry. Co. England; 1905-06 location and constrn. of C.N.R.; 1906-07 on staff of city engr. Toronto, Ont.; 1908, deputy city engrg. West Toronto; 1909, priv. practice, Toronto, report on Lake Superior Br. G.T.P.Ry. for Ry. Commn.; 1910, res. engrg. C.N.P.R. in B.C.; 1911-14, engr. for Howe Sound & Northern Dev. Co., B.C.; 1914, reconnaisance survey, plans, reports, etc. for rly. from Findlay Forks, B.C. to Peace River; 1915, asst. engrg. Can. Explosives, Nanaimo; 1916-17, engaged on Victoria Breakwater for Sir John Jackson & Co., 1917-18, various engrg. works; 1918-19, engr. for Moore & Silverton, Vancouver; 1919-23, member of firm Robertson & Devey, cons. engrs; drydock plans, oil tanks design of steel and concrete structures, bridge, dam, and canal works etc.; 1923, designer steel and concrete highway bridges for North Carolina State Highway Commn; 1924 to date, designer Chesapeake & Ohio Ry. Co. steel and concrete structures.
References: T. H. White, C. H. Rust, C. E. Cartwright, E. G. Matheson, J. Kilmer W. Anderson, C. M. Morssen.

KIRKPATRICK—EVERETT CHARLES, of 47 Ainslie Rd., Montreal West, Que. Born at Montreal, Feb. 3rd, 1885, Educ., B.Sc., McGill Univ. 1906; summers while at univ. surveys, and machine shopwork; since graduation employed continuously with Steel Co. of Can. & Mtl. Rolling Mills, as dtfsman, supt. of constrn., and for last 6 or 7 years as mechanical engr. i/c design of new plant and i/c operation of power depts. for the Steel Co. of Canada's plants in Montreal.
References: H. M. Jaquays, D. C. Tennant, J. T. Farmer, A. R. Roberts, C. V. Christie.

MIDGLEY—FRANK HAROLD of Galt, Ont. Born at Cambuslang, Scot., May 26th, 1884. Educ., C. E. Associate Royal Technical Col., Glasgow; 1900-1906, articled pupil to Niven & Hoddin, C. E. Glasgow; 1906, asst. engr. i/c of drainage, waterworks etc. surveys, plans, estimates, supervision of constrn. final adjustments, etc. with contractors; dftsman, Dom. Bridge Co. Lachine, Que,; 1907-12, topographer, dftsman. leveller, transitman, with C.P.R. survey parties; 1912-15, res. engr. on constrn. of double track, Lake Superior Divn. C.P.R., 1907 to date, continuous service with C.P.R. engrg. dept.; at present, engr., Lake Erie & Northern & Grand River Rlys. (subs. of C.P.R.) i/c maintenance and constrn.
References: J. M. R. Fairbairn, P. B. Motley, D. Hillman, J. Haddin, C. A. D'Abbadie.

YORATH—CHRISTOPHER JAMES, of 2211-7th St., Calgary, Alta. Born at Cardiff, Wales, 4th, Nov. 1880. Educ., A.M.I.C.E. Cardiff Wales 1905; asst. to contractors engr. Mount Stuart drydock, Cardiff, asst. to city engr. Cardiff, municipal engrg. wks, electrification of horse-drawn street rly., drainage, road, constrn., bridges, public baths, sewage disposal, town planning etc.; 1902-13 deputy engr. Acton Boroug Council, London, Eng., engaged on design and supervision of municipal engrg.; 1913-21, city commr., of Saskatoon; 1921-24 city commr., of Edmonton, in both cases responsible for all pub., wks., and munic. administration, including operation of public utilities, street rly., elec. lt. and pr., waterworks etc.; at present, pres. and mng. dir. of Can. Western National Gas Light, Heat & Power Co., pres. and mng. dir. of Northwestern Utilities Ltd., pres. and mng. dir. of the Gas Production & Transportation Co.

FOR TRANSFER FROM JUNIOR TO HIGHER GRADE

DESMARAIS—RAYMOND JOSEPH, Walkerville, Ont. Born at Walkerville, Ont., Nov. 8th, 1894. Educ., 1 yr. Univ. of Detroit, Windsor Collegiate Inst., I.C.S. (C.E.) 1910-17, rodman, chainman, dftsman, transitman, Owen McKay, O.L.S. Walkerville, 1917-19, transitman and leveller, i/c party under Owen McKay; i/c party under R. W. Code, O.L.S., work included surveys, subdivisions, drainage, pavements, sewers, sidewalks, railways, bridges; 1920-22, designg. engr., city engr's office, Windsor Ont. 1922- to date, asst. city engr. Windsor, Ont.
References: M. E. Brian, C. R. McColl, J. C. Keith, W. J. Fletcher. J. J. Newman, H. W. Patterson.

FOR TRANSFER FROM STUDENT TO HIGHER GRADE

ELEY—FREDERICK CHARLES, of 140 Montrose Ave., Toronto, Ont. Born at London Ont., Nov. 15th, 1897. Educ., B.A.Sc., Univ. of Tor. 1921; summer 1917, machine shop operative, Benjamin Electric Co., Toronto; June 1918–Oct. 1919, switch and switchboard assembler and finishing dept.; summer 1920, stockkeeper for same firm; summer 1921, assembler; 1921-22 mfg. dept. and cost dept., lighting equipment, wiring device, switch and switchboard design, estimating work, and checking designs; 1922 to date, engr., i/c design proposals and pr. sales, Benjamin Electric Co.
References: A. S. Cook, F. R. Ewart, D. M. Fraser, R. W. Angus, G. W. Winkler.

FARRELL—ALFRED JAMES, of 4874 Westmount Ave., Westmount Que. Born at Montreal, Que., May 15th, 1900. Educ., B.Sc., McGill Univ. 1924; Oct. 1924 to Jan. 1925 training in the Planning Dept. of the Can. Consolidated Rubber Co.; 1925 i/c installation of rubber flooring for the Can. Consolidated Rubber Co. to present date.

Members of Council for 1926

PRESIDENT

*GEO. A. WALKEM, Vancouver, B.C.

VICE PRESIDENTS

*A. S. DAWSON, Calgary, Alta.
†PETER GILLESPIE, Toronto, Ont.
*K. B. THORNTON, Montreal, Que.
†W. G. MITCHELL, Quebec, Que.
†GEO. D. MacDOUGALL, New Glasgow, N.S.

PAST PRESIDENTS

J. M. R. FAIRBAIRN, Montreal, Que.
J. G. SULLIVAN, Winnipeg, Man.
ARTHUR SURVEYER, Montreal, Que.

COUNCILLORS

*L. M. ARKLEY, Kingston, Ont.
*E. V. BUCHANAN, London, Ont.
*G. H. BURBIDGE, Port Arthur, Ont.
‡J. L. BUSFIELD, Montreal, Que.
*E. V. CATON, Winnipeg, Man.
*F. O. CONDON, Moncton, N.B.
*R. L. DOBBIN, Peterborough, Ont.
*JOHN DOW, Lethbridge, Alta.
†J. T. FARMER, Montreal, Que.
*O. S. FINNIE, Ottawa, Ont.
*F. C. GREEN, Victoria, B.C.
*A. W. HADDOW, Edmonton, Alta.
*E. G. HEWSON, Toronto, Ont.
*J. H. HUNTER, Montreal, Que.
*E. LAVOIE, Chicoutimi, Que.
*O. O. LEFEBVRE, Montreal, Que.
*H. R. MacKENZIE, Regina, Sask.
†GEO. R. MacLEOD, Montreal, Que.
‡C. M. McKERGOW, Montreal, Que.
*W. F. McLAREN, Hamilton, Ont.
†D. L. McLEAN, Winnipeg, Man.
*JAS. MUIRHEAD, Vancouver, B.C.
*A. B. NORMANDIN, Quebec, Que.
‡J. M. OXLEY, Toronto, Ont.
*J. E. PORTER, Ford, Ont.
†J. L. RANNIE, Ottawa, Ont.
*W. C. RISLEY, Sydney, N.S.
*C. H. E. ROUNTHWAITE, Sault Ste. Marie, Ont.
*T. S. SCOTT, Niagara Falls, Ont.
*R. S. TROWSDALE, Calgary, Alta.
*A. G. TAPLEY, St. John, N.B.
†H. K. WICKSTEED, Toronto, Ont.
*C. H. WRIGHT, Halifax, N.S.

*For 1926 †For 1926-27 ‡For 1926-27-28

TREASURER
MAJOR GEN. SIR ALEX. BERTRAM, Montreal.

SECRETARY
R. J. DURLEY, Montreal.

OFFICERS OF BRANCHES

HALIFAX
Chairman, H. W. L. DOANE
Vice-Chair., W. A. WINFIELD
Sec.-Treas., K. L. DAWSON, 115 Morris Street, Halifax, N.S.
Executive, W. F. McKNIGHT, H. S. JOHNSTON, W. P. COPP, J. S. MISENER, R. R. MURRAY, J. G. W. CAMPBELL, H. F. BENNETT, D. W. MUNN, W. A. WINFIELD, C. W. ARCHIBALD, H. C. BURCHELL
(Ex-Officio) C. H. WRIGHT,

CAPE BRETON
Chairman, W. C. RISLEY
Vice-Chair., W. S. WILSON
Sec.-Treas., D. W. J. BROWN, Bank of Commerce Bldg., Sydney, N.S.
Executive, J. J. McDOUGALL, W. E. CLARKE, J. R. MORRISON
(Ex-Officio) S. C. MIFFLEN, GEO. D. MACDOUGALL

ST. JOHN
Chairman, W. R. PEARCE
Vice-Chair., A. R. CROOKSHANK
Sec.-Treas., W. J. JOHNSTON, Box 1417, St. John, N.B.
Executive, G. STEAD, S. R. WESTON, E. A. THOMAS, G. G. HARE
(Ex-Officio) A. G. TAPLEY

MONCTON
Chairman, C. S. G. ROGERS
Vice-Chair., A. S. GUNN
Sec.-Treas., M. J. MURPHY, Eng. Dept., C.N.R., Moncton, N.B.
Executive, A. F. STEWART, J. R. FREEMAN, J. D. McBEATH, F. B. FRIPP, G. C. TORRENS, G. E. SMITH
(Ex-Officio) F. O. CONDON

SAGUENAY
Chairman, C. N. SHANLY
Vice-Chair., G. E. LAMOTHE
Sec.-Treas., BURROUGHS PELLETIER, Box 181, Chicoutimi, Que.
Executive, E. LAVOIE, J. E. A. McCONVILLE, J. L. DELISLE, A. A. MacDIARMID

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, A. B. NORMANDIN
Vice-Chair., S. L. deCARTERET
Sec.-Treas., LOUIS BEAUDRY, P.O. Box 115, Quebec, Que.
Executive, T. E. ROUSSEAU, H. CIMON, L. C. DUPUIS, A. LARIVIERE

MONTREAL
Chairman, C. J. DESBAILLETS
Vice-Chair., C. V. CHRISTIE
Sec.-Treas., C. K. McLEOD, 318 Lagauchetiere St.W., Montreal, Que.
Executive, A. DUPERRON, A. R. KETTERSON, J. A. McCRORY, P. L. PRATLEY, JAS. ROBERTSON, F. C. LABERGE
(Ex-Officio) C. M. McKERGOW, J. M. R. FAIRBAIRN, GEO. R. MacLEOD, K. B. THORNTON, ARTHUR SURVEYER, O. O. LEFEBVRE, J. T. FARMER, J. H. HUNTER, J. L. BUSFIELD

OTTAWA
Chairman, J. D. CRAIG
Sec.-Treas., F. C. C. LYNCH, Nat. Resources Intelligence Br., Dept. of the Interior, Ottawa, Ont.
Executive, A. E. DUBUC, J. ALBERT EWART, S. J. FISHER, W. A. RUSH, A. K. HAY
(Ex-Officio) J. L. RANNIE, A. F. MACALLUM, O. S. FINNIE

PETERBOROUGH
Chairman, A. L. KILLALY
Vice-Chair., B. L. BARNS
Secretary, P. MANNING, 551 Weller St., Peterborough, Ont.
Treasurer, A. B. GATES
Executive, W. M. CRUTHERS, W. E. ROSS, R. C. FLITTON, D. L. McLAREN, J. H. MacINTOSH, A. H. MUNRO

The Chicago Drainage Canal

A Review of the Historical, Technical, Financial and International Features

J. L. Busfield, B. Sc., M. E. I. C.
Consulting Engineer, Montreal, Que.

Paper read before the Montreal Branch, March 4th; Kingston Branch, March 17th; Toronto Branch, March 18th; Peterborough Branch, April 8th, and Niagara Peninsula Branch, April 21st, 1926.

History of the Drainage Canal

The Chicago drainage canal has the main object of providing a means of diverting water from lake Michigan westwards into the Des Plaines river and ultimately into the Illinois and Mississippi rivers, for the purpose of diluting and carrying away the sewage of the city of Chicago and surrounding municipalities in order to prevent its discharge into lake Michigan, where it would have the effect of contaminating the water supply. The drainage canal is also used for navigation and power development purposes. The history of the project on its present lines, while full of noteworthy events, is of comparatively short duration. If, however, a reference to the orginal thought of making a water connection between lake Michigan and the Illinois valley is included, it is necessary to go back to the 17th century, at which period references were made by the explorers Joliette, LaSalle and others to the possibility of reaching the gulf of Mexico from lake Erie by way of lake Michigan and the Des Plaines and Illinois rivers.

The first definite event in the life of the project was an Act of Congress on March 3rd, 1822, granting a right-of-way through public lands for the proposed canal, which lapsed through non-compliance with its conditions. It was followed by another Act dated March 3rd, 1827, granting to the state of Illinois certain lands for the construction of a canal between lake Michigan and the Illinois river. It might be noted in passing that at this date, practically one hundred years ago, Chicago did not exist. It was not until nine years after the land grants had been made, namely 1836, that construction was actually started on the Illinois and Michigan canal, but owing to various delays, particularly those due to difficulties in financing, it was not completed and put into operation until twelve years later, 1848, in which year the canal was opened from Bridgeport to LaSalle. This canal had a bottom width of 36 feet and a depth of 6 feet. The original plans had been for a deep cut canal at the level of lake Michigan, but the financial difficulties above referred to led to a modification of the plan and it was built partly at a higher level. Water was supplied from the Chicago river by a lift-wheel at Bridgeport, and while this was not of sufficient quantity to reverse the flow of the river, it nevertheless can be looked upon as the first actual diversion of water belonging to the lake Michigan watershed into the Illinois valley, and only came about as a necessity for the operation of the canal.

The first sewer system was put into operation in Chicago in 1856, when the population had become about 80,000. These sewers discharged into the Chicago river. At this time, Chicago was becoming the important railway centre of the middle west, and this was one of the principal factors leading to its subsequent phenomenal growth.

To return to the canal,—it was apparently looked upon as a success from the traffic point of view, as it was decided to improve it by lowering the summit level and carrying it through at the level of lake Michigan. This work was accomplished in the years 1866 to 1871, and at the same time the flow in the canal from the Chicago river was increased to 1,000 cubic feet per second. Pumping was still adhered to, as the natural flow through the canal was only about 700 cubic feet per second.

There is little to record during the next decade, but by the eighteen eighties the sewage problem was becoming a serious factor in the growth of the city. Apart from any question of actual construction of sewers, which in itself has always been a difficult matter owing to the extreme flatness of that part of the country, the discharging of sewage into lake Michigan was seriously contaminating the water supply, the death rate from typhoid fever reached alarming proportions, and indeed it may be noted in passing that for the period of twenty years subsequent thereto the death rate from typhoid fever was greater than that of any of Chicago's sister cities in the lake region. This state of affairs led to the appointment of a Drainage and Water Supply Commission in 1885. This commission reported in

January, 1887, in favour of a drainage canal with a capacity of 10,000 cubic feet per second, connecting the Chicago and Des Plaines rivers. This may be said to be the origin of the present undertaking. The commission concluded its labours shortly after presenting its report.

The legislature of the state of Illinois took direct action, however, by an Act which came into force on July 1st, 1889. This Act created the Sanitary District of Chicago for the purpose of disposing of the sewage of Chicago and contiguous territory and determining the method of administration and financing. The district was given rights to construct a main drainage canal, to build sewage treatment and disposal plants, and to construct docks. The drainage canal was specifically covered in the Act. It was to be at lake level, parallel to the old Illinois and Michigan canal, and to have a bottom width of 160 feet, minimum depth of 18 feet, a minimum capacity of 10,000 cubic feet per second, and carry a flow at all times of at least 3 1-3 cubic feet per second for each 1,000 population tributary to the canal. It was also provided in the Act of 1889 that that part of the canal excavated in earth could be constructed in consecutive stages, but that the rock section should be immediately excavated to the full section. The Act also provided that when the flow became 5,000 cubic feet per second the canal shall be declared a navigable stream. When the Act was put into force, the territory covered by the Sanitary District covered only a part of the area occupied by the city of Chicago and comprised 185 square miles with a population of 1,140,000. From time to time, however, there have been amendments to the Act increasing the size of the district, until to-day it covers an area of 437.39 square miles, includes 49 municipalities in addition to the city of Chicago, and serves a total population of about 3,500,000.

Three years after the passing of the Act, i.e. in 1892, work was commenced on what is the present main drainage canal, and carried on continuously, until its completion at the end of 1899. Water was turned into the canal on January 2nd, 1900, while the flow through the canal was commenced two weeks later. It might be mentioned in passing that great interest was taken by engineers throughout the world in the construction work, as new methods of rock excavation and handling had been devised without which the cost of the undertaking would have been absolutely prohibitive. It was the first occasion when channelling machines were used on a large scale, thus providing a smoother waterway, requiring a smaller section than would have been required with the older method of excavation.

The main drainage canal was constructed as far as the controlling works at Lockport, at which point it was to discharge into the Des Plaines river. It was appreciated, however, that the capacity of the Des Plaines river, between Lockport and Joliet, would be insufficient for the augmented flow, so between the years 1898 and 1901 considerable work was done in widening and improving this part of the river. It must also be noted that at this period no provision was made for navigation through the drainage canal.

While this work was going on, the Sanitary District of Chicago applied to the United States secretary of war for permission to alter various structures in order to permit the passage of 5,000 cubic feet per second through the Chicago river. This permission was granted by the acting-secretary on July 3rd, 1896.

Prior to the completion of the canal, an Act was passed by the United States Congress on March 3rd, 1899, giving the secretary of war jurisdiction over all navigable waters, subsequent to which a new permit was issued by the secretary of war on May 8th, 1899, covering the provisions for the protection of navigation in the Chicago river.

On April 9th, 1901, the secretary of war reduced the permissible flow through the Chicago river to 3,333 cubic feet per second. However, on December 5th of the same year, he permitted the Sanitary District to increase the foregoing amount to 5,000 cubic feet per second between the hours of 4 p.m., and 12 midnight, daily. In the meantime the district commenced the work of improving the river by the removal of bridge piers and by widening, in order to reduce the velocity. On January 17th, 1903, the secretary of war granted a permit for the diversion of 5,833 cubic feet per second continuously until March 31st of that year, subsequent to which the flow was not to exceed 4,167 cubic feet per second. This permit remained in force until 1925.

During this period, and, indeed, until quite a few years later, it is not apparent that there was any direct opposition to the principle of diversion of water from lake Michigan by the Sanitary District of Chicago, but, nevertheless, there were many watchful eyes, as indicated by the fact that from the very early days of the undertaking, reports and investigations were being made by many interested parties, and in particular, some years before the completion of the canal, the Canadian government retained J. L. P. O'Hanley, C.E., to report on the probable effect of the diversion at Chicago on the levels of the Great Lakes. O'Hanley's report was dated February 29th, 1896, and amounted to a confirmation of the opinion of the United States chief of engineers, to the effect that there was insufficient data available for a determination sufficiently accurate to serve any useful purpose.

On May 14th, 1903, the Illinois State legislature passed an Act amending the original Act of 1899 by which they added the North Shore and Calumet regions to the original district and at the same time authorized the development of such water powers as might be incidental to the drainage canal scheme. The work of extending the main drainage canal from the Lockport controlling works, four miles further downstream, was forthwith commenced. At the same time, the present power house and navigation lock were built at the new end of the canal. The power house was put into operation on November 26th, 1907, and has been continuously operated ever since.

In order to provide sufficient water to flush out the South Fork of the South Branch of the Chicago river, (into which the stock yards empty their sewage), a conduit was built at 39th street, connecting the pumping station on lake Michigan with the South Fork. This was put into permanent operation on December 28th, 1905. Similarly it was found that with the growth of the population on the north side, there was insufficient natural flow in the North Branch, and this was partially remedied by the construction of a conduit at Lawrence avenue, connected with a pumping station near the lake. This conduit was put into operation on May 28th, 1909. At the same time a new channel was being cut, (the North Shore channel), making a direct connection from the lake at Wilmette, (13 miles north of the mouth of the Chicago river), to the North Branch. This was put into operation on November 29th, 1910.

While the development of the work on the north side was being undertaken the district was also looking to ways and means of preventing pollution of lake Michigan water by the discharge of the Little Calumet river on the south side of the city. Studies were commenced in 1907 for reversing the flow of this river, and diverting lake Michigan water through the Calumet river and a new channel connecting with the drainage canal at Sag. In 1908 the Sanitary District applied to the secretary of war for permission to withdraw 4,000 cubic feet per second through this channel in addition to the flow through the Chicago river. This was refused, but the Sanitary District ignored the refusal and action was taken against it in the United States courts. The district again applied for a permit for the Calumet-Sag channel, and on June 30th, 1910, this was obtained but it was specifically provided that the total withdrawal from lake Michigan should not exceed the 4,167 cubic feet per second originally allowed. It is therefore of interest to note at this point that this is the first of the permits which gives any indication that the problem was being dealt with from the view-point of the effect of the diversion on lake navigation, as heretofore it seems to have been effects in the Chicago river which were of prime consideration.

The Calumet-Sag channel was started on September 18th, 1911, and was put into operation on August 26th, 1922, but this project cannot be said to be completed as the Calumet river section still has to have considerable improvement work carried out.

To return to the legislative history, during all this period, while construction of many parts of the undertaking was going on, there were investigations and reports being made almost continuously, and indeed have continued up to the present date. The history of all these investigations and reports would fill a volume in itself; it must here suffice to refer to the principal bodies, which were the International Waterways Commission, boards of engineers appointed by the Canadian government, and by the United States government, and by the Sanitary District itself. The United States Lakes Survey, the United States Corps of Engineers, numerous consulting engineers, many of them of world-wide fame, have studied and reported on the problem, and lent their quota to the information and opinions at hand.

At the same time it must not be forgotten that the legal fraternity have had a finger in the pie as well as engineers. Applications to Congress, to the secretary of war, suits in various courts, numerous hearings, actions of one kind or another, interpretations of acts and treaties, have all lent a hand in providing bases for lengthy legal battles and conferences. Out of the chaos of all this examination and cross-examination, one event of supreme importance stands out and must be noted in order to give a proper conception of later events and present-day arguments. Subsequent to a long study and reports in 1906 and 1907 by the International Waterways Commission, (appointed in 1905), the boundary waters treaty between Great Britain and the United States was concluded on January 11th, 1909. This treaty, which is still in effect, covers all the terms agreed to by the two countries for the use and control of the Great Lakes, St. Lawrence river and boundary waters.

On February 28th, 1912, the secretary of war opened the hearing of an application from the Sanitary District of Chicago for permission to divert a quantity of water not to exceed 10,000 cubic feet per second. The Canadian government and shipping interests opposed to the application were heard on March 27th, 1912, and on January 8th, 1913, the secretary of war refused the application.

When it was found that, notwithstanding the refusal of the secretary of war to grant a permit for more than the original amount of 4,167 cubic feet per second, the Sanitary District was withdrawing considerably larger quantities, the United States government instituted legal proceedings by taking out an injunction against the district. This was fought out in the United States district court at Chicago, and it was only after a long-drawn-out legal battle with many delays that a final decision was rendered by Judge Carpenter on June 18th, 1923, finding against the Sanitary District. The case was appealed to the United States Supreme Court, which again upheld the federal government in a judgment rendered on January 5th, 1925. The decision rendered was on the question of jurisdiction of the secretary of war and judgment was to the effect that the Sanitary District had no authority to exceed the quantity permitted by the secretary of war.

The Sanitary District forthwith applied to the secretary of war for a permit to divert an annual average of 10,000 cubic feet per second, and on March 3rd, 1925, a permit was issued authorizing the Sanitary District to—

> "divert from lake Michigan, through its main drainage canal and auxiliary channels, an amount of water not to exceed an annual average of 8,500 cubic feet per second, the instantaneous maximum not to exceed 11,000 cubic feet per second....."

The principal conditions* are that sewage treatment must be carried out to the extent of 100 per cent treatment for 1,200,000 people by the end of 1929; the deposit of $1,000,000 towards the cost of remedial works on Great Lakes; installation of controlling works for Chicago river; metering of Chicago's water supply. It is understood that the sewage outflow amounting to about 1,200 cubic feet per second is not included in the foregoing amount of 8,500 cubic feet per second.

In the meantime, it must not be overlooked that while all these legal battles were proceeding, history was being made on other lines. It is stated that as early as the year 1908, immediately following the recommendations of the International Waterways Commission, studies were being made by the engineering department of the Sanitary District of ways and means for treating their sewage wastes. Laboratories and experimental stations were established and have been continuously in operation ever since. Special investigations were made on domestic sewage from 1908 to 1911; on the trade wastes from the stock yards 1912 to 1918; on the tannery wastes 1919 to 1922; and on the corn products wastes from 1920 to date. A small treatment plant was first built for the municipality of Morton Grove, largely as an experiment. This was followed by the construction of an activated sludge plant at Maywood, (Des Plaines River plant), which was commenced in 1920 and put into operation on August 1st, 1922. Similarly the Calumet sewage treatment plant, of the Imhoff tank and trickling filter type, was commenced in 1920, and put into operation on September 11th, 1922. A very large plant for the north side was commenced in the year 1923, and will be put into operation in 1927 or at the latest 1928.

The Engineering Board of Review

On September 23rd, 1924, the Sanitary District of Chicago retained a board of engineers to review the past procedure and the proposed future programme of the Sanitary District and their effects upon all interests involved. This board consisted of twenty-eight engineers selected from among the prominent engineers throughout the United States. A number of meetings were held and the board divided into committees, each handling a specialized subject and making an intensive study thereof. The board then held its private sessions in New York and presented its first report and recommendations on December 20th, 1924. This was followed by a more elaborate document dated January 23rd, 1925, which consists of the technical basis for the recommendations. Still later the reports of the various committees have been and are still being published as appendices to the main report. These appendices in themselves constitute authoritative scientific documents on the respective subjects treated upon. The recommendations of the board have been widely published.

---

*For full text of permit, see Eng. News-Record—March 12th, 1925, p. 448.

Summary of Present Status

The present status may be summed up as follows:

1. A flow of from 8,000 to 10,000 cubic feet per second is being maintained through the drainage canal, the quantity depending on the stage of lake Michigan. This quantity includes about 1.200 cubic feet per second discharge from the sewers.
2. The secretary of war of the United States, acting with authority established by the United States supreme court, has authorized the diversion of 8,500 cubic feet per second from lake Michigan, with 11,000 cubic feet per second instantaneous maximum demand, until December 31st, 1929. This quantity is exclusive of the sewage flow.
3. The Sanitary District has two important sewage disposal plants in operation, namely Des Plaines River and Calumet, a third on the road to completion, namely North Side, and is embarked on a programme of increasing the treatment of sewage at the rate of 100 per cent treatment for 1,200.000 people by 1930, with continual expansion thereafter.
4. The city of Chicago has undertaken the metering of its water supply to the end that consumption be reduced. This work is to be effected at the rate of 10 per cent per annum for 90 per cent of the population.
5. Plans are being prepared for controlling works on the Chicago river to prevent reversals of flow.
6. The United States chief of engineers and the United States district engineer make periodical inspections to insure that the above programmes are being carried out.

Position of Canada

Whatever the effects of the diversion at Chicago, the position of Canada in regard thereto is fixed by the boundary waters treaty of January 11th, 1909, between Great Britain and the United States. In order to completely understand the position, however, it is necessary to go back further than that. Prior to the completion of the drainage canal, Canada wanted to know what effect it would have on lake navigation, and retained Mr. O'Hanley to report thereon, without any definite result, except that the impression was given that there might be a general lowering of the lakes by as much as 6 inches. In their 1906 report, the Canadian section of the International Waterways Commission recommends that "the diversions by the Chicago drainage canal should be limited to the use of not more than 10,000 cubic feet per second," and makes allowance for this quantity in reaching their conclusion as to the permissible diversion at Niagara Falls for power purposes. Subsequently, in 1907, the International Waterways Commission as a body reported on the drainage canal with particular reference as to whether there should be a limit placed on the amount of the withdrawal at Chicago. Their report concludes with the recommendation that the Chicago drainage canal be limited to 10,000 cubic feet per second. It is very definite, however, that the subject was discussed always from the point of view of sanitary necessity and that navigation and power were secondary considerations.

The International Waterways Commission was a purely advisory board and did not bind either country. The definite binding agreement was made in the form of the Boundary Waters Treaty, 1909, which makes no specific mention of the diversion at Chicago, but uses approximately the same ratio for the diversions at Niagara as recommended by the International Waterways Commission.

Different interpretations have been put on the meaning and intent of this treaty, especially as to whether it really included the Chicago diversion or not in its reference to existing uses of boundary waters, and also as to whether the primary use of boundary waters, namely, "Uses for sanitary and domestic purposes," includes such a use as the present instance.

When the Sanitary District applied for 10,000 cubic feet per second in 1912, Canada strenuously opposed the application, and has consistently adopted the same attitude ever since.

However, it must not be overlooked that for many years after the drainage canal had been put into operation, representatives of Canada tacitly acquiesced in the proposition for sanitary reasons. Certainly there were many investigations as to the effect on lake levels, and so forth, but apparently there was no official action of protest taken, and indeed, the indications are that in the years prior to 1910 the diversion was not looked upon with any great degree of apprehension except by a very few people who were possibly a little more foresighted than others.

Physical Description of the Drainage Canal, Pumping Stations, Treatment Plants and Water Supply System

The Drainage Canal

Prior to the construction of any of the parts of the navigation or drainage canal projects, there was a small village situated at the mouth of the Chicago river. This river had two distinct branches, one flowing in a southerly direction, known as the North Branch, and the other flowing in a northerly direction, generally parallel to the lake shore and known as the South Branch. The latter in turn was fed by a West Fork and South Fork. The North and South Branches met at a point about a mile west of the lake, and from there flowed in an easterly direction into the lake through the common outlet.

About 10 miles west from the lake and parallel thereto, the Des Plaines river flowed in a southerly direction until opposite the West Fork of the South Branch of the Chicago river, from which point it followed a westerly and south-westerly direction, joining the Kankakee river at about 50 miles from Chicago, the two rivers then forming the Illinois river, which in turn flowed into the Mississippi river at Grafton, Illinois.

Main Drainage Canal

The main drainage canal connects the Chicago river with the Des Plaines river and provides the means of withdrawing water from lake Michigan, reversing the natural flow of the Chicago river and of the South Branch, carrying this water through an artificial canal and discharging it into the Des Plaines river between Lockport and Joliet.

The canal leaves the Chicago river at Robey street in the city of Chicago, and extends from there in a westerly and south-westerly direction through the valley of the Des Plaines river, a distance of 32.3 miles, to a power house at its downstream end, in the village of Lockport. The canal passes through the villages of Summit, Argo, Willow Springs, Sag, Lemont, Romeo and Lockport, and was constructed to the north of and parallel with the Old Illinois and Michigan navigation canal. At various places along the route, the drainage canal was built along the bed of the Des Plaines river, the latter being diverted at these places to the north.

For the purpose of a physical description the canal must be divided into four sections. The earth section extends from Robey street to Summit, and is 7.8 miles long. It has a bottom slope of 1 in 40,000, bottom width of 162 feet, side slopes 1 to 1 on the north and 2 to 1 on the south side. The earth and rock section extends from Summit to Willow Springs, 5.3 miles, has a bottom slope of 1 in 40,000, bottom width 202 feet and side slopes of 2 to 1. The rock section

extends from Willow Springs to the Lockport controlling works, a distance of 14.95 miles, has a bottom gradient of 1 to 20,000, a bottom width of 160 feet, with vertical masonry or channelled rock sides. The fourth and last section, from the controlling works to the power house, is 5.25 miles long and is constructed with a clay and rock levee on the right bank, and a concrete wall with rock back-filling on the left bank, with a distance of 160 feet between. The depth throughout the channel for normal conditions of lake Michigan level is 24 feet, but this of course varies with the flow.

At Willow Springs, on the north side of the canal, a spillway was built in order to permit the Des Plaines river to discharge into the canal at flood stages, as the canal had greater carrying capacity than the river between this point and Lockport. This spillway is 397 feet long and its crest is about 20 feet above the water level in the canal.

The controlling works at Lockport were built on the west side of the canal and consist of seven Stoney sluices, 30 feet wide, 20 feet vertical travel, and one Bear-trap dam, 160 feet wide with 15 feet of travel.

With the extension of the canal to the Lockport power house a butterfly dam was built across the canal. This dam is 184 feet long and 30 feet high, and ordinarily is kept parallel to the flow of the canal. On each wing there are six small butterfly valves, each 4 by 6 feet, by means of which the dam can be used either to entirely shut off the flow or for controlling purposes.

The main drainage canal is crossed by eight highway bridges and seven railway bridges, all of the swing type, with the exception of the 8-track railway bridge in Chicago, which is of the rolling type. They have a clearance of 16½ feet minimum. Four highway and three railway bridges were also built over the diversions of the Des Plaines river. When the canal was first constructed as far as the controlling works there was no provision for through navigation into the Des Plaines river, but with the extension to the power house, a lock was built adjacent thereto, 22 feet wide, 130 feet long and with 12 feet over the mitre sills. This lock provides for a lift of 40 feet and was the highest ever built at the time of its construction. In this way the drainage canal was first made available for through navigation in the year 1907, but has only been very sparsely used for that purpose, in fact the swing bridges have not had the motors for operation installed.

At the present time a new lock is under construction by the state of Illinois on the east side of the old lock, having a length of 600 feet, a width of 110 feet and 14 feet over the sills.

In order to take care of the discharge of the canal in the Des Plaines river and to augment the head available for power development a large amount of excavation work was done in the river between the Lockport power house and Joliet.

The drop in water level through the canal under present conditions varies with a great many factors, such as the level of lake Michigan, the quantity of flow, the relative proportions through the main channel and through Calumet-Sag channel, and a number of factors of minor effect. In order, however, to give an idea of the actual slope obtained, the following data for a specific instance may be of interest:—

Elevation of lake Michigan....	2.50 feet below Chicago City datum
Elevation at Lockport..........	11.00 " " " " "
Flow in main channel..........	7,600 cubic feet per second
Flow in Calumet-Sag channel...	900 " " " "
Total flow....................	8,500 " " " "

Flow Through the Canal

The flow through the canal represents the sum of the flow from the Chicago river, the North Shore channel, the North Branch and 39th street conduit and the Calumet-Sag channel together with the discharge from the sewers. The distribution is about as follows:—

1. Main river..................	6,200	cubic feet per second.
2. North Shore channel.........	800	" " " "
3. North Branch................	100	" " " "
4. 39th Street conduit.........	500	" " " "
5. Calumet-Sag channel.........	900	" " " "
6. Sewage......................	1,200	" " " "
Total.........................	9,700	" " " "

The quantity under item "1" will be about 5,000 cubic feet per second when the total flow at Lockport is 8,500 cubic feet per second. The following table gives the average flow through the canal yearly since 1901.*

Year	Mean for Yr.	Year	Mean for Yr.	Year	Mean for Yr.
1900	2,990 c.f.s.	1909	6,495 c.f.s.	1917	8,726 c.f.s
1901	4,046 "	1910	6,833 "	1918	8,826 "
1902	4,302 "	1911	6,896 "	1919	8,595 "
1903	4,371 "	1912	6,938 "	1920	8,346 "
1904	4,793 "	1913	7,839 "	1921	8,355 "
1905	4,479 "	1914	7,815 "	1922	8,858 "
1906	4,473 "	1915	7,738 "	1923	8,348 "
1907	5,116 "	1916	8,200 "	1924	9,465 "
1908	6,443 "				

In a recent report to the United States chief of engineers, Major Putnam, United States district engineer, excludes sewage from the amount of diversion. It must be remembered, however, that the total flow through the drainage canal represents "diversion," regardless of whether it is the original water of the Chicago river, sewage, or lake Michigan water, because if the canal did not exist all these waters would flow into lake Michigan. It might also be noted that in a report dated November 1st, 1923, Major Putnam gives average yearly flows through the canal, and his figures, subsequent to the year 1907, are considerably less than those quoted above.

The whole question of flow, slopes, values of "n" in the Kutter formula, and the hydraulic characteristics of the canal have been the object of many studies by the engineers of the Sanitary District, and of the United States government, and it is anticipated that some very interesting and valuable data will be published in the near future.

Chicago River

In order to provide sufficient waterway and also to maintain velocities low enough to permit navigation, considerable work was done in the improving of the channel of the Chicago river and its South Branch. The channels have been excavated to a width of 200 feet with an average depth of 26 feet, although in the South Branch the depth is reduced to 16 feet at the dock lines. Similarly, the North Branch was improved by widening, straightening and deepening; the dimensions of new cuts being 90 feet wide by about 12 feet deep.

On the South Branch, fourteen centre-pier bridges were replaced by Bascule bridges with a clear span of 120 feet and clearance of 16½ feet.

Lockport Power House

The power house, which is built normal to the main canal, is a concrete and steel building with tile roof, 385 feet long, 70 feet wide, and 47 feet high. At the east end of the building, two sluiceways for control purposes, one 12 feet wide, leading from the forebay, and the other, 48 feet wide, direct from the main canal. They are both controlled by gates of the sector type, with a vertical range of 14 feet.

The power house equipment consists of seven 6,000-

*See Engineering Board of Review—Part II, page 12.

horsepower horizontal turbines, each having six runners mounted on one shaft, with wicket gates operated by Lombard governors. They are direct-connected to seven 4,000-kilowatt generators, operating at a speed of 163.6 revolutions per minute and delivering 60-cycle alternating current at 6,600 volts. Three small turbines drive exciters of 350 kilowatts capacity each. Current is stepped up by oil- and water-cooled transformers (21 of 1,333 kilowatts) to 44,000 volts for transmission to the terminal station at 39th street, and Western avenue, Chicago, a distance of 30 miles. The transmission line carries three 3-phase circuits on two cross-arms on galvanized steel towers 60 feet high, spaced 350 feet apart.

The electrical system is tied in with that of the Commonwealth Edison Company and a load factor of practically 100 per cent is obtained at the plant. Peak loads are helped out by the steam plant at 39th Street pumping station. The output of the plant is divided between the city of Chicago for municipal lighting purposes, the Sanitary District, (engineering department), for pumping purposes, some small municipalities and a small commercial load which is being abandoned as rapidly as contracts will permit. With the completion of plants for the treatment of sewage, the total output of the Lockport plant will be insufficient to take care of the Sanitary District's own load.

The plant operates under a varying head depending on the level of lake Michigan and the flow permitted through the canal. When the lake was at an elevation about 1.5 feet below Chicago city datum, there was a head at the plant of 31.5 feet, and an output of 12,000 kilowatts.

North Shore Channel

It was found that the North Branch of the Chicago river had insufficient flow to carry off the sewage of the district feeding into it. To remedy this condition and also to provide an outlet for sewers in the northeasterly part of the district, a new canal, known as the North Shore channel, was built from Wilmette on lake Michigan, 13 miles north of the Chicago river, to a point on the North Branch at Lawrence avenue. This channel has a bottom width varying from 26 to 30 feet, with side slopes of 2 to 1, and 3 to 5, a bottom gradient of 1 in 20,000, and depth of 13.5 feet. Its capacity is 1,000 cubic feet per second.

In order to provide this flow the water has to be lifted 3 feet above the lake Michigan level at Wilmette, which is accomplished by four screw pumps, 9 feet in diameter. Each pump is driven by a 150-horsepower motor.

A lock, 130 feet long by 32 feet wide by 11 feet deep, is provided for navigation purposes. The channel is crossed by twenty highway and three railway bridges.

Calumet-Sag Channel

As the population of Chicago spread to the south and also with the development of the northern part of Indiana, the condition of the discharge of the Calumet river became a menace to the health of the people of Chicago, and steps were therefore taken to reverse the flow of this river by the construction of the Calumet-Sag channel, leaving the little Calumet river at Blue island, and connecting with the main drainage canal at Sag. This drainage canal has a length of 16.2 miles and a capacity of 2,000 cubic feet per second. The earth sections, comprising a total length of 10.8 miles, have bottom widths of 36 feet, with side slopes of 2 to 1, or 50 feet width, and 1 to 1 slopes. The depth is 20 feet and bottom gradient 1 in 37,000. The rock sections, comprising 5.4 miles, have the same depth and gradient, but are 60 feet wide with vertical channelled rock or concrete sides. Owing to the restricted capacity of the Calumet river, this channel has only been used for a flow of 700 to 900 cubic feet per second.

Figure No. 2—Main Drainage Canal at Romeo, Ill., looking upstream.

Controlling works combined with a navigation lock are built at the entrance to the channel, and passing places for vessels are provided every three miles in the canal. The channel is crossed by seventeen highway and seven railway bridges, all of the fixed span type with a clearance of 16½ feet.

Pumping Stations

The Sanitary District has constructed and in operation a series of pumping stations for various purposes.

Thirty-Ninth Street Pumping Station

This station serves to pump sewage from the south side between 31st and 87th streets, west from lake Michigan through a 20-foot conduit below 39th street to the South Fork of the South Branch of the Chicago river. The station is also used for intermittent pumping of fresh water from the lake through the conduit, for flushing purposes. It serves a district about 22 square miles in area, and pumps sewage varying in volume from 45 to 1,000 million gallons per day.

The equipment of this station consists of eight boilers with a total capacity of 2,600 horse power; two low-head pumps, 14 feet 9 inches diameter, driven by triple expansion steam engines for flushing purposes with a capacity of 1,000 cubic feet per second each, four vertical shaft centrifugal pumps, with a total capacity of 650 cubic feet per second, also driven by triple expansion steam engines of the horizontal type, and a 4,000-kilowatt turbo-generator set, which is used for peak load purposes at such times as the steam capacity of the plant is required for pumping sewage.

Lawrence Avenue Pumping Station

The Lawrence Avenue pumping station is located on Lawrence avenue, east of Broadway, and pumps the sewage of the North Side, comprising an area of six square miles, through a conduit 16 feet in diameter, which discharges into the North Branch of the Chicago river. It also pumps lake water through the conduit for flushing and dilution purposes. The pumpage of sewage varies from 25 to 190 million gallons per day.

Evanston Pumping Station

The Evanston pumping station is located just north of the city of Chicago in the municipality of Evanston, and pumps sewage from this district through a 10-foot conduit discharging into the North Shore channel. It serves an area of about 600 acres. The equipment consists of six centrifugal pumps driven by 25-horsepower electric motors, with a total capacity of 135 cubic feet per second.

Figure No. 3—Entrance to North Shore Channel, showing Pumping Station and Lock at Wilmette.

Ninety-Fifth Street Pumping Station

The 95th Street pumping station was built by the city of Chicago, but is operated by the Sanitary District. It serves a district to the south of 95th street and is electrically operated with power from Lockport or from the Calumet power station.

Calumet Pumping Station

The Calumet pumping station is located at 125th street and Indiana avenue and pumps sewage from the Calumet intercepting sewer into the Calumet sewage treatment plant through two large conduits. When the flow exceeds the capacity of the treatment plant, namely, 56,000,000 gallons per day, the sewage is turned into the Calumet-Sag channel, and if the flow still exceeds the capacity of the two, the excess is turned directly into the Calumet river.

The equipment consists of six pumps, three driven by 250-horsepower electric motors, and three by 1,000-horsepower motors, with a total capacity of 950 cubic feet per second. Two additional motors of 375 horse power each are provided for use in place of the large motors when conditions are such as to require pumping direct to the river.

Adjacent to the pumping station is a power house equipped with four full-Diesel-type engines of 750 brake horsepower each, direct connected to 500-kilowatt, 3-phase, 60-cycle, 2,300-volt generators operating at 180 revolutions per minute.

In addition to the foregoing there are some small pumping stations built by the city of Chicago operated by the Sanitary District.

Intercepting Sewers

In order to divert the discharge of the many sewer outlets from the Chicago river or its branches to the treatment plants, over 50 miles of intercepting sewers had to be built. These sewers vary from small tile to large reinforced concrete structures, the largest being 24 feet by 27 feet high.

Sewage Treatment Plants

Morton Grove, Glen View and Northbrook Plants

These three treatment plants are all of the Imhoff type, with trickling filters, and serve small suburban municipalities outside the city limits in the north-western section of the Sanitary District. The effluent is discharged into the North Branch, and while these treatment plants undoubtedly cause a great improvement in the condition of the North Branch, they do not have much effect on the sewage disposal problem of the district as a whole.

Des Plaines River Plant

The Des Plaines river sewage treatment plant, located just west of the Des Plaines river and south of Roosevelt road, serves an estimated population of about 40,000 and 50,000 people residing in Melrose Park, River Forest, Forest Park, Maywood, and part of Oak Park and the Speedway hospital. This is an activated sludge plant. The sewage arriving at the treatment works is pumped through a lift of about 28 feet by three vertical pumps, each of a capacity of $6\frac{1}{2}$ cubic feet per second, driven by a 50-horsepower induction motor. The ordinary dry weather flow is about 5 million gallons per day, and the total capacity of the plant as at present installed is about $6\frac{3}{4}$ million gallons per day. In the same building with the pumping station are blowers to compress the air for the activated sludge process. These are driven by induction motors: four at 150 horse power, one at 75 and one at 30 horse power. The sewage is pumped through a Venturi meter into duplicate grit chambers, which are followed by a Riensch-Wurl self-cleaning screen. The screened sewage is then aerated in four tanks with filtros plate diffusers. Two of the tanks, 10 and 15 feet deep respectively, are arranged for the ridge and furrow type of aeration, one tank, 10 feet deep, is arranged for the circulating type of aeration, and the fourth unit, 10 feet deep, is of the ridge and furrow type followed by separate re-aeration of the sludge. The aerated liquor is settled in settling tanks, one-half of which have hopper bottoms, and the other half, Dorr clarifiers. For pressing and drying the excess sludge from the tanks to form commercial fertilizer, there is provided a press and dry house. Centrifugal and stuff pumps, as well as duplicate ejectors, feed two presses of the platen type, one containing eighteen bags, each 5 by 8 feet, and the other ninety bags, each 4 by 6 feet. With these the water content is reduced from 99 per cent to about 80 per cent. The press cake is then dried in a rotary dryer of the Atlas type, 4 feet in diameter by 30 feet long, the dried sludge being passed through a screen and bagged for use. A crusher is provided for breaking up the tailings.

Calumet Plant

The Calumet sewage treatment plant, located at 125th street and Cottage Grove avenue, is handling the sewage of the territory south of 87th street, east of Western avenue and west of lake Michigan, and north of the Calumet river. Sedimentation in Imhoff tanks is used at this plant. The works consist of coarse bar screens with one-inch openings, a grit chamber with five channels in which the velocity is reduced to about one-half foot per second to drop grit, and thirty units of Imhoff tanks of the double deck type in which the sewage is settled in the upper compartments, and the sludge collected and digested in the lower chambers. The digested sludge is dried on underdrained sand beds and finally disposed of by dumping. Two activated sludge units and a trickling filter of crushed stone, 0.74 of an acre in area and approximately 6 feet deep, are also provided for comparative studies on complete treatment sewage. The trickling filter is equipped with two secondary settling tanks with hopper bottoms. The plant has a capacity of 56,000,000 gallons per day, and serves a population of 180,000. A machinery building houses the four blowers with a combined capacity of 6,500 cubic feet per minute at $8\frac{1}{2}$ pounds pressure for supplying air to the activated sludge units and the sludge lifts in the Imhoff tanks, and also the three centrifugal pump units for feeding the trickling filter, and also an Oliver vacuum filter and Atlas dryer for de-watering the excess sludge. Offices and chemical laboratory are in a separate building.

North Side Plant

The North Side treatment plant is under construction and will not be in operation until late in 1927, or early in 1928. It is stated to be the largest activated sludge plant in the world. When completed it will provide for a population of 800,000 people, and a flow of 175,000,000 gallons per day. The sewage will be pumped from the intercepting sewers through a lift of 48 feet, passed through grit and screen chambers into three batteries of aeration tanks, each approximately 420 feet square. The sludge will not be entirely settled out at this plant, but will be pumped to the projected west side plant, where it will be pressed and dried.

Cost of Works

The cost to the end of 1924 of the foregoing works is summarized in the following table*:—

Cost of Canal System and Appurtenances

Main drainage canal	$ 28,418,214.78
Des Plaines river improvement	2,333,571.72
Main channel extension	3,167,003.05
Chicago river improvement	12,903,773.66
North Shore channel	4,138,105.25
Calumet-Sag channel	14,159,215.51
Sewage pumping stations	980,622.76
Auxiliary sewers	2,229,012.08
Miscellaneous construction	1,389,238.15
North Shore sewers	2,453,996.55
Bare construction cost	$ 72,172,753.51
Administration, legal expense, clerical expense, damages, etc	5,729,813.46
Interest on bonds for construction	17,055,898.00
Expenditures by city of Chicago	6,706,804.37
Lockport power house	1,395,712.95
Total to Dec. 31st, 1924	$103,060,982.29

Cost of Sewage Treatment Projects

Sanitary improvements	$ 282,117.52
Des Plaines river project	3,357,669.23
Calumet project	17,853,719.45
North Side project	7,119,620.93
West Side project	295,164.28
Miscellaneous plants and sewers	387,484.50
Bare construction cost	$ 29,295,775.91
Administration, legal expense, clerical expense, damages, etc	2,325,799.06
Interest on bonds for construction	6,923,188.71
Total cost of sewage treatment plants to Dec. 31st, 1924	$ 38,544,763.68

The Sanitary District of Chicago

The organization which has the direction of such important works as have been described in the foregoing pages is naturally a large one. The Sanitary District of Chicago is governed by a body of nine trustees, who are elected by the people with primary and secondary elections. The trustees hold office for six years and election of three members occurs every two years.

The Sanitary District now embraces an area of 437.39 square miles, of which 205 square miles, (47 per cent), is comprised of the city of Chicago. The distribution of population, however, is more pertinent, as 91 per cent of the population served lies within the city limits and only 9 per cent in the large area outside the limits, in which there are forty-nine separate small municipalities. The total population served is about 3,500,000.

The engineering department of the district is under the direction of Edward J. Kelly, M.A.S.C.E., who has charge of the greater part of the work of the organization. The following is a summary of the budget for 1926:—

Annual Appropriation for 1926

Engineering Department	$30,107,792
Department of Maintenance and Operation	2,918,266
Illinois Valley Department	71,517
Department of Law	419,540
Department of the Clerk of the District	192,365

Water Supply of the City of Chicago

The Sanitary District has no jurisdiction or control over the water supply system of Chicago, which is entirely operated by the Department of Public Works of the city. The system consists of ten pumping stations with a total installed pump capacity of 1,349 million gallons per day. The water is obtained from intake cribs in lake Michigan, of which there are six in number, with numerous tunnels and cross-connections to the various pumping stations. The total consumption per day averages about 820 million gallons, which corresponds to 278 gallons per capita per day. In terms of flow, it might be noted that the quantity of water used is equivalent to about 1,250 cubic feet per second.

The following table* gives the location and particulars of the intakes:—

Name	Distance from shore	Distance from Chicago River	Depth of water
1. Wilson Avenue	3 miles	5.25 miles north	33.5 feet
2. Carter H. Harrison	2.6 "	2.0 " "	33.8 "
3. 2-Mile	1.75 "	1.25 " "	29.0 "
4. 4-Mile	3.4 "	1.0 " south	38.0 "
5. Hyde Park	2.0 "	7.0 " "	32.0 "
6. Edward F. Dunne	2.0 "	7.0 " "	32.0 "

It is not possible to separate the quantity of water taken in at each crib, owing to the cross connection to various pumping stations, but on broad lines it may be stated that considerably over 60 per cent of the total water supply is taken from lake by the three cribs in closest proximity to the Chicago river.

The whole of the supply is treated with chlorine and the records of consumption show that nearly 3 parts per 10,000,000 are used, which represents a dose somewhat larger than average conditions usually found.

Plans for Future Works

Sewage Treatment Plants

In addition to the plants now under construction, the trustees of the Sanitary District passed a resolution on December 26th, 1924, adopting the recommendations of the Engineering Board of Review, providing that all sewage will be treated by the year 1945, which they consider is as early as possible with due regard to sound engineering and financing. The following is the general outline of the proposed procedure taken in the chronological order of the recommendations.

The Des Plaines river plant is to be increased from its present capacity for a population of 40,000 to provide for a population of 105,000, with a corresponding increase in flow from 4 to 10.5 million gallons per day.

The Calumet plant is to be increased from its present capacity for a population of 200,000 to provide for a population of 320,000, with a corresponding increase in flow from 56 to 72 million gallons per day. It is also proposed to install additional trickling filters for the present plant so that the degree of purification will be increased as well as the capacity.

The North Side plant when completed under the present programme will provide for a population of 800,000 and is to be increased to provide for 1,122,000, with a corresponding increase in flow from 175 to 200 million gallons per day.

The future treatment of industrial wastes has been provided for, but it is probable that the plans will undergo radical changes, owing to recent developments in the possibilities of utilizing the wastes, particularly from the corn products industry. In the future the wastes from this industry will be small in quantity and comparatively innocuous. In the case of the packing industry, the problem has not reached such a satisfactory stage, either from the point of view of utilization or from that of the responsibility of the industry itself. Plans provide for the construction of an activated sludge plant with a capacity of 40 million gallons per day, which would correspond to a population equivalent of 1,250,000. There have been negotiations and controversies between the Sanitary District and the producers for many years, but whatever the outcome as far as responsibility goes, provision is being made for the construction of this plant.

The West Side plant is to provide for an area of 57.2 square miles in the centre of the city immediately to the north of the main drainage canal, and including the Loop District, the total population of which, including transients, is estimated to be 1,915,000 by 1945. The plans for this plant provide primarily for Imhoff sedimentation tanks to take care of a flow of 414 million gallons per day, and later for the installation of trickling filters, with an ultimate capacity of 440 million gallons per day.

The South-West Side plant is to provide for an area of 59.0 square miles immediately to the south of the drainage canal, with a population of 1,322,000, and will be built in stages, with Imhoff sedimentation tanks with a capacity of 301 million gallons per day, followed by trickling filters, the whole with an ultimate capacity of 344 million gallons per day.

In addition to the foregoing it is recommended that provision should be made for treating the sewage of the outlying parts of the Sanitary District as the development of the cities and villages may make necessary.

It is estimated that the foregoing works which will serve a population of nearly 6,500,000 will cost about $100,000,000, including necessary pumping works, intercepting sewers and so forth, but exclusive of the amount already expended.

Water Supply

As far as the future plans for water supply are concerned the outstanding feature at the moment is the fact that the city has adopted a definite programme for the installation of meters. The result of this will be that the present enormous per capita consumption of 280 gallons per day will be steadily reduced and consequently for a number of years the actual total consumption will decrease, notwithstanding the rapid growth of the city. This means that no extensive programme is necessary for providing additional pumpage capacity or intakes. On the other hand, the condition of the supply, even with the use of the drainage canal, has been far from satisfactory, and the dosing with chlorine has been utilized to a degree which is even now producing unpleasant results. The chief sanitary engineer of the health department of the city of Chicago recently stated that "The water supply of Chicago is becoming more and more potentially dangerous, and the increasing quantities of chlorine required for disinfecting the same will render it quite objectionable for drinking purposes."

The city engineer of Chicago says in a report to the commissioners of public works that "The filtering of the Chicago water supply is rapidly becoming a very important question irrespective of the great plans for sewage purification works of the Sanitary District." He further states that in view of the persistent opposition in the past to metering, it has been out of the question to accomplish any results in the direction of filtering, but in view of present conditions he has made a preliminary study for filtration plants. While the plans for filtration are in an embryo state and therefore subject to radical changes, nevertheless it is of interest to note that preliminary studies have been made from which it appears that the complete filtration and water purification plants will cost about $40,000,000.

The Present Need for the Diversion

Whatever truth there may be in statements to the effect that Chicago should have done this, that, or the other, the situation as it stands to-day has to be faced. Any discussion of an immediate stoppage of the diversion or even of a large reduction in the quantity is simply a waste of breath, for the simple reason that under conditions as they now exist, the direct result of such action would be without any doubt a very serious typhoid epidemic. The present system of chlorination of the water supply would be totally inadequate to counteract the extent of the pollution which would exist under such circumstances. It must be remembered that Chicago is differently situated as compared with many other cities on the Great Lakes; firstly, it is over three times as large as any other of the Great Lakes cities and many more times larger than most of them; secondly, there is practically no perceptible current in the lower end of lake Michigan, and the sewage discharge is largely at the mercy of the wind and very apt to remain in close proximity to Chicago; thirdly, the outlet of the Chicago river is in the midst of the group of water intakes. In other words, it must be taken as axiomatic that Chicago's sewage under present-day conditions must be kept out of lake Michigan, and the problem therefore becomes one of determination of how much water is necessary to carry the sewage away. This leads to an examination of the whole system of sewage treatment and disposal now in existence.

Sewage Disposal

The method of discharging sewage into a large body of water or into a running stream is known as the dilution method. The process, however, represents something more than dilution, as, in order to prevent the sewage becoming putrescent, even though diluted, oxidization of the organic matter must take place. It is this oxidization which makes it possible for sewage to be discharged into a stream from one city, while further downstream a second city may use the same stream for its water supply with perfect safety. Any ordinary source of fresh water supply such as a lake or running stream contains a certain amount of dissolved oxygen, while on the other hand sewage contains a large amount of organic matter which requires so much oxygen to completely oxidize it. This latter quantity is known as the "oxygen demand" of the sewage. It is the relationship between the amount of dissolved oxygen and the oxygen demand (oxygen balance), which determines whether a stream will become putrescent or not. If the supply of dissolved oxygen exceeds the demand, the organic matter in the sewage will become oxidized and the water become purified; if, on the other hand, the dissolved oxygen available is less than the demand, a negative oxygen balance will ensue, and in turn the stream will become putrescent. In other words, when there is no oxygen available at all, the sewage will become septic and produce unpleasant odours. As long as oxygen is present, the stream will be in an aerobic condition.

In the case of sewage treatment plants artificial means are taken to reduce the oxygen demand of the sewage. An activated sludge plant concentrates the natural action of a running stream into a short period of time, and then provides means for the withdrawal of the solid matter in the form of sludge. In such a plant the oxygen demand may be reduced as much as 85 or 90 per cent. In the Imhoff tank system no attempt is made to oxidize the organic matter, but it is simply a means of settling out the sewage solids, and has the effect of reducing the oxygen demand about 30 to 35 per cent. It is frequently customary to provide a further stage of treatment to the effluent from the Imhoff tanks, either by the activated sludge or by the trickling filter method. In either of these cases the combined result gives a total reduction in the oxygen demand of about 85 to 90 per cent.

Characteristics of Chicago's Sewage

One of the principal characteristics of the sewage of Chicago is that owing to the abnormally high rate of water consumption, and also to the use of combined sewers, it has a large volume in proportion to the population served. This refers to the ordinary domestic sewage. The sewage from the industries, on the other hand, has a degree of concentration far greater than the domestic sewage.

The Sanitary District of Chicago has made extensive tests covering a long period, of the oxygen demand of its sewage, from which they determine an average value of 0.24 pounds per capita per day. The United States Public Health Service has made a number of investigations of the oxygen demand of the sewage of cities from which it would appear that while the Chicago figure is not abnormally high, it is nevertheless somewhat higher than the average. This applies to ordinary domestic sewage. In the case of the packing and corn-product industries, analysis was made to determine the total oxygen demand of the various wastes, and then by applying the factor 0.24 an equivalent human population was obtained.

The oxygen demand of a given volume of sewage is not satisfied immediately, but takes a number of days, and may be said generally to be normally 99 per cent satisfied in a period of twenty days at 68° F., the effect of lower temperature being to increase the time, or decrease the degree of satisfaction. The rate of satisfaction is not directly proportional to the time, as after a period of five days the demand is 68 per cent satisfied, seven days, 80 per cent, ten days, 90 per cent, and so forth.

Figure No. 5—Chicago River showing Junction of North and South Branches.

(Note line of demarkation between polluted water from North Branch and fresh water from lake Michigan.)

It will be appreciated that with constantly fluctuating sewage discharge flows and temperatures, the oxygen balance at any point is subject to daily and seasonal variations, but many records and surveys of the condition of the Des Plaines and Illinois rivers have been made, not only by the Sanitary District, but also by the United States Public Health Service. The study and analysis of the various records is a subject in itself, and is very fully covered in Part III, Appendix I, of the Report of the Engineering Board of Review, from which much of the basic data used herein has been taken. It must be understood that only the broadest principles are being discussed herein, and the author does not attempt either to substantiate or refute the statements of the Board of Review. It has been found that Chillicothe, 150 miles from lake Michigan, is the critical point, or in other words, the farthest downstream point where there would be danger of there being a negative oxygen balance. The time of passage from the lake to Chillicothe is about seven days, with a flow of 8,700 cubic feet per second. At the seven-day period, the oxygen demand is normally 80 per cent satisfied and beyond this point re-aeration takes place rapidly.

The present population of the Sanitary District is about 3,500,000, while the equivalent population of the packing and corn-products industries may be placed at 1,300,000; hence the total human and equivalent population whose sewage has to be taken care of amounts to 4,800,000. Before determining the oxygen demand, consideration has to be given to the effect of the existing treating plants. The Des Plaines river plant has the effect of reducing the oxygen demand of about 40,000 people by 85 per cent, making a net reduction therefore of 34,000 people, while at Calumet the reduction may be placed at 80 per cent for 200,000 people or a reduction of 160,000 people. The net total human and equivalent population to be served is therefore 4,600,000 in round figures. The oxygen demand, (at 0.18 pounds per capita per day for seven-day demand), therefore, averages 828,000 pounds per day. It must be borne in mind, however, that the oxygen demand varies between summer and winter. It will reach an extreme minimum of about 33 per cent less than the average in the winter and an extreme maximum of

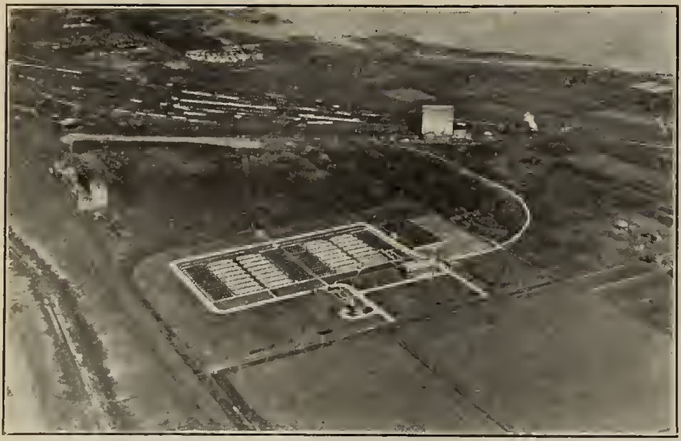

Figure No 6—Calumet Sewage Treatment Plant.

about 30 per cent more than the average in the summer. Average winter conditions therefore might be represented by an oxygen demand of 610,000 pounds per day, and average summer conditions by an oxygen demand of 995,000 pounds per day.

Owing to the fact that practically no attempt has been made to settle out the sewage solids, large accumulations of sludge occur in the bed of the canal and river which have a very large oxygen demand. The deposits of sludge occur where the velocity is low, principally in the earth and rock section of the drainage canal, in the Des Plaines river between Joliet and Ottawa and also between LaSalle and Chillicothe. It is estimated that the total oxygen demand of these sludge deposits amounts to about 1,200,000 pounds per day. This quantity varies of course with the temperature and other conditions, but may be taken as a general indication of the requirement.

The total oxygen demand under present-day conditions may therefore be taken as being about 2,000,000 pounds per day on the average for a seven-day demand, without taking into account the small additional amounts required by the sewage of some of the small towns located on the Des Plaines or Illinois rivers.

The Supply of Oxygen

There are three principal sources of supply of oxygen to meet the demand—first, lake Michigan; second, the air in contact with the canal and river surface; third, tributary rivers.

The amount of dissolved oxygen in lake Michigan has been found to vary from a minimum of about 8 parts per million in summer, to a maximum of 13 parts per million in winter, which represents a general average of about 95 per cent of saturation. These figures are the result of a series of tests made by the Sanitary District at the 39th Street pumping station. Taking the average of these figures, and assuming a diversion of fresh water of 8,500 cubic feet per second, a simple mathematical calculation gives the quantity of dissolved oxygen obtained from lake Michigan as 436,000 pounds per day.

During its contact with the air, water which is depleted of its normal amount of dissolved oxygen will absorb oxygen from the air (this is known as *re-aeration*). The rate at which this absorption takes place depends on the degree of depletion of the dissolved oxygen, the temperature, the rate of movement of the water through the air, the depth of the water and so forth. In the case of water in which the oxygen has been practically exhausted, and which is flowing with a broken surface as in a rapid, the rate of absorption may be as high or even higher than 50 pounds per 1,000 square feet per day. On the other hand, where there is some oxygen present and where the stream is flowing very slowly, the rate of absorption becomes less than one pound per 1,000 square feet per day. Applying this principle to the drainage canal, there is first of all the canal section with comparatively slow moving water where the absorption is found to be about 2 pounds per 1,000 square feet per day, which gives the possibility of absorbing a total of about 98,000 pounds of oxygen per day. Between Lockport and Joliet, the river flows swiftly and the absorption becomes very much greater in proportion and reaches a total of 100,000 pounds per day. Between Joliet and Ottawa, a rate of 4 pounds per 1,000 square feet is applied, giving 820,000 pounds, and between Ottawa and Chillicothe, 2 pounds per 1,000 square feet, giving 442,000 pounds. Of course, this absorption can only take place as the primary amount of dissolved oxygen is used up.

The tributary rivers above Chillicothe are the Des Plaines, the Kankakee, the Fox and Vermilion. The first of these is negligible as a source of oxygen supply as its flow is small, and its own oxygen demand is high. The Kankakee, on the other hand, has a flow averaging about 5,000 cubic feet per second, and has excess oxygen to the extent of about 6.5 parts per million, which therefore makes available about 175,000 pounds per day. The Fox river averages about 1,740 cubic feet per second with 5.75 parts per million, giving 54,000 pounds of oxygen per day, and finally, the Vermilion with a flow of 1,000 cubic feet per second gives 31,000 pounds per day.

The following table summarizes the sources of oxygen supply with a flow of about 9,700 cubic feet per second in the canal, which includes sewage:—

Lake Michigan	436,000	pounds per day
Drainage canal	98,000	" " "
Des Plaines river to Joliet	100,000	" " "
Des Plaines and Illinois rivers to Ottawa	820,000	" " "
Illinois river, Ottawa to Chillicothe	442,000	" " "
Kankakee river	175,000	" " "
Fox river	54,000	" " "
Vermilion river	31,000	" " "
Total	2,156,000	pounds per day

This quantity is somewhat in excess of the oxygen demand of 2,000,000 pounds, and further downstream the river continues to re-aerate and purify itself.

It must be borne in mind that in the foregoing calculations, no attempt has been made to go into the subject any more fully than is necessary to show the principles involved, and the unit quantitative values have been adopted from the studies of the Engineering Board of Review. A complete analysis of the situation involves not only seasonal fluctuations but also the introduction of a number of factors of minor importance.

Effect of Obstructions

The major obstructions which occur in the section of the rivers under discussion are the power house at Lockport, a small dam at Joliet, a dam at Marseilles, and another near Henry. The effect of the power house at Lockport is the elimination of four miles of rapids, and the dam at Marseilles also creates a long reach of slack water which would otherwise be flowing swiftly. The other dams are of minor effect. The obstructions have a detrimental effect in two ways: first, the slowing up of re-aeration, and secondly, the causing of the sludge deposits which are now creating such a large oxygen demand. In the former case, it is no exaggeration to state that the amount of oxygen which could be absorbed between lake Michigan and Chillicothe, (provided the water had not already become saturated), would exceed the present quantity by 750,000 pounds per day, if there were no obstructions. Similarly, the present demand of 1,200,000 pounds of oxygen per day by the sludge deposits, might well be reduced to one-half this amount. Of course this supposition introduces new factors into the situation, as, for example, change of areas, change in velocities and so forth, but there is no gainsaying the fact that if there were no dams or other obstructions in the way of the natural flow of the river, the quantity which would have to be withdrawn from lake Michigan in order to maintain aerobic conditions might be reduced as much as twenty-five per cent.

Reversals of the Chicago River

Prior to the construction of the drainage canal, the Chicago river had a North Branch flowing south, and a South Branch flowing north. The two branches met at the "Fork," and from there flowed about one mile easterly into lake Michigan. The reversal of the Chicago river is accomplished by providing an outlet from the South Branch with larger capacity than the flow of the river itself. This process may possibly be more clearly illustrated by figures. If, for example, the combined flow of the two branches amounted to 1,000 cubic feet per second, this would be the quantity flowing easterly through the Chicago river into lake Michigan. If, however, 300 cubic feet per second were drawn out of the South Branch, the flow in the Chicago river would be correspondingly reduced and would become 700 cubic feet per second. If the quantity withdrawn were 1,000 cubic feet per second, the Chicago river between the Forks and the lake would have no flow. Finally, when the amount taken out reaches, say 3,000 cubic feet per second, this quantity would be made up of 1,000 cubic feet per second natural flow of the river, collected from the north and south branches, and 2,000 cubic feet per second of additional water withdrawn from lake Michigan, the latter causing a current through the Chicago river in a westerly direction, which is now the condition which normally exists. Paradoxically, if the river flows in its natural direction, i.e., into lake Michigan, it is referred to as reversal of flow. It is this reversal of flow which has to be prevented as far as possible, because it means that raw sewage is discharged freely into lake Michigan quite close to the source of the water supply. A reversal will take place whenever the flow of the Chicago river exceeds the capacity of the canal at the particular elevation of lake Michigan. For example, while conditions are fairly normal on the lake, but with a low elevation, it is not out of the ordinary for a local rainstorm to cause a sudden freshet which exceeds in volume the capacity of the canal for that elevation; consequently the excess flow discharges into lake Michigan. Another cause of a reversal is the sudden dropping in elevation of the surface of the lake which sometimes occurs through atmospheric disturbances. In this case, a reversal naturally takes place for a short time, but is not likely to be of long duration as a readjustment of levels in the river and canal corresponding to the lowered level of the lake soon takes place.

The frequency with which reversals are apt to take place depends on the quantity normally being passed through the drainage canal, and the number of times the discharge of the Chicago river is likely to exceed this quantity.

According to a report* on the diversion of water from lake Michigan by the district engineer of the United States Engineer Office, it is estimated that rates of storm run-off of the Chicago river have the following frequency:—

3,000 cubic feet per second,	10 to 12 times per year.
4,167 " " " "	7 to 8 " " "
5,000 " " " "	5 to 6 " " "
7,500 " " " "	3 to 4 " " "
9,500 " " " "	2 times in 3 years.

*Report on the Diversion of Water from Lake Michigan, November 1st, 1923.

He then sums up the situation with the statement that "Positive insurance against discharge of the river into the lake under present conditions would require a flow in the neighbourhood of 10,000 feet per second at the time of maximum flood."

There is no doubt that reversals could be prevented by the construction of controlling works which could have made the reversal of flow independent of the quantity of diversion. Suggestions on these lines, however, were not approved on account of placing an obstruction in the way of navigation.

Summary of Present Needs

Apart from the determination of the actual quantity of diversion necessary for present-day needs, which has been shown to average about 8,500 cubic feet per second of fresh water from lake Michigan, but to be subject to a wide seasonable variation, there are four very important conditions which enter into this determination which may be summarized as follows:—

First, the actual quantity of water necessary for dilution purposes and necessary to maintain an aerobic condition in the canal and Des Plaines-Illinois river, is largely increased owing to the dams for development of power and for improvement to navigation.

Second, the actual quantity of water is also materially increased, owing to the deposits of sludge for which these dams are largely responsible.

Third, the actual quantity of water necessary to prevent the continuance of sludge deposits is materially increased by the presence of these dams.

Fourth, the actual quantity of water necessary to prevent reversals of the Chicago river could have been very much reduced if it had not been for the fear of placing an obstruction in the way of navigation in the Chicago river.

The Future Need for the Diversion

Discussion of the future needs or necessity of the diversion naturally leads into a sphere of speculation in which many of the principal elements may be matters of opinion or, at the best, of estimation. It is possible, however, to discuss the principles involved and reach certain fairly definite conclusions without the introduction of any uncertain elements.

With regard to the word necessity, it must be understood that this word is being used herein in its strictest sense, and refers to the necessity of safeguarding the health of the community, and is not used with any idea of broadening its meaning to cover the desirability of providing a waterway or power development, as this phase is not a necessity but a fortuitous condition leading to a commercial benefit.

The question which naturally arises with regard to the future of the drainage canal is to what extent can the amount of diversion be reduced in the future. Can it be entirely eliminated, and, if not, what will be the amount of diversion absolutely necessary? If all plans for sewage treatment and water filtration, both approved and embryo, are carried out, the situation at some future date would be that the whole of the sewage of Chicago would be undergoing treatment before discharge into the Chicago river, and the whole of Chicago's water supply would be undergoing filtration and chlorination. To reach this condition will involve the expenditure of say $175,000,000 and will take anywhere from fifteen to thirty years, depending on the ability of the Sanitary District and city of Chicago to finance the projects. It is unlikely that such a programme could be completed in less than twenty years, by which time the population may have reached 5,000,000, while the packing and other industries will still possibly have a population-equivalent of

1,000,000. If all the sewage is fully treated to the greatest possible extent, the reduction in oxygen demand will average about 85 per cent, the total effluent will therefore be equivalent in oxygen demand to a population of 900,000, but there will be no solids in the effluent. That it is not desirable to discharge this amount of polluted water in the comparatively stagnant waters of lake Michigan, even if extensive filtration plants are in operation at all communities on the lake or in the vicinity, is only a statement of fact, but whether the resulting condition would seriously imperil the health of the people, is a matter of opinion; and at the same time there are what might be called partly sentimental considerations, all of which have to be weighed in the balance against the value of the diverted water. There is little doubt, however, but that the opinion on the side of preventing the dumping of sewage effluent into the water supply will win out in the end. Hence the future must be looked upon from the point of view that there will be diversion and it is therefore necessary to determine the quantity necessary for sanitary reasons.

As in the case of the present need the amount of oxygen demand has first to be determined. Taking the population, both human and equivalent, at 6,000,000, regardless of what year such population is reached, and assuming that all sewage is treated, the oxygen demand will be equivalent to that of a population of 900,000. If there is no change in the characteristics of the sewage from the present-day conditions, the twenty-day oxygen demand would therefore be 216,000 pounds per day. That is to say one day's sewage would require this amount of oxygen within a period of twenty days. With the complete treatment of sewage there will be no sludge deposits to create an extra demand for oxygen, therefore 216,000 pounds per day may be taken as the total demand to be supplied on the average throughout the year.

With the premise that aerobic conditions must be maintained in the canal, this involves the average withdrawal of fresh water from lake Michigan of about 1,200 cubic feet per second, with less in winter and more in summer. This, of course, allows for re-aeration effects during the passage of the water along the canal. The combined flow of sewage effluent and lake water reaches its minimum oxygen content about the time it reaches Lockport, (about $3\frac{1}{2}$ days), at which time the oxygen demand exerted is 55 per cent of the total. After this point the rate of re-aeration will exceed the demand so that a continuance of aerobic conditions is assured.

If the summer condition alone is examined, it is found that in order to maintain the aerobic condition, the flow of fresh water from lake Michigan must be increased to 1,700 cubic feet per second, due to the greater demand in the sewage effluent, and the smaller supply of dissolved oxygen in lake Michigan. In this case the minimum oxygen content or the critical point is not reached until considerably below Lockport. This computation is based on the assumption that the Illinois waterway project now under construction is completed so far as the stretch of river below Lockport is concerned. This work will have the effect of drowning out the present swift water, hence very materially reducing the rate of re-aeration. If the river was in its natural condition and without the existence of the power house at Lockport, the amount of diversion of fresh water necessary in summer time for 6,000,000 total human and equivalent population would be reduced to about 1,400 cubic feet per second or less, provided in all cases that complete treatment of all sewage is in effect.

Reversal of Flow

That there is no insurmountable difficulty involved in the prevention of the reversals is recognized by the fact that the Sanitary District of Chicago is now preparing plans for submission to the United States secretary of war in accordance with the latter's ruling that plans shall be submitted and controlling works completed and in operation by July 1st, 1929. Whatever form such controlling works take, whether simply a protective gate or whether a lock and gates, there will be some obstruction to navigation, either continuously or occasionally, depending on the design of the works. Heretofore, it has been this question of obstruction to navigation which has prevented the installation of some form of controlling works. With such works in operation at some point on the main outlet of the Chicago river, the question of reversal of flow can be entirely dissassociated from the quantity of diversion provided the design of the works is made with that object in view. On the other hand, if the design is made on the basis of creating the least obstruction to navigation, it may well be that the maintenance of a large diversion quantity will be necessary.

Summary of the Future Needs

From the point of view of what is actually necessary to dispose of the effluent of Chicago's sewage, the conclusion is reached that the extreme minimum which it may ever be possible to utilize is in the neighbourhood of 1,200 cubic feet per second together with sewage to the extent of about 1,500 cubic feet per second, making the total diversion out of lake Michigan 2,700 cubic feet per second. It is possible, however, that this quantity might not be sufficient for maintaining continuously decent conditions in the canal and Des Plaines river, because there may be times of storm run-offs, and other unusual conditions which would exert an extraordinary demand. It is also quite certain that the works now being undertaken by the state of Illinois in the construction of the Illinois waterway will have the effect of permanently increasing the amount of diversion necessary for sanitary reasons.

The Benefits of the Canal

The benefits of the Chicago drainage canal, whether actual or claimed, whether positive or imaginary, may be divided into two categories: the first, the saving of human lives and safeguarding the health of a community; the second, the benefits connected with trade, commerce or in some other way involving an economic or financial advantage. These two categories must not be confused. That the former is of paramount importance, will be readily admitted, but in dealing with the subject, there should be no interjection of benefits to trade and commerce as a means of adding weight to the importance of the benefit of saving life. The two elements, human life and commerce, are not of the same denomination and cannot be added. Furthermore, the question of saving human life is one on which nations will freely remove artificial barriers, but as soon as pecuniary matters are introduced, the barriers are immediately raised and apparent. It must not be overlooked, however, that the problem of safeguarding the health of a community ultimately becomes one of dollars and cents, because it is the financial power of a community which determines to a large degree the extent and nature of the enterprises which it can undertake for the bodily welfare of its citizens, and the growth of a large city would be impossible if the cost of providing any one of its essential utilities is unduly high.

Benefit to Health

Prior to the construction of the drainage canal, the greater part of the sewage of the city of Chicago was discharged directly into lake Michigan by the Chicago river. At the same time the city's sole source of water supply was the lake. There being practically no perceptible currents in the lake, except such as were set up by winds, it frequently occurred that strongly polluted water reached the intakes, with the natural result of many deaths from typhoid fever.

As previously referred to, the typhoid death rate reached very serious proportions in the eighties, as a result of which the Drainage and Water Supply Commission was appointed. This commission consisted of three engineers, namely: Rudolf Hering, Benezette Williams and Samuel G. Artingstall. The first part of their report, dated January 1887, and addressed to the mayor and council of the city of Chicago, deals with sewage disposal. They state that "Among the possible methods of getting rid of the Chicago sewage, there are but three that have been deemed worthy of an extended consideration, namely, a discharge into lake Michigan, a disposal upon land, and a discharge into the Des Plaines river." With regard to the first proposition they state that owing to the lack of current in lake Michigan, it would be necessary to widely separate the sewage discharge from the water intake, and also that "While it might be practicable to allow the sewage in its crude form to enter the lake under such conditions for many years, the necessity would arise later for clarifying it at least partially previous to its discharge." With regard to disposal on land, after explaining the nature and extent of the works required and also their cost, they state that "It appears that this project is decidedly the least expensive for the present as well as for the future." The second part of the report deals with the question of water supply and is based on the assumption that sewage will be diverted from lake Michigan by way of the Des Plaines river.

This report and investigation apparently formed the technical basis of the "Act of the State of Illinois" which was passed two years later, and presumably the drainage canal was embarked upon because, according to the abovementioned report, it was not only an entirely satisfactory method of disposal with particular reference to water supply, but was also by far the cheapest. The land disposal method was reported upon as being prohibitively expensive. No estimate was made of the separation of sewage outlets and water intakes. Repeating, it may therefore be said that the drainage canal was embarked upon because it appeared to be the best method from the health point of view with due regard to the cost of the undertaking. The two things cannot be separated. From the point of view of health alone, one would judge that the order of merit would have been: 1. land disposal; 2. Des Plaines river; 3. discharge into the lake.

The benefit to the health of the community can best be seen by studying the death rate from typhoid fever over a period of years, as published by the Sanitary District, and based on Chicago Department of Health Records.

Years	Average Typhoid Death rate per 100,000
1870-1879	57.9
1880-1889	63.7
1890-1899	66.8
1900-1909	22.6
1910-1919	6.4
1920-1924	1.3

While it cannot be suggested that the whole of the improvement in the death rate from typhoid is attributable to the drainage canal, it must nevertheless be admitted that it probably contributed to the improvement to a greater degree than any other single action. The improvement did not reach a marked degree for the first five years after opening the canal, because there were frequent reversals of the Chicago river into lake Michigan, and because many of the intercepting sewers were not completed. At the same time it was not until 1922 that the sewage of the Calumet district was kept out of the lake. In later years the introduction of chlorination of the water supply was another factor which had a marked effect on the lowering of the death rate.

Consideration must also be given to the fact that notwithstanding the adoption by Chicago of what was the least expensive method of disposing of its sewage, the per capita cost to the city has been far greater than the cost for similar work to any of the major cities of the United States, and therefore cannot exactly be classed as a cheap method.

As the situation stands to-day Chicago has spent $120,-000,000. on sewage disposal and is committed to a total expenditure of $250,000,000. by 1945. Even with the increased population by that time, the per capita cost of its sewage disposal works will still be very high. The question, nevertheless, arises:—Could Chicago do anything else under present-day conditions? The only possible alternative would be the abandonment of the drainage canal means of disposal; the discharge of the effluent from sewage treating plants into lake Michigan, and the installation of filtration plants for its water supply and change in the location of the water intakes. The financing and construction of such a project would take many years to accomplish, and in the meantime the diversion will have to continue to a greater or less degree. At the same time, sanitary experts look upon the discharge of effluent from even the most modern sewage disposal plants into the waters of lake Michigan, in such volume as necessary, for a city the size of Chicago, as a step in a backward direction, especially in view of the fact that a very large population bordering on the lake is dependent on the lake waters for domestic consumption.

Power Development

Such benefits as may accrue from the drainage canal which are directly or indirectly of a commercial nature cannot be accepted as argument for the use of water which belongs somewhere else, unless it is properly compensated for.

One of the first benefits of this nature is the hydroelectric plant at Lockport, which under state legislation is only incidental to the sanitary use of the drainage canal. While the policy is to dispose of the output of this plant *at cost*, nevertheless, there has been a large economic saving distributed among the city of Chicago, the Sanitary District, other municipalities, and some commercial concerns, owing to the very fact that this cost was lower than the current rate of the local power company. At the present time the power is sold to the four groups of customers at rates which just about balance the cost of production, which in turn is made up of fixed charges on the investment in the power house and part of the canal extension, and of operation and maintenance costs. There have also been a number of years in the past when a direct profit of as much as a quarter of a million dollars was made. On the other hand, the relationship of this development at Lockport to the total power market of the district is small, as it only represents about five per cent of the total power consumption.

Future changes in the river, caused by the building of dams, will concentrate the head which is at present wasted, into four sites, at each of which power may be developed. The following table gives a list of the sites and the power available at each site, including Lockport, under varying flows, from the diverted water alone. Allowance is made in each case for the amount of water necessary for navigation purposes, that is to say, the amount necessary for the operation of the locks, which has been stated by various authorities to be about 1,000 cubic feet per second. If the quantity of traffic on the waterway did not reach expectations, then there would be so much more water available for power.

Approximate horse power obtainable from

Site	Head	2,000 c.f.s.	4,167 c.f.s.	7,000 c.f.s.	10,000 c.f.s.
Lockport.......	34 ft.	3,400 h.p.	10,800 h.p.	20,400 h.p.	30,600 h.p.
Brandon Road..	30 "	3,000 "	9,500 "	18,000 "	27,000 "
Dresden Island..	17 "	1,700 "	5,380 "	10,200 "	15,300 "
Marseilles......	23 "	2,300 "	7,280 "	13,800 "	20,700 "
Starved Rock...	18 "	1,800 "	5,700 "	10,800 "	16,200 "
Total........	....	12,200 h.p.	38,200 h.p.	79,200 h.p.	109,800 h.p.

It will therefore be seen that there is a possibility of developing about 100,000 horse power in the Illinois valley from the present amount of diversion, and there is no doubt but that it could be immediately utilized. The potential value of this power is, of course, problematical, but on whatever basis it is estimated, whether by the net commercial benefit, or whether by the saving over cost of coal production, or whether by the cost of coal necessary to produce the same power, the value to the state of Illinois of this power is represented by something well over a million dollars a year.

Illinois Waterway

While there have been many references to the drainage canal in connection with its availability for navigation purposes, so far the benefit has been negligible, as the traffic has never amounted to a volume worthy of consideration. Instead, therefore, of there having been a benefit to navigation in the past, it might almost be said that the induced velocities in the Chicago river have in many instances been detrimental to navigation.

With the plans and construction now under way for the Illinois waterway, there will undoubtedly be a large saving in the cost of construction through increased flow in the river which induces greater depths, thus reducing the quantity of excavation necessary.

The Illinois waterway, which is now under construction by the state of Illinois, is part of the "Lakes-to-the-Gulf" waterway, which has the object of connecting lake Michigan with the gulf of Mexico for medium draft vessels by means of the Des Plaines, Illinois and Mississippi rivers, with the drainage canal as the first link. The present construction programme covers the Des Plaines and Illinois rivers from Lockport to Utica, a distance of 58 miles, and will provide for 9-foot draft in rock, 8-foot in earth, with locks 600 by 110 by 14 feet over sills. From Utica to Grafton, at the outlet of the Illinois with the Mississippi, a distance of about 230 miles, the present system provides for 7-foot draft. On the Mississippi from Grafton to St. Louis, there is a 6-foot waterway, from St. Louis to Cairo 8-foot, and from Cairo to the gulf 9-foot. The Ohio river scheme connecting with the Mississippi at Cairo has provision for 9-foot draft, and will provide a means of bringing coal from the Pennsylvania coal fields to Illinois and into lake Michigan.

In the development of its present plans for the I linois waterway the state of Illinois is undoubtedly interested in maintaining a large flow through the drainage canal. The cutting off entirely of this flow would make the present undertaking impossible, as 1,000 cubic feet per second is needed for the operation of the locks, and even with the 1,000 cubic feet per second the work would be enormously expensive as compared with its probable cost under present conditions. The benefit of saving in construction cost is fairly definite and amounts to as much as 30 million dollars for a diversion of 10,000 cubic feet per second.* The benefit that may accrue to the commerce of the country through the completion of this waterway is problematical. The state of Illinois Chamber of Commerce estimates that the traffic will amount to as much as 20,000,000 tons a year, of which figure 15,000,000 tons represents coal destined to Chicago.

*Report of Committee No. 3, Engineering Board of Review, page 8.

To go further afield, there is the suggestion that navigation on the Mississippi river will also be materially assisted by the increased flow. This, however, is subject to argument on account of the peculiar characteristics of this river.

Summing up the benefits accruing from the drainage canal, there is, first of all, a very decided benefit to the health of the community served, obtained at a cost very much less than by any other method; second, there is, or has been a small benefit from the production of hydro-electric power; third, there is a benefit to the state in the reduction of the construction cost of the Illinois waterway; and, finally, there may be a benefit to commerce, of problematical amount, through the said waterway being made possible.

Damages

The first of the damages which have been caused by the diversion is that to the Des Plaines and Illinois rivers and to the people adjacent thereto, owing to the effect of the sewage in the water, and increased quantity of water. The effects may be classed under three headings, namely, sanitary, flooding and effects on the fishing industry. The conditions in each case have been examined by the district engineer of the United States, of Chicago, who explains each situation, and apparently the sanitary condition of the river is disagreeable, but not seriously so; that the effect on fish life is beneficial rather than otherwise; and that land damages are being paid for by the Sanitary District.

Effect on Navigation—Great Lakes and St. Lawrence River

In 1896, Mr. O'Hanley reported that there was insufficient data for a reasonably accurate determination of the effect of the withdrawal of any given quantity of water from lake Michigan on the levels of the Great Lakes and St. Lawrence river. Since that time, however, most careful surveys, gaugings and meterings have been made on all the lakes with the result that to-day there is no question but that the actual effect of any given amount of diversion may be determined with reasonable accuracy. By applying the amount of diversion to the rating curves of the various lakes at their outlets, or to the St. Lawrence river as the case may be, the effect is simply a matter of mathematical calculation. The results reported by Colonel J. G. Warren, Corps of Engineers, U.S. Army, in his "Report on Diversion of Water from the Great Lakes and Niagara River," are generally accepted as being an accurate interpretation of the effects in question. Part of the results of his investigations are given in the following table, which gives the lowering of level in the various lakes by diversion of water through the drainage canal at Chicago.

Quantity of Diversion, c.f.s.	4,000	6,000	8,000	10,000
Lake Michigan............	0.20 ft.	0.30 ft.	0.40 ft.	0.50 ft.
Lake Huron............	0.20 "	0.30 "	0.40 "	0.50 "
Lake St. Clair............	0.16 "	0.24 "	0.31 "	0.39 "
Lake Erie............	0.19 "	0.29 "	0.39 "	0.49 "
Lake Ontario............	0.20 "	0.30 "	0.40 "	0.50 "

The above figures apply to the low level stage of each of the lakes. For higher stages there is a small variation in the amounts but only in the hundredths of a foot. To all intents and purposes, therefore, the utilization of the amount of six inches is accurate enough as representing the effect of the maximum diversion at Chicago.

Great Lakes Navigation

Before an intelligent idea can be obtained as to the effect of this lowering of the water levels of the Great Lakes system, it is essential that the general nature of the lake traffic should be comprehended.

The commerce of the Great Lakes is enormous. It exceeds the water-borne traffic of any trade route in the world, amounting as it did in 1923 to over one hundred million tons of freight carried per annum. Furthermore, in view of the fact that the navigation season extends over a period of eight months only, say the middle of April to the middle of December, the intensity of the traffic is very great. In order that this commerce may be properly transported, the whole traffic and system has to be very highly organized. The bulk of the freight is carried in very large vessels, of a modern type, designed and built specially to meet the needs of the traffic and of the lake conditions. They are not only of large tonnage, but also of large carrying capacity per ton of dead weight. The result of this highly organized system is that not only is the commerce most expeditiously handled, but it is also handled at an extraordinarily low cost. This is partly made possible by the fact that there are no tolls and the improvements to waterways have been made by the Canadian and United States governments.

The traffic has a load factor of approximately 3 to 1 in favour of eastbound traffic, that is to say, for every ton of traffic carried east, only one-third of a ton is obtained on the westbound trip. Obviously therefore, from the viewpoint of the trade at large, any question of the effect of the lowering of the lake levels on the carrying capacity of the vessels on their westbound trips is of comparatively small account, as there is ample tonnage in the westbound movement to take care of three times the volume of traffic. There is naturally, however, some loss to the operators, as more vessels have to be put into the westbound carrying service than would otherwise be the case, and an economic loss is therefore involved. The great bulk of the traffic westbound, (about 90 per cent), is coal from lake Erie ports.

Of the eastbound traffic, 80 per cent is ore from Minnesota and northern Michigan, while 19 per cent is grain from Fort William, Port Arthur and Duluth-Superior. The bulk of the ore is loaded at Duluth, Agate Bay and Ashland, Minnesota, and Marquette, Michigan. About 83 per cent is shipped to lake Erie ports, with Cleveland, Ashtabula and Buffalo taking the largest quantities, (about 20 per cent each).

The grain traffic, although smaller in tonnage, is nevertheless of great importance, on account of its high value, and is, of course, of supreme importance to Canada.

Approximately 280 million bushels of wheat and 165 million bushels of other grains pass through the Sault Ste. Marie canals in one season. Of this amount about 18 per cent goes to Georgian Bay ports, 22 per cent by the Welland canal to Montreal, and the balance nearly all to lake Erie ports, with Buffalo taking nearly 50 per cent.

Description of the Route

It has been shown that the bulk of the lake traffic is from ports on lake Superior to ports on lake Erie. The vessels pass down lake Superior and reach their first obstruction at Sault Ste. Marie, which is fourteen miles down the upper St. Mary's river from the foot of lake Superior.

At Sault Ste. Marie, there are five locks through which vessels are lowered approximately 20 feet to the lower St. Mary's river. These locks are as follows:—

Figure No. 7—North Side Sewage Treatment Plant under Construction.

Lock	Length	Width	Draft		Date Completed
			Design	Actual	
Canadian Lock..	900 ft.	60 ft.	22.0 ft.	17.7 ft.	1895
U.S. Weitzel....	515 "	60 "	14.0 "	12.0 "	1881
U.S. Poe.......	800 "	100 "	22.0 "	17.5 "	1896
U.S. Davis.....	1,350 "	80 "	24.0 "	24.0 "	1914
U.S. Sabine.....	1,350 "	80 "	24.0 "	24.0 "	1919

After leaving the locks, vessels pass down the St. Mary's river channel into lake Huron.

While obviously the Chicago diversion has no effect on the elevation of lake Superior, nevertheless, traffic to and from lake Superior is affected by the lowering of the water level on the downstream side of the locks, thus reducing the depth over the sills by about six inches for 10,000 cubic feet per second diversion.

After traversing lake Huron, the St. Clair river is entered, but it is not until the outlet of the St. Clair river into lake St. Clair is reached that any serious restriction in depth is found. At this point the river spreads over the St. Clair flats and artificially dredged channels have to be maintained. Lake St. Clair, which is about $5\frac{1}{2}$ feet below lake Huron level, is comparatively shallow with sand and clay bottom. For twenty miles below lake St. Clair, past the city of Detroit, no restrictions are encountered, but before entering lake Erie, 3.1 feet below lake St. Clair, shallow channels again occur. Below this point the only restriction to the draft of vessels is that occurring in harbours, although it must be remembered that lake Erie is a very shallow lake compared with the others.

In order that full advantage may be taken of fluctuation of levels in the various lakes and waterways, constant watch is kept upon the conditions, and vessels loading are kept in close touch by telegraphic advice to the end that they may load down to the maximum possible inch. Even with these precautions groundings are of frequent occurrence. For this reason any lowering of the lake levels in general has a direct reaction on the loading of all those vessels which are large enough to come within the draft limits, which applies to the majority of vessels.

The relationship between lake levels and permissible drafts of vessels is a subject of great importance and interest,

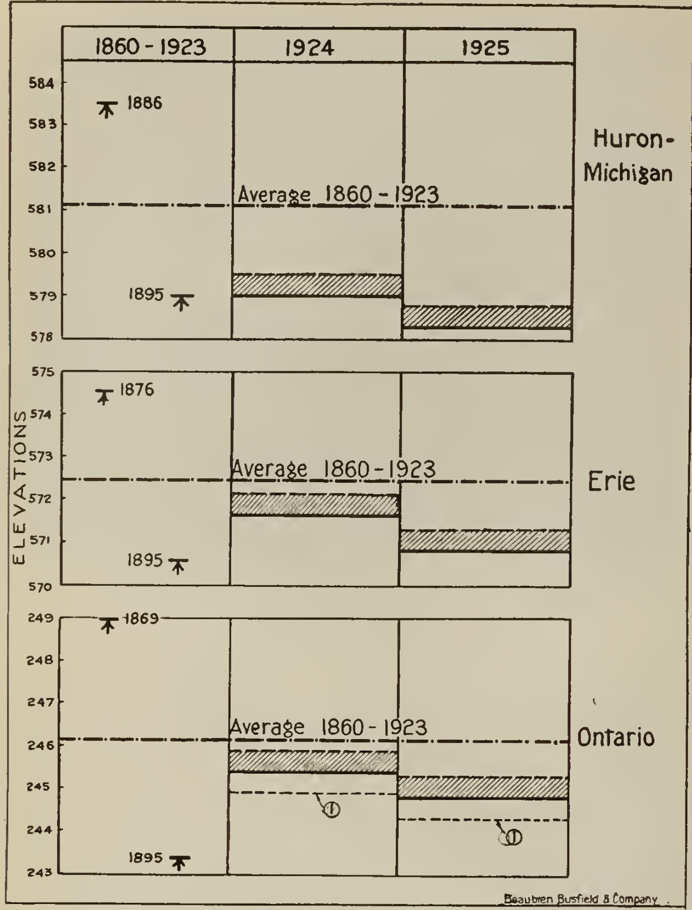

Figure No. 8—Average Lake Levels.
(Based on hydrographs of United States Lakes Survey.)

Arrows indicate extreme high and low water levels between 1860 and 1923.

Hatched portions indicate lowering effect caused by diversion of 10,000 cubic feet per second at Chicago.

Actual average lake levels in 1924 and 1925 indicated by full lines.

Dotted line: 1, represents level to which lake Ontario would have receded but for compensating effect of the Gut dam.

but beyond the scope of this paper, as only the broad principles involved need be discussed in order to comprehend the effect of the diversion at Chicago on the commerce of the Great Lakes.

Lake Levels

During the past few years, there has been a steady lowering of lake levels until in the case of some of the lakes an unprecedented low elevation has been reached. It has already been stated that the effect of the diversion at Chicago is about 6 inches at low lake stages. This is not a matter of guesswork, but is fairly close and reliable mathematical computation obtained by determining the difference in elevation of the various lakes or waterways, corresponding to measured changes in flow at the outlets of such lakes or waterways.

The claim is made by some authorities that the level of lakes Michigan and Huron has been lowered some inches by the dredging and excavation work in the St. Clair and Detroit rivers. This may be so, and indeed, the records of lake levels seem to indicate that such is the case. On the other hand, it is also claimed that a large amount of the excavated material has been so deposited in the channels as to act as compensation for the excavation.

Diversions of water for power purposes and for the Welland and Erie canal all have an effect on the elevation of lake Erie even though the greater part of such diversions are returned to the same system. Taking the discharge of lake Erie at the round figure of 200,000 cubic feet per second, 60,000- cubic feet per second or 33 per cent is withdrawn from Niagara falls, which has a very considerable lowering effect on the Chippawa-Grass Island pool, which in turn has a lowering effect on lake Erie. A small percentage of the above represents direct withdrawals from lake Erie for the New York State barge canal and for the Welland canal. The effect of all these withdrawals is estimated by the Board of Review at 4 inches for lake Erie, with an effect of 2 inches on lakes Huron and Michigan. It may be found, however, on further investigation that actually there is no lowering effect owing to compensation resulting from the dumping of excavated material into the Chippawa—Grass Island pool.

The major lowering of the lake levels has been caused by climatic conditions naturally following a long period of less-than average rainfall, and of unusually dry and warm summers, causing greater evaporation. An examination of the hydrographs of the Great Lakes covering the years 1860 to 1925 indicates that the level of lakes Michigan and Huron in 1925 was on the average 2.8 feet lower than the average for the whole period; of this amount approximately 2 feet is attributable to climatic reasons. Lake Erie has not been affected quite so much, as the lowering in 1925 due to climate may be placed at about 10 or 11 inches.

Regardless of whatever effect these different causes have, there is no getting away from the fact that the drainage canal is the direct cause of lowering all the levels about six inches below what would otherwise be the case. On the other hand, it must be recognized that in years of plenty, when the lake elevations are on the high side of the cycle, the lowering by six inches would not affect so many vessels or cargoes.

Effect of Reduced Draft

It has been shown that from a broad commercial point of view, it is eastbound traffic which has to be considered in relationship to the effect of the diversion, as the westbound traffic is not so seriously interfered with. The eastbound traffic consists of practically two commodities: ore and grain.

During the last five years approximately 55,000,000 tons of freight have been carried eastbound per year. An examination of the statistics of lake commerce, passing the canals at Sault Ste. Marie, indicates that the bulk of the traffic is carried in vessels varying from 3,000 to 7,000 tons net register, corresponding in length from 430 to 600 feet. One inch of draft on vessels of this size represents about 80 tons of cargo, therefore a lowering of the draft by 6 inches means 480 tons per vessel. These vessels carry average cargoes of about 6,000 tons, and about 9,000 vessel-trips are required to handle the total eastbound movement. Under anything like ordinary circumstances the lake levels will be sufficiently high for about one-half the season to provide full drafts regardless of the diversion at Chicago, hence it may be said that about 4,500 vessel-trips are affected, which in turn means 2,160,000 tons loss of carrying capacity. In other words, it may be said that additional carrying capacity to the extent of over 2 million tons per annum has to be provided. The actual cost of handling ore and grain is presumably something less than the freight rate which averages about 80 cents per ton for ore and somewhat higher for grain. If it is taken at 75 cents per ton, it then works out that the cost to Great Lakes navigation of the diversion of 10,000 cubic feet per second at Chicago is $1,620,000. per annum.

The Lake Carriers Association of Cleveland, Ohio, has made careful studies of this whole situation and they have estimated that one inch drop of water level is equivalent to a loss of 500,000 tons carrying capacity of the whole fleet, and therefore 6 inches represents a loss of 3,000,000 tons. With a cost of transportation of 80 cents a ton, this represents a loss of $2,400,000. per annum. The application of the actual freight rate may not be a true indication of the cost of handling the amount of freight which might have been carried by the same number of vessel-trips, if they had been able to carry more cargo per trip, but is probably close enough to give a broad indication of what the lowering means in dollars and cents.

While no doubt somebody loses this amount of money, or to put it in another way, while this represents the additional cost of handling the freight in an average year, it will readily be seen that when it comes to a question of responsibility there are many factors involved which make it a difficult problem to solve. If the subject is being discussed from the point of view of the people at large, however, the chief consideration must be as to whether or not the commerce of the country is being handicapped.

However, out of all the argument which can be made on the subject, there is one fact which stands out beyond dispute and that is that the Chicago drainage canal undoubtedly has an adverse effect on the lake traffic. That the Sanitary District admits this fact is evidenced by its offer to pay for its share of remedial works for counteracting such effect.

Remedial Works

In discussing remedial works with regard to the Great Lakes, differentiation must be made between compensation works and regulation works. The former have the effect of imposing an artificial obstruction to a waterway, which backs up the water and therefore counteracts the lowering effect which may have been caused by the dredging of channels, or by the withdrawal of water. Regulation works, on the other hand, have the function of providing a means of varying the capacity of a waterway and thus of actually regulating the discharge from a lake or flow in a river.

With regard to remedial works for the Great Lakes, the problem is one with many complications, as the general requirements are as follows:—

First—The elevation of the lakes must be raised at the low water stage.

Second—The high water elevation of the lakes must not be changed from existing conditions.

Third—The least possible obstruction to navigation must be provided.

Fourth—The works must be of such a nature as not to induce troubles from ice conditions, and if possible to improve upon present conditions.

Consideration of the first two requirements immediately eliminates compensation works from any further study. The works must therefore be regulatory and must provide means for storing some of the flood discharge of the lake, but yet at times of maximum flood must provide an outlet with a capacity at least as large as exists at present. At the low water stage the works must permit the passage of a larger quantity of water than now flows at the low stage, but must maintain the level of the water at a higher level stage.

Such regulation works have been built and are in operation at Sault Ste. Marie since 1916. By their means, lake Superior is now under regulation with an improved low level, but in order to remedy the lowering effect caused by the diversion at Chicago it is the levels of lakes Michigan, Huron and Erie which have to be remedied. Remedial works for this purpose have been under discussion by the various authorities concerned for many years. Under some plans it has been considered sufficient to build the works at the outlet of lake Erie into the Niagara river, and that there would be sufficient backwater effect through the Detroit and St. Clair rivers to raise lakes Huron and Michigan. On the other hand, plans have also been studied for two projects, one at the foot of lake Huron, the other at the Niagara river. The objection is raised to the lake Huron project that it will place an obstruction in the path of navigation on the busiest waterway in the world.

The position to-day is that the problem is not entirely solved, but there is no doubt that before very long a satisfactory solution will be found, and remedial works will be built which will at least have the effect of maintaining the desired depths in all the main waterways, regardless of the fluctuation in rainfall, and withdrawal by Chicago. The position of the Sanitary District with regard to these works is that they have agreed to bear their share of the cost as determined by the United States chief of engineers, and, in accordance with the permit of March 2nd, 1925, have deposited a million dollar bond with the secretary of war as a guarantee of good faith. It is only fair, however, to add that the trustees of the Sanitary District have been on record for many years as willing to bear the cost of compensation works as soon as the United States authorities would agree on the form to be built.

Effect of Remedial Works

Properly designed, constructed and operated, remedial works may have the effect of counteracting not only the reduction in lake levels by the diversion at Chicago, but also of the lowering caused by the diversion at Niagara Falls, and also of the lowering which periodically occurs, due to climatic reasons. In other words, the remedial works may maintain a lake level approximately equivalent to an average condition without any diversions. In this way, the present adverse effect on lake traffic may be entirely eliminated.

A second function of the works will be the improving of the regime of the outflow from lake Erie, that is, the Niagara river. By withholding some of the natural run-off during the high water period, additional water may be made available during the low water period. The discharge, for instance, of the Niagara river goes as low as 160,000 cubic feet per second, but with regulation of the upper lakes, it has been estimated that this may be increased to 180,000 cubic feet per second. The obtaining of such a result would require most careful operation of the whole storage system and it is improbable that quite such a good result would be continuously in practice, but, nevertheless, it is quite within the bounds of reason that the low flow of the Niagara river may be continuously increased by an amount at least equivalent to the amount of the diversion. At first glance, it would therefore appear that suggested remedial works will immediately have the effect of counteracting the effects of the diversion on the whole of the waterway from the Great Lakes to the gulf of St. Lawrence, partly by raising the levels of the lakes and partly by providing additional low water flow below lake Erie, but this will not be the case, as will be shown later.

St. Lawrence Canals

Heretofore the discussion has been confined to the Great Lakes as representing the major part of the traffic. It must not be forgotten, however, that the effect of the diversion at Chicago is continuously felt all the way down the St. Lawrence system, (including lake Ontario), until tidal water is reached. Furthermore, the actual lowering effect of the diversion is somewhat greater in the reaches of the St. Lawrence than it is on the Great Lakes, and according to Colonel Warren, amounts to 9 inches at low water in the reach of the river above Morrisburg.

The Welland canal forms the connecting link between the Great Lakes and the St. Lawrence waterway, and is now limited to vessels of 14 feet draft, but is being rebuilt with locks providing for 30 feet over the sills, and the canal itself with a depth of 25 feet.

The St. Lawrence river between lake Ontario and Montreal is 180 miles long, and is made up of a series of canals flanking various rapids with intermediate reaches. The rapids are utilized to a limited extent for downstream navigation although the lower ones are confined to passenger vessels. The following table gives general particulars of each of the six canals.

	Length miles	No. of Locks	Locks length feet	Width feet	Depth feet
Galops	7.33	3	270	45	14
Morrisburg	3.67	2	270	45	14
Farrans Point	1.25	1	800	50	14
Cornwall	11.00	6	270	45	14
Soulanges	14.00	5	280	45	15
Lachine	8.50	5	270	45	14

A project for improving and deepening the waterway from the Great Lakes is now being studied and reported upon by the Joint Engineering Board for the St. Lawrence Waterway.

Traffic on the St. Lawrence canals for the year 1924 amounted to a total of 5,536,374 tons, of which 4,593,618 tons or 83 per cent was eastbound and 942,756 tons or 17 per cent westbound. Here again it is eastbound traffic therefore in which the question of drafts most seriously enters, although there is quite a volume of westbound package freight business in which the vessels are loaded to draft limits. Of the 4,593,618 tons eastbound, 3,532,755 tons (77 per cent) is grain, 662,787 tons (14 per cent) is coal, and the balance miscellaneous.

The average cargo carried by eastbound vessels amounted to about 1,850 tons involving 2,360 trips per season. The loss per vessel of 9 inches draft would be represented by about 300 tons for vessels operating on this route. A large proportion of the traffic is moved during the latter part of the season, at a time when the water levels are at their lowest; the effect of the lower levels is therefore very seriously felt. If 1,000 trips are affected, it means that additional shipping has to be supplied for the movement of 300,000 tons, which would represent about 160 vessel-trips per annum with average cargoes. This in turn represents a cost per annum of approximately half a million dollars on the assumption that the vessels are only plying between Port Colborne and Montreal.

As a matter of fact the money end of the matter hardly represents the seriousness of the situation. It is well known that the grain traffic on the St. Lawrence route is badly handicapped to-day owing to the limited capacity of the canal system. Naturally the reducing of the cargo-carrying capacity of the vessels using the canals is introducing another serious handicap on top of the first one. During the limited period for movement of the grain prior to the close of navigation, there is no question but what every inch counts.

The Port of Montreal

As Chicago is the great railway junction of the middle west, so is the port of Montreal the great junction for international water-borne traffic. On the one hand, it is the great western terminus of ocean navigation to which vessels from seventeen different countries come, while on the other hand, it is the eastern terminus of the traffic of the Great Lakes-St. Lawrence system. The two great transportation systems are brought together and their goods interchanged under the auspices of the port of Montreal.

As the St. Lawrence canal system has its lower outlet into the harbour of Montreal at the lower lock of the Lachine canal, the foregoing references covering the St. Lawrence canals apply to this part of the traffic.

With the increasing size of the ocean-going vessel, the depth of the navigable waterway leading from the open sea into Montreal harbour has had to be continually increased, but for a number of years past, has been maintained at about 30 feet. The intention has been to ultimately provide a 35-foot waterway, but with the increasing difficulty of maintaining even the 30-foot depth at all times it is probable that some radical change will have to be made in the system with the increasing development of the port.

It is no exaggeration to state that a large percentage of outbound vessels load up to the last inch permissible with the river depths available at the time of sailing. In many instances vessels are unable to take on their full load at Montreal, and have completed their loading at Quebec. An examination of the records of water levels in the harbour indicated that in the past twenty-five years the levels have dropped below the height necessary to maintain the 30-foot channel ten times, while in the past five years it has been below at some period in every year. Records also show that the low level period extends over the months of August to November inclusive, or four months out of the seven during which the port is open for navigation. The latter four months, incidentally, are the busiest, and include the peak of grain shipments.

The traffic of the port, according to the last published report of the Harbour Commissioners, amounts to the following:—

Imports—General	1,472,933	tons
Exports "	931,854	"
Local "	1,918,346	"
Lumber	225,000	"
Grain	4,662,456	"
Miscellaneous	100,000	"
	9,310,589	"

This traffic was handled by 1,223 vessel-trips, representing an average cargo of 7,600 tons. It is probable that somewhat more than 4/7 of this number, or say 750, come within the period when there is limitation upon drafts, but of this number many are small vessels, and according to studies made by the Shipping Federation of Canada, about 100 vessel-trips are affected. These vessels will range from the large liners of about 16,000 tons down.

At the time of writing, the Shipping Federation of Canada are making a study of the number of vessels affected and the loss of cargo per vessel, and definite figures are not as yet available. The effect of low water levels, however, is a very serious one, as many complications are introduced. For example, some of the oil-burning steamers have to stop at Quebec for the express purpose of filling up their oil tanks. Some vessels are also delayed at Quebec taking on cargoes which should have been loaded at Montreal. Some vessels have to make the whole voyage across the Atlantic short of many tons of cargo. That the situation is a very serious one is expressing it very mildly.

Remedial Works for St. Lawrence River

Owing to the intervention of lake Ontario the additional low water flow made available by suggested remedial works at the outlet of lake Erie would not have the same effect on the river St. Lawrence. That is to say, if for example it were possible to maintain an additional flow of 10,000 cubic feet per second from lake Erie during the extreme low water period, this quantity would to a large extent be stored in lake Ontario and instead of increasing the low water discharge thereof, it would be spread more uniformly over the year, so that the low water discharge might only be increased by say, 1,000 cubic feet per second. Therefore, in order that the effect of the Chicago diversion on the St. Lawrence river be remedied, regulatory works for lake Ontario become necessary.

The lowering of lake Ontario has already been partly compensated for by the construction in 1903 of the Gut dam, across one of the small channels of the St. Lawrence, opposite the upper end of the Galops canal. This dam has had the effect of raising lake Ontario about 5 inches at low water and 8 inches at high water. This work, however, has no beneficial effect on the levels below this point.

In order to remedy low water conditions on the St. Lawrence river, regulatory works at some place suitable for the control of lake Ontario will be required. Such works may increase the low water flow by an amount at least equivalent to the withdrawal at Chicago, but, even so, it must not be overlooked that even greater benefits could be obtained if the withdrawal did not exist.

The present status of the matter is that the commission to the Joint Engineering Board for the St. Lawrence Waterway instructs the board to take into consideration the effects of the diversion at Chicago in designing regulation works for the lake system, and in view of the fact that their report is due within the near future, it is inopportune to refer further to the subject.

Summary of Effect on Navigation

As shown in the foregoing paragraphs, there are three great navigation systems, which are seriously affected by the diversion at Chicago; namely, the Great Lakes, the upper St. Lawrence and the ocean traffic from Montreal. While an attempt has been made to give an indication of the monetary effect, it must be borne in mind that this is really only a very general indication and that the interference with or obstructing of the traffic of a great trade route has effects more far-reaching than can be represented by a simple mathematical calculation.

Effect on Power Development

In considering the effect of the diversion at Chicago on power development, the first principle which must be clearly understood is that any remedial works, no matter of what nature, cannot entirely replace the value of the diverted water for power development purposes. Regulation works may increase the low flow of the Niagara and St. Lawrence rivers and thus increase the amount of power that might be developed, but if there were no diversion at Chicago, the amount of power obtainable would be just so much increased over and above such improvement as might be made by the regulation works.

Power developments or sites affected by the diversion are Niagara Falls and the various sites on the St. Lawrence river. At Niagara Falls the uses of water for power purposes are divided between Canada and the United States, and in the upper part of the St. Lawrence joint ownership is again involved. The lower part of the St. Lawrence, including the Coteau, Cedars, Cascades and Lachine rapids, is under the entire ownership of Canada. To go into the power situation fully leads one into a field of speculation and uncertainty with little possibility of any stable conclusions, but from the broad economic point of view certain quite definite conclusions as to the effect of the withdrawal at Chicago can be reached. In the first place the whole question of power development on the St. Lawrence is undergoing intensive study by the Joint Board of Engineers and at the same time there are most involved problems in connection with public policies with regard to the development in both Canada and the United States, so that a statement regarding what is a possibility to-day may become an impossibility to-morrow.

Power at Niagara Falls

In round figures, the quantity of 10,000 cubic feet per second is capable of producing 300,000 horse power at Niagara Falls. Looking at the situation as it stands to-day, the fact stands out that even if the diverted quantity were available, it could not be used, as the boundary waters treaty limits the United States to the use of 20,000 cubic feet per second, and Canada to 36,000 cubic feet per second for power purposes at Niagara. These quantities are already being utilized, and therefore theoretically, any additional water made available in the Niagara river would have to go over the falls and have no value, except that of maintaining the beauty of the falls.

On the other hand, ignoring treaty and other limitations, there is certainly a direct economic loss to somebody, as the 300,000 horse power obtainable from the diverted water, or at least a large proportion of it, could be immediately developed at Niagara without the installation of any machinery, and without changing the flow over the falls. Incidentally the demand for power is such that it could all be utilized immediately.

The St. Lawrence River

In this case the situation is somewhat different. If the diversion were non-existent, the amount of water now utilized, say 10,000 cubic feet per second, could not be utilized for power development. Unlike Niagara falls the potentialities of the St. Lawrence river for power have been practically untouched, and for this purpose the effect of the diversion can hardly be felt until such time as the power resources of the river are being utilized to an extent approaching the limit of development. That this will not be at any very distant day must be clear to any one who has the most rudimentary knowledge of the power situation centering on the St. Lawrence, and the situation that existed not so very long ago when it appeared as though the loss of possible power output was something that could only occur at a very remote time, is no longer existent.

In the International section of the St. Lawrence there have been numerous different plans suggested for development of power, but regardless of what plan is utilized, provided reasonably full advantage is taken of the total head available, a quantity of water amounting to 10,000 cubic feet per second would produce somewhere in the neighbourhood of 75,000 to 85,000 horse power. Similarly in the purely Canadian section of the St. Lawrence, between lake St. Francis and Montreal, there is a potentiality in the same amount of water amounting to 100,000 horse power or more.

The quantity of water diverted may not amount to a large percentage of the low flow of the St. Lawrence, nevertheless the total economic value of all the power which might be obtained from the diverted water, namely something approaching 500,000 horse power, is so great that it represents the power required by industries who would spend on the average $200,000,000 annually in wages alone.

Conclusion

In conclusion the author wishes to express his appreciation of the courtesies and assistance extended to him by many different people, including in particular the engineers of the Sanitary District of Chicago, without whose hearty assistance the physical description of their undertaking would have been impossible.

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Volume IX May 1926 No. 5

Maritime Professional Meeting

Sydney, N.S., August 17th and 18th, 1926.

A tentative programme has been prepared for the forthcoming Maritime Professional Meeting which will be held under the auspices of the Cape Breton Branch of The Institute at Sydney, N.S., on August 17th and 18th, 1926.

The provisional programme provides for two papers, the first of which will be on the Humber development in Newfoundland, and arrangements are being made for the second paper to deal with the subject of coal. Extensive arrangements are being made for visits to works of interest and for the entertainment of members attending the meeting. In connection with the latter, there will be an informal dinner and dance on the evening of the first day, and the meeting will close with a banquet on the evening of the second day.

Transatlantic Wireless Telephony

Canadians, and particularly Canadian engineers, cannot fail to be interested in an important advance which has recently taken place in the development of telephonic communication across the Atlantic. Experiments in one-way radio telephone transmission from the United States to England have been conducted for some years, and a measure of success was attained in 1915. The tests of 1923* showed a marked improvement in clarity and uniformity of reception, and a further notable achievement has now to be recorded.

On March seventh last, a number of persons in London were able, by the latest development in telephonic communication, to carry on individual conversations with persons in New York, speech being heard with little or no difficulty at both ends.

This date is the fiftieth anniversary of that (March 7th, 1876), on which a United States patent was granted to Dr. Graham Bell, a Scotsman who had emigrated to Canada and afterwards worked in the United States, for his invention covering the electrical transmission of speech by undulating currents.

In Bell's time no one had any idea of the powerful weapon which the invention of the thermionic valve would place in the hands of telephone engineers, nor indeed did anyone dream that wireless telephony would be a possibility, much less that conversation would be carried on over three thousand miles of ocean and six hundred miles of land.

The results now obtained have been made possible by the tireless research of engineers on both sides of the Atlantic, particularly by the work of the technical staff of the Bell Telephone Laboratories and the Radio Corporation in the United States, and of the British Post Office and the International Western Electric Company in Great Britain.

While it is not to be expected that a public telephone service between Great Britain and the United States will be inaugurated at an early date, this marvellous result may possibly follow in due course if the experimental transmissions continue to operate successfully.

The chief difficulties encountered in attempting a regular service of this kind are due to diurnal and seasonal variation in the ratio of signal strength to static noise, and it is understood that commercial success will largely depend on whether these disturbing influences can be satisfactorily dealt with.

During the recent tests the circuits terminated at the London Trunk Exchange of the British Post Office in Queen Victoria Street, and in the Walker Street headquarters of the American Telegraph and Telephone Company in New York. Speech from New York was conveyed by a land line about seventy miles long to the transmitting station of the Radio Corporation at Rocky Point, Long Island, and thence by wireless on a wave length of 5,260 metres to the British receiving station at Wroughton in Wiltshire, some three thousand three hundred miles distant from Rocky Point, thence over an underground line ninety miles to the London Exchange. In the reverse direction speech from London was conveyed to Rugby by an eighty-mile underground line, from Rugby by wireless on a wave length of 5,770 metres to Houlton, Maine, thence by a land line six hundred miles to New York. During the demonstration each person present was permitted to converse for two minutes with another person on the other side of the Atlantic, and the opportunity was naturally taken to interchange congratulations between British and American scientists and engineers.

Many difficulties still remain to be overcome both in connection with the wireless transmission and the land line

*See Journal A.I.E.E., August 1923.

circuits, but the satisfactory results which have now been obtained indicate most favourable prospects for further development.

International Screw Thread Standardization

It is remarkable that in many continental European countries, where the metric system is in use, a very large proportion of the screw threads used in mechanical engineering work are made to inch measurement, and follow the system of screw thread standards originated in England by Sir Joseph Whitworth. Metric threads are in use also in these countries, but principally for the smaller sizes below 6 mm. diameter.

In England the Whitworth system is, of course, universally adopted, except for fine threads, for which one of finer pitch (the "British Standard Fine Thread"), is employed. In the United States the question has been authoritatively dealt with by the National Screw Threads Commission, and the resulting thread system, based on the Sellers form, together with its appropriate tolerances, has been completely defined, is generally accepted in the United States, and is largely used in Canada. With the exception of the half-inch size (which has thirteen threads per inch as against the British twelve), the American series of coarse threads has the same relation of pitch to diameter as the Whitworth, but a slightly different thread profile, with a 60° angle, instead of 55° as in the Whitworth thread. The differences in the two systems, resulting of course in lack of interchangeability, made themselves felt during the war, and there has been a feeling on both sides of the Atlantic that an effort should be made to devise some means of getting over this difficulty, so that for all work, or at all events for all work not requiring the highest class of fit between bolt and nut, a British standard nut should be capable of assembly with an American standard bolt, and vice versâ.

Informal discussions have taken place on several occasions between representatives of the British Engineering Standards Association, the Canadian Engineering Standards Association, and the American Engineering Standards Committee, and the question has recently been receiving attention at the third International Conference of Secretaries of the various national standardizing bodies, which has just been held in New York.

At this conference a suggestion was made by Sir Richard Glazebrook, based on an idea originally put forward from the American side, that a form of thread should be studied which would assemble either with the British or the American thread; such a thread having the necessary clearance at crest and root, a thread angle of $57\frac{1}{2}°$, and tolerances on pitch and pitch-diameter similar to those accepted for the present standard threads.

The practical interchangeability of such a thread with the British and American was demonstrated by a series of accurate gauges prepared at the National Physical Laboratory, and the scheme was considered so promising as to merit careful consideration by all the national standardization organizations represented at the conference. If the details of such a system can be satisfactorily worked out, there would seem to be a reasonable prospect of its adoption by some of the countries where both British and American screwed material is in considerable use, and in this manner the way might be opened for its eventual use in Great Britain and the United States. The movement thus initiated is an encouraging step along the road of international standardization.

OBITUARIES

Louis A. Herdt, M.E.I.C.

News of the death of Louis A. Herdt, D.SC., F.R.S.C., M.E.I.C., has been received with deep regret by members of The Engineering Institute of Canada throughout Canada.

The late Dr. Herdt was an outstanding figure in the electrical engineering branch of the profession, and in addition to being Macdonald professor of electrical engineering at McGill University, he was vice-president of the Montreal Tramways Commission and president of the Electrical Service Commission for the city of Montreal.

Dr. Herdt was born at Trouville, France, on June 14th, 1872, and early in life left his native land to come to Canada. He was educated at the Montreal High School and McGill University, from which he graduated in 1894 after a brilliant course in electrical engineering. In 1902 he took his Master of Engineering degree, and in 1910, the degree of Doctor of Science. He held the degree of Electrical Engineering from the Montefiore Electrotechnical Institute of Lièze, Belgium, and was also a graduate of the Laboratoire Central d'Electricité, Paris. On his return to Canada, he joined the staff of McGill University in 1896, being successively demonstrator in electrical engineering, lecturer, assistant professor, associate professor, and finally head of the department.

Among other engineering works, Dr. Herdt had been consulting engineer on the following:—hydro-electric plant, Joliette, Que; hydro-electric plant, Rimouski, Que.; hydro-electric plant, Lachine canal; steam electric plant, Witness Printing Company, Montreal; hydro-electric development, city of Winnipeg, Man.; hydro-electric plant, A. C. Edwards Company, Ottawa; street railway system, Winnipeg Electric Railway Company.

In 1905 Dr. Herdt was appointed Officier de l'Académie de France and Chevalier de la Légion d'Honneur in 1923. He was also a Fellow of the American Institute of Electrical Engineers, and was elected Associate Member of The Engineering Institute of Canada (then the Canadian Society of Civil Engineers), on January 5th, 1899, and was transferred to Member on November 13th, 1909. During the year 1906, and from 1909 to 1912 inclusive, Dr. Herdt served on the council of the Institute.

Andrew C. Loudon, A.M.E.I.C.

It is with regret that we record the death of Andrew C. Loudon, A.M.E.I.C., vice-president of the Superheater Company Limited, which occurred in Montreal on April 11th, 1926.

The late Mr. Loudon had been operating executive in charge of all branches of the company's activities since 1919. He was born at Valleyfield, Que., on July 7th, 1883, and was a graduate of McGill University, from which he received the degree of B.Sc. in 1906.

With the exception of one summer during which he was engaged on survey work, Mr. Loudon, prior to graduation, was associated with the Grand Trunk Railway as special apprentice. After completing his course at McGill University, he was draughtsman with the American Locomotive Company for two years. Subsequently he accepted the position of locomotive foreman with the Grand Trunk Railway during the latter part of 1907 and 1908. In 1909 he was with the Delaware and Hudson Company as draughtsman for a short period, later joining the staff of the A.F. & S.F. Railway. In 1910 he was appointed general foreman with the Grand Trunk Railway at Winnipeg, Man., which position he occupied until 1912, when for four years he was editor of the mechanical department of Railway Age.

In 1916 he joined the Locomotive Superheater Company and was acting assistant chief engineer, executive assistant and Canadian manager, and, subsequently in 1919, he was appointed to the position which he occupied at the time of his death.

Mr. Loudon was admitted to The Institute as Associate Member on July 22nd, 1919.

Leroy Thorne Bowes, A.M.E.I.C.

A promising career came to a sad termination on Monday March 15th, when Leroy Thorne Bowes, A.M.E.I.C., of the Hydrographic Survey, Ottawa, passed quietly away at the Ottawa Civic Hospital. The late Mr. Bowes had been in poor health since last July, following a painful accident on one of the St. Lawrence Ship Channel vessels below Quebec. From that date he had fought a courageous downhill struggle and throughout the many dreary months of his illness the fortitude and cheerfulness exhibited by him had won for him the sympathetic wonder and admiration of his large circle of friends and colleagues in The Engineering Institute of Canada, Professional Institute, and the Civil Service at large.

A native of New Brunswick, born in Sackville in 1890; a graduate in Science and Arts of Acadia University in 1912, he came into the Civil Service at Ottawa the following year, joining the staff of the Canadian Hydrographic Survey, immediately following which he spent four adventurous years in James Bay waters, on the chartering of sections of the northern sea routes. He was also engaged in similar service on the Great Lakes and St. Lawrence river and gulf, and in 1921 was a member of the hydrographic staff sent to Hamilton Inlet on the Labrador coast, to procure evidence for the Department of Justice in connection with international boundary disputes.

The late Mr. Bowes had always a fondness for literature, coming as he did from a Maritime family prominent in journalism, and was beginning to make an enviable name for himself as a writer of poetry and prose.

The large representative gathering of Institute members and friends in attendance at his funeral on Wednesday, March 17th, bore evidence of the esteem in which the late Mr. Bowes was held.

PERSONALS

Frank Folemsbee, Jr., S.E.I.C., is on the staff of the division of sewers of the City of Miami, Florida.

Harry Jardine, S.E.I.C., has been appointed district engineer with the Department of Public Highways, Ontario, covering provincial and county highways of Brant, Wentworth, Oxford and Wellington.

Joseph Hardouin, A.M.E.I.C.,who has for a number of years been in charge of survey parties for the Topographical Surveys Branch, has been transferred to the Natural Resources Intelligence Service of the Department of the Interior, Ottawa, Ont.

T. W. Creighton, S.E.I.C., who is on the engineering staff of the Canadian Pacific Railway Company, has been transferred from Lethbridge, Alta., to the divisional engineer's office at Kenora, Ont. Mr. Creighton graduated from the Royal Military College, Kingston, in 1921.

S. J. Davies, A.M.E.I.C., who recently resigned from the position of petroleum engineer with the Dominion government for Alberta, has entered private practice in Calgary as consulting engineer on oil and gas projects, and has been retained by the government of Alberta in a consulting capacity.

B. H. Segre, A.M.E.I.C., has been transferred from the Topographical Surveys Branch to the Natural Resources Intelligence Service of the Department of the Interior, Ottawa, Ont. Mr. Segre has been engaged on Dominion land surveys since 1907. He is a graduate of the University of Toronto of the class of 1913, and is also a Dominion Land Surveyor.

Miss H. M. White, Jr.E.I.C., formerly assistant plant engineer, Department of Telephones, Saskatchewan Government, has accepted a position on the engineering staff of the Northern Electric Company in Montreal. Miss White is a graduate of Dalhousie University, from which she received the degree of B.A. in 1921, after which she completed the engineering course at the same university.

W. H. Norrish, A.M.E.I.C., has been transferred from the Topographical Surveys Branch to the Natural Resources Intelligence Service of the Department of the Interior at Ottawa. Mr. Norrish has been connected with the Topographical Surveys Branch engaged in land survey work in western Canada for a number of years. He is a graduate of Queen's University and is also a Dominion, Ontario, and Alberta Land Surveyor.

W. Hamilton Munro, M.E.I.C., S.P.S., '04, has been appointed manager of the Nova Scotia Tramways and Power Company, Limited. Mr. Munro resigned as sales manager of Canadian Vickers Limited, Montreal, in order to go to Halifax, and reports having encountered a spirit of enthusiasm, good fellowship and business earnestness there which gives him much satisfaction in having chosen Halifax as a home.

H. R. Burton, S.E.I.C., has been appointed town assessor and town engineer of Fort Erie, Ont. Mr. Burton graduated from the University of Toronto, receiving his degree of B.A.Sc. in civil engineering in 1921, and since graduating has been with the Canadian Inspection Company, the city architect's department, Toronto, and the Canada Creosoting Company. Mr. Burton served for three years overseas with the Divisional Signal Corps.

Donald G. Robertson, Jr.E.I.C., is located at East Templeton, Que., on the construction of the new paper mill for the International Paper Company. Mr. Robertson graduated from Queen's University in 1924 in civil engineering and was for a short time in the Southern Canada Power Company on the construction of their power development at Hemming's Falls, Drummondville, Que., and has recently been with the Riordon Pulp and Paper Corporation at Temiskaming, Que.

H. M. Jaquays, M.E.I.C., manager of eastern plants of the Steel Company of Canada Limited, with headquarters at Montreal, has been elected to fill the vacancy on the board of directors of the company caused by the death of the late Robert Hobson, M.E.I.C. Mr. Jaquays was born at Frelighsburg, Que., on November 10th, 1870, and received his degree of B.Sc. from McGill University in 1896. He was engaged for several years on engineering work in England and the United States, and returned to Canada in 1901 to join the staff at McGill University, where he was lecturer and assistant professor in mechanical engineering. In 1906 he became chief engineer of Montreal Rolling Mills Company.

A. E. Berry, A.M.E.I.C., has been appointed acting sanitary engineer in the Ontario Department of Health, succeeding F. A. Dallyn, M.E.I.C. Mr. Berry had been assistant sanitary engineer with the department since September 1919. He was born in St. Marys, Ontario, in

1894, and after matriculating from St. Marys' Collegiate Institute he attended the Faculty of Applied Science, University of Toronto, graduating in civil engineering with honours in 1917, and four years later, in 1921, he received his degree of M.A.Sc., and in 1923 he was awarded his degree of C.E. in the University of Toronto for a thesis on "The Collection and Disposal of Municipal Refuse." Following graduation, Mr. Berry was employed with the Ontario Department of Health for a short period after which he went overseas and served with the Royal Engineers. On his return to Canada, he joined the engineering staff of the Department of Health and later became assistant sanitary engineer.

ELECTIONS AND TRANSFERS

At the meeting of Council held on April 27th, 1926, the following elections and transfers were effected:—

Members

BOLTON, Launcelot Lawrence, M.A., B.Sc., (Queen's Univ.) Asst. Deputy Minister, Dept. of Mines, Ottawa, Ont.

JONES, Charles Hugh LePailleur, Lake Superior Paper Co., Spanish River Pulp & Paper Mills Ltd., Fort William Paper Co., Ltd., Manitoba Pulp & Paper Co. Ltd., and Kaministiquia Power Co., Sault Ste. Marie, Ont.

Associate Members

ATTFIELD, Arthur Evans, examiner of topography, Dept. of National Defence, Ottawa, Ont.

CAMERON, Edward Parke, B.Sc., (McGill Univ.), Forest Products Labs. of Can., Montreal, Que.

CUTTLE, William Gordon, B.Sc., (McGill Univ.), steam plant supt., Laurentide Co. Ltd., Grand 'Mere, Que.

DUFFY, Rob Roy, B.Sc. in Arts, (Arcadia Univ.), B.Sc., (McGill Univ.), asst. land surveyor, Price Bros., Chicoutimi, Que.

FORTIER, Henri, engr., technical service of City of Montreal, Que.

HERBISON, Robert Milliken, mech'l. designer and field engr., Dom. Bridge Co. Ltd., Lachine, Que.

KENNEDY, Duncan, res. engr. on substructure of Montreal-South Shore Bridge for Monsarrat & Pratley, Montreal, Que.

MONTIZAMBERT, Harry Bell, res. engr., Highways Br., Dept. of Public Works, Strathmore, Alta.

PEARSON, Vernon, mech'l. supt. of Provincial Gov't. of Alta., Edmonton, Alta.

REID, James William, B.Sc., (McGill Univ.), Board of Railway Commissioners, Calgary, Alta.

ROSS, Alexander Daniel, M.Sc., (Mass. Inst. of Tech.), asst. elec'l. engr., Wayagamack News Limited, Three Rivers, Que.

THOMAS, Arthur, with topog'l. surveys, Dept. of Nat'l. Defence, Ottawa, Ont.

Juniors

HYMAN, Howard Davison, B.Sc., (McGill Univ.), Mattagami Pulp & Paper Co., Ltd., Smooth Rock Falls, Ont.

McKILLOP, Vernon Archibald, B.A.Sc., (Univ. of Toronto), asst. elec'l. engr., Public Utilities Comm., London, Ont.

McQUEEN, Neil, geologist, Imperial Oil, Ltd., Toronto, Ont.

SMITH, Robert Macfie, B.A., B.Sc., (McGill Univ.), Shawinigan Water & Power Co., Montreal, Que.

Affiliate

O'BRIEN, John Ambrose, managing director, M. J. O'Brien Ltd., Ottawa, Ont.

Transferred from class of Associate Member to that of Member

HARRIS, Richard C., divn. engr., Calgary Division, C.P.R., Calgary, Alta.

TRAILL, John James, B.A.Sc., C.E., (Univ. of Toronto), engr. of tests, hydraulic dept., Hydro-electric Power Comm. of Ont., Toronto, Ont.

Transferred from class of Junior to that of Associate Member

CROMBIE, Hugh Arthur, B.Sc., (McGill Univ.), i/c estimating dept., Dom. Engineering Works, Ltd., Montreal, Que.

DUSTAN, Ernest Bruce, B.A.Sc., (Univ. of Toronto), designing dftsman. with Hydro-electric Power Comm. of Ont., Toronto, Ont.

EADIE, Robert Scott, B.Sc., and M.Sc., (McGill Univ.), with Dominion Bridge Co., Lachine, Que.

FULTZ, Stephen Lloyd, B.Sc., (N.S.Tech. Coll.), with N.S. Power Comm., Halifax, N.S.

HAMER, Thurston Moseley, B.Sc., (McGill Univ.), western railroad engrg. representative, Air Reduction Sales Co., Chicago, Ill.

McKINNEY, James Harold, junior engr., Dept. of Public Works, St. John, N.B.

NORRIS, Charles Adam, B.A.Sc., (Univ. of Toronto), constrn. engr., Bremner Norris & Co., Montreal, Que.

- Report of the Proceedings of the first international management congress in Prague.

Abstracts of Papers read before the Branches

Chicago Drainage Canal Diversion

Francis King, K.C., General Counsel, Dominion Marine Association, Kingston Branch, February 8th, 1926.

Mr. King gave first a rapid sketch of the legislation touching the question. The history of the subject is now more than a century old, there being legislation by the United States federal government as far back as 1822 and a further act in 1827 to subsidize a canal at Chicago. The Supreme Court of the United States has now removed these two original statutes from the discussion. The Sanitary District of Chicago was chartered by the Illinois legislature in 1889 and proceeded to reverse the flow of the Chicago and Calumet rivers, to build subsidiary channels and to dispose of its sewage by diluting and flushing it into the Des Plaines, the Illinois and the Mississippi rivers at the expense of the water lost to the commerce of the Great Lakes and the comfort and health of the riparian owners on the rivers mentioned. In 1899 the Federal Statute, under which successive secretaries of war have "permitted" diversion of certain limited amounts of water, was enacted. It was designed to assert and exercise the control over commerce and navigation, which lies with Congress. The permit of 1912 maintained the limit at 4,167 cubic feet per second against a strong plea for more, and at that time Canada and the Dominion Marine Association were both prominent in the fight at Washington to prevent excessive withdrawal of water from lake Michigan. Then came the action in the Federal Court in Illinois to restrain the Sanitary District from exceeding the amount of this permit. Trial was delayed, Judge Landis (of Chicago) held the case six years before giving judgment in 1920, and then for three years more before resigning. The judgment was promptly signed by his successor, enjoining the district from exceeding the permit. On the appeal to the Supreme Court came the famous judgment confirming the injunction, declaring that navigation on the lakes was injuriously affected, and that Canada had rights which should be respected (at least by the treaty of 1910), and that Congress was supreme and could protect the Great Lakes. The judgment mentioned the right of the district to apply for a better "permit." Of course the application was made. It was strongly contested, although the Dominion government made no such visible or emphatic demonstration of its wishes as was hoped for, and the result was the present permit of 8,500 cubic feet per second, good for five years, with conditions, including stipulations for the gradual building of sewerage disposal plants and the ultimate reduction of the quantity of water withdrawn to 4,167 cubic feet per second. Beaten on the sanitation plea, the district now tried to enlist the states in the Mississippi valley in support of bills legalizing 10,000 cubic feet per second, on the ground that this is necessary for navigation down to the gulf of Mexico—not to the gulf of St. Lawrence—an argument obviously having only one real motive, and just as obviously fallacious in view of the admitted fact that 1,000 cubic feet per second is enough for navigation and that the extra amount has already developed currents in Chicago's harbour which have ruined her lake trade. Finally reference was made to the action now pending in the Supreme Court in Washington brought by states bordering on the lakes to assert their rights in these waters against Chicago and the state of Illinois.

Mr. King stated that the Chicago drainage canal diversion had lowered the level of the Great Lakes at least six inches and the effect of this, in decreased carrying capacity of the lake fleet, was estimated in argument in the Supreme Court of the United States at figures as high as $3,000,000. or $4,000,000. a year. To this must be added the immense loss, almost incalculable, to harbours, docks, wharves, canals, buildings and other works, and in fact to all riparian rights. The calculation as to the ships could be checked on the basis of the known loss in carrying capacity of at least 50 to 100 tons per ship per inch of draft, or 300 to 600 tons per ship for six inches lost. In 1912 one graphic illustration was that this lost draft meant the complete capacity of the whole Canadian fleet on one trip—one full trip lost from the season.

The Dominion Marine Association insisted that no action should be taken by Canada which would commit the Dominion in any way to participation in the big St. Lawrence development scheme, until the leak at Chicago was satisfactorily controlled. It was true that power needs in eastern Ontario demanded some initial development at Morrisburg, and that Ontario had offered to stand the cost including works to take care of navigation. But Canadian vessel owners protested against this except as an integral part of a complete scheme for the whole river, and objections to that at present seemed almost insuperable. The expense alone "must give us pause." Incidentally the Dominion Marine Association was not asking for the deep waterway as was commonly supposed. Pressure behind that scheme came from a rather motley crowd of interests with arguments containing much more theory than fact. The one solid basis for the scheme was the possible elimination of a multiplicity of dangerous currents and the centralization of power plants at a certain few points, with the river conserved primarily for navigation and incidentally for power. At the present the canals are frequently sources of power at the expense of the safety of navigation.

Mr. King referred to the unfortunate fact that very few had any idea just what the Canadian government had been doing to assert its rights; rights which exist not only under the treaty of 1910 (see particularly section three referred to by the Supreme Court of the United States), but also stand firmly on the principles recognized by the law of nations and founded on abstract justice; rights which would be similarly violated if the waters of the Danube were robbed to benefit the trade of the Rhine valley, or the Rhine sources were diverted to the Black sea. The Minister of the Interior made a statement in the House of Commons on the twenty-fifth of January on the "lucus a non lucendo" principle. Canada had protested but the nature of the protests were apparently still under the seal of diplomatic secrecy. One could wish for some strong pronouncement just at present which might remind a friendly neighbour now engaged in legislation that the bills before Congress, to legalize a diversion of 10,000 cubic feet per second, propose to deal with something in which the United States of America have not more than a half interest, west of lake St. Francis, and none below, except a right of passage for its ships under the Ashburton Treaty.

The Economic and Engineering Situation in Canada

Brig.-Gen. C. H. Mitchell, C.B., C.M.G., C.E., M.E.I.C., Dean of the Faculty of Applied Science, University of Toronto, Toronto, Ont. Toronto Branch, February 18th, 1926.

If one were drawing a curve of the progress for Canadian development since the War it would take an uncertain form, advancing and receding, sometimes sharply, sometimes slowly, but it would move continuously upward.

Gen. Mitchell said that we were still in a transitional stage, but indications were not wanting that we had passed most of these difficult places in our progress, and that conditions were again set for a pronounced rise in our curve of progress. We saw definite indications on all sides that such was the case, even if we went cautiously, and appraised with moderation. No one sign might mean very much, but all, taken in conjunction, made a significant and favourable accumulation.

Some of these outstanding conditions, the speaker said, were:—

(1) World conditions—The Locarno treaty.
(2) The stabilizing of the world's financial markets, and particularly the return of sterling to parity, reflected in our own Canadian exchange.
(3) The great growth in Canadian foreign trade, and the excess of Canadian exports over imports.
(4) The steadying effect of the huge Canadian grain crop of 1925 on our whole economic position.
(5) The steady growth in gross revenue from all the industries of Canada which, in millions, worked out at 46 in 1922, 49 in 1923, 53 in 1924 and 56 in 1925, Ontario's industries representing a steady ratio of 44 per cent. This meant that the purchasing power of the country was increasing.
(6) The steady increase in savings deposits in the banks—although not in proportion to (5) owing to the extravagances of the times.
(7) The ratio of bank deposits to current loans. Deposits were still largely in excess of loans, but expanding business was calling them into use.

The engineering situation in Canada, said the speaker, was a reflex of the economic situation, and the work of the engineering profession was more sensitive to the economic condition of the country than any other. The growing complexity surrounding the development of Canada's resources and industries was more and more involved with the science of the engineer, and the inevitable era of prosperity would go hand in hand with an increase in engineering activity. Much of the expenditure of the next ten years would be on construction, and in firmly establishing channels of trade and commerce, and the burden of wise technical decision and careful economic administration would fall on the engineering profession.

A résumé was given of engineering activity, and of coming engineering developments from coast to coast, stressing the fact that the construction of highways, elevators, etc., necessary to convey and house the grain, and other products of agriculture; the redemption of the earth's treasures by mining; the problem of transportation by rail, by road, by canal; the varied requirements of municipal life; the great water power developments, and harbour developments; the advances of industrial chemistry, (to mention but a few, in the paper, rubber, paint and aluminum industries), were all factors weaving the engineer's handiwork into the economic life of the nation.

Artificial Silk

A. D. Hone, Principal of the Technical School, Sault Ste. Marie, Sault Ste. Marie Branch, March 5th, 1926.

The basis of all processes is cellulose $(C_6H_{10}O_5)n$. This is a complex material, about the constitution and properties of which there is still a great deal to be learned. The two main varieties found in nature are cotton, which is practically pure cellulose, and wood fibre. Ordinary wood is not pure cellulose as lignin is present in it and holds the fibres together. In the process of making chemical pulp, the lignin is dissolved by the calcium sulphite used, and the resultant pulp is practically pure cellulose and may be used for making silk. The ground or mechanical pulp is not suitable.

The first attempt to make a substitute for silk was made by John Mercer, who took out a patent in 1850 which covered the transformation of cotton into a silk-like fabric. The reason why cotton has not a bright lustre is because the fibres consist of a flat twisted tube. In order to be lustrous, a fibre must be smooth and straight. Mercer's process consisted in treating the cotton with a strong caustic solution; this has a tendency to thicken and shorten the fibre, but if the fibre is kept stretched it is straightened and rendered more cylindrical and thus is given a lustre. Cotton so treated is called "Mercerised Cotton."

The first process for making artificial silk used as a base nitrocellulose. This is made by treating ordinary cotton with a mixture of equal parts of nitric and sulphuric acid. Nitro-cellulose is soluble in a mixture of alcohol and ether. The resultant solution is known as Collodion. The Collodion is forced into water at high pressure, the nitro-cellulose is precipitated through a fine opening as a smooth cylindrical thread possessing a high lustre. This thread is wound on a spindle and denitrated with ammonium sulphide, whereupon the cellulose is recovered. The silk so formed is known as "Collodion Silk" or "Chardonnet Silk."

Another variety of artificial silk is known as "Cupro-ammonium" or "Paulp Silk." It is also made from cotton by treating with a solution of copper hydroxide in ammonia and dissolves cellulose without change. In making silk, the resultant solution is forced through fine openings into an acid coagulating bath. This process is still in use, particularly in Italy and Germany.

A third variety is known as "Cellulose Acetate Silk" or "Celanese Silk." The process of making this is rather complex and involves the use of a rather expensive reagent, acetate anhydride. In this process pure cellulose is treated with this reagent, sulphuric acid, which acts as a condensing agent, and acetic acid. A solution of cellulose acetate is thus obtained which is precipitated by pouring into water. The cellulose acetate thus obtained is soluble in acetone, and the resultant solution is used for dressing aeroplane wings. When the acetone evaporates, it leaves the cellulose acetate as a thin transparent film which is both water- and fire-proof. A film like this may be used in moving-picture machines and has the advantage over a cellulose film of being non-inflammable. If this solution is forced through a fine opening into a coagulating bath, for example calcium chloride, the cellulose acetate is recovered as a fine lustrous filament. This process is carried on extensively in England. Its disadvantages are that the chief reagent is expensive and the process is long and complicated. A difficulty, which has since been overcome by the discovery of special dyes, was that it is also difficult to dye.

The chief variety of artificial silk is known as "Viscose Silk." This is cheapest in manufacture and is gradually displacing the other varieties. It is made by treating ordinary chemical pulp with caustic soda, forming alkali cellulose and dissolving this product in carbon bisulphide. The resultant substance is called cellulose sodium zanthate and is a compound of cellulose containing sodium and sulphur, the composition of which varies with the quantities of reagents used. Formula—$Na_2CS_2OC_6H_9O_4$. The commercial process is described as follows:

The cellulose base for this process is provided by wood pulp. The logs, after being stripped free from bark, are cut into very small chips, which are boiled for some considerable time under pressure in a solution of calcium sulphite. The fibres after such digestion are washed, bleached and subsequently made into sheets by passing first over an endless band of fine metal gauze and then over a number of steam-heated drums.

The first stage of the process consists of soaking the pulp in a solution of caustic soda until saturated. The excess of soda is removed by pressure and the soft wet sheets of alkali cellulose thus obtained are ground into a floury mass in a milling machine. This floury mass is matured by standing and then treated with carbon bisulphide to form an orange-coloured, somewhat sticky mass known as cellulose sodium zanthate, which is easily soluble in weak caustic soda to form a viscous solution known as viscose, from which filaments of cellulose are regenerated by the decomposing action of an acid.

The viscose, after being freed from small bubbles of air, dirt and other foreign matter, is forced through a metallic nozzle containing very small holes, into an acid spinning bath where the precipitation of cellulose in the form of continuous filaments takes place. These filaments forming one thread, are taken from the spinning bath over a glass roller, through a vertical reciprocating tube, into a circular box, rotating upon a vertical spindle. Centrifugal force throws the thread to the side of the box, where it builds up into an annular cake, the twist being imparted to the thread by the revolution of the box at several thousand turns per minute.

The cake from the spinning room is now reeled into skeins, in which form the silk is freed from acid, sulphur and other impurities.

The artificial silk obtained by this process has a tensile strength much smaller than that of true silk; this is especially true when it is wet.

Kind of Silk	Dry Tenacity grammes	Wet Tenacity grammes	Elongation per cent.
Viscose	1.75	.75	20.0
Natural	2.5	2.0	21.0

If the thread is placed under tension and it is touched with a drop of water, it will break almost immediately at the point where it is moistened. Great care, therefore, has to be exercised in washing articles made from it. This is one reason why it is used so extensively mixed with wool and cotton. It is much more lustrous than real silk from which it may be distinguished by treating with forty per cent hydro-chloric acid. This reagent dissolves the real silk in two or three minutes but merely renders the artificial silk a gelatinous mass. At first it was used only for such articles as braid and neckties and was not considered washable; now it is being used for stockings, socks, scarves, underwear—in short every article that may be manufactured from pure silk, and is rapidly displacing the latter. Its use has increased tremendously in the last few years and new factories for its manufacture are being built all over the world. Production 1910, 17 million pounds; 1912, 20 million pounds; 1924, over 100 million pounds. They can hardly be constructed fast enough to keep up with the demand, for example, the December issue of the Society of Chemical Industry states that works are being put up in England, in Lancashire, Bristol, London, Warrington, Olden, Kent, and that at other centres modifications are taking place on an extensive plan suitable for this purpose. At Bristol the plant will produce 27,000 pounds per week. The plant at London will have an output of 22,400 pounds per week, and the Kent mills are being designed to ultimately give a production of 100,000 pounds per week.

In Canada a plant has been recently established at Cornwall, This company is known as Courtauld's Limited, and I am greatly indebted to them for the samples on display and also considerable of the information contained in this paper. The daily papers recently contained an announcement that a large factory is to be erected at New Westminster by a syndicate headed by the Whalen interests which will make use of British Columbia pulp. It appears to me that Sault Ste Marie is ideally situated between the east and west for an industry of this kind. The raw material is easily accessible and there is an excellent supply of power for the purpose.

The address was illustrated by samples and experiments by which small fibres of artificial silk were produced.

A lively discussion followed Mr. Hone's paper, many interesting points being brought out. Mr. Kloss in reply to a question from W. S. Wilson, A.M.E.I.C., stated that in 1920 the production of artificial silk amounted to 45,000,000 pounds, but that in 1925 it amounted to 175,000,000 pounds and also 1,600 tons of artificial horse hair had been produced. The decrease in horse hair in this country is due to the increase of the automobile.

A. E. Pickering, M.E.I.C., and Wm. Seymour, M.E.I.C., moved a hearty vote of thanks to Mr. Hone for his very interesting paper.

Industrial Development in Saskatchewan

R. N. Blackburn, M.E.I.C.,

Chief Mechanical Superintendent, Department of Public Works, Province of Saskatchewan.

Address of retiring Chairman read before the Saskatchewan Branch of the Engineering Institute of Canada, March 11th, 1926.

Up to the present time the development of our province has been principally in the direction of agriculture and its progress in that respect has been most remarkable. Last year the province produced more wheat than all the rest of Canada put together, namely a little over 240,000,000 bushels out of a total wheat crop, for the whole of Canada, of about 416,000,000 bushels. Unfortunately, wheat growing appears to partake largely of the nature of a gamble with nature and there is always considerable risk of a crop failure. Also while wheat growing at the present price of wheat, namely about $1.30 per bushel at Fort William, may be fairly profitable in a good year, present prices will probably not be maintained permanently, and our province will always be seriously handicapped by the high freight rates to seaboard, which, if the price of wheat is much reduced, may render wheat growing unprofitable.

Accordingly we find that our agricultural experts are advising farmers to go in for mixed farming, which means principally the raising of sufficient stock to consume a large portion of the products grown on the farm. But while there is a steady development in this direction in the province, it is doubtful if the development is keeping pace with the rapid increase in wheat production. Mixed farming would no doubt be more profitable and would make more rapid progress if we had a larger industrial population in the province.

While it is natural that agriculture should be the first industry to be developed, it would seem that the development of other industries ought not to lag too far behind. At the present time the development of our province seems somewhat lop-sided. We have a very large demand for farm help at certain seasons, at harvest time there is a great influx of labourers, but immediately the threshing is over there is no other work for them to do, and they have to leave the province. In the winter the surplus rural population flocks to the towns, where there is only work for a very small proportion of them; the rest often leave the country permanently. These conditions might be remedied, or at any rate the situation might be greatly relieved, if our other industries were further developed.

Now manufacturing industries cannot be established in a day. Even where the raw materials of an industry are right at hand, development is often slow; practically all that can be done by a government is to try to make conditions favourable to the development of industry and then allow the industries to develop naturally. The northern part of our province is rich in minerals, but these minerals are too far from a market to be worked profitably at the present time, and it may be some considerable time before they are developed to any great extent. In the southern part of the province there are immense clay and coal deposits which are as yet only slightly developed. In the centre portion of the province, the industries most likely to be established will be those depending largely on agriculture for their raw materials, such as the manufacture of leather goods, sugar, paper made from flax and wheat straw, building felt and so on, together with those industries in which the freight on the raw material is not a very large item in the total cost of manufacture.

The Importance of Cheap Power

While cheap power for industries is very desirable, its importance is often exaggerated in the mind of the public. In some industries such as the electro-chemical industries, cheap power is of *supreme* importance, since power is the principal item in the cost of manufacture. In the manufacture of aluminium for example, the writer understands that it requires about 25,000 k.w. hrs., or nearly 5 horsepower years, to make one ton of aluminium, but leaving out of the question industries of this type, the importance of very cheap power is not so great as many people seem to think.

The following table gives the average cost of labour, raw materials, fuel and power in a number of industries, in percentages of the total manufacturing cost:—

	Wages, Taxes, etc.	Raw Materials	Fuel and Power
Average of all manufacturing industries	20.4%	77.5%	2.1%
Iron and Steel Industries	19.6%	86.2%	1.4%
Food Products	12.4%	63.1%	1.4%
Textiles	35.5%	62.6%	5.4%
Paper	32.0%	77.5%	2.1%

The above table does not include the electric light and power industry. This is rapidly becoming one of the most important industries, not only because artificial light is essential to modern civilization, but also because the demand for industrial power is not sufficiently great in the smaller industrial concerns to justify the installation of the most modern equipment and the most skilled attendance. The actual cost of the power used in such cases may be many times greater than the cost at which the same power could be supplied from a large central power plant.

Accordingly we find that much attention is being given in many countries to extensive schemes of power generation and distribution. In England, a national board of experts is about to be appointed with wide powers to construct large central power stations at the coal mines and to distribute the power to the villages and towns throughout the country. The government proposes to appropriate $75,000,000. for the preliminary costs of organization and standardization, and the board will have power to borrow all the monies required for the actual construction. In the United States plans for the installation and development of new power generating stations and the interconnection of existing power systems are being developed to such an extent that President Franklin T. Griffith, at the 48th Annual Convention of the National Electric Light Association held in San Francisco last June, stated that: "$2,000. a minute must be raised in the next ten years to finance the electric light and power industry of the United States." The capital invested in the United States in the electric industry exceeds seven billion dollars and is being augmented at the rate of over one billion dollars per year. In Canada the total capacity of the plant installed in hydro-electric and fuel power stations at the beginning of 1925 was 3,569,275 h.p., of which about 94 per cent was hydro-electric power, and an additional 719,000 h.p. was installed during the year. The capital invested in water power in January, 1924, in Canada was $687,000,000.

Saskatchewan's Power Resources

In this province we have comparatively little water power available; the amount of continuous water power available at minimum ordinary flow being estimated at 513,480 h.p. as compared with over three million horsepower available in Manitoba, about five million horsepower in Ontario and nearly seven million horsepower available in Quebec.

The water power available in Saskatchewan is situated in the northern part of the province, a long distance from any centre of population and is not likely to be developed for some time. We are thus limited for any extensive power scheme to our coal resources, and there is little doubt that we shall eventually see large power generating stations situated in our coal fields and the power distributed to, at least, the southern, and probably also the central portions of the province.

It does not follow that because we have so little water power available in Saskatchewan that power will necessarily be costly in this province. In the Regina municipal power plant, the average cost per kilowatt hour generated at the switchboard in 1924 with coal costing on an average $8.37 per ton, was only 1.97 cents per kilowatt hour including fuel, labour, maintenance and overhead charges. Under similar conditions a plant stationed at the mine, using Saskatchewan coal at $2.00 per ton, could generate power at less than 1½ cents per kilowatt hour. With an improved load factor, and especially if small coal which would be otherwise unsaleable were used for power production, or if the power were generated as a by-product of a coal distillation or carbonization process, the cost of power would be very considerably reduced.

Under such conditions power could be generated at the mine at a cost which would compare not at all unfavourably with hydro-electric power.

By way of comparison the present scheduled light and power rates are given for hydro-electric power in Toronto and Winnipeg and for steam generated power in Regina.

	Cost in cents per kilowatt hour.		
	Toronto cents	Winnipeg cents	Regina cents
Domestic light	2.1	3⅓	4 to 6
Commercial light	4 (av'ge)	....	....
Power	1.38	3⅓ to 0.8	5 to 2½
Power (off peak)	....	....	3½ to 1¾

The above rates are subject to discounts, varying with the amount of power consumed.

The cost of power transmission depends not only upon the distance the power is transmitted, but also varies considerably with the quantity of power to be transmitted. The total electrical output of the Regina municipal power plant in 1925 was 21,373,905 k.w.hrs., and the cost of transmitting this amount of power from, (say), Estevan or Bienfait to Regina would probably be greater than the cost of the freight on the coal required to generate the power at the present Regina plant. Under present conditions, with a single transmission line, it would also be necessary to maintain the present municipal plant as a stand-by for use in case of a breakdown of the transmission line and a transmission scheme for power generated at the mines would naturally have to bear the overhead charges of the standby plant. This would appear to put such a scheme entirely out of the question at the present time. The cost of transmission per kilowatt hour would be reduced, however, if the total power to be transmitted were sufficiently increased. There is, however, a definite limit to which power generated at the mine mouth can be economically transmitted *even in large quantities*, and this limit under present conditions would probably average about 200 miles. For distances greater than this, it will in most cases be found more economical to ship the coal by railway and generate the power locally.

This situation might be considerably changed and the distance to which electrical power can be economically transmitted considerably increased, if sufficient power could be disposed of to the towns and villages along the line of route; or alternatively, if the transmission line forms part of the network of a large distribution system.

A good deal of progress has been made in the United States and to some extent in Ontario in the development of rural power lines. The power requirements of the average farm are not very large and consequently the power distribution lines must be of the cheapest possible construction in order to keep the cost of power sufficiently low to be attractive. In many cases a lead-covered cable is simply laid in a trench ploughed along the road allowances and it has been found that in many cases an average of three farm consumers to the mile is sufficient to make a rural power distribution scheme economically possible. The number of farmer consumers in this province, however, would probably not average even this, but it might be found commercially practicable, in some districts at least, to transmit power generated at central stations to the villages along the lines of railway. The installation of automatic sub-stations would still further reduce the cost of operation. While it is of course very desirable that any power scheme adopted should be self-supporting, the contingent advantages of cheap power and light to our smaller towns and villages should not be entirely overlooked.

Utilization of Saskatchewan Coal

There are also other advantages in connection with the generation and distribution of power from central stations situated at the mine mouth, one of the most important of which is the development of our own coal deposits. As you all know we have millions of tons of coal deposits in the southern part of our province. Unfortunately, the coal is of lower grade than the Alberta and British Columbia coals with which it has to compete, and the development of our mining industry has accordingly been comparatively slow.

A good deal of investigation work in connection with the carbonization of Saskatchewan coal and the briquetting of the carbonized residue has already been done by the provincial and federal governments, but the results so far obtained have not been as promising from a commercial point of view as could have been desired. According to the report of the Lignite Utilization Board, the production cost of lignite char briquettes would average from $9.50 to $10.50 per ton at the plant, and at this price there would not appear to be a large market for them in competition with western coals. This production cost could no doubt be reduced if a carbonizing and briquetting plant were operated by a mining company, which could not only use coal for carbonizing and briquetting which is at present unsaleable, but which might gain such other contingent advantages in operating a briquetting plant in conjunction with their mine, as would put the industry on a more profitable basis. But even allowing for this, the prospects for a *briquetting plant only*, do not appear sufficiently attractive to promise a very great immediate development of the lignite coal mining industry.

It is important to remember, however, that since the investigations were first undertaken, the fuel situation has considerably altered, with the result of entirely changing the problem to be solved. The investigations referred to, were undertaken with the object of providing a substitute for anthracite coal, which was then the fuel in general use for domestic heating, and the price of which was continually advancing while the available supply was a diminishing quantity. Owing to the continually increasing cost of anthracite coal, our people have been practically compelled to use soft coal for domestic heating. They have now become accustomed to the use of soft coal and there would probably be very little demand now for anthracite coal, even if the price of anthracite were considerably lower than it is. The problem at the present time is not so much to find a substitute for hard coal, but rather to find ways and means of developing the use of Saskatchewan coal in competition with the higher grade Alberta coals. Almost the only purposes for which anthracite coal is used in the province at the present time is for gas producers, and there is no reason why its use for that purpose should not be entirely superseded by Saskatchewan lignite.

At the Melville municipal electric light and power plant a 250-h.p. suction gas producer was used to supply producer gas to three gas engines used for generating electric current. The fuel used was American anthracite costing $16.80 per ton delivered at the plant. The plant was burned in September, 1923, and although the gas producer was very little damaged by the fire, it was decided to purchase two new gas producers suitable for Saskatchewan lignite, and to discard the existing anthracite producer. The result has completely justified the change. Last year, owing to the difficulty of obtaining a sufficient supply of Saskatchewan lignite of the proper grade, it was necessary to use a considerable quantity of Pembina coal at $7.23 per ton delivered, in place of Saskatchewan coal at $4.43 per ton delivered, but even with this disadvantage the average fuel cost in 1925 was only 1¾ cents per kilowatt hour as compared with an average fuel cost with anthracite in 1922 of 4.49 cents per kilowatt hour. If Saskatchewan coal alone had been used, the average fuel cost would have been a little less than one cent per kilowatt hour. The difficulty of obtaining an ample supply of Saskatchewan coal of the proper grade for gas producers has since been overcome.

Saskatchewan lignite is also being used in gas producers at the Swift Current municipal electric light and power plant. The coal costs $5.25 per ton delivered, and the average fuel cost last year was 1.05 cents per kilowatt hour.

One of the obstacles to the more extended use of Saskatchewan coal for power generation is that on account of its high moisture content and the consequent lower furnace temperature obtained, it is difficult to obtain as high a boiler rating as with higher grade coal. Where the steam boiler capacity is already somewhat limited, which is frequently the case, the steam user is usually unwilling to incur the heavy expense of installing the additional boiler capacity required for the Saskatchewan lignite, even though it could in many cases be demonstrated that it would be profitable to do so. The high moisture content also makes the coal more difficult to ignite, and certain types of mechanical stokers which operate satisfactorily with higher grade coals are not at all suitable for Saskatchewan lignite. Saskatchewan coal also disintegrates on being burned, and where a travelling grate is used much of the coal drops unburned through the bars.

The furnace temperature can be increased and the coal caused to ignite more readily by the provision of proper reflecting arches, but as the ash of Saskatchewan coal is readily fusible, the higher temperature causes a great deal of "clinkering." This clinkering becomes very objectionable even in the ordinary type of furnace, if it is attempted to force the boilers at all.

In order to obtain the best results from Saskatchewan coal, specially designed furnaces would appear to be required and further experimental research in this direction is much needed. There is good reason to believe that suitable furnaces for Saskatchewan lignite both hand fired and mechanical, which would permit fairly high boiler ratings to be carried, could be developed at very little cost for experimentation. Considerable advance has also been made recently in the carbonization of coal and the recovery of carbonization by-products, and although the writer is not aware of any commercial carbonization plant in England or the United States which is at the present time being operated successfully from a financial standpoint, several processes are being developed which give promise of very favourable results.

In order to be commercially successful with *Saskatchewan coal*, however, it would appear that a carbonizing and briquetting plant must be combined with a central power plant which could utilize the gases evolved during the carbonizing process for generating power, or alternatively, the gases could be used for burning clay products, etc. In any case, the tar recovered from the carbonizing process is only sufficient to act as binder for briquetting about *one-half* of the char produced and the remainder should preferably be burned, probably in pulverized form, in a central power plant. The writer believes that a combined plant of this kind could be installed with a good prospect of financial success. Such a plant might be installed, in the first instance, on a comparatively small scale and the power distributed locally. When the economic feasibility of such a combined plant was satisfactorily demonstrated, the plant could be extended as desired and would form the nucleus of what would without doubt ultimately develop into a province-wide power generation and distribution scheme.

EMPLOYMENT BUREAU

Situations Vacant

Pulp Mill Engineers

A large pulp mill in the province of Quebec requires the services of a number of experienced pulp and paper mill engineers for engineering office, including chief draughtsman, structural designer, designer familiar with boiler house and steam plant work, and mechanical designers. Apply giving full particulars regarding age, education, experience, married or single, and salary required, to Box No. 153-V.

Situations Wanted

Civil Engineer

Technical graduate, University of Manitoba, 25 years of age, good personality, one year surveying experience, two years municipal engineering training, including design and construction of concrete pavements and sewers, reinforced concrete floor design, etc., desires position with municipal engineering firm in Ontario or Quebec. At present employed. Apply Box No. 206-W.

Civil Engineer

Civil engineer, graduating this year, desires employment where further engineering experience may be obtained. Apply Box No. 209-W.

Members' Exchange

The Engineering Library of one of our Canadian Universities is anxious to complete its file of the Engineering Journal. The missing numbers they require are Vol. 1, Nos. 1, 2 and 6, 1918, and Vol 2, No. 1, 1919. Any members having spare copies of these numbers of the Journal might forward the same to the secretary to be transmitted to the library.

BOOK REVIEWS

Chemical Colouring of Metals and Allied Processes

Samuel Field and S. R. Bonney, London, Chapman and Hall, 1925 Cloth, 8¾ x 5½ in., 264 pp., illus., 10/6 net.

Many of the smaller metal-working shops, unable to command adequate technical assistance, are obliged to fall back on the so-called Trades Formulae Books for information and guidance in their metal finishing problems. The task, by no means an enviable one, of separating the wheat from the chaff and deriving useful and applicable knowledge from these ill-assorted stores is too often attended with expense, discouragement and failure, where an elementary understanding of the principles involved in the utilization of such formulae would bear very different results.

It is to amplify and elucidate the meagre information on colouring processes that "Chemical Colouring of Metals and Allied Processes," by Samuel Field and S. R. Bonney (Chapman and Hall), has been presented. Its value to the metal finisher is unquestioned, and even the old hand may, with advantage, follow in its pages the natural laws upon which his many, and doubtless successful, procedures are based.

The initial chapters are given over to a highly condensed, though sufficient, summary of the general laws of chemical identity and combination, leading up to an exhibition of the use of chemical symbols and formula weights. From general observation shop practice seldom realizes or takes advantage of these essentials in the calculation of quantities or bath charges, where even such acquaintance with their value as afforded by Messrs. Field and Bonney's treatise would well repay the shop supervisor.

Following chapters take up individually the production of various colour effects on metals, grouped under the headings of the metals in most common use. The text indicates in each case the basic reactions in the processes, and gives instructions for satisfactory operation. A useful chapter on cleaning precedes this particularization and the subject is given quite comprehensive treatment from the chemical as well as the mechanical aspect. Electro-deposition is accorded a prominent position, and this admittedly complex art, while incapable of concentration in its entirety into the space at the disposal of the authors, is handled in a readily comprehensible manner.

On the whole, Messrs. Field and Bonney have supplied a handbook which fulfils a definite and useful purpose in the colour treatment of metals, correlating as it does the practical intricacies of this trade with the underlying scientific structure.

Merchant Ship Types

A. C. Hardy., 316 pp., illus., tables, diagrs.

Price $4.50. Chapman & Hall, London, 1924.

This work is described by the author as "A survey of the various units engaged in the water transport of people and merchandise." It contains general descriptions of vessels ranging from mammoth ocean passenger liners, such as the Cunard liner "Aquitania," down to tugs and trawlers, including many special types, such as oil tankers and colliers. There are photographs of a large number of vessels, also folding plates showing general arrangement plans, to small scale, of ten different types.

In the chapter devoted to the ocean cargo carrying vessel is given a short general description of the terms tonnage, subdivision and freeboard, also an explanation of the considerations entering into the preliminary design of a vessel, all of which information is given in terms which should be readily understood, even if the reader has not studied the subject.

The author has collected a great deal of useful information regarding the various types of merchant vessels afloat to-day and presents it in concise form, thus providing a convenient work of reference for students of naval architecture or marine engineering, as well as for those interested in merchant shipping as a whole.

It cannot be classed as a text book on naval architecture or marine engineering nor does the author seem to present it as such. His endeavour has been to discuss the subject of transport along the lines of grouping vessels into different classes and of showing generally how the service in which any individual type of vessel is to be employed governs her construction and design. In the writer's opinion he has dealt with this subject in a very satisfactory manner.

To students and to those who desire to acquire some general knowledge as to modern merchant vessels, their design, construction, etc., this interesting work is recommended.

R. J. McClelland, a.m.e.i.c.

Constructional Steelwork

Harry Atkin., 212 pp., illus., diagrs. Price $3.00, Chapman & Hall, London, 1924.

A recent addition to the library of the Engineering Institute of Canada is a book published lately entitled "Constructional Steelwork" written by Mr. Harry Atkin and published by Messrs. Chapman & Hall, London. This book is a manual of workshop processes, methods and machines based on the practice in various structural steelwork shops in Great Britain.

One of the purposes of the book is to arouse the interest of young men in the structural steel business and the book describes theory and practice in such a way as to emphasize the close relation that should exist between them. It is to be doubted whether in the United States or Canada the benefits of this close relationship have been realized to as great an extent as they have in Great Britain and Ireland.

The author of the book reveals a knowledge of working conditions and human nature. It would appear, as might be expected, that operations such as smithing and handling are done more usually by manual labour than is the case in this country. Moreover the apprentice system seems to be in vogue to some extent. The shops described in the book, some of them about 40 ft. wide, correspond to the smaller shops in America.

Mr. Atkin calls attention to the slight differences in structural steel obtainable from various sources. Such differences probably need emphasis in this country also where various specifications are used and steel not made by the open-hearth process sometimes finds access to structural shops, particularly in Canada.

The book describes templet making, sawing, smithing and punching. It does not state whether templets are always considered necessary nor just what economy if any can be effected by the use of shears instead of saws or spacer or profile punches instead of single punches. It would be very interesting indeed to have some information by means of which comparisons could be made between the total costs of shop operations in Great Britain and America. The prevalence and size of the drills and edge planers as illustrated would indicate that British practice is somewhat more stringent than American in the finish demanded in structures of medium size.

Mr. Atkin appreciates to the full the fact that different shops have different methods which may be respectively the best for each. This is equally true of different countries and his book should be very valuable in so far as it affords a basis of intelligent comparison between British practice and our own.

D. C. Tennant, m.e.i.c.

Marine Engineering Repairs

Engineer Capt. F. J. Drover, R.N., Cloth 5½ x 8¾ in., 227 pp., illus. Price 9/6 net. Chapman & Hall, London, 1925.

Engineers in charge of marine machinery have always been remarkable for their resourcefulness and ingenuity in carrying out emergency repairs, often at sea, and under very difficult conditions with the preservation of life and property depending on their efforts.

Captain Drover's book, besides containing data regarding work of this kind, is a compendium of information of a very practical nature, as to the most approved methods of care and maintenance for marine machinery, and it will be found useful in many instances by engineers charged with the operation of modern steam or diesel engine driven power stations on shore.

Dealing first with reciprocating steam machinery, the adjustment and repair of the modern types of steam turbine units follow. The chapters on pipe systems, joints and glands, condenser defects (including corrosion) and the management and repair of auxiliary machinery, pumps, evaporators and distillers, refrigerating machines, air compressors, etc., are valuable, and are followed by a fairly comprehensive treatment of boiler work, with particular reference to the troubles arising in connection with the storage and use of oil fuel.

The sections on diesel engines are somewhat brief but draw attention to such important topics as lubrication troubles, difficulties in starting and in maintaining valves and fuel systems.

The book can be recommended as a sound and clear presentation of a highly technical subject.

Standard Electrical Dictionary

T. O'Connor Sloane & A. E. Watson., Cloth, 5 x 7¼ in., 790 pp., illus. Price $5.00. Norman W. Henley Publishing Co., New York, 1924.

This appears to be a reprint of an older dictionary to which have been added a smaller, somewhat more modern part dealing with newer terms and appliances, and a third section devoted entirely to radio.

Erratum

In the April, 1926 number of the Engineering Journal page 216 line 38, for *Vouvray* read *Veurdre*.

BRANCH NEWS

Border Cities Branch

W. H. Baltzell, M.E.I.C., Secretary-Treasurer.

The Border Cities Branch held its regular monthly meeting on Friday, March 12th, in the Prince Edward hotel, Windsor. Chairman A. J. M. Bowman, A.M.E.I.C., presided, and twenty-five, including the speaker, partook of the dinner.

The chairman called attention to the fact that the engineers on this Border were not interesting themselves sufficiently in the affairs of the community and thereby were missing many excellent opportunities to be of service to the community, and by reflection, to themselves. He stressed the fact that engineers are prone to leave all public service problems to others often not so competent to analyze or discuss them, to inform the public or reach logical conclusions. He told the assembly that he was prompted to this by the remarks made by the President, George A. Walkem, M.E.I.C., during his recent short visit. Major Walkem outlined the work being done by the engineers of Vancouver in connection with public affairs and urged upon us our duty in this regard.

After a short discussion it was moved by J. E. Porter, A.M.E.I.C., seconded by L. McGill Allan, A.M.E.I.C., that this branch become affiliated with the Border Chamber of Commerce, either as a section of the same or, in case we are not in position to meet the requirement of the Chamber by-laws, arrange to have a strong engineering committee appointed consisting of such branch members as are also members of the Chamber of Commerce. This carried unanimously.

Domestic Refrigeration

The speaker of the evening was Mr. A. McLay of the Detroit Edison Company, Detroit, and his subject was "Domestic Refrigeration."

He explained the rudimentary principles of refrigeration, and dwelt on the causes of decomposition of foods, growth of bacteria, development of ptomaines, rapidity of their production, their eventual self-destruction under certain conditions, and the ever increasing necessity of food preservation owing to the relatively decreasing areas being used for food production.

In reference to mechanical refrigerating machines for domestic use, he stated that there are now about 1,300 in use in the city of Detroit, including those in use in ice cream parlors. At Detroit the cost per year of electricity is about $22.50 for a refrigerator of about fifteen cubic feet capacity gross or eleven cubic feet net, about four cubic feet space being required by the cooling coil. Assuming a ten-year life of apparatus and no scrap value at the end of that time, the total cost per year would be about $72.00. However, as the apparatus is as yet too new to fix its serviceable life and as it is not yet being produced in what is now known as "quantity production" there is every reason to believe that these costs will eventually be materially reduced.

Mr. McLay spoke for about an hour, after which there were many interrogations from those present, showing that all were keenly interested in the subject, and following the discussion a hearty vote of thanks was tendered to the speaker.

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

The annual meeting of the branch was held on March 13th, when A. L. Ford, M.E.I.C., presided as chairman. The first report to be received was that of the secretary-treasurer, G. P. F. Boese, A.M.E.I.C., who recounted the year's activities and gave a financial statement which showed a healthy state of affairs. He reported an average attendance at meetings of approximately sixty members, which was a record for the branch, also that the largest attended meeting on record was held during the season.

In the absence of F. K. Beach, A.M.E.I.C., chairman of the Programme Committee, W. St.J. Miller, A.M.E.I.C., read his report which contained a résumé of the committee's activities in the way of arranging papers on subjects of topical interest as well as those of general interest to engineers in particular.

The chairmen of other subcommittees reported as follows:—R. S. Trowsdale, A.M.E.I.C., Applications and Credentials, stated that sixteen applications had been dealt with during the year. Prize Committee was represented by J. H. Ross, A.M.E.I.C.; Acquaintance Committee by R. M. Dingwall, A.M.E.I.C.; Attendance Committee by J. A. Spreckley, A.M.E.I.C. The branch news editor reported that rebates received for news submitted for the Journal were just about up to the record established for the last two years, and incidentally it was observed that this amount was practically the equivalent of that shown as balance in the bank on the financial statement.

Election of Officers

Scrutineers F. M. Steel, M.E.I.C., and J. A. Spreckley, A.M.E.I.C., presented the results of the ballots to the chairman, who announced the following election of officers for the ensuing year:—Chairman, J. H. Ross, A.M.E.I.C., a member of the faculty at the Institute of Technology and Art; Vice-Chairman, F. K. Beach, A.M.E.I.C., and Secretary-Treasurer, H. R. Carscallen, A.M.E.I.C., both of the Water Power and Reclamation Service. New members on the executive—W. St.J. Miller, A.M.E.I.C., J. Haddin, M.E.I.C., and R. Mackay, A.M.E.I.C.

Regrets were expressed on all sides over the retirement of G. P. F. Boese, A.M.E.I.C., from the office of secretary-treasurer. Mr. Boese has so successfully filled that office for a number of terms and his thoroughness and adaptability to the work were keenly appreciated by not only the members of the executive, but by members of the branch at large. It is somewhat of a relief, however, that he will remain a member of the executive for at least a year longer. Mr. Carscallen as the elected secretary expressed his willingness to do his best, and stated that he could hardly hope to fill the position as efficiently as the late secretary—but we shall see. Those who know him are willing to back his complete success.

At this meeting it was decided to name the heads of committees *conveners* in place of *chairmen*, in order not to conflict with the word *chairman* as applied to the head officer of the branch.

A. L. Ford, A.M.E.I.C., on retiring from the chair expressed an appreciation of the work of the executive and committees as having been of great assistance in enabling the branch to enjoy a most successful year. He then introduced J. H. Ross, A.M.E.I.C., as the new chairman whose inaugural remarks carried a note of assurance that the coming year was going to be the best yet.

Lethbridge Branch

N. H. Bradley, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Lethbridge Branch, held on Saturday, March 6th, was a general business meeting without a speaker.

The Chairman of the Branch, Robert Livingstone, M.E.I.C., being unable to be present, H. W. Meech, A.M.E.I.C., occupied the chair.

The meeting was opened with our usual dinner, throughout which the "Rainbow Orchestra" gave several musical numbers. Following the dinner, community singing was led by Robert Lawrenec, A.M.E.I.C., and solos by A. J. Branch, A.M.E.I.C., Wm. Meldrum, A.M.E.I.C., and R. Lawrence, A.M.E.I.C., were greatly appreciated.

In the annual balloting for officers seventy-five per cent of the Branch members made returns, the result of the ballot being as follows:

Chairman	J. T. Watson, A.M.E.I.C.
Vice-Chairman	G. N. Houston, M.E.I.C.
Committeemen	J. B. deHart, A.M.E.I.C.
	Chas. Raley, A.M.E.I.C.
	A. Thomson, A.M.E.I.C.
Ex-Officio	Robt. Livingstone, M.E.I.C.
	John Dow, M.E.I.C.
Secretary-Treasurer	N. H. Bradley, A.M.E.I.C.

In addition to the above officers, Geo. Brown, A.M.E.I.C., and C. J. Broderick were elected auditors for the current year.

London Branch

E. A. Gray, A.M.E.I.C., Secretary-Treasurer.

The regular March meeting was held in the Board room of the Public Utilities Commission Wednesday, March 24th, at 8.15 p.m. Several subjects were listed for informal discussion including, "Use of Concrete in Underpinning," the discussion being led by J. R. Rostron, A.M.E.I.C., and the "Town Management System of Civic Government," discussion of which was led by W. P. Near, M.E.I.C.

Many interesting points were brought out during the discussions, the meeting proving of such interest that it was decided to hold several more of the same nature in the near future.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

A most enjoyable dance was held by the branch at the Welland Inn, St. Catharines, on April 7th, 1926. About 130 members and their friends were in attendance, coming from all parts of the peninsula.

The arrangements for catering and the orchestra were excellent and much credit is due to the committee which gave so freely of its time in order that the dance might be successful.

One of the features was a demonstration of the new Brunswick Palephotophone during the supper hour; there is without doubt great possibilities in this machine for dancing as the tone can be so increased in volume that it will fill a large hall.

Another feature was a fine example of what might be termed the "modern classic dance" as interpreted by an engineer. Mr. J. E. Sears, who is evidently a hard working student and lover of the terpsichorean art, evoked a great deal of interest with his demonstration and much favourable comment was heard.

The committee which so ably looked after the preparations for the dance was composed of the following members: A. W. L. Butler, A.M.E.I.C., chairman, A. R. Bond, A.M.E.I.C., C. H. Mathewson, A.M.E.I.C., E. P. Murphy, A.M.E.I.C., R. H. Harcourt, A.M.E.I.C.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Engineers hear Expert on Radio

The annual popular lecture of the Ottawa Branch was delivered on April 15th, at the Victoria Memorial Museum before a large attendance of members and their friends, by Major W. Arthur Steel, M.C., A.M.E.I.C., of the Royal Canadian Corps of Signals, who took as his subject, "Electrons and the Vacuum Tube as used in Radio Reception." Many interesting experiments on the conduction of electricity in vacua, illustrating the fundamentals of the vacuum tube, were carried out.

Major Steel has had a very wide experience in radio, both in peace and in war. He has recently been responsible for the design and installation of the new system of radio telegraph stations serving the Northwest Territories and for the development of ground radio communication in Canada. J. D. Craig, M.E.I.C., director-general of surveys and chairman of the branch, presided.

Irrigation in Egypt

Some of the marvellous engineering skill that went into the construction of an irrigation scheme in Egypt many decades ago was interestingly related on April 8th by Mr. Grote Stirling, M.P., Assoc. M. Inst. C.E., in an address to the Ottawa Branch, at the Chateau Laurier. Mr. Stirling spoke as an engineer and yet his address was not too technical, being readily understood by any one unacquainted with engineering problems.

After first tracing the history of irrigation in Egypt, Mr. Stirling held the close attention of his audience with a most informative talk on irrigation in British Columbia. Irrigation was necessary in B.C., to develop small areas and the problem there consisted of carrying considerable quantities of water over rough steep places to these small areas of highly valued land, valuable on account of the crops they produced. He dwelt particularly on the intricate engineering problems encountered in one of these irrigation schemes.

An Announcement

John Murphy, M.E.I.C., called attention to the impending visit to Ottawa of delegates who will be attending a big convention in New York of the International Electrotechnical Commission. They will be in Ottawa on May 1st, the Capital forming part of their itinerary on a tour of the United States and Canada. While here the Ottawa Branch of the Institute will escort them on a tour of inspection of the big paper mill project at Chelsea, being built by the International Pulp and Paper Company.

International Co-operation in Geodetic Survey Work

Large sums of money were being saved each year by the United States and Canadian governments as a result of international co-operation in geodetic survey work, Major C. V. Hodgson told the members of the Ottawa Branch, gathered at luncheon in the Chateau Laurier, March 19th.

Major Hodgson is assistant chief, Division of Geodesy, United States Coast and Geodetic Survey, Washington, and with H. G. Avers, was in Ottawa to confer with Canadian officials on certain features of co-operative geodetic work being carried on by the survey branches of both countries.

This work formed the best example of international economy that he knew of. Over $100,000 had been saved on the international boundary alone as a result of one belt of triangulation across the continent. This co-operation had been extended to the Alaskan and the Pacific coast boundaries.

Mention was made at the luncheon of the international meeting of engineers which was to take place in New York and which was to be followed by a tour of the United States and Canada. Ottawa would be visited by the party on May 1st, and a local committee of the Engineering Institute would receive them.

J. D. Craig, M.E.I.C., chairman of the branch, presided at the luncheon. Major Hodgson paid a fine tribute to the work of the Canadian engineers and said that in many ways the Canadian geodetic survey was ahead of that of his own country.

Quebec Branch

Louis Beaudry, S.E.I.C., Secretary-Treasurer.

Although no news of the activities of this branch has been given in the Journal for some time past, meetings were held regularly at which very interesting addresses and papers were presented as it will be noted in the following brief report.

Power Development in the Province of Quebec

On Monday, January 11th, Fraser S. Keith, M.E.I.C., Manager of the Department of Development, Shawinigan Water and Power Company, addressed the branch on the subject of "Power Development in the Province of Quebec," at a luncheon meeting held at the Chateau Frontenac.

Mr. Keith, at first, took his audience, step by step, over the road of progress that had been followed by the human race in various countries of the world, from the old slave-driving methods to the discovery and development of electrical energy.

After, the speaker disclosed interesting figures regarding the hydraulic development in the province of Quebec. At the end of the year 1910, Quebec had installed 330,000 h.p., or 33 per cent of the total for Canada. In the year of 1925, Quebec had produced an additional of 439,000 h.p., which was equal to 60 per cent of the total increase throughout the whole Dominion. Mr. Keith also stated that, according to statistics compiled by himself, by 1930 it will reach over 50 per cent of that total production, notwithstanding the increase in the other provinces.

Four interesting films were also shown by the Shawinigan Water and Power Company.

Mr. Keith was introduced to the gathering by our chairman, A. B. Normandin, A.M.E.I.C., and A. R. Decary, M.E.I.C., honorary chairman of the branch, thanked the speaker on behalf of the branch.

The Engineer and the Commission of Public Services

F. Chas. Laberge, M.E.I.C., member of the Commission of Public Services, dealt with this interesting subject at an evening meeting held at the Chateau Frontenac, on Monday, January 25th.

The speaker said that the reason for the development of public services was the adoption of new methods of modern life. What was considered a luxury a few years ago is now a necessity. Small municipalities have the telephone and electric light, while large cities have also tramways, gas services, aqueducts, sewers, etc. The Commission of Public Services was established in order to meet the need of regulating all these services.

Mr. Laberge outlined the powers conferred on the commission by the government, and also the work it is doing.

The speaker concluded by saying that the commission depends to a large extent on the knowledge of the engineer for settling many difficulties. He invited the engineer to become familiar with the laws concerning the commission. In that way much money would be economized for the good of everybody.

Mr. Laberge was tendered a vote of thanks moved by J. Duchastel de Montrouge, M.E.I.C., and our chairman, A. B. Normandin, A.M.E.I.C., also added his thanks for this very interesting lecture.

General Meeting

On Tuesday evening, February 16th, a general meeting was held at the City Hall. At this meeting, the affairs of the branch and of the Institute were studied in a discussion open to all the members of the branch.

Chairman A. B. Normandin, A.M.E.I.C., presided at that meeting which was largely attended and proved quite useful.

The Telephone

This was the subject of the lecture delivered at the evening meeting held at the City Hall on Monday, February 22nd, by Capt. G. M. Hudson, A.M.E.I.C., division plant engineer of the Bell Telephone Company at Montreal.

After having briefly traced the history of the telephone, Mr. Hudson clearly described the telephone instrument's parts and explained their respective functions. The speaker also drew a comparison between the telephone system and the power system. On the telephone the amount of power on the line is very small, while the power for the transmission lines is very great.

Mr. Hudson also described the function of the transmitter which changes the sound waves into electrical waves, and also the receiver which reverses the electrical waves into sound waves. He then described the condenser and the condenser coil.

The above descriptions were illustrated by means of lantern slides and films.

The speaker was heartily thanked by S.L. deCarteret, A.M.E.I.C., and A. B. Normandin, A.M.E.I.C., chairman.

Transportation

R. A. C. Henry, M.E.I.C., director of the Bureau of Economics, Canadian National Railways, delivered an address, entitled "Transportation," before the members of the Quebec Branch, at an evening meeting held on Monday, March 8th, at the Chateau Frontenac.

The speaker, who was introduced by A. B. Normandin, A.M.E.I.C., in a brief résumé traced the history of the steam railways on this continent. He first drew the attention of his hearers to the fact that the first steam railway was built in the city of Quebec in 1830, when a line was laid to carry stone from the King's wharf to the Citadel.

The lecturer then reviewed the development of railway transportation in Canada, the origin of the Canadian Pacific, the Transcolonial, the Canadian Northern and the Grand Trunk Railways. To-day, this country, with a population of about 9,000,000, has 40,000 miles of railways.

The speaker went on to describe the work required to move the great crops of grain every year. The whole crop, or at least the larger part of it, must be moved to the head of the lakes between October 1st and December 15th, and this meant that the railways had only 75 days to handle some 280,000,000 bushels of grain, or an average of 3,700,000 bushels a day. Since a car can carry about 1,200 bushels, it would take from 55,000 to 60,000 cars to move the crop during the short space of time at the disposal of railways.

Mr. Henry concluded his lecture with some very interesting remarks on transportation by road and the tremendous development of the automobile industry on this continent.

R. J. F. King, A.M.E.I.C., thanked the speaker on behalf of the branch.

Diversion of Water from the Great Lakes by Chicago

On Monday, April 12th, de Gaspé Beaubien, M.E.I.C., consulting engineer of the city of Montreal, addressed the Quebec Branch on the subject of "Diversion of the Water from the Great Lakes by Chicago," at a luncheon meeting held at the Chateau Frontenac.

At the first of his address, Mr. Beaubien gave a short history of the Chicago drainage question. It has existed, he stated, since 1842 when the city found it necessary to divert a few hundred feet of water per second from lake Michigan. In 1871, this diversion was increased to 1,000 c.f.s., while to-day 10,000 c.f.s. is required for the city's sewerage system.

The speaker then passed on to the question of damage done to navigation. From this diversion had resulted a drop of six inches in the lake levels, nine inches in the St. Lawrence from lake Ontario to Montreal, and six inches to one foot at Montreal. The loss suffered by our hydraulic powers must also be considered. This loss for a diversion of 10,000 c.f.s., is more than 100,000 h.p., said the speaker.

Mr. Beaubien went at length into the standing, both financial and political, of the "Sanitary District" of Chicago, the state body which controls all sanitary and sewage problems for an area containing 487 square miles, and which involves, beside the city of Chicago, thirty-eight other municipalities. The speaker declared that this body had a well organized propaganda bureau and was prepared to carry out their fight to the bitter end. The present administration in the United States, Mr. Beaubien declared, was inclined to look with favour on the Canadian aspect of the diversion, and now was the time for action.

A. B. Normandin, A.M.E.I.C., introduced Mr. Beaubien to the gathering, and A. Amos, A.M.E.I.C., thanked the speaker heartily, on behalf of the branch.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer

The regular January meeting of the branch was held at the Kitchener hotel on the 20th of the month, R. N. Blackburn, M.E.I.C., the chairman, presiding. The meeting was preceded by a dinner attended by twenty-one members and guests. When the routine business had been disposed of, the programme for the evening, consisting of papers on "Transportation," was commenced.

Transportation

The chairman called on S. T. Lewis, M.E.I.C., division engineer of the Canadian Pacific Railway, for his paper on "The Miracle of Transportation." Mr. Lewis described the advantages and advances of transportation in a paper particularly rich in speculative and philosophical illustrations. The speaker pointed to the parallel advances of civilization and transportation particularly on this continent, and the corresponding lack of progress in countries lacking in transportation facilities. In concluding Mr. Lewis sounded a note of optimism with regard to progress and prosperity in Canada, predicting that within the near future mineral production would place the country in so sound a financial condition that agricultural depression would not have the effect it now has.

D. W. Houston, A.M.E.I.C., was then called on for his paper entitled "The Street Railway of Today and Tomorrow." Mr. Houston dealt with street railway problems, principally the competition offered by gasoline driven vehicles. The street railways had at first tried to keep these vehicles out of competition but are now meeting the competition by studying the wants of the car rider and trying to meet them. It is the opinion of authorities that the street railway will continue to be the chief transportation facility for local use. In many of the larger communities the motor bus is being used to supplement street railway operations. It was the opinion of the speaker that with the growth of our western cities the motor bus would be used in co-ordination with existing street railways.

The chairman then called on P. C. Perry, A.M.E.I.C., division engineer of the Canadian National Railways, for his paper on "Railway History in Canada." Mr. Perry recorded that there are at present fifty-four railway companies in Canada, operating some 40,000 miles of trackage, of which a little over one-half is operated by the Canadian National System. The oldest steam railway was chartered as the Champlain and St. Lawrence in 1835, and built from Laprairie on the St. Lawrence to St. John on lake Champlain. The speaker narrated many interesting facts concerning the development of the different railways such as the original use of wide gauge on the Grand Trunk Railway, building of the Grand Trunk bridge at Montreal, the political and strategical considerations which entered into the building of the Intercolonial Railway and the varying surveys and choices of route for the Canadian Pacific Railway between Winnipeg and Vancouver. Mr. Perry showed that in costs per ton mile Canadian railways compared very favourably with railways of other countries.

Highways and Drainage

A regular meeting of the branch was held on February 18th, at the Kitchener hotel. In the absence of the chairman, H. S. Carpenter, M.E.I.C., presided. H. R. MacKenzie, A.M.E.I.C., took the opportunity of thanking the members of the branch for their support in electing him as councillor for this district. The papers for the evening dealt with the subject of "Highways and Drainage."

The chairman called on H. R. MacKenzie, A.M.E.I.C., for his talk on "Progress and Construction of Provincial Highways." For the benefit of members who had not seen them before, Mr. MacKenzie showed some very fine lantern slides illustrating highway construction. Mr. MacKenzie then gave some figures showing the growth of highway work under Federal Aid from its commencement in 1919 to the past year. Figures were also given showing the costs of different classes of work. In conclusion the speaker dealt with the economic and social benefits of improved highways.

D. C. M. Davies, A.M.E.I.C., was then called on to read his paper on "Bridges and Bridge Sites." Mr. Davies gave a very comprehensive outline of the various factors concerned, such as choice of site, approaches, materials, value to traffic and maintenance.

The chairman then called on M. B. Weekes, M.E.I.C., for his paper on "Drainage Development in Saskatchewan." Mr. Weekes outlined briefly the scope and intention of the Drainage Act and described the results obtained by the schemes at Water Hen lake and in the Yellow Grass district.

Annual Meeting

The ninth annual meeting of the branch was celebrated by a banquet at the Kitchener hotel on the evening of March 11th, 1926. R. N. Blackburn, M.E.I.C., presided and forty members and guests sat down to the dinner, enhanced by refreshments from the government cellars. Following the dinner the toast list was commenced by drinking to The King. The chairman then welcomed our guests to the meeting and asked their forbearance for a short time while a small amount of routine business was being despatched.

Mr. Blackburn then gave his address as retiring chairman of the branch. He commented on the fact that, to the present, development in the province has been almost entirely along agricultural lines. Prosperity or the reverse is therefore dependent on the yearly success or failure of the farmer. A remedy to this situation would be the development of other industries. The speaker then went on to show the possibilities for industrial development. The questions of fuel and power, including its distribution, were dealt with at some length as was also the problem of the development of the coal mining industry in southern Saskatchewan. In closing, Mr. Blackburn said that commercial success with Saskatchewan coal seemed to depend on combining a carbonizing or briquetting plant with a central power plant.

H. S. Carpenter, M.E.I.C., on behalf of the branch, presented Mr. Blackburn with an Institute badge, at the same time complimenting him on his faithfulness and success in conducting the affairs of the branch during his term of office.

The scrutineers presented their report as showing the election of officers to be as follows:

Chairman..............	W. H. Greene, M.E.I.C., Moose Jaw.
Vice-Chairman.........	M. B. Weekes, M.E.I.C., Regina.
Secretary-Treasurer....	R. W. E. Loucks, A.M.E.I.C., Regina.
Committeemen.........	J. W. D. Farrell, A.M.E.I.C., Regina.
(2 years)	A. M. Macgillivray, A.M.E.I.C., Saskatoon.
	P. C. Perry, A.M.E.I.C., Regina.

Nominating Committee

L. A. Thornton, M.E.I.C., Regina.
H. T. Crosbie, M.E.I.C., Yorkton.
J. D. Peters, A.M.E.I.C., Moose Jaw.
W. R. Warren, A.M.E.I.C., Regina.
G. M. Williams, A.M.E.I.C., Saskatoon.

Messrs. J. McD. Patton, A.M.E.I.C., and Stewart Young, A.M.E.I.C., were elected auditors by acclamation.

The chairman then called on R. W. E. Loucks, A.M.E.I.C., to propose the toast to The Province. In his proposal Mr. Loucks described the early happenings in the West, outlined the growth since the province was formed and projected its future development and prosperity. The response was made by the Hon. T. C. Davis, Minister of Municipal Affairs and Minister in charge of Bureau of Labour and Industries. Mr. Davis professed a very keen concern towards any subject touching on the development of Saskatchewan. Having been born in Saskatchewan he had been able to follow the growth of the West with the closest interest. Mr. Davis pleaded for the fullest use of Saskatchewan products in the construction programmes of the coming years.

Mr. R. S. Salmond then regaled the members in his own hilarious style with a couple of Scotch songs, red whiskers and plaid thrown in.

D. W. Houston, A.M.E.I.C., was then called on to propose the toast to The Institute. In his well-known humorous vein, Mr. Houston traced his progress from one responsibility to another since becoming a member of the Institute. The response was made by H. R. MacKenzie, A.M.E.I.C., Institute councillor for this district. Mr. MacKenzie spoke of the benefits obtainable from membership in the Institute, showing these benefits to be proportional to one's effort to attainment. The speaker also mentioned the erroneous ideas of engineers held by a portion of the public. Mr. MacKenzie stressed the need of engineers taking a more active part in public life.

Mr. Wood, a guest of the branch, gave two humorous monologues with piano accompaniment, which were much appreciated.

The toast to Allied and Sister Professions was moved by S. R. Parker, A.M.E.I.C., who voiced the opinion that the naval architect was the first professional man in the earth's history; that doctors and surveyors came later; that the youngest profession was that of electrical engineering. Dr. Morrison replied on behalf of the medical profession and stated as his belief that there had been a Great Surgeon at work before any other profession. Dr. Morrison said that the common aim of both medicine and engineering was the betterment of conditions for the human race and went on to outline some of the advances recently made in medical science. F. B. Reilly, A.M.E.I.C., replied on behalf of the Regina Architects Association. D. A. Smith, A.M.E.I.C., made response for the Saskatchewan Lands Association, showing the antiquity of land surveying. Mr. J. R. Young responded on behalf of the Saskatchewan Section American Institute of Electrical Engineers and hoped for the closest co-operation between that body and the E.I.C.

The toast to The Ladies was proposed by J. McD. Patton, A.M.E.I.C. The response on behalf of The Ladies was made by our chairman-elect, W. H. Greene, M.E.I.C., who deplored the absence of the ladies from the meeting.

Report of the Executive Committee

To Members of the Saskatchewan Branch:

Your Executive Committee have to report as follows concerning the condition of the branch and its operations during the past year:

The membership is 112 as compared with 128 reported this time last year and is made up as follows:

Honorary Members	1
Members	19
Associate Members	70
Juniors	7
Students	9
Affiliates	2
Branch Affiliates	4
Total	112

The Executive Committee have held eight meetings for planning and conducting the affairs of the branch. The number of branch meetings has been reduced to one per month and the attendance has been fairly satisfactory. During the summer a special meeting was held in honour of a visit from R. J. Durley, M.E.I.C., the general secretary of the Institute. Just recently Major Geo. A. Walkem, M.E.I.C., the new president of the Institute, made an informal visit to the branch on his return from the east.

Attached hereto is a financial statement showing current accounts for the past year's operations and a statement of assets and liabilities. This statement has been examined by your auditors.

It may be of interest to the members to know that owing to our reduced membership, rebates have been received from headquarters at the rate of 30 per cent instead of 25 per cent as formerly.

Attention should probably be called to the smallness of the deficit on meetings, indicating that this expense is almost entirely borne by members attending the meetings.

(Signed) J. W. D. Farrell, A.M.E.I.C.,
Secretary-Treasurer.

Financial Statement 1925-1926

Expenditure

Office expenses	$ 79.26
Meeting expenses	17.70
Honorarium, 1923-24	100.00
Scholarship	50.15
Sundries	36.65
	$ 283.76
Bank balance	113.38
	$ 397.14

Revenue

On hand from 1925	$ 68.88
Branch dues	61.00
Headquarters rebates	250.60
Sundries	16.66
	$ 397.14

Assets

Bank balance	$ 113.38
Headquarters rebates—current, (est'd)	221.10
Headquarters rebates—arrears, (est'd)	63.60
Branch dues—arrears, (est'd)	74.00
Branch dues—current, (est'd)	25.00
Furniture and Library	50.00
	$ 547.08

Liabilities

Branch dues paid in advance	$ 23.00
1926 Scholarship	50.00
Accounts payable	156.47
	$ 229.47
Surplus	317.61
	$ 547.08

This is to certify that we, your auditors, have examined the books and vouchers of the Saskatchewan Branch of the Engineering Institute of Canada and believe the above statement represents the correct financial position of the branch.

(Signed) A. C. Garner, M.E.I.C.
J. N. de Stein, M.E.I.C.
Auditors.

Sault Ste. Marie Branch

A. H. Russell, Jr.E.I.C., Secretary-Treasurer.

A regular meeting of the Sault Branch was held on Friday, March 26th, 1926, in the Y.W.C.A. following a dinner.

C. H. Speer, M.E.I.C., chairman, called the meeting to order and the business was disposed of before he introduced the speaker, Carl Stenbol, M.E.I.C., superintendent of the mechanical department of the Algoma Steel Corporation, who gave a most interesting paper on "Wind Measurements."

Wind Measurements

Mr. Stenbol pointed out that when any structure was designed, that wind loads were taken into account and that in all structures that are anchored to foundations the wind loads were easily taken care of, but in the case of movable structures, such as ore bridges, coal bridge and stackers, it was a different proposition. It can readily be seen that in the case of the ore bridge, accurate data on the wind must be obtained in order that the bridge may be stopped and securely clamped to the rails in the case of a strong wind arising. The bridges at the Algoma Steel Corporation are equipped with the "Stenbol" wind gauge so that the velocity of the wind is recorded and as soon as it registers 35 miles per hour the operator shuts down the bridge and applies the clamps.

Mr. Stenbol is deserving of great credit for this wind gauge. After making a careful study of wind, he found that the available formula and gauges differed considerably in results. During a heavy windstorm in 1911, readings taken at different points by different instruments varied from 60 to 20 miles per hour. The standard formula for United States is $P=0.004v^2$, and that of Great Britain is $P=0.003v^2$, showing a difference of 25 per cent. Having all these facts to contend with, Mr. Stenbol determined to design a gauge and calibrate. After making five tests under the best conditions possible, mean readings were taken and he established the formula $P=0.0034v^2$ for his gauge, which is known as the pressure plate type.

A model and photographs of his gauge were shown. A most interesting chart showing the wind pressure and direction at the same time by means of two pens was shown. This chart was made by Mr. Stenbol's gauge at the steel plant and covers a period of 24 hours.

A general discussion followed and a hearty vote of thanks was tendered to Mr. Stenbol.

St. Lawrence Waterway and Chicago Drainage Canal.

Part of an address by Mr. James Harper, president of the Minnesota Arrowhead Association, was read. This article dealt with the relation between the St. Lawrence waterway and the Chicago drainage canal. Two of the outstanding points were:—First, the decrease in freight rates which would result by having the ocean traffic through to the Great Lakes, thus allowing a direct water route. Since the Panama canal has been opened goods can be shipped from the Pacific coast and delivered to New York, by boat, cheaper than the same articles from Wisconsin and Minnesota shipped by rail. Secondly, at present in the Chicago district there is developed a considerable quantity of electrical power by utilizing the diverted waters, and they propose to develop more power from the same source. The speaker gave this as one reason why Chicago does not want to do away with their drainage canal. Mr. Harper clearly showed that to get the development of the "Deep Waterway" meant hard work and consistent organization.

Toronto Branch

J. W. Falkner, A.M.E.I.C., Secretary-Treasurer.

The Chicago Drainage Canal*

Two of the objects of the Engineering Institute of Canada, amongst others, are "to facilitate the acquirement and interchange of professional knowledge amongst its members" and "to enhance the usefulness of the profession to the public"; and these objects were abundantly fulfilled at an open meeting of the Toronto Branch held on March 18th, 1926, when J. L. Busfield, M.E.I.C., gave an illustrated lecture before several hundred members, and friends of members, on "The Chicago Drainage Canal."

Mr. Busfield dealt with this much discussed project—of the nature, history and magnitude of which the public at large, and even perhaps many members of our profession have only had very general ideas—in an authoritative and impartial manner, and covered very fully the many aspects of the case, historical, technical, financial and international; the numerous excellent lantern slides making it easy to follow the massed detail presented.

As an engineering project this canal directly interests all engineers; as affecting the diversion of waters from a waterway in which Canada has riparian and international rights, it is of consequence to all citizens, and a knowledge of the facts is essential to right public opinion. There is no one more qualified to speak on such a matter than a practising engineer, and those present felt that Mr. Busfield had done a great public service in coming to Toronto to give this lecture.

Annual Meeting

The annual meeting of the Toronto Branch was held on Thursday evening, March 25th, 1926, in room 22 of the Mining building, of the University of Toronto. About thirty-five members were present, Professor T. R. Loudon, M.E.I.C., being in the chair.

The secretary read the notice to members, calling the annual meeting, and the minutes of the annual meeting held on March 19th, 1925, were read and approved.

The Nominating Committee acted as scrutineers to count the ballots.

The retiring chairman gave a short address, in which he particularly emphasized the question of meetings and the attendance by members.

The secretary-treasurer presented the annual report and financial statement of the branch for the year.

Reports by the chairmen of the following sub-committees were read and adopted:—

Programme—T. R. Loudon, M.E.I.C.
Finance—J. G. R. Wainwright, A.M.E.I.C.
Publicity—S. G. Talman, A.M.E.I.C., and J. W. Falkner, A.M.E.I.C.
Attendance—L. W. Wynne-Roberts, A.M.E.I.C.
Library—A. C. Oxley, A.M.E.I.C.
Student Relations—W. L. Thompson, S.E.I.C.

A number of members then took part in a discussion on meetings and attendance, and the chairman contributed his views on this subject and concluded by expressing his appreciation and warmly thanking the officers of the Executive, the Annual Meeting Committee, and members for their support and assistance during his term of office.

Geo. A. McCarthy, M.E.I.C., chairman of the Nominating Committee, then reported the new officers elected for 1926-1927:—

Chairman—J. G. R. Wainwright, A.M.E.I.C. (Acclamation)
Vice-Chairman—R. B. Young, M.E.I.C.
Sec'y-Treas.—J. W. Falkner, A.M.E.I.C.
Committeemen—A. E. K. Bunnell, A.M.E.I.C. (2 years)
H. W. Tate, A.M.E.I.C. (2 years)
L. W. Wynne-Roberts, A.M.E.I.C. (2 years)
A. T. C. McMaster, M.E.I.C. (1 year)
I. H. Nevitt, M.E.I.C. (1 year)

Mr. Wainwright then took the chair and made a short address thanking the members for the honour conferred on him. Messrs. Young, Wynne-Roberts and Falkner also made a few appropriate remarks and thanked the members for their election.

R. O. Wynne-Roberts, M.E.I.C., on behalf of the branch, very effectively moved a hearty vote of thanks to the retiring chairman, secretary, and members of the Executive, which was seconded by Geo. A. McCarthy, M.E.I.C., and carried. Professor T. R. Loudon, M.E.I.C., aptly replied, followed by the secretary and J. A. Knight, A.M.E.I.C., who offered strong support for the coming year.

Vancouver Branch

P. H. Buchan, A.M.E.I.C., Secretary-Treasurer.

President Walkem Tendered Dinner by Branch

The Vancouver Branch held a dinner at the University Club on the evening of Saturday, March 13th, in honour of Major Geo. A. Walkem, M.L.A., M.E.I.C., president of The Engineering Institute of Canada, who had returned, a few days previously, from several weeks' tour of the central and western branches of the Institute, following the annual meeting in Toronto.

To describe adequately the pleasurable features of that occasion would require a combination of journalistic abilities not found in the present associate editor of the branch. One would need to be a parliamentary reporter, a social editor, a musical critic and a good bartender all rolled into one. It is safe to say, however, that the affair was an unqualified success, and that all those members of the branch who were unable to attend missed the best party ever given by the Vancouver Branch.

The dinner was the outcome of a general desire to celebrate the occasion on which a member of the Vancouver Branch has been elevated to the highest office in the Institute. The only other British Columbian engineer who has occupied that office is F. C. Gamble, M.E.I.C., a member of the Victoria Branch, who was elected in 1915. The occasion was of further interest, arising from the fact that the guest of honour is also president of the Association of Professional Engineers of B.C., and a very popular figure in the engineering profession in the province.

The dinner arrangements were in charge of a committee under the direction of L. F. Merrylees, A.M.E.I.C. Notices were sent to all of the district members of the branch, as well as branch residents; and it was most gratifying to the committee to witness an attendance of over forty guests and to receive communications of regret from a large number unable to be present.

The presiding officer was W. H. Powell, M.E.I.C., chairman of the Vancouver Branch. Following the toast to the King, Mr. Powell on behalf of the Vancouver Branch, formally congratulated the guest of honour, Major Walkem, on his election to the office of president of the Institute.

In responding to his toast, President Walkem described the functions of the Engineering Institute of Canada as being analogous to a privately owned university for engineers. He outlined its growth in prestige and influence since its inception in 1887, when it was originally incorporated as the Canadian Society of Civil Engineers. He stated that its educational value among engineers had been an increasingly important factor in bringing the engineering profession in Canada to its present high standard, and prophesied that its future progress would be marked by the upward trend of that standard, and by the improved relationship of engineers to employers and the public, generally. He showed how the standards and activities of the Institute, especially in the older provinces of the Dominion, had received such strong endorsation by employers and the public, that it is becoming general practice to give members of the Institute preference when appointments are made.

President Walkem referred to the recent efforts of the Institute towards fostering the growth of the professional engineer movement, and stated that the influence and facilities of the organization had been definitely placed at the disposal of the professional engineering bodies of the various provinces to assist in bringing about close cooperation and uniform standards. A meeting in Montreal, attended by delegates from each provincial body, had already been productive of very encouraging results. E. A. Wheatley, A.M.E.I.C., registrar of the Association of Professional Engineers of B.C., had been the delegate from the local body at that meeting, and since his return, several of the recommendations of the meeting had been placed in effect here.

*This paper has been presented before a number of branches of the Institute and is published in full in this issue of the Journal.

The speaker also drew attention to the duty of engineers to take an active part in public life, by offering themselves for service in public bodies. He said that the education and professional training of engineers equipped them with abilities of the utmost value in public service, and that their lack of interest in such opportunities had not only caused the profession to suffer, but had been detrimental to the Dominion as a whole. He voiced his gratification that an increasing number of engineers in Canada had assumed duties in public capacities, during tne past few years, and that the example of these men was having noticeable effect in the encouragement of other engineers to follow suit. He urged those present to give this matter their earnest consideration, as he believed that only by such a movement would the engineering profession ever be of maximum benefit to the nation.

Special interest was attached to the dinner by the presence at the guest table of two veteran members of tne Vancouver Branch, Thomas H. White, M.E.I.C., and James H. Kennedy, M.E.I.C. The senior member of this group of "Pioneer Railway Builders," H. J. Cambie, M.E.I.C., was unavoidably absent, and greatly missed by everyone. The sincere respect and unquestioned popularity of the trio was very marked when their health was proposed during the evening. Mr. White, on behalf of Mr. Camoie and himself, acknowledged the demonstrations of friendship in a brief but well-chosen address, followed by Mr. Kennedy, whose naive wit provoked considerable amusement amongst his listeners.

The more serious aspects of the after-dinner programme were offset by an address on "Reminiscences of Army Life," given by Mr. E. E. Delauvault, who served throughout the war in the Corps of Interpreters of the French Army, and by a very enjoyable musical programme rendered by Ernest Smith, A.M.E.I.C., assisted by several members of the New Westminster Operatic Society. The instrumental and vocal selections given exhibited musical talent of very superior quality and were received with many requests for encores. Mr. Delauvault's picturesque descriptions of the duties of interpreters and their relation to the interior economy of the British Army in France were keenly enjoyed, not only as interesting side lights on the late war, but as a series of anecdotes of a more or less personal nature relating to the humorous phases of life behind the lines.

A very able contribution to the success of the dinner was the menu card which was designed and executed by W. G. Gale, A.M.E.I.C. The artistic aoilities of Mr. Gale show a high degree of excellence, as also does his originality of design.

President Walkem not only expressed his genuine pleasure in being the guest of honour at this function, but bespoke the success of future occasions of this nature, and hoped that the executive would let pass no opportunity which might arise to bring the members of the branch together under similar enjoyable circumstances. In the aftermath of the dinner, the numerous comments of those present bore testimony to the president's appreciation of the need for such events in the life of the branch, and indicated that the next committee which undertakes a similar enterprise will be rewarded with even greater success.

Victoria Branch

E. G. Marriott, A.M.E.I.C., Secretary-Treasurer.

At the close of a business meeting held in the branch club room on March 3rd, J. H. McIntosh, S.E.I.C., gave a paper on "The Manufacture of Cement." Several diagrams illustrating the growth of production of Portland Cement on the North American continent, and the varying amounts imported were shown, after which the historical development of cements was sketched up to the time that Joseph Aspdin of Leeds took out letters patent for "Portland Cement"; the improvements since that date were then outlined.

It was pointed out that the varying quality of the raw materials demands, under present-day standards, the services of a works chemist whose duties are not only to obtain a mixture of suitable composition, but to see that proper control ensures continuance of the desired proportions, so that the finished cement can always be relied on to have the same characteristics.

The processes in manufacture were outlined, and illustrated, not only by photographs, but by an excellent series of samples taken at different points in the progress from slurry to clinker as it passes through the rotary kiln.

At the close of the paper, Mr. E. Tomlin, director-treasurer of the B.C. Cement Company, added a few remarks on costs, and particularly emphasized the quick-hardening properties of the Bamberton cement, due to the superior quality of the raw materials obtained, backing up his assertion by a reference to the record-breaking speed obtained with movable forms on the Prince Rupert grain elevator.

A lively discussion followed in regard to quick-setting and quick-hardening of cement, and as to the causes of various difficulties met with, the meeting adjourning at 11 p.m.

Congratulations were extended to Mr. McIntosh on the excellence of his paper, and thanks to Mr. Tomlin for much information given. Mr. Tomlin kindly extending an invitation to the members of the Victoria Branch to visit the works at Bamberton at a later date.

Victoria Fire Department

On March 16th, at the invitation of Fire Chief Stewart, members and friends met at the Central Fire hall, and after being welcomed by the chief, the latest piece of apparatus, an American-La France pumper, capable of delivering 300 gallons per minute at the end of 1,200 feet of hose, was run out, connected to a hydrant, and two fire-streams pumped. The other motor apparatus in the fire hall was inspected, with particular interest in the 75-foot aerial, and the various smaller equipment, including the life-line and gun.

Humidity readings, taken every few hours at the Yates Street hall, have been kept during 1925. While the value of these has not been fully settled as yet, press notices as to dangerous atmospheric conditions seemed to have been of considerable service, as the number of fires in July and August, 1925, were only 50 per cent of those of the previous year.

Various record books and report forms were shown, and the party then adjourned to the operating room, where the operator in charge outlined the methods by which the box alarms were automatically recorded, and the various fire halls notified. A separate automatic alarm system, connected with the parliament buildings and other structures of note in the city, which comes into play when the heat in the buildings exceeds a fixed degree, was also examined. While in the operating room, the deputy chief turned in an alarm from one of the city boxes, so that the whole of the operations and responses from the fire halls could be followed.

On returning to the Central hall, in which the motor apparatus stands in readiness, a zero call (the fire alarm by telephone), was received, and with a scuffling overhead as the alarm gong rang, and a rush by door, and rapid descent by post, in a few seconds two of the motors were manned ready for directions.

Retiring to the firemen's bandroom, the chief mentioned some of the historical fires in the city, adding a résumé of the various causes that had led to the burning of residences, etc., in the past few years.

Victoria has two fire protection areas, the business part having a high pressure system directly connected to the Humpback reservoir, with a hydrant pressure of 125 pounds to the square inch; the residential section having an average pressure of 65 pounds to the square inch from Smith's Hill reservoir.

In the event of a breakdown in the city supply from the Humpback, a high pressure pumping station can boost the pressure from Smith's Hill, or can connect directly with salt water in case of need.

The training of the fire-fighting staff was briefly dealt with, and the wide knowledge of all apparatus and its use emphasized by the statement that, owing to the adoption of the two-platoon system, the legal requirement of one day's rest in seven, and the allowance of an annual holiday, out of a fire-fighting force of 74, it was necessary to have 32 qualified drivers.

At the close of his talk, Fire Chief Stewart answered a number of questions, and the thanks of the members of the branch were then expressed by F. C. Green, M.E.I.C., member of council, who acted as chairman owing to the regrettable absence of the branch chairman, J. N. Anderson, A.M.E.I.C., through illness.

The Pacific Great Eastern Railway

On the last day of March, T. Kilpatrick, general manager of the Pacific Great Eastern Railway, gave a concise review of matters affecting that much discussed line.

After giving numerous figures as to costs, and annual deficits, Mr. Kilpatrick emphasized the gradual advance being made, and stated that for a recent month, the receipts on the main line from Squamish north showed a surplus over operating expenses. He considered the P.G.E. should be looked upon as a colonization line, and time should be given to prove its real value. Specific cases were given of increase in freight through the growth of farming, cattle-raising, and the discovery of large deposits of soda.

Following the line from Squamish to Quesnel, Mr. Kilpatrick drew attention to the scenic attractions at different points, fishing, hunting, mineral and timber wealth, agricultural and range land available, and various water-power sites.

Garibaldi park, with the construction of twelve miles of road, would make it possible for citizens of Vancouver to reach glaciers within five hours of their city.

In the area around Quesnel lake, there was sufficient timber with approved methods of cutting to keep a pulp and paper development of considerable size working in perpetuity.

The development of the Bridge River power site by the B.C. Electric Railway Company would mean much to the province and the railway; it was an ideal site, as, with a comparatively short tunnel, 1,200 feet of head could be obtained, giving a development variously estimated as from 400,000 to 700,000 horse power.

In conclusion it was pointed out that the people of the province occupied a somewhat similar position to the shareholders of a company, and that it was to their benefit to do their utmost to make it a paying line, instead of indulging in a lot of criticism, much of which was unjust.

Mr. Kilpatrick was the recipient of many congratulations on his excellent presentation of facts and his vision of future progress, and received a hearty vote of thanks from the Victoria Branch for his kindness in addressing them.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
Stanley A. Neilson, A.M.E.I.C., Branch News Editor.

Montreal-South Shore Bridge

The Montreal-South Shore bridge formed the subject of an interesting lecture, illustrated with lantern slides, which was delivered by P. L. Pratley, M.E.I.C., on March 25th to the Montreal Branch.

Mr. Pratley opened his address with a lucid description of the various bridges that have been projected from time to time to augment the means of transportation between the north and south shores of the St. Lawrence at Montreal, now supplied by the Victoria Jubilee bridge, which is no longer capable of taking care of the vast amount of traffic that is required of such a connecting highway.

The Victoria tubular bridge was officially opened in 1860, and was replaced by the present structure in 1898. Other projects have since been considered, but it was not until last year that authorization was given and the first sod was turned on June 3rd last year.

Mr. Pratley then proceeded to outline the construction that has already been executed, showing a series of slides demonstrating certain piers in course of erection and in their completed form.

A short discussion followed the reading of the paper after which a vote of thanks moved by J. J. York, M.E.I.C., was tendered to the speaker by the chairman, F. P. Shearwood, M.E.I.C.

Modern Problems of Synchronous Converters

April 1st brought some bad weather, but the members of the branch who braved the storm were well rewarded by the very fine paper on the above subject which was read by E. B. Shand.

Mr. Shand dealt with the recent developments of the synchronous converters discussing the troubles of flashing, the starting of rotary converters, the ventilation of this type of apparatus and other interesting problems. The paper was well illustrated with slides and was followed by a brief discussion.

In moving the vote of thanks, P. S. Gregory, M.E.I.C., said that he was glad to hear someone speak with authority on this subject and he was also glad to hear that the synchronous converter had been tamed as he had always considered it a wild animal to be put in a place by itself and left alone.

G. A. Wallace, A.M.E.I.C., occupied the chair.

Cost System for a Large Engineering Establishment

J. S. Houston, comptroller of the Dominion Engineering Works, addressed the Montreal Branch on the above subject on the evening of April 8th, and gave some interesting information on the special problems in accounting which are developed in an engineering manufacturing establishment.

W. C. Adams, M.E.I.C., occupied the chair.

Some Features of Hemmings Falls Power Development

On April 15th, the Montreal Branch had the pleasure of hearing J. S. H. Wurtele, M.E.I.C., tell of some of the difficulties experienced during the building of the above mentioned plant. Mr. Wurtele discussed the reasons for the selection of the size and type of units, the position and type of dam, the number and size of sluice gates, etc.

The damage done by a sudden flood which brought down thousands of sticks of pulpwood and carried away the concreting trestle, was well illustrated by a number of slides. Ice troubles before and after the erection of the dam were also discussed and aroused quite a bit of interest judging by the number of questions that were asked. The proper allowance for ice pressure to be used in the design of the structures was also a point of considerable interest.

Questions were also raised regarding concrete mixing, placing and the proportion of plums.

S. F. Rutherford, A.M.E.I.C., proposed the vote of thanks which was tendered to the speaker by the chairman, J. A. McCrory, A.M.E.I.C.

Tribute to Prof. L. A. Herdt, M.E.I.C.

C. J. Desbaillets, M.E.I.C., chairman of Montreal Branch, spoke as follows before the meeting on April 15th:—

Gentlemen:—

The members of the Institute are deeply moved by the death of Dr. Louis Anthime Herdt, M.E.I.C., which came last Sunday, the 11th of April, at noon. In him, the young generation loses a valuable educator; the engineer of to-day, a faithful and devoted companion; and humanity, a gentleman.

Born in France, he came to this country as a boy; he was educated at McGill, and took further degrees at the Ecole Spéciale d'Electricité of Montefiore, in Belgium. Successively demonstrator and lecturer at McGill, he rose to the rank of professor, then head of the electrical department.

His research in the electrolysis field, his work and publications on the compounding of alternators gained for him the title of Doctor of Science and the decoration of Officier d'Académie.

Later, he was elected chairman of the Canadian National Committee of the International Electrotechnical Commission; chairman of the Electric Service Commission; vice-chairman of the Tramways Commission of Montreal; and member of numerous societies and clubs which would take too much time to mention here. Three years ago, he was made Chevalier de la Légion d'Honneur by the French Government. He was a member of council of this Institute for five consecutive years.

Internationally known, the Governor of Bermuda called upon him to make a report on an important transportation problem, and his recommendations were followed. He investigated in Sweden the application of electricity to blast furnaces. From east to west, large developments will remain a tribute to his skill and to his untiring energy. His conceptions were well balanced, his vision precise, and consequently his advice valuable.

His integrity made him the arbitrator of many important cases, and I cannot help mentioning one remark he made to me after having rendered his decision in a rate controversy between the city of Montreal and a public utility company:—"Well," he said, "a few more of these arbitrations and I am a ruined man." In order to render a disinterested judgment, he had sold (not passed to a third party for the time being), all the stock he had in that company at a loss far exceeding the amount of his fee.

When the war broke out, he went to France and reported to the military authorities. He was told: "What can we do with a Doctor like you? Go back to Canada and if we need your class we will let you know." He came back with a broken heart. But when Captain Dulieux came from New York looking for someone to take charge of the inspection of war material purchased by France in Canada, the work was considerable, the specifications from abroad had to be adapted to the manufacturing process of this country, Louis Herdt stepped forward and said: "I will do it;" and he put in, besides his regular duties, two years of strenuous work, and he refused to be paid for it.

This is the gentleman we have lost.

Death would be useless if it did not teach us a lesson, and this is the lesson of this sad case. A few weeks before his death Louis Herdt told me: "If I am in this state, I deserve it; I kept on working without rest, without vacations, without relaxations. Don't do the same, a man must take care of himself. Take care of yourself. Take care of the ones that are working for you; give them their vacations when they need them, not when it is convenient to you alone."

There is his advice. . . . kindness to the end.

Gentlemen, I propose that the following resolution be passed and presented to his family as a mark of esteem on the part of his colleagues of the Institute:—

Resolution

It is the desire of the Montreal Branch of The Engineering Institute of Canada to express their deep regrets on the death of Dr. Louis Anthime Herdt, past Member of The Engineering Institute of Canada, past chairman of the Canadian National Committee of the International Electrotechnical Commission, past member of the Council of the Institute for five consecutive years.

His strong personality, his admirable character and his highly developed sense of professional integrity gained the hearts of all who came in contact with him.

Internationally known, this eminent engineer and technical educator leaves behind him the remembrance of a gentleman devoted to his friends, kind to his pupils, always ready to lead the way to work because he believed in work.

The Montreal Branch feels his loss deeply, recognizes the magnitude of the services he rendered to the Institute, and wishes to offer to his bereaved family the expression of their profound and sincere sympathy.

International Electrotechnical Commission

Members of the above commission are arriving in Montreal in the early evening of May first, and are to be entertained at a cabaret.

On May second they will be driven around the city in the morning, entertained to lunch, and then driven around the Island in the afternoon. The party are leaving for Boston in the evening.

Papers and Meetings Committee

This committee are at work on next year's programme and will welcome suggestions and contributions. Send yours to the Branch Secretary.

Presentation of the Plummer Medal

At the meeting of the Montreal Branch on April fifteenth, C. E. Bronson, assistant inspecting engineer, New York Central Lines, was present to receive the Plummer Medal, which, in accordance with the report of the Plummer Medal Committee, was presented to him for his paper on "Steel Rails," presented before the Montreal Branch of the Institute on October 30th, 1924, and printed in the

December 1924 issue of the Journal. The presentation was made by K. B. Thornton, M.E.I.C., who made a few appropriate remarks. Mr. Bronson replied as follows:—

Mr. Chairman, Members of the Institute, and Guests:—

In accepting this distinguished medal, I feel deeply honoured as its recipient, and appreciate the hearty and cordial manner in which the presentation is made by the Engineering Institute of Canada.

Little did I anticipate such an honour some eighteen months ago when addressing you upon the subject "Steel Rails," and the news of the award came as a delightful surprise.

While the speaker takes great personal pride in the award, the paper itself was not necessarily noted for its originality or research features, being more a record of the progress and achievements to which hundreds have contributed both past and present. It is in reality a tribute to all of the men who have utilized their skill, talent and efforts towards the development of the rail in particular, and railroad service in general.

Remarkable progress can be recorded for steel rails during the past two years. The general acceptance by the manufacturers and railroads of the 1925 American Railway Engineering Association specification has created the 39-foot rail as the standard of length; also classification of rails as to fitness and chemistry, improvements in details of manufacture, further use of special composition rails, together with the installation of heavier sections.

Upwards of five million dollars will be expended by the steel plants for necessary changes to accommodate the longer length rails, and in a number of ways will virtually revolutionize mill practice. The mills are taking these progressive steps without passing the cost along to the railroads, and shows the spirit of co-operation which is indeed gratifying.

The past year has been a momentous one for the New York Central Lines, marking as it does the installation of the first 45,000 tons of 7-inch, 127-pound Dudley section rail in the main line high speed tracks between New York and Chicago. The System has also standardized on the three tie supported joint with 38-inch heat treated splice bars, and heat treated bolts; decided on and installed canted and cambered tie plates after two years of extensive research, arranged for pre-boring and adzing of ties before treatment, and has purchased copper bearing spikes and tie plates in large quantities for more widespread use.

The first rolling of the 127 pound section will be made shortly of Hadfield manganese steel, and will be the highest and widest base section ever rolled of this peculiar steel.

Eight thousand tons of the one and one-half per cent manganese rails are being purchased, and the noticeable ease with which it pours, the quiet setting in the molds, the toughness and flow properties in the various rail shaping passes, and finally the resistance to deflection under impact coupled with higher exhausted ductility augur well for the future possibilities of its use in rails. The same material has proven its merit in the automotive industry as a forging steel of unusual toughness and strength either with or without heat treatment.

While research should continue for still further improvement in steel rails, there are equally important problems in the steel field to be investigated in such materials as wheels, axles, tires, forgings, draft gears, springs, frames and numerous other commodities. Research covering any of these lines should be largely of a practical nature on the railroad, in the shops and in the steel mills for refinement in manufacture and more intelligent use of the materials in service, supplemented by such chemical, physical, metallurgical and microscopic work as the exigency of the case becomes essential.

Researches and investigations need not be narrowed down to the confines of some quiet little laboratory to delve into the mysteries of atoms, molecules and the structural condition of crystals, for the problems we face are practical in nature in the realm of applied science rather than theoretical in the field of pure science. Our steel purchases each year are in enormous tonnages, made from heats of such size that a high degree of practical experience and skill is required to attain the necessary refinement in quality to meet the demands of present-day service.

The feeling is somewhat prevalent that the limit of endurance of carbon steels has been reached and that a super-steel is necessary to meet our requirements. Various alloy and heat treated steels are advocated to solve the problem. The speaker believes the sound advice of the late Dr. H. M. Howe, one of the foremost American metallurgists, made nearly ten years ago, that well-made carbon steel is equal if not superior in many respects to the so-called "fancy steels," and can be purchased at much lower prices and with less hazards. While the alloy steels are known to produce wonderful qualities of toughness and tenacity, the greatest care is required in handling these somewhat tender steels, and frequently detrimental effects are encountered which more than outweigh anticipated advantages.

An excellent example of this point is found in the automotive industry. The popular thought a few years ago was that alloy steels were essential for inherent strength and stability to withstand shocks and hardships of service. The reversion to carbon steel and one and one-half per cent manganese steel has been quite marked.

What we need at the present time is to strive for an improvement in the quality of our present grades of steel rather than make a radical departure to the use of alloy and heat treated steels; together with more intelligent understanding of their service utility.

This distinguished medal which I understand is presented from time to time, and the pride one feels in winning its award, acts as an incentive and inspiration to us to strive upward and onward; to seek the light of knowledge and its useful application for service; to aim for and aid in the betterments and improvements within the respective fields we are engaged in, to the end that the results may be beneficial to the welfare, safety and comfort of humanity.

All honour to the man through whose lofty ideals this award was made possible, and my sincere thanks and gratitude to the Engineering Institute of Canada for the bestowal upon me of this distinguished emblem, which will also be cherished as a token of your own high ideals and purposes.

Convention of Canadian Chemists

A convention of Canadian Chemists will be held at the Windsor Hotel, Montreal, May 31st, June 1st and 2nd. The committee in charge of the arrangements for the convention have announced the following tentative programme:—

CELLULOSE SYMPOSIUM

"The Bearing of X-Ray Analysis on the Constitution and the Technical Application of Cellulose Derivatives."

"Recent Scientific Developments in the Field of Textile Chemistry"—Professor Herzog, director of the Faserstoff Institute, Berlin-Dahlem.

"Canada's Opportunity in the Field of Cellulose Chemistry"—Professor Hibbert, McGill University.

"Nitro-Cellulose, its Manufacture and Uses"—J. Bascom Wiesel, Hercules Power Company.

"Effect of Heating on Cellulose"—Professor J. Watson Bain, University of Toronto.

"Nitro-Cellulose Lacquers—Developments and Uses."—T. W. Smith, The Flint Varnish Company.

In addition to the regular papers given by Professor Herzog, an X-Ray demonstration of "Fibre Analysis" will be given in co-operation with the Department of Physics at McGill University.

In addition to the above there will be papers on artificial silk, although the authors for the same have not yet been decided upon.

GENERAL PROGRAMME

"Electrical Properties of Refractory Materials" from the viewpoint of a physical chemist—Professor J. B. Ferguson, University of Toronto.

"Alkali Hydroxides as Catalysts in Oxidation Processes."—by Dr. M. C. Boswell, University of Toronto.

"The Present State of the Bios Question"—W. Lash Miller, University of Toronto.

"Saturated Solutions of Gases at Pressures up to 200 Atmospheres" (illustrated)—Dr. F. B. Kenrick, University of Toronto.

"Experimental Study of the Carbon Arc with currents up to 800 amperes" (illustrated)—Professor T. J. Burt-Gerrans, University of Toronto.

"The Effect of Radiation on Reaction in Gels"—Dr. A. F. C. Cadenhead, Queen's University, Kingston.

"Gasoline and Substitute Motor Fuels, with special reference to Synthetic Methanol and Synthol"—E. E. Gilmore, Testing Laboratory, Ottawa.

"Examination of Used Lubricating Oils" —P.V. Rosewarne, Fuel Testing Laboratory, Ottawa.

"Electrolytic Iron from Ilmenite Ores"—R. H. Monk, McArthur, Irwin Company, and R. J. Trail, Department of Mines, Ottawa.

"Dyeing Difficulties"—W. R. Allen, The Ciba Company.

"Principles of Corrosion and Methods of Testing"—Frank N. Speller, M.E.I.C., National Tube Company, and Dr. R. P. Russell, Massachusetts Institute of Technology.

"Study of Reaction of Sulphur on Linseed Oil"—G. S. Whitby and Miss H. B. Chataway, of McGill University.

"Study of Diffusion of Oxygen in Silver"—Dr. F. M. G. Johnson and E. W. R. Steacie, of McGill University.

"Problem of Oxidation in Organic Chemistry"—Dr. W. H. Hatcher, McGill University.

"Reaction between Halogen Hydrides and Unsaturated Hydrocarbons"—Dr. O. Maass and C. Severtz, McGill University.

It is expected that a complete programme will be available shortly.

Full information regarding the convention can be obtained from Mr. Harold J. Roast, consulting chemist, 145 Mill Street, Montreal.

Major-General Sir Alexander Bertram, M.E.I.C.

Members of the Institute, throughout the Dominion and abroad, will learn with profound regret of the death of Major-General Sir Alexander Bertram, M.E.I.C., which occurred on Saturday morning, April 24th, 1926, at his home, 315 Kensington avenue, Westmount, Que.

Sir Alexander's genial personality and distinguished career won for him a multitude of friends and admirers, not only among the engineers and industrialists with whom he was so actively associated, but also among men in all walks of life, and the news of his death will come as a great shock to all those who have been privileged to come in contact with this remarkable man.

His loss will be particularly felt in connection with the affairs of the Institute, of which he has been Treasurer since 1919, and to which his services have been invaluable.

In good health up to almost the last, Sir Alexander passed away surrounded by members of his family, and in an atmosphere of love and kindliness that was a part of the very man himself.

To the public generally he is best known as the man who in the dark days of war, when it became apparent that the Empire was engaged in a struggle for existence, built up through knowledge and thoroughness an organization that as time went on saw to it that Canadian soldiers were supplied with all that was needed in the matter of shells. To his friends he was known for the last thirty years at least as a captain of industry, ever ready to serve in good causes, to help friends and to cheerfully bear all the burdens which went with his high ideas of citizenship.

Sir Alexander Bertram was 73 years of age, but far from showing signs of age, had been attending to his business affairs at his office in Montreal, headquarters of John Bertram and Sons, Limited, within comparatively few days of his death. He was stricken with illness only last Monday, after attending a meeting of the Engineering Standards Association at the headquarters of the Institute, to which organization he gave much of his time and knowledge.

Born at Dundas, Ont., on February 18, 1853, the son of John Bertram, prominent even in those earlier days of Canada's industrial life, he was quickly initiated into craftsmanship, for at the age of fourteen he went to work in his father's plant, a plant he was destined to head in later years, and to see grow under his direction into a great institution. He was head of the company when he died, and its active director. Until 1912 he lived at Dundas, extending his affairs throughout the country, and it was in 1912 that the operations of the company had reached such magnitude that he felt it necessary that he personally should move to Montreal to supervise matters from there.

With the militia he had been associated from the age of sixteen when he joined the 13th Regiment at Hamilton as a bugler boy. He won his way forward rapidly and became commander of the 77th Wentworth Regiment of Hamilton, and later was appointed to the command of the 3rd infantry brigade, which gave him the rank of brigadier-general. He was on the reserve of officers when the world war broke out in 1914, and he immediately offered his services to Sir Sam Hughes, Minister of Militia at the time. In those early days of the war, when it was realized that Canada needed haste and knowledge in the matter of providing munitions, the Government turned to Sir Alexander Bertram, it being the unquestioned opinion that he was the best qualified of all industrial men in Canada to form the necessary organization to do the work. Not only had the Government of the day faith in him, but its faith was also shared by brother manufacturers from one end of the country to the other, and as chairman of the shell committee, which was called into being, he set to work. At that time Canada produced nothing but some 18-pound shrapnel shells at the Dominion Arsenal in Quebec, hence it was necessary for the committee to commence from the ground, and so earnestly did Sir Alexander and his colleagues set about and execute their plans that there grew up in a comparatively short time workshops which turned out shells in great quantity for the service not only of Canadian soldiers but for the Allies generally. At that time the United States was not in the shell making business, and Sir Alexander Bertram and those with him had to aid that country in turning its great industrial machine to the task of shell making. There came here men from the Bethlehem Steel Corporation and other vast United States organizations to learn what must be done. So strenuous was the task, and so earnestly did he give himself up to the work, that Sir Alexander's health broke down in 1915 and a rest of three months became imperative.

MAJOR-GENERAL SIR ALEXANDER BERTRAM, M.E.I.C.
Born, Dundas, Ont., February 18th, 1853.
Died, Montreal, Que., April 24th, 1926.
Treasurer of The Engineering Institute of Canada, 1919-1926.

What the activity of Sir Alexander Bertram and his colleagues meant to Canada in an industrial way is shown by the fact that the British Government in 1914 was not aware that Canada could quickly be placed in a position whereby it could supply needed munitions, yet in January of 1915 it was estimated that fifty Canadian manufacturers were engaged in this industry, and the steel plants throughout the country had their organization well under way for continuing and enlarging the work.

His interest in the military organization of Canada went further than actual connection with militia regiments. He was a deep believer in the theory that young Canadians should be trained to shoot, and trained to shoot straight. In 1909 he commanded the Canadian Bisley team which did so well in England in that year, the Canadians carrying off three cups—the McKinnon, the Kolopore and the Queen's Jubilee, the first time in Bisley history when all three cups were won by one team.

Sir Alexander at the time of the Bisley shoot was given the Colonial Auxiliary officers' decoration. His interest in rifle shooting led to him taking an active part in the affairs of the Dominion Rifle Association, and he was president of that organization for a number of years. Only a few weeks ago Sir Alexander was honoured by the association, he being, together with E. W. Beatty, Sir Henry Thornton, and General Sir Arthur Currie, made an honorary life member of the association.

Sir Alexander took a pride in the fact that he had grown up from the commencement in the engineering business, and was ever ready to aid fellow engineers. He joined the Institute in 1911 when he was elected Member on October 14th of that year. His devotion to the interests of the Institute is well known to all its members but more particularly to the executive officers who have served on its council during the past eight years. In addition to being Treasurer of the Institute, he was on the Council during the years 1919 to 1921 and served on many of its committees. He was chairman of the Engineering Standards Committee of the Institute, and vice-chairman of the Main Committee of the Canadian Engineering Standards Association, and attended a meeting of that committee at the Institute headquarters on Monday, April 19th, which was his last public appearance.

Sir Alexander was also interested in golf, lawn bowling, and curling, and was a member of the Thistle Curling Club, of the Beaconsfield Golf Club, of the Senneville Club, as well as of a host of other clubs, such as the Mount Royal, the St. James Club, the Rideau Club of Ottawa, the Hamilton Club, the Rotary and Railway Clubs—in fact there were few clubs in Canada where at some time or other he was not welcomed with pleasure. He had an excellent memory for men and things, was ever cheery and encouraging to younger men, so that he was liked and admired wherever he went.

Preliminary Notice

of Applications for Admission and for Transfer

April 19th, 1926

The By-laws now provide that tne Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of tne record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in May 1926.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council, shall be required to pass an examination before a board of examiners appointed by the council The candidate shall be examined on the theory and practice of engineering with special reference to the branch of engineering in which he has been engaged. This examination may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the first year in such a course, shall be required to pass an examination in the following subjects: geography, history (that of Canada in particular), arithmetic, geometry, euclid (books I, IV and VI), trigonometry, algebra up to and including quadratic equations.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed successfully an examination equivalent to the final examination of a high school or the matriculation of an arts or science course. He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination equal to that prescribed for admission to the grade of Junior in the foregoing section and he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ADDIE—DONALD KYLE, of Montreal, Que., Born at Sherbrooke, Que., Aug. 17th, 1902; Educ., B.Sc., McGill Univ. 1925; about 3 yrs. machine shop and foundry apptceship; 5th engr. S.S. "Cabotia", Anchor-Donaldson Line, 1921; engrg. staff Price Bros., Kenogami (summer) 1923; engr. i/c survey 2nd power transmission line between St. Joseph d'Alma and Kenogami with Grande Decharge Development, 1924; at present mech. engr. and at times night supt. with Dom. Glass Co. Ltd., Point St. Charles factory.

FOR TRANSFER FROM CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

BOWNESS—ERNEST WILLIAM, Edmonton, Alta., Born at Kensington, P.E.I., Aug. 12th, 1878; Educ. B.Sc., McGill Univ. 1905; 1903 (summer) studied hydro-elect. and elect. ry. installations in Europe; 1904 (summer), Pittsburgh shops of Westinghouse Elect. & Mfg. Co.; 1905-07, lecturer in engrg. Case School of Applied Science, Cleveland, Ohio, also consltg. and testing work for Cleveland firms; 1907, with Chas. Mitchell, on survey and report of water power devel. on Bow River and tribs.; 1908, survey and report of Seven Falls and Chaudiere Basin hydro elect. dev. for C. H. Grant, also consltg. work re choosing of motor equipment and extensions, and later, valuation of Levis City Ry.; 1909, engr. and salesman in Vancouver office of Can. Westinghouse Co., later mgr. of Calgary office; 1910, in B.C. office of Smith, Kerry & Chase i/c hydro-elect. work; 1911, report on Mt. Hood Ry. & Power Co. hydro-elect. steam and elect. Ry. scheme in Portland, Ore., later engr. and mgr. of light and power dept., organized and i/c of new business, line operating publicity divs., etc.; 1912, employed by North-western Elect. Co. re Salmon River dev.; 1912-14, efficiency engr. for Edmonton, Alta.; 1914-18, mgr. and engr. Edmonton Power Co.; 1918-19, exam. and report with estimates on N.S. water powers for New Glasgow plant of N.S. Steel Co.; 1919-23, consltg. engr. in Edmonton; 1924, misc. work including report on proposed steam elect. plant for Edmonton; at present, consltg. engr. for International Utilities Corp. of N.Y.

Modern Problems of Synchronous Converters

An outline of recent developments and means adopted to overcome various problems

E. B. Shand,

Power Engineering Department, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, April 1st, 1926.

The engineering development of the synchronous converter may be said to date from the early nineties of the last century so that it can be considered as having had over thirty years of existence. The converter, combining as it does the functions of both a d.c. generator and a synchronous motor, is in principle a more complicated piece of apparatus than the electrical machines being built in this early period, so that it is not surprising to find that some of the problems encountered in its development were found to be particularly difficult. As an instance of this the "hunting" problem might be mentioned.

The action of hunting in a synchronous converter is essentially the same as in a synchronous generator or motor, but it proved very baffling for a long time in the case of the former machine on account of the complication resulting from commutation. In the alternating current machines a limiting amount of hunting might result in no great disadvantage, but when the converter hunted even with slight magnitude it was invariably accompanied with sparking at the brushes. It is frequently possible to follow the oscillation of hunting from the fluctuations of the visible sparking at the d.c. brushes. The general phase of the trouble due to hunting was solved with the introduction of an efficient system of damper windings in the pole-faces of the converter and with the greatly decreased use of the reciprocating prime-mover which imparted its speed fluctuations to the frequency of the electrical energy supplied to the converter.

Flashing*

Another problem, closely related to that of hunting, still remained; this was the problem of flashing at the commutator. Railway converters of the order of 600 volts d.c., gave by far the most trouble of this sort, and those operating on 60 cycles more than those of 25 cycles. The most frequent cause of flashing is due to heavy and sudden overloads caused by short-circuits on the d.c. load circuit. These faults are almost always on the trolley wire or somewhere in the car equipment, so that if feeders between the substation bus and the trolley wire are of sufficient resistance the load surge will be limited thereby. For a considerable period these long feeders seemed to be the most effective, but there came an insistent demand for a converter which would withstand more severe overloads. As a consequence a very considerable amount of work was done investigating the causes of the trouble and the possible remedies for it.

Speaking briefly in this connection it may be said that when the converter is operating under normal conditions the electrical input and output are equal, if the small internal losses are neglected, and the relations of the a.c. and d.c. components of current in the armature result in a nice state of balance of its magnetic forces. These forces are not entirely annulled at all places on the periphery but their value at any point will be small. The reactance effects in a converter and the external circuit produces a phase displacement with load, so that when the load on a converter is increased its armature must drop back through a small angle, necessitating a small momentary drop of speed. Conversely, when a load is removed the armature will accelerate forward to a slightly advanced angular position.

In spite of the fact that these angular changes are so small, if they take place in a short period of time as represented by the most severe load surges, the rotational energy liberated or consumed may be comparable with the total load on the machine. In the case of a short circuit almost at the terminals of the converter, it has been found that even for a medium sized machine the initial rate of rise of the direct current may be as great as several million amperes per second, and during such a transient the power output may be furnished in about equal proportions from the a.c. supply system and from the stored kinetic energy of the rotor. This unbalance of electrical power is accompanied by a corresponding unbalance in the magnetic forces of the armature, and the fluxes set up generate high voltages in the coils undergoing commutation. There is this difference,

*E. B. Shand.—An Analytical Investigation of the Causes of Flashing of Synchronous Converters. Trans. A.I.E.E. 1922.

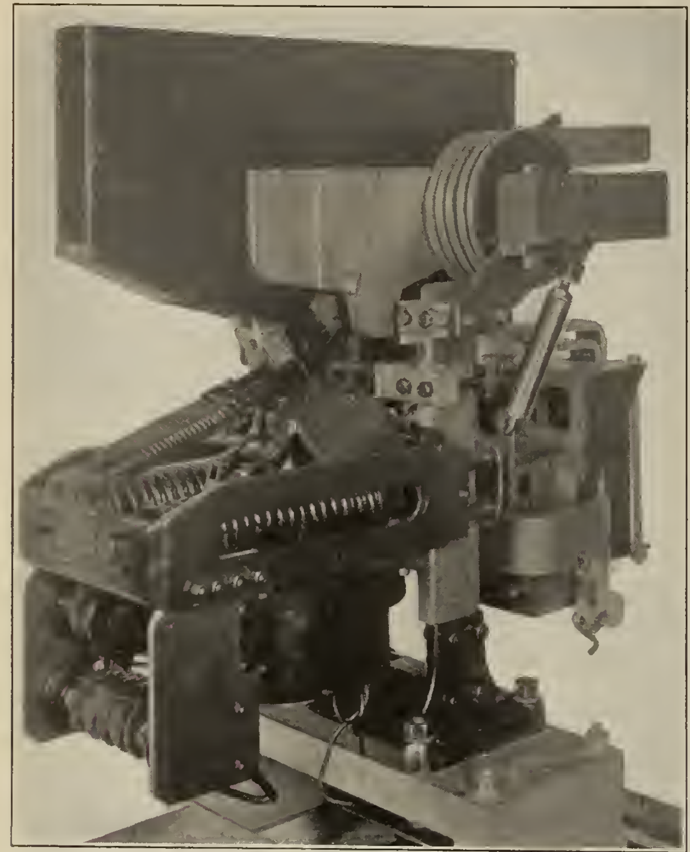

Figure No. 1.—3,000-Ampere, 1,500-Volt, High-Speed Circuit Breaker.

then, between the d.c. generator and the synchronous converter on short-circuit: while the ampere turns of the commutating pole of the former machine always bear the same proportion to those of the armature so that the overload limitation is merely due to the heavy current being commutated, in the case of the converter the resultant ampere-turns of the armature are determined not only by the load current but also by the rate of change of load, for which condition there is no simple means of compensation. These transient conditions add a heavy burden to the commutation requirements of the converter which are not found in the d.c. generators.

It has been found from actual investigation that the commutating voltages generated during a transient decrease of load have a much more serious effect in producing flashes than during a transient of increase. This confirms many observations made in service which indicated that the converter usually flashes when the circuit-breaker opens rather than at the instant of maximum current. When a circuit-breaker opens suddenly on short circuit the power input accelerating the rotor may be instantaneously considerably more than the rating of the machine.

In these short transient periods the commutating-poles form low reluctance paths for the unbalanced magnetic forces, and it is probable that commutating conditions would then be much better, if these poles could be suddenly removed and replaced again when the load becomes steady. The high-reluctance commutating-pole constitutes a means of improving the condition. In this arrangement additional air-gaps are used in the magnetic circuit of the commutating-poles. This increases the air-gap reluctance at the critical position, yet by increasing the ampere-turns to the proper amount the advantages of the ordinary commutating-pole on steady loads are retained.

A second means of protection against flashing has been to insulate all vulnerable parts in the vicinity of the commutator. Experiment has demonstrated that if an arc, once having formed on the commutator, cannot pass to any adjacent part of fixed polarity it will be relatively harmless, and that it will not persist beyond the opening of the circuit-breaker. This type of protection is probably of greatest service in preventing momentary flashes from developing into serious flash-overs.

In the type of design here considered a flash barrier has been placed on either side of the brush-arm to protect the brushes and brush mechanism. The cross-connections between brush-arms have been completely insulated. Some time ago it was found the gases developed during the short-circuiting of some of the largest railway converters could short-circuit the brush-holder arms to its supporting ring. To prevent this, very large intervening insulating washers, somewhat dish-shaped, were developed, which increased the creepage distance over the insulation to several times that ordinarily used, and renders this possibility of flashing still more remote.

A large number of the type of converters considered in the above discussion have now been in service over a period of time extensive enough to give definite operating data. They have shown themselves to be a very decided improvement over the converters of ten years ago. It can be stated very conservatively that the newer machines can stand 50 per cent more severe short-circuit conditions than the old ones. Glancing at some standard recommendations for the minimum feeder resistance, that for a 1,000 k.w., 600-volt, 60-cycle railway converter is 0.038 ohms, which will probably correspond to from 2,000 to 3,000 feet of feeder.

The high-speed circuit-breaker for d.c. circuits has been developed as an auxiliary means for the protection of commutating machines from the effects of short-circuits. It is intended for use where the operating conditions are very severe, which usually means that the feeder resistance is much less than that required to give the machine adequate protection. Engineers had been looking for such a circuit-breaker fifteen years ago, but the difficulties were so great in building a practical piece of apparatus that it has been only within the last few years that a thoroughly satisfactory breaker has been developed.

In considering the case of severe short-circuits the d.c. current of the converter builds up at a faster rate than in a corresponding generator, showing that the effective inductance of the converter armature is the smaller. If the circuit-breaker is to give protection under these conditions it must operate quickly enough to limit the current to a safe value only a few thousandths of a second after the short-circuit occurs.

For converters the high-speed circuit-breaker has a second function, viz., to cut off the converter from the short-circuit before the inertia transients have developed. The ordinary type of carbon circuit-breaker will operate in a period of slightly less than one-quarter of a second; and a good high-speed circuit-breaker in less than one-tenth of this time. There is one period of time between these two at which the condition of the inertia transient is most unfavourable, and at which, if the d.c. circuit were quickly interrupted, the tendency to flash due to this cause would be a maximum.

In the types of high-speed circuit-breakers which have been developed both in Europe and America, the ordinary type of mechanical latches have been dispensed with, the breaker being held closed by the pull of an electro-magnet. To trip this device the load current is used to produce a magnetic force to transfer the armature flux to another path, thus releasing the moving contacts. In some cases the

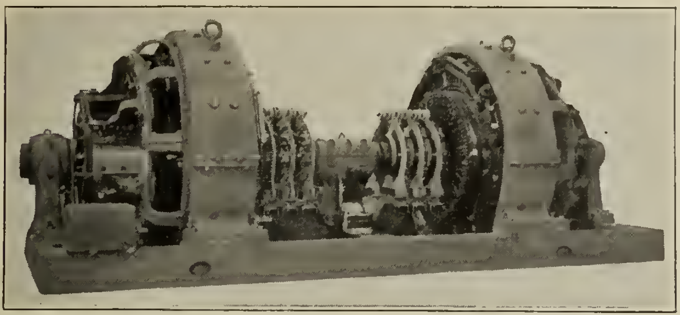

Figure No. 2.—2,000-Kw., 1,500-Volt, 50-Cycle Converter Unit.

speed of this action has been increased by using the inductive surge of the short-circuit current to add to the tripping current. The actual opening of the contacts is accomplished by very powerful springs. Figure No. 1 shows a high-speed circuit-breaker constructed on the basis discussed above. This breaker is rated at 3,000 amperes and for 1,500-volt service.

A series of short-circuit tests were made recently on a synchronous converter intended for severe railway service and to be protected by this circuit-breaker. The converter unit was rated at 2,000 k.w., 1,500 volts, 50 cycles, and it consisted of two 750-volt converters, connected in series and mounted on the same bedplate. Figure No. 2 is a photograph of the complete unit. This arrangement, it might be remarked, differs somewhat from a practice in Europe where a number of single unit converters for 1,500 volts, 50 cycles have been built. It is the opinion here that the more liberal design made possible by using two machines makes the two-unit set more reliable and satisfactory.

In the tests referred to, short-circuits of different severity were thrown on the set, the most severe being a complete short-circuit where the resistance across the terminals of the converter was only that of the cable necessary to connect the apparatus together. Several of these short-circuits were thrown on the machine within a short interval without any apparent distress. An oscillograph record of one of these short-circuits is included here as figure No. 3. The initial rate of current rise is approximately 4 million amperes per second, but the circuit-breaker limits the current to 20,000 amperes in 0.007 second and operates completely in from 0.012 to 0.015 second. The peak value of current is approximately fourteen times the normal rating of the machines, which demonstrates its undoubted capability of carrying heavy load surges.

It should be mentioned that the conditions of these tests are more severe than what may be expected in actual service. The resistance of the short-circuit and the ground return will always be appreciable, and the inductance of the feeder and the trolley wire will always reduce the rate of current rise and assist the breaker. With 1,000 feet of feeder or trolley wire between the machine and the short-circuit the rate of current rise will be reduced to about one-half, giving the apparatus a large margin of safety.

Shunt-Wound Converters

Before leaving the subject of these railway type converters it may be mentioned that, while formerly all converters for this type of service were designed with fairly strong series fields to give flat compounding of voltage when operated from high reactance transformers (usually about 15 per cent reactance), the present tendency is somewhat in favour of shunt-wound converters with transformers of normal reactance, *i.e.*, of the order of 6 per cent or 8 per cent, which will give the converter a drooping voltage characteristic to the extent of about 4 per cent or 5 per cent.

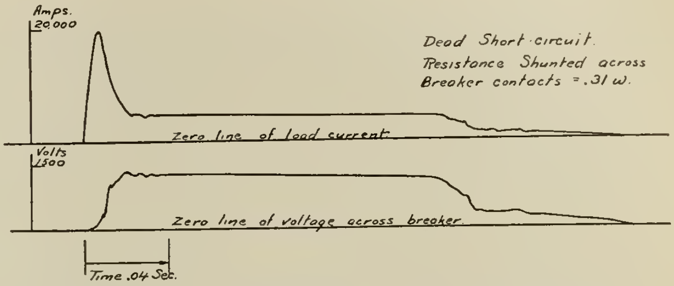

Figure No. 3.—Oscillograph Record of Short-Circuit.

With the low reactance transformers the angular displacements with load will be reduced and with them the kinetic energy transients on short circuits, so that with the low reactance transformers the converters are enabled to withstand heavier momentary overloads. With the changed conditions of operation brought about by the automatic substation and by the tendency to distribute substation capacity even where there are dense traffic conditions, advantages are found for the drooping voltage characteristic. At periods of heavy load on a substation the lowering of the line voltage with the shunt machine will tend to reduce the load taken from it and becomes a protective element. This is sometimes done forcibly in automatic substations by inserting a resistor in series with the converter, but with the shunt-wound converter their use is simplified, as the same result is accomplished inherently to a limited extent in the machine itself.

In heavy city service where it is becoming the practice to feed the trolley network from a number of substations of limited capacity distributed over the area, the shunt voltage characteristic permits a much more equable distribution of load between the substations.

Developments in Starting Converters

The method generally employed to start synchronous converters has been to apply a reduced voltage obtained from taps on the transformer secondaries to the collector rings, and to let the converters come up to speed operating as induction motors. The development of effective damper windings was necessary for the successful application of this

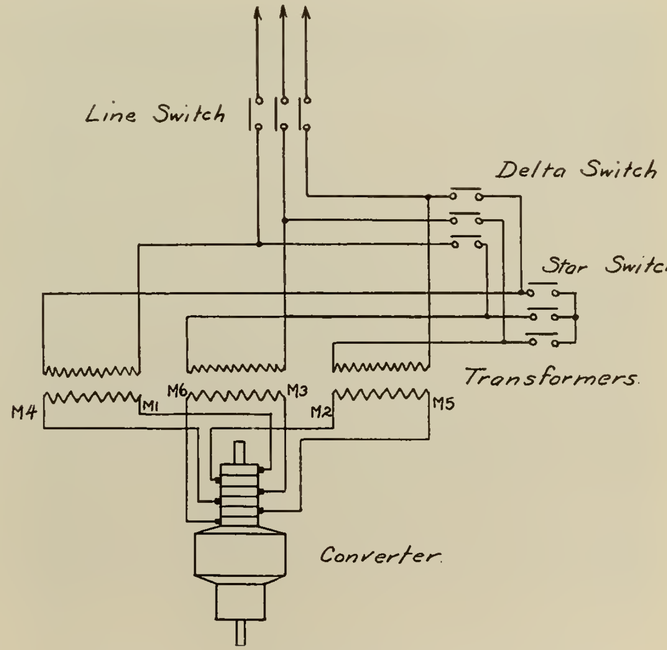

Figure No. 4.—Diagram for Star-Delta Switching.

method. For the large and heavy current machines the starting switches become unwieldy to operate, and the necessity of running an additional set of heavy cables from the transformers to this switch is sometimes undesirable. To obviate these difficulties a system of high tension switching is now frequently used on these machines whereby the transformer primaries are connected in star during the starting period, giving 58 per cent of normal voltage to the collector rings; then for normal operation the primaries are connected in delta. This is known as the "star-delta" system of starting. The starting voltage is usually somewhat higher than would be used with tap-starting, but the converter can be designed so that an excessive starting current will not be drawn from the supply line.

In addition to the main oil circuit-breaker, two other breakers are required to complete the star and delta connections. A simple diagram of the connections is shown in figure No. 4. After the converter is brought up to speed and synchronized in the star connection, the changeover is accomplished by pressing a single push-button which opens the star breaker. The latter is so interlocked that the delta breaker will then close automatically. If the voltage of the converter and the supply voltage are not in phase when the delta switch closes, a very severe surge will result. The usual arrangement is that the full voltage applied to the rings will be 30 electrical degrees behind the corresponding starting voltage. This allows the converter to drop back this amount during the time interval for the switching operation. The coincidence of these angular relations is not always close enough to eliminate the shock, so that it has been found desirable to have some means for eliminating it. Some interesting experimental work has recently been done on this subject by Mr. W. B. Anderson. It was found that a discrepancy of 15 or 20 degrees was sufficient to cause a mechanical shock on a very large converter which was too severe to be permitted in ordinary service. With the aid of the oscillograph, the necessary time delay to be introduced into the switching circuit was predetermined so that the delta switch would be closed at the instant when the converter voltage was in phase with the voltage of the transformer secondary. When this was tried out the changeover could be accomplished without perceptible effect or shock on the converter. The use of such an adjustment will constitute a very appreciable improvement in the starting of the larger converters.

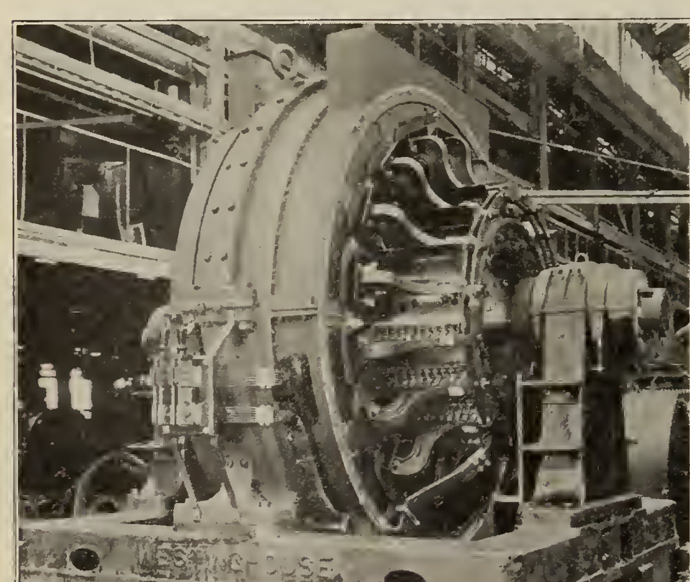

Figure No. 5.—Semi-Enclosed 3,000-Kw., 600-Volt, 60-Cycle Converter.

Ventilation*

Probably the most serious limitation of the rating of electrical machines comes from the rise in temperature of the insulating material. As a consequence the problem of ventilation is one of perennial importance. Several phases of this problem as connected with synchronous converters are of interest at the present time.

In the early stages of the engineering development of the converter it was found that great improvements in the cooling of the machines could be made by increasing the ventilating passages through the armature and field structure and exposing the windings wherever possible to the action of the cooling air. The increases in the ratings of electrical apparatus during this period were very great indeed, although they were not due entirely to this one cause. Somewhat later, however, it was found that very often a large amount of additional air circulation could be obtained without adding materially to the effectiveness of cooling, although the windage loss was increased proportionately. This produced a further development of the type so that although the windings were still left exposed as much as possible, the air was limited in volume but controlled to produce greater efficiency in its cooling action. To accomplish this result it has been necessary to study carefully the relation between the natural circulating paths in the machine and the temperatures of the different parts, and to introduce baffles and blowers to give the proper amount of air where required. When not complicated with the presence of a booster (as in the booster-converter type), it is found that the losses at the front end of the machine are considerably greater than at the rear, so that the former requires more ventilation. This greater loss results from the brush friction and the brush resistance losses on the commutator. Although the commutator temperature might rise to very high temperatures without affecting its mica insulation, such temperatures will produce high stress and consequent mechanical deformations in the commutator which will injure its commutating capabilities. High temperatures will affect the operation of the brushes as well. It is necessary, therefore, that the commutator temperatures be kept within moderate limits. It is frequently found desirable to obstruct the entire opening into the rear of the converter armature so that the cooling air must be taken from the front end, and thus give the commutator and adjacent parts its full benefit. Inclined blowers placed between the armature and commutator have been used to increase the air velocities.

Another condition in connection with ventilation has been that of the recirculation of air in a machine, by which is meant that the air on being expelled from the converter may be sucked in through the machine again, thus raising the air temperature at the intake considerably above that of the surrounding air in station. Although this is generally more serious in connection with motor generator sets with the open type of ventilation it must be given some consideration when arranging the ventilating scheme of a converter.

During the past few years a more general aspect of the ventilation problem has come into prominence; it is that aspect which extends the problem to include the whole substation. There are a number of factors influencing this situation; for instance, the high cost of land and buildings have forced the concentration of large power units into small and often inaccessible spaces, such as the basements of office

*F. T. Hague.—Ventilation and Noise Control of Substation Machinery. Electric Journal, March 1924.

buildings in city districts, where the free access and exit of the cooling air is much restricted. In such cases it has been found that the ambient air may rise to such high temperatures that the full rated load could not be put on the machines without raising the internal temperatures of the insulation above their safe limits, with the additional consideration that the room temperatures would be exceedingly uncomfortable for the operating staff. It has seemed desirable, therefore, to enclose the converters in some way and to bring air ducts from the outside to the machines, or to bring ducts away from the machines to the outside, or to use both ducts to constitute a completely enclosed ventilating system comparable to what is commonly used for turbine-generators.

There are other reasons which render the enclosure of converters desirable; as the first of which might be mentioned the effect of copper dust from the collector-brushes. Although a very real improvement has been made during the past few years in the metal-graphite brushes used on collector rings it is an inherent characteristic that they will give off dust as they wear. If in a heavy current machine the volume of dust given off with a normal rate of wear be calculated, it will be found surprisingly large. Where the natural ventilation can take this dust into the machine it will form a conducting coating on the insulating surfaces and will pack into the interstices of armature coils, interfering with their ventilation. If the air circulation is directed to prevent this dust from entering the armature, a considerable improvement will be effected. Another benefit derived from enclosed machines is the suppression of noise. When machines are located in a business district such as the basement of an office building, it is necessary that the noise be definitely limited. In a residential district a noisy substation will inconvenience the residents, and in the case of an enclosed machine the suppression of noise is considerably simpler than with the open machine.

The conditions met with are so varied, and the development of the art with respect to enclosing converters is so new that no general practice has developed in this connection and each case is considered by itself when investigated from this standpoint. It is natural also that it has happened that the types of enclosures have been evolved through the co-operation of the operators who understand the specific requirements of the installation and the manufacturers who know the capabilities of the converters. It is very obvious that the problem of enclosing a commutating machine is considerably more difficult than a machine like an alternator. However, it has been done with success in a number of installations.

The enclosures of converters may be divided into two general classes, the semi-enclosed and the totally enclosed. The former class consists of those with arrangements for only one duct, usually the exhaust duct, the intake being taken directly from the operating room, and sometimes with the commutator or collector rings exposed. With this last-mentioned arrangement the enclosing parts are simplified considerably, but where the elimination of noise is sought it may not be sufficient, for the commutator noise cannot be suppressed. The semi-enclosed arrangement necessitates large volumes of cooling air to be brought into the station which may result in discomfort to the operators in winter.

An example of this type of enclosure is shown in figure No. 5. The machine is a 60-cycle railway converter rated at 3,000 k.w. The main consideration for enclosing this particular machine was one of high ambient temperature. With 4,000 k.w. of installed capacity the temperature of the substation was found to be uncomfortably warm during the summer months, so that when it was proposed to increase this to 10,000 k.w., some means for carrying away the heated air were deemed necessary. The commutator was left exposed on account of the possibility of flashing with 600-volt machines. The method of enclosure consists in placing end bells of sheet metal on the frame to come down in close proximity with the armature. In addition, the air paths within the armature may be set so that the air will pass into these end bells. The exhaust ducts are fitted both at the top and at the bottom of the frame so that two ducts, one in the basement and one overhead, would be taken outside the substation. The air pressure developed within the machine is sufficient to drive the air through these ducts under ordinary circumstances. In this particular installation noise was not particularly objectionable so that there was no necessity on this account for the complete enclosure of the machine.

Where it is wished to isolate the cooling system entirely from the main body of the substation it is necessary to completely enclose the converter and use both intake and outlet ducts to the outside. This allows the circulation of large volumes of air without affecting the temperature of the substation. It also permits the use of filtering systems which are justified in some cases, the use of external blowers to control the amount of air circulated, and it allows more complete suppression of noise than any other way. The importance of clean air for converters is emphasized when the windings are removed from an armature after its service for a year or two in a dusty district of a city. Many of the smaller passages and the interstices of the winding will be found to be packed solidly with dirt. When a substation is located in a basement it is often necessary to construct such long ducts to the free air that an auxiliary blower has to be used. This is convenient in allowing some control over the amount of air circulated but very frequently the power required is larger than is desirable.

One type of complete enclosure is shown in figure No. 6. The machine is of the booster type for three-wire lighting service and is rated at about 4,000 k.w. The enclosure or housing extends in two main parts from the frame to the bedplate to cover completely both commutator and collector

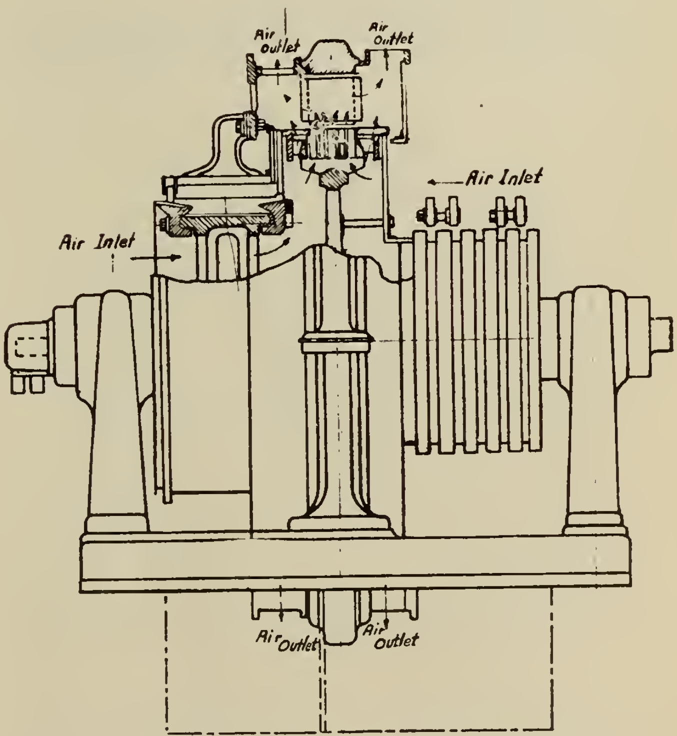

Figure No. 5a.—Details of Semi-Enclosed 3,000-Kw. Railway Converter.

Figure No. 6.—Completely Enclosed Booster Converter.

rings. The brushes on both ends of the machine are made accessible through parts which are furnished with removeable glass covers. In addition a door is furnished on each side of the commutator for further access. The air is led through the intake duct to the pit under the converter and after passing through the machine in the general direction of from the front to the rear it is taken through an overhead exhaust duct over the collector rings.

A somewhat different type of enclosure is indicated in the cross-section view, figure No. 7. It might be described as a housing supported from the machine bedplate or from the floor and large enough to completely cover the machine, frame and all, with space enough inside to allow the operator to make necessary inspections and adjustments. Doors are provided for access to the interior. As in the last-mentioned arrangement the air enters from below the commutator and leaves from above the collector rings. In the particular case shown, considerable care was taken in the placing of baffles within the machine itself as well as in the housing to direct the air and also to prevent recirculation. This has been a carefully considered arrangement and it is believed that it will prove very satisfactory.

A number of other schemes have been tried out but those mentioned above are typical and will give some idea of the tendencies of this development. It is probable that after more experience has been acquired with this phase of ventilation the general arrangement for enclosures will become standardized to some extent but that condition may not be reached for some time. It may be true also that for completely enclosed ventilating systems more study will have to be given to the characteristics of the ventilating system as a whole, considering the converter as one component part of it, for it seems that better efficiencies are yet attainable.

In referring to the noise problem, it may be mentioned that in cases where these closed ventilating systems are used the noise, due to both windage and magnetic causes, may be confined within the ducts, but if the intake or outlet are in the vicinity of other buildings all the noise may be found to be concentrated at some undesired point. Sometimes these ducts can be raised above surrounding buildings, but if not practicable it may be necessary to place baffles of felt or similar material within the ducts to act as mufflers.

In cases where the suppression of noise and not ventilation has been important, a solution has been found by making the whole substation sound proof. The building costs will be increased considerably and it is probable that their use will be found justified only in special cases.

Unbalanced Voltages

Recently some peculiar operating phenomena led to a cursory investigation of the effect of unbalanced voltages on

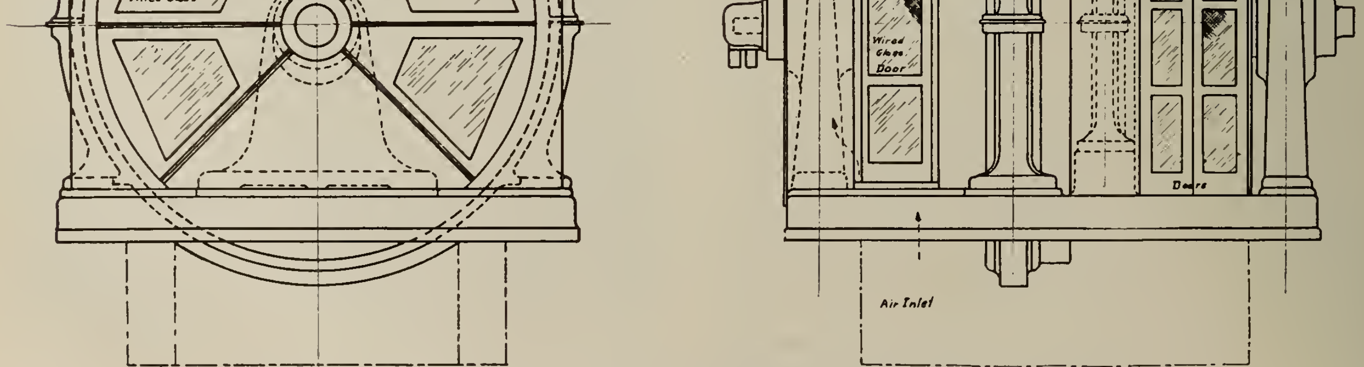

Figure No. 6a.—Details of Completely Enclosed 17,000-Ampere Converter.

a converter. In a large central station system including a high-voltage distribution network which supplies synchronous converters along with other apparatus, it was found that on the occasion of faults on the high tension line the converters were frequently found tripped off the line. Although the momentary drop in voltage might be serious, the fact that converters will operate with full load current on relatively low voltages (25 to 50 per cent of normal), without pulling out of step, this seemed to be precluded as a possible explanation. Further consideration of the problem indicated that the voltage unbalance which exists when such faults occur might furnish an explanation of the phenomenon.

When any balanced electrical machine is connected to a system of unbalanced voltage it immediately tends to act as a phase balancer to the system by circulating large currents through its own windings. The amount of current circulated in this way is proportional to the voltage unbalance and the total impedance of the circuits. Such problems have been attacked satisfactorily by considering the unbalanced system of voltages as made up of two balanced systems, the phase sequence of one system being of normal phase rotation and the other of reverse phase rotation. The relation of the magnitude of the latter system of voltages to that of the former represents definitely the amount of voltage unbalanced. The resulting currents may be treated in the same manner.

The reverse phase rotational quantities of voltage and current bear the ordinary relation to impedance. In the case of machines rotating at, or near, synchronous speed the counter-rotational currents produce a field rotating at double synchronous speed with respect to the stator so that the stator will produce a strong damping action on the fluxes. The result of this is that the impedance to these negative sequence voltages is very low and a small amount of voltage unbalance will produce a large current unbalance. In a series of tests it was found that a voltage unbalance of 17 per cent at the collector rings the unbalanced component of current was 100 per cent of the normal current rating of the machine. It can readily be seen that when disturbances on the a.c. system result in unbalanced voltage all the converters on the system will act as phase converters, taking magnetizing current from the phases of high voltage and delivering it to the phases of low voltage and that when the disturbance is severe enough in character the resulting currents in some of the connections to the converter may be sufficient to operate the overload relay and trip the machine from the line.

Various analyses and tests have been made to show that the effect of unbalanced voltage supplied to an induction motor is to increase the losses seriously. A similar analysis for a converter shows that the effect for this type of apparatus will be still more serious. The well-known effect, under normal conditions of operation when the partial neutralization of the two current components in the converter armature causes a decrease in the loss, is entirely upset. The average armature loss for a given load will be increased while the unequal distribution of the currents in the various phase belts causes the losses at certain points to be relatively greater than the average increase. In the tests referred to above, the 17 per cent voltage unbalance at the collector rings produced additional losses in the machine as determined from input-output measurements to the extent of from 10 per cent to 15 per cent of the full load rating of the converters. The above data indicate that the possibility of unbalanced conditions in the voltage supply, either abnormally or permanently introduce serious complications in the operation of the converter, and therefore they should be carefully guarded against.

Current Collection

The problem of the collection of current is an ever-present one with the synchronous converter, and its gradual progress requires the expenditure of considerable effort. At the present time, however, the requirements are greater than ever before. The difficulties represented in modern commutator construction can be appreciated only when the characteristics of the principal elements, the copper and the mica, are considered. Copper, even when hard-drawn, is much inferior to steel as a material of construction, so that all stresses in the commutator-bar must be kept to a low value.

For very long bars the copper-section must be made large for this purpose. The mica plate is still much less satisfactory. It is not homogeneous but is composed of small flakes bonded together with some such material as shellac. It can be used only in compression, and even here its characteristics are uncertain. These depend largely on the type and amount of bond and on the treatment it has received. It is found, for instance, that when mica plate is subjected to the action of heat and pressure it will take a permanent deformation, and that when the temperature is of moderate value the process may extend over a period of months. In addition to these conditions the operating temperatures will produce unequal expansions of the various component parts of the commutator and it must be provided for that neither excessive stresses nor any undesirable slackness will occur in these temperature cycles. In spite of these limitations the commutator should have a true and smooth surface at all times so that the quality of commutation will not be affected. The conditions met with in the larger converters are considerably more exacting than those found in the ordinary type of direct-current machinery; therefore, the commutator problem is closely connected with converters.

The collection of current from the a.c. side of converters,

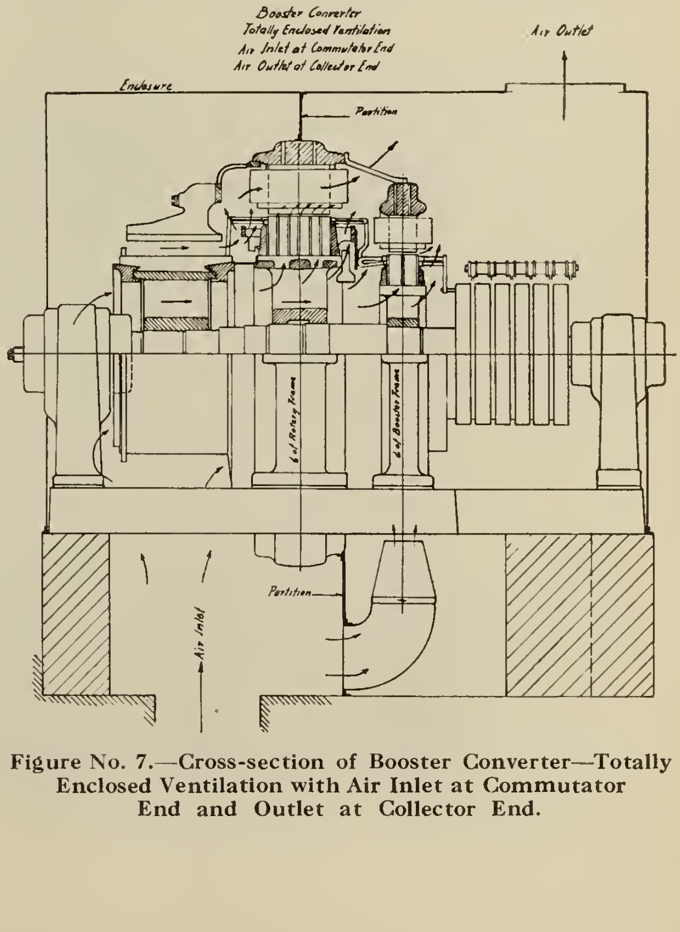

Figure No. 7.—Cross-section of Booster Converter—Totally Enclosed Ventilation with Air Inlet at Commutator End and Outlet at Collector End.

although in general a simpler process than from the d.c. side, has also been the cause of much study. Many details have been arranged to maintain the brushes in close contact with the rings. The metal-graphite brushes ordinarily used on the collector rings are found to be somewhat sensitive to the least sparking or high contact temperatures; thus maintenance of this close contact is found essential to satisfactory operation.

The characteristics of brushes both for collector rings and for commutators are the subject of careful study, for these constitute an important element in the converter.

Automatic Switching

So far as the converter itself is concerned the introduction of automatic and supervisory control has brought about no great fundamental changes in apparatus. A motor-operated brush-lifting mechanism to be used during the starting period and thermostatic bearing relays have been added, but otherwise a converter for this service will be the same as when manually operated. These developments, however, have changed some of the ideas regarding the application of converters. This type of equipment gives the means of reducing the operating costs at expense of capital cost.

Ordinarily it becomes economical to use automatic substations of smaller capacity and to have them distributed to a greater extent. In interurban railway service the substations will be placed at closer intervals to reduce the line copper loss. For service in congested city areas the same advantages of distributing the substation capacity are found, but in addition there has been some tendency to use supervisory control in such cases rather than completely automatic control. With this arrangement these converters may be started and stopped at will with the object of distributing the load to a number of machines that operate at their point of maximum efficiency. If carried to completeness the converting apparatus for the supply of such an area could be remotely controlled from one point with the same ease obtained in a single manually operated substation. With this method it is found that very appreciable economies can be effected in the reduction of the total power losses of the system.

It may be said in conclusion that a limited number of converter problems have been briefly considered in this paper. The synchronous converter is used in a number of highly organized types of application of which the principal ones might be stated as: motive power for railways, three-wire city lighting, mining and industrial applications, of which a very special type of service is encountered in electro-chemical plants. Each of these types of apparatus has certain requirements peculiar to itself, raising special and often new problems to be solved so that the state of the art is never allowed to remain at rest.

Aviation and Modern Engineering Practice

Recent Developments in the Application of Aerial Transportation to Engineering Problems

Wing Commander E. W. Stedman, O.B.E., M.E.I.C.,
Royal Canadian Air Force, Department of National Defence, Canada.

Abstract of paper read before the Montreal and Peterborough Branches of the Engineering Institute of Canada, November 26th, 1925, and February 11th, 1926, respectively.

An engineer has been defined as one whose art and aim is devoted towards the harnessing of the great forces of nature to the use and services of man. In order that an engineer can carry out his work, it is necessary for him to employ methods that have been well established and that he knows will give him the desired results. It is, however, necessary for each engineer to consider continually whether the methods that he is using take advantage of all the most recent advances made by other people, and in fact whether his methods can be called modern engineering practice.

The object of this paper is to set out some of the facts concerning aviation, showing the work that has been done, and outlining the work that the author thinks can be done by aviation for engineers, in the hope that it may prove the first stepping stone by interesting more engineers in this line of development and lead them to investigate whether they also can use aviation with advantage in their work.

Engineers in aircraft work at the end of the war were convinced that, if properly developed, photographic surveying from the air could be carried out, and in order to convince professional surveyors, they undertook a certain amount of photographic work for this purpose, with the result that very soon the professional surveyors took this work up with enthusiasm, and very valuable results were soon achieved.

It is a question for each engineer to consider carefully, and to decide for himself, whether or not aircraft can be used for his work, particularly in view of the valuable work being done by aircraft for other branches of engineering.

Transportation

In Europe one of the most obvious uses of aviation was the provision of transportation between centres of dense population, and the London-Paris route was particularly attractive, because in ordinary circumstances this journey involved changing from railway to steamboat and back to railway.

For successful air transportation, run on schedule, a ground organization is just as necessary as for any other means of transportation. The aerodromes, beacons, radio communication, emergency landing grounds, etc., are all of as much importance as railroad tracks, stations, signals, etc., are in railway transportation, and until these ground facilities are provided aircraft are as useless for passenger transportation as automobiles would have been before the advent of the hard road.

The usefulness of air transportation has been well demonstrated by the subsidized routes in Europe, but the development of air transportation must be handled by large corporations, comparable with the railway companies, and preferably by corporations already specializing in the transportation business.

The only air route operated regularly in Canada was established by the Laurentide Air Service in 1924 to run from Haileybury, Ont., to the Rouyn gold fields. This route was run with great reliability and was much used by mining engineers, prospectors, and others, and also for the conveyance of telegrams, letters and goods. It was continued this year by Captain Broatch.

Transportation by air can be extended to goods, express matter and mail. A good example of the latter is the United States Air Mail which has been run with conspicuous success, and is now being made to include long stages flown at night.

Another useful air transportation service is that to be found in Quebec where the Dominion Aerial Exploration Company (now known as Canada Airways Limited) has carried out a good deal of work during the past summer. This company operating for Messrs. J. D. Lacey and Company, provided air transportation for forest surveys and the sketching of timber types over the limits of Messrs. J. R. Booth and Company. The fact that an established company, such as Messrs. J. D. Lacey and Company, noted for its conservative policy, should decide to adopt aircraft as an assistance in carrying out forest surveys indicates that aircraft have a definite place in this work.

A similar operation was carried out by the Dominion Aerial Exploration Company for Mr. Thomas Maher in connection with a cruise over the timber limits recently obtained by the Port Alfred Pulp and Paper Corporation. The same company made a general reconnaissance for the Department of Lands and Forests of the province of Quebec, covering 20,000 square miles, during which the general waterways and timber types were sketched.

The same company provided transportation for Mr. Henri Boulanger in connection with a ground survey of the headwaters of the Hamilton river watershed on the Labrador slopes in northern Quebec. In this case aircraft were provided for the purpose of taking provisions from Seven Islands up to an advanced base at Lac Ashuanipi. Over 12,000 pounds of goods were transported in this way and thus saved twenty-four portages, one of which was ten miles long. The work was estimated to take three months by canoe, whereas by employing aircraft, the main party went in light by canoe and made the journey in three weeks. Upon their arrival at the base, they found that 8,500 pounds of provisions and gear had already been delivered. The balance of the year's supply was delivered by air within two weeks, and during that time the party had received two visits from their chief. It is to be remarked that there were no losses by the air transportation, whereas it is usual to allow for a considerable percentage of material lost when taken by canoe.

In passing, it is only necessary to mention that aircraft transportation can be usefully employed by persons engaged upon *geological reconnaissance*, because changes in formation can be easily recognized from the air.

Under this heading for transportation, mention must be made of the fishery patrols. Some considerable success has attended this comparatively new line. The patrols seek out the fishing boats and observe that the fishery laws relating to time of fishing, length of net, etc., are observed.

Another regular use of aircraft has been in the payment of treaty money to the Indians, thereby saving a great deal of time and labour in visiting the many remote posts.

Vertical Photography

One of the most important developments in aerial photography has been the production of vertical photographs. Useful applications are for purposes such as city planning where many easily recognized points in the city have already been accurately mapped. By using these known points the material appearing in the photographs can be plotted on the maps.

A similar application is in city tax revisals where a series of vertical photographs taken over the city give at once an indication of all alterations to city properties since the last assessment. The increased taxes so collected offset many times the cost of the photographs. The Fairchild Aerial Surveys (who have also a company in Canada) have completed some very successful work along this line in Connecticut.

Figure No. 1.—Aeroplane View of Power Plant, Pointe du Bois, Man.

Vertical photographs are also used for such things as plant layouts, traffic studies, navigation charts, harbour studies, water power development, flood control, etc. Examples of these are also supplied by the Fairchild Aerial Surveys, Inc. For instance, the Alabama Power Company mapped last year about 500 square miles of the Tallapoosa River valley and used the maps before the Federal Power Commission in making application for permits for several water power developments; harbour surveys have been made of the harbours of Mobile, New Orleans and Boston; city maps have been made of Kansas City, Newark and New York City; a traffic study map of the heart of Los Angeles was made for the Automobile Club of Southern California; a flood control map was made of the Colorado River delta covering about 325 square miles of waste land subject to shifting channel conditions.

Vertical photographs show clearly all sand bars in rivers and such photographs would be of great assistance in producing navigation charts of rivers subject to changing sand bars.

In Canada the Fairchild Aerial Surveys have photographed 400 square miles for the Topographical Survey Branch, Department of the Interior, and have partially finished 2,000 square miles for the province of Quebec, this latter consisting of a vertical photographic traverse filled in by sketching. They have also completed 400 square miles of photographic map for the Quebec Streams Commission.

Preliminary railway surveys can be quickly made by means of contoured aerial photographs. Messrs. Brock and Weymouth are engaged upon this work in Canada with considerable success. Two contour maps have been supplied for use of the Canadian National Railway for preliminary location. These maps had a horizontal scale of 400 feet to the inch with 20 feet interval and 10 feet interval contours respectively. This company is now working upon a map for use in connection with power development in the Saguenay, and this map will have a horizontal scale of 500 feet to the inch and 10 feet interval contours.

Oblique Photography

The most important use of oblique photography at the present time is in the method of preliminary mapping as developed by Mr. Narraway.

The essential thing about this method, which is best suited to flat country, is that the aircraft should fly at a predetermined height over the country to be mapped and take a series of oblique photographs, which include the horizon. It is usual to take one view forward and then one to each side.

The photographs so obtained are used by a land party whose duty it is to locate certain well marked points on each photograph, but also the photographs are used as a guide to indicate to the ground party the route to be taken. In this way the party can pass quickly through the country locating a few points as they go. By plotting the located points and applying a system of grids it is easy to plot the details of each of the photographs and so produce quickly a preliminary map.

There are many good points about this method which are not apparent at first. In the ordinary ground map a white space does not mean blank ground, but merely that that part has not been covered; on an air map all the ground has been covered and a white space means that there is nothing there. Also it is possible to indicate in the air map the nature of the top cover as this can be recognized from the photographs. The Oisean sheet is an excellent example of a map produced by this method.

Other uses of oblique photographs are for timber cruising, for distinguishing different timber types, for preparation of navigation charts and for such things as views of power plants, factories, bridges, dams, wharves, piers, etc. (See figure No. 1.)

A use for these photographs that has no small value is

Figure No. 2.—Aeroplane View of Mount Assiniboine.

for advertising, such as photographic scenes of mountains along a railway route. (See figure No. 2.)

DUSTING

Messrs. Huff Daland and Company have conducted experiments in conjunction with the United States Board of Agriculture and have demonstrated that dusting of cotton plantations with calcium arsenate as protection against the boll weevil can be more effectively carried out by the use of an aeroplane than by any other method.

The method used is to carry a hopper of the poison in an aeroplane and fly low over the cotton fields. As soon as the beginning of a cotton field is reached, the discharge of the hopper is opened and the dust allowed to fall out. The stream of dust is scattered by the blast from the propeller and driven downwards into the cotton plant. This method can be used for the protection of other forms of crops and of trees.

FOREST FIRE PROTECTION

During the past few years, a great deal of work has been done upon the use of aircraft for forest fire protection. The organization of the Royal Canadian Air Force is used for fire detection and suppression in the lake Winnipeg district where use is made of seaplanes or flying boats.

In the forest reserves of the Crow's Nest, Bow River and Clearwater on the eastern slopes of the Rocky Mountains, fire detection is carried out by the Royal Canadian Air Force, using land aircraft with wireless communication. The suppression work is carried out by the usual land service.

Some of the most important forestry work in Canada is carried out by the Ontario Provincial Air Service. In 1924, the Ontario provincial government established its own air service as part of the Forestry Branch, and this service has operated with great success during the last two seasons under the able direction of Captain Maxwell.

The Right Honourable James Lyons, minister of lands and forests (Ontario Government), recently wrote that at the end of last year they were satisfied that the service had proved successful beyond a doubt and that 90 per cent of the fires never got beyond 100 acres due to the fact that as soon as a fire was detected men were placed in a position to control it immediately.

In conclusion, the author desires to say that if anybody wishes to obtain more information upon what has been done or can be done by aircraft, he will be pleased to either advise them himself or put them in touch with people more qualified to advise. Many aircraft are operating in Canada today, and in most cases if an aircraft is operating in a district it can carry out many other duties than it is doing at present with an all round reduction in costs. The Civil Aviation Branch of the Royal Canadian Air Force is in a position and anxious to help co-ordinate this work.

Patents and Inventions

A General Review of the Subject with Details of Requirement under the Canadian Patent Act

Gerald S. Roxburgh, A.M.E.I.C.,
Manager, Fetherstonhaugh & Company, Winnipeg, Man.

Paper presented before the Winnipeg Branch, The Engineering Institute of Canada, December 17th, 1925.

By the creation of monopolies to first and true inventors in the right of using their inventions, a species of property is created in favour of inventors, as a reward for the benefits which they have conferred on humanity, by the exercise of their thought, knowledge, and industry. It is to the interest of the community that persons should be induced to devote their time, energies and resources in furtherance of the development of arts and manufactures, and this was recognized in England at an early period. No measure of reward can be conceived more just or equitable, and bearing a closer relation to the benefit conferred by an inventor, than to grant him the sole right of making, using and vending his invention for a limited period of time.

In the corrupt age of the Stuarts, it is not to be wondered at, that the prerogative of the crown to grant monopoly rights to first and true inventors should have been made a lever for assuming a prerogative to grant monopoly rights in trade generally. To such an extent had this abuse been carried in the reign of James the First that it was deemed advisable by the legislature that the rights of the crown in respect of letters patent should be declared by legislative enactment. This was the origin of the Statute of Monopolies which was given Royal assent on March 24th, 1624.

It has been supposed that the prerogative of the crown to grant letters patent for inventions was created by this statute, but the most cursory perusal of its enactments and of the authorities which preceded it, shows clearly that, so far from the statute giving to the crown any right which it did not previously possess, it had as its intention the limiting the right of the crown, and the declaring of that which had always been the common law upon the subject. In the first section of this act, for instance, we find it recited, " That all monopolies, and all commissions, grants, licenses, charters, and letters patent heretofore made or granted or hereafter to be made or granted . . . . are altogether contrary to the laws of this realm, and so are and shall be utterly void and of none effect, and in no-wise to be put in use or execution."

Notwithstanding the above, section 6 saved the granting of letters patent to inventors in the following words: " Provided also, and be it declared and enacted, that any declaration before mentioned shall not extend to any letters patent and grants of privilege for the term of fourteen years or under, hereafter to be made of the sole working or making of any manner of new manufactures within this realm, to the true and first inventor and inventors of such manufactures, which others at the time of making such letters patent and grants shall not use, so as also they be not contrary to the law, nor mischievous to the State by raising of prices of commodities at home, or hurt of trade, or generally inconvenient; the said fourteen years to be accounted from the date of the first letters patent or grant of such privilege hereafter to be made, but that the same shall be of such force as they should be if this Act had never been made and of none other."

So it is that in the present day, notwithstanding the various statutes which have been passed in relation to letters patent for inventions, these monopolies are still granted upon the mere motion of the sovereign, in the exercise of His royal prerogative, and that all that has been done, has been declaratory of the limits within which that prerogative should be exercised, and of the method of procedure to be adopted in obtaining letters patent for inventions.

The congress of the United States has power to promote the progress of science and useful arts by securing for limited times to inventors the exclusive right to their discoveries, such being set forth in the Constitution of the United States of America, article 1, section A, and this constitutional law is the foundation of the patent laws of the United States. Congress has from time to time enacted certain statutes, the principal enactment being section 4886 of the Revised Statutes of the United States as amended March 3rd, 1897.

Subject to certain conditions and limitations, this section provides that any person who has invented or discovered any new and useful art, machine, manufacture or composition of matter, or any new and useful improvements thereof, may obtain a patent therefor. Statute law identical with this was enforced in the United States since April 10th, 1790, except that the conditions and limitations attending it varied somewhat from time to time and except that compositions of matter were not mentioned in the statute prior to February 21st, 1793, although they were doubtless covered by the word " manufacture " which the early statute contained.

From the above it will be seen that an invention is not found but is created, being the result of original thought. Laws of nature can never be invented by man though they may be discovered by him and when discovered they may be utilized by means of an art, a machine, a manufacture or a composition of matter. It is the invention of one or more of these for the purpose of utilizing a law of nature and not the discovery of that law that may be rewarded with a patent.

The British patent act does not in general affect Canada, except as regards international arrangements for the protection of inventions. The earliest statute on patents found in the legislation of the provinces now constituting the Dominion, is an act of Lower Canada, passed in 1823, termed "An Act to Promote the Progress of Useful Arts in the Province." The first patent act of the province of Upper Canada was passed in 1826 with the same intent. At that time only an inhabitant of the provinces could obtain a patent for an invention and the term was fourteen years.

In 1849, after the union of the provinces, an act was passed to consolidate and amend the laws and patents for invention, and one of the provisions at the time was that the invention must be one not known or used in the provinces by others, and not at the time of the application for patent in public use or on sale in the provinces by others. Shortly after this the Bureau of Agriculture received patent applications.

In 1869 a further act was passed, being the first after Confederation, and the Patent Office was constituted for the first time, the Minister of Agriculture being made the Commissioner of Patents. By this act patents were granted for five years and could be renewed for two further terms of five years, making fifteen years in all. Certain conditions were imposed relative to manufacturing and importing which had to be complied with to maintain the patent in force, and further there was a restriction that the applicant be a resident of Canada for at least one year. In 1872 this latter restriction was removed, so that foreigners could obtain patents on the same terms as Canadians.

In 1892 the term for patents was extended to eighteen years, divided into three six year terms, with a Government fee payable for each six years. Section 7 of this act set forth what constituted an invention and reads: "Any person who has invented any new and useful art, machine, manufacture or composition of matter or any new and useful improvement in any art, machine, manufacture or composition of matter which was not known or used by any other person before his invention thereof, and which has not been in public use or on sale with the consent or the allowance of the inventor thereof for more than one year previous to his application for patent therefor in Canada, may obtain a patent."

The term " any person " included both men and women and foreigners of all description. An application could be made also in joint names where parties were co-inventors.

Principles or Laws of Nature Not Patentable

As before stated, principles or laws of nature are not patentable, although when discovered, they may be utilized and patent obtained. The dividing line is very fine, and a number of very important decisions have been rendered by the Supreme Court of the United States on this question.

One case related to the casting of rollers or cylinders in a mould, it being desirable to give a rotary motion with the object of throwing the flog or dross into the centre instead of the circumference of the casting. The fact that rotary motion would so result was an understood law of nature, an understood operation of centrifugal force. The problem was to produce a motion more conveniently and more uniformly than by stirring the liquid metal with a circular movement of an implement inserted therein. James Harvey solved this problem by discovering that the rotary motion desired could be imparted to melted metal by injecting that metal into a mould tangentially. Litigation arose on the patent and coming before the Supreme Court was held to be a patent for a process.

Samuel Morse, inventor of the telegraph, did not discover either of the laws of nature which he utilized. He did, however, invent a machine by means of which those laws could be utilized to carry information from a distant point. The machine was dependent for success on several laws of nature, and lacking any one of them would have failed. In one claim of his patent he attempted to cover the use of an electric current for making intelligible signs at a distance, and this particular claim was held void by the court.

In connection with the telephone we have likewise the question of the utilization of the laws of nature in a patentable combination. It had been known for centuries that articulate sounds could be produced at a distance from the place where they were originally uttered by means of using two metal diaphragms attached to a tightly drawn cord. Such instruments were called string telephones and they used a law of nature. It had also been discovered by Faraday that when an armature is moved in front of an electro-magnet which is being magnetized by an electric current passing through its coil, the motion modifies the current and that those modifications correspond to the movements of the armature in duration, direction and strength. It was also known that the electric current thus modified would cause corresponding modified movements in the armature of another electro-magnet. In 1876, Dr. Graham Bell invented his telephone with which we are all familiar. That invention consisted in mounting two diaphragms upon two armatures, arranged, combined and movable and enabling one of the armatures to transmit and the other to receive such minute vibrations as those caused in the air by the human voice, and it also consisted in the process of transmitting sounds by causing electrical undulations to occur upon the conducting wire. The Supreme Court held this to be a patent for a process as well as for an apparatus and held the process claim to be valid.

The point it is desired to emphasize is that in the several cases cited, each produces a process which utilized several laws of nature and each of them claimed the entire process he produced, including the use of all those laws, in the order and method described.

What Constitutes an Invention

By far the greater number of patents are for machines and improvements of machines, and these are combinations of mechanical parts or elements; all of the parts of a machine may be old, while the machine as a whole as also the sub-combinations which are contained therein are proper subjects of patent. An improvement in a machine may consist of an addition thereto or a subtraction therefrom, or in substituting for one or more of its parts something different, or in so re-arranging the parts as to make it work better than before.

The distinction between what is a machine and what is a manufacture cannot be stated so that its application will be clear and satisfactory to every mind. However, if an inventor is uncertain, no evil need result, as he does not require to state or know whether the thing he invents is a machine, a manufacture or a composition of matter. It may be laid down, generally speaking, that if a new combination and an arrangement of known elements produces a new and beneficial result never attained before, it is evidence of invention.

There is a distinction between elements in a legitimate combination and what is known as aggregation. A good example of aggregation is the rubber on the end of a lead pencil. While this article was sold by millions, the patent which was obtained was held by the courts to be void, because there was no joint operation performed by the pencil and the rubber.

It is not invention to combine old devices into a new machine without producing any new mode of operation, although, on the other hand an old combination with a new mode of operation may be invention. In Canada and the United States, an applicant must swear that he invented the invention, so that he cannot file an application for a patent on something he did not invent, even though it may be entirely new in the country. In Canada, the applicant must be the first inventor throughout the world and not merely in Canada, and an invention is not new if it has been known or used by any person, and such prior user need not have been in public, nor is publication necessary.

In Great Britain, in so far as novelty is concerned, the question is whether the invention has before the patent been used or published in such a way that it must be said to be in the possession of the public. In the United States novelty is not negatived by prior knowledge and prior use in a foreign country, provided the invention has nowhere been patented to another person, and has nowhere been described in a printed publication. An invention must also have utility, that is, it must be capable of producing a result and that a good result. The patent offices do not enter into the question of efficiency in its ordinary meaning.

Filing an Application

The above gives a brief outline of what constitutes an invention, and in order to protect an invention an inventor has to prepare and file his patent application in the country in which he desires protection.

The application consists of a petition, a specification describing the invention fully and clearly in connection with the drawings, if it can be illustrated, together with a statement of claim, which latter in the average case embodies elements in combination. An oath is also filed, the oath being the same in substance for every inventor, and stating that the applicant is the inventor of the invention and that certain other conditions, as required by the patent act, are true.

There is nothing to prevent an applicant from filing and prosecuting his own application, but unless he is very familiar with the procedure he should employ a competent attorney. The patent office will not select an attorney for an applicant, although a register of attorneys is maintained in the patent office, and in the rules and forms of the patent office the department suggests that the services of an attorney should be obtained.

The fee for filing in Canada is now $15.00 which must be forwarded with the application, and after the patent office has examined the application and the case is ready to be issued, a notice of allowance is sent calling for the final fee of $20.00, which can be paid at any time within six months from the date of the notice. After the final fee is paid, the patent issues in six weeks.

Examination

In the patent office, there are a number of different examining divisions with competent examiners in charge, and the filed application is given a serial number and a filing date and is turned over to the examiner in the division where it logically falls. The examiner's principal business is to see that the applicant obtains no claim for anything which is not new, and any application may accordingly have one or more claims thereof rejected in view of certain earlier or prior patents which are cited. These issued patents are considered by the applicant or his attorney, and if any claim is obviously old, it is withdrawn. However, amendments are permitted in which the claim or claims can be modified to distinguish from the prior cited art and cover what is actually new, and in the amendments, arguments are advanced in support of the claims.

If the examiner finally concludes there is no invention whatever, he rejects the application, and the applicant can then appeal if he so desires. In Canada, the appeal is from the decision of the Commissioner of patents to the Governor-in-Council. In the United States, it is first to the Board of Examiners-in-Chief, then to the Commissioner of Patents, and then to the Court of Appeal of the District of Columbia.

Government Fees, Taxes and Other Obligations

At the present time when one pays the final government fee in either Canada or the United States, the patent is paid up for the full term, that is eighteen years in Canada and seventeen years in the United States. The life of a patent in Great Britain is sixteen years, in Germany eighteen years, in Spain and Belgium twenty years, and in the remaining important foreign countries fifteen years. In some cases the expiration of a patent in one country shortens the life of a patent in another country.

In most European countries there is also a tax payable to the government to maintain the patent in force. In Great Britain one has to pay taxes on the fifth and following years. In France and Germany taxes are payable yearly throughout the life of the patent, and it should be noted that in the latter countries, the patent dates from the date of filing, so that in France and Germany one may have to pay a tax even before the patent has issued.

Outside of these taxes some of the countries impose other requirements relating to manufacture and importation in order to maintain a patent in force. A United States patent once granted has no restriction in this regard. In Canada, until recently, a patent became null and void at the end of two years from the date thereof unless the patentee within that period, or an authorized extension, commenced and after such commencement continuously carried on in Canada the construction or manufacture of the invention in such a manner that any person desiring to use it could obtain it or cause it to be made for him by some manufacturer or establishment in Canada, and further it became void if after the expiration of twelve months from the granting thereof, or an authorized extension of such period, the patentee imported the invention. The extensions mentioned could be obtained by filing a petition setting forth satisfactory reasons for not manufacturing or for importing, and the petition had to be filed within a fixed period. It will be observed that in so far as manufacturing is concerned, the condition which would satisfy the clause was rather indefinite, and the question as to what constituted manufacturing was always a more or less debatable one and rather unsatisfactory to the patentee.

The above mentioned manufacturing clause was a hardship when considered in connection with some types of inventions, such as telephone attachments, street car fenders, attachments to locomotives and other such devices controlled by large public or private corporations, where, obviously, it was useless for a man who had, say, invented a street car fender, to be compelled to manufacture it within a fixed period or lose his rights. Relief was obtained under the compulsory license clause, which permitted any such patentee on an application within six months from the issue of his patent, to file a petition requesting, for reasons set forth, that his patent be brought under the conditions of the said clause. If favourably considered, the commissioner could order that the patent, instead of being subjected to the conditions of the manufacturing clause, could be subject to the following conditions:

"Any person at any time, while the patent continued in force, could apply to the commissioner by petition for a license to make, construct, use and sell the patented invention and the commissioner, hearing the person applying and the owner of the patent, and concluding that the reasonable requirement of the public in reference to the invention had not been satisfied, could make an order under his hand and the seal of the patent office, requiring the owner of the patent to grant a license to the person applying, in such form and upon such terms as to the duration of the license, the amount of royalties, the security of payment and otherwise as he, the commissioner, under the circumstances, deemed just. If the owner of the patent refused or neglected to comply with the commissioner's order within three months, the patent became null and void."

Protection of Inventions Which are Not Perfected

In Canada, one can protect an invention which he has not perfected by filing a caveat, which embodies a description of the invention as far as it has been developed, with or without plans, and by paying a small filing fee. This caveat is preserved in secrecy. Having filed a caveat, the Commissioner of Patents has to advise the applicant if anyone else makes an application for a patent for an invention which would interfere with his claim, and the applicant within three months is required to file a patent application. If it is then found that the applications are conflicting, they are submitted to the arbitration of three skilled persons, each applicant choosing one and the commissioner the third, and the decision of such arbitrators is final in so far as concerns the granting of the patent. The arbitrators can summon any person to appear and compel him to give evidence.

If the caveator does not file a patent application within one year from filing his caveat, the commissioner is released from the obligation of giving notice, and the caveat then remains as a matter of proof as to novelty or priority of invention, if required.

In practice it is found that the greater number of inventions presented have been sufficiently developed, in so far as the basic idea is concerned, to warrant filing a patent application instead of a caveat, as the development required is usually that which one familiar with the art to which the invention appertains could readily suggest in order to make the article better from a manufacturing standpoint, while not adding anything new or patentable.

The average inventor, having filed a caveat, does not usually develop his invention with dispatch, relying on the caveat protection, and obviously this is bad policy, for the reason that he leaves himself open to conflicting applications and the incidental expense and trouble. There are no doubt certain cases which have not been sufficiently developed to warrant a patent application, but caveat protection should be used with discretion. It is interesting to note that caveat protection was available in the United States until a few years ago, when it was withdrawn, and the reason may have been that it was an abused privilege.

Fluctuation in Number of Patents Issued

For a considerable number of years prior to the Great War, there had been very few important changes in the Canadian Patent Act, and from shortly after Confederation up to the year 1914 there had been a steady increase in the number of patents annually taken out in Canada. During the period of the war, there was an initial falling off, as would be expected, then a slight recovery due to war inventions, and then a gradual falling away, which in 1919, the year after the war, had placed the number of patents taken out approximately the same as in the year 1904. In 1921 provision was made by a special act, whereby no patent in force on the 1st day of August 1914, or subsequently granted, should be void through failure to construct or manufacture, or by the importation of, the invention covered by the patent between the said date and the 10th day of January 1922, and further by this act fees which had become payable since the first of August 1914 could be paid at any time until the expiration of a period of one year from the coming into force of the act with the same effect as if paid within the time prescribed. Further, the time for filing applications was extended.

The above concessions naturally resulted in a comparatively large increase in the patents granted in 1921, and when the term for these special privileges expired in 1922, there was a natural rapid falling off in the number of patents issued that year.

In the Act to amend the Patent Act of 1921, a change was made in regard to the payment of the government fees, and the term patent (6, 12 and 18 years) was done away with, the filing fee, previously $20.00, was reduced to $15.00, and when the application was found to be allowable, a notice of allowance was given and the applicant could then pay the final fee at any time within six months; the patent would subsequently issue, and was paid up for the full term of eighteen years. The holding back by applicants of their final fees resulted in a large number of patents being issued in the year 1923, and from 1923 to 1924 there was an apparent falling off but it was really a return to normal.

Residence of Inventors

As regards the countries from which application for Canadian patents originate, it may be noted that from the years 1911 to 1924, United States inventors account for 65 to 78 per cent of the total issue. The percentage of British, German and French inventors filing in Canada is relatively small, so that approximately 15 to 17 per cent are Canadians. Residents of Great Britain, its colonies and possessions, account for 8 to 10 per cent, and the remaining small percentage comes from inventors in some twenty-five other countries.

In 1924 resident Canadian patents were divided as follows:—

Ontario	44 per cent	Manitoba	6 per cent
Quebec	20 per cent	Nova Scotia ..	3 per cent
British Columbia	11 per cent	New Brunswick	1 per cent
Alberta	8 per cent	Prince Edward Is.	a few
Saskatchewan ...	7 per cent		

The question is often asked, how many patents actually make money? The questioner possibly has in mind some person who in his lifetime only took out one patent, and is not thinking of the manufacturer or other business man who is, from time to time, protecting by patent the valuable inventions which are discovered in his business and which really form the foundation on which that business is built.

In the year 1924, the Canadian Consolidated Rubber Company obtained thirty-seven patents; the Canadian General Electric Company, one hundred and three patents; the Canadian Westinghouse Company, one hundred and thirty-one; the International Western Electric Company, one hundred and twenty-five; the International Cash Register Company, thirty-one; the Northern Electric Company, one hundred and one; the United Shoe Machinery Company, fifty-nine. Taking it for granted that the smaller manufacturers are doing likewise, one can conclude that the greater percentage of patents are valuable, and it is accordingly hardly fair, as some do, to judge patent values by the opinion of the casual person, of whom one possibly hears most about, but who represents only a small proportion of the patents actually granted.

In regard to perpetual motion, a considerable number of such devices continue to be presented, and most of them are rather complex. The applicant for this type of patent is usually illiterate, of foreign extraction, and distrustful, and is one of the hardest individuals to convince, as he has usually small knowledge of fundamental mechanical laws. Both the Canadian and United States patent offices will accept applications for such devices, but no patent will be granted until a working model is furnished.

Early Patents

The first Patent Record published in Canada, covering the period from 1824 to 1872, lists the Canadian patents from the beginning of the patent office in June 1824. In this book there are two series of patents, the first series from number one to number 3325, being those in force prior to Confederation. The second series, after Confederation, are numbered from one on and the numbers of the patents at the present time are of this second series.

Generally speaking these earlier patents were what would be expected of individuals working out their destiny in a new country. We find many patents for threshing machines, churns, spinning machines, various farm implements, stoves, boats, water wheels, grist mills, saw mills, fanning mills, cider presses and so forth. Patent No. 12 was the first for a steam engine and was dated June 25th, 1830. Another steam engine occurs in 1839, a rotary steam engine in 1843, a furnace or hot air generator in 1846, an electro-magnetic telegraph in 1847, a hydraulic cement in 1854, a rotary pump in 1857, a Portland cement in 1863, crystallized sugar from Indian corn or other cereal, grain or roots, in 1865, peat fuel in 1865, the manufacturing of peat into coal by process of steam in 1867, a steam injector in 1868, a steam turbine and rotary engine in 1868 and many other interesting devices as time goes on.

From the number of patents taken out on the manufacture of pulp in the earlier days, say between 1854 and 1868, the pulp and paper industry was an important issue even at that time. One by the name of J. Taylor, of Toronto, took out the first patent in 1855 which was a method of manufacturing printing paper from the straw of wheat, oats and the like or from any other kind of straw.

Trend of Inventions 1924

It may be interesting at this time to refer to the report of the Commissioner of Patents relative to the year 1924 wherein he states, "Inventions relating to transportation were more numerous than any other, but land vehicles and accessories, which is the largest single class of invention, declined nearly 30 per cent. Railway appliances and rolling stock were about the same as last year, with the exception of a large increase in draft gear and buffer applications. There were decreases in air and water navigation. Inventions pertaining to agriculture and animal husbandry declined nearly 20 per cent. Applications relating to dyeing, bleaching, chemicals, medicines, fertilizers, metallurgy and electro-chemistry were slightly in excess of last year."

"The interest in wireless communications, especially in the development of vacuum tubes, was well maintained, but there was a marked decrease in telephone applications."

"Woodworking machinery and tools were somewhat greater than last year."

"Printing press and typewriter applications increased. Many of the typewriter applications were directed to the lessening of noise, folding portable machines and bookkeeping machines."

"Pulp and paper making machines and processes increased nearly 50 per cent."

"Steam engines increased slightly but internal combustion motors declined nearly 20 per cent. In this class there was a larger number of inventions for the diesel and semi-diesel type of engine."

"In some other classes such as wooden buildings, metal founding, hoisting machinery, dish washing machines, liquid fuel burners, weaving, cordage manufacture and life preservers there were substantial gains."

Relations of Employee to Employer Regarding Inventions

With regard to the rights of employees in respect to inventions which they have made, it may be stated that employees are entitled to their own inventions and to patents granted therefor, so that in the absence of a contract to the contrary, an employee is entitled to a patent for an invention which he makes even though it may relate to the business of his employer. If he develops the invention in the time and at the expense and with the tools and materials of his employer, then the latter will have an implied license or shop right to use such invention in his business, but he cannot demand an assignment of the patent.

Employers who wish to secure inventions relating to their own business, which are made by others while in their employ, should have a contract with the employee. Even with such a contract the employer cannot apply for a patent in his own name, as it must be applied for by the employee and assigned to the employer. Many large corporations employ regular staffs of experimenters and inventors, and most of these concerns have contracts with these employees which provide that the latter are to assign to the company all inventions made by them in the regular course of their employment. If the employee makes an invention at home or away from the company's plant and out of hours or on something not connected with his regular employment with the company, it belongs to him unless perhaps he has contracted absolutely to assign to his company everything he invents for a certain period. If there is no contract and if the employee has taken out a patent, the employer cannot prevent him from licensing other parties to make, use and sell the patented device, or from selling the patent outright, or from making, using and selling the device himself.

If an employee really invents something of value to his employer, the latter should not feel that he is being "held up" because that employee invokes his legal rights to secure the best advantage from his creation. It should be gratifying at least that the improvement has been made by the employee rather than a competitor.

Recent Important Changes in Act

On September 1st, 1923, the existing Patent Act was, for the greater part, repealed, and in the new Patent Act, which came in force on September 1st, 1923, there were some important changes.

Under the old act, in applying for patent, the applicant had to state that the invention had not been in public use or on sale with his consent or allowance as such inventor for more than *one year* previous to his application for patent therefor in Canada. This now reads *two years*. Previously also one had to make the application within one year from the date of issue of the first foreign patent for the invention. Now, by a recent judgment of the Exchequer Court, sections 7 and 8 of the new act have been interpreted as permitting the filing of an application for patent within two years from the date of issue of the first foreign patent, the other conditions of section 7 being met. It has not been decided whether to appeal from this judgment to the Supreme Court or to amend the section to bring it into accord with the patent office's construction thereof. In the meantime, however, applications coming within the terms of the judgment will be accepted, and will be proceeded with in due course.

The new Act contains a section covering the case where an applicant has agreed in writing to assign a patent, when granted, to another party or to a joint applicant, and refuses to proceed with the application, or a dispute arises between the joint applicants as to proceeding with an application. In such a case the commissioner, upon hearing the parties and concluding that one of them ought to be allowed to proceed alone, can permit this to be done and grant a patent to him.

A further section was added in connection with inventions relating to substances prepared or produced by chemical processes and intended for food or medicine, and it provides that in such cases the specifications shall not include claims for the substance itself, except when prepared or produced by the special methods or processes of manufacture described and claimed, or by their obvious chemical equivalents.

Further, in the case of a patent for an invention intended for, or capable of being used for, the preparation or production of food or medicine, the Commissioner of Patents shall, unless he sees good reason to the contrary, grant to any person applying, a license limited to the use of the invention for the purposes of the preparation or production of food or medicine, but not otherwise, and in settling the terms of the license and the royalty, the commissioner shall have regard to the desirability of making the food or medicine available to the public at the lowest possible price consistent with giving to the inventor due reward for the research leading to the invention. This section, however, only applies to patents granted after the passing of this act.

The previous two-year requirement relative to manufacturing, and the one year permitted for importation, have been done away with, and the act now states that every patentee shall satisfy the reasonable requirements of the public with reference to his patent and to that end shall adequately manufacture the patented article or carry on the patented process within Canada. Anyone, however, may present a petition to the commissioner contending that the requirements of the public have not been satisfied and asking that the patentee be ordered to supply the patented article at a reasonable price, or grant a license for the use of the invention at reasonable terms. If the parties cannot come to an arrangement between themselves, the commissioner shall proceed to hear and determine the matter, and if he concludes that the reasonable requirements of the public have not been satisfied, he can order the patentee to supply the article within reasonable limits at such price as may be fixed by him. There is a provision, however, that the commissioner shall not make such an order before the expiration of three years from the date of the patent. The act also sets forth under what conditions it may be considered that the reasonable requirements of the public have not been satisfied.

Under the present act any one interested, and at any time not less than three years after the date of a patent, may apply to the commissioner for the revocation of the patent on the ground that the patented article or process is manufactured or carried on exclusively or mainly outside Canada to supply the Canadian market with the invention covered by the patent. The commissioner again has the right to hear the parties, and decide the matter, and unless the patentee proves that he is manufacturing to an adequate extent in Canada or gives satisfactory reasons why such is not done, the commissioner may make an order revoking the patent forthwith, or after such reasonable time as may be specified in the order, unless in the meantime it is shown to his satisfaction that the invention or process is being manufactured or carried on within Canada to an adequate extent. If, however, within the limited time set in the order, the manufacturing is not carried on to an adequate extent and the patentee gives satisfactory reasons why it is not, the commissioner can extend the period, but such extension shall not exceed twelve months.

There is also a section which permits the patentee to apply to the commissioner for the restoration of a patent which has become void through the non-payment of fees or failure to construct or manufacture, or on account of the importation of the invention, provided the application is made within two years from the date of such voidance.

If a patent is so restored any person who has constructed, manufactured, used or sold the invention in

Canada during the period of voidance may continue to construct, manufacture, use or sell the invention in as full and ample a manner as if the patent had not been restored and revived.

On September 1st, 1923, Canada's adherence to the International Convention for the Protection of Industrial Proprietory Rights was secured. One of the principal articles of this convention is, that in those countries belonging to the Union, which includes most of the principal countries of the world, a period of priority of twelve months is given, that is to say, where an application is filed in a convention country, twelve months is given in any of the countries belonging to the convention in which to make application for a patent, notwithstanding any publication or use in any country. The benefits of the convention, however, must be claimed when filing the application.

Engineers as a body should give the inventor a kindly hearing, consider his problems and encourage rather than discourage him, for no other group of persons owes so much to inventors as does the engineering profession.

Discussion on The Design of East York Sewers and Their Construction by Contract and Day Labour

Discussion of paper presented by R. O. Wynne-Roberts, M.E.I.C., Consulting Engineer, Toronto, Ont., and Grant R. Jack, A.M.E.I.C., Engineer, Township of East York, before the Annual General Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., January 28th, 1926.

Mr. A. G. Dalzell, M.E.I.C.

Mr. Dalzell remarked that it is the function of the engineer to use the right materials in the right way and place, and in the most economical manner, and that it would some day be realized that it is also his function to see that his fellowmen are rightly and economically placed when new communities are formed, so that they reap the greatest advantages at the lowest cost.

The citizens of the township of East York and the citizens of Toronto forming essentially one community, it was impossible to distinguish the boundary line that formed the political division, but because of this division the citizens of the township had been forced to construct a combined sewer system against the natural drainage flow, and to take their sewage for treatment and disposal to a site miles away from the logical outfall.

It was well known that the designers of the system did all they could to find a better solution, but because the authorities that govern the separate communities, comprising what should be the Toronto Metropolitan district, had been unable to establish one joint authority to construct and maintain the larger public utilities, each separate authority had gone its own way. Thus the community would always carry a greater burden of taxation because of the failure to co-operate.

In too many instances new and growing communities that are favoured with easy means of sewage disposal embarked on sewer construction without proper plans, or study of the whole area. Inefficient sewers and futile expenditures were the inevitable result. In this case the whole area had been carefully studied, and a system of sewers designed and largely constructed which appeared to be entirely adequate.

The methods of construction appeared to conform to the best modern standards, though the designers had perhaps been obliged to concede some points to satisfy the desire of the authorities to encourage local labour and local manufacturers. The details of construction showed careful consideration of points that are often overlooked. Manholes were too often regarded as mere peepholes to be used to see if a sewer is working. It was often forgotten that, if they are to serve the purpose of cleaning or clearing a sewer, they should be large enough to allow two men to work, and to stand upright when at the bottom.

The authors' design afforded sufficient headroom but he considered three feet as a better minimum width. In his opinion the horseshoe pattern of manhole step gave a very uncomfortable and insecure hold for the hand, and the staggered placing made footing very precarious. In small manholes a ladder could easily and cheaply be constructed by placing short lengths of galvanized pipe across one angle, giving a better hold for hands and feet, and no obstruction to the dropping of buckets or tools down the manhole.

Consideration should be given in the design of manholes as to the possibility of their being used for the disposal of snow. In many instances the use of sewers was justified, but manholes should be designed and allocated for the purpose. Drop manholes were particularly effective for snow removal.

Drop manholes required to be very carefully constructed or they might be very dangerous traps even for experienced sewer workmen. For large and important manholes he would favour side entrance chambers with access from the sidewalk, particularly in locations where the street car lines intersect.

Mr. Dalzell had had experience with day labour forces, and whilst he did not recommend that all sewer construction should be done in this manner he considered that every municipality is justified in maintaining at least one efficient gang. He had never placed any reliance on cost subdivision as made out by foremen. A forman had quite sufficient to do to supervise his men and keep them working without booking whether a man is pumping or backfilling. A record of the total time spent on the work is all that should be expected.

Cost records would be best secured by employing special cost clerks, or student engineers, and moving them from job to job. Municipal authorities often objected to such an addition to the engineer's payroll, but have proved amenable to reason if it is shown how small is the cost compared to the total expenditure of the work.

He congratulated the authors on the preparation of a concise and interesting paper.

Mr. Geo. Phelps, A.M.E.I.C.

Mr. Phelps remarked that the City of Toronto had had experience of annexing adjoining areas, which had been sewered, but not adequately sewered for ultimate purposes. Should the time arrive when East York becomes a part of the city, there was no reason to fear a repetition of this unsatisfactory condition. East York must necessarily remain for a long time chiefly a residential area, and the run-off curve used by the authors practically parallelled the Toronto curve for residential areas, but was about 30 per cent higher.

Raymond's zone principle was no doubt satisfactory for calculating sewer discharges, particularly if the drainage area were approximately a sector of a circle with the discharge point at the centre. Not infrequently, however, an area was so shaped as to be more nearly a sector with the point of concentration at, and the flow towards, the circumference. In the latter case, the maximum discharge in the sewer would occur near the beginning of a storm, and that part of the area at the upper end of the sewer would have little effect on the maximum discharge.

The direction of travel of a storm in relation to the line of the sewer, which is usually, and almost necessarily, ignored, had a considerable bearing on the rate of concentration, and with such an unknown factor involved, refinements in calculating composite co-efficients of run-off would not appear to be of great value. Storms were often observed to travel in a certain direction, and return in the opposite direction with about equal intensity, perhaps half-an-hour later. If this movement were down the line of sewer in the first case, and up in the second, at the rate of say 10 miles per hour (about 14 feet per second), the maximum rate of flow would be far greater in the first than in the second case.

He was of opinion that an even simpler method of calculating run-off than that adopted by East York and described as Raymond's zone principle, might be adopted for designing such a system with equally reliable results.

In Toronto heavy thunderstorms of about 5 or 10 minutes duration were found to give the worst conditions, and a storm was considered as covering the whole contributory area at a given intensity according to the length of duration, the impermeability being varied for the class of district. The rate corresponding to time of concentration multiplied by the co-efficient of impermeability was taken as the run-off.

In designing trunk sewers the flows were checked at different points on the sewer for different periods of concentration, and the maximum run-off at any point governed the size of the trunk from this point down, irrespective of the total time of concentration from the most remote point of the sewer.

This method, giving a run-off curve for residential areas, following closely at 30 per cent below the East York curve, had been used in Toronto for about seven years and closely checked by gaugings, both of rainfall and sewer discharges, and he was of the opinion that the results given in this way are as near actual conditions as would be obtained by the Raymond or any other method.

As a basis of design, the rainfall rate allowed was:—

Time of concentration		Rate per hour	
0 - 15	minutes	2	inches
15 - 20	do	1.7	do
20 - 30	do	1.5	do
30 - 40	do	1.3	do
40 - 60	do	1.1	do

The co-efficient of impermeability varied from .35 for residential areas to .75 for areas in the centre of the city. In calculations, instead of using a rainfall curve, he had found that stops in the rainfall rates were simpler in application and quite sufficiently accurate, as, in computing run-off, all that could be hoped for was an approximation to actual conditions, which are extremely uncertain and variable.

Mr. H. S. Philips, M.E.I.C.

Mr. Philips had been particularly interested in the solution of the sewerage problems of the East York area, since he had laid out the sewers in the adjacent portion of the city of Toronto.

From a brief examination of the general outline it would appear that the engineers' original scheme of a single westerly treatment plant and a pumping station for the Danforth Park Area was the logical one. He believed that the additional cost of land for a disposal work site would be outbalanced by the saving on deep tunnels constructed northerly through difficult ground.

The authors had accumulated a vast amount of data in determining the intensity curve for use in East York, and he would like to know the probable storm interval covered by this curve. From published records of rainstorms which have occurred in Toronto since 1895, he found that for durations of five to twenty-five minutes the East York curve had been exceeded on two or three occasions. For longer durations the precipitations have been a little greater.

The rainfall intensity for Hamilton, Ont., was represented by the equation of 20-T°-65, with inlet times varying from five to fifteen minutes according to the character of the district, this being considerably higher than the one used by the authors. A Friez rainfall recording gauge had been installed in 1918, and since that time two gauges had been added. The curve adopted had been exceeded once during the last eight years.

The authors did not state the impervious percentage of the district in connection with their run-off per acre, and probably the run-off co-efficients for the pervious and impervious areas which were used in designing the county of York sewers some years ago were adhered to.

Would the authors state whether Y or Tee branches were used on pipe sewers for house connection stubs? While there are some advocates of the Tee branch method, he believed that with pipes properly bedded the Y branch is the better.

He would also ask whether a vitrified brick invert was included in the brick sewers, as a paving brick invert was specified for the monolithic concrete sewers. In the city of Hamilton some of the large sewers which had been constructed recently were of brick work and in some cases of monolithic concrete. Their use had been entirely for storm overflow purposes, and as this entailed only their use on a very small number of days in the year, it had not been considered necessary to build in a special invert to withstand heavy wear. In the combined sewers recently built in Hamilton, some inverts had been lined with a half vitrified pipe and in other cases, with vitrified segment liners.

Referring to the distribution costs for the 15-inch sewer, average 12 feet deep, which was constructed at an average cost of $11.21 per foot in sand and gravel, this cost seemed to be slightly higher than that for sewers in the city of Hamilton, where on Crosthwaite avenue, 1,500 feet of sewer, average depth 11 feet, about one-third each, 12-inch, 15-inch and 18-inch pipe had been laid at an average cost of $7.77 per foot. This work had been done in the winter by relief labour, and about 5 feet of the depth was shale. An adjoining street had been sewered 1,800 feet long by contract in similar ground at a rate of $3.57 per foot; most of the shale in this case had been taken out by a digging machine.

With reference to the design of the standard manhole, he considered that 2 feet 4 inches as the minimum width of manhole was too small, 3 feet being preferable in his opinion. The cities of Toronto and Hamilton were also using frost batter on the upper walls of manholes.

He desired to compliment the authors on their treatment of the difficult problems of rainfall run-off and sewer design, and also on their excellent sewer-cost and design calculation sheets.

Mr. N. MacNicol, Jr.E.I.C.

Mr. MacNicol remarked that the authors had referred to the placing of junctions on trunk sewers at intervals of 25 feet. Where excavation was open cut, connections were encased in concrete and brought to within 12 feet of the surface of ground.

This would appear to be good practice in the particular case referred to in the paper, and also when it is known that a pavement is soon to be laid over the sewer, but that investigation of other situations may advise a different procedure.

When Etobicoke township began laying sewers the matter was given consideration. Some 12½ miles of sewers were to be constructed in the Long Branch district. The survey showed that the average street was 25 per cent built up. Deducting 25 per cent from the total length for street intersection, flankages, etc., the number of junctions which would be required, placing one each way every 25 feet, would be 4,000. Taking 12-inch pipe as average, the cost of a junction was $3.00 and for straight pipe $1.20.

By placing junctions only for existing houses and at every 25 feet fronting vacant lots where sewer was over 18 feet deep, the initial cost had been reduced to $3,050, and an initial expenditure of approximately $4,000 was saved.

After the sewers were completed, connections began and it was found that in measuring for location of junction occasionally both time and junctions were lost. The inability to locate a junction definitely may seem due to carelessness, and this is probably correct to some extent.

Those dealing with the construction of sewers knew, however, that under the best conditions, there are opportunities for errors to creep in, as the records are tabulated by the inspector and pass through the office files.

In his opinion the conditions under which junctions should be installed at the same time as the sewer is constructed were briefly as follows:—

(1) When main sewer is in open cut and over 18 feet deep.

(2) For all depths, when it is known that a pavement is to be laid over the sewer within a year or two.

(3) When the actual location required for a junction can be determined, and it is known that the connection will be used within two years.

In all other cases better results would be obtained, and an economy effected, by tapping the main sewer and installing the connection in the location most suitable to the other portion of the service at the time required.

He desired to submit a few data as regards cost in the Long Branch sewer system in the township of Etobicoke, which as previously stated comprised some 12½ miles of sewer, varying in size from 9 inches to 48 inches.

Work was commenced about May 1st, 1924, and completed early in January, 1925. About 15 per cent of the total length was in sandy soil, and 35 per cent in blue clay. On the remaining 50 per cent of the job boulders and solid rock were encountered, the thickness of rock varying from 6 inches to a maximum of 2 feet 6 inches.

The equipment included one trench excavator, three steam shovels, one mechanical back-filler and one air compressor. Some sections of the work were carried out by hand, so that during the bulk of the contract, six separate pipe-laying gangs were working simultaneously. The contractor completed the work in 8 months.

The following table showed the costs of labour and material for the different sizes for depths under or over 10 feet. From the corresponding distribution sheet given by the authors, it would appear that Etobicoke unit costs are low, but it must be remembered that the figures given in the paper were for "day-labour" winter work.

Mr. A. F. Macallum, M.E.I.C.

Mr. Macallum asked for the authors' opinion as to the percentage of water going to the catch-basins upon grades of say, five per cent on paved streets. He knew of a number of cases where most of the water flows over and past catch-basins on such grades and on to another sewer where calculation had not allowed for it. His experience with different formulae for run-off had been that their accuracy is limited and depends on whether the local conditions fit the assumptions used. Under the conditions existing in the northern portion of the country a greater run-off occurs during the spring than at any other season of the year because of the greater amount of impervious area. Not only are areas impervious in the spring season that are not so during the summer and autumn, but the water in these areas will reach the sewers more rapidly.

Mr. Wynne-Roberts' Reply

Mr. R. O. Wynne-Roberts in reply observed that Mr. Dalzell had referred to the need for municipal co-operation in the matter of sewers, which need had been advocated for a long time by the suburban municipalities, but they were often unable to wait for its realization.

LONG BRANCH SEWERS—Cost Data

Size inches	Average Depth		Total length feet	Total Cost		Unit Cost		Total unit cost	Remarks
	Under 10 ft.	Over 10 ft.		Labour	Material	Labour	Material		
9	8.7		23,735	$34,466.81	$10,468.60	$1.45	$ .44	$1.89	About half in sand, the remainder in clay and rock. Blasting continuously.
9		10.5	3,864	7,530.47	1,746.60	1.95	.45	2.40	
10	8.7		1,394	1,815.31	857.22	1.30	.61	1.91	Mostly sand.
10		11.0	890	1,489.90	527.20	1.67	.60	2.27	Hard clay, 2′ rock.
12	8.7		12,839	22,686.67	7,878.70	1.77	.61	2.38	Some sand, remainder clay and rock.
12		11.9	8,949	21,010.13	5,544.40	2.35	.62	3.17	
15	8.6		2,099	2,349.01	2,089.10	1.12	1.00	2.12	Stiff blue clay with stones.
15		12.2	5,783	13,733.21	5,704.50	2.38	.99	3.37	Stiff blue clay, boulders and rock.
18		13.1	98	283.97	166.60	2.89	1.70	4.59	Clay and boulders.
21		11.6	1,467	3,474.24	2,370.00	2.37	1.61	3.98	Clay and ledge rock.
24		13.9	612	1,594.11	1,525.00	2.60	2.50	5.10	Clay and ledge rock.
27		15.7	3,337	33,053.90	7,900.00	9.90	2.37	12.27	Segment block sewer, quick sand.
48		13.4	442	4,692.65	2,608.98	10.62	5.90	16.52	Segment block sewer, stiff blue clay, with some rock.

Mr. Philips had stated that the Toronto run-off is apparently about 30 per cent less than that adopted for East York, but he would point out that in the first case overflow outfalls are available as reliefs, while in the latter no such reliefs are possible. An overflow in the major part of East York would flow down hill into the city, which had to be avoided, hence the provision for a larger run-off. The Toronto computed run-off, however, was low when compared with that of other cities. As it was understood that the time of entry is estimated at about eight minutes, it was not clear how a five-or ten-minute storm can cause any serious surcharging of the sewers. The city records of sewer gauging would be most useful information if they were made available, as very little data had been published in Canada on the subject of storm water flows in sewers.

Mr. Philips had referred to the west outfall which was originally suggested, and enquired if it would be more economical than the present north outfall. The difficulty lay in the prospective great cost of land, and, moreover, it was not desirable to locate the outfall in a developed district. The west outfall would have necessitated tunnels in difficult ground but their aggregate length would have been slightly less than was the case for the northern outfall.

The impermeable area was estimated at 25 to 30 per cent and allowance for the time of entry was 8 to 20 minutes, each depending upon locality.

Inverts of brick sewers are of best shale brick, and in monolithic concrete, paving bricks are used.

Mr. MacNicol's contribution to the discussion was instructive, but there was no portion of East York which is strictly comparable with Long Branch with respect to trench conditions. The typical cost-sheet, which represented one week only, was presented to illustrate the method employed, and not as an example of the cost of the work. The cost of a 15-inch sewer in another section of Woodville avenue, at 10 feet deep was $6.03; whilst another 15-inch sewer, 11 feet 6 inches deep, on a street with less constructional difficulties, cost only $2.14 per foot run. The conditions on Woodville avenue were difficult. One contractor who had to build a tunnel sewer under an adjoining street, under compressed air 23 pounds pressure, also had great difficulties to overcome.

With regard to Mr. Macallum's enquiry about the quantity of water entering catch-basins, although investigations had been made, it was not possible to do more than estimate the flow and allow ample inlet capacities as conditions vary.

In general, he might state that the total cost of the scheme would be about $2,100,000, equivalent to about $1,400 per acre, a figure which is almost as low as under pre-war conditions.

Assuming that the capacity of the sewer system was 30 per cent more than in Toronto, the cost would be about 5 per cent greater.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME IX JUNE 1926 No. 6

Maritime Professional Meeting

Sydney, N.S., August 17th and 18th, 1926

Amendments to By-laws

The amendments to the By-laws proposed by the Legislation and By-laws Committee in 1925, approved by Council on November 17th, and presented to the Annual Meeting in Toronto in January, 1926, were duly sent out for the approval of members by letter ballot returnable April 30th.

The scrutineers have now reported to Council that the affirmative votes in all cases exceeded 75% of the total votes cast.

In accordance with the regulations of the Institute, the amendments thus carry and become effective immediately. A revised edition of the By-laws is therefore being printed, and will be issued to members of the Institute as soon as ready.

The amendments will be found on page 24 of the January number of the Journal.

The Kelvin Medal

Lord Kelvin held the Chair of Natural Philosophy at the University of Glasgow for upwards of fifty years. During his long scientific career he carried out remarkable mathematical and physical investigations which led to his recognition as the foremost physicist and most influential and accomplished scientist of his time.

He was one of the founders of the dynamical theory of heat. In hydro-dynamics he developed and extended the theroy of vortex motions originated by Helmholtz. His last great memoir was entitled "On the Motions of Ether produced by Collisions of Atoms or Molecules containing or not containing Electrons."

Lord Kelvin's form of compass, introduced in 1876, was generally adopted, and is still largely used, especially in the mercantile marine. He served on a committee of the British Association for collecting and collating tidal observations, and invented or suggested three important tidal instruments: a Tide Gauge, a Tide Analyser, and a Tide Predicter. His invention of the sensitive mirror galvanometer, and later, of the siphon recorder, overcame the difficulties of submarine telegraphy. He introduced the "curb" system of signalling and took an active part in the laying of the 1858 cable, and he directed the electrical arrangements of the "Great Eastern" when laying the successful cables of 1865 and 1866.

A large part of his work related to the theory of Electricity and Magnetism. About 1880, he invented the quadrant electrometer and absolute electrometer, and later, the ampere and watt balances. He also introduced for generating stations a recording feeder-log.

He was president of a commission formed in connection with the problem of utilizing the water-power at Niagara Falls.

The Kelvin Medal, in commemoration of Lord Kelvin's work, is awarded triennially by a committee consisting of the Presidents of eight leading Engineering Institutions in Great Britain, and is a mark of distinction in engineering work or investigation of the kinds with which Lord Kelvin was especially identified. It was awarded for the first time in 1920 to Dr. W. C. Unwin, F.R.S., of London, and to Dr. Elihu Thomson of Lynn, Mass., in 1923, and will again be awarded in 1926.

The Council of The Institute, in common with the Councils of all the leading Engineering Societies throughout the world, has been invited to suggest the name of the person deemed by it most worthy to receive the medal for this year, and will consider the matter at an early meeting.

Meetings of Council

MEETING OF MARCH 23RD, 1926

A meeting of Council was held at eight p.m. on Tuesday, March 23rd, Vice-President K. B. Thornton, M.E.I.C., in the chair, and eight members of Council being present.

The report of the Finance Committee was considered, and in connection with it that committee's recommendations as regards a number of special cases of members whose fees are in arrears, and in which requests for extension of credit were made. The resignations of fifteen members were accepted.

The following matters of special business were considered:—

The desirability of publishing in the Journal notes regarding business transacted at Council.

Suggested improvements in the form of certificates of membership.

Arrangements desirable for representation of the Institute and its branches in connection with the forthcoming visit of the delegates of the International Electrotechnical Commission.

Correspondence regarding the action of the Income Tax Commissioners in disallowing deduction of income tax on members' fees to the Institute.

The draft by-laws of the Cape Breton Branch were submitted to Council for approval, and referred to the Legislation and By-laws Committee for consideration and report.

A request from the secretary of the Montreal Board of Trade was considered for the appointment of a representative of the Engineering Institute of Canada on a committee which is to be formed for the purpose of "taking such action as will consolidate public opinion behind a movement for the protection of our waterways, and the restoration of the levels of the Great Lakes and River St. Lawrence, so seriously affected by the Chicago water diversion and other causes." After discussion it was decided in this case that any action which might appear to anticipate the report of the boards of engineers which are now investigating this matter would be inadvisable.

Council approved the personnel of the following committees:

Gzowski Medal and Students' Prizes,
Library and House,
Legislation and By-laws,

and also the lists of officers of the Calgary and Saskatchewan branches for the year 1926-27.

The following elections and transfers were effected:—

Elections

Members	3
Associate Members	13
Juniors	5
Students	10

Transfers

Associate Member to Member	7
Junior to Associate Member	5
Student to Associate Member	10
Student to Junior	14

Forty-three applications for admission and transfer were scrutinized and classified for the ballot returnable April 27th.

Consideration was given to ten special cases in connection with applications involving requests for special consideration or waiving of the Institute's requirements for the Institute's examinations.

The Council rose at eleven forty-five p.m.

Meeting of April 27th, 1926

A meeting of Council was held at eight p.m. on Tuesday, April 27th, Vice-President K. B. Thornton, M.E.I.C., in the chair, and seven members of Council being present.

The monthly report of the Finance Committee was approved, indicating that the expenditure of the Institute up to date had been within the budgeted amounts.

Recommendations of the Finance Committee regarding extension of credit, and removal from the membership list, were approved in connection with thirteen cases, and the resignations of four Associate Members and two Students were accepted. Five applications for re-instatement were considered.

The following matters of special business were dealt with:—

Scrutineers were appointed for the letter ballot re Amendments to By-laws closing on April 30th.

Correspondence with the Cape Breton Branch regarding the Maritime Professional Meeting to be held in Sydney on August 17th and 18th was considered and noted, and an advance authorized to assist the Branch in regard to preliminary expenses.

Correspondence with the Winnipeg Branch regarding the proposed Western Professional Meeting was submitted, and a suggestion that this meeting be held in Estevan jointly with the local sections of the American Institute of Electrical Engineers and the Canadian Institute of Mining and Metallurgy was not approved. Council, while encouraging joint meetings of the Institute's Branches with sections or branches of allied societies, has not adopted the policy of holding general meetings of the Institute jointly with such branches.

A proposed amendment in the by-laws of the Peterborough Branch was submitted, and discussed, dealing with a change in the mode of election of the Branch Executive Committee. This proposal, not being in accordance with the Institute's by-laws, was referred to the sub-committee of Council, which is at present looking into the matter of the divergencies now existing between the by-laws of the various branches.

Mr. W. P. Dobson, M.E.I.C., of the staff of the Hydro-Electric Power Commission of Ontario, was added to the Canadian National Committee of the International Electro-technical Commission.

On the announcement of the death of Sir Alexander Bertram, M.E.I.C., the following resolution was unanimously passed:

> "The Engineering Institute of Canada has suffered a great loss in the death of Major-General Sir Alexander Bertram, for eight years Treasurer of the Institute.
>
> The country mourns a distinguished and public-spirited citizen, Canadian industry a true leader of men, and the engineering profession an eminent and resourceful engineer.
>
> His organizing skill and intimate knowledge of machine-tool design and manufacture were shown not only by the growth and development of the enterprises he directed, but also by his notable achievement in the production of munitions in Canada at a time when these were vitally needed by Great Britain.
>
> Council, in offering its respectful sympathy to the family, desires to mark its appreciation of the man and his work, and particularly of the unselfish and willing service which he gave to The Engineering Institute of Canada for so long a period."

The question of publication from time to time in the Journal of notes regarding business transacted at Council meetings having been considered, it was decided to authorize the publication of such notes.

A list of officers of the Toronto Branch for the year 1926-27 was submitted and approved.

An invitation having been received for the Institute to take part in the Marcelin Berthelot Centenary in Paris, in October, 1927, it was decided to authorize one of the members resident in Paris to act as the Institute's representative provided that this can be arranged for.

The following elections and transfers were effected:

Elections

Students	2

Transfers

Associate Member to Member	2
Junior to Associate Member	8
Student to Associate Member	4
Student to Junior	10

Thirty-one applications for admission and transfer were scrutinized and classified for the ballot returnable May 18th.

Consideration was given to eighteen special cases in connection with applications for admission, each case involving a request for special consideration or waiving of the Institute's requirements for examinations for Associate Member or Junior.

A number of members of the Institute who are in considerable arrears as regards payment of fees, having been notified that their indebtedness must be liquidated by April 1st, and having failed to do so, were removed from the list of members as follows:—

Members	11	Students	35
Associate Members	59	Affiliates	2
Juniors	17		

The Council rose at eleven-thirty p.m.

OBITUARY

Thomas J. Brown, M.E.I.C.

Thomas J. Brown, M.E.I.C., of Sydney Mines, N.S., one of Nova Scotia's most prominent mining engineers and until recently Deputy Minister of Works and Mines in that province, died suddenly at the Victoria General Hospital, Halifax, on May 8th, 1926.

The news of Mr. Brown's untimely death comes as a great shock to his many friends in the engineering profession, particularly in eastern Canada, where he had for so many years been an outstanding figure in industrial life.

The late Mr. Brown was born at Sydney Mines, N.S., on January 24th, 1867, and for nearly forty years he was actively associated with the mining industry, commencing his career as office boy at the General Mining Association at Sydney Mines. At an early date he entered the employ of the Low Point, Barrachois and Lingan Company as paymaster, and in 1894 he was appointed manager of the company, later moving to Victoria Mines as manager of that colliery. In 1895 he was appointed manager of the Caledonia colliery for the Dominion Coal Company, and after a few years in that position he returned to Sydney Mines, having been in charge of the sinking of No. 2 shaft and also manager at Princess Colliery. In 1902 he became general superintendent of the collieries of the Nova Scotia Steel Company and then was transferred to New Glasgow, where he retained his position as general mines superintendent. A few years later Mr. Brown became general manager of the Scotia Steel and Coal properties and he held that position for upwards of fifteen years. He severed his connection with the Scotia concern about 1917 and took charge of the Inverness Coal and Railway Company's properties, but when D. H. MacDougall became president of the Nova Scotia Steel and Coal Company, Mr. Brown rejoined Scotia and again became general superintendent of the Steel and Coal properties.

After the formation of the British Empire Steel Corporation Mr. Brown retired as general superintendent at Sydney Mines and he became president of the Indian Cove Company, and in 1922 he succeeded Hiram Donkin, as Deputy Minister of Works and Mines, holding that post until recently, announcement of his retirement having been made but a few days before his death.

During the past few years Mr. Brown took a very prominent part in seeking to adjust the problems which confronted the coal mining industry in Nova Scotia. His services as an adjuster of difficulties were always sought and few, if any, men who held official posts with the coal operators in Cape Breton were held in higher esteem by the mine workers than the late Mr. Brown.

In its editorial columns of May 8th, 1926, the Halifax Evening Mail pays tribute to the work of the late Mr. Brown and concludes its editorial with: "There was only one 'Tom' Brown; he is gone; and we are all the poorer. For he was an individual, if ever there was one. He never copied; he did things his own way. He was a pioneer and a builder. He blazed new trails, but always loved to go back over the old ones. The blazing of new trails was his work; the exploring of old trails his recreation. He sunk the greatest shaft in this country, but he never forgot the old workings. That was 'Tom' Brown and his career—a career that reached the top of modern efficiency, but still had its roots in other times and other methods."

Mr. Brown was admitted to The Institute as Member on October 24th, 1907.

PERSONALS

Raymond Lanctot, Jr.,E.I.C., who graduated from McGill University with the degree of B.Sc. in 1924, is at present with the Aluminum Company of Canada at Arvida, Que.

Dr. Arthur Surveyer, M.E.I.C., past-president of The Institute, was elected president of the Canadian Club of Montreal at its annual meeting on April 26th, 1926.

P. T. Davies, M.E.I.C., commercial manager, Southern Canada Power Company, was elected first vice-president of the Electrical Club of Montreal at its annual meeting recently.

H. C. Seely, S.E.I.C., who graduated from the University of New Brunswick with the degree of B.Sc. in electrical engineering this spring, is now with the Canadian General Electric Company at Peterborough, Ont.

B. P. Rapley, S.E.I.C., who has until recently been located with the Newfoundland Power & Paper Company at Corner Brook, is now with the Imperial Oil Limited at Sarnia, Ont.

Fraser S. Keith, M.E.I.C., manager of the department of development, Shawinigan Water and Power Company, formerly general secretary of the Institute, has been elected second vice-president of the Electrical Club of Montreal.

C. W. Boast, M.E.I.C., who recently was located at Niagara, Wisc., is with the Spruce Falls Company at Kapuskasing, Ont., as maintenance engineer. Mr. Boast received his degree of B.Sc. from McGill University in 1917.

J. E. Jackson, A.M.E.I.C., is manager of the engineering and surveying for Mr. Guy Kennedy of Detroit, Mich. Mr. Jackson graduated from the University of Toronto in 1909, and received his commission as Ontario and Dominion Land Surveyor in 1911.

A. M. Patience, S.E.I.C., of Toronto, Ont., has resigned from his position as lecturer in radio engineering on the staff of the University of Toronto, and has been appointed chief engineer of the Standard Radio Manufacturing Corporation, Limited, of that city. Mr. Patience received his degree of B.A.Sc. from the University of Toronto in 1924.

A news despatch from Shediac, N.B., contains news that a mountain in the Canadian Rockies has been named after Major C. F. Hanington, M.E.I.C., who is a native of Shediac Cape and a son of the late Hon. Daniel Hanington, for years president of the Legislative Council at Fredericton. In this announcement the Geographic Board of Canada states that Major Hanington was assistant engineer to E. W. Jarvis, in the exploration of the Smoky River Pass in 1875.

J. G. MacLachlan, A.M.E.I.C., division engineer of the Kamloops-Kelowna Lumby line of the Canadian National Railways, has been appointed division engineer of construction, operation, and maintenance, of the Hudson Bay Railway, with headquarters at The Pas, Manitoba. In this position Mr. MacLachlan succeeds the late Mr. R. A. Hazelwood.

Stanley A. Neilson, A.M.E.I.C., who graduated from McGill University in 1916 with the degree of B.Sc., has joined the group department, Montreal Division, Sun Life Assurance Company of Canada. Mr. Neilson, who is chairman of the publicity committee and branch news editor for the Montreal Branch, has been associated for the last four years with the firm of Walter J. Francis & Company, consulting engineers, Montreal.

Dr. A. Frigon, A.M.E.I.C., appointed Head of Electrical Commission in Montreal

Dr. A. Frigon, A.M.E.I.C., director of studies, Ecole Polytechnique and director of technical education in the Province of Quebec, has been appointed chairman of the Electrical Commission of Montreal, succeeding the late Dr. L. A. Herdt. Dr. Frigon is a native of Montreal and was born in that city on March 6th, 1888. He is a graduate of Ecole Polytechnique of Montreal and received his degrees of B.A.Sc., E.E. and C.E. from that University. He has had extensive and varied experience in the electric power industry in Quebec, having been connected with the Montreal Light, Heat and Power Consolidated, the Quebec Public Utilities Commission and various other organizations. He was engaged in private practice in Montreal in the capacity of consulting engineer.

B. S. McKenzie, M.E.I.C., appointed Secretary of C.E.S.A.

B. S. McKenzie, M.E.I.C., has been appointed Secretary of the Canadian Engineering Standards Association at Ottawa, which position became vacant on the appointment of R. J. Durley, M.E.I.C., as general secretary of The Institute.

Mr. McKenzie has had a wide and varied experience in engineering which should be of greatest assistance to him in the carrying out of his new duties.

Mr. McKenzie was born at Almonte, Ont., in 1876. He is a graduate of McGill University, having received his degree of B.A. in 1900 and B.Sc. in 1901. Prior to graduation he was for a short period with the town engineer at Brookline, Mass., and later with Messrs. T. Pringle & Sons, Montreal, on hydro-electric development at Shawinigan Falls, Que. From 1901-07 he was with the bridge department of the Canadian Pacific Railway, rising to the position of chief draughtsman on structural steel. In 1907 and for the following year he was assistant chief engineer with the same company, Eastern Division, engaged on railway and maintenance work. In 1909 he was on the staff of the Quebec Bridge Commission on the final design of that bridge. During 1910-12 he was with the Grand Trunk Railway at Winnipeg as assistant engineer of bridges. In 1912 he entered consulting practice in Winnipeg, specializing on hydro-electric power work, foundations, underpinning, cement testing, structural work, and industrial reports and investigations. In 1920 he discontinued his consulting practice and became construction engineer with the Dryden Paper Company at Dryden, Ontario, engaged on the design and construction of the company's hydro-electric plant, houses and mill extensions. From 1921-23 he was with the Manitoba Power Company as field engineer on the Great Falls development on the Winnipeg River, and in 1923 he moved to Montreal and became consulting engineer with the Dominion Engineering & Inspection Company. Since 1925 he was with the Ottawa-Montreal Power Company on investigations and property surveys.

Mr. McKenzie joined The Engineering Institute of Canada as Student on May 22nd, 1902, and was transferred to Associate Member on April 8th, 1911, and to full membership on April 22nd, 1919. He was on the Council of The Institute in 1920 and was the first chairman of The Institute's committee on the Deterioration of Concrete in Alkali Soils.

F. P. Shearwood, M.E.I.C., appointed Treasurer of The Institute

F. P. Shearwood, M.E.I.C., was appointed treasurer of The Institute at the meeting of Council held on April 27th, succeeding the late Major-General Sir Alex. Bertram. Mr. Shearwood has taken an active interest in The Institute for many years.

He joined The Institute as an Associate Member on April 8th, 1892, and was transferred to Member on November 17, 1904, and was elected to Council in 1909 and again in 1921 and the two succeeding years. In 1923, following the death of president Arthur St. Laurent, when the late Walter J. Francis was called upon to assume the office of president, Mr. Shearwood was also called upon to assume the office of vice-president. In the following year he was elected vice-president for a term of two years. Mr. Shearwood has also been on a number of committees of The Institute. He was

F. P. SHEARWOOD, M.E.I.C.

chairman of the Finance Committee of the Council during the years 1923-4-5, and was appointed a member of that committee following the annual meeting this year.

Mr. Shearwood was born in London, England, on September 2nd, 1866, and was for three years engaged on railway work in Brazil. In September 1887 he entered the employ of the Dominion Bridge Company, where he rapidly rose through junior positions to that of assistant engineer and finally to his present position as chief engineer of the company.

Degree of Doctor of Science Conferred upon E. E. Brydone-Jack, M.E.I.C.

The University of New Brunswick at the Encaenia exercises on May 13th, 1926, honoured the engineering profession when the degree of Doctor of Science was bestowed on E. E. Brydone-Jack, M.E.I.C., of Victoria, B.C.

Dr. Brydone-Jack is a native of Fredericton, N.B., where he was born in 1871. He received his degree of B.A. from the University of New Brunswick in 1891, and his degree of C.E. from the Rensselaer Polytechnic Institute of Troy, N.Y. in 1894. Prior to completing his academic studies he was engaged principally on survey and railway maintenance work. In August of 1894 he joined the staff of the Pottsville Iron & Steel Company, Pottsville, Pa., where he remained for nearly a year as draughtsman. In May 1895 he entered the engineering department of the Pennsylvania Steel Company, Steelton, Pa., resigning in 1898 to accept the position of engineer in charge of the Siebert House branch office of the Keystone Bridge Works at Pittsburgh, Pa. In 1900 he was engineer in charge of detail designing for the Fort Pitt Bridge Works, Canonsburg, Pa.

In September 1901 to February 1905 he became Dean of Engineering Faculty and professor of civil engineering with the University of New Brunswick and from May 1902 to May 1905, he was city engineer for the city of Fredericton. For eight months, from February 1905 to September 1905, he was engineer in charge of the draughting department of the Virginia Bridge and Iron Works, Roanoke, Va. In 1905 he joined the staff of the Dalhousie University, Halifax, as professor of civil engineering, continuing in this position until 1907, when he was consulting engineer for the Canadian Northern Railway and at the same time occupied the position of professor of civil engineering at the University of Manitoba. Since 1907 Dr. Brydone-Jack has been supervising engineer for the Public Works of Canada at Victoria, B.C.

Dr. Brydone-Jack has been a Member of The Engineering Institute of Canada since April 19th, 1906, and is also a member of the American Society of Civil Engineers, the Association of Professional Engineers of Manitoba, and a past-president of the Association of Professional Engineers of British Columbia.

Recent Graduates in Engineering

Congratulations are in order to the following Students of the Institute who have recently completed their courses at the various universities.

University of Alberta

Degree of B.Sc.

Grindley, Frank Llewellyn, B.Sc., (Ci.), Edmonton, Alta.
Hunter, Harry Melville, B.Sc., (Ci.), Calgary, Alta.

University of Toronto

Degree of B.A.Sc.

Chorolsky, Eugene, B.A.Sc., (Ci.), Regina, Sask.
Complin, Edward Reginald, B.A.Sc., (Ci.), Toronto, Ont.
Jennings, George Lorne, B.A.Sc., (Ci.), Toronto, Ont.
Menzies, John Ross, B.A.Sc., (Ci.), Brantford, Ont.
Pearson, John Wallace, B.A.Sc., Toronto, Ont.
Sudden, Edwin Alexander, B.A.Sc., (Ci.), Galt, Ont.

Ecole Polytechnique

Special Prize

Mathieu, Albert, Montreal, Que., The Ernest Cormier Prize.

Degree of B.Sc.

Mathieu, Albert, B.Sc., (Ci.), Montreal, Que.
Lalonde, Jean-Paul, B.Sc., (Ci.), Outremont, Que.

Queen's University

Degree of M.Sc. (with honours)

Boyd, Ivan William, M.Sc., (Me.), Kingston, Ont.

Degree of B.Sc. (with honours)

Roney, Gerald Van Luven, B.Sc., (Ci.), Kingston, Ont.

Degree of B.Sc.

Snyder, Horace Hemstreet, B.Sc., (Me.), Orient Bay, Ont.
Stewart, Harvey Weeden, B.Sc., (El.), Kingston, Ont.

University of New Brunswick

Degree of B.Sc.

Carten, Francis Tracey, B.Sc., (Ci.), Fredericton, N.B.
Foulkes, Thomas, B.Sc., (E.E.), Campbellton, N.B.
Gough, Robin William, B.Sc., (E.E.), Fredericton, N.B.
MacPhail, Gordon Miller, B.Sc., (Ci.), Woodstock, N.B.
Seely, Harold Chipman, B.Sc., (E.E.), Fredericton, N.B.

University of British Columbia

Degree of B.A.Sc.

Buchanan, Thomas G., B.A.Sc., (El.), Vancouver, B.C.
Abernethy, Gordon McKellar, B.A.Sc., (For.), Vancouver, B.C.
Timleck, Curtis James, B.A.Sc., (Me.), New Westminster, B.C.

ELECTIONS AND TRANSFERS

At the meeting of Council held on May 18th, 1926, the following elections and transfers were effected:

Members

CURRY, Angus Downes Mathwin, asst. to consulting naval engr. Dept. of National Defence (Naval Service), Ottawa, Ont.

DOBIE, Robert, mech'l supt., Can. Gen. Elect. Co., Peterborough, Ont.

GILMORE, Ross Earlby, M.A. (McMaster Univ), supt., Fuel Testing Laboratories, Mines Branch, Dept. of Mines, Ottawa, Ont.

PEARSE, Langdon, A.B. (Harvard Coll.), B.Sc. and M.S. (Mass. Inst. of Tech.), sanitary engr., Sanitary Dist. of Chicago, member of firm Pearse, Greeley & Hasen of Chicago, Ill.

Associate Members

BRANDON, Harry Elmer, B.A.Sc. (Univ. of Toronto), station structural and mech. engr. with H.E.P.C., Toronto, Ont.

ELLIS, Frank Dormer, B.A.Sc. (Univ. of Toronto), divnl. engr., constrn. dept., Sterling Appraisal Co. Ltd., Toronto, Ont.

LEGG, Harry Gale, engr. to ch. archt.'s br., Dept. of Public Works, Ottawa, Ont.

MADDOCK, Charles Orville, B.A.Sc. (Univ. of Toronto), building valuation engr., Sterling Appraisal Co. Ltd., Toronto, Ont.

MURRAY, Matthew Randolph, field engr. on constrn. power house and dam, Shawinigan Engrg. Co. Ltd., at St. Narcisse, Que.

SAGAR, William Lister, B.A.Sc. (Univ. of Toronto), mgr., Industrial Laboratories Ltd., also instructor in civ. engrg. structural and municipal, Univ. of Toronto, Toronto, Ont.

SPROULE, John Emdon, B.Sc. (McGill Univ.), Layout and inspection of transmission lines, H.E.P.C., Toronto, Ont.

Juniors

DENNISON, George Henry Edward, office and gen'l. dfting., surveying, etc., with Spanish River Pulp & Paper Mills, Sault Ste. Marie, Ont.

POTTER, Charles Edward, B.A.Sc. (Univ. of Toronto), transitman, Wayagamack Pulp & Paper Co., Three Rivers, Que.

TOYSE, Arthur McFarlen, B.A.Sc. (Univ. of Toronto), dfting. and design on reinf. concrete work with Chapman & Oxley, architects, Toronto, Ont.

Affiliates

KELLNER, Hugh, ch. engr., Windsor Water Works, Windsor, Ont.

LOVE, Leonard Vincent, equipment engr., Ont. Dept. of Highways, Toronto, Ont.

For transfer from Class of Associate Member to that of Member

DeHART, Joseph Bertram, B.Sc. (Civil), M.Sc. (Mining), (McGill Univ.), dist. inspr. of mines, Government of the Pro. of Alberta, Lethbridge, Alta.

KIRKPATRICK, Everett Charles, B.Sc. (McGill Univ.), mech. engr., i/c. design of new plant and in charge operation of power depts. for the Steel Co. of Canada's plants in Montreal, Que.

MacDAIRMID, Archibald Alexander, B.Sc. (McGill Univ.), ch. engr., Price Bros. & Co. Ltd., Kenogami, Que.

YORATH, Christopher James, pres. and mng. director, Can. Western National Gas Light, Heat & Power Co., Northwestern Utilities Ltd., and Gas Production & Transportation Co., Calgary, Alta.

For transfer from the Class of Junior to that of Associate Member

TURTLE, Alfred Claude, shop elec'l. engr., Transcona Shops, C.N.R., Winnipeg, Man.

For Transfer from Class of Student to that of Associate Member

HEARTZ, Richard Edgar, B.Sc. (McGill Univ.), gen'l. office work, Shawinigan Engineering Co., Montreal, Que.

REYNOLDS, William Melville, B.Sc. (Queens Univ.), field engr. on power house constrn., Backus-Brooks Co., Kenora, Ont.

For transfer from class of Student to that of Junior

BURBANK, Jerome Douglas, B.A.Sc. (Univ. of Toronto), elec'l. helper, Can. Nat. Elec. Rys., Niagara, St. Catharines and Toronto Ry., Toronto, Ont.

ELEY, Frederick Charles, B.A.Sc. (Univ. of Toronto), engr., i/c. design proposals and pr. sales, Benjamin Electric Co., Toronto, Ont.

FORSTER, Irwin Hickson, B.A.Sc. (Univ. of Toronto), design work on penstocks, surge tanks, etc., Horton Steel Works, Bridgeburg, Ont.

HANNA, Harold Benjamin, B.Sc. (Queens Univ.), office engr. for W. I. Bishop Ltd., on constrn. of Price Bros. & Co. Ltd., Riverbend Paper Mill, Riverbend, Que.

HEATLEY, A. Harold, B.A.Sc. (Univ. of Toronto), chemist on analytical work, research development and production with Roessler & Hasslacher Chemical Co., Niagara Falls, N.Y.

HIGBEE, John Carveth, B.A.Sc. (Univ. of Toronto), engr. of properties with Clayton C. Townes Co., of Cleveland, at present on Lake Sebring Development at Sebring, Fla., U.S.A.

SMEATON, Victor Charles William, computer, valuation dept., C.N.R., Toronto, Ont.

Proposed Canadian Electrical Code

On May 10th and 11th, the special Committee on Canadian Electrical Code appointed by the Main Committee of the Canadian Engineering Standards Association, convened in Ottawa for a discussion of the preliminary draft of the first portion of such a code, covering proposed Rules and Regulations for Electrical Installations in, on, or over Buildings, using Potentials of 10-5,000 volts. This draft has been prepared by two engineers appointed by the above special committee, as authorized at a meeting in Montreal of that committee, held on May 20th, 1924.

Those present at the meeting were: A. A. Dion, M.E.I.C., Ottawa Electric Company, in the chair; W. P. Dobson, M.E.I.C., and A. G. Hall, representing the Province of Ontario; Lt.-Comdr. C. P. Edwards, A.M.E.I.C., Director of Radio, Department of Marine, Ottawa; H. D. Johnson, representing the wire and cable manufacturers; J. W. Hughes, A.M.E.I.C., electrical engineer, Canadian Pacific Railway Company; J. N. Mochon and S. N. Walsh, A.M.E.I.C., representing the Province of Quebec; E. P. Philip, representing the Telephone Association; Wills Maclachlan, M.E.I.C., consulting electrical engineer, Toronto; John Murphy, M.E.I.C., electrical engineer, Board of Railway Commissioners, Ottawa; C. M. Tait, representing the Canadian Fire Underwriters' Association; W. J. Canada, representing the Underwriters' Laboratories of Canada; W. T. Morrison, representing the National Electric Light Association; W. F. McKnight, A.M.E.I.C., and H. F. Strickland, the compilers of the draft code, and B. Stuart McKenzie, M.E.I.C., secretary of the Canadian Engineering Standards Association, were also present.

Since the meeting on May 20th, 1924, copies of the draft code have been submitted to the various provincial sub-committees and comments received from them. These comments were consolidated and distributed in circular form for further criticism. At the meeting recently held in Ottawa, these criticisms were carefully considered, much discussion ensued, and as a result, the draft is now ready for revision.

It was felt that the regulations covering grounding and radio installations required some further study; special sub-committees have been appointed to go into this, and their findings will be incorporated in the revised draft.

Considerable discussion took place as to the advisability of combining rules covering both fire hazard and personal safety, and it was the consensus of opinion that it would be advisable to combine both in one code, for ease of reference and for convenience in practical use. It was considered that this proposed Canadian code should conform, as far as possible, to the National Electrical code and the National Electrical safety code of the United States, but that there were some conditions in Canada which should not be overlooked and which should be taken care of in the Canadian code. It was therefore agreed to proceed with the publication of Part 1 as soon as possible; while Part 2 (covering standards for construction, specifications and testing of electrical equipment), will be published later, as the draft of this is not yet complete.

It is a somewhat difficult matter to harmonize the views of the different provinces in this work, but it was felt that great progress had been made at this meeting and that it would soon be possible to have in operation in Canada, an electrical code which will eventually be acceptable throughout the country.

The representatives of the National Fire Protection Association and the National Electric Light Association, in attendance at the meeting, reported the progress which had been made by American committees working along similar lines.

An International Standardizing Body

The desirability of forming an international body to develop and perfect industrial standards was recently discussed at an international conference in New York. The immediate stimulus to this movement arose out of several international undertakings of basic importance, the majority of which are in the mechanical industries.

Examples of these are the standardization, on a national scale, of ball bearings, (which is now in large measure an accomplished fact); the harmonizing of European and American screw thread systems upon which interchange and replacement of bolts, nuts and other threaded parts depend; unifying specifications for zinc; and the standardization of gaging methods and limits and fits necessary to interchangeable manufacture and mass production generally.

Electrical questions of the kind have for a number of years been effectively dealt with by a technical body of world-wide scope, the International Electrotechnical Commission. Other matters, however, have been without a similar central body to deal with them.

In spite of the difficulties of distance and exchange, no less than eighteen of the existing twenty national standardizing bodies of the world were represented at the Conference. Australia and Hungary alone were without delegates.

Since the war, bodies such as the Canadian Engineering Standards Association, The British Engineering Standards Association, and the American Engineering Standards Committee have co-operated through periodical conferences of their secretaries, and in this way various subjects have been discussed and partly or wholly worked out within the last three or four years, aside from those in the electrical field which, as already mentioned, have been dealt with by the International Electrotechnical Commission. In the absence of more direct means of securing the required co-operation between the several countries in this work, the national standardizing bodies arranged the necessary co-operation in each of these subjects by correspondence and other informal procedure. Now, however, the scope of the work to be done in the way of agreeing upon international standards has grown so much that a more efficient machinery of co-operation is considered necessary.

A few months ago, C. le Maistre, secretary of the British Engineering Standards Association, in co-operation with W. H. Tromp and G. L. Gerard, secretaries of the Dutch and Belgian associations, respectively, presented a definite proposal for the formation of an international body. This came before each of the national standardizing bodies throughout the world, and has been fully discussed by them. The conference just held was an outcome of this discussion, with a view to developing details of the organization which is to be created.

At the early sessions of the Conference, which opened on Thursday, April 15th, the generally favourable attitude of all the nations concerned toward international co-operation was expressed by the several delegates. Recommendations as to the details of a plan of organization, and the importance of the problem of its relation to the existing International Electrotechnical Commission remain to be thrashed out. The decisions of the Conference are in the form of recommendations to the various national standardizing bodies for final decision after consultation with the industries in their respective countries.

In connection with the Conference, which was held in conjunction with the meeting of the International Electrotechnical Commission, informal technical meetings took place looking toward international uniformity in screw threads, bolts, and nuts, limits and fits for interchangeable manufacture, gears and "preferred numbers."

C. F. Skinner, chairman of the American Engineering Standards Committee, presided, and the delegates were:—

AUSTRIA	P. Brettschneider.
BELGIUM	E. Uytborck.
CANADA	R. J. Durley, M.E.I.C.
CZECHOSLOVAKIA	V. List, B. Rosenbaum.
DENMARK	Represented by Swedish delegates.
FINLAND	Represented by Swedish delegates.
FRANCE	G. J. Darrieus, P. Girault, E. Roth.
GERMANY	Otto Kienzle, A. Maier.
GREAT BRITAIN	L. B. Atkinson, R. E. Crompton, Sir Archibald Denny, Sir Richard Glazebrook, P. Good, C. le Maistre, C. P. Sparks.
HOLLAND	W. H. Tromp.
ITALY	N. Ratti.
JAPAN	M. Y. Inomata, Shoji Konishi.
NORWAY	K. Heiberg.
POLAND	P. Drzewiecki, A. Roginski.
RUSSIA	M. Chatelain, M. Lapiroff-Scoblo, M. Zischievsky.
SWEDEN	A. F. Enstrom, A. Kruse, S. E. Osterberg.
SWITZERLAND	C. Hoenig
UNITED STATES	P. G. Agnew, G. K. Burgess, C. E. Skinne

The Two Great Caissons for the New Canadian Government Graving Dock at Esquimalt, British Columbia

In January, 1925, the Department of Public Works of the Dominion government awarded to Yarrows Ltd., of Esquimalt, B.C., of which N. A. Yarrows, A.M.E.I.C., is general manager, the contract for the construction of the two big steel caissons for the $6,000,000 government graving dock being built in Esquimalt harbour.

Two gates are required due to the fact that the dock is divided into sections, so that the whole dock does not have to be pumped out for a small ship, and also that two vessels can dock and leave, independently of each other.

The arrangement of the sills necessitated the caissons being slightly different in dimensions, but only as far as depth was concerned, so that when in position in their respective berths the top decks would come flush with the coping level. At the same time, they are both adaptable to any of the berths, which arrangement provides for the drydocking of each caisson as a ship, or, in the event of damage to one, the drydock is not rendered out of commission. The caissons are both reversible, so that either side can be accessible for painting, which can be carried out on the drydock side when pumped out.

The principal dimensions of the caissons are as follows:—

Length......	138 feet 6 inches	138 feet 6 inches
Beam........	27 feet	27 feet
Height......	46 feet	49 feet

Figure No. 1.—View of one of the Caissons just prior to Launching.

On being awarded the contract, Yarrows Ltd., entered into an arrangement with the Canadian Bridge Company, of Walkerville, Ontario, for the fabrication of the required steel, and at the same time, all the detail and working drawings and general arrangements were prepared and submitted to the government for approval.

As fabrication proceeded, the material was shipped by rail to Yarrows' yard, a distance of over 2,000 miles, where erection was at once commenced.

Owing to the comparatively limited depth of water, the launching of such an unusual structure, which would draw 21 feet in an upright launching position, presented a problem of an unusual character for the builders to solve. This difficulty was successfully overcome by the unique method of building the caissons on an angle of 30 degrees (as shown by the accompanying figure No. 1), which method proved highly satisfactory with regard to both erection and launching.

The 49-foot caisson was the first to be built, and was launched on December 9th, 1925, and behaved, both during the launching and when in the water, in exact accordance with the builders' calculations. The launching weight was 715 tons and, when in the water, the caisson floated with a list of 23 degrees.

For purposes of stability, 500 tons of concrete ballast, with a depth of 10 feet, is carried in the lower sections between the two end bulkheads; 250 tons bringing the caisson into an upright position.

Each caisson has a total of six decks, No. 1 and No. 2 being superstructure decks. The keel and stems on both sides are fitted with Australian iron bark, 5 inches thick and 24 inches wide, which is adopted for the purpose of making a water-tight joint with the masonry face of the drydock sills; no less than 20 tons of iron bark being required for each gate. This wood, among its other qualifications, is impervious to the attack of the teredo, with which the waters are infested. The only other wood employed in the construction is white oak, which is used for side fenders.

The amount of steel used in each caisson is approximately 1,875,000 pounds, the average thickness of the shell plates being ⅝ inch and ¾ inch, and the decks ½ inch; and as a matter of passing interest nearly 200,000 rivets are used in each gate.

The entire exterior and interior steel surfaces of the caissons are preserved with an application of bituminous solution and enamel, the latter applied hot in the usual manner.

The caissons are each equipped with two vertically operated centrifugal pumps of 1,600 gallons per minute capacity, the suctions being carried into a sump in the concrete ballast. These pumps are each operated by a 20-h.p. alternating current electric motor, located on No. 2 deck, the current being supplied by flexible cable from the dock side.

On the same deck, the inclinometer and depth gauge are installed, together with the necessary starters and resistances for the motors. The hand wheels controlling, through vertical spindles, the opening and shutting of the scuttling, or flooding, valves below, are also on this deck, from which will be seen that the entire operation of the caisson is controlled from deck No. 2. This compartment is painted white, for the sake of appearance and cleanliness, and fourteen portholes are placed on each side for light and air.

The flooding valves are so located that, by their manipulation a fore and aft trim can be maintained when sinking into position.

The total weight of each caisson in completed condition is 1,500 tons. Each draws 28 feet 6 inches of water in light condition, and when flooded, the submerged draft is 45 feet 6 inches in the case of the 49-foot gate and 42 feet 6 inches in the case of the 46-foot caisson.

The first caisson was towed from Yarrows' yard to the drydock, a distance of 300 yards, on February 9th, 1926, and the dock was pumped out for the first time on February 17th, when the gate proved a satisfactory, water-tight fit. The second caisson was successfully launched on April 12th, before a large and representative gathering, including the Lieutenant-Governor of British Columbia. It might be of some interest to mention that when the drydock is pumped out, the caisson has to withstand a total water pressure of 4,700 tons.

The graving dock, which is of the most modern character, is 1,150 feet in length and 149 feet in width. It has a depth of water over the sill at high tide of 40 feet. The pumping plant is electrically operated and can empty, in 3½ hours, the 43,000,000 gallons which the dock contains at high tide.

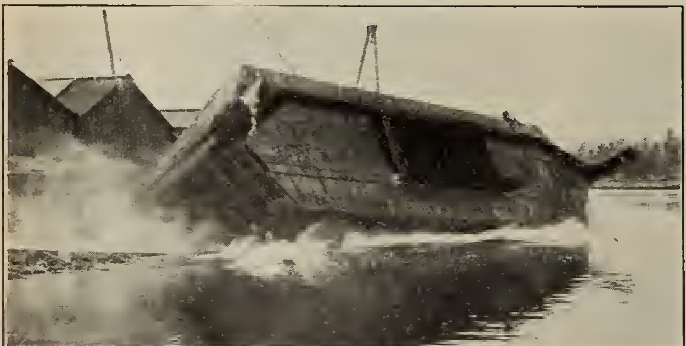

Figure No. 2.—View of one of the Caissons in the act of Striking the Water during Launching.

Figure No. 3.—View of Caisson in place with the Drydock Pumped out.

Lighting and Industrial Efficiency*

The relation between lighting and production is direct and close, for bad lighting hampers output, increases spoilage, leads to accidents, causes eye strain and general fatigue, and leads to irritation, exasperation, and nervous strain. Of the numerous instances which might be quoted of increased output immediately following increased intensity of illumination the following are representative. A study of New York letter handlers showed that in the delivery division, change from 3.3-to 5.9-foot candles resulted in a 19.3 per cent increase in production. Similarly, a production test in an Ohio factory among workers engaged in the inspection of steel parts of roller bearings showed that with 5-foot candles 407 pieces were inspected each hour; with 6-foot candles, 424; with 13-foot candles, 440; and with 20-foot candles, 458. Further, the gain was chiefly net gain for it was estimated that the added cost of current and lamp renewals, etc., took away no more than one-fifth of the increased effectiveness. On this point, the net gain resulting from increased intensity of illumination, a study in certain English factories showed that while the cost of improvement amounted to 1.9 per cent. of the pay roll the increased production amounted to 15.5 per cent. The very conservative conclusion of the Commonwealth Edison Company of Chicago after an investigation of 93 factories was that increased cost of lighting amounting to not more that 5 per cent. of the pay roll would lead to an increased oroduction of 15 per cent. As a corollary to such findings laboratory experiments have shown conclusively that speed of vision is dependent on intensity of light. Just as with the camera dim light necessitates longer exposure, so with the human eye. Thus in operations which are visually controlled the greater the light, within certain limits, the greater the speed.

As regards the relation of light to accidents, the National Safety Council report that a careful analysis of 91,000 accidents showed that 24 per cent were due either wholly or in part to poor lighting.

Natural and Artificial Lighting

Natural lighting is more important than artificial lighting because it is normally available during from 65 to 75 per cent of the working time, and since it involves fewer shadows and less glare. Apart from direct sunlight the greater the quantity of natural light the better. Windows, therefore, should be as many as possible, subject to other considerations, and should be set as close to the ceilings as possible, top light being much more effective than bottom light. Given enough windows, efficient natural illumination depends on three very simple points: First, the windows must be kept clean, since even when far from obviously dirty 50 per cent of light may be being obstructed. Second, they must be free from obstruction by articles piled on the sills. Third, walls and ceilings should be light in colour and should be kept clean so that their reflection value may be utilized. It is a striking fact that the contrast between intensity of light out of doors and light indoors is enormous. Even with good window space, daylight illumination in the middle of a room is only about one-thousandth of the outdoor illumination.

The Main Factors in Good Artificial Lighting

The main factors upon which a good lighting system depends are the following:—

1. Degree of illumination—that is the number of foot candles provided.
2. Brightness, which is dependent both on the degree of illumination provided and the reflecting capacity of the material worked on, and the surroundings.
3. The angle at which light sources are placed.
4. Avoidance of glare.
5. Avoidance of shadows.
6. Maintenance.

In planning any lighting system all these points must be considered together. It is useless, for instance, to provide high illumination but ignore the other factors.

Degree of Illumination

The illumination requirements of different processes vary enormously and ought to be individually considered. There are many codes for industrial lighting which lay down minimum standards for various roughly classified purposes. For example the present New York code sets the following requirements:—

Foot-candles at Floor Level—Modern Practice

1. Roadways and yard thoroughfares	0.05 to 0.25
2. Storage	0.50 " 1.00
3. Stairs, stairways, halls, hallways, passage ways, aisles, exits, elevator entrances, and elevator cars	1.00 " 2.00
4. Work not requiring discrimination of detail	1.00 " 2.00
5. Rough manufacturing requiring discrimination of detail	2.00 " 4.00
6. Rough manufacturing requiring closer discrimination of detail	3.00 to 6.00
7. Fine manufacturing	4.00 " 8.00
8. Special cases of fine work	7.00 " 15.00

In England the Departmental Committee on Lighting in Factories and Workshops has suggested the following standards:—

(a) 5 foot-candles for very fine processes.
(b) 3 foot-candles for fine processes.
(c) 0.25 foot-candles at floor level for other processes.

These are minimum standards only and in practice are frequently and desirably exceeded. Further, it must be remembered that each separate process really requires separate and careful study.

Brightness

Brightness, or the amount of light *returned* from a surface, is the most important factor in industrial lighting, and is dependent on the degree of illumination received by the surface and the reflection capacity. Thus with light coloured and clean ceilings and walls which have high reflecting values the same degree of illumination gives more visibility than with dark or dirty surroundings where the light is absorbed and the reflection ratio is low. Similarly if the material worked on is white it will reflect about 80 per cent of the light received, while black materials, only reflecting 0.8 per cent of the light received, will require 100 times the illumination to reach the same degree of visibility.

The Angle at which Light Sources are Placed

One cause of waste of light, and incidentally of unnecessary glare, is the mistaken assumption that the nearer the light source to the work the greater the illumination. While this is true where the light source is vertically over the work, it is not necessarily true where the light is not vertically over the work. For these cases there is one definite height at which the source will give maximum illumination.

Avoidance of Glare

Glare is a very important and very difficult problem in industry for it necessitates consideration of each light source in relation to every person within a 100 foot radius. Glare may result from any or all of three causes:

(a) from looking directly at a bright source of light.
(b) from reflected light on a shiny surface.
(c) from a bright source of light near but not in the line of vision.

(a) The prevention of glare can be accomplished by two means, either the interjection of something between the eye and the light source, or change in the position of the source relatively to the eye. The light can be kept from the eyes either by opaque screens or by translucent shades. While screening allows of greater concentration of light where needed, it does not give general light and moreover needs to be done very scientifically if it is to be effective for every person in the room. Concerning both the question of shading and the question of position of the source relatively to the eye the English Committee made the following recommendation:

"Every light source, except one of low brightness, (by low brightness is meant an intrinsic brilliance of not more than five candles per square inch), within a distance of 100 feet from any person employed shall be so shaded that no part of the filament, mantle, or flame is distinguishable through the shade, unless it be so placed that the angle between the line from the eye to an unshaded part of a source and a horizontal plane is not less than 20°, or in the case of any person employed at a distance of 6 feet or less from the source, not less than 30°."

For glare from reflected light on a shiny surface screening is unsatisfactory, and the only remedy lies in changing the relative positions of the light and the surface. For certain textile materials, however, both shiny and uneven, this is ineffective and the only way of preventing some of the small surfaces from catching the light is to shade the source until this is accomplished. Tissue paper is especially suitable for this.

Other Factors to be Considered in Connection with Glare

1. Contrast in brightness between the light source and the working surfaces and surroundings. The eye should not be subjected to conditions which necessitate constant readjustment from great light to comparative darkness.

2. Length of time during which the source of glare is in the field of vision. Where an operator is engaged at work which keeps his field of vision fixed for long periods, light sources should be of lower brightness and lower candle power than is necessary for other operators whose field of vision shifts from time to time.

---

*R. M. Hutton, Division of Industrial Hygiene, Department of Health, Ontario.

Avoidance of Shadows

The more concentrated the light source the deeper the shadow. Thus indirect lighting where the light is reflected from walls and ceilings is practically shadowless. Where direct lighting is used, however, shadows can be prevented by changing the relative positions of the light source and the shadow-forming object, or by using an extra light to counteract the shadow.

Maintenance

Maintenance is usually the most neglected factor in lighting. It should be taken into consideration from the start, and as it is impossible to keep either light sources or walls and ceilings 100 per cent perfect, allowance for inevitable wastage of light should be made and the illumination provided should at the start be higher than the standard actually desired.

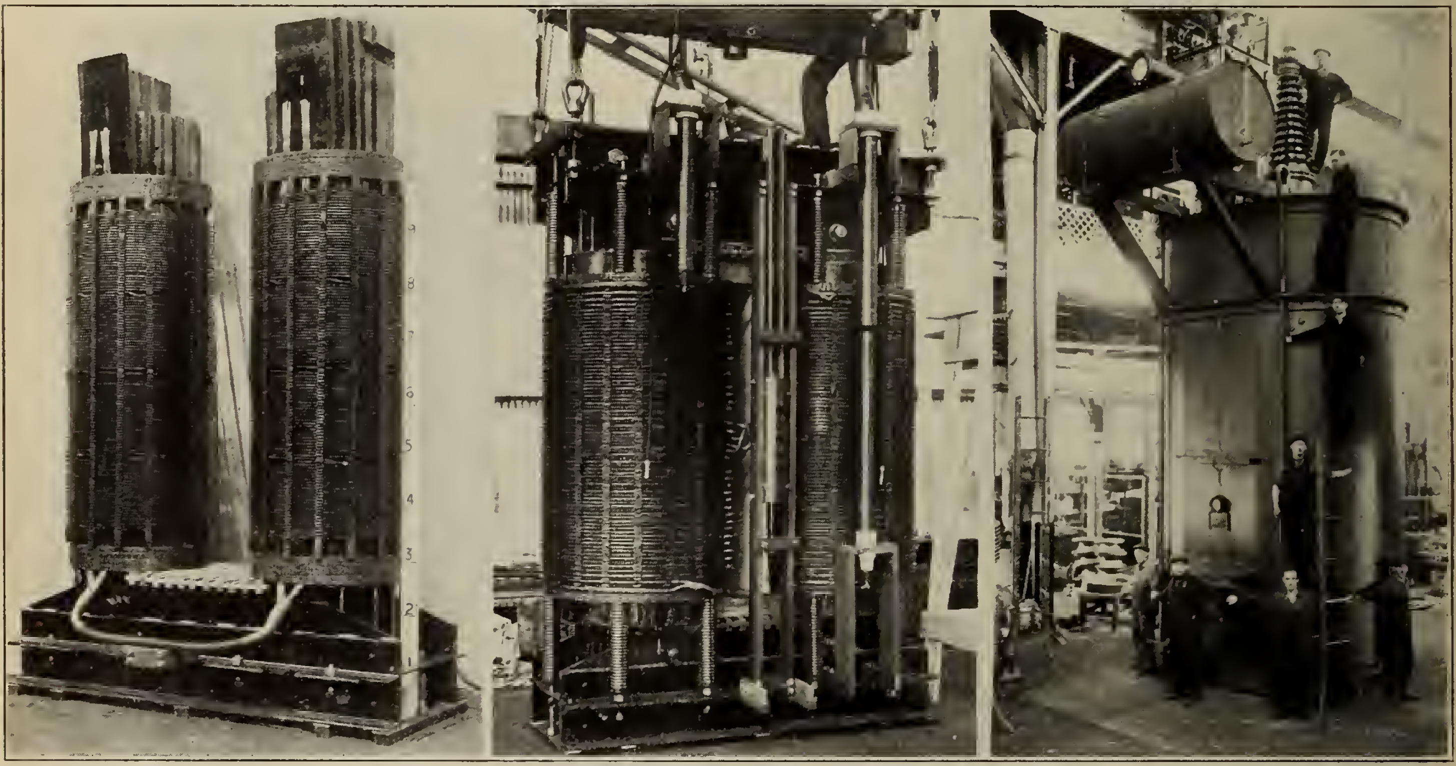
The loss of light caused by dirty walls, ceilings, and windows, and by dirty globes is enormous. Tests have shown that even windows which do not appear dirty may be causing a 50 per cent loss of light. In a study of the loss of light caused by deposits of dust, the American Illuminating Engineering Society found that in a case where nothing was done for maintenance, intensity could be increased 80 per cent by renewing burnouts in multilight fixtures, and 90 per cent by cleaning the lighting units. In a case where there was occasional maintenance, the washing of lamps and reflectors caused a 37 per cent increase in intensity, and the refinishing of walls and ceilings a 40 per cent increase.

The continued use of lamps after they have become blackened is purely wasteful as the amount of current used is out of all proportion to the light produced.

Illumination an Engineering Problem

The reason for adopting a correctly designed and well maintained lighting system is, briefly, that lighting has an enormous bearing on health and efficiency, and that accordingly good lighting directly promotes output. In the attainment of good lighting the appreciation of scientific principles can frequently obviate needless expense. Thus, relatively low wattage lamps correctly placed and correctly equipped with shades and reflectors will produce the same illumination as much higher wattage lamps hanging open and badly placed. In actual practice industry produces many lighting problems which are exceedingly difficult to solve, but their solution is well worth the expenditure of time and money.

One of the Largest and Highest Voltage Transformers built in the British Empire



It is of interest to note that with the completion of the first two units of an order of twelve transformers for the Aluminum Company of Canada in connection with their large industrial development at Arvida, Que., that these transformers are the largest as well as the highest voltage as yet built in the British Empire. Each unit has a capacity of 25,000 Kv.a. and is designed to operate in banks of three delivering power to the transmission line at 154,000 volts. The accompanying illustrations give some idea of the proportions of these transformers which stand 27 feet 4 inches from the floor to the top of the high voltage bushing and weigh 160,000 pounds.

The transformer is lifted directly from the base through four heavy lifting rods which pass up through a projection of the cover.

This base is provided with eight wheels which are set in groups of two and articulated, thus insuring that the load is uniformly distributed on all wheels.

An expansion tank insures that the hot oil does not come into contact with the air, thus practically eliminating oxidation of the oil and to a large extent preventing sludging.

The high voltage leads are of the oil-filled, one-piece porcelain type.

The core, about which the windings are assembled and which constitutes the magnetic circuit of the transformer, also functions as the foundation or tie bolt to the complete assembly. This core, built up of high grade transformer sheet steel, is constructed in a number of sections having oil passages between, the whole being securely bolted together. This permits the oil to circulate up through the core, reaching all points and insuring against abnormal temperatures at any part of the structure.

Heavy structural steel clamps securely keyed to the core form a very rugged support for the windings and insulation. The windings are of the circular coil construction.

The low voltage winding consists of a continuous helix or spiral wound directly over spacing strips on a heavy insulating cylinder which gives mechanical support and at the same time serves as a one-piece barrier between the windings and the core. This construction permits the oil to circulate in and out between all turns of the windings. The high voltage winding consists of a stack of disc coil sections assembled over an insulating cylinder, the whole being impregnated as a unit, thus giving an unbroken film of insulating compound over all parts of the winding.

The insulation between high voltage and low voltage windings consists of a number of heavy insulating cylinders assembled concentrically, thus forming a continuous barrier.

These transformers are being constructed by the Canadian General Electric Company and represent the latest attainments of transformer engineering.

BOOK REVIEWS

Port Administration and Operation

By Brysson Cunningham. Chapman and Hall, London, 1925. Cloth, 5½ in. x 8¾ in., 169 pp., illus., 13/6.

The methods of port administration throughout the world are of so widely varying a character and the classes of authorities administering them are so numerous, that there has been for some time a distinct need for a book giving a review of the various systems and schemes of operation adopted by the different ports, and this need has been ably supplied by Dr. Cunningham in his latest work.

The book first deals with the classification of the different kinds of ports and then goes on to review the various types of government, control and administration, such as Federal, State, City, Harbour Board, Port Trust, Port Authority, Private Ownership, Railway Control, etc. A large number of examples are given in considerable detail, principally of ports in Great Britain and the United States, diagrams of the organization of many ports are included and the advantages and disadvantages of the various systems are discussed. The author points out, however, that local conditions have so much effect on ports that a system of control working in a highly satisfactory manner in one part of the world may be quite unsuitable in another. There is a review of the different methods and systems of tolls by which the ports obtain their revenue from rates, dues, charges, rents, etc., and a discussion of the business of warehousing, customs arrangements and free port areas. The subject of port labour is dealt with, the author indicating that there is room for a great deal of improvement in the organization of port labour, and there is an interesting chapter on Belt Railroad Lines owned and operated by the port to connect up the various trunk railroad systems coming into the port, which are much more extensively used on this side of the Atlantic than in Great Britain or other European countries. The questions of policing and by-laws are also dealt with, and an appendix gives specimen by-laws by way of indicating the principles on which they are drawn up. There are also other appendices and the book is illustrated by a number of photographs of ports in various parts of the world, and diagrams. To any one engaged or interested in port operation the book can be thoroughly recommended as a valuable study, as the information concisely contained therein could only otherwise be procured by a very large expenditure of time and effort.

E. H. James, m.e.i.c.

Concrete Plain and Reinforced

Vol. 1. Theory and Design of Concrete and Reinforced Structures—by the late Frederick W. Taylor, Sanford E. Thompson and Edward Smulski, with a chapter by Henry C. Robbins. 4th edition. John Wiley and Sons, New York, 1925. Cloth, 6 in. x 9 in., 969 pp, illus., $8.00.

Confronted with the problem of dealing with the enormously extended mass of new material on concrete and reinforced concrete, the authors of this work decided in preparing their fourth edition to change it from a one-volume to a three-volume treatise. The preceding edition was about as bulky as it is practicable to make a single volume, and rather than increase its size, or on the other hand deliberately restrict the material to such as might be compassed in a single volume, the decision was made to spread the work out and make it still more ambitious than it had been. While this means additional cost to the purchaser, it probably was a wise decision to have available a comparatively exhaustive work on the subject. Simple one-volume texts are useful for the purposes of students, but the field of the practising enginer must be supplied as well as of that the learner.

The twenty-two chapters of Vol. I deal with the following subjects: Materials and Methods for Making Concrete, Reinforcement, Tests of Reinforced Concrete, Theory of Reinforced Concrete, Reinforced Concrete Design, Design of Flat Slab Structures, Concrete and Reinforced Concrete Columns, Foundations and Footings, Piles, Building Construction, Wall-Bearing Construction, Basement Walls, Roof Construction, Stairways and Other Openings, Steel Window Sash, Structural Plans for Buildings, Architectural Treatment of Exterior and Interior of Reinforced Concrete Buildings, Concrete in Construction of Theatres and Auditoriums, Reinforced Concrete in Different Types of Buildings, Reinforced Concrete Chimneys, Retaining Walls, Tables and Diagrams.

It is thus seen that the first volume deals both with reinforced concrete design and with construction. Volume II will discuss concrete materials and construction, presumably of non-reinforced work, while Vol. III will be devoted to special structures in reinforced concrete.
